Abstracts of the 41st Annual Meeting

The Toxicologist

Oxford University Press

Volume 66, Number 1-S, March 2002

Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the symposium, platform, poster discussion, workshop, roundtable, and poster sessions of the 41st Annual Meeting of the Society of Toxicology, held at the Opryland Hotel and Convention Center, Nashville, Tennessee, March 17–21, 2002.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 385.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 411.

The abstracts are reproduced as accepted by the Program Committee of the Society of Toxicology and appear in numerical sequence.

Additional Late-Breaking Abstracts are issued in a supplement to this publication and are available at the 41st Annual Meeting and through the Society of Toxicology Headquarters office.

Copies of *The Toxicologist* are available at $45 each plus $5 postage and handling (U.S. funds) from:

Society of Toxicology
1767 Business Center Drive, Suite 302
Reston, VA 20190-5332

No text or graphics may be copies or used without written permission from the Society of Toxicology.

This abstract book has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each article appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its Boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.

1 USE OF LASER CAPTURE MICRODISSECTION (LCM) IN MOLECULAR TOXICOLOGY RESEARCH.

J. I. Everitt. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Laser capture microdissection (LCM) is a recently developed technique that allows one to rapidly procure morphologically defined cell populations from sections of heterogenous tissues using direct visualization. This technique has greatly expanded the ability of the toxicologist to conduct molecular analyses on a wide array of specific target cells and tissues of interest. Cells obtained by microdissection have been used as a source of genomic DNA, the isolation of mRNA amenable to reverse transcription polymerase chain reaction (RT-PCR), and the generation of expression libraries. LCM has been combined with cDNA microarray hybridization techniques and proteomic methods to provide new and exciting approaches for combining gene expression with traditional morphological methods. This seminar will review microdissection methods and equipment and discuss the utility of LCM in toxicology studies.

2 A PRACTICAL APPROACH TO BLOOD AND LYMPHOID TISSUE (BLT) IN TOXICOLOGY ASSESSMENTS.

J. C. Schuh[1], L. Lanning[2], G. Travlos[3], P. Mann[4] and M. Leach[5]. *[1]Applied Veterinary Pathobiology, Bainbridge Island, WA, [2]BioReliance, Rockville, MD, [3]NIEHS, Research Triangle Park, NC, [4]Experimental Pathology Labs, Inc, Research Triangle Park, NC and [5]BASF, Worcester, MA.*

Blood, bone marrow, thymus, spleen, lymph nodes and mucosa-associated lymphoid tissue are a complicated but important interactive system of tissues and cells modulated directly and indirectly by xenobiotics. Evaluation of blood and lymphoid tissues (BLT) has always been part of a standard histopathology and toxicology screen but advanced evaluations of BLT are becoming increasingly important to the rapidly changing fields of immunotoxicology and immunotherapeutic development. The objective of this basic course is to provide contemporary information on the pathophysiology of BLT useful to individuals in regulatory and research areas of toxicology. This course will review important features of i) basic anatomy, function, and evaluation of blood and blood forming organs, ii) anatomy and function of lymphoid tissues and their component parts, iii) terminology, iv) general and toxic immunomodulation, and v) pathophysiology (neoplastic and non-neoplastic responses). Species, sex and age specific differences that may affect the design and outcome of studies, and techniques used to evaluate BLT will be discussed. A practical understanding of the anatomy, terminology, and toxicologic pathology associated with BLT, will aid toxicologists in making proper interpretation of treatment-related changes in safety and efficacy studies, and in communicating this information between disciplines, within teams and to regulatory agencies.

3 ALTERATIONS IN GENE EXPRESSION AS A MECHANISM OF TOXICANT ACTION.

R. N. Hines[1], Q. Ma[2], G. K. Andrews[3] and P. E. Mirkes[4]. *[1]Medical College of Wisconsin, Milwaukee, WI, [2]CDC/NIOSH, Morgantown, WV, [3]University of Kansas Medical Center, Kansas City, KS and [4]University of Washington, Seattle, WA.*

Over the last several years, it has become apparent that many environmental toxicants exert their effects by the activation or disruption of specific signaling pathways, ultimately resulting in alterations in gene expression. With the completion of the human genome project and the advent of many powerful new technologies, there has been a revolution in our understanding of these mechanisms on the molecular level. The proposed continuing education course is designed to review our current state of knowledge regarding toxicant-induced alterations in gene expression and also identify future directions and research opportunities. The first speaker will focus on our current understanding of the mechanism(s) whereby four receptors, i.e., the Ah receptor (AhR), the Constitutive Androstane Receptor (CAR), the Pregnane X Receptor (PXR), and the Peroxisome Proliferator Activated Receptor (PPAR), mediate the toxicity of four broad classes of chemicals. In contrast to these specific receptor mechanisms, metals exert their toxicity through both stress-response pathways, as well as specific metal-responsive transcription factors. The second speaker will focus on our current understanding of these pathways of toxicant action. The third speaker will review the many exciting discoveries in our understanding of how toxicants alter gene expression during specific windows of development and thereby exert their teratogenic effects. Finally, the fourth speaker will discuss the role of tissue-selective transcription factors on the expression of xenobiotic metabolizing enzymes and how this process impacts toxicant susceptibility. As an advanced course, this curriculum should appeal to toxicologists whose research is in or immediately peripheral to this focus area, but who are interested in gaining a better understanding of the overall subject and its future direction.

4 INTEGRATING TOXICOLOGIC PATHOLOGY INTO COMPOUND EVALUATION AND RISK ASSESSMENT.

D. C. Wolf[1], J. F. Hardisty[2], R. T. Miller[3] and J. I. Everitt[4]. *[1]USEPA, Durham, NC, [2]Experimental Pathology Laboratory, Research Triangle Park, NC, [3]GlaxoSmithKline, Research Triangle Park, NC and [4]CIIT Centers for Health Research, Research Triangle Park, NC.*

Pathology endpoints are the central response around which human health risk assessment is determined. This course is designed for the general toxicology community to gain an understanding of the basics of toxicologic pathology. Toxicologic pathology encompasses the study of changes in tissue morphology that help define the risk of exposure to xenobiotics. The first presentation will review the basics of pathology studies including tissue processing, pathology review, standard techniques, and efforts being made to standardize the conduct, review, and reporting of pathology studies which are important for appropriate interpretation of data. Other speakers will discuss the structural and functional aspects of the liver and kidney and the general concepts of mechanisms of injury, species and sex differences, background and induced lesions, which are necessary for appropriate risk characterization. The liver is the most common target for xenobiotic-induced adverse effects and the kidney has a central role in filtration, metabolism, and excretion and is frequently a site of toxic injury. Correlating clinicopathology with morphologic and functional alterations is necessary for full understanding of adverse effects. Finally, diagnostic terminology, study data relative to cancer bioassay findings, the steps in tumor development, and their relevance to human health risk will be presented.

5 BASIC PRINCIPLES AND PROTOCOLS IN MOLECULAR TOXICOLOGY.

W. B. Mattes[1], J. W. Davis, II[2], M. K. Walker[3], J. P. Vanden Heuvel[4], M. S. Denison[5] and C. B. Marcus[3]. *[1]Pharmacia, Kalamazoo, MI, [2]Schering Plough Institute, Lafayette, NJ, [3]University of New Mexico, Albuquerque, NM, [4]Pennsylvania State University, University Park, PA and [5]University of California- Davis, Davis, CA.*

Many of the mechanisms through which xenobiotics affect tissues or cells occur at the molecular level. Over the past ten or fifteen years the use of molecular techniques to dissect mechanisms of toxicity has grown greatly. These techniques are used to identify growth regulatory pathways, alterations in gene and/or protein expression, as well as protein:DNA and protein:protein interactions. Accordingly, there has been an explosion in the number of reagents and kits that are commercially available. While these kits and reagents have facilitated the detection of mechanisms of toxicity, a basic understanding of the methods used is just as important. This course will detail a number of basic techniques currently in use in an attempt to give a researcher new to this area information as to which tools may be most relevant with regards to their specific research area. Presentations will include the practical considerations when setting up a given technique as well as references that will help the investigator trouble shoot these systems. Finally, actual data will be shown in an effort to demonstrate the kinds of information that can be obtained by these experiments and the ways in which this information can be interpreted and used to develop hypothesis-driven research. This is a basic level course intended to introduce to the researcher the tools and references that are available to him or her.

6 TWO-STEPPING THROUGH TOXICOGENOMICS: A BASIC PRIMER.

M. J. Cunningham[1], T. Zacharewski[2], R. Somogyi[1] and B. A. Merrick[3]. *[1]Molecular Mining Corporation, Kingston, ON, Canada, [2]Michigan State University, East Lansing, MI and [3]NIEHS, Research Triangle Park, NC.*

Toxicogenomics as used here is broadly defined as gene and protein expression technologies and their application to addressing pertinent issues of toxicology. This basic course will start with an overview of how genomics and proteomics came into existence. Different microarray formats will be covered including cDNA, oligonucleotide, fiber optic, and high-throughput versions of gene expression microarrays as well as a broad overview on proteomics and data analysis. Several landmark papers will be discussed showing how genomics and proteomics can be applied. An in-depth presentation will follow detailing how to set up and run your own microarrays and will cover array manufacture, sample preparation, array hybridization and scanning, and image analysis. In addition, setting up and running 2D protein gels will be discussed as well as their interpretation using mass spectroscopy. With all of these technologies, complex data sets are generated and the final presentation will discuss alternative statistical and bioinformatic methods which can be used to analyze the data.

7 CHALLENGES IN DEVELOPMENT OF ANTICANCER DRUGS.

V. Reddy[1], A. Smith[2], J. T. Tomaszeski[2], R. E. Parchment[3], J. K. Leighton[4], J. Wright[2] and A. Worobec[4]. *[1]Eli Lilly and Company, Greenfield, IN, [2]National Cancer Institute, Rockville, MD, [3]Karmanos Cancer Institute, Detroit, MI and [4]USFDA, Rockville, MD.*

Preclinical and clinical drug development for anticancer drugs differ from other pharmaceuticals, because of the life-threatening nature of the disease. Treatment with anticancer drugs at clinically efficacious doses usually induces serious side effects but often less threatening to patients than their disease. The design of preclinical toxicology studies for anticancer drugs is intended to identify a safe clinical starting dose, characterize toxicities that may be encountered in human clinical trial, and determine whether these toxicities are reversible, manageable, and predictable. This basic course will focus on different aspects of preclinical and clinical anticancer drug development. The first speaker will present differences in the preclinical drug development philosophy between different classes of anticancer drugs (e.g., cytotoxic, immunomodulators, and modulatory drugs). The second speaker will discuss the prediction of human tolerated dose using *in vitro* hematotoxicity tests and the integration of this knowledge into preclinical modeling and toxicology. The third speaker will focus on regulatory considerations for preclinical development of anticancer drugs. The fourth speaker will discuss the clinical development of anticancer drugs. The final speaker will review the special preclinical and clinical regulatory issues associated with the development of biologics for the treatment of cancer. This basic drug development course is targeted to government, biotechnology and pharmaceutical toxicologists, as well as physicians and general toxicologists with an interest in cancer chemotherapy.

8 INCORPORATION OF PHARMACOKINETIC AND PHARMACODYNAMIC DATA INTO RISK ASSESSMENTS.

J. C. Lipscomb[1], L. Haber[2], B. Meek[3], K. Krishnan[4], G. L. Kedderis[5] and H. Clewell[6]. *[1]USEPA / ORD/NCEA, Cincinnati, OH, [2]Toxicology Excellence for Risk Assessment, Cincinnati, OH, [3]Health Canada, Ottawa, ON, Canada, [4]University of Montreal, Montreal, PQ, Canada, [5]CIIT Centers for Health Research, Research Triangle Park, NC and [6]ENVIRON Corporation, Ruston, LA.*

The increasing attention to chemical-specific mechanistic data in human health risk assessments should encourage researchers and programmers to identify and develop risk-relevant information. Recently, guidance for replacing default uncertainty factors with adjustment factors based on chemical-specific data has been made available. This course will investigate recent and emerging approaches to metabolism, pharmacokinetics, and pharmacodynamics with respect to producing data adequate for inclusion in human health risk assessments, and methods to use such data in risk assessment. Physiologically-based pharmacokinetic (PBPK) modeling has developed risk-relevant information, but the "validation" of these models for some chemicals in humans may be problematic. In some instances, the best available data may be generated *in vitro* and *in silico* and require extrapolation to the *in vivo* setting. PBPK models then become attractive and can be used to estimate risk-relevant, mechanistically-related PK outcomes, and variance thereof, when adequate biochemical and physiologic/anatomic information are incorporated. Human interindividual variance is presently addressed in the uncertainty factors (UFH) used to derive safe levels of exposure. The quantification of human variance through *in vivo, in vitro,* and *in silico* approaches will be presented. This will include the evaluation of genetic and environmental modulation of biochemical individuality (e.g., polymorphisms and co-exposures) and their impact on tissue dosimetry and age-related differences in humans.

9 TOXICOLOGY OF NATURALLY OCCURRING TOXINS - DON'T MESS WITH MOTHER NATURE!

F. W. Oehme[1], R. W. Coppock[2], K. L. Wallace[3], M. E. Peterson[4], B. Furbee[6] and R. Ko[5]. *[1]Kansas State University, Manhattan, KS, [2]Alberta Research Council, Vegreville, AB, Canada, [3]Good Samaritan Regional Medical Care-Phoenix, Phoenix, AZ, [4]Reid Veterinary Hospital, Albany, OR, [5]California Deparatment of Health Seravices, Sacramento, CA and [6]Indiana Poison Center, Indianapolis, IN.*

Natural toxins are generally not recognized for their true importance. The benign perception that nature is all healing is contradicted by the numerous but often little appreciated public risks from contact with venomous animals and use of plants as herbal remedies. Lack of understanding these hazards produces a false sense of societal security. To update the SOT membership about the range, potency, and mechanisms of action of poisons found in nature, this basic course will illustrate the chemical risks, compositions, mechanisms of action, effects and effective therapies for animal venoms, growing plants, and herbal products. Each speaker is a nationally recognized expert in their presentation's themes. Drs. Wallace and Peterson recognize and manage snake, reptile, and arthropod envenomations in their daily toxicology practices. Poison Center director, Dr. Furbee, overviews repeated exposures to poisonous plants with a working knowledge of each plant's poisonous principle(s). Dr. Ko's west coast laboratory deals with the variety of toxicology events from herbal products. Each speaker will provide personal experiences and the characteristics, toxicologic mechanisms and effects of specific intoxications, alerting toxicologists more familiar with sterile and urban environments with the circumstances and dangers afforded by Mother Nature. This unique continuing education course gives insight into the living dangers around us by providing current toxicological knowledge about these everyday lifestyle hazards. "Naturally Occurring Toxins" will be timely, of wide professional and public interest, and certainly stimulating to our broad audience.

10 REGULATION OF DRUG AND CHEMICALLY-INDUCED APOPTOTIC CELL DEATH: NEW *IN VIVO* PERSPECTIVES.

S. D. Ray[1], S. B. Pruett[2], J. Kang[3] and N. Jena[4]. *[1]Long Island University, Brooklyn, VA, [2]Louisiana State University Medical Center, Shreveport, LA, [3]University of Louisville, Louisville, KY and [4]M.I.T., Cambridge, MA.*

Apoptosis is a natural consequence *in vivo,* and there is now substantial evidence that apoptosis plays an important role in the toxic effects of a number of drugs and chemicals. Although it is a naturally-orchestrated self-limiting program, a vast majority of the investigators employ *in vitro* models to interpret *in vivo* mechanisms. While *in vitro* assays are relatively sensitive, specific, and reliable, an ongoing question is the reproducibility of such mechanisms in complex *in vivo* systems. Therefore, one of the primary goals of this course is to discuss coherently numerous proposed pathways that regulate this cell suicidal process and test their feasibility in *in vivo* models. The overall objectives of this CE course are: (i) an overview of role of apoptosis during target organ toxicities (cardiotoxicity, hepatotoxicity, nephrotoxicity, and immunotoxicity), (ii) a broad review of mechanisms of action of target-organ specific apoptogenic drugs and chemicals; and (iii) a discussion of mechanisms that regulate apoptosis at the organ, cellular, sub cellular, and molecular levels. Since oxidative stress, caspases, caspase-activated DNAse, reactive oxygen species, mitochondrial, and cell cycle-related events are known to modulate this process, their contributory roles will be a brief part of the curriculum. The concepts gained from this course will be useful to teachers and researchers involved in target organ toxicology, biochemical toxicology, general toxicology, carcinogenesis, molecular toxicology and mechanistic toxicology.

11 INTERNAL DOSIMETRY: MEASUREMENT OF DNA DAMAGE AS AN INDICATOR OF INTERNAL EXPOSURE TO GENOTOXICANTS.

B. S. Shane[1], M. Poirier[2], L. Marnett[3], R. Tice[4] and B. Finette[5]. *[1]Integated Laboratory Systems, Research Triangle Park, NC, [2]NIH, Bethesda, MD, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Integrated Laboratory Systems, Durham, NC and [5]University of Vermont, Burlington, VT.*

Large molecular weight chemical carcinogens, including polycyclic aromatic hydrocarbons, aromatic and heterocyclic amines, and aflatoxins, are encountered in the ambient environment, the work place and in our food supply. These carcinogens usually require metabolic activation before becoming adducted to DNA. The covalent DNA adducts which are formed, often termed "bulky" adducts, distort the conformation of the DNA helix and are typically removed from the DNA by nucleotide excision repair. However, some proportion of these adducts are not repaired and following cell division can result in a mutation. Other pro-mutagenic events (malondialdehyde-DNA adducts) occur as the result of oxidative damage resulting from endogenous metabolic processes and exposure to xenobiotics that initiate a lipid peroxidation cascade. A third type of DNA damage results from agents that induce strand breaks or crosslinking. The first two talks will discuss the spectrometric-, immunochemical-, and postlabeling-based approaches that can be used to measure both bulky adducts and those caused by lipid peroxidation products. The third talk will describe the single cell gel (Comet) assay that is used to measure strand breaks, alkali-labile sites, and crosslinking. The final talk will focus on the consequence of DNA damage, namely mutations, particularly those found in infants and young children. The measurement of these mutations using the T-lymphocyte cloning assay that quantifies the mutant frequency (MF) of the HPRT gene will be described. This course will be suitable for those toxicologists that are interested in the latest techniques used to measure DNA damage and how these endpoints can be used as an internal dosimeter for epidemiological monitoring of human populations.

12 TOXICITY PROFILING OF GENES AND PROTEINS BY TOXICOLOGISTS: ADVANCED TOPICS IN TOXICOGENOMICS.

B. A. Merrick[1], D. Dixon[1], C. Corton[2], P. Bushel[1], F. A. Witzmann[3] and S. Rabatin[4]. [1]*NIEHS, Research Triangle Park, VA,* [2]*CIIT Centers for Health Research, Research Triangle Park, NC,* [3]*Indiana University Medical School, Indianapolis, IN and* [4]*Applied Biosystems, Santa Fe, NM.*

Chemical toxicity profiling using gene expression technologies will soon become more accessible to practicing toxicologists through contract, industrial, and academic core facilities. It is anticipated that gene expression data for many compounds will begin to appear in preclinical drug evaluations, new drug applications, and environmental risk assessment documents as well as basic toxicology research. Although many toxicologists have an understanding of genomics and proteomics, the best use of their applications, attendant bioinformatics, and associated databases still present a challenge. This advanced course is aimed at research and industrial toxicologists to better familiarize them with gene expression technologies at the transcript and protein level. The course is structured around four areas, genomics, genoinformatics, proteomics, and proteoinformatics. Experts in each area will cover the latest technological advances, specific applications and how to relate and interpret the high toxicogenomic information density with bioinformatic tools and relevant databases.

13 STRATEGIES AND ISSUES IN NON-CLINICAL DEVELOPMENT OF INTRAVENOUS INFUSION DRUG PRODUCTS.

W. Halliwell[1], G. Lulham[2], G. Washer[3], K. Hew[4] and J. A. Cavagnaro[5]. [1]*Schering-Plough Research Institute, Lafayette, NJ,* [2]*JTI MacDonald Corp., Toronto, ON, Canada,* [3]*ClinTrials BioResearch, Ltd., Senneville (Montreal), PQ, Canada,* [4]*Purdue Pharma L.P., Ardsley, NY and* [5]*Access BIO, Leesburg, VA.*

A large number of pharmaceutical and biotechnology products intended for administration by intravenous infusion in the clinic have entered into non-clinical development during the past decade. Many of these have shown early success in the clinic and subsequently required additional safety evaluation. Non-clinical testing has also utilized the intravenous route to avoid issues associated with short drug half-life or poor absorption that preclude using more traditional clinical dosing routes. Additionally, continuous infusion studies are conducted with non-infusion drugs to control blood levels, such as fetal/neonatal exposure, for mechanistic studies. As a result, the use of intravenous infusion for non-clinical studies has increased steadily over the past number of years. There are unique design, conduct, and interpretation issues associated with this route of drug administration as a tool in evaluating product safety. Toxicologists and regulators in pharmaceutical/biotech product development are increasingly likely to be involved in designing, conducting, interpreting, and assessing mechanisms of toxicity for non-clinical safety programs using the intravenous infusion route. The goal of this course is to explore the scientific and technical challenges associated with the use of continuous and intermittent intravenous infusion in drug development. The utility and special considerations of this treatment route for reproductive studies of intravenously infused drug products and non-infusion products where there may be a need to achieve specific systemic exposures will also be addressed.

14 CURRENT APPROACHES FOR VALIDATION AND REGULATORY ACCEPTANCE OF NOVEL TEST METHODS.

S. Green[1], L. M. Schechtman[3], W. S. Stokes[2], K. Hamernik[4], A. Worth[5] and H. Koeter[6]. [1]*Howard University College of Medicine, Washington, DC,* [2]*NIEHS, Research Triangle Park, NC,* [3]*USFDA, Rockville, MD,* [4]*USEPA, Washington, DC,* [5]*ECVAM, Varese, Italy and* [6]*OECD, Paris, France.*

New technologies such as toxicogenomics are providing a mechanistic basis for the improvement of existing toxicity testing methods and for the development of new improved methods. Such methods may be faster, more economical, and reduce animal use. In order for regulatory authorities and industries to embrace methods using new technologies, there must be an effective process for determining their scientific validity and acceptability for regulatory use. Enactment of the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) Authorization Act of 2000 established ICCVAM as a permanent committee, and requires federal agencies to determine that methods are valid for their proposed use prior to their adoption. Federal regulatory agencies have implemented processes to consider the applicability and acceptability of ICCVAM-recommended methods, and to inform the regulated community of their decisions. A parallel organization has been established in the European Union (European Center for the Validation of Alternative Methods, ECVAM). Five methods have successfully completed the ICCVAM and ECVAM evaluation/validation processes and have been adopted by regulatory authorities. International acceptance of new methods is an essential prerequisite for widespread use. This course will review new initiatives by national and international authorities to achieve acceptance of new and revised toxicological testing methodologies. Current issues relevant to validation and regulatory acceptance will be addressed. This course is targeted for toxicologists and scientists involved in developing, validating, or using toxicological test methods to meet national and international regulatory testing requirements. The course is particularly relevant as differential gene expression is rapidly being applied to new and existing test methods to identify more sensitive and specific decision criteria.

15 IMAGING THE MITOCHONDRIAL PERMEABILITY TRANSITION PORE IN TOXIC INJURY.

D. A. Fox[1] and J. J. Lemasters[2]. [1]*University of Houston, Houston, TX and* [2]*University of North Carolina, Chapel Hill, NC.*

Mitochondria in excitable and non-excitable tissues are the direct and indirect targets of many xenobiotics that produce apoptotic and necrotic cell death. Determination of the temporal and sequential relationships between the opening of the mitochondrial permeability transition (PT) pore, mitochondrial depolarization and swelling, cytochrome c release and caspase activation during cell death and of the molecular mechanisms underlying each of these events are critically important. In toxicology, understanding the role and molecular mechanisms of PT pore opening will allow the development of pharmacological and genetic strategies to prevent inappropriate apoptosis as well as to initiate and control the apoptotic process for therapeutic purposes. Current evidence suggests that the PT pore is a complex of the voltage-dependent anion channel (VDAC), the adenine nucleotide translocase (ANT) and cyclophilin-D (CyP-D) formed at contact sites between the inner and outer mitochondrial membranes. This symposium provides four presentations from investigators using state-of-the-art imaging techniques such as confocal microscopy and electron tomography as well as biochemical and cell biological techniques to determine the mechanisms of PT opening and the role of these proteins in the PT pore during exposure to ethanol, heavy metals, solvents and under conditions that produce hypoxia, calcium overload and death receptor ligation. The presentations will explore intrinsic cellular and tissue differences in susceptibility to PT pore opening as well as outcomes in heart, liver, brain and retina in developing and adult tissues and isolated cells. Detailed mechanistic studies also will provide metabolic, pharmacological and transgenic strategies for cytoprotection. The major objective of this symposium is to present and discuss up-to-date knowledge on the role of PT pores in toxicology using techniques at the single cell level. This symposium should have broad appeal to all toxicologists examining mechanisms of cell death.

16 PATHOPHYSIOLOGY OF THE MITOCHONDRIAL PERMEABILITY TRANSITION.

P. Bernardi[1], V. Petronilli[1] and F. Di Lisa[2]. [1]*Biomedical Sciences, University of Padova, Padova, Italy and* [2]*Biological Chemistry, University of Padova, Padova, Italy.*
Sponsor: D. Fox.

We are studying the properties of the mitochondrial permeability transition pore (PTP) in cells and tissues, and we describe here our results on the relationships between PTP opening and cell death in two models. (i) We have investigated the relationship between PTP opening, mitochondrial depolarization, cytochrome c release and occurrence of cell death in MH1C1 hepatoma cells treated with a Ca^{2+} ionophore or arachidonic acid, a potent PTP inducer. We could detect both transient and long lasting PTP openings. While cell viability was hardly affected by PTP openings of short duration, longer PTP openings caused mitochondrial depolarization followed by release of cytochrome c and cell death. Thus, modulation of PTP open time appears to be the key element in determining the outcome of stimuli that converge on the PTP. (ii) We have studied the role of the PTP in ischemia-reperfusion damage of the heart by investigating metabolism of NAD^+, which is released from mitochondria when the PTP opens and then hydrolyzed by glycohydrolase, an enzyme associated with the outer mitochondrial membrane. Perfused rat hearts subjected to global ischemia for 30 min displayed a 30% decrease in tissue NAD+ content, which was not modified by extending the duration of ischemia. Reperfusion resulted in a more severe reduction of both total and mitochondrial contents of NAD^+, which could be measured in the coronary effluent together with lactate dehydrogenase. The addition of 0.2 μM cyclosporin A (CsA) or of its analogue MeVal-4-Cs maintained higher NAD^+ contents, especially in mitochondria, and protected the heart from reperfusion damage. Thus, PTP opening in the heart can be documented as a CsA-sensitive release of NAD^+, which is then partly degraded by glycohydrolase and partly released when sarcolemmal integrity is compromised. Once released from the matrix, NAD^+ could be transformed into cyclic ADPribose, thus promoting Ca^{2+} release from intracellular stores and amplifying the effects exerted by an initial rise of $[Ca^{2+}]_i$.

17 THREE-DIMENSIONAL RECONSTRUCTIONS OF ROD MITOCHONDRIA AFTER LEAD-INDUCED APOPTOSIS REVEAL AN INCREASE IN CONTACT SITES THAT IS BLOCKED BY Bcl-xL OVEREXPRESSION.

G. A. Perkins[1], L. He[2], A. T. Poblenz[3] and D. A. Fox[4]. *[1]Neurosciences, Univ. California, San Diego, La Jolla, CA, [2]Cell Biology, Univ. North Carolina, Chapel Hill, NC, [3]MD Anderson, Univ. Texas, Houston, TX and [4]College of Optometry, Univ. Houston, Houston, TX.*

Developmental lead exposure in rats and mice produces a progressive loss of rods that correlates with an apoptotic mechanism driven by retinal lead and calcium overload. We used wild-type and transgenic mice overexpressing Bcl-xL only in photoreceptors to examine the influence of Bcl-xL on mitochondria in lead-induced apoptosis. Our previous *in vitro* data demonstrated that Bcl-xL exerts its cytoprotective effect at the mitochondrial level. We accumulated evidence that the mitochondrial permeability transition (MPT) is the apoptotic mechanism in wild-type mice exposed to lead and is blocked by Bcl-xL overexpression. This is the first *in vivo* evidence that Bcl-xL overexpression regulates apoptosis. Because the MPT is involved, alterations in mitochondrial ultrastructure are expected. We used electron microscope tomography to investigate at high resolution the three-dimensional (3-D) structure of rod mitochondria in retinas of wild-type and Bcl-xL mice. We analyzed more than 50 tomographic reconstructions under four conditions: wild-type control, wild-type lead-exposed, Bcl-xL transgenics and Bcl-xL lead-exposed. At a resolution of 5-7 nm, the only detectable structural modifications produced by developmental lead exposure involved the mitochondrial contact sites. No mitochondrial swelling or ruptures of membranes were observed. The surface area and density of contact sites in the apoptotic mitochondria were about twice that of the control mitochondria and the Bcl-xL mitochondria both with and without lead exposure. Coupled with our biochemical and morphological assays, this structural work shows that Bcl-xL overexpression in photoreceptors provided complete protection against developmental lead-induced, rod-selective alterations to mitochondrial function and structure. Supported by NIH Grants ES03183, EY06891, EY09213 and RR04050.

18 IMAGING OF THE MITOCHONDRIAL PERMEABILITY IN MODELS OF NEUROTOXICITY.

M. A. Philbert. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Three models of chemically-induced glial, neuronal and progenitor cell-specific damage will be presented. The chemicals to be discussed produce tissue, region and/or cell-specific lesions in neural tissues. First, 1, 3-dinitrobenzene (DNB) produces a pattern of lesions in the brainstem similar in distribution and severity to those observed in the mitochondrial encephalopathies or produced by antimetabolites such as pyrithiamine and alpha-chlorhydrin. However, brainstem astrocytes are the primary target of DNB toxicity. Time-lapse confocal microscopy reveals a 10-fold difference between the sensitivity of brainstem astrocyte mitochondria to induction of the permeability transition as compared to their cortical counterparts. Second, the 2-nitroimidazole radiation-sensitizer, CI-1010, induces retinal degeneration in photoreceptor cells. Simultaneous optical imaging of the mitochondrial membrane, reactive oxygen species and cell viability permits resolution of the sequence of events leading to induction of the MPT and oxidative stress. Finally, use of confocal fluorescence microscopy enables imaging of the establishment of a mitochondrial membrane potential prior to the onset of migration from the neural crest. Challenge of neural crest cell cultures with ethanol inhibits polarization and rapidly attenuates the mitochondrial membrane potential during migration. The toxic effects of ethanol may be prevented by pre-incubation with bongkrekic acid but not cyclosporin A (CsA). The developmental significance of the inability of CsA to inhibit membrane depolarization is currently under investigation. These studies show the utility of time-lapse and real-time confocal microscopy for the *in vitro* investigation of mechanisms of neurotoxicity. (This work was supported by PHS Grant NIH-ES08846)

19 MICROSCOPY OF CELL DEATH: MITOCHONDRIAL PATHWAYS TO APOPTOSIS AND NECROSIS.

J. J. Lemasters. *Cell and Developmental Biology, University of North Carolina, Chapel Hill, NC.*

Inhibition of mitochondrial oxidative phosphorylation progresses to uncoupling when opening of cyclosporin A (CsA)-sensitive permeability transition (PT) pores permeabilizes the mitochondrial inner membrane to small solutes. Protection by CsA against oxidative stress, ischemia/reperfusion, tumor necrosis factor-alpha exposure, Fas ligation, calcium overload, Reye-related drug toxicity and excitotoxicity implicate the mitochondrial permeability transition (MPT) in necrotic and apoptotic cell death. Confocal microscopy visualizes directly inner membrane permeabilization in single mitochondria within living cells from the translocation of impermeant fluorophores, such as calcein, between the cytosol and the mitochondrial matrix. Simultaneously, mitochondria release membrane potential-indicating fluorophores, indicating mitochondrial depolarization. Subsequently mitochondria swell, causing outer membrane rupture, and release of cytochrome c and other proapoptotic proteins from the intermembrane space. *in situ* a sequence of decreased mitochondrial NAD(P)H, increased mitochondrial free calcium and increased mitochondrial ROS formation promote the MPT and cell death. Necrotic or apoptotic cell death depends, in part, on ATP levels. If ATP levels fall profoundly, necrotic killing occurs. If ATP is maintained, apoptosis follows the MPT. The MPT also signals mitochondrial autophagy, a process that removes damaged or superfluous mitochondria. Features of necrosis, apoptosis and autophagy frequently occur together after toxic injury. A new term, necrapoptosis, describes such death processes that begin with a common stress or death signal, progress by shared pathways, but culminate in either necrosis or apoptosis depending on modifying factors such as ATP.

20 REGULATION OF ARYL HYDROCARBON RECEPTOR-MEDIATED SIGNAL TRANSDUCTION.

A. Puga. *Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH.*

The AH Receptor (AHR) is a ligand activated transcription factor that mediates many of the biological responses to halogenated and polycyclic aromatic hydrocarbons. Like many transcription factors, the AHR is a modular protein containing many distinct amino acid motifs. These motifs include i) basic regions involved in DNA binding and nuclear import, ii) a helix-loop-helix (HLH) domain involved in dimerization to ARNT and nuclear export, iii) a PAS domain involved in multiple functions such as dimerization, ligand binding and hsp90 binding and iv) a large C-terminal domain involved in transactivation function and possibly protein stability and localization. The presence of these motifs and their overlap of functions implies that the AHR has to undergo a wide range of interactions with many endogenous cellular proteins. Thus, central questions in the analysis of AHR function include how these interactions ultimately affect the magnitude and duration of AHR response to ligand exposure and in what sequence the events occur. Insight into these questions has come from the direct analysis of the AHR protein *in vitro* and *in vivo* in the presence and absence of ligand. These studies have highlighted the need to understand the mechanism of how the AHR moves through the cell and whether specific nuclear import and export domains provide areas for the cell to control AHR function and gene regulation. In addition, it has become clear that the AHR may influence cellular signaling events through interactions with other signaling pathways (for example, NF-κB, Rb etc). Therefore, it is essential to define the proteins involved in these interactions and how they might influence the traditional model of AHR-mediated signaling. Taken together, these types of studies will provide important insights into the events that impact the AHR-mediated signal transduction pathway before and after ligand binding.

21 MECHANISTIC EXAMINATION OF THE ROLE OF XAP2 IN ALTERING AH RECEPTOR SUBCELLULAR LOCALIZATION.

G. H. Perdew and J. R. Petrulis. *Department of Veterinary Science and the Center for Molecular Toxicology, Penn State University, University Park, PA.*

The unliganded mouse aryl hydrocarbon receptor (mAhR) is a cytoplasmic, tetrameric complex consisting of the AhR ligand binding subunit, a dimer of heat shock protein 90, and the hepatitis B virus X associated protein 2 (XAP2). XAP2 increases mAhR localization in the cytoplasm. Studies were performed to determine the mechanism of cytoplasmic retention of the mAhR/XAP2 complex. In the presence of XAP2 the mAhR is retained in the cytoplasm and does not undergo dynamic ligand independent nucleocytoplasmic shuttling. One possible mechanism is through anchoring of the mAhR/XAP2 complex to the cytoskeletal matrix. This possibility was tested by disruption of both tubulin and actin networks using colchicine and cytochalasin B, respectively, no effect on the subcellular localization of the AhR complex was observed. An additional NLS(Nuclear Localization Sequence) was added to the mAhR/YFP fusion protein and fluorescence microscopy revealed that AhR/YFP/NLS was no longer retained in the cytoplasm in the presence of XAP2, suggesting that XAP2 does not tether the receptor complex. A second possible mechanism of cytoplasmic retention of the mAhR by XAP2, is through blocking access to, or altering the conformation of, the bipartite NLS. The former possibility was tested by the use of an antibody directed against the mAhR's NLS and the results indicated that the NLS is accessible even in the presence of XAP2 in the core receptor complex. Whether or not XAP2 alters the conformation of the bipartite NLS leading to reduced importin binding remains a possibility. The

human AhR (hAhR) has been shown to differ biochemically from the mAhR. The ability of XAP2 to influence localization of the hAhR was examined. Results suggest that XAP2 does not influence localization or nucleocytoplasmic shuttling of the hAhR. Additionally XAP2 was unable to enhance hAhR levels, in contrast to what has been observed with the mAhR.

22 EXAMINATION OF THE AH RECEPTOR-RETINOBLASTOMA PROTEIN INTERACTION AND IMPACT ON CELL CYCLE CONTROL.

C. J. Elferink. *Pharmocology and Toxicology, University of Texas Medical Branch, Galveston, TX.* Sponsor: R. Pollenz.

The aryl hydrocarbon receptor (AhR) belongs to the basic helix-loop-helix/PAS family of transcription factors that regulate critical functions during development and tissue homeostasis. Within this family, the AhR is the only member conditionally activated in response to ligand binding, typified by 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). The novel finding that the retinoblastoma tumor suppressor protein (pRb) interacts directly with the AhR through two distinct receptor domains spurred our interest in AhR-mediated cell cycle control. We have characterized one of the binding domains. More recent evidence revealed that TCDD-induced AhR-mediated G1 cell cycle arrest in 5L hepatoma cells depends on coactivation by the pRb. The cell cycle arrest seems to require p27Kip1 and a pRb activity apparently distinct from its function as a repressor of E2F-mediated transcription. In contrast, experiments using synchronized 5L cells linked AhR activity with a proliferative response, suggestive of a more complex role for the AhR in cell cycle control. These studies identified an unexpected connection between the persistence of AhR signaling and cell cycle control.

23 IMPACT OF AH RECEPTOR DEGRADATION ON GENE TRANSCRIPTION.

Q. Ma. *Toxicology and Molecular Biology Branch, Health Effects Laboratory Division, NIOSH/CDC, Morgantown, WV.*

Transcriptional regulation of gene expression represents a means of control for many fundamental cellular processes, such as cell growth and differentiation, and for responses to endogenous and exogenous signals, such as the adaptive/toxic responses to environmental chemicals. As such, transcription factors that mediate gene expression to specific signals are often tightly regulated to ensure physiologically adequate gene transcription and thus, the homeostasis of the cell. The ubiquitin-26S proteasome-mediated proteolysis has been implicated in the regulation of various types of cellular proteins. In this study, we analyzed the mechanism of agonist-induced degradation of the Ah receptor and its functional impact on AhR-mediated gene transcription to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). Biochemical and genetic data reveal that TCDD induces ubiquitination of AhR and shortening of the half-life of the protein through the 26S-proteasome mediated protein degradation. The agonist induced AhR degradation can be blocked by using inhibitors of the 26S proteasomes (MG123 and lactacystin) or cycloheximide, a potent inhibitor of protein synthesis; these data implicate a labile factor in controlling the degradation of AhR, which we designated Ah receptor degradation promoting factor (ADPF). Furthermore, inhibition of the AhR degradation by inhibitors of the 26S proteasomes or protein synthesis markedly enhances the induction of CYP1A1 by TCDD, a phenomenon termed superinduction; these findings suggest that the agonist-induced, ADPF-mediated degradation of AhR serves as a mechanism by which gene transcription by AhR is negatively controlled in cells. This view is supported by the observation that inhibition of the AhR degradation by either MG132 or cycloheximide superinduces a number of other AhR target genes, including TiPARP, a novel TCDD-inducible poly(ADP-ribose) polymerase. Our findings provide new insights into the control of the activity of agonist activated AhR through a regulated, proteasomal protein degradation pathway. Our current research is aimed at cloning of ADPF.

24 DIRECT ANALYSIS OF THE COMPLEX RELATIONSHIP BETWEEN NUCLEAR EXPORT AND AH RECEPTOR-MEDIATED GENE REGULATION.

R. S. Pollenz, Z. Song and S. Dabirshahsahebi. *Biology, University of South Florida, Tampa, FL.*

The AH receptor (AHR) is a modular protein containing distinct amino acid motifs that confer function to the receptor. Studies have revealed that the AHR contains both nuclear localization (NLS) and nuclear export (NES) signals that control in part, the subcellular location of the AHR and may influence the ability of the AHR to be activated. Thus, studies were performed to examine the relationship between the nuclear export of the AHR and AHR-mediated gene regulation. Blockage of nuclear export in human HepG2 cells with leptomycin B (LMB) resulted in a ligand-mediated increase in the level of AHR•ARNT complex in the nucleus and correlate reductions in agonist stimulated AHR degradation. However, despite the presence of high levels of the AHR•ARNT dimmer, induction of numerous AHR-responsive reporter genes and endogenous *CYP1A1* was reduced by 78-89%. To determine whether there was a direct relationship between blockage of export of the AHR and the reduced levels of gene regulation, stable cell lines were produced that expressed an AHR with a mutant NES. Immunohistochemical and biochemical analysis of these cells and direct comparison to cells expressing a wild type AHR protein showed that mutation of the NES *did not* affect the ability of the cells to induce endogenous *CYP1A1* following ligand exposure. To confirm these results and evaluate the temporal aspect of the signaling pathway, wild type and NES mutant AHR protein were produced *in vitro* and then microinjected directly into the nucleus of various culture cells. While export was blocked, the injected cells induced high levels of *CYP1A1* following agonist exposure. These findings demonstrate that it is possible to generate an AHR protein defective in nuclear export that functions in agonist-mediated gene induction. This implies that the negative affect of LMB on gene induction is independent of the nuclear export of the AHR and involves a novel factor that must interact with the AHR-mediated signal transduction pathway. Supported by NIEHS grants ES08980 and ES10401

25 REGULATORY AND INDUSTRY APPROACHES TO IMMUNOTOXICOLOGY ASSESSMENT OF PHARMACEUTICALS IN EUROPE, JAPAN, AND THE UNITED STATES.

J. L. Weaver and K. L. Hastings. *Div. Applied Pharmacology Reseach, USFDA, Laurel, MD.*

Assessment of pharmaceuticals for potential immunotoxicity seeks to identify adverse effects such as immunosuppression and/or activation of the immune system resulting in drug allergy or autoimmunity. A variety of methods have been used to evaluate potential drug-induced alterations in immune function. The usefulness of these assays in drug development has been extensively debated. Regulatory agencies in Europe, the United States, and Japan have published, proposed, or considered guidances for immunotoxicology assessment of pharmaceuticals over the past several years. In each case, the documents reflect the consensus of opinion within the regulatory agency as to the most reasonable and effective strategy to detect the potential of new drugs to cause adverse immune system effects. There are differences in the specific testing strategies suggested and in the scope of the issues these documents seek to address. For example, the issue of potential for drug allergy is not covered in all cases, and some of the strategies for evaluating potential immunosuppression are not completely harmonious. In this roundtable session, representatives from regulatory agencies and the pharmaceutical industry will discuss immunotoxicity testing of pharmaceuticals. Areas of agreement and disagreement among the parties will be addressed to elucidate the basis for the different approaches proposed.

26 EMEA GUIDELINES.

E. Putman. *Preclinical Assessment Group of the Medicines Evaluation Board, National Institue of Public Health, Bilthoven, Netherlands.* Sponsor: J. Weaver.

The Note for Guidance on Repeated Dose Toxicity was released in July 2000 by the CPMP (www.emea.eu.int/pdfs/human/swp/104299en.pdf). This Note for Guidance was revised to update the guidance on immunotoxicity. Immune toxicity screening is incorporated in the Note for Guidance in accordance to the tiered testing approach, i.e. an initial screening phase and extended studies. The tiered testing approach is considered sufficiently reliable to be used in a regulatory setting. Tiered testing strategies have been developed to assess direct immunotoxicity (suppression or stimulation). Hypersensitivity or testing for autoimmune potential is not in the scope of this Note for Guidance. In attempting to prevent an increase in animal use and number of studies the SWP decided not to issue a separate guideline on immunotoxicity, but to update the Note for Guidance on Repeated Dose Toxicity. As a result, repeated dose toxicity test evaluation has been extended to include immunotoxicity screening. The initial screening phase is designed to enhance the sensitivity of standard toxicity testing for immune toxic effects, preferably without the use of satellite animals. The NK-cell activity assay and lymphocyte subset phenotyping are selected because they fulfil these criteria. As an alternative, the primary antibody response to T-cell dependent antigen is suggested which allows a more holistic screen of the immune system. For the interpretation of the initial immunotoxicity screen the CPMP document advocates an integrative analysis of the changes in the immune system and other types of toxicity and the health status of the test animal. If the initial screening phase suggests direct immunotoxicity, follow-on studies in animals may be warranted on a case-by-case basis to further study

the altered immune response. The design of extended animal studies will depend on the nature of the immunological changes observed in the initial screening phase. It should include comprehensive *in vivo* or *ex vivo* assays of immune function. For guidance on hypersensitivity testing see (www.emea.eu.int/pdfs/human/swp/214500en.pdf).

27 CURRENT PRACTICE OF IMMUNOTOXICOLOGY TESTING IN JAPAN.

K. Nakamura. *Developmental Research Labs., Shionogi & Co., Ltd., Osaka, Japan.*
Sponsor: J. Weaver.

Immunotoxicology studies of pharmaceuticals have been under intensive discussion for years in Japan. In most Japanese pharmaceutical companies, evaluation of unintended immunosuppressive effects of drugs is initiated by the results of standard nonclinical toxicology studies and/or their pharmacological effects. In the standard nonclinical toxicology studies, lymphoid organ weights are measured, and hematological and histopathological findings are collected. Cellularity of the spleen and bone marrow, distribution of lymphocyte subsets, antibody response to a T-cell dependent antigen, lymphocyte blastogenesis, mixed lymphocyte reaction, NK cell activity, delayed-type hypersensitivity and CFU-GM have been additionally examined in several companies. These parameters were selected based on the immunotoxicological features of test compounds. Antigenicity studies are widely conducted. Considering the genetic restriction of immune responses against low molecular weight compounds, it is very difficult to reproduce the immune responses of all humans, who have different genetic backgrounds, in animal experiments. Japanese pharmaceutical companies, being aware of the limitation of the study, send the results of animal experiments to clinical doctors. The philosophy of conducting antigenicity studies in Japan has not been accepted in the USA and Europe. There are two guidelines concerning immunotoxicology testing in Japan, which are guidelines for skin sensitization studies and skin photosensitization studies. Drugs applied to the skin are tested under these guidelines. The former guideline includes several tests such as maximization and Buehler tests. I anticipate that local lymph node assay will be added in the near future. The latter guideline includes several methods such as Harber and Morikawa methods. Japanese pharmaceutical companies are attempting to set the best procedures for immunotoxicological evaluation, and insisting that this subject should be internationally discussed especially since the guidance (or the draft guidance) documents for immunotoxicology studies were issued from the EMEA and the FDA.

28 REGULATORY CONSIDERATIONS FOR IMMUNOTOXICOLOGY ASSESSMENT OF INVESTIGATIONAL DRUG PRODUCTS IN THE UNITED STATES.

L. L. Reid. *Division of Dermatologic and Dental Drug Products, FDA, Rockville, MD.*

A functional immune system is vital to human survival. Assessment of adverse effects on the immune system is therefore important in the overall nonclinical evaluation of drug toxicity. Evidence of immunotoxicity can usually be observed in standard nonclinical toxicology studies, but in some cases additional studies are important. The purpose of this presentation will be to discuss the recently published Draft Guidance for Industry entitled "Immunotoxicology Evaluation of Investigational New Drugs" (www.fda.gov/cder/guidance/3010dft.htm). The discussion will center on the parameters that should be routinely assessed in toxicology studies to determine potential effects of investigational new drugs on immune function, cases when additional specific immunotoxicity studies should be conducted, and when additional mechanistic information could help evaluate the significance of a given drug's effect on the immune system. The utility and use of the recently accepted local lymph node assay to detect potential contact sensitizers will also be discussed along with the utility of other assays designed to test various aspects of the immune system including immunosuppression, antigenicity, hypersensitivity, autoimmunity and adverse immunostimulation.

29 TIMING, DATA INTERPRETATION AND EXPERIENCE WITH THE IMMUNOTOXICITY ASSESSMENT OF NEW DRUG CANDIDATES: A PHARMACEUTICAL INDUSTRY VIEW.

J. L. Dean[1] and B. Remandet[2]. [1]*Sanofi-Synthelabo Research, Sanofi-Synthelabo Inc., Malvern, PA and* [2]*Sanofi-Synthelabo Recherché, Sanofi-Synthelabo Inc, Montpellier, France.*

Recently the CPMP has adopted and the FDA drafted, guidelines for the immunotoxicity assessment of pharmaceuticals. This has resulted in much discussion in the industry concerning the timing, choice and validity of methods proposed and the need for such testing of new drug candidates (NCEs). During the past 15 years several inter-laboratory evaluation studies (e.g., NIEHS, IPCS, BGA, and privately sponsored) were conducted to optimize and evaluate methods and approaches using reference compounds in rodents in order to define their predictive value for detecting toxicity to the immune system. These published studies provided the basis for the CPMP and pending FDA Guidelines. Knowing that regulations were probably forthcoming, we at Sanofi-Synthelabo (SSL) have applied immunotoxicity methods to evaluate new drug candidates during pre-clinical development for the past 10 years. SSL has evaluated more than 25 NCEs from multiple therapeutic classes as well as reference compounds (azathioprine, dexamethasone, cyclophosphamide and cyclosporin A). Our experience and recommendation relative to timing of the studies, the use of multiple animal species, the interpretation of the various immunotoxicity assays and the outcome from the evaluation of NCEs and reference standards will be discussed. Our experience has led us to believe that immunotoxicity parameters may represent an important adjunct for the safety assessment of NCEs, that these methods must be carefully integrated into the drug development process, and yield an unexpectedly low frequency of positive results. The decision to do an immunotoxicity evaluation should probably be driven by a pathologic or clinical hematology finding, by the drug's indication or chemical class, or the indication for which the NCE is being evaluated (e.g., anti-Aids NCE) on a case-by-case basis.

30 *IN VIVO* FORMATION OF CERAMIDE-LIKE *N*-ACYLATED AMINOPENTOLS FROM HYDROLYZED FUMONISIN B_1.

K. A. Voss[1], H. U. Humpf[2], M. C. Sullards[3], K. Allgood[3], M. Hartl[2], R. T. Riley[1] and A. H. Merrill, Jr.[3]. [1]*Toxicology & Mycotoxin Research, ARS, USDA, Athens, GA,* [2]*Lehrstuhl für Lebensmittelchemie, Universität Würzburg, Würzburg, Germany and* [3]*Department of Chemistry & Biochemistry, Emory University, Atlanta, GA.*

Fumonisins are toxic and carcinogenic mycotoxins found in corn-based foods. Alkaline conditions such as those used for making masa from corn convert fumonisins to their hydrolyzed forms. The subchronic liver and kidney effects of hydrolyzed fumonisin B_1 (HFB_1), also referred to as aminopentol (AP_1), and fumonisin B_1 (FB_1) in rodents are similar and HFB_1, like FB_1, inhibits the enzyme ceramide synthase. Fumonisin metabolism has not been shown. However, formation of the ceramide-like compound *N*-palmitoyl aminopentol$_1$ (PAP_1) from palmitoyl-CoA and HFB_1 by rat liver microsomes *in vitro* has recently been reported. PAP_1 was more toxic (using cell death as the endpoint) than FB_1 or HFB_1 to cultured HT29 human colonic cells. To determine if PAP_1 or other *N*-acylated aminopentols (AAP_1) are formed *in vivo*, male rats (n=3) were given 52, 115 or 230 HFB_1/day (ip injection) for 5 days. Controls (n=2) received the saline vehicle. Two rats/group were euthanized 2 hours after the last dose. Remaining animals were killed 3 weeks later. HFB_1 was not toxic and did not cause microscopic kidney or liver lesions. It did, however, partially inhibit ceramide synthase, as shown by increased sphinganine and sphingosine concentrations in liver and kidney. Mass spectrometric analysis revealed a series of AAP_1 compounds in liver of the HFB_1-exposed rats. The metabolites' acyl groups ranged in length from C_{16} (PAP_1) to C_{24}. C_{24} compounds were most abundant, ranging from 0.5-2.4 nmole/g tissue, while up to 0.3 nmole/g of the other metabolites were found. Lesser amounts were detected in kidney and blood. The AAP_1 metabolites were not persistent; none were detected 3 weeks after the final dose. These findings demonstrate that HFB_1 is a substrate for ceramide synthase *in vivo*. The effects of AAP_1 metabolites in animals chronically exposed to HFB_1 warrant investigation.

31 FUMONISIN B_1 (FB) ALTERS OUABAIN-INSENSITIVE BUT NOT OUABAIN-SENSITIVE ^{86}RB UPTAKE IN LLC-PK_1 CELLS WITHOUT ALTERING MEMBRANE PERMEABILITY.

R. T. Riley[1,3], H. S. Yoo[2] and S. S. Rentz[3,1]. [1]*Toxicology and Mycotoxin RU, USDA-ARS, Athens, GA,* [2]*College of Pharmacy, Chungbuk National University, Cheongju, South Korea and* [3]*Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

FB is a fungal inhibitor of sphingolipid biosynthesis found in corn worldwide. Inhibition of ceramide synthase causes an increase in free sphingoid bases and depletion of glycosphingolipids and sphingomyelin. Free sphingoid bases can modulate Na+/K+ ATPase activity and altered glycosphingolipid expression can modulate plasma membrane ion permeability and other membrane functions. FB also causes lipid peroxidation in rat hepatocytes and cultured cells. The purpose of this study was to determine if FB can alter membrane ion permeability, Na+/K+ ATPase function, or induce lipid peroxidation in LLC-PK1 cells. Altered membrane ion permeability and Na+/K+ ATPase function was assessed by comparing 86Rb (a transport analog for potassium) efflux and ouabain-sensitive and ouabain-insensitive 86Rb uptake in sub-confluent LLC-PK1 cells exposed to 20 µM FB (a minimally cyto-

toxic concentration) for 72 h. Lipid peroxidation was assessed using the thiobarbituric acid assay in cultures grown under similar conditions but in growth medium without phenol red and at 50 μM FB (a cytotoxic concentration). The results show that 20 μM FB for 72 h had no effect on 86Rb efflux from 86Rb loaded LLC-PK1 cells nor was there any increase in thiobarbituric acid substances at 50 μM. These findings are consistent with the conclusion that under these conditions FB had no effect on membrane permeability. There was also no significant effect on ouabain-sensitive 86Rb uptake indicating that FB had no effect on Na+/K+ ATPase function. There was however a significant inhibition in ouabain-insensitive 86Rb uptake indicating that a minimally cytotoxic but ceramide synthase inhibitory concentration of FB can modify potassium transport processes. A possible target is the ouabain-insensitive phospholipid-dependent 86Rb uptake associated with transporters such as that of the non-gastric H+/K+ ATPase.

32 FUMONISIN B1 INDUCES DECREASED EXPRESSION OF P42 MAP KINASE IN LLC-PK1 CELLS.

S. S. Rentz[1,2], J. L. Showker[2], F. I. Meredith[2] and R. T. Riley[2,1]. [1]*Pharmaceutical & Biomedical Sciences, University of Georgia, Athens, GA and* [2]*Toxicology & Mycotoxin RU, USDA/ARS, Athens, GA.*

Fumonisin B1 (FB1) is a fungal toxin produced by *Fusarium verticillioides*, a common pathogen of corn. FB1 inhibits ceramide synthase, a key enzyme in the *de novo* sphingolipid biosynthesis and turnover pathways. Free sphingoid bases, sphingoid base metabolites, ceramide and more complex sphingolipids generated in the biosynthesis and turnover pathways modulate many downstream signals including mitogen-activated protein (MAP) kinases. In LLC-PK1 (porcine renal proximal tubule epithelial) cells, FB1 inhibits cell proliferation, induces apoptosis, and alters cell-cell contact in a time and concentration-dependent manner. The increased apoptosis and decreased cell proliferation can be prevented by ISP-1, an inhibitor of serine palmitoyltransferase, the first and rate-limiting enzyme in *de novo* sphingolipid biosynthesis. However, the downstream signaling pathways that are affected by FB1 disruption of sphingolipid metabolism are not well understood. The purpose of this study was to determine, in LLC-PK1 cells, changes in expression of p42 MAP kinase, also called extracellular signal-regulated kinase 2 (ERK2) in response to a FB1 concentration known to inhibit cell growth and induce increased apoptosis. Significant inhibition of cell growth was first noted after 48 h exposure to FB1 (50 μM). However, p42 MAP kinase was decreased at 24 h and at all subsequent time-points (48 and 72 h) relative to the concurrent control. FB1 treatment in the absence of serum further reduced the expression of p42 at 48 and 72 h. In order to determine if decreased p42 expression was due to FB1-induced elevation in free sphingoid bases, cells were treated with a combination of ISP-1 and FB1. ISP-1 did not reverse the decreased expression of p42 caused by FB1. However, ISP-1 alone also caused a decreased expression of p42, indicating that FB1-mediated changes in expression of p42 could be independent of alterations in sphingoid bases but dependent on *de novo* sphingolipid biosynthesis.

33 EFFECT OF FUMONISIN B_1 ON PROTEIN KINASE C-α IN CULTURED RENAL LLC-PK_1 CELLS.

N. V. Gopee and R. P. Sharma. *Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Fumonisin B_1 (FB_1) is a ubiquitous, potent, and naturally occurring mycotoxin produced by the fungus *Fusarium verticillioides*. It has been implicated in fatal and debilitating diseases in both animals and humans. FB_1 is known to induce toxicity by disruption of *de novo* sphingolipid biosynthesis *via* inhibition of ceramide synthase and induction of numerous proinflammatory cytokines, including tumor necrosis factor α. Protein kinase C (PKC) is a serine/threonine kinase involved in a number of signal transduction pathways, including apoptosis and carcinogenesis. As sphingolipids are the natural inhibitors of PKC, it is conceivable that FB_1 may affect PKC-regulated functions. FB_1 has been shown to cause both activation and repression of PKC depending on the dose, cell type and PKC isoform. This study investigated the acute temporal and dose effects of FB_1 on PKC isoforms in pig renal epithelial cells (LLC-PK_1). Exposure of LLC-PK_1 cells to 1 μM FB_1 caused a rapid and transient translocation (5 min) of PKCα from the cytosol to the plasma membrane. A time-dependent increase in the stabilization of cytosolic PKCα (15-30 min) was followed by a decrease at 120 min. PKC isoforms -δ and -ε were unaffected by FB_1 at all time periods. PKCα membrane translocation increased in a dose-dependent manner with a significant increase at 0.3 μM and 1 μM FB_1. Subsequent inhibition of PKCα at FB_1 concentrations ≥ 3 μM FB_1 was observed. Pretreatment of LLC-PK_1 cells with the PKC activator, phorbol 12-myristate 13-acetate (PMA) resulted in a further increase in PKCα translocation as compared to PMA alone. The FB_1-induced PKCα translocation was reversed by pretreatment of LLC-PK_1 cells with 100 nM Calphostin C, an inhibitor of PKC. The serine palmitoyl transferase inhibitor, myriocin, did not prevent the FB_1-induced translocation of PKCα. The ability of FB_1 to induce PKCα translocation in LLC-PK_1 cells and ultimately its signal transduction pathways may have implications in its ability to produce both apoptosis and carcinogenesis. (Supported in part by NIH grant ES09403).

34 SERUM BIOCHEMICAL AND LIPID CHANGES IN SINCLAIR MINIPIGS FED LOW LEVELS OF FUMONISIN B1 FOR SIX MONTHS.

W. M. Haschek[1], R. L. Fredrickson Jr[1], P. D. Constable[1], G. W. Smith[1], R. M. Eppley[2] and M. E. Tumbleson[1]. [1]*College of Veterinary Medicine, University of Illinois, Urbana, IL and* [2]*USFDA, Washington, DC.*

The fumonisin mycotoxins are common contaminants of corn. A major concern for humans ingesting fumonisin contaminated food is the cardiotoxicity and hypercholesterolemia observed in swine and nonhuman primates. Fumonisin induced hypercholesterolemia has been identified in all species, and in swine at doses as low as 1 ppm fumonisin B1 (FB1). To further examine the Dose-Response relationship of FB1 induced hypercholesterolemia and changes in lipid profile, 35 Sinclair minipigs (barrows, 7 to 14 wk of age) were fed FB1 at 0, 0.5, 1.0, 2.0 or 10.0 ppm (7 pigs/group) for 6 months. Purified FB1 was obtained from the FDA. FB1 containing feed was mixed in 10 kg premix batches and diluted with mycotoxin free base diet to 10 ppm FB1. Pigs were weighed and blood obtained by jugular venipuncture after 24 hr of fasting; weekly for the first 6 wk and then every 2 wk. Hepatic enzyme activities and concentrations of serum cholesterol, triglycerides, high and low density lipoproteins, bilirubin, bile acids, blood urea nitrogen, creatinine and electrolytes were determined. Complete blood counts also were performed. At wk 18, since no changes were observed in the parameters listed above, the dose in the high dose group was increased from 10 to 30 ppm FB1. No significant differences were observed in serum biochemistry or lipid parameters in fumonisin treated pigs, compared to control pigs, during the 6 month study. This is in contrast to previously reported hypercholesterolemia in pigs fed 1 ppm FB1 for 8 weeks (Rotter et al., 1996); however, Yorkshire pigs were used, and hypercholesterolemia did not occur in swine fed FB1 at 10 ppm. Based on this study in which doses bracketed the FDA recommended maximum levels of 2 to 4 ppm FB1, concern regarding potential FB1 induced atherosclerotic effects does not appear warranted. Supported by USDA-CSREES grant #928-39453, FDA and ILSI.

35 SPHINGOLIPID CHANGES AND PATHOLOGY IN SINCLAIR MINIPIGS FED LOW LEVELS OF FUMONISIN B1 FOR SIX MONTHS.

R. L. Fredrickson Jr[1], P. D. Constable[1], G. W. Smith[1], M. E. Tumbleson[1], R. M. Eppley[2] and W. M. Haschek[1]. [1]*College of Veterinary Medicine, University of Illinois, Urbana, IL and* [2]*USFDA, Washington, DC.* Sponsor: W. Haschek-Hock.

The fumonisin mycotoxins disrupt sphingolipid biosynthesis resulting in increased levels of sphingosine (So) and sphinganine (Sa) in tissue and serum. This appears to be the first detectable fumonisin induced biochemical change in swine. To examine the fumonisin B1 (FB1) induced Dose-Response of So and Sa and correlate it with morphologic changes in a low dose long term study, 35 Sinclair minipigs (barrows, 7 to 14 wk of age) were fed FB1 at 0, 0.5, 1.0, 2.0 or 10.0 ppm (7 pigs/group) for 6 months. Purified FB1 was obtained from the FDA. FB1 containing feed was mixed in 10 kg premix batches and diluted with mycotoxin free base diet to 10 ppm FB1. At wk 18, since no changes were observed in biochemical or lipid parameters, the highest dose was increased from 10 to 30 ppm FB1. At study end, pigs were weighed, euthanized and necropsied. Major organs were weighed and samples of all major tissues and arteries fixed in 10% formalin. Samples for sphingolipid analysis were frozen in liquid nitrogen and kept at - 80 C until Sa and So were determined by HPLC. Fumonisin induced gross or histological alterations were not observed, nor did absolute organ weights or organ to body weight ratios differ among groups. In the highest dose (10 to 30 FB1 ppm) group, Sa and So concentrations were increased in kidney, heart, aorta, and urine; Sa was increased in liver and lung; while neither Sa nor So were increased in brain. These results, as well as the lack of serum biochemical and lipid changes in the same study (see sister abstract), support the earlier assumption that changes in sphingoid bases are the earliest detectable biochemical changes induced by FB1, and appear to indicate the NOEL for FB1 is more than 2 ppm, which is more than the FDA proposed regulatory limit of 1 to 2 ppm. Supported by USDA-CSREES grant #928-39453, FDA and ILSI.

36 MOLECULAR SIGNATURE OF DIOXIN IN MURINE VASCULAR SMOOTH MUSCLE CELLS: ROLE OF THE ARYL HYDROCARBON RECEPTOR IN CARDIOVASCULAR DISEASE.

J. K. Kerzee and A. Puga. *Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Cardiovascular disease, primarily associated with disorders of atherosclerotic etiology, is the main cause of morbidity and mortality in the United States. Overt and cumulative exposure to environmental or occupational toxicants may play a role in the onset and progression of this disease. More than 35 different predisposing risk

factors for atherosclerosis have been identified, but little is known of the mechanism of action of environmental agents, due in part to lack of epidemiological studies and in part to lack of adequate animal models. Dioxins, such as 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), have been implicated as risk factors for atherosclerosis in humans. The objective of these studies was to test the hypothesis that TCDD exposure results in an aryl hydrocarbon receptor (AHR)-dependent reprogramming of gene expression in vascular smooth muscle cells (vSMCs). To test this hypothesis, we used gene arrays to examine genes involved in cell cycle regulation and apoptosis, as well as cytokines, chemokines and their receptors. Numerous cell cycle and apoptotic genes were found to be deregulated by 1nM TCDD in quiescent and synchronized vSMCs from *Ahr*$^{+/+}$ mice, but not in vSMCs from *Ahr*$^{-/-}$ mice. TCDD increased the mRNA levels of p21$^{Cip1/Waf1}$, mdm2, caspase 1, and cyclin D1 compared to controls by 2.7, 2.4, 2.2, and 1.8 fold, respectively. Decreases in TCDD-mediated gene expression were observed for p15^{Ink4b} and p57^{Kip2} compared to controls by 2.7 and 2.3 fold, respectively. At the protein level alterations in expression were detected for mdm2, caspase 1, and p15^{Ink4b}. These data suggest that vascular toxicants, such as TCDD, may alter gene profiles in vSMC in AHR-dependent manner that can translate into functional changes at the protein level. These finding may help us define a molecular fingerprint of vascular toxicants of utility to reduce the use of animals in toxicity testing. (Supported by Colgate-Palmolive/Society of Toxicology Postdoctoral Fellowship and NIH F32ES11250-01).

37 ARYL HYDROCARBON RECEPTOR (AHR) NULL MICE EXHIBIT HYPERTENSION AND INCREASED PLASMA ENDOTHELIN LEVELS.

A. K. Lund[1], N. L. Kanagy[2] and M. K. Walker[1,2]. [1]*College of Pharmacy, University of New Mexico, Albuquerque, NM and* [2]*Cell Biology and Physiology, University of New Mexico, Albuquerque, NM.*

AhR is a ligand-activated transcription factor known to mediate the toxicity of compounds such as 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), polychlorinated biphenyls and polycyclic aromatic hydrocarbons. Upon activation, AhR dimerizes with the aryl hydrocarbon nuclear translocator protein (ARNT). This complex then translocates into the nucleus where it binds to dioxin response elements (DREs) and upregulates a series of xenobiotic metabolizing enzymes. ARNT also heterodimerizes with hypoxia inducible factor 1 alpha (HIF1a), which then binds to hypoxia responsive elements (HREs), increasing transcription of hypoxia-induced genes. We have shown that AhR null mice develop cardiac hypertrophy by 5 months of age and exhibit increased HIF1a signaling in the heart. In addition, endothelin-1 (ET-1) is upregulated by hypoxia and the HIF1a signaling pathway. ET-1 is a circulating peptide associated with hypertension and cardiac hypertrophy. Thus, we tested the hypothesis that AhR null mice exhibit hypertension associated with increased plasma ET-1. Catheters were surgically placed in the femoral artery of both wildtype C57Bl6 and AhR null mice, age 4 -6 months. Mean arterial blood pressure (MAP) was averaged over a 10 minute recording period on day 3 post surgery and then the mouse was sacrificed and blood collected. Plasma ET-1 was measured using an RIA. AhR null mice exhibited significantly higher MAP compared to wildtype (wildtype, 98.9 ± 1.9; null, 128.2 ± 3.0 mm Hg; $p < 0.001$). AhR null mice also exhibited significantly higher plasma ET-1 compared to wildtype (wildtype, 8.4 ± 1.1; null, 11.3 ± 0.7 fmol/ml; $p < 0.04$). Thus, AhR null mice exhibit hypertension associated with increased plasma ET-1 levels. These data suggest that the increased hypertension afterload and increased plasma ET-1 could contribute to cardiac hypertrophy in AhR null mice. Supported in part by NIH grant ES-10433 and American Heart Association Desert Mountain Affiliate 0151511Z.

38 TOWARD MECHANISMS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN CARDIOVASCULAR EMBRYOTOXICITY: IDENTIFICATION OF CANDIDATE GENES USING cDNA MICROARRAYS.

H. M. Handley[1], M. W. Grow[2], J. J. Stegeman[1] and M. C. Fishman[3]. 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a powerful teratogen that perturbs the developing cardiovascular system of zebrafish. In embryos exposed to TCDD, the heart is distended and beats weakly, circulation is greatly reduced, and there is pericardial and yolk sac edema and regional hemorrhage. The molecular changes responsible for such cardiovascular embryotoxicity have yet to be defined. To address this problem, we developed zebrafish cDNA microarrays consisting of nearly 5, 200 adult heart cDNA clones, known heart markers, nuclear receptors and cytochrome P450s. Using these arrays, we have characterized alterations in embryonic gene expression resulting from TCDD exposures ranging from ED10 to ED100 for cardiovascular symptoms. Induction of CYP1A was consistently the strongest, most sensitive response. Expression of CYP19A (aromatase), AhR2, and ARNT also increased significantly after all TCDD exposures. Finally, more than fifty novel transcriptional responses were identified from among the adult heart cDNAs. By correlating the magnitude of transcriptional changes with that of toxicity, we have generated a list of genes that are likely to be involved in cardiovascular embryotoxicity. NIH #P42-ES07381

39 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) INDUCES FUNCTIONAL ACTIVATION OF THE GAMMA-INTERFERON ACTIVATED SEQUENCE IN RAT HEPATIC ENDOTHELIAL CELLS.

D. E. Heck[1], P. Zhou[1], J. D. Laskin[2] and C. Gardner[1]. [1]*Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and* [2]*Env. and Community Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.*

The ubiquitous environmental contaminant 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a developmental toxicant, potent tumor promoter in mice, and putative human carcinogen. TCDD elicits effects through altering gene expression in susceptible cells. We have found that exposure to TCDD results in activation of the interferon-gamma (IFN-g) activated sequence (GAS). Binding of IFN-g to its cellular receptor initiates tyrosine phosphorylation of STAT proteins, dimerization and subsequent translocation to the nucleus through interactions with a combination of second-messenger molecules, resulting in activation of GAS elements in the promoter regions of IFN-g-sensitive genes. Activation of GAS elements plays an important role in modulating expression of an array of genes important in inflammation. We have found that, similar to IFN-g, TCDD induces expression of type 2 nitric oxide synthase, type II MHC and COX 2 in rat hepatic endothelial cells. The toxicity of TCDD is mediated largely through binding of the environmental toxicant to the Ah receptor. We have found that the TCDD-bound Ah receptor directly interacts with STAT 1a modifying its activity. Moreover, in a manner similar to that of IFN-g, TCDD-mediated induction of gene expression results in functional alterations to hepatic endothelial cells. Nitric oxide production and prostaglandin release were modified in endothelial cells following TCDD-treatment. Through up regulation of STAT 1a, NOS2, type II major histocompatibility antigen, cyclooxygenase2 and other proinflammatory proteins, endothelial cells become immunologically activated, a process that plays an important role in inflammation and tissue injury. Our findings suggest that TCDD functions in endothelial cells by interacting in the IFN-g signaling pathway. We speculate that IFN-g mimetic activities, mediate, in part, the toxicity of TCDD in the liver. Supported by NIH ES 06897.

40 ARYL HYDROCARBON RECEPTOR (AHR) NULL MICE SHOW INCREASED CARDIAC HYPOXIA SIGNALING, BUT NO INCREASE IN CARDIAC HYPOXIA.

E. A. Thackaberry[1], S. M. Smith[1], D. M. Gabaldon[2] and M. K. Walker[2]. [1]*Environmental Toxicology Center, University of Wisconsin, Madison, WI and* [2]*College of Pharmacy, University of New Mexico, Albuquerque, NM.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) has been shown to cause cardiac malformations in the chick embryo and these effects are likely mediated by the AhR. Upon TCDD binding, AhR dimerizes with AhR nuclear translocator (ARNT), binds dioxin response elements, and upregulates xenobiotic metabolism genes. In response to hypoxia, ARNT also heterodimerizes with hypoxia-inducible factor 1 alpha (HIF1a). The HIF1a/ARNT complex then binds to hypoxia responsive elements, and facilitates transcription of hypoxia-responsive genes such as vascular endothelial growth factor (VEGF). This suggests that cross-talk between the TCDD and hypoxic signaling pathways could exist within the heart. We have previously reported that AhR null mice develop cardiac hypertrophy by 5 mo, as measured by increases in heart weight, heart/body weight ratio, and the cardiac hypertrophy markers, beta-myosin heavy chain and myosin light chain-2V. Here we show that AhR -/- mouse hearts have increased HIF1a protein and upregulate the hypoxia-responsive gene VEGF at 5 mo. We then used ^{3}H-misonidazole (MISO), which binds tissues in a pO_2-dependent manner, to determine the relative oxygen concentrations in wildtype and AhR -/- mouse hearts. At 3 mo, a time when no significant increase in heart weight nor HIF1a protein is seen in AhR -/- mice, no increase in MISO binding was observed. At 5 mo, when AhR -/- mice show a significant increase in both heart weight and HIF1a protein, there was still no increase in cardiac MISO binding. These data show that AhR -/- mice develop a significant increase in signaling through the cardiac HIF1a-mediated pathway despite normoxic conditions within the heart. This suggests that the increase in cardiac HIF1a signaling may be caused by disregulation of the HIF1a pathway due to a loss of AhR within the heart, and not by impaired oxygenation of the myocardium. Supported by NIH ES10433 and AHA Desert Mountain Affiliate 0151511Z.

41 GLOBAL GENE EXPRESSION PROFILES IN CHEMICAL ATHEROGENESIS.

C. D. Johnson, K. P. Lu, P. D. Beremand, T. L. Thomas and K. S. Ramos. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Environmental hydrocarbons have been implicated as significant risk factors in human atherosclerotic vascular disease. Using benzo(a)pyrene (BaP) as a model compound, this laboratory has shown that interference with gene transcription is a critical event in the induction of proliferative (i.e atherogenic) phenotypes in vascular smooth muscle cells (vSMCs). The complexity of the cellular response elicited by BaP requires characterization of interactive gene networks involved in the atherogenic response. To achieve this objective, vSMCs isolated from the thoracic aorta of adult C57BL6J were established in serial culture and used as a model to evaluate the atherogenic response to BaP. G0 synchronized cultures were released into growth by addition of fetal bovine serum in the presence of DMSO (control) or 3 uM BaP for 8 hr, a regimen known to modulate vSMC phenotypes *in vitro*. Control and treated mRNAs were isolated and labeled with Cy3 and Cy5, respectively, and hybridized to custom-made mouse cDNA microarrays of 960 genes spotted in triplicate. Array intensities were evaluated as prescribed by GeneSpring® software to identify differentially expressed genes. Over 150 genes were altered in vSMCs by BaP treatment. Genes coding for RAS, cholesterol-regulated CR36 protein, several heat shock proteins, retinoic acid repressible protein, and insulin-like growth factor 1 receptor were significantly upregulated. Other genes increased by atherogen treatment included peroxiredoxin, cofilin, bromodomain PHD finger transcription factor, TIF1 beta, GTP-binding protein, G protein gamma-2 subunit, recA /RAD51, and BAF53a. These results confirm previous findings and implicate genes involved in ras signaling, oxidative stress, DNA repair, and chromatin remodeling in the atherogenic response elicited by BaP. (Supported by NIH grants ES 04849 and ES09106. CDJ is a postdoctoral fellow in NIEHS training grant ES 07273).

42 IMMUNOMODULATORY EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN IN LUNG CELLS AND/OR TISSUE.

J. M. Martinez, C. A. Afshari, C. R. Miller and N. J. Walker. *NIEHS, Research Triangle Park, NC.*

Interferon (IFN) can play a role in development of primary tumor and shape tumorigenicity. Previous results using real-time RT-PCR and microarray analysis of human peripheral lung airway epithelial cells (HPL1A), showed repression of several IFN regulated genes and induction of IFN regulatory factor 4 (IRF4) when treated with 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD). We hypothesize that TCDD alters the response of HPL1A cells to interferon. Since IFN-gamma is known to inhibit cell proliferation, cells were treated with 1X104 units/ml for 24 hours plus or minus TCDD (10nM) pretreatment. An aqueous soluble tetrazolium/formazan assay was used to detect cell growth changes. Up to 30 nM concentrations, TCDD did not cause any cell growth changes compared to cells given vehicle (FBS) only. By comparison, treatment with INF-gamma caused a 28 % decrease in cell growth ($P < 0.001$). Pre-treatment with TCDD (10nM), reduced this decrease in cell growth caused by INF-gamma by approximately 50 % ($P < 0.001$). Our next objective was to do a cross-species comparison looking at *in vivo* gene expression in rat lung. We sought to determine how TCDD treatment affected interferon regulatory factor 4 (IRF4) and myxovirus (influenza) resistance 1, homolog of murine interferon-inducible protein p78 (MX1). Sprague-Dawley rats were treated by oral gavage twice weekly. Control animals were given vehicle (corn oil) only, and the treated group consisted of a subacute treatment (350 ng/kg twice a week). Using RNA isolated from rat lung tissue, we analyzed IRF4 and MX1 expression by real-time RT-PCR. We found that IRF4 was induced after 5 weeks TCDD treatment, while MX1 was suppressed. This inverse gene relationship was the trend of expression we previously found in the HPL1A cell line. Overall, this data suggest a novel role for TCDD in immunomodulation in human lung cells that appears to be conserved in rats

43 MATRIX-DEPENDENT ALTERATIONS IN REL PROTEIN EXPRESSION AND NF-KAPPAB ACTIVITY AFTER OXIDATIVE INJURY.

E. S. Williams[1], A. Ridall[2], E. Wilson[1] and K. S. Ramos[1]. [1]*Center for Environmental and Rural Health, Texas A&M University, College Station, TX and* [2]*Health Science Center, University of Texas, Houston, TX.*

Repeated cycles of chemical injury by allylamine induce proliferative (i.e. atherogenic) vascular smooth muscle cell phenotypes in male rats. Activated smooth muscle cells display matrix-specific changes in proliferation that correlate with NF-kappaB binding activity. Injured cells exhibit a proliferative advantage when seeded on plastic, fibronectin, or laminin, but not collagen. These cells also display altered patterns of osteopontin expression, secretion, and cleavage, coupled with changes in the expression of several integrin subunits. Integrin-mediated increases in NF-kappaB activity may occur as a result of altered expression profiles of NF-kappaB constituent proteins. To test this hypothesis, the present studies examined changes in Rel protein expression in populations of control and oxidatively stressed cells following repeated cycles of allylamine injury. Sprague-Dawley rats (175-180 g) were gavaged once daily with allylamine (70 mg/kg) for 20 consecutive days. Vascular smooth muscle cells were isolated by enzymatic digestion, and cells maintained in serial culture for up to 25 passages. Western analysis demonstrated that Rel-A protein levels decreased in allylamine cells seeded on plastic, with concomitant appearance of a novel 50kDa immunoreactive protein. Furthermore, p50 protein levels increased in allylamine cells seeded on plastic, but not on collagen, fibronectin, or laminin. Seeding of allylamine cells on plastic, but not collagen, fibronectin, or laminin reduced Rel-B protein levels relative to controls. These results suggest that changes in Rel protein expression may contribute to the expression and/or maintenance of allylamine-induced atherogenic phenotypes. (This work was supported in part by NIH grants HL62539 and ES09106).

44 TOXICOGENOMICS: FINGERPRINTING TOXIC COMPOUNDS USING GENE EXPRESSION PROFILES.

L. Suter-Dick, F. Boess, R. Gasser, C. de Vera, F. Crameri, M. Bedoucha, S. Evers and S. Albertini. *PRNS/Toxicology, F. Hoffmann-La Roche, Basle, Switzerland.*

In the recent past there has been considerable interest in linking the modulation of gene expression to the toxicity of drugs. Toxicogenomics is considered a valuable tool for the understanding of underlying mechanisms of toxicity and for the early prediction of toxic liabilities in toxicological studies. It is expected that gene expression profiles will generate fingerprints typical of classes of toxicants, as well as provide new and sensitive toxicity markers. In this paper we established and investigated the effect of five hepatotoxic compounds with a similar mechanism of toxicity on gene expression profiles in male Wistar rats. The so-called "direct acting compounds" tested in this study were Thioacetamide, Bromobenzene, CCl4, dichlorobenzene and hydrazine. The gene expression in the liver was evaluated using Affymetrix GeneChip® microarrays. Genes regulated by at least 4 of these compounds were considered characteristic for these toxins. This "direct acting fingerprint" was then compared with the modulation of the same genes caused by four steatotic compounds (Tetracycline, Amiodarone, Doxycycline and Amineptine) and by 1, 4-DCB, a non-toxic regioisomer of the "direct acting" compound 1, 2-DCB. The results presented in this paper show that gene expression profiles can be used to distinguish "direct acting" compounds from other types of compounds such as the non-toxic compound 1, 4-DCB and the tested steatotic compounds. Furthermore, the assessment of the modulation of gene expression in two experiments performed independently with the same compound showed good reproducibility of the gene expression profiles. In conclusion, gene expression profiles in liver after exposure to hepatotoxins are reproducible and characteristic of classes of toxins. Gene expression fingerprints allow different types of toxins to be distinguished from each other and from non-toxic compounds.

45 COMPOUND PROFILING USING CDNA ARRAY BASED DIFFERENTIAL GENE EXPRESSION OF HUMAN AND RAT HEPATOCYTES.

T. Hansen[2], M. Dangers[2], J. Borlak[2], B. Gerstmayer[1], S. Tomiuk[1], K. Hofmann[1], F. Hübel[1] and A. Bosio[1]. [1]*MEMOREC Stoffel GmbH, Cologne, Germany and* [2]*Centre for Drug Research and Medical Biotechnology, Fraunhofer Institute ITA, Hannover, Germany.* Sponsor: H. Muhle.

Compound profiling strategies are of great interest in the process of developing new pharmaceuticals. Combinatorial chemistry and high throughput screening technologies are flooding the development pipelines with possible candidates and efficient and reliable tools are required to properly rank them. Target validation and early predictive toxicogenomics are areas which can be especially forwarded through microarray applications. We have started to set up a ToxSAYS™ database, where we are determining the gene expression of more than 1, 000 well-defined human and rat ortholog genes in response to treatment with the 150 most frequently prescribed drugs and a whole range of chemicals with known toxicological effects. For the development of this database, we investigate gene expression profiles in primary rat and human hepatocytes, and in tissues and organs from GLP-compliant four-week toxicity studies. The selected genes are involved in Toxicology-relevant cell activities like apoptosis, cell cycling, proliferation, DNA damage/repair, inflammation, oxidative stress, transport and metabolism. For each gene 200 -400 bp cDNA fragments are rigidly selected to avoid cross reactions between high homologous gene families. Starting with a set of toxic compounds e.g., Aroclor 1254, Allylalcohol, Galactosamine, Concanavaline, Acetaminophen and Thioacetamide we demonstrate the induction of distinct gene expression profiles by each of these

compounds. A correlation of gene expression profiles with a time and dose dependent mode of action is exemplified showing the significant regulation of genes which are targeted by the Ah-ARNT transcription factor in response to Aroclor 1254.

46 GENE EXPRESSION CHANGES IN RAT LIVER ASSOCIATED WITH CHOLESTASIS.

F. J. Elcock, A. J. Winkley, N. Simecek, R. M. Yallop, K. L. Blackwell, P. A. Shaw, W. Wu and S. E. Wildsmith. *Safety Assessment, GlaxoSmithKline Pharmaceuticals, Herts, United Kingdom.* Sponsor: M. Tirmenstein.

Microarray technology enables the investigation of large scale gene expression in response to toxic insult. By generating expression data on many genes simultaneously it is feasible that compounds could be classified according to their gene expression pattern or "signature." The aim of the following work was to determine whether different mechanisms of hepatotoxicity could be distinguished based on differential gene expression analysis. Oestrogens and oestrogen glucuronides have been chosen specifically for the purpose of this study as they have long been implicated in the pathogenesis of intrahepatic cholestasis. To complement these, one structurally-related oestrogen that does not cause cholestasis and the model hepatotoxins alpha-naphthyl isothiocyanate and carbon tetrachloride have been added for comparative purposes. Male Sprague-Dawley rats, 250-335g were administered with either 17-alpha-ethinyloestradiol, estradiol-17-beta-D-glucuronide, oestriol-17-beta-D-glucuronide, oestriol-16-alpha-(beta-D-glucuronide) or oestradiol-3-beta-D-glucuronide at 5mg/kg/day. Alpha-naphthyl isothiocyanate and carbon tetrachloride were administered at 50mg/kg/day and 100mg/kg/day respectively. Compounds were administered to five animals per compound group for a series of four days followed by necropsy on day five. The liver from each animal was immediately snap frozen in liquid nitrogen and stored at -80°C. Following this, total RNA was extracted and gene expression analysis carried out using a proprietary cDNA microarray system. Six replicate microarray hybridisations were performed for each RNA sample and the data were analysed by univariate and multivariate analysis. The results showed a difference in gene expression associated with different treatment groups. We propose that this technology is useful for gene expression pattern profiling associated with different hepatotoxicants and may facilitate predictive toxicology.

47 DNA MICROARRAY ANALYSIS OF PROTOTYPE HEPATOCARCINOGENS IN PRIMARY RAT HEPATOCYTES.

K. L. Kolaja[1], J. A. Kramer[2], R. T. Bunch[1], S. W. Curtiss[2], C. Jackson[2], D. L. Morris[2] and J. C. Davila[2]. [1]*Global Toxicology, Pharmacia, Skokie, IL and* [2]*Global Investigative Toxicology, Pharmacia, St Louis, MO.*

An *in vitro* study was performed using primary rat hepatocytes to evaluate the gene expression profiling of known rodent hepatocarcinogens. Adult rat hepatocytes were cultured with Matrigel and treated with 2AAF, 4AAF, bemitradine (BEM), doxylamine (DOX), methapyrilene (MET), tamoxifen (TAM), and phenobarbital (PHEN) for 48 hr at concentrations ranging from 1 to 500 µM. Doses determined to be toxic by MTT reduction and LDH leakage were not evaluated for gene expression. Messenger RNA was isolated from cultured hepatocytes and used to prepare Cy3- and Cy5-labeled cDNA probes. The probes were hybridized against Incyte RatGEM 1 microarrays, which contain approximately 7, 800 arrayed sequences. Several approaches were used to analyze the profiling data, statistical evaluations, including gene clustering, correlations with phenotypes, and pathway analysis. Characteristic P450 induction profiles were observed as 2AAF, 4AAF, BEM, MET, and TAM treatment induced CYP1A1; 4AAF, BEM, and PB treatment induced CYP2B1; and 2AAF, 4AAF, BEM, DOX, TAM and PB induced CYP3A1. Clustering the expression data with predicted carcinogenicity or genotoxicity identified several candidate molecular markers that may be predictive of carcinogenicity and of genotoxicity such as thymosin beta 4. Interestingly, clustering analysis results from *in vitro* treatment of these same compounds led to a completely different subset of genes identified after *in vivo* treatment.

48 INVESTIGATION OF THE GENE EXPRESSION PROFILES OF HEPATOTOXIC AND NON-HEPATOTOXIC THIOXANTHONE ANTI-TUMOR AGENTS USING cDNA MICROARRAYS.

L. T. Roadcap, V. D. Shultz, T. E. White and A. E. Roberts. *Toxicology, Sanofi-Synthelabo Research, Malvern, PA.*

Gene array technology may prove useful for investigating molecular mechanisms and screening new drug candidates. The utility of microarrays will depend on the extent to which they can identify and predict the genes that are changed in target organs. Sanofi-Synthelabo is studying the utility of microarrays using a series of 5 thioxanthone anti-tumor agents. Within this series of DNA-damaging anti-tumor agents there are both hepatotoxic (3) and non-hepatotoxic (2) compounds. The gene expression profiles of these compounds are being compared as a means of identifying genes associated with hepatotoxicity. HepG2 human hepatoblastoma cells were exposed to each thioxanthone at a concentration that results in 20-30% cell death (MTT reduction). Cells were exposed to compound for a period of 4 hours to approximate the *in vivo* half-life of the thioxanthones. Cells were incubated for 44 additional hours (w/o compound) to mimic the time frame for appearance of hepatotoxicity *in vivo*. mRNA was isolated and radiolabeled cDNA probes were generated and hybridized to Clontech Human Toxicology II™ arrays. The expression of 144 genes was altered by the thioxanthones (≥ 1.5-fold increase or decrease over untreated controls). Genes whose expression was changed included those involved in apoptosis, cell signaling, cell cycle regulation, DNA damage and repair, stress response, and xenobiotic metabolism. Of the total list of changed genes, 10 were changed only by hepatotoxic thioxanthones (e.g., GST homolog); 17 others were changed only by non-hepatotoxic thioxanthones (e.g., ERK4; MAPK4). As expected for DNA-damaging agents, genes such as p53, WAF1/p21, GADD153, GSHPX1, c-jun, and ERCC1 were changed by all 5 thioxanthones. These results suggest there are gene expression changes specific to hepatotoxic thioxanthones. A more extensive time course analysis of gene expression is being performed to determine the molecular pathways associated with the onset of hepatotoxicity.

49 GENE EXPRESSION PROFILES OF 4-AMINOBIPHENYL AND BIPHENYL IN MOUSE LIVER.

C. A. McQueen[1], B. Chau[1], V. E. Richards[1] and G. Watts[2]. [1]*Pharmacology and Toxicology, University of Arizona, Tucson, AZ and* [2]*Arizona Cancer Center, Tucson, AZ.*

Arylamines such as 4-aminobiphenyl (4ABP) are human and animal carcinogens. Biotransformation results in the formation of electrophilic products that can react with DNA causing mutations leading to the development of tumors. While the genotoxicity of 4ABP is well defined, little is known about alterations that may occur in the expression of genes in target tissue. A study was initiated to profile the changes in gene expression associated with acute exposure to the carcinogen 4ABP. The noncarcinogenic structural analog biphenyl (BP) was also tested in order to assess the contribution of reactive arylamine products to changes in expression patterns. Adult male C57Bl/6 mice were given an oral dose 120 mg 4ABP or BP/kg. Controls received corn oil. After 24h, livers were harvested. RNA was isolated and used to synthesize cDNAs labeled with Cy3 or Cy 5. Labeled cDNAs from control and treated animals were competitively hybridized to a 5300 microarray created using mouse cDNA clones obtained from Research Genetics, then scanned to detect fluorescence intensities. Data were examined based on 3 replicate experiments. Initial analysis at p=0.01 identified 270 genes with 4ABP-induced changes in expression and 59 with BP. With the additional stringency of a 2 fold change in expression, 60 genes were altered with 4ABP while BP induced no effect. An alternative analysis based on a 2 fold change in expression ratio and a minimum fluorescence intensity of 200 also showed no changes with BP exposure but 4ABP-induced changes in 124 genes. There were 55 genes up regulated and 69 down regulated. These included genes related to stress responses such as MT-1, TGF*beta* and Grpl2. 4ABP and BP, differing only in the presence of an animo group at the 4-position, generated compound specific gene expression profiles. These data support the conclusion that the increased number of genes affected by 4ABP is linked to its potential for further activation and formation of electrophilic products. (Supported by ES 09812 and ES 10047).

50 ASSESSMENT OF HEPATOCYTES AND LIVER SLICES AS *IN VITRO* TEST SYSTEMS TO PREDICT *IN VIVO* GENE EXPRESSION.

J. Stahl[1], A. de Peyster[1], B. Jessen[2] and G. Stevens[2]. [1]*Graduate School of Public Health, San Diego State University, San Diego, CA and* [2]*Drug Safety Evaluation, Pfizer Global R&D/Agouron Pharmaceuticals, San Diego, CA.*

Primary hepatocytes and precision cut liver slices are two common *in vitro* systems used to predict and evaluate xenobiotic induced hepatotoxicity. Toxicogenomics has recently been used to assess changes in gene expression in a variety of *in vitro* and *in vivo* systems. However, comparisons of changes in gene expression in response to toxicant exposure *in vitro* to those observed *in vivo* have not been performed. This study was conducted in rats to assess the changes in gene expression in primary hepatocytes, precision cut liver slices and *in vivo* after exposure to known hepatotoxicants. Five representative compounds, phenobarbital (PB), carbon tetrachloride (CCl_4), Wy-14, 634, alpha-naphthylisothiocyanate (ANIT) and tacrine were selected for their broad range of mechanisms in hepatocellular response. *in vivo*, male rats (4/group) were treated with acute doses of PB (100 mg/kg), CCl_4 (1ml/kg), Wy-14, 634 (150 mg/kg), ANIT (150 mg/kg) or tacrine (30 mg/kg) and sacrificed 24 hours later. *in vitro*, hepatocytes and liver slices were incubated with

PB (0.1 mM), CCl_4 (0.3 mM), Wy-14, 634 (0.5 mM), ANIT (0.1 mM) or tacrine (0.05 mM) for 24 hours. Total RNA was extracted from the three test systems and gene expression measured using Affymetrix U34A rat GeneChips. Very few genes that change with *in vivo* treatment were observed in either of the two *in vitro* systems. However, changes in gene expression in tissue slices appeared to provide a better correlation to the *in vivo* setting than hepatocytes. Additional time points and doses (or concentrations) will be required to elucidate the true correlation between the models.

51 GENE EXPRESSION PROFILING REVEALS MULTIPLE TOXICITY ENDPOINTS INDUCED BY HEPATOTOXINS.

Q. Huang, S. Jadavey, O. DiSorbo, R. Stoll and K. Blanchard. *Toxicology, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT.*

Microarray technology, which examines global gene expression changes, has a huge potential to revolutionize the processes of drug discovery and development. In the current study, gene expression profiling was used to investigate the mechanisms of hepatotoxicity induced by therapeutic agents. Acetaminophen, methotrexate, methapyrilene, and phenytoin are known to cause different types of hepatotoxicity. The challenge is whether gene expression profiles can distinguish these subtypes of hepatotoxicity. Sprague-Dawley rats were orally dosed with acetaminophen (4500 mg/kg/day for 6, 24, and 72h), methotrexate (1 mg/kg/day for 1, 7 and 14 days), methapyrilene (100 mg/kg/day for 1, 3, and 7 days) or phenytoin (300 mg/kg/day for 14 days). Hepatic gene expression was assessed using gene arrays containing 700 targets. Significant changes in gene expression induced by each compound were categorized into subsets according to functionality, providing insight into the mechanisms of toxicity. For example, induction of cathepsin and other inflammatory related genes by acetaminophen and methapyrilene correlated with findings such as necrosis and inflammatory cell infiltrates. While increased microsomal enzyme expression correlated with hepatocellular hypertrophy induced by phenytoin. Although it is not possible to provide a complete interpretation of all gene changes, the current study suggests that this approach is useful in delineating subtypes of hepatotoxicity.

52 ASSESSMENT OF HEPATOTOXIN-INDUCED DIFFERENTIAL GENE EXPRESSION *IN VITRO* USING cDNA MICROARRAY TECHNOLOGY.

H. M. Harries, C. M. Duggan and V. A. Baker. *SEAC, Unilever, Bedfordshire, United Kingdom.* Sponsor: D. Basketter.

Toxicogenomics is a powerful tool for investigating molecular mechanisms of toxicity and predicting adverse effects by monitoring large-scale gene expression profiles. First however, it is necessary to evaluate the data generated using microarray technology with compounds of well characterised toxicity. Hepatotoxicity, being one of the most well researched toxic endpoints, was chosen for this purpose. HepG2 cells were exposed (in triplicate) to four classic hepatotoxins; carbon tetrachloride (CCl_4), clofibrate, ethanol (EtOH) and dimethylformamide (DMF) for periods of 2h and 24h at high and low doses corresponding to 50% and 20% cell death (as determined by MTT assay) respectively. Following exposure, mRNA was isolated, ^{33}P labelled cDNA probes constructed and used to probe Atlas™ Human Toxicology II arrays (Clontech). Probed arrays were exposed to X-ray film, and the images captured and analysed using AtlasImage™ software. Data revealed relatively few changes in gene expression following 2hr exposure compared to 24hr exposure, this being more pronounced at the higher doses. Although there was some similarity in differential gene expression observed across chemicals, a number of hepatotoxin-specific gene expression changes were identified, reflecting their different mechanisms of toxicity. For example, treatment with EtOH (both concentrations) gave rise predominantly to differential expression of genes involved in metabolism (e.g. CYP3A3) and stress response (e.g.β crystallin A4), whereas CCl_4 (both concentrations) resulted in gene expression changes involved in extracellular transport (e.g. OCTN1) and cell signalling (e.g. tyrosine protein kinase receptor). Real Time PCR was used to confirm expression for selected genes. In conclusion, these results suggest that specific patterns of gene expression may be associated with different mechanisms of hepatotoxicity, which may be useful as early markers of toxicity

53 GENE EXPRESSION PROFILING OF CULTURES OF PRIMARY RAT HEPATOCYTES TREATED WITH HYDRAZINE.

J. E. Eldridge[1], S. Berberich[2], S. M. Hussain[3], J. M. Frazier[4] and C. Wang[3]. *[1]Chemistry, United States Air Force Academy, Colorado Springs, CO, [2]Biochemistry and Molecular Biology, Wright State University, Dayton, OH, [3]ManTech Environmental Technology Inc., Dayton, OH and [4]Operational Toxicology Branch, Air Force Research Laboratory, Wright-Patterson AFB, OH.*

Hydrazine and its derivatives are colorless liquids used by the Department of Defense as reducing agents in aircraft and propellant systems. Various toxic effects have been associated with exposure to hydrazine, including skin irritation, convulsions, hepatotoxicity, hemolytic effects, neurotoxicity, genotoxicity and it is also a suspected carcinogen. However, there are limited data on genomic effects related to hydrazine exposure. In this study, primary cultures of rat hepatocytes were treated with 0, 25, or 50 mM hydrazine for 4 hours at 37 °C. Total RNA was isolated immediately following the exposure to determine mRNA expression profiles using the Affymetrix RatTox U34 and the Affymetrix RatGenome U34A arrays. Our results indicated that hydrazine exposure caused a significant induction of stress related genes (e.g., *hsp*70s and *hsp*40s), transcription factors such as AP-1 and Sp-1 and a moderate induction of various cellular proliferation growth factors (e.g., VEGF, HB-EGF, CYR 61 and Egr1), but a significant (more than 2-fold) down-regulation of certain phase I and phase II drug metabolizing enzymes (e.g., CYP 450s, GSTs and NQO1). In addition, a significant down-regulation of the stress related heme oxygenase gene was seen. These results will provide important data for a complete risk assessment for hydrazine and serve as a baseline for evaluating the toxicity of newly synthesized high-energy chemicals as candidate replacements for hydrazine.

54 ANALYSIS OF THE SHORT TERM EFFECTS OF TREATMENT WITH PROTOTYPE HEPATOCARCINOGENS AS ASSESSED BY DNA MICROARRAYS.

J. A. Kramer[1], K. L. Kolaja[2], R. T. Bunch[2], S. W. Curtiss[1], J. C. Davila[1], C. J. Jackson[1] and D. L. Morris[1]. *[1]Global Investigative Toxicology, Pharmacia Corporation, St Louis, MO and [2]Global Toxicology, Pharmacia Corporation, Skokie, IL.*

Chronic administration of high doses of certain compounds may induce hepatocellular tumors in rodents. Gene expression profiling can be utilized to characterize transcriptional responses to such treatments and improve our understanding of the mechanisms by which hepatocarcinogens produce tumors. The objective of this study was to evaluate chemically-induced changes in gene expression that may be altered during toxicity, and to identify expression patterns that may be predictive of carcinogenicity. Male Sprague-Dawley rats were treated daily for 5 days with one of three doses of several mutagenic or non-mutagenic carcinogenic or non-carcinogenic compounds. The compounds used were bemitradine, clofibrate, phenobarbital, tamoxifen, 2-AAF, 4-AAF, doxylamine, methapyrilene, and isoniazid. A single animal in one group died, but in general, all compounds and doses were well tolerated and no other mortality was observed. No gross abnormalities were noted at necropsy. Messenger RNA was isolated from livers of each animal and used to prepare Cy3- and Cy5-labeled cDNA probes. The probes were hybridized against Incyte RatGEM 1 microarrays, which contain approximately 7, 800 arrayed sequences. Several approaches were used to analyse the profiling data, statistical evaluations, including gene clustering, correlations with phenotypes, and pathway analysis. Clustering the expression data with predicted carcinogenicity or genotoxicity identified candidate molecular markers that may be predictive of carcinogenicity and of genotoxicity. Among those genes whose expression may predict carcinogenicity was TSC-22, a TGF-beta regulated gene encoding a leucine zipper that may be involved in developmental differentiation. Additional insight into the mechanisms of toxicity of some of the individual compounds was obtained through pathway analysis of genes affected by different dose levels of individual compounds.

55 TRANSCRIPTOMIC AND PROTEOMIC FINGERPRINTING OF HYDRAZINE TOXICITY IN PRIMARY RAT HEPATOCYTES.

C. Wang[1,4], F. A. Witzmann[2], D. W. Quinn[3], S. M. Hussain[1,4] and J. M. Frazier[4]. *[1]ManTech Environmental Technology, Inc, Dayton, OH, [2]IUPU, Columbus, IN, [3]Air Force Institute of Technology, WPAFB, OH and [4]AFRL/HEST, WPAFB, OH.*

Any toxic chemicals will disturb gene expression and will give rise to a specific "fingerprint" of chemical toxicity. These changes in gene expression are extremely sensitive and unique, and can serve as biomarkers of the ultimate toxicity. Hydrazine (Hz) is used as fuel and propellant in aircraft and rockets. Hz is a hepatotoxic chemical, causing cirrhosis and necrosis in liver and it is a suspected carcinogen. There are limited data on the mechanisms of Hz toxicity, particularly on how Hz affects gene expression. To fingerprint Hz toxicity, rat primary hepatocytes were exposed to Hz at 0, 50 or 75 mM for 2 hrs at 37 °C. Total RNA was isolated at -2 (pretreatment), 0, 3, 6, 12 and 24 hrs post exposure to determine mRNA expression profiles using the Affymetrix RatTox U34 array. Cell lysates were also prepared at the same time points to determine global protein expression by 2D gel electrophoresis followed by peptide fingerprint and mass spectrometry. Our results indicated that (1) Hz modulated gene expression profiles, exhibiting time-course and dose-dependent responses for certain genes; (2) effects of Hz on gene expression profiles in rat primary hepatocytes were consistent with the results of cytotoxicity data, however, transcript responses seemed to be more sensitive; (3) based on approximate 110 proteins identified out of 1400 spots on 2D gels, protein expression was not well

correlated to the corresponding mRNA expression; (4) Hz modulation of transcripts resulted in time-specific patterns for certain genes, with an immediate significant induction of stress genes (ie., *hsp*40s and *hsp*70s), but a delayed dose-dependent up-regulation of apoptosis genes (ie., caspase-2 and fos) suggesting possible delayed apoptosis of cells. The transcriptomic and proteomic fingerprints of Hz toxicity in primary rat hepatocytes can help in identifying early biomarkers that can be used to predict human health effects.

56 IDENTIFICATION OF GENES ASSOCIATED WITH DRUG-INDUCED HEPATOCYTE PROLIFERATION IN THE RAT.

T. Orton, L. Hole, S. Gould, G. Betton, J. Tugwood and J. Sidaway. *Safety Assessment, Astrazneca, Macclesfield, United Kingdom.*

Most rodent non-genotoxic hepatocarcinogens transiently increase hepatocyte proliferation during the first week of chronic exposure. Many of these agents also induce cytochrome P450 (CYP) enzymes at the level of gene expression by activating liver specific nuclear receptors such as the pregnane-X-receptor (PXR). Pregnenolone 16a-carbonitrile (PCN) and the glucocorticoid receptor (GR) agonist dexamethasone (Dex) are CYP3A inducers and PXR ligands. However, whereas PCN is a mitogen in the rat liver, Dex is not. The purpose of this study was to use Affymetrix transcript profiling technology to discriminate between gene expression changes caused by the two drugs and potentially identify genes associated with compound-induced hyperplasia. PCN (100mg/kg po), Dex (50mg/kg po) and corn oil (vehicle control) were administered daily to male Sprague-Dawley rats. RNA was isolated from rat livers after 6, 24 and 96 hours of drug exposure and used to generate cRNA probes for hybridisation to Affymetrix Rat U34A GeneChips. Genes were divided into functional categories and the expression changes (two fold change threshold and $P<0.05$ by Students t test) categorised according to whether they were common to both drugs or unique to one drug alone. CYP3A gene expression was upregulated at 24 and 96 hours by both drugs, although most changes in this category occurred at 6 hours and included genes involved in proliferation (cyclin G and CDK activating kinase). A small number of genes were uniquely regulated by PCN at 6 and 24 hours and mainly consisted of genes associated with proliferation (p21, cyclin B) and signalling (rhoB, IkB). Dex specific changes predominated at the later time points with suppression of genes involved in proliferative and immune pathways. A model is proposed in which PCN induces genes involved in cell cycle progression *via* PXR, whereas Dex suppresses DNA synthesis through the activation of GR, which has been previously demonstrated to inhibit growth factor induced signal transduction pathways.

57 ESSENTIALITY OF BRAIN EDEMA IN BINGE ETHANOL INDUCED BRAIN DAMAGE: PROTECTIVE EFFECT OF THE DIURETIC ACETAZOLAMIDE.

S. Kumar, E. J. Neafsey and M. A. Collins. *Cell Biology, Neurobiology and Anatomy, Loyola University Medical Center, Maywood, IL.*

Binge alcoholism results in brain damage. Though brain damage was suggested as a result of synaptic excitotoxic events, the underlying mechanisms are uncertain. Earlier results using the diuretic Furosemide (Faseb J. 12:221; 1998) suggest that non-synaptic regulation of brain cell volume may be more important for the occurrence of neuronal degeneration due to binge alcohol abuse than activation of synaptic excitatory receptors. As Furosemide is an efficient anti-oxidant agent, the protective effect of Furosemide was related to its anti-oxidant activity rather than reduction in edema (Hamelink et al., Soc. Neurosci. Abst. 2000). To test the essentiality of brain edema in binge ethanol induced brain damage, the diuretic drug acetazolamide (AZT) was used. AZT, a carbonic anhydrase inhibitor, is a different class of diuretic compared to Furosemide (Na/K/Cl channel inhibitor). AZT is not an anti-oxidant as established by the oxygen radical absorbance capacity (ORAC) assay. Male Wistar albino rats were separated into four treatment groups as control (saline), AZT (30 mg/kg b.w; i.p.), ethanol (ETOH; 30% orally gavaged), ETOH+AZT. Rats were treated for 8 days. Blood ethanol levels were comparable and insignificant in ethanol treated rats and ETOH+AZT treatment group. Brain edema was quantified following the method outlined by Elliot and Jasper (1949). AZT significantly ($p<0.001$) reduced brain edema in ETOH+AZT treated rats compared to ETOH treated rats. In addition to blocking brain hydration, AZT treatment reduced degeneration in ETOH intoxicated rats. The protective effect of the diuretic AZT was also confirmed in an *in vitro* model of binge ETOH toxicity using organotypic hippocampal-entorhinal cortex culture. The results of the *in vivo* study in tandem with *in vitro* organotypic culture suggest brain edema as an essential upstream event leading to brain damage independent of the anti-oxidant activity of the diuretic. Further studies aimed at quantitative analyses of brain edema in organotypic cultures are under way.

58 ROLE OF NITRIC OXIDE SYNTHASE-GENERATED REACTIVE INTERMEDIATES IN THE NEUROTOXICITY OF NITROARENES.

J. J. Tobias and R. T. Miller. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

We are using *E. coli*-expressed and purified neuronal nitric oxide synthase (nNOS) and the dinitrobenzene isomers (DNBs) as models of metabolism-dependent neurotoxicity. 1, 3-DNB is the most extensively studied of the DNB isomers, however the mechanism(s) involved in the CNS toxicity of 1, 3-DNB is unknown. The primary cellular targets involved in 1, 3-DNB-mediated CNS toxicity are glial cells and vascular tissue within discreet regions of the brain, including the cerebellum. Neuronal death appears to follow an initial damaging event to the glial and vascular elements and it has been postulated that 1, 3-DNB-mediated CNS toxicity is associated with the production of free radicals. Considering that nNOS is found in very high concentrations in the cerebellum, the same brain region targeted by 1, 3-DNB, we have initiated studies examining the interaction of the DNBs with nNOS. We have found that the DNBs redox cycle in the presence of nNOS resulting in an accelerated rate of NADPH oxidation in the rank order 1, 4-DNB > 1, 2-DNB > 1, 3-DNB. The increased NADPH oxidation leads to production of superoxide anion radical which traps the enzymatically-produced nitric oxide (NO•) resulting in increased nNOS activity. 1, 4-DNB is the most potent in this respect, with 1, 3-DNB being the least potent. However, although nNOS activity is increased by the DNBs, the products of the nNOS reaction, as measured by DCDHF oxidation, shift from NO• and L-citrulline in the absence of the DNBs, to the powerful oxidant peroxynitrite and L-citrulline in the presence of the DNBs. Furthermore, peroxynitrite production is blocked by inclusion of either superoxide dismutase or nitro-L-arginine in the enzyme assays. Collectively, these data demonstrate that in the presence of the DNBs, nNOS is converted from a NO• synthase to a peroxynitrite synthase. These studies have established a foundation from which more advanced experimentation into the production of reactive intermediates by the nNOS-DNB interaction can be based.(Supported by the Research Challenge Trust Fund at the University of Kentucky)

59 IMMUNOHISTOCHEMICAL AND *IN SITU* HYBRIDIZATION STUDY OF METALLOTHIONEIN (I & II, III) EXPRESSION IN THE BRAIN OF AGED DOG.

A. Shimada, M. Maeda, Y. Mizutani, M. Sawada and T. Morita. *Veterinary Pathology, Tottori University, Tottori, Japan.*

Dogs are known to share a variety of morphological age-related brain changes with humans; the changes include neuronal loss and amyloidosis in the cerebral cortex, dystrophic axonal changes and ubiquitin deposition in the white matter. Iron also accumulates with age in the brain of dogs, the change may relate to the degenerative structural changes through iron-induced oxidative injury. Little is known, however, of the metallothionein (MT) related protection mechanism in the brain against oxygen radical species. To study the roles of MTs in the brain, the expression patterns of metallothioneins (I & II, III) were compared between the brains with severe age-related changes and those with mild changes (immunohistochemistry, *in situ* hybridazation). Total MT level was analyzed by the mercury-binding assay. Intense MT-I & -II immunoreactivity as well as signals for MT-I & -II mRNA were shown in the hypertrophic astrocytes in the brains with severe age-related changes. These MT-I & -II positive astrocytes dominated in the thalamus, cerebral cortex and medulla, where remarkable age-related changes were observed. In contrast, MT-I & -II expression was considerably weak in the brains of dogs with mild age-related changes. In aged dog brain, a population of hypertrophic astrocytes also showed MT-III immunoreactivity and signals for MT-III mRNA. On the other hand, neurons in both aged and young dog brains showed strong MT-III immunoreactivity and signals for MT-III mRNA regardless of the intensity of the age-related changes. Total MT concentration in brain was higher in gray matter than white matter and in young dogs than aged dogs: age-related loss of neurons, significantly rich in MT-III, is responsible for the latter finding. These results suggest, in addition to MT-I & -II, MT III may also be induced in astrocytes in relation to the progress of the age-related morphological changes, playing an important role in the protection of the brain tissue from the toxic insults responsible for the brain aging.

60 NEURONAL VESICULAR MONOAMINE TRANSPORTER (VMAT2) AS A NOVEL MARKER FOR METHAMPHETAMINE-INDUCED NEUROTOXICITY IN MICE.

K. A. Hogan[1] and P. K. Sonsalla[2]. [1]*Toxicology, Rutgers Univ., New Brunswick, NJ and* [2]*Neurology, UMDNJ-RWJMS, Piscataway, NJ.*

Methamphetamine (METH)is a synaptic toxicant in experimental animals. Neurochemical indices demonstrate loss of nerve terminal integrity in animals and humans following toxic doses of METH. Studies in human abusers with acute

METH intoxication report no decrement in postmortem measures of [3H]-dihydrotetrabenazene (DTBZ) binding to the neuronal vesicular monoamine transporter (VMAT2). This finding in humans, which is unexplored in mice, is unexpected in light of significant decrements observed in other neurochemical indices. In the present studies, [3H]-DTBZ binding was performed in striatal homogenates of METH-treated mice at time points between 1-85 days post-METH. These studies reveal that VMAT2 binding in striatal homogenate may not be a reliable index of nerve terminal loss at early time points (1-4 days) following METH intoxication. In contrast to significant loss of other neurochemical indices, [3H]-DTBZ homogenate binding gradually declined. On day 1 [3H]-DTBZ homogenate binding was not significantly decreased (-8%); by day 2, however, binding showed a significant decline (-34%), reaching a nadir by day 4 (-60%). To explore differences between [3H]-DTBZ binding and other measures of nerve terminal loss, [3H]-DTBZ homogenate binding was compared to [3H]-DA uptake into striatal vesicles 1 day post-METH. This measure of vesicular function was readily compromised, which is consistent with the early compromise of DAT(-77%)and TH (-65%). These results suggest that [3H]-DTBZ binding in homogenate may not adequately reflect nerve terminal status at early time points. However, at time points after day 4, loss of [3H]-DTBZ binding in homogenate (-60%) closely paralleled loss of TH activity (-51%). Over the course of 85 days, loss of [3H]-DTBZ binding and TH activity were not as substantial as loss of DAT binding and DA content. Recovery of measures occurred at the same rate; although measures demonstrating recovery persisted below control values, indicating a lasting neurotoxic effect in METH-treated mice.

61 THE TRIGGERING ROLE OF DOPAMINE IN NEUROTOXIC DAMAGE CAUSED BY AMPHETAMINE.

E. A. Anderzhanova, V. S. Kudrin, I. I. Afanasev, P. Saransaari, E. Riitamaa, S. S. Oja and K. S. Rayevsky. *Physiology, University of Tampere, Tampere, Finland.*
Sponsor: S. Ali.

The breakdown products of dopamine (DA) are potentially neurotoxic but neuronal damage due to amphetamine (Amph) treatment may not only be produced by DA radical metabolites. The aim of present study was to explore the relationships between extracellular DA, glutamate (Glu) and taurine (Tau) and hydroxyl radical (OHž)generation during subchronic Amph treatment (5 mg/kg, 4 injections i.p. with 2-hour intervals). The extracellular levels of DA, Glu and Tau were estimated by means of HPLC and the generation of OHž with salicylate method in the rat neostriatum by microdialysis. Amph caused an immediate increase in the extracellular DA concentration up to 950%, which effect was quickly reduced to the baseline values. The subsequent Amph injections were followed by a much smaller increase in the extracellular DA concentration (about 300%). Amph produced marked increase in the OHž generation, the first wave was observed 80 min after the second injection and persisted during 2 hours (up to 700%), and the second increase incurred after the 4-th injection (up to 400%). Amph (5 mg/kg) caused a marked gradual increase in the Glu and Tau levels (up to 500 and 450% of the predrug value, respectively) by the end of experiment. Our results suggest a triggering role DA in neurochemical changes which lead to neuronal damage. The changes in extracellular DA, Glu, Tau and OHž reflect different subsequent phases of Amph neurotoxicity.

62 IDENTIFICATION OF A PROTECTIVE RESPONSE IN A TRANSGENIC MOUSE MODEL OF ALZHEIMER'S DISEASE.

T. D. Stein and J. A. Johnson. *Pharmacy, University of Wisconsin—Madison, Madison, WI.*

Alzheimer's disease (AD) is associated with increased levels of the toxic peptide, ß-amyloid (Aß). This disease is modeled in Tg2576 mice by overexpression of a mutant form of human amyloid precursor protein ($HuAPP_{Sw}$). However, despite high Aß levels, plaques do not develop in these mice until an average age of 12 months, and there is no neuronal loss in the hippocampus of mice as old as 16 months. Using an Affymetrix microarray system, we compared mRNA expression levels in the hippocampus and cerebellum of three six-month-old $HuAPP_{Sw}$ mice to three age-matched, non-transgenic controls. A ranking analysis based on Affymetrix's difference call was used to determine significant increases and decreases. RT-PCR of selected genes confirmed our results. Microarray analysis of the hippocampus demonstrated increased expression of transthyretin (TTR; 29.5-fold), a protein shown to sequester Aß and prevent plaque formation, as well as a number of genes involved in neuronal proliferation, differentiation, and tissue remodeling. Of the 23 genes increased in the hippocampus, five were involved in growth factor pathways. Three genes involved in the activation of the insulin-signaling pathway were differentially regulated, including a 16.6-fold increase in insulin-like growth factor 2 (IGF2). Immunohistochemistry confirmed the hippocampal increases of TTR and IGF2. The cerebellum is typically unaffected in AD and does not develop a significant age-dependent increase in Aß levels in $HuAPP_{Sw}$ mice. When comparing the cerebellar gene expression in $HuAPP_{Sw}$ mice to controls, the fold increase of TTR was reduced to 3.2-fold. Other genes differentially regulated in the hippocampus showed no changes at all in the cerebellum. Therefore, the slow progression and lack of full-fledged pathology in the hippocampus of $HuAPP_{Sw}$ mice may result from the increased expression of protective and growth-inducing genes. Specifically, TTR and the insulin-signaling pathway may play an important role in mediating this protective response. (Support: ES08089, ES10042, & BWF New Investigator Award).

63 OXIDATIVE DNA DAMAGE PRECEDES AMYLOID PLAQUE FORMATION IN AMYLOID PRECUSOR PROTEIN (APP) TRANSGENIC MICE: AN ANIMAL MODEL OF ALZHEIMER'S DISEASE.

W. Jeng[1], M. A. Chishti[2], D. Westaway[2] and P. G. Wells[1,3]. [1]*Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada,* [2]*Centre for Research in Neurodegenerative Diseases, University of Toronto, Toronto, ON, Canada and* [3]*Department of Pharmacology, University of Toronto, Toronto, ON, Canada.*

Reactive oxygen species (ROS) are implicated in neurodegenerative conditions such as Alzheimer's disease (AD), but their role in the mechanism of neurotoxicity is unclear. Here, we provide the first evidence that DNA oxidation precedes amyloid plaque formation in amyloid precursor protein (APP) mice, a transgenic mouse model of AD. To determine the relation of oxidative DNA damage, lipid peroxidation and amyloid beta (Aβ) plaque deposition, a characteristic hallmark of AD, we examined the frontal cortex, hippocampus and cerebellum of APP mice, compared to age-matched wild-type controls, for endogenous DNA oxidation evidenced by 8-oxo-2'-deoxyguanosine formation, and lipid peroxidation determined by thiobarbituric acid reactive substance formation. In the frontal cortex, oxidative DNA damage was enhanced within 6 weeks in APP mice, peaked at 5 months ($p<0.01$) and returned to basal levels by 7 months. DNA oxidation was similarly elevated in hippocampal but not cerebellar tissues. In contrast, plaque formation was not observed until after 3 months of age in the frontal cortex and hippocampus, nor was lipid peroxidation elevated in any tissue at any age. These results suggest that ROS-mediated oxidation of oligonucleotides, as distinct from lipid, may constitute an early event in the pathogenesis of AD. (Support: Canadian Institutes of Health Research)

64 POTENTIAL ROLE OF MITOCHONDRIAL COMPLEX II ACTIVITY IN REGIONAL DIFFERENTIAL CNS SENSITIVITY TO 1, 3-DINITROBENZENE-INDUCED ENCEPHALOPATHY.

A. D. Phelka, M. J. Beck and M. A. Philbert. *Environmental Health Sciences, University of Michigan, Ann Arbor, MI.*

Exposure to 1, 3-dinitrobenzene (DNB) produces an edematous, glio-vascular lesion that is initially confined to brainstem nuclei with high energy requirements. Selective vulnerability of brainstem astrocytes to DNB is mediated by a ten-fold lower threshold for opening of the mitochondrial permeability transition (MPT) pore. Exposure of brainstem astrocytes to 100 uM DNB results in complete loss of mitochondrial membrane potential by 10 min, while their cortical counterparts remain unaffected for at least 1 hour. However, the loss of membrane potential in brainstem astrocytes is prevented by pretreatment with the known MPT pore inhibitor, cyclosporin A (CsA). DNB also decreases mitochondrial reducing potential by inhibiting FAD-linked reduction at complex II. Therefore, it is hypothesized that inhibition of mitochondrial complex II (succinate dehydrogenase) is causally linked to regional differences in susceptiblity to activation of the MPT by DNB. Using cultured neonatal rat brainstem and cortical astrocytes, complex II was localized histochemically. Complex II activity is significantly inhibited in both brainstem and cortical astrocytes at 0.5, 2, 5, and 24 hours following *in vitro* exposure to 100 uM DNB. Although the observed inhibition of SDH was prevented by pretreatment CsA in brainstem astrocytes after 0.5 and 2 hours, CsA pretreatment failed to significantly prevent inhibition of complex II activity in cortical astrocytes. These results suggest that either 1) inhibition of complex II is independent of the mechanism of DNB-induced opening of the MPT, or 2) differential regional regulation of the MPT subsequent to inhibition of complex II confers anatomical protection/vulnerability. However, the possibility that complex II activity is directly inhibited by DNB remains to be determined.

66 ANTIOXIDANT PROTECTION AGAINST ETHANOL-INDUCED CELL LOSS IN CEREBELLAR GRANULE CELL CULTURES.

K. H. Horn[1], L. M. Kamendulis[1], C. R. Goodlett[2,3] and J. E. Klaunig[1,2]. [1]*Pharmacology and Toxicology, Indiana University, Indianapolis, IN,* [2]*Medical Neurobiology, Indiana University, Indianapolis, IN and* [3]*Psychology, IUPUI, Indianapolis, IN.*

Ethanol exposure during development can cause decreases in neuronal cell populations resulting in permanent neurological deficiencies. Cerebellar granule cell cultures are vulnerable to ethanol toxicity and are useful for investigating mechanisms

of cell death. Oxidative damage resulting from ethanol-induced increases in reactive oxygen species, have been suggested as a mechanism of ethanol-induced cell death. Recent studies utilizing antioxidants showed protection against ethanol-induced cell loss. The purpose of the present study was to investigate the possible protective effects of the antioxidants, vitamin E and Trolox against ethanol-induced cell loss in cerebellar granule cell cultures during their peak time of ethanol vulnerability (one-day-in-vitro). Cerebellar granule cells were isolated from Long Evans rat pups and grown for 24 hours. Cultures were exposed to ethanol (0, 83, 166, 332mg/dl) for 24 hours and viable cells were quantified. In addition, cultures were exposed to 332mg/dl ethanol in the absence or presence of either vitamin E (0, 33, 100uM) or Trolox (0, 33, 66, 100uM) and assessed for viability. Results confirm a dose-dependent (14-29%) decrease in viable cell number following 24-hour ethanol exposure. Addition of antioxidants (vitamin E or Trolox) at concentrations of 100uM, protected against the ethanol-induced cell loss returning viability to that of controls (96% and 99.5%). This study suggests a role for oxidative stress, *via* either increased production of reactive oxygen species or decreased endogenous antioxidant levels, as a possible mechanism for ethanol-induced cell death in cerebellar granule cell cultures.

67 IDENTIFICATION OF A DRUG TARGETING EFFECT BY TERT-BUTYLHYDROQUINONE ON ANTIOXIDANT RESPONSE ELEMENT-DRIVEN GENE EXPRESSION USING MICROARRAYS.

J. A. Johnson and J. Li. *School of Pharmacy, University of Wisconsin, Madison, WI.*

Increasing evidence indicates that the antioxidant response element (ARE) and Nrf2 mediate transcriptional activation of NADPH:quinone oxidoreductase and other detoxification enzymes in response to tert-butylhydroquinone (tBHQ). The current study was designed to investigate the gene expression profile induced by tBHQ and determine the time-dependent gene expression patterns associated with treatment. We have analyzed gene expression induced by tBHQ (10 mM) in IMR-32 human neuroblastoma cells by means of large-scale oligonuclotide microarray. Of the 9670 genes examined, 101 showed dynamic changes with treatment from 4h to 48h. The peak of transcriptional up-regulation happened at 8 hours and lasted until 24 hours. RT-PCR for selected genes also confirmed the similar gene expression pattern. Western Blot showed changes in the corresponding encoded proteins that remained elevated for 48 hours. Gene cluster (SOM) analysis was used to group these genes into 12 distinct clusters with striking patterns that appear to correlate with their specific function. These included genes involved in detoxification and cellular antioxidant defense, neuronal proliferation and differentiation, and signal transduction. A search for potential transcription factors binding site(s) in the 5'-flanking regions of the selected gene set was performed by MatInspector. The most notable observation was that genes induced by tBHQ had putative Nrf-2 binding sites, implying that a specific drug targeting effect exists. However, gene cluster analysis showed that not all of potential ARE-driven genes have the same expression profile indicating the complexity of trancriptional regulation is not dependent upon a single transcription factor or signal transduction pathway. (Funded by ES08089, ES10042, BWF New Investigator Award).

68 RETINOIC ACID INDUCED DISRUPTION OF CAMP-INDUCED HUMAN SVG CELL DIFFERENTIATION: MORHOLOGY AND GLOBAL GENE EXPRESSION EFFECTS.

L. D. Burgoon[1,3], K. Y. Kwan[2,3], M. R. Fielden[2,3], J. E. Trosko[3,4] and T. R. Zacharewski[2,3]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI, [2]Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, [3]National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and [4]Pediatrics & Human Development, Michigan State University, East Lansing, MI.*

Previous work has shown that treatment of human SVG cells with 5 μM forskolin (F) and 200 μM 3-isobutyl-1-methylxanthine (iBMX) increases cAMP levels resulting in differentiation and dramatic morphologic changes. We show that co-treatment with 0.5 μM retinoic acid (RA) enhances these morphologic changes as measured by increases in the total number of processes ($p = 0.03$) and the length of processes contacting an adjacent cell (LPT; $p < 0.01$) over time. At 36h, RA inhibited regression of LPT ($p = 0.02$) with increases in mean process length ($p = 0.04$). A custom, SVG-specific cDNA microarray (2, 990 genes) was used to investigate the temporal changes in gene expression during cAMP induced differentiation. Temporal changes were identified using two different techniques. First, an incomplete block design, individual gene mixed-model ANOVA was used for analysis, followed by t-tests using a step-down Bonferroni adjustment. The mixed model included treatment, time, dye and treatment x time as fixed effects, and spots as random effects. To identify genes with significant expression changes during differentiation, least squares means of F/iBMX treated cells were compared to time-matched vehicle control samples utilizing t-tests. For comparison, a second technique utilizing Shannon Entropy filtering of normalized microarray data from treated, vehicle control, and untreated/time 0 h control cells, with Principal Components Analysis (PCA) of the filtered data to result in the identification of expression patterns was used. Results from the two divergent approaches were comparable and identified significant temporal and treatment effects on gene expression, although some differences were observed.

69 BREVETOXIN EXPOSURE AUGMENTS Ca^{2+} OSCILLATIONS IN CEREBROCORTICAL NEURONS.

T. F. Murray[1], S. M. Dravid[1] and D. G. Baden[2]. *[1]Physiology and Pharmacology, University of Georgia, Athens, GA and [2]Center for Marine Science Research, University of North Carolina, Wilmington, NC.*

Florida red tide brevetoxins are potent sodium channel neurotoxins. Brevetoxins produce acute neuronal injury and death in cerebellar granule cells. This neurotoxic response is prevented by coapplication of tetrodotoxin or antagonists of the NMDA receptor. The neuroprotective efficacy of NMDA receptor antagonists has been attributed to the ability of brevetoxins to evoke the release of glutamate from cerebellar granule cells. Brevetoxins also produce a rapid increase in cytoplasmic $[Ca^{2+}]$ in cerebellar granule cells with a potency consonant with that for neurotoxicity. Brevetoxin produces Ca^{2+} influx through three pathways: NMDA receptors, L-type Ca^{2+} channels and the reverse mode of operation of the Na^+/Ca^{2+} exchanger. Oscillations in intracellular [Ca2+] induced by neuroreceptors in the plasma membrane provide critical signals to control cellular processes. To determine whether brevetoxin influence Ca^{2+} homeostasis generalized to neuron types besides cerebellar granule cells, we assessed the actions of brevetoxin (PbTx-2) on spontaneous Ca^{2+} oscillations in murine cerebrocortical neurons. This primary culture displays spontaneous oscillations in the presence of physiological concentrations of Mg^{2+}. PbTx-2 exposure produced a concentration dependent augmentation of the Ca^{2+} oscillation amplitude with a potency consonant with that for activation of sodium channels. The ability of brevetoxins to affect calcium signals may affect cellular processes involved in development and learning.

70 DEXTROMETHORPHAN PRODUCES CELL DEATH IN CEREBROCORTICAL NEURONS BY INHIBITION OF NMDA RECEPTORS.

S. M. Dravid and T. F. Murray. *Physiology and Pharmacology, University of Georgia, Athens, GA.*

Dextromethorphan (DXM) is the active ingredient of commonly used antitussive preparations and represents a drug of abuse. We investigated the effect of persistent exposure of DXM and its metabolite dextrorphan (DX) on cell survival in murine primary cerebrocortical culture. A 48 h exposure to DX and DXM caused a concentration dependent rise in LDH efflux and number of pyknotic nuclei as visualized by Hoechst 33258 dye staining. Other NMDA receptor antagonists were also evaluated for their propensity to produce a neurotoxic action. The rank order of potency for neurotoxicity was dizocilipine ((+) MK-801) > phencyclidine (PCP) > DX > DXM. This rank order corresponds well with the respective binding affinities of these compounds for the NMDA receptor. Coexposure of cerebrocortical neurons with NMDA and noncompetitive antagonists reduced LDH efflux, further suggesting the involvement of NMDA receptors in the neurotoxicity. A 48h exposure to NMDA antagonists increased caspase-3 activity, but had no significant effect on caspase-1 activity. Intracellular Ca^{2+} concentrations have been found to be critical for cell survival especially during development. Real time alterations in intracellular Ca^{2+} were monitored in fluo-3 loaded cortical neurons exposed to MK-801 using a fluorescent plate reader (FLIPR). Acute exposure to MK-801 reduced the amplitude of calcium oscillations exhibited by neocortical neurons in a concentration dependent manner. These findings suggest that persistent exposure to DXM and DX produce toxicity in cortical neurons, which may be triggered by a decrease in intracellular Ca^{2+} due to the blockade of NMDA receptor.(Supported by DA 07218)

71 GENE TRANSFER OF THE Q/R EDITED GLUR2 GLUTAMATE RECEPTOR SUBUNIT PROTECTS MOTOR NEURONS FROM DISEASE-RELATED TOXICITY.

H. D. Durham[1], M. M. Doroudchi[1], A. A. Bianchi[1], S. Minotti[1], J. E. Sowden[2] and D. A. Figlewicz[2]. *[1]Neurology & Neurosurgery, McGill University, Montreal, PQ, Canada and [2]Neurology / Neurobiology & Anatomy, University of Rochester, Rochester, NY.*

There is considerable evidence that the presence of Ca^{++}-permeable AMPA receptors on motor neurons contributes to their vulnerability to excitotoxic injury and other insults associated with disease. Mutations in the SOD1 gene underlie some

familial cases of the motor neuron disease, amyotrophic lateral sclerosis (FALS). Using a primary culture model of FALS in which G93A mutant SOD1 was expressed in motor neurons of dissociated spinal cord cultures, we demonstrated that blockade of these receptors by the specific antagonist JSTX-3 prevented motor neuron death. In the present study, we tested the hypothesis that reducing Ca^{++}-permeability of AMPA receptors by overexpression of Q/R edited GluR2, the glutamate receptor subunit that prevents Ca^{++} entry through the receptor channel, would also be neuroprotective. Q/R-edited GluR2 (flop isoform) was cloned from rat cerebellar mRNA and expressed in motor neurons of mouse spinal cord cultures by intranuclear microinjection of plasmid expression vectors. Control vectors were "empty" vector and unedited GluR2 flop, which does not prevent Ca^{++} influx through the receptor channel, produced by site directed mutagenesis. Expression of GluR2 and localization to synapses was verified by double-label immunocytochemistry with anti-GluR2 and antibodies to other GluR subunits. 70-80% of motor neurons microinjected with G93A mutant SOD1 expression vector died over a 9 day period. Q/R edited GluR2 flop, but not unedited GluR2, significantly delayed motor neuron death induced by mutant SOD1. Thus, Ca^{++} influx during neurotransmission increases vulnerability of motor neurons to toxic insult and modulation of AMPA receptor properties is a potential therapeutic strategy in ALS. Supported by MDA.

72 CHARACTERIZATION OF HISTAMINE H1 RECEPTOR BINDING SITES IN FISH.

A. El-Nabawi, J. A. Choich and E. K. Silbergeld. *Toxicology, University of Maryland Baltimore, Baltimore, MD.*

The teleost brain is largely similar to that of higher vertebrates, but much less is known about specific neurochemistry. In mammals, the histamine receptor has been well characterized and consists of three subtypes, H1, H2, and H3. However, in fish, little work has been carried out in identifying the presence of different subtypes of histamine receptors or on pharmacological characterization of these types. The present study was designed to pharmacologically characterize the histamine H1 receptor in the fish brain using a radioligand binding assay. Specific [3H]pyrilamine binding increased in a linear fashion, with increasing concentrations of protein over the range of 50ug to 300ug. Association of [3H]pyrilamine to the membranes was time and temperature dependent, and equilibrium was achieved after 30 min. Saturation studies revealed that the specific binding of [3H]pyrilamine to the H1 receptor was saturable, reversible, and of high affinity. Competition studies indicated that the binding was readily displaced by specific histamine H1 agonists and antagonists. In contrast, the selective histamine H2 and H3 receptor agonists and antagonists were very weak competitors for the [3H]pyrilamine binding sites. These results present strong evidence for the existence of the histamine H1 receptor in fish brain, and that the pharmacological profile of the H1 receptor in fish brain is apparently similar to mammalian brain (Supported by NIEHS PP 1 P01 ES09563).

73 EVIDENCE OF HISTAMINE H1 AND H2 RECEPTORS IN FISH BRAIN AS CHARACTERIZED BY THE 2-DEOXYGLUCOSE METHOD.

J. A. Choich, A. El-Nabawi and E. K. Silbergeld. *Toxicology, University of Maryland Baltimore, Baltimore, MD.*

Non-mammalian species, such as fish, make ideal sentinel species for supplying essential information concerning human health issues related to environmental toxicology. However, methods for identification and characterization of mechanisms of neurotoxicity are underdeveloped. We have developed an *in vivo* neurochemical method to evaluate neuro-active agents, according to specific regional activities within the CNS by using [14C]2-deoxyglucose (2-DG) to trace regional metabolic activity in the fish brain (Choich et.al., 2001). We have used this method to characterize histaminergic pathways. Histamine is an amino acid neurotransmitter involved in arousal, attention, and sensory processing and cognition, and also plays a role in pituitary hormone secretion and appetite control. Structurally, the fish brain is well characterized, yet little information has been discovered about the existence and functioning of histamine neuropathways in fish. Living, healthy fish (4 fish, Tilapia nilatica, 10g-bw) were injected i.m. with 2uCi of [14C]2-DG and allowed to swim (30min.) in freshwater with and without a histamine H1 and H2 agonist (.01mM, 1mM, and 10mM of histamine dihydrochloride from Sigma). Fish were sacrificed and brains processed using autoradiography as described by Choich et.al. (Toxicology Methods, Nov. 2001). The experiment was repeated in triplicate. Using digital image analysis, a clear Dose-Response in regional 2-DG uptake was evident (increasing as dose concentration of histamine was increased, as compared to controls), providing evidence of histamine H1 and H2 receptors in fish, and demonstrating the applicability of our *in vivo* method to provide both quantitative and qualitative information on neuro-active agents and their direct effect on specific regions in fish brain. Supported by NIEHS PP 1 P01 ES09563.

74 *IN-VIVO* REACTIVITY OF THE AXONAL TOXIN 1, 2-DIACETYLBENZENE WITH NEUROFILAMENT AND MICROTUBULE PROTEINS.

M. S. Kim, M. J. Taylor, M. I. Sabri and P. S. Spencer. *Center for Research on Occupational & Environmental Toxicology (CROET), Oregon Health & Science University (OHSU), Portland, OR.*

Repeated treatment of young adult Sprague-Dawley rats with 1, 2-diacetylbenzene (1, 2-DAB), but not with 1, 3-diacetylbenzene (1, 3-DAB), induces irritable behavior, reduced body weight gain and evolving leg weakness with neurofilament-filled giant axons in spinal cord and associated roots. 1, 2-DAB (but not 1, 3-DAB) reacts readily *in vitro* with amino acids (especially L-lysine and glycine) to form a blue pigment, which is also evident in the tissues and urine of systemically treated rats. In-vitro studies with purified bovine axonal proteins and rat spinal cord slices demonstrate reactivity of 1, 2-DAB (but not 1, 3-DAB) with neurofilament proteins relative to tubulin (unpublished data). Here, we report the action of 1, 2-DAB *vs.* 1, 3-DAB on neurofilament proteins and beta-tubulin in living nerve tissue. Surgically exposed male rat sciatic nerves were bilaterally bathed for 5 min. with saline + 2% acetone vehicle or vehicle containing 2, 5, 25 or 50 mM 1, 2-DAB or 1, 3-DAB. Treated nerves were excised, desheathed and homogenized in aqueous 8M urea containing protease-inhibitor cocktail. Protein (6 microgram) from each sample was subjected to Western blot analysis. Neurofilament triplet proteins, but not tubulin, showed a concentration-dependent decrease in nerve tissue treated with 1, 2-DAB (but not 1, 3-DAB); the hierarchy of reactivity (NF-H > NF-M > NF-L) with 25 mM 1, 2-DAB was comparable to that seen in spinal cord slices incubated *in vitro* with this chromogenic neurotoxin. These studies show that 1, 2-DAB preferentially targets protein components of axonal neurofilaments relative to that of microtubules. Toxicogenomic studies are underway to confirm these findings and to identify other axonal protein targets of 1, 2-DAB. Supported by NIEHS Center grants 1 P42 ES 10338 and 1 U19 ES11384.

75 GASOLINE OXYGENATES ENHANCE MUSCIMOL-STIMULATED CHLORIDE FLUX IN RAT BRAIN SYNAPTONEUROSOMES.

S. V. Iyer[1], M. M. Iba[2] and J. V. Martin[1]. [1]*Biology Department, Rutgers University, Camden, NJ and* [2]*Department of Pharmacology and Toxicology, EOHSI, Rutgers University, Piscataway, NJ.*

Gasoline oxygenates are used to increase the efficiency of automobile fuel combustion. Commonly used additives are ethyl-*tert*-butyl ether (ETBE), methyl-*tert*-butyl ether (MTBE), and *tert*-amyl-methyl ether (TAME). The major metabolic product of ETBE and MTBE is *tert*-butyl alcohol (TBA), while TAME metabolism produces *tert*-amyl alcohol (TAA). These ethers and their alcohol metabolites have neurological effects similar to those of ethanol and anesthetics. One of the effects of ethanol is its interaction with the subtype-A of the receptor for the major inhibitory neurotransmitter, γ-aminobutyric acid (GABA). Since we had previously observed that these chemicals alter binding of $GABA_A$ receptor ligands, we studied their effects on the function of the receptor using rat-brain synaptoneurosomes (SNS), a preparation of sacs of pre- and postsynaptic membrane. $GABA_A$ receptor function was assessed by measuring the uptake of added $^{36}Cl^-$ into the SNS in the presence of varying concentrations of each additive or its metabolite, and muscimol, the agonist for the receptor. In addition, ethylether and ethanol were tested for the sake of comparison. $^{36}Cl^-$ uptake into the SNS was terminated after 5 seconds using picrotoxin, an agent that blocks the $GABA_A$ receptor channel. Each tested compound enhanced muscimol-stimulated uptake of ^{36}Cl at lower concentrations, while higher concentrations were less effective. The maximum stimulatory effect occurred at 10mM (for ethanol), 0.7 mM (for ethylether), 0.3mM (for MTBE), 1mM (for ETBE), 0.3 mM (for TAME), 5 mM (for TBA), and 3 mM (for TAA). The results suggest a potential role of the $GABA_A$ receptor in some of the neurotoxic effects of gasoline additives. (Supported by NSF grant IBN-981089)

76 EFFECTS OF ACRYLAMIDE AND 2, 5-HEXANEDIONE ON RAT TIBIAL NERVE SODIUM AND POTASSIUM CHANNELS.

D. W. Sickles. *Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA.*

Changes in nodal Na and K channel quantity and distribution by acrylamide (ACR) or 2, 5-hexanedione (2, 5-HD) were evaluated as potential mechanisms in the production of neurotoxic symptoms. Sprague-Dawley rats (225-250g; n=3/group) were given either high (50mg/kg/d i.p. for 9 days) or low (2.8mM drinking water for 49d) dose ACR or high (400mg/kg/d for 39 days) dose 2, 5-HD; untreated littermates served as controls. At the endpoints, animals were ataxic and demonstrated significant hindlimb paralysis, particularly both ACR groups. Fixed tibial nerves were gently teased to single fibers and processed for identification of Na (monoclonal anti-sodium, clone K58/35, Sigma #S8809) and K (rabbit

anti-Kv1.1 voltage gated, Chemicon #AB5174) channels using anti-mouse IgG_1-FITC and TRITC-conjugated goat anti-rabbit IgG $F(ab')_2$ secondary antibodies, respectively. Fluorescence microscopy revealed control Na channels concentrated in a rectangular strip traversing the axon at each node. Control K channel fluorescence consisted of irregular-shaped paranodal strips of variable intensity. The following observations were made without knowledge of experimental group. ACR_{high} reduced nodal Na channel fluorescence with a narrowed and distorted distribution. ACR_{low} reduced Na channel fluorescence in the majority of nodes, although some retained normal shape and intensity. 2, 5-HD_{high} reduced fluorescence intensity of some; although many appeared normal. ACR_{low} and ACR_{high} produced a dramatic reduction in the intensity of K channel fluorescence; some nodes were devoid of fluorescence. 2, 5-HD_{high} produced a wide variety of results; fluorescence intensity ranging from normal to a complete absence of paranodal K fluorescence. In summary, ACR produced reductions in both Na and K channel concentration in nodes and paranodes independent of the dosing rate. 2, 5-HD affected K channels more than Na channels. Reduced Na and/or K channel quantity or altered distribution may precipitate failures in action potential propagation and neurobehavioral symptoms. Supported by the MCG Research Institute.

77 USING MICROELECTRODE ARRAYS TO IDENTIFY NEURAL RESPONSE PATTERNS FOLLOWING EXPOSURE TO A KNOWN NEUROTOXICANT.

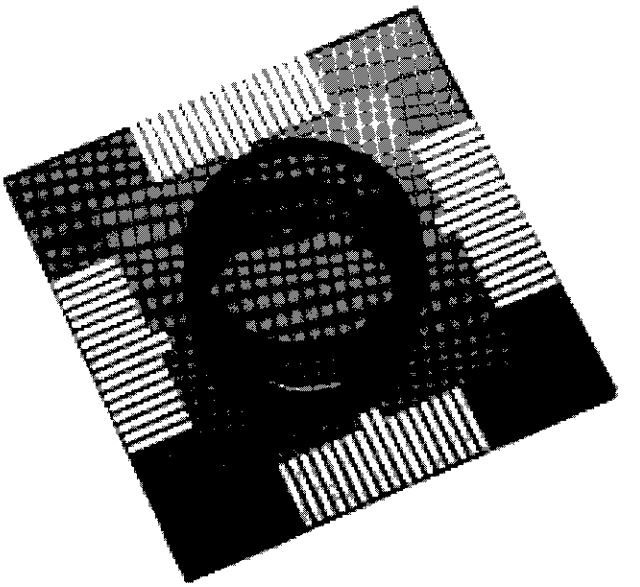
J. Rossi III, T. Deak, S. McInturf, F. McDougle, G. Ritchie and M. Bekkedal. *Neurobehavioral Effects Laboratory, NHRC Detachment/Toxicology, Wright-Patterson AFB, OH.* Sponsor: R. Carpenter.

Exposure to non-lethal amounts of neurotoxic agents disrupts brain activity, and often results in negative neurobehavioral consequences. To develop effective treatments for such exposures, it is important to understand how the neurotoxic compounds alter neuronal activity and to correlate these changes with the behavior deficits. There are a variety of methods that can be utilized for assessing altered neural communication, one of which is *in vitro* work with microelectrode arrays. Slices from specific brain regions, selected for their known contributions to behavior, are used to assess spontaneous electrical activity in the tissue. Modulation of spontaneous activity by different doses of neuroactive compounds is also assessed. Trimethylolpropane phosphate (TMPP) is a known neuroactive toxicant formed during partial pyrolysis of some turbine lubricants. TMPP has convulsant properties, and causes lasting, likely permanent, changes in neurobehavioral responding following short term exposure to low doses. The goal of this research was to evaluate the changes in responsivity of neural systems that could account for the previously observed *in vivo* effects. Rat hippocampal slices were mounted on 64-channel microelectrode arrays (Panasonic Med. System) and evoked field potentials were recorded. Tissue exposure to TMPP produced dramatic changes in the evoked potentials characterized by a shorter latency to peak response, and an erratic wave form. Similar to the lasting behavioral effects, TMPP exposure caused lasting changes in responses of neural circuits in hippocampal slices. Extensive washing of the preparation did not alleviate the altered evoked potentials. The results suggest that the convulsant properties of TMPP are sufficient to cause long term changes in neural responses that may account for the lasting neurobehavioral consequences. The results also support the application of microelectrode array techniques for evaluation of neurotoxic effects.

78 RECRUITMENT OF PAROXYSMAL AFTER-DISCHARGE IN A MOUSE BRAIN AMYGDALAR TISSUE SLICE USING A PLANAR MICROELECTRODE ARRAY.

J. Rossi, S. McInturf, F. McDougle, M. Bekkedal and G. Ritchie. *Toxicology, Naval Health Research Center, WPAFB, OH.* Sponsor: R. Carpenter.

The Panasonic Med.-64 microelectrode array system (Panasonic, Japan) was utilized to successfully demonstrate recruitment of paroxysmal after-discharge responses of *in vitro* tissue slice preparations from adult mice. Slices were prepared to allow placement of both the amygdala and pyriform cortex on a single Med.-64 microarray probe. Repeated tetanic pulse trains [intensity = 400 microamps; pulse train duration = 20 ms; pulse duration = 2 ms; interpulse interval = 0.5 ms] were delivered to a single electrode within the basolateral amygdala. A second electrode position demonstrating a consistent and reliable evoked response to the amygdalar stimulation was selected to measure recruitment responses. With successive stimulation of the basolateral amygdala during a single 2-h session, a paroxysmal spike-wave discharge (SWD) response significantly exceeding the amplitude of the initial evoked response was observed to develop at the pyriform cortex recording site in 75%+ of all slices tested. It was demonstrated that an *in vitro* murine tissue slice preparation could be used to demonstrate electrically induced recruitment of paroxysmal after-discharge responses in a remote brain area. This system may provide a novel clinical tool for investigation of mechanisms of epiletogenesis, as well for evaluation of toxicant-induced changes in neural function and antiepileptic drug (AED) treatments.



79 SPATIOTEMPORAL PATTERN OF NEURODEGENERATION IN CNS OF ACRYLAMIDE (ACR)INTOXICATED RATS.

J. F. Ross[1], E. J. Lehning[2] and R. M. LoPachin[2]. [1]*The Health & Environmental Safety Alliance, 442 Oliver Rd, Cincinnati, OH and* [2]*Anesthesia Research, Montefiore Medical Center, Bronx, NY.*

The influence of dose-rate on spatiotemporal characteristics of neurodegeneration in CNS of ACR intoxicated rats has not been well documented. Therefore, animals were exposed to daily ACR at either 50 mg/kg (i.p.) or 21 mg/kg (p.o.) and brains and spinal cords were processed using de Olmos' amino cupric silver stain for detecting degenerating nerve cell bodies, dendrites, axons and terminals. For each dose-rate, experimental times were selected according to the development of ACR-induced neurological defects; i.e., ataxia and hindlimb foot-splay. Results show that, in spinal cord, ACR intoxication at either dose-rate produced nerve terminal degeneration in several gray matter regions (e.g., layers 5-7 of intermediate zone, lamina 10, intermediolateral cell column). However, axon degeneration in spinal white matter was related to dose-rate; i.e., the lower ACR dose rate (21 mg/kg/d)was associated with significant axon degeneration primarily in the gracile fasciculus and pyramidal tract, whereas during higher dose-rate exposure axon involvement was rare. In cerebellum, selective Purkinje cell damage was evident regardless of dose-rate. This effect was characterized by early degeneration of Purkinje cell dendrites in the molecular layer and nerve terminals in cerebellar and vestibular nuclei. The onset of axon argyrophilia in cerebellar white matter was relatively delayed. In hindbrain, both dose-rates produced predominant nerve terminal degeneration in precerebellar nuclei (e.g., lateral reticular nucleus), gracile and cuneate nuclei and certain nuclei of the reticular formation (e.g., pontine nucleus). Neither dose-rate caused axon degeneration in hindbrain white matter. Thus, nerve terminal degeneration in the CNS is a consistent effect of ACR across dose-rates, whereas axon degeneration is either delayed or occurs only during low dose intoxication. This supports the hypothesis that the nerve terminal is a primary site of ACR action. Sponsored by NIH grant ES03830-16

80 ACRYLAMIDE (ACR) BINDS SPECIFIC PRESYNAPTIC PROTEINS IN RAT BRAIN.

R. M. LoPachin, S. Mansukhani and S. Das. *Anesthesia Research, Montefiore Medical Center, Bronx, NY.*

We hypothesize that the nerve terminal is the primary site of ACR action and that binding of this toxicant to critical thiol-containing SNARE proteins disrupts presynaptic structure and function. As an initial investigation of molecular mechanisms, we characterized the binding of ACR to synaptosomal proteins. Rat cerebral cortex synaptosomes (250 µg protein) were prepared on Percoll gradients and were incubated in oxygenated medium for 1 hr with ^{14}C-ACR (7 µCi; 5 mCi/mmole). Labeled synaptosomal proteins were resolved by gel electrophoresis and then trans-

ferred to nitrocellulose membranes. Protein bound radiolabel was visualized on autoradiographs formed by exposing membranes to X-ray film for 21 days. Comparion of coomassie blue-stained gels with autoradiographs revealed that, among numberous potential targets, six ACR-labeled proteins could be identified. The estimated molecular weights of several unknowns matched that of specific SNARE proteins; e.g., SNAP-25 (25 kDa), synaptophysin (38 kDa) and synaptotagmin (58 kDa). Radiolabeling of proteins could be completely prevented by preincubation with the sulfhydryl reagent N-ethylmaleimide (NEM; 4 mM), but not by exposure to propionamide (10mM) or to the monothiol-reducing agent, dithiothreitol (4 mM). Determination of the relative sulfhydryl reactivates of ACR, NEM and idoacetamide (IA) showed that these chemicals were equally efficacious with respect to reducing DTNB-determined synaptosomal -SH content, although the order of potency differed; NEM>IA>ACR. These data suggest that ACR forms sulfhydryl adducts with specific presynaptic proteins and provide initial support for our hypothesis that ACR neurotoxicity is mediated by nerve terminal sites of action. Sponsored by NIH grant ES03830-16.

81 ELECTRON MICROSCOPIC EVALUATION OF THE CEREBELLAR CORTEX IN ACRYLAMIDE EXPOSED RATS.

B. S. Jortner[1], E. J. Lehning[2], S. K. Hancock[1], K. Lowe[1], A. Kuo[1], J. Hinckley[1] and R. LoPachin[2]. *[1]Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA and [2]Anesthesia Research, Montefiore Medical Center, Bronx, NY.*

Male Sprague-Dawley rats (250-275 g) were administered 50 mg/kg acrylamide intraperitoneally for 5 or 11 days, and then sacrificed for ultrastructural examination of the cerebellar cortex. Light microscopy revealed regions of vacuolization of the molecular layer in treated rats. Beginning on day 5, transmission electron microscopic study of the cortex demonstrated a selective effect on the Purkinje cells. Some nuclei were eccentric in location. Their perikaryal cytoplasm contained disordered and diminished Nissl substance, particularly its rough endoplasmic reticulum component, and increase in tubular and vesicular profiles. Occasional large double membrane lined vacuoles, likely representing swollen astrocytic intrusions into the altered perikaryon, were noted. Swollen Purkinje cell dendrites containing electron dense aggregates of degraded organelles were present in the molecular layer. Altered mitochondria were a prominent feature of these degraded masses, which sometimes filled post-synaptic regions of the dendrites. Adjacent astrocytes were swollen. Rare degenerating myelinated axons were seen in the granular layer. These findings indicate that the Purkinje cell is a cerebellar target during acrylamide intoxication, and confirm in part the findings of an earlier electron microscopic study (Cavanagh and Gysbers, J. Neurocytol. 12:413-437, 1983). We also demonstrate a cellular and ultrastructural basis for our companion silver impregnation study of degenerating cerebellar Purkinje cells (Ross et al., Abstracts of the 2002 Society of Toxicology meeting). Supported by NIH grant ES03830-16.

82 *N, N*-DIETHYLDITHIOCARBAMATE, BUT NOT *S*-METHYL- *N, N*-DIETHYLDITHIOCARBAMATE, PRODUCES A DISULFIRAM-LIKE SCHWANNOPATHY IN RATS.

E. G. Tonkin, H. L. Valentine and W. M. Valentine. *Pathology, Vanderbilt University Medical Center, Nashville, TN.*

Disulfiram, a dithiocarbamate drug used in alcohol aversion therapy, produces a peripheral neuropathy that was characterized in rats as a segmental demyelination accompanied by generation of *S*-(*N, N*-diethylcarbamoyl)cysteine (DETC-Cys) adducts. To assess the role of cysteine carbamylation in disulfiram toxicity, 2 disulfiram metabolites, *N, N*-diethyldithiocarbamate (DEDC) and *S*-methyl- *N, N*-diethylthiocarbamate (MeDETC), were administered parenterally to male Sprague-Dawley rats *via* osmotic infusion pumps for 4 and 8 weeks. Following exposure, hemoglobin and spinal cord axonal proteins were isolated and analyzed for the presence of DETC-Cys adducts, while peripheral nerve and spinal cord sections were obtained and examined by light and electron microscopy for the presence of morphological lesions. Globin preparations from both DEDC- and MeDETC-exposed animals were found by RP-HPLC to contain a late-eluting β-globin peak, the quantity of which increased as a function of exposure level and duration, consistent with the formation of a DETC-Cys adduct on the β_3-globin chain. The presence of DETC-Cys protein adducts was verified after hydrolysis of both globin and spinal cord axonal proteins by LC-MS/MS analysis. The quantity of DETC-Cys adducts produced on hemoglobin and axonal proteins was two fold greater for MeDETC relative to DEDC. Demyelinated axons, myelin edema, and other Schwann cell lesions similar to those seen with disulfiram treatment, were observed in all peripheral nerves examined from animals treated with 0.25 or 0.35 mmol/kg/d DEDC for 8 weeks. No lesions were detected following exposure to MeDETC at any time point or dose level. These results indicate that parenteral administration of DEDC produces a neuropathy similar to disulfiram, but the lack of peripheral nerve lesions following MeDETC treatment in the presence of higher levels of DETC-Cys adducts suggests that formation of DETC-Cys adducts is not responsible for development of neuropathy. (Supported by NIEHS grants ES06387 & ES00267).

83 PROTECTION AGAINST METHANOL-INDUCED RETINAL TOXICITY BY LED PHOTOSTIMULATION.

J. T. Eells, M. M. Henry, P. Summerfelt, M. T. Wong-Riley, E. V. Buchmann and H. T. Whelan. *Medical College of Wisconsin, Milwaukee, WI.*

Decrements in mitochondrial function have been postulated to be involved in the pathogenesis of macular degeneration, diabetic retinopathy, Leber's hereditary optic neuropathy and methanol intoxication. Formic acid is the toxic metabolite responsible for the retinal and optic nerve toxicity produced in methanol intoxication. Previous studies in our laboratory have documented formate-induced mitochondrial dysfunction and retinal toxicity in a rodent model of methanol intoxication. Photostimulation by monochromatic red to near-infrared radiation has been postulated to enhance mitochondrial activity by stimulation of cytochrome oxidase. The present studies were undertaken to test the hypothesis that exposure to 670 nm light from light-emitting diode (LED) arrays would protect the retina against the mitotoxic and cytotoxic actions of formate. One group of animals was intoxicated with methanol in the absence of LED treatment and a second group was intoxicated with methanol and exposed to LED treatment (670 nm for 1 min 45 seconds = 50 mW/cm^2, 4 joules/ cm^2) at 5, 25, and 50 hours after the initial dose of methanol. Blood formate concentrations did not differ between the two treatment groups and averaged 5.6 ± 1.0 mM at 72 hours. At 72 hours of methanol intoxication, retinal function was assessed by measurement of ERG responses and retinas were prepared for biochemical and histologic analysis. ERG responses recorded in methanol-intoxicated animals revealed profound attenuation of both rod-dominated and UV-cone mediated responses. In contrast, methanol-intoxicated animals exposed to LED treatment exhibited a complete recovery of rod-dominated ERG responses and partial recovery of UV-cone mediated ERG responses. These data provide evidence that LED phototherapy protects the retina against the cytotoxic actions of formate and are consistent with the hypothesis that LED photostimulation improves mitochondrial respiratory chain function. (Supported by NIH RO1-ES06648, RO1-EY11396, P30-EY01931 and NASA NAS8-99015).

84 THE INDUCTION OF AMYLOID PRECURSOR PROTEIN AND α-SYNUCLEIN IN ASTROGLIA BY DIETHYLDITHIOCARBAMATE (DDC) AND COPPER WITH OR WITHOUT GLUTATHIONE (GSH).

S. Cheng and L. D. Trombetta. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

α-synuclein has been hypothesized to provide a nucleation centre during the formation of senile plaques. It has been shown that α-synuclein undergoes self-oligomerization when β-amyloid (Aβ) is present. Glial cultures produce the Kunitz-protease inhibitor (KPI) -containing APP. The KPI-containing APP protein may be implicated in Alzheimer's disease (AD) pathogenesis. Astroglia may play a role in the pathogenesis of AD. The role of xenobiotics in the pathogenesis of neurodegenerative disease has been suggested. The mechanism of DDC neurotoxicity is thought to involve Cu++ chelation and to interact with SH group to destroy the GSH homeostasis and inhibit sulfhydryl enzymes. GSH has been shown to protect against DDC cytotoxicity. Cu has been shown to induce the self-oligomerization of α-synuclein. APP contains a Cu-binding site. APP reduces bound Cu++ to Cu+, and could induce the formation of hydroxyl radicals. In this study, rat astroglia were grown in complete medium on glass chamber slides or T75 flasks. Astroglia were treated with DDC 17.5 μg/ml, Cu 0.2 μM, or DDC 17.5 μg/ml + Cu 0.2 μM in medium for 1 hr. Cells were washed in PBS and refed with complete medium with or without 10 mM GSH. Immunocytochemistry was performed at 4 and 8 hr post treatment using APP or α-synuclein primary antibodies followed by gold conjugated secondary antibody. Results showed the increase of APP and α-synuclein production occurring in a time-dependent manner. At 4 hr post treatment, the cells contained small positively stained material deposited throughout the cytosol. This material increased in size and density over time, and by 8 hr it appeared as a dense aggregate surrounding the nucleus. Western Blots were performed at 4 and 8 hr post treatment using APP or α-synuclein primary antibodies followed by horseradish peroxidase-linked secondary antibody. Immunoblots supported immunocytochemistry results. GSH showed significant protection at 8 hr post treatment.

84A CYCLIC AMP-DEPENDENT PROTEIN KINASE INDUCTION BY POLYCHLORINATED BIPHENYLS (PCBs) STIMULATES CREB PHOSPHORYLATION *VIA* A CALCIUM-DEPENDENT, PKC-INDEPENDENT PATHWAY IN CORTICAL NEURONS.

J. R. Inglefield, W. R. Mundy, C. A. Meacham and T. J. Shafer. *NTD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

We have previously demonstrated that the PCB mixture, Aroclor 1254 (A1254), increases the phosphorylated form of CREB (pCREB), the cAMP-responsive element binding protein. This transcription factor is important in nervous system development and plasticity. Phosphorylation of CREB results in its activation and is

mediated by a variety of stimuli, including activation of protein kinases A and C and increases in intracellular calcium. As such, the present experiments were designed to determine the mechanism(s) by which PCBs increase pCREB. Using digital microscopy, semi-quantitative fluorescent immunocytochemistry of serine-133 phosphorylated CREB was performed in primary cultures of cortical neurons in the presence and absence of A1254 and agonists and antagonists of PKA, PKC, and intracellular Ca^{2+}. Cellular pCREB flourescence intensity was analyzed with the aid of image analysis software. The pCREB responses were represented as Gaussian populations where the half-maximal fluorescence (EC_{50}) of the population was the comparator across treatment groups. In controls, pCREB was constitutively and non-uniformly expressed. A1254 (2-20 μM) increased pCREB immunoreactivity in a dose-dependent manner. A1254 (10 μM) or the agonists glutamate, forskolin and phorbol myristate acetate increased the EC_{50} values for pCREB fluorescence by 36±5, 51±15, 47±9 and 40±10%, respectively. PKA inhibitor peptide (30 min preincubation) completely inhibited, whereas BAPTA-AM or tetrodotoxin partially inhibited, and the PKC inhibitor, bisindoylmaleimide, did not inhibit pCREB induction by A1254 (10 μM, 40 min). We also examined whether cAMP is involved in the activation of PKA by PCBs. The adenylate cylcase activator, forskolin, but not A1254 (2-20 μM) elevated intracellular cAMP levels. These data support a role of a PKA and intracellular Ca^{2+} pathways involved in PCB-induced CREB phosphorylation. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy).

84B ACTIVATION OF MAP KINASE BY THE PERSISTENT BIOACCUMULATIVE TOXICANTS PCBs AND PBDEs IN DEVELOPING CORTICAL CULTURES.

W. R. Mundy, J. R. Inglefield and T. J. Shafer. *Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Alteration of calcium signaling has been proposed as a possible mechanism contributing to the developmental neurotoxicity of polychlorinated biphenyls (PCBs). Little is known, however, regarding the actions of structurally related compounds such as polybrominated diphenyl ethers (PBDEs), flame retardants whose levels are rising rapidly in the environment. We examined the actions of the PCB mixture Aroclor 1254 (A1254), which is known to alter calcium homeostasis, and a PBDE mixture (DE71), on activation of the mitogen-activated protein kinase (MAPK) cascade. MAPK is a critical regulator of cell division and differentiation which can be activated by numerous signals including increases in intracellular calcium. Immature primary cultures of rat cortical neurons were deprived of serum overnight and exposed to A1254, DE71, or the agonists glutamate and KCl. Activation of MAPK was assessed by measuring the dually-phosphorylated, active form of MAPK by SDS-PAGE and immunoblotting with a phospho-specific antibody. In immature cortical neurons, activation of ionotropic and metabotropic glutamate receptors with glutamate resulted in a time- and concentration-dependent increase in phospho-MAPK. This activation could be partially blocked using calcium-free buffer in the presence of the calcium chelator BAPTA. Similar effects on MAPK activation were observed after depolarization of cortical neurons with KCl. Stimulation with both A1254 and DE71 (1-30 μM) resulted in a time- and concentration-dependent increase in phospho-MAPK. A1254 was more potent than DE71, and the effects were partially blocked in the absence of calcium. These results suggest that PCBs and the structurally related PBDEs can affect the MAPK kinase cascade, a critical mediator of cell development and neuronal plasticity. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy).

85 QUANTIFICATION OF CYP GENE EXPRESSION DETERMINED BY LIGHTCYCLER TECHNOLOGY.

N. Katsutani, N. Toritsuka, T. Dodo, T. Sekido, T. Aoki, S. Sawada and S. Motooka. *Developmental Safty Assessment Research, Eisai Co., Ltd., Gifu, Japan.*

Changes in drug-metabolizing enzymes sometimes alter toxicological consequences. Although drug-metabolizing enzymes, especially cytochrome P450 (CYP) levels, after exposure of chemicals are generally assessed by expressing protein levels using western blotting, it is considered that quantification of their gene expression levels provides equivalent or more valuable information. However, the combined method of RT-PCR and Northern blotting, which has been generally used, is time consuming. We have achieved quantification of CYP gene expression levels by real-time PCR (LightCycler™, Roche). RNA was isolated from rat liver and reverse transcription was conducted. Gene expression of CYP was quantified by the real-time PCR method consisting of PCR in a capillary tube and online monitoring of fluorescence of SYBR Green I, which is specifically bound to stranded DNA produced by PCR reaction. Using this method CYP induction after administration of dexamethasone (DEX) and 3-methylchoranthrene (3-MC), well known enzyme inducers, were examined. DEX (60 mg/kg) or 3-MC (30 mg/kg) was given by an i.p. injection to female SD rats, and liver samples were collected 24 hours later. Primers corresponding to CYP molecular species (CYP1A2, 2B1, 2B2, 3A2, 3A9, 3A23) and ß-actin were used and all the molecular species examined were quantifiable. Significant enzyme induction was observed in CYP2B1 and 3A23 in the DEX treated group and in CYP 1A2 in the 3-MC treated group. The advantages of this method are that analysis time can be reduced to less than 60 minutes without risk of contamination and use of labor-intensive gel electrophoresis, and that multiple samples (maximally 32 samples containing controls) can be examined simultaneously. These results suggest that real-time PCR by LightCycler™ can be a useful tool for rapid determination of altered CYP gene expression and possibly other target genes induced by chemical exposure.

86 EFFECT OF PCB EXPOSURES DURING DEVELOPMENT ON THE P450-MEDIATED METABOLISM OF ORGANOPHOSPHORUS INSECTICIDES IN RAT LIVER MICROSOMES.

A. Kachroo and J. E. Chambers. *CEHS, Mississippi State University, Mississippi State, MS.*

Phosphorothionate insecticides can be activated to their oxon metabolites by desulfuration or detoxified by dearylation, both reactions are mediated by P450's. The effect of gestational/lactational exposure to PCB's (polychlorinated biphenyls) on hepatic microsomal metabolism of the organophosphorus insecticides diazinon, azinphosmethyl, dimethoate, and coumaphos was determined. The dams were administered the PCB mixture Aroclor 1254 from GD6 to PND 22. The potential of detoxication, *via* dearylation, of coumaphos and diazinon was monitored using HPLC methodology in naive male rats (PND 3, 12, 21, 33, 70), and in male and female rats exposed to PCB's (PND 15 and 23). Data showed a general increase in pyrimidinol (diazinon dearylation) production with age, with 70d and 33d statistically different from one another, and from the other ages 3, 12, 21 which were not statistically different from one another. PCB treated rats showed a statistically significant increase in pyrimidinol production at all ages and in both sexes. Analysis of coumaphos phenol production showed a general age-related increase with no statistical difference within the naive rat group; however data in PCB treated animals showed a similar trend as with diazinon dearylation. Diazinon, dimethoate, and coumaphos desulfuration potentials (measured indirectly using acetylcholinesterase inhibition) showed no significant differences among ages, but did exhibit a general age-related increase in naive rats. Data for azinphosmethyl activation exhibited an age-related increase with 70d and 33d not statistically different from one another, but different for the rest of the ages studied. PCB treated rats showed significantly greater desulfuration for diazinon, azinphosmethyl, and coumaphos at all ages and with both sexes. Dimethoate desulfuration showed no statistical difference in the PCB treated groups. The data indicate that age-related differences in desulfuration/dearylation potential for naive rats is compound specific as is the ability to be induced by PCB exposure (EPA R 825296-01).

87 *IN VITRO* METABOLISM OF OCTAMETHYLCYCLOTETRASILOXANE BY HUMAN AND RAT MICROSOMES.

P. A. Jean[1], E. Usuki[2], J. M. McKim Jr[1], A. Madan[2], A. Parkinson[2] and K. P. Plotzke[1]. [1]*Dow Corning Corporation, Midland, MI and* [2]*XenoTech LLC, Kansas City, KS.*

Exposure of rats to Octamethylcyclotetrasiloxane (D4) induces CYP450 enzymes in the liver, and causes hepatomegaly and transient increases in hepatocyte proliferation similar to phenobarbital (PB). It also appears that these enzymes are capable of recognizing D4 as a substrate and may play a role in its metabolism and elimination in the rat. This study was designed to determine if D4 is metabolized by liver microsomes from humans or rats and to identify which specific CYP450(s) are responsible for the metabolism in humans. 14C-D4 was incubated with recombinant (r) human CYP450s and liver microsomes (rat & human) at 37°C for up to 2 hr and at various protein concentrations. Incubation extracts were analyzed by HPLC with radiometric detection. Chromatograms from PB-rat incubations contained at least 8 distinct peaks (metabolites M1-8) whereas only 2 metabolites (M5, M8) were detected in saline-rat incubations. Human incubations gave rise to predominately 1 metabolite (M8) with M5 detected only at high protein concentrations. Of the rCYP450s evaluated, only rCYP2B6 (M5 & M8) and rCYP3A4 (M8) produced metabolites. Formation of M8 and/or M5 by human microsomes and rCYP3A4 was not proportional to time or protein concentration. Formation of M8 by rCYP2B6 was proportional to protein concentration but not time. M8 formation in saline-rat incubations was proportional to protein concentration but not time. In PB-rat incubations a few metabolites showed proportionality between formation and incubation time and/or protein concentration, however M8 did not. These experiments revealed that rat and human liver microsomes are capable of me-

tabolizing D4 and PB induction in rats greatly enhances the ability of liver microsomes to metabolize D4 to a variety of metabolites. The use of rCYP450s and inhibitory polyclonal antibodies demonstrated that human CYP2B6 and CYP3A4 are likely involved in the observed metabolism. Supported in part by Silicones Environmental, Health and Safety Council of America

88 PRECISION-CUT HUMAN LIVER SLICES AS A MODEL TO EXAMINE CHANGES IN CYTOCHROME P450 EXPRESSION TO PREDICT OR PRECLUDE POTENTIAL DRUG-DRUG INTERACTIONS.

H. J. Einolf, S. Bedi-Singh and V. Fischer. *Drug Metabolism and Pharmacokinetics, Novartis Pharmaceuticals Corporation, East Hanover, NJ.*

Precision-cut human liver slices offers a practical alternative to hepatocyte cell cultures to examine cytochrome P450 (CYP) induction by compounds to predict or preclude potential drug-drug interactions. Induction of P450 gene expression was measured in human liver slices by real-time PCR using probes/primers developed to specifically recognize CYP1A1, CYP1A2, CYP3A4, CYP2C8, CYP2C9, or CYP2C18 mRNA. Liver slice viability was monitored by measurement of ATP, GSH, and K^+ content. Minimal loss in slice viability occurred between 24 and 48 h (1.2- and 1.7-fold decreases in K^+ and ATP content, respectively), whereas, more significant losses of viability occurred by 72 h. CYP1A1 and CYP1A2 gene expression was induced by β-napthoflavone (50 μM), with respect to vehicle control, 99- and 110-fold at 24 h of treatment and 19- and 55-fold at 48 h, respectively, which indicated that maximal induction occurred at or prior to 24 h. Inducers of CYP3A4, carbamazepine (CARB, 50 μM), rifampicin (RIF, 50 μM), phenobarbital (PB, 0.5 mM), and dexamethasone (DEX, 50 μM) induced CYP3A4 gene expression 2.4-, 4.6-, 7.6- and 3.6-fold at 24 h, and 2.9-, 7.1-, 18-, and 10-fold at 48 h, respectively. Known inducers of CYP2C enzymes, RIF, PB, and DEX increased CYP2C9 mRNA expression by 1.9-, 3.1-, and 2.3-fold at 24 h and by 1.9-, 3.7-, and 3.9-fold at 48 h, respectively. RIF, PB, and DEX induced CYP2C8 mRNA expression by 6.0-, 7.0-, and 7.4-fold at 24 h and 2.7-, 5.7-, and 4.6-fold at 48 h, respectively. DEX induced CYP2C18 mRNA by 48 h (2.4-fold), whereas PB and RIF had little effect. The levels of induction of CYP2C and CYP3A4 mRNA were similar to induction levels found recently in human hepatocytes. These studies indicated that induction of P450 gene expression can be measured in human liver slices with a single treatment of inducer within 24 h of slice culturing and up to 48 h with minimal reduction in slice viability.

89 DEVELOPING AN *IN VITRO* MODEL SYSTEM TO EVALUATE SWITCH-LIKE BEHAVIORS OF HEPATOCYTES IN RESPONSE TO VARIOUS ENZYME INDUCERS.

C. T. French, L. S. Chubb, R. E. Billings and M. E. Andersen. *Department of Environmental Health & International Center for Risk Assessment, Colorado State Univ., Fort Collins, CO.*

Cytochrome P450 induction in liver by a variety of enzyme inducing chemicals demonstrates switch-like behaviors. As dose increases, more cells become fully induced rather than observing a proportionate induction in all cells in the liver. These inducers interact *via* different receptor systems, indicating that this switch-like response is a generic property of induction with these cells. The molecular mechanisms that control these switches remain unknown. We have developed an *in vitro* model system using cultured rat hepatocytes to study this phenomenon with prototypical inducers. In this study we examined induction of CYP 1A1 protein and CYP 1A1 mRNA by PCB 126, a prototypical aryl hydrocarbon receptor (AhR) agonist. Hepatocytes from male Sprague-Dawley rats were treated for 24 hours after attachment on plates at PCB126 concentrations ranging from 10^{-5} to 10^{-10} M. Total CYP1A1 protein was evaluated in cell homogenates by densitometry of Western blots and for CYP1A1 mRNA by quantitative PCR. The EC50s for induction of both protein and mRNA were in the range of 2 to 5 nM. These integrated responses of populations of hepatocytes were compared with responses of individual cells by visualization of treated cells on plates. Protein was visualized by CYP 1A1 immunohistochemistry. While induction of individual cells and the Dose-Response for increasing numbers of cells stained with increasing dose was evident by immunohistochemistry, further refinements of imaging techniques are necessary to derive quantitative estimates of numbers of cells induced at each dose level. Nonetheless, the combined evaluation of population and cell level responses of hepatocytes offered by this *in vitro* model permits characterization of the induction switch and provides a system to probe the molecular mechanisms that underlie non-linear dose-response behaviors for these receptor-mediated toxicants. This work was supported by a contract from the American Chemistry Council.

90 EVALUATION OF AFLATOXIN B1 AND OTHER CHEMICALS IN GENTEST© CELL LINES: CYP-MEDIATED TOXICITY IS DIMINISHED BY CO-TREATMENT WITH SPECIFIC INHIBITORS.

S. E. Boldt and D. E. Amacher. *Molecular and Investigative Toxicology, Groton Laboratories, Pfizer Global Research and Development, Groton, CT.*

Many xenobiotics are more toxic when metabolized by cytochrome P450 enzymes (CYPs). The intent of this study was to test such chemicals in Gentest© cell lines, human lymphoblasts that have undergone stable transfections resulting in expression of human CYPs. Aflatoxin B1 (AB1) was tested in the cell lines h1A2v2, h3A4/OR, h2E1/OR, 2C9-Arg/OR, 2D6-Val, MCL-5 (CYP1A2, 3A4, 2E1, 2A6, and elevated native 1A1), and the control lines cHol and cHyg (no CYP over-expression) for 72 hours alone and concurrently with inhibitors. Inhibitors used were as follows: 5 μM furafylline (1A2), 10 μM ketoconazole (3A4), 10 μM sulfaphenazole (2C9), 10 μM 4-methylpyrazole (2E1), 10 μM quinidine (2D6), and 15 μM aminobenzotriazole (ABT, all). Furafylline inhibited CYP-mediated AB1 toxicity completely in the h1A2v2 cells but not in the MCL-5 cells. Ketoconazole inhibited AB1 toxicity completely in the h3A4/OR cells but not in the MCL-5 cells. Co-treatment with ABT in the MCL-5, h1A2v2, and h3A4/OR cell lines did not inhibit toxicity. AB1 did not demonstrate toxicity in the other cell lines. Aflatoxin B2, B2a, and G2a were not toxic to any of the cell lines at the concentrations tested. Aflatoxin G1 (AG1) and Aflatoxin G2 (AG2) displayed CYP-mediated toxicity similar to that of AB1. Aflatoxin M1 (AM1) was toxic only to the h1A2v2 and MCL-5 cell lines when tested up to 0.5 μM, while Aflatoxin M2 did not exhibit toxicity in any of the cell lines when tested up to 0.25 μM. Colchicine, which is directly toxic, was used as a positive control in these assays. In conclusion, based on results with these cell lines, AB1, AG1, and AG2 toxicities are CYP-generated, and are mediated principally by CYP1A2 and to a lesser extent by CYP3A4.

91 COAL DUST IS A MODIFIER OF PULMONARY CYP1A1 INDUCTION IN RATS.

M. Ghanem[1,2], L. Battelli[1,2], M. Kashon[1], V. Vallyathan[1], J. Y. Ma[1], M. Barger[1], J. Nath[2], V. Castranova[1] and A. F. Hubbs[1]. *[1]Health Effects Laboratory Division, NIOSH, CDC, Morgantown, WV and [2]West Virginia University, Morgantown, WV.*

Cytochrome P4501A1 (CYP1A1) plays an important role in pulmonary carcinogenesis. Pulmonary CYP1A1 metabolizes inhaled exogenous agents, such as cigarette smoke-associated polycyclic aromatic hydrocarbons, into potent carcinogens. We hypothesized that intrapulmonary deposition of particulate might modify susceptibility to inhaled carcinogens by modifying induction and activity of pulmonary CYP1A1. To test this hypothesis, male Sprague-Dawley rats were intratracheally instilled with 0, 2.5, or 10 mg of respirable coal dust or iron oxide. Saline was instilled as a control. Eleven days later, they were treated with the CYP1A1 inducer β-naphthoflavone (NF; 50 mg/kg IP) or vehicle (corn oil). Three days after that, they were sacrificed and the level of functional CYP1A1 in the lungs was measured as ethoxyresorufin-*O*-deethylase (EROD) activity. Lung CYP1A1 protein induction and localization of CYP1A1 protein to alveolar type II cells was assessed by dual immunofluorescence staining for CYP1A1 and cytokeratin 8 (a cytoskeletal protein expressed in type II cells). We found that pulmonary EROD activity was significantly greater in coal dust/NF and iron oxide/NF rats than in saline/NF rats. Increasing coal dust lung burden accentuated the enhancement of EROD induction while increasing iron oxide lung burden diminished the enhancement seen at the lower lung burden. Immunofluorescence demonstrated that within the alveolus, a smaller proportion of CYP1A1 staining was associated with alveolar type II cells in coal dust/NF or iron oxide/NF rats than in saline/NF rats. These findings demonstrate that pulmonary exposure to coal dust modifies the inducibility and localization of CYP1A1 in the lung. These results suggest that respirable coal dust is not a simple co-variable in mixed exposures but a complex modifier of CYP1A1 induction that alters CYP1A1 activity and localization in the lung.

92 INDUCTION OF CYTOCHROMES P450 1A1 AND 1B1 BY MOTORCYCLE EXHAUST PARTICULATE IN HUMAN BREAST CANCER MCF-7 CELLS.

T. H. Ueng, H. W. Wang and F. W. Chen. *Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan.*

The effects of motorcycle exhaust particulate (MEP) on cytochrome P450 (P450)-dependent monooxygenases were determined using MCF-7 human breast cancer cells treated with organic extracts of MEP. Treatment with MEP extract caused concentration- and time-dependent increases of monooxygenase activity in S9 fractions. Treatment with 50 μg/ml MEP extract for 24 h increased BENZO(A)PYRENE hydroxylase and 7-ethoxycoumarin, 7-ethoxyresorufin and methoxyresorufin O-dealkylases activities in S9. Treatment with 1 or 10 μg/ml MEP extract for 24 h markedly enhanced catabolism of 17 β-estradiol in MCF-7

cells. Co-treatment of the cells with 2 μM α-naphthoflavone, a P450 inhibitor and arylhydrocarbon receptor antagonist, blocked the increase of BENZO(A)PYRENE hydroxylase activity induced by treatment with MEP extract alone. Immunoblot analyses of S9 proteins using a mouse monoclonal antibody 1-12-3 against rat P450 1A1 and a rabbit polyclonal antibody against human P450 1B1 revealed that MEP extract induced proteins immunorelated to P450s 1A1 and 1B1. RNA blot analysis of total RNA using a human P450 1A1 3'-end and a human P450 1B1 RT-PCR product cDNA probes showed that MEP extract increased the levels of P450s 1A1 and 1B1 mRNA hybridizable to the respective cDNA probes. Treatment with 10 μM BENZO(A)PYRENE, a component of MEP extract, for 24 h induced catalytic activity, protein, and mRNA of P450s 1A1 and 1B1 in MCF-7 cells. Treatment with MEP extract increased P450s 1A1 and 1B1 proteins and mRNA levels in NCI-H322 human lung carcinoma and CL5 human lung adenocarcinoma cells. The extract also increased P450 1A1, but not P450 1B1, protein and mRNA in HepG2 human hepatoma cells. The present findings demonstrate that MEP extract has the ability to induce P450s 1A1 and 1B1 in the estrogen-responsive MCF-7 cells. Induction of the carcinogen- and estrogen-metabolizing P450s 1A1 and 1B1 may be an important factor to consider in assessing the potential health effects associated with human exposure to ME.

93 REGIONAL INDUCTION OF CYP1A1 PROTEIN DURING TREATMENT OF RATS WITH MIXTURES OF PCB126 AND PCB153.

L. S. Chubb, S. A. Benjamin, J. T. Painter, C. E. Dean and M. E. Andersen. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Colorado State University, Fort Collins, CO.*

Liver enzyme induction by various inducers is regional and has all-or-none, switch-like characteristics *in vivo* and *in vitro*. We have evaluated enzyme induction and liver tumor promotion of a mixture of planar (PCB126) and non-co-planar (PCB153) PCBs in Fisher rats using a modified Ito initiation-promotion study. Starting two weeks after DEN initiation, rats were gavaged 3 times per week with PCBs. In a second study, enzyme activity for CYP1A1 was estimated in liver microsomes from Sprague-Dawley rats treated with PCBs for 13 to 30 weeks. In the Ito study, concentrations of PCBs in liver were determined for rats treated with mixtures or with either compound alone. At moderate doses, there was a more than additive increase in CYP1A1 activity in the multi-week dosing study and an increased liver concentration of PCB153 in mixture treated rats in the Ito study. At moderate to high doses, there were less than additive increases in number and area of GST-P+ foci. In the Ito study, exposure to PCB126 caused regional induction of CYP1A1, starting in the centrilobular region at 0.1 μg/kg/day and progressing outward until all the liver was induced at 10.0 μg/kg/day. In the high dose PCB126 rats that also received a high dose of PCB 153 (10, 000 μg/kg/day), the PCB153 concentrations reached 76 μg/g liver, 3-fold higher than those treated with PCB153 alone. In the mixture treated rats, the pattern of induction changed. Instead of complete induction of CYP1A1 throughout the liver as in the high dose PCB 126 rats, the pattern was regional showing preferential periportal staining, a reversal of the normal centrilobular pattern. This unexpected regional interaction may correlate with the inhibitory interactions for GST-P+ foci. This will also be studied in an *in vitro* switching model (CT French et al., this meeting). This work was supported by contract #1467 from the American Chemistry Council and NIEHS grants SBRP ES05949, KO8 ES00314 and KO8 ES00380.

94 INFLUENCE OF SIGNAL TRANSDUCTION PATHWAYS ON TCDD-MEDIATED *CYP1A1* GENE EXPRESSION.

D. E. Machemer[1] and R. H. Tukey[1,2]. [1]*Department of Pharmacology, University of California San Diego, La Jolla, CA and* [2]*Department of Chemistry & Biochemistry, University of California San Diego, La Jolla, CA.*

Cytochrome P450 1A1 (CYP1A1) catalyzes the hydroxylation of a variety of xenobiotic compounds and is strongly induced by halogenated and polycyclic aromatic hydrocarbons. Protein kinase C (PKC) has been implicated in the regulation of this response, since 1) several PKC inhibitors have been shown to inhibit induction by Ah receptor ligands, and 2) phorbol esters are synergistic to TCDD-mediated induction of *CYP1A1*. To define the role of PKC in regulation of the *CYP1A1* gene, we examined the effect of specific PKC inhibitors on this response. Experiments were conducted using the human HepG2 TV101L cell line, which stably expresses the firefly *luciferase* gene under control of the *CYP1A1* promoter (-1612 bp). TV101L cells were treated with 5 nM TCDD for 6 hours in the presence or absence of staurosporine or each of several specific PKC inhibitors (GF109203X, Gö6983, and Gö6976). TCDD alone did not significantly stimulate PKC activity. Phorbol 12-myristate 13-acetate (PMA) caused a 2- to 5-fold increase in luciferase activity both in the absence of TCDD (untreated compared to PMA treated TV101L cells) and the presence of TCDD (TCDD treated compared to TCDD and PMA cotreated TV101L cells). TV101L cells cotreated with TCDD and staurosporine exhibited a dose-dependent inhibition of PKC activity and of *CYP1A1*-luciferase activity at similar staurosporine concentrations. However, TV101L cells cotreated with TCDD and a specific PKC inhibitor showed a difference of approximately one order of magnitude between inhibitor concentrations necessary for dose-dependent inhibition of PKC activity and inhibitor concentrations necessary for dose-dependent inhibition of *CYP1A1*-luciferase activity. The magnitude of this difference was the same for TV101L cells cotreated with TCDD, PMA, and each of the specific PKC inhibitors. Combined, these results suggest that the actions of PKC may not constitute the sole component of *CYP1A1* regulation. (Supported in part by USPHS grant ES10337.)

95 HIGHER STABILITY OF TCDD-REGULATED CYP1A1 AND CYP1B1 mRNA IN THE MURINE AH RECEPTOR-DEFICIENT HEPA VARIANT THAN IN THE WILD TYPE HEPA-1C1C7 CELL LINE.

S. E. Eltom[1] and C. R. Jefcoate[2]. [1]*Pharmacology, Meharry MedicalCollege, Nashville, TN and* [2]*Pharmacology, University of Wisconsin, Madison, WI.*

The induction of CYP1A1 and CYP1B1 mRNA by 2, 3, 7, 8 tetrachloro-dibenzo-*p*-dioxin (TCDD) in Hepa-1 cells, wild type (WT) and the low Ah receptor (AhR) level variant (LA1) was examined. The kinetic analysis of the induction showed major differences related to the stability of the AhR and its two regulated genes. TCDD treatment of Hepa cells results in increased transcription of CYP1A1 and CYP1B1 with a subsequent down regulation of the AhR. We show here that nuclear translocation of the receptor is a pre-quisite for this depletion and that simultaneous treatment with actinomycin D reversed the TCDD-activated loss of AhR in WT. This indicates that continuous transcription is necessary to maintain receptor degradation by an apparently labile protease. In LA1 cells, however, AhR proteolysis was high in absence of TCDD treatment, and actinomycin D treatment stablized the cytosolic AhR levels only in LA1 cells, suggesting that the transcription-sensitive AhR degradation in LA1 cells is cytosolic rather than nuclear and might have contributed to the 10-fold lower constitutive AhR levels in LA1 variant. The transcription of CYP1A1 and CYP1B1 mRNA by TCDD in WT cells each exhibited bursts of activity in the initial hour which were about 3-fold greater than in LA1 cells, approximately in proportion to the respective nuclear AhR levels after 1 hr. However, the induced mRNA levels in LA1 exhibited a slow and prolonged increase reaching 50-80 percent of the WT steady state levels by 20 h. The decay of both CYP1A1 and CYP1B1 mRNA following inhibition of transcription by actinomycin D was much slower in LA1 cells. This slower mRNA turnover therefore, compensates for lower initial transcription rate and allows LA1 to gradually approach WT steady state levels. Thus, altered regulation of the AhR responsive genes in LA1 may result from the instability of the AhR due to this causative protease redistribution.

96 EFFECTS OF POLYCYCLIC AROMATIC HYDROCARBONS AND POLYCHLORINATED BIPHENYLS ON INDUCTION OF CYP1A1, CYP1A2, AND CYP1B1 IN LIVER AND LUNG TISSUES IN ARYLHYDROCARBON RECEPTOR KNOCK-OUT MICE.

T. Shimada[1], Y. Suzuki[1], T. Kawai[1], M. Hashimoto[1], E. Azuma[1], T. Nakajima[1], K. Inoue[1], M. Shindo[2] and Y. Fujii-Kuriyama[3]. [1]*Osaka Prefectural Institute of Public Health, Osaka, Japan,* [2]*Kinki University, Osaka, Japan and* [3]*Tohoku University, Sendai, Japan.* Sponsor: E. Guengerich.

CYP1A1 and CYP1B1 are the most important enzymes in the initial step of oxidation of polycyclic aromatic hydrocarbons (PAHs) to form reactive intermediates and ultimate carcinogens. Arylhydrocarbon receptor (AhR) knock-out mice are shown to be resisitant to BENZO(A)PYRENE (B[a]P)-induced carcinogenesis, probably due to the inabilities to activate B[a]P by specific P450s in these mice. It is interesting to know which P450s are induced by PAHs and polychlorinated biphenyls (PCBs) in AhR(+/+) and (-/-) mice. These mice were injected i.p. with several PAHs and PCBs and were sacrificed at 3 days after the treatment. Levels of mRNA of Cyp1a1, Cyp1a2, and Cyp1b1 in liver and lung tissues and activities of liver microsomal P450s were measured. Cyp1a1 mRNA was very low in liver and lung tissues in untreated mice and was highly induced in AhR(+/+) mice by PAHs. 3, 4, 3', 4'-Tetrachlorobiphenyl induced liver and lung Cyp1a1 in AhR(+/+) mice, whereas PCB mixtures induced Cyp1a1 mRNA only in the liver. Cyp1a2 mRNA was increased with 3-methylcholanthrene and Kanechlor 500 in AhR(+/+) mice and was not detected in lung. Cyp1b1 was expressed constitutively in liver and lung tissues and was induced by PAHs and TCB in AhR(+/+) mice. Liver microsomal activities to oxidize several xenobiotics and carcinogens were found to be good indicators for the induction of individual P450s by PAHs and PCBs. Our results support that Cyp1a1, Cyp1a2, and Cyp1b1 are differentially induced in liver and lung tissues of AhR(+/+) mice by PAHs and PCBs through AhR and these may be related to the occurrence of tumor formation caused by PAHs in the target organs. (Supported in part by Grants from the Ministry of Education, Science, and Culture of Japan, the Ministry of Health and Welfare of Japan, and the Petroleum Energy Center.)

97 CYTOCHROME P450 2E1(CYP2E1) IS THE PRIMARY ENZYME RESPONSIBLE FOR ETHYL CARBAMATE (EC) METABOLISM: STUDIES USING CYP2E1-NULL MICE.

U. Hoffler[1,2] and B. Ghanayem[1,2]. [1]*Meharry Medical College, Nashville, TN and* [2]*NIEHS, Research Triangle Park, NC.*

EC is a fermentation product that is found in alcoholic beverages and some foods. It has been suggested that CYP2E1 is involved in EC metabolism. To directly assess the role of CYP2E1, EC metabolism was compared in CYP2E1-null (KO) and wild type (WT) mice. Carbonyl-14C-EC was administered (po) to male KO and WT mice at 10 or 100mg/kg. Mice were placed in metabolism cages that allowed for the quantitation of expired CO2, organic volatiles, urine, and feces. 14C derived from EC in tissues were dose-dependent and significantly higher in the KO *vs.* WT mice. Present data showed that CPY2E1 is the primary enzyme responsible for the metabolism of EC to CO2, however, other enzymes were involved. To identify these enzymes, the metabolism of 10mg/kg EC was compared in KO and WT mice pretreated with the CYP inhibitor 1-aminobenzotriazole (ABT, 50mg/kg ip) or the esterase inhibitor paraoxon (PAX, 1mg/kg ip). ABT resulted in significant inhibition of EC metabolism to CO2 in both genotypes. Moreover, higher levels of 14C derived from EC were detected in the tissues of ABT or PAX pretreated mice. In conclusion, these data demonstrated that CYP2E1 is the primary enzyme responsible for the metabolism of the carbonyl moiety of EC to CO2, however, other CYPs and esterases play a less significant role. The table below summarizes EC disposition at 24 hr after dosing:

	100mg/kg EC		10mg/kg EC		ABT+10mg/kg EC		PAX+10mg/kg EC	
	WT	KO	WT	KO	WT	KO	WT	KO
CO_2	95.0±5.2	46.1±5.0[a]	91.9±2.7	37.6±3.0[a]	13.0±2.3[a]	14.6±0.9[a]	96.0±1.2	35.1±1.7[a]
Organic Volatiles	0.5±0.2	2.6±0.9[a]	0.2±0.1	3.8±1.0[a]	3.6±0.1[a]	3.2±1.6[a]	0.7±0.1[a]	4.9±0.1[a]
Urine	3.5±1.2	3.9±0.8	2.3±0.4	5.6±2.1[a]	4.8±0.6[a]	4.2±0.3[a]	0.2±1.0[a]	1.1±1.2[a]

Values are the mean±SD of 3-4 mice. [a] and [b] denote statistically different values (P≤0.05) from corresponding WT and EC-only, respectively.

98 CYP1A1(-/-) KNOCKOUT MICE, WHICH HAVE A FUNCTIONAL AROMATIC HYDROCARBON RECEPTOR, ARE PROTECTED AGAINST DIOXIN, AS WELL AS BENZO(A)PYRENE, TOXICITY IN SPECIFIC TISSUES.

S. Uno, T. P. Dalton, A. P. Senft, H. G. Shertzer and D. W. Nebert. *Center for Environmental Genetics and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Dioxin (2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin; TCDD) is a persistent environmental contaminant of unusual potency, owing to the fact that it is negligibly metabolized and it binds with high affinity to the aryl hydrocarbon receptor (AHR). The AHR is a ligand-activated transcription factor responsible for the up-regulation of numerous genes. It is thought that dioxin toxicity might result, at least in part, from chronic activation of one or more of these genes – leading to chronic oxidative stress; numbered among these genes are the cytochrome P450 1 (*Cyp1*) family members, *Cyp1a1*, *Cyp1a2* and *Cyp1b1*. Indeed, we have shown that the *Cyp1a2(-/-)* mouse is protected against dioxin-mediated hepatotoxicity. We also found that *Cyp1a1(-/-)* mice are more resistant to BENZO(A)PYRENE (BaP)-induced lethality, compared with *Cyp1a1(+/-)* mice. Although CYP1A1-dependent BaP-induced liver toxicity and metabolism do not correlate with CYP1A1-independent formation of BaP-DNA adducts. We then treated congenic *Cyp1a1(+/+)* or *Cyp1a1(-/-)* mice with a single high dose of dioxin (200 μg/kg, i.p.) and measured several endpoints of dioxin toxicity. First, all male *Cyp1a1(+/+)* animals died within 4 weeks following treatment, whereas the male *Cyp1a1(-/-)* mice and female animals of both genotypes did not die. The remaining analyses were performed on the surviving female animals. Serum ornithine carbamoyltransferase activities were not significantly different between *Cyp1a1(+/+)* and *Cyp1a1(-/-)* mice. On the other hand, the *Cyp1a1(+/+)* female mice had significantly smaller thymuses and displayed splenic atrophy, compared with that in the *Cyp1a1(-/-)* females. These results suggest that, like the *Cyp1a2(-/-)* mouse, *Cyp1a1(-/-)* mice may show limited protection against dioxin toxicity, but that the degree of protection will likely be tissue-specific. ***–Supported, in part, by NIH grants P30 ES06096, and R01 ES10133 and ES08147.***

99 THE ROLE OF PON1-192 AND P450 PATHWAYS IN PHOSPHOROTHIOATE METABOLISM BY HUMAN LIVER.

E. Mutch[1], A. K. Daly[2] and F. M. Williams[1]. [1]*Environmental Medicine, University of Newcastle, Newcastle upon Tyne, United Kingdom and* [2]*Pharmacological Sciences, University of Newcastle, Newcastle upon Tyne, United Kingdom.* Sponsor: J. Timbrell.

In order to be toxic to the nervous system phosphorothioate pesticides (OPs) require activation to the oxon by the cytochromes P450. The oxon may then be detoxified by the hydrolytic A-esterase, PON1. The balance between the activation and detoxication pathways may influence susceptibility to OP toxicity because it governs the concentration of circulating oxon. The aims of this study were define the influence of PON1-192 genotype and P450 expression on the capacity of human liver microsomes (n=27) to metabolise parathion and chlorpyrifos. The study showed wide ranges in hepatic expression of CYP3A4 (n.d.-147 pmol/mg protein) and CYP2C8 (0.013-0.259 pmol/mg protein). CYP3A5 was expressed in five (23%) of the twenty-two livers (6-77 pmol/mg protein). The correlations between parathion activation to paraoxon and expressed CYP3A4/5 and CYP2C8 proteins were significant ($p<0.05$), suggesting the involvement of these isoforms in the reaction. However, correlations between chlorpyrifos metabolism and expression of CYP3A4/5 and CYP2C8 were not significant. There were wide ranges in activity for paraoxon and chlorpyrifos-oxon hydrolysis for individuals with the same PON1-192 genotype. Individuals with the RR genotype preferentially hydrolysed paraoxon, while individuals with the R and Q genotype hydrolysed phenylacetate and chlorpyrifos-oxon at similar rates. Correlation analysis of oxon hydrolysis by human microsomes showed that the three phenotypes were not well resolved and therefore could not be used to predict PON1-192 genotype. Individual expression of the participating P450 isoforms were more important than PON1 in determining hepatic capacity to metabolise parathion. PON1-192 genotype did not relate to metabolic capacity towards chlorpyrifos and other factors may be more important determinants of toxicity to this phosphorothioate.

100 CYP2A6 AND P53 IMMUNOREACTIVITY INDUCED BY SMOKING IN NON-SMALL CELL LUNG CANCER PATIENTS.

T. Oyama, A. Matsumoto, T. Isse and T. Kawamoto. *Departments of Environmental Health, University of Occupational and Environmental Health, Kitakyushyu-shi, Japan.*

CYP2A6 is a well known enzyme to metabolize nitrosamines in tobacco smoke. CYP2A6 mRNA is also observed in bronchial epithelial cells. On the other hand, p53 mutation is one of the most common genetic alternations found in human tumors including those of lung. p53 gene mutations lead to a nuclear accumulation of the p53 protein. The incidence of this mutation is related to the smoking index of the patients. The elevated concentration of carcinogens may act to produce these p53 alterations. In this study, we examined 19 patients with non-small cell lung cancer (NSCLC) for CYP2A6 and p53 staining and correlate the findings with lifetime cigarette consumption. We also revealed the relationships between CYP2A6 and p53 immunoreactivity in NSCLC. [Materials and Methods] We examined 19 Japanese patients with NSCLC who underwent surgical resection at UOEH. There were 11 men and 8 women ranging in age from 52 to 83 years (mean, 67 years). Ten patients had stage I & II disease, and 9 stage III & IV. Histological typing of the tumors was performed according to the WHO classification (adenocarcinoma; 12 cases, squamous cell carcinoma; 7 cases). The amount of lifetime cigarette consumption was classified by Brinkman Index (BI; cigarettes/day x years). Immunohistochemical staining (IHC) was performed on 3 mm paraffin-sections. The monoclonal antibody MAB-2A6 (Gentest) and DO-1 (Oncogene Science Inc.,) were used for IHC. We defined as CYP1A1 positive cases when more than 10% of bronchial cells were stained and as positive cases when more than 10% of tumor nuclei were stained. [Results and conclusions] The CYP2A6 positive rate in NSCLC patients with BI of more than 1000 (86%; 6/7) was significantly higher than that with BI less than 1000 (33%; 4/12). The positive rate of p53 expression in NSCLC patients with BI of more than 1000 (86%; 6/7) was significantly higher than that with BI less than 1000 (25%; 3/12). There was no significant relation between CYP2A6 and p53 expressions. Smoking may induce CYP2A6 and p53 expressions.

101 IDENTIFICATION OF NOVEL POLYMORPHISMS IN THE 5'-UNTRANSLATED REGION OF HUMAN CYTOCHROME P450 1B1.

C. M. Vezina[1], S. T. Koury[2], L. R. Olson[1] and A. T. Drahushuk[1]. [1]*Pharmacology and Toxicology, University at Buffalo, Buffalo, NY and* [2]*Biotechnical and Clinical Laboratory Sciences, University at Buffalo, Buffalo, NY.*

The human cytochrome P450 1B1 (CYP1B1) is a dioxin-responsive CYP capable of metabolizing and activating a variety of procarcinogens into their ultimate carcinogenic forms. Expression of the CYP1B1 gene varies considerably among humans, which may influence individual susceptibility to cancer. In order to determine whether genetic differences in CYP1B1 contribute to variability in gene expression, DNA was isolated from human tissue specimens and the -1139 to +19 region (relative to the transcription initiation site) of CYP1B1 was surveyed for genetic polymorphisms by the methods of Polymerase Chain Reaction-Single Strand Conformation Polymorphism (PCR-SSCP) and DNA sequencing. Three novel genetic polymorphisms, designated G-787A, T-350C, and C-238T were identified and their genetic frequencies were determined by Restriction Fragment Length

Polymorphism (RFLP) analysis. The -1139 to +19 region of CYP1B1 was cloned into a reporter plasmid and variant alleles for each polymorphism were introduced by site-directed mutagenesis. Wild type and variant reporter constructs were analyzed for their ability to induce transcription *in vitro* in transiently transfected Human MCF-7 breast adenocarcinoma cells. None of the variant alleles demonstrated significant differences in constitutive or dioxin-induced gene expression compared to the wild type constructs. These results may indicate that variations in the expression of human CYP1B1 are not influenced by genetic factors in the immediate vicinity of the transcription initiation site. (Supported in part by USEPA R825808 and Multidisciplinary Research Pilot Program, University at Buffalo.)

102 INHIBITION OF TCDD-INDUCIBLE CYP1A1 EXPRESSION IN MURINE HEPA-1C1C7 CELLS BY O, P'-DDT.

J. Y. Kim and H. G. Jeong. *Pharmacy and Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Cultured mouse hepatoma Hepa-1c1c7 cells were treated with either o, p'-DDT or TCDD or in combination to assess the role of o, p'-DDT on CYP1A1 expression. o, p'-DDT alone did not affect CYP1A1-specific 7-ethoxyresorufin O-deethylase (EROD) activity. In contrast, the TCDD-inducible EROD activities were markedly reduced upon concomitant treatment with TCDD and o, p'-DDT in a dose dependent manner. Treatment with ICI 182.780, an estrogen-receptor antagonist, did not affect the suppressive effects of o, p'-DDT on TCDD-inducible EROD activity. The TCDD-inducible CYP1A1 mRNA levels were markedly suppressed upon concomitant treatment with TCDD and o, p'-DDT that is consistent with their effects on EROD activity. A transient transfection assay using dioxin-response element (DRE)-linked luciferase and electrophoretic mobility shift assay revealed that o, p'-DDT reduced transformation of the aryl hydrocarbons (Ah) receptor to a form capable of specifically binding to the DRE sequence in the promoter of the CYP1A1 gene. These results suggest that the down regulation of CYP1A1 gene expression by o, p'-DDT in Hepa-1c1c7 cells might be an antagonism of the DRE binding potential of the nuclear Ah receptor but is not mediated through the estradiol receptor [This work was supported by KFDA Grant (ED2001-14) and RCPM].

103 INACTIVATION OF CYTOCHROME P450 2E1 BY CAPSAICIN.

S. J. Smeal, C. A. Reilly and G. S. Yost. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

Capsaicin is the principle pungent component of "hot peppers" and of pepper spray products used for self defense. Previous research has demonstrated that dihydrocapsaicin interacted with hepatic drug-metabolizing enzymes, specifically P450 2E1, and caused a loss of activity and protein adduct formation. In this study, the mechanism of P450 2E1 inactivation by capsaicin has been characterized. A 2E1 enzyme assay composed of recombinant human P450 2E1, NADPH, and p-nitrophenol at 37°C was used. Enzyme activity was determined by spectrophotometric detection of 4-nitrocatechol, the hydroxylated product of p-nitrophenol. We observed both a time- and concentration-dependent decrease in P450 2E1 activity when capsaicin and NADPH were included in incubation mixtures. Increasing concentrations of capsaicin (up to 1 mM) decreased the rate of p-nitrophenol hydroxylation up to 90%. Approximately 43% of P450 2E1 activity was lost upon preincubation for 30 minutes in the presence of 100 μM capsaicin and NADPH. The rate of inactivation of P450 2E1 was 0.025 min^{-1}. The apparent K_i value was 23.8 μM. We have previously shown that glutathione (2mM) increased the metabolism of capsaicin by human liver microsomes. One hypothesis for this observation was that the metabolism of capsaicin by P450 2E1 produced a reactive intermediate, possibly through the oxygenation or dehydrogenation of the phenolic ring of capsaicin. Protection of CYP2E1 was also observed with the addition of reduced glutathione (1mM). These data suggested that capsaicin was an uncompetitive, mechanism-based inhibitor of P450 2E1, and that the electrophilic reactive intermediate that inactivated 2E1 was released from the active site of the enzyme. These studies indicate that exposure to capsaicin may elicit drug interactions by irreversible inhibition of a vital enzyme, CYP2E1. This work supported by a grant from the National Institute of Standards and Technology (Department. Commerce # 60NAN-BOD0006).

104 INHIBITION OF CYTOCHROME P450 METABOLISM BY METALLOPORPHYRINS.

B. J. Day[1]. [1]*Medicine, National Jewish Med. & Res Ctr, Denver, CO and* [2]*Toxicological Sciences, University of Colorado Health Sciences Ctr, Denver, CO.*

Manganese containing metalloporphyrins have been shown to possess a wide variety of antioxidant properties, including the scavenging of superoxide, hydrogen peroxide, lipid peroxides and peroxynitrite. These compounds are currently being developed as therapeutic agents in the treatment of stroke, organ transplant, and cancer. The goal of these studies was to determine whether these compounds interfer with cytochrome P450 metabolism, both *in vivo* and *in vitro*. Groups of 4 rats were treated with AEOL-10113 (0.5 mg/kg, SQ) and 24 hours later benzyloxyresorufin O-dealkylase (BROD)activity was assess from their liver microsomes. AEOL-10113 markedly depressed BROD activity by greater than 50%. Untreated rat liver microsomes were used to determine the *in vitro* concentration of AEOL-10113 that inhibits BROD activity by 50% (IC_{50}). AEOL-10113 exhibited an IC_{50} of 0.2 μM in the BROD assay. The maganese containing metalloporphyrin, AEOL-10113, is a potent inhibitor of cytochrome P450s. Given AEOL-10113's potent ability to scavenge reactive oxygen species, it is possible that these compounds scavenge the cytochrome P450 activated oxygen intermediate that is necessary for cytochrome P450 catalytic activity.

105 INHIBITORY EFFECTS OF GOLDENSEAL METHYLENEDIOXYPHENYL COMPOUNDS ON HUMAN CYTOCHROME P450S: CYP2C9, CYP2D6, AND CYP3A4.

P. Chatterjee and M. R. Franklin. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

A large segment of the population is consuming phytomedicinals concomitant with conventional prescription or OTC drugs. The concurrent use of herbal medicinals carries a potential risk for adverse drug-botanical pharmacokinetic interactions, particularly as a result of inhibition of cytochrome P450s. Goldenseal (Hydrastis canadensis), a popular immunostimulant botanical, contains three methylenedioxyphenyl (MDP) alkaloids, berberine, (+ & -)-hydrastine, and hydrastinine. In human liver microsomes, both berberine and hydrastinine, inhibited (CYP2D6) bufuralol-1'-hydroxylation, (IC50 s of 15 and 30 uM respectively). Berberine also inhibited (CYP3A4) testosterone-6b-hydroxylation (IC50 of 120 uM. Of the two isomers of hydrastine, neither inhibited CYP2D6, both equally inhibited (CYP2C9) diclofenac-4'-hydroxylation (IC50 of 150 uM, and only the (-) isomer inhibited CYP3A4 (IC50 of 20 uM. Therefore at least 3 CYPs could be affected by MDPs contained in goldenseal. Examination of isozyme selectivity of inhibition by model MDP compounds piperonyl butoxide, safrole, isosafrole, and methylenedioxybenzene itself, indicate that it is highly compound dependent. Piperonyl butoxide inhibited all three (IC50 s of 25, 200 and 0.2 uM for CYP2C9, CYP2D6 and CYP3A4 respectively) whereas safrole and methylenedioxybenzene only inhibited CYP3A4 (IC50 s of 0.4 and 12 uM respectively). Isosafrole was a strong inhibitor of both CYP2D6 and CYP3A4 (IC50 s of 0.2 and 3 uM respectively). [For comparative purposes, quinidine showed an IC50 value of 0.05 uM towards CYP2D6, sulfaphenazole and phenytoin showed IC50 values of 3 and 300 uM respectively towards CYP2C9, and ketoconazole, phenytoin and carbamazepine showed IC50 values of 0.07, 80 and 300 uM respectively towards CYP3A4.]

106 CHARACTERIZATION OF NONSPECIFIC EFFECTS OF PHOSPHOROTHIOATE OLIGODEOXYNUCLEOTIDES ON CYTOCHROME P450 3A2 AND CYTOCHROME P450 2C11 IN MALE SPRAGUE-DAWLEY RATS.

G. Pacheco[2], S. P. Henry[1], R. Geary[1] and A. de Peyster[2]. [1]*Toxicology & Pharmacokinetics, ISIS Pharmaceuticals, Carlsbad, CA and* [2]*School of Public Health, San Diego State University, San Diego, CA.*

Phosporothioate oligodeoxynucleotides (PS ODNs) are being studied for treatment of various diseases and are designed to bind specific regions of a target gene to block translation of proteins. PS ODNs can also have nonspecific effects in rodents that lead to immune stimulation as demonstrated by the production of inflammatory cytokines. The purpose of our research is to study the nonspecific effects of PS ODNs on hepatic metabolism in rodents. Certain inflammatory cytokines (IL-2, IL-6, IL-12 and IFN) are known to reduce the activity of specific cytochrome P450 isozymes. Cytochrome P450 3A2 and 2C11 are predominate isoforms of the liver and if altered pose concern for potential drug-drug interactions. Six to eight week old male Sprague-Dawley rats were injected subcutaneously with 5, 15, or 50 mg/kg of ISIS 2105 every other day for a total of three doses. Twenty-four to 30 hours after the last injection, livers, spleens and blood samples were collected. Microsomes were isolated from whole livers and hepatic cytochrome P450 (CYP 3A2 and CYP 2C11) activity was determined by a testosterone hydroxylation assay. Spleen weights were used as a marker for immune stimulation. Plasma attained after a 50 mg/kg dose of PS ODN were measured for cytokine (IL-6) levels by ELISA. Dose-dependent suppression of CYP 3A2 and CYP 2C11 activity was observed, with approximately a 3-fold decrease at the highest dose (50 mg/kg). The decrease in CYP P450 activity was correlated with a dose-dependent increase in spleen weight. Furthermore, IL-6 levels were significantly elevated (approximately 2.5 fold over control) 8 hours post injection. Decreased activity of CYP 3A2 and

CYP 2C11 suggests that cytokines released in response to PS ODN treatment can suppress hepatic metabolism. Additional studies are pending to further study the direct and indirect effects of PS ODN on hepatic metabolism.

107 CYTOCHROME P450 3A2 ANTISENSE MORPHOLINO OLIGOMER AVI-4472: A 14-DAY TOXICITY STUDY IN MALE RATS.

V. Arora, A. D. Krocker, M. T. Reddy and P. L. Iversen. *Research & Development, AVI BioPharma, Inc., Corvallis, OR.*

Cytochrome P450 (CYP) 3A2 is recognized as the rat ortholog of the human CYP3A4 enzyme, which plays a role in the metabolism of more than half of clinically relevant xenobiotics. Phosphorodiamidate Morpholino Oligomers (PMO) are third generation antisense agents that have immense therapeutic potential. The objectives of this study were to: (1) evaluate the toxicity and tissue distribution of CYP3A2 antisense PMO AVI-4472 following daily intraperitoneal injections to male rats for 14 days at two dose levels; and (2) to study the reversibility of observations following a 14-day recovery period. Male Sprague-Dawley rats were injected with vehicle, 3.0 or 30.0 mg/kg/day AVI-4472 intraperitoneally for 14 days. Results indicate that animals in all groups maintained good general health and there were no significant differences in body or organ weights between any groups. Hematological examination revealed an increase in monocyte count to 522±212 in the high dose group compared with 192±90 in the vehicle group ($p<0.05$). This index returned to normal following 14 days of recovery. There was a decrease in total bilirubin content to 0.35±0.08 mg/dl in the high dose group compared with 0.60±0.23 mg/dl for the vehicle group ($p<0.05$). This index did not recover following 14 days of no treatment. Organ distribution of the PMO was identified in all organs where the target enzyme is detectable, namely kidneys, liver and small intestines (descending order of recovery) at the end of the 14-day treatment period. PMO was also detectable in these organs at the end of the additional 14-day no-treatment period. We conclude that it is feasible to administer AVI-4472 systemically to male rats for long-term suppression of the CYP3A2 enzyme.

108 ALTERATIONS IN HISTONE ACETYLATION ARE ASSOCIATED WITH PHENOBARBITAL INDUCTION OF THE RAT CYP2B2 GENE.

S. A. Auerbach[1], F. Liu[2] and C. J. Omiecinski[2,1]. *[1]Pharmacology, University of Washington, Seattle, WA and [2]Environmental Health, University of Washington, Seattle, WA.*

Phenobarbital (PB) exposures result in the marked induction of a number of biotransformation enzymes in the liver of mammalian organisms, including certain cytochrome P450s (CYP). This process is mediated by the activation of the CAR/RXR nuclear receptor complex and is inhibited by the phosphatase inhibitor okadaic acid. Remodeling of chromatin structure is an important event associated with the activation of specific genes by chemical inducers. Previously, it was reported that PB-induced transcriptional activation of the rat CYP2B2 gene involved tissue-specific alteration of chromatin structure surrounding a key regulatory element, termed the PB responsive unit, or PBRU. We used a chromatin immunoprecipitation assay and a primary rat hepatocyte culture system to demonstrate that PB exposures result in enhanced histone H3 acetylation, specifically within the PBRU region of the CYP2B2 gene. The changes noted in H3 acetylation were correlated with the binding of RXR_{α} to the PBRU. Furthermore, we demonstrate that okadaic acid inhibits the changes in histone acetylation and blocks the recruitment of RXR_{α} to the PBRU. Characterizing the molecular events associated with xenobiotic induction will enhance our ability to predict the biological and toxicological impact of chemical exposures in affected cells. (Supported by NIH grant GM32281 and the Burroughs Wellcome Fund)

109 EFFECTS OF MATERNAL DIETARY VITAMIN E SUPPLEMENTATION ON DEVELOPMENTAL BIOLOGY AND PHENYTOIN EMBRYOPATHIES.

J. M. Maricic[1], C. S. Chen[1] and P. G. Wells[1,2]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Dept. of Pharmacology, University of Toronto, Toronto, ON, Canada.*

The antioxidant vitamin E (VE) given *i.p.* protects pregnant mice from embryonic DNA oxidation and teratogenicity caused by the reactive oxygen species (ROS)-initiating drug phenytoin (PHT). Also, maternal dietary supplementation with low (0.1-2.0%) but not high (10%) levels of VE reduces both endogenous and PHT-enhanced DNA oxidation. Here, we examined the effect of maternal dietary VE (dl-α-tocopherol-acetate) supplementation on normal embryonic development and PHT teratogenicity. Virgin CD-1 females were placed on either a normal or VE-supplemented (0.1%, 2.0%, or 10% [w/w]) diet for 4 weeks and mated. Dams were administered PHT (65 mg/kg *i.p.*) or its saline vehicle on gestational days (GD) 12 and 13 at 0900 hr. In vehicle controls on GD 19, spontaneous fetal resorption incidence was reduced 84% by 0.1% dietary VE ($p<0.006$), less so (61%) by 2% VE ($p<0.05$), and least by 10% VE ($p>0.05$). In PHT-treated animals, 0.1% VE reduced PHT-enhanced fetal resorptions by 68% ($p<0.02$), but this protective effect was lost at higher VE doses. PHT-enhanced fetal weight loss ($p<0.01$) was reduced to the level of vehicle controls at 2.0% and 10% VE. VE did not significantly alter PHT-initiated fetal cleft palate incidence, which was greater than in vehicle controls ($p<0.02$), and higher VE diets of 2.0% and 10% non-significantly enhanced postpartum lethality in a dose-dependent fashion. The VE effects on resorptions are congruent with those on DNA oxidation, where 0.1% VE, but not higher doses, provided optimal protection from both endogenous and PHT-enhanced DNA oxidation. The protection by VE suggests ROS involvement in at least some PHT embryopathies, possibly involving embryonic DNA oxidation, but the biphasic nature of VE protection suggests caution in the design of therapeutic strategies. The results from vehicle controls show that even endogenous levels of ROS are embryopathic, suggesting developmental benefits from maternal dietary VE supplementation (Support: CIHR)

110 DEVELOPMENTAL TOXICITY OF DI- AND TETRACHLOROETHANE AND DICHLOROPROPANE IN THE RAT WHOLE EMBRYO CULTURE SYSTEM.

J. E. Andrews, H. Nichols and E. S. Hunter. *RTD, DBB, USEPA, Research Triangle Park, NC.*

Disinfection of drinking water with chlorine results in numerous chlorinated byproducts (DBPs). Among these are the di-substituted propanes and the di-and tetra- substituted ethanes. We chose to evaluate the developmetal toxicity of 1, 3-dichloropropane (1, 3DP), 2, 2-dichloropropane (2, 2DP), 1, 1-dichloroethane (1, 1DE) and 1, 1, 2, 2-tetrachloroethane (TCE) in rat whole embryo culture (WEC) due to their presence in drinking water and a lack of developmental toxicity data available for these compounds. Gestational day (GD) 9 rat embryos were exposed to 2.5-7.6 mM 1, 3 DP, 8.7-19.4 mM 2, 2 DP, 8.9-23.8 mM 1, 1DE, or 0.5-2.9 mM TCE for 48 hours and then evaluated. All compounds were dysmorphogenic in rat WEC. 1, 3 DP was dysmorphogenic at all concentrations >3.8 mM and embryolethal at concentrations >5.1 mM. Anomalies were opened neural tube, rotational and eye defects. DEVSC, HL, SN and CRL were significantly reduced at concentrations >3.8 mM. 2, 2DP was dysmorphogenic in rat WEC at concentrations >11.6 mM and embryolethal at concentrations >14.5 mM. Anomalies were predominantly open neural tube, heart defects and rotational defects. DEVSC was significantly reduced at concentrations >11.6 mM. 1, 1DE was significantly dysmorphogenic at 17.9 mM but also significantly embryolethal (35%). The anomalies were eye defects but there was overall delayed embryonic development at the higher exposure concentrations. TCE was dysmorphogenic at concentrations >1.4 mM and embryolethal at concentrations >2.4 mM. Anomalies were primarily heart, eye and rotational defects. The relative developmental toxicity for the four compounds was TCE>1, 3DP>2, 2DP>1, 1DE. The pattern of anomalies was inconsistent between the 4 compounds suggesting that their toxicity is probably expressed through different mechanisms. The concentrations of these DBPs required to induce dysmorphology are much higher than those for the haloacetic acids, another class of DBPs that we have studied extensively. This abstract does not reflect EPA Policy.

111 A NEW ANIMAL MODEL FOR AUTISM: EFFECTS OF EARLY EXPOSURE TO SODIUM VALPROATE IN MICE.

A. K. Halladay[1], P. McRae[2], K. R. Reuhl[2] and G. C. Wagner[2]. *[1]Pharmacol. and Toxicol., Rutgers Univ., Piscataway, NJ and [2]Psych., Rutgers Univ., Piscataway, NJ.*

Early exposure to environmental agents may have a role in the etiology of pervasivedevelopmental disorders (PDD) including autism. Such exposure may cause neurobehavioral retardation or regression (wherein an acquired behavior is lost), or intrusions (wherein acquired behaviors are overshadowed by other behaviors abberant in form or frequency). Teratogenic effects of the antiepileptic drug sodium valproate (VPA) have been well documented in the form of neurological deficits and decreases in Purkinje cell number, which have been associated with autism. In the present study, PND 14 male BALB/c mice were tested for skills corresponding to cerebellar development. Following initial testing, pups were treated with 200 mg/kg sc sodium valproate (VPA), retested on these tasks 24hr, 2, 3 and 4 days later and examined for emergence of habituation of motor activity and spatial learning ability on PND 23-26. Treatment with VPA on day 14 produced a regression in mid-air righting as well as an established negative geotropic response; that is, while pups had developed these abilities before treatment, these behaviors were lost for up to 72 hours after VPA administration. In addition, treated pups showed a delay in navigation of a water maze task with no alterations in the habituation of motor activity. VPA-induced changes in developmental behaviors were not observed when

VPA (200 mg/kg sc) was administered daily on days 13-16 of gestation. Finally, in order to investigate regressions on later emerging skills such as spatial learning, PND 23 pups were trained for 4 days on the water maze and also allowed to habituate to an open field, then treated with VPA (200 mg/kg) on day 26. A regression in water maze ability was seen 48 hours later, manifested as an increase in escape latency in the water maze compared to those days prior to treatment. These data propose a new behavioral model for PDD which can be used to assess the role of known teratogens on behavioral development. (Supported by ES 07148 and by Johnson and Johnson).

112 EFFECTS OF LOW LEVEL TECHNICAL CHLORDANE ON SELECTED SEX STEROID MEDIATED PARAMETERS IN PREPUBERTAL RATS.

F. O. Johnson[1], V. E. St. Omer[1], K. M. Mizinga[2], B. C. Datiri[1], M. M. Mansour[1], R. D. Mosha[3] and E. O. Abdalla[1]. Sponsor: R. Dalvi.

Technical chlordane is a highly persistent toxic environmental pollutant and a formerly used pesticide. Humans and other mammals are being exposed to low levels of chlordane and their long-term effects during critical developmental periods are not well documented. This study evaluated the effects of technical chlordane on sex steroid mediated parameters (anogenital distance [AGD], testicular descent, preputial separation, testes, seminal vesicles, prostate, testosterone, uterus and ovaries) of prepubertal rats in a multigenerational study. Sprague-Dawley rats, F1 adult and their F2C offspring were exposed, pre- and postnatally to daily levels of chlordane (0.0, 0.125, 0.25 and 1.0 mg/kg) until termination. F2C rats on PND 1 manifested increases ($p<0.05$) in AGD, a biomarker of androgenicity. Treatment also delayed the ontogeny of balano-preputial separation and testicular descent (androgenic biomarker) in F2C males. While in females, chlordane delayed vaginal opening (an estrogen dependent parameter). Plasma testosterone concentrations on PND 30 were reduced ($p<0.05$) in treated males but not females. The physical maturational parameters (balano-preputial separation, testicular descent and vaginal opening) correlated with changes in plasma testosterone concentrations. Dose related reductions occurred in absolute and relative organ /brain weight ratio of testes, uterus and liver. In conclusion, chlordane exhibited androgenic-like activities *in utero*, and both anti-androgenic (males) and anti-estrogenic (females) responses during prepubertal development. Therefore, humans may be at risk from chlordane as an endocrine disruptor. (Supported by: MHPF/ATSDR #U50/ATU3922660008).

113 EMBRYOTOXICITY ASSOCIATED WITH SPERMATOZOA BENZO(A)PYRENE-DNA ADDUCTS TRANSFERRED TO FERTILIZED EGGS.

S. B. Hooser and P. Collodi. *Veterinary Pathobiology & Animal Science, Purdue University, West Lafayette, IN.*

Sperm benzo(a)pyrene-DNA adducts can be transferred to fertilized embryos. Using 33P-postlabeling, we have previously identified a DNA adduct [(+) anti-BPDE-deoxyguanosine] in trout sperm treated with benzo(a)pyrene diol epoxide (BPDE). When BPDE-treated sperm were used to fertilize untreated trout eggs, the same adduct was found at 24h. To assess developmental effects, trout sperm were incubated with 50 ug/ml BPDE or saline for 1h, washed and used to fertilize untreated trout eggs. For 10d, and at 15d post-fertilization, eggs were examined microscopically. Eggs hatched at 20d and fry were weighed. At 24h post-fertilization, eggs in both groups had visible cell masses indicating 100% fertilization. By 72h, gastrulation was observed in 96% of PBS embryos but was delayed in embryos from BPDE-treated sperm with gastrulation in only 77%. At 5d, approx. 95% of PBS embryos had formed a complete body axis compared to approx. 60% of BPDE embryos. Between days 6 and 10, approx 85% to 95% of PBS embryos (n=50 each day) had normal development with 98% having eye spots & beating hearts on day 10. In contrast, only approx. 50% of BPDE embryos (50 each day) appeared normal. Of the abnormals, half had no noticeable development while the others had truncated body axes with disorganized cell masses. At 15d, 95% (of 212) PBS embryos had normal development compared to 32% (of 143) from BPDE-treated sperm. Eggs from PBS-treated sperm hatched at 72% (1369 of 1912 eggs) with normal trout fry, while only 8% (85 of 1137 eggs) from BPDE-treated sperm hatched. Those that hatched appeared & weighed the same as PBS fry. Non-viable eggs from BPDE-treated sperm had varying forms of abnormal development ranging from none, to elongated masses of cells, to various degrees of truncated development. Sperm adducts did not affect fertilization rate, but were associated with embryotoxicity: delayed gastrulation; incomplete body axis formation; abnormal development; and decreased hatching. Assistance provided by the Bodine State Trout Hatchery, IN Department. of Natural Resources.

114 CONTRASTING DEVELOPMENTAL ROLES FOR ATAXIA TELANGIECTASIA-MUTATED (ATM) IN MODULATING THE EMBRYONIC RESPONSE TO ENDOGENOUS AND XENOBIOTIC-ENHANCED REACTIVE OXYGEN SPECIES (ROS) IN ATM KNOCKOUT MICE.

Y. Bhuller[1] and P. G. Wells[1,2]. [1]*Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada and* [2]*Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, Canada.*

The ATM protein is a key ROS sensor and signal transducer in the genotoxic stress response pathway, and can trigger p53-dependent DNA repair. We have shown that pregnant Atm-knockout mice are more sensitive to the embryopathic effects of ionizing radiation, and here we determined if they are similarly more susceptible to the embryopathic effects of the ROS-initiating drug phenytoin. Female wild-type (+/+) or heterozygous (+/-) Atm knockout mice were mated with +/- males, and dams were treated with phenytoin (65 mg/kg ip) or its saline vehicle on gestational days (GD)11 and 12 (plug=GD1). Resorptions and fetuses were genotyped and characterized on GD19. With untreated (vehicle controls) +/- dams, fetal body weight was lower in homozygous Atm null (-/-) fetuses compared to +/- and +/+ littermates ($p<0.05$). Independent of treatment, there were opposite Atm gene dose-dependencies in pre- and post-implantation death. Implantations were 45% lower in +/- than +/+ dams ($p<0.05$). In contrast, in +/- dams, no resorptions had a -/- genotype, compared to a substantial incidence with +/- (45%) or +/+ (55%) genotypes in +/+ and +/- dams ($p<0.05$). This strain was relatively resistant to phenytoin embryopathies. In +/+ dams, phenytoin did not cause fetal body weight loss nor enhance resorptions or postpartum lethality. However, with +/- dams, fetal body weight loss was enhanced by phenytoin in -/- Atm fetuses compared to both their +/- and +/+ phenytoin-exposed littermates ($p<0.05$), and to -/- vehicle controls ($p<0.05$). Conversely, phenytoin-initiated postpartum lethality was increased in offspring of +/+ compared to +/- dams ($p<0.05$). These results suggest that ATM plays important and contrasting developmental roles, and provide the first evidence that ATM affords protection against some, while enhancing other, embryopathic effects of ROS-initiating teratogens. (Support: Canadian Institutes of Health Research)

115 TRICHLOROETHYLENE, TRICHLOROACETIC ACID AND DICHLOROACETIC ACID: DOES *IN UTERO* EXPOSURE TO THESE CHEMICALS AFFECT EYE DEVELOPMENT?

D. A. Warren[1], L. J. Graeter[2], S. R. Channel[1], J. S. Eggers[1], C. D. Goodyear[3], K. L. MacMahon[1], G. L. Sudberry[1], J. R. Latendresse[2], L. W. Fisher[1] and W. H. Baker[1]. Maternal exposure to high doses of TCE has been implicated in eye malformations in fetal rats, primarily micro-/anophthalmia. Coincident with a cardiac teratology study of TCE and its metabolites, TCA and DCA, the potential for these compounds to induce ocular terata was examined. Pregnant, Sprague-Dawley rats were orally treated on gestation days 6-15 with bolus doses of either TCE (500 mg/kg), TCA (300 mg/kg), DCA (300 mg/kg) or the prototypical teratogen, all-*trans* retinoic acid (RA, 15 mg/kg). The heads of gestation day 21 fetuses were not only examined grossly for external malformations, but nearly 600 fetal heads were sectioned using a modified Wilson's technique and subjected to computerized morphometry that allowed for the quantification of lens area, globe area and interocular distance. Gross ocular malformations were essentially absent in all treatment groups except for the RA group in which 26% of fetuses exhibited micro-/anophthalmia. Lens area, globe area and interocular distance were significantly reduced in the TCA, DCA and RA treatment groups, but not the TCE treatment group. However, the reduced body weights of TCA-, DCA- and RA-treated fetuses appear sufficient to explain the changes in these dependent variables. Based upon these preliminary results, neither TCE nor its acid metabolites can be characterized as ocular teratogens. With respect to TCE, this differs from earlier reports generated with a different rat strain and larger doses.

116 EVALUATION OF ULTRASOUND TRANSIT-TIME FLOWMETRY TO MEASURE UTERINE BLOOD FLOW DURING PREGNANCY IN THE RAT.

C. Lerche-Langrand, A. Arnaud, O. Foulon, A. Blacker and H. Vincent-Girard. *Experimental Toxicology, Aventis CropScience, Sophia-Antipolis, France.*

Uterine blood flow (UBF) is the major determinant of oxygen and other essential nutrient transport to the fetus. Alterations of UBF during pregnancy may impair fetal development. In recent years, many techniques have been developed for organ blood flow measurement, including ultrasound flowmetry. The aim of the present

study was to evaluate this technique for quantifying UBF in pregnant rats. Maternal UBF, and heart rate were measured on sperm-positive Sprague-Dawley rats on Gestation Day (GD) 21 by using a flowmeter and 1 mm flow probes (1RB, Transonic Systems, Ithaca, NY). Mean absolute and relative UBF were 2.96 ± 1.60 ml/min and 0.029 ± 0.015 ml/min/g of gravid uterus, respectively, and heart rate was 393 ± 36 rpm. These values were within the expected ranges reported in the literature. We then investigated the effects on UBF of phenylephrine, a postsynaptic alpha-adrenergic agonist agent which induces uterine vasoconstriction. Pregnant Sprague-Dawley rats on GD21 were given subcutaneously 12.5 mg/kg phenylephrine and UBF was measured continuously for up to 25 minutes after injection. We found that UBF decreased up to 91% when compared to the control values recorded before injection, whereas HR was unchanged. Overall our results indicated that the ultrasound transit time flowmeter system appears as a promising technique to determine UBF in pregnant rats and to identify negative effects induced by vasoconstrictive agents.

117 POSTNATAL INORGANIC LEAD EXPOSURE DECREASES THE NUMBER OF SPONTANEOUSLY ACTIVE MIDBRAIN DOPAMINE NEURONS AND ALTERS THE SENSITIVITY OF NUCLEUS ACCUMBENS NEURONS TO D1 RECEPTOR STIMULATION.

D. K. Pitts, M. Tavakoli-Nezhad and A. J. Barron. *Pharmaceutical Sciences, Wayne State University, Detroit, MI.* Sponsor: G. Corcoran.

The effect of postnatal lead (Pb) exposure on the electrophysiological activity of midbrain dopamine(DA) neurons was examined during postnatal development. Single-cell electrophysiological recordings were made in the substantia nigra (SN) and ventral tegmental area (VTA) of chloral hydrate anesthetized rats. 21-day-old male Sprague-Dawely rats were exposed to Pb- or Na-acetate in the drinking water for a period of 3 to 6 weeks or 7 to 13 weeks. This exposure resulted in a significant Pb-dependent decrease in the number of spontaneously active DA neurons at the time of recording. The 250 and 500 ppm level of Pb exposure produced a significant decrease in the number of spontaneously active DA neurons in both the SN and VTA. Apomorphine challenge during some electrophysiological recordings indicated that this decrease in activity was most likely not due to depolarization-inactivation. The effect of selected Pb exposure levels, 250 and 500 ppm, were examined during the postnatal period using tyrosine hydroxylase (TH) immuno-histochemistry to determine if Pb affected the survival of dopamine neurons within SN and VTA. TH immunohistochemical studies revealed that the reduction in the number of spontaneously active DA neurons in animals treated with 250 and 500 ppm Pb was not related to the physical loss of cells (e.g., necrosis or apoptosis). Using the same exposure protocol (250 ppm Pb for 3 to 6 weeks) microiontophoretic studies of neurons in the nucleus accumbens was conducted using micropipettes loaded with the D1 receptor agonist, SKF-38393. Nucleus accumbens neurons from Pb-treated animals were found to be significantly less sensitive to SKF-38393 relative to controls. These results indicate that exposure to Pb at clinically relevant levels has significant effects on the function of dopaminergic circuitry without causing dopamine neuron loss.

118 CRITICAL PERIOD FOR INCREASED NEONATAL MORTALITY INDUCED BY PERFLUOROOCTANE SULFONATE (PFOS) IN THE RAT.

R. C. Grasty[1,2], B. E. Grey[1], J. Thibodeaux[1], C. Lau[1] and J. M. Rogers[1]. *[1]Reproductive Toxicology Division, NHEERL, ORD, EPA, Research Triangle Park, NC and [2]Department of Toxicology, UNC Chapel Hill, Chapel Hill, NC.*

PFOS belongs to a class of fluorinated organic chemicals with broad industrial use. Despite a reduction in the manufacturing of products containing PFOS and many of its metabolic precursors, levels of accumulated PFOS in the environment warrant evaluation of its potential for toxicity. The present study investigated the critical period for increased neonatal mortality caused by PFOS. Timed-pregnant Sprague-Dawley rats were treated by oral gavage with 25 mg/kg PFOS (potassium salt in 0.5% Tween-20) for four consecutive days during either GD 2-5, 6-9, 10-13, 14-17 or 17-20. Controls were given vehicle daily throughout GD 2-20. Blood samples were taken the day after the last day of dosing to determine maternal PFOS levels. Dams were allowed to continue normal pregnancy through birth. Maternal weight gain was reduced in treated animals during dosing and returned to near control levels by term. Similar patterns were seen in food and water consumption. Average litter size was normal in all groups compared to controls with no significant difference in average pup weight on the day of birth. PFOS induced decreases in neonatal survival were seen for each group while controls remained at about 100% survival. Mortality increased as the dosing period fell later during gestation with the latest group (GD 17-20) approaching 100% mortality. All deaths occurred before PD 4 with most taking place during the first 24 hours. Growth retardation was observed in surviving pups of treated dams and gross dissection suggested underdeveloped lungs. A second study compared postnatal survival between dams treated with 100 mg/kg PFOS on GD 17 or 20. Both groups had a high rate of neonatal death with no significant difference between the two. Analysis of maternal PFOS levels are in underway. These results demonstrate that the critical period for PFOS induced neonatal mortality in the rat occurs near birth. This abstract does not reflect EPA policy.

119 MATERNAL AND DEVELOPMENTAL TOXICITY OF PERFLUOROOCTANE SULFONATE (PFOS) IN THE RAT.

C. Lau[1], J. M. Rogers[1], J. R. Thibodeaux[1], R. G. Hanson[1], B. E. Grey[1], B. D. Barbee[1], J. Richards[2] and J. L. Butenoff[3]. *[1]Reprod. Toxicology Div., USEPA, Research Triangle Park, NC, [2]Exp. Toxicology Div., USEPA, Research Triangle Park, NC and [3]Med. Dept., 3M, St. Paul, MN.*

The maternal and developmental toxicity of PFOS, an environmentally persistent compound used as surfactants and insecticides, were evaluated. Timed-pregnant Sprague-Dawley rats were given 1, 2, 3, 5, or 10 mg/kg/day PFOS/K+ by gavage on GD 2 through term. Controls received 0.5% Tween-20 vehicle (1 ml/kg). Some rats were killed on GD 21 for teratological examination, others were allowed to deliver, and postnatal growth and development were monitored. PFOS levels in serum and liver were determined. Maternal weight gain was suppressed by PFOS, likely due to reduced food and water intake. Serum cholesterol, triglycerides, thyroxine (T4) and triiodothyronine (T3) in PFOS-treated dams were lower than those in controls, but TSH was not affected. PFOS did not alter the number of implantations or live fetuses at term, although small deficits in fetal weight were noted in the high dose groups. Cleft palate, anasarca, cardiac ventricular septal defect, and small/hemorrhagic lung were detected, primarily in the 10 mg/kg group. Live birth was observed in all groups; however, neonates in the 10 mg/kg group were moribund and died within 4-6 h. While newborns in the 5 mg/kg group appeared viable, >95% were found dead within 24 h; postnatal growth was retarded in the survivors. Cross-fostering of pups to control dams at birth did not improve the survival rate, nor adverse effect seen in control pups nursed by PFOS-exposed dams. Postnatal viability was greater in the lower dose groups and surviving neonates appeared to thrive, but mild hypothyroidism (only T4 reduction) and delays in eye opening were noted. These dose-dependent adverse effects will be compared to the body burdens of PFOS. Our results indicate both maternal and developmental toxicity of PFOS in the rat; while PFOS altered the thyroid status, this hormonal imbalance is not likely the sole contributor to neonatal mortality. This abstract does not reflect EPA policy.

120 PERFLUOROOCTANESULFONATE-INDUCED PERINATAL MORTALITY IN RAT PUPS IS ASSOCIATED WITH A STEEP DOSE-RESPONSE.

J. Butenhoff[1], R. York[2], A. Seacat[1] and D. Luebker[1]. *[1]3M Medical Department, Corporate Toxicology, 3M, St. Paul, MN and [2]Argus Research Division, Charles River Laboratories, Horsham, PA.*

To better define the dose-response of perinatal mortality observed in prior reproduction studies with perfluorooctanesulfonate (PFOS), female rats were administered potassium PFOS by oral intubation at dose levels of 0, 0.4, 0.8, 1.0, 1.2, 1.6, and 2.0 mg/kg/d for 42 days prior to mating to untreated males, during mating and through the end of gestation (cesarean section) or four days of lactation (natural delivery). At day 21 of gestation, fetuses from eight litters in the 0, 1.6, and 2.0 mg/kg/d dose groups were taken by cesarean section. All remaining dams were allowed to litter, and were sacrificed with litters on day 5 of lactation. For all or some of the groups, PFOS sera levels, serum lipids, glucose and thyroid hormones were measured at both time points. Milk cholesterol and liver PFOS were also measured on lactation day 5. Significant decreases in cholesterol and increases in LDL were observed in all fetuses from the 1.6 and 2.0 mg/kg/d PFOS dose groups on day 21 of gestation. On day 5 of lactation, dams had significantly decreased serum cholesterol at all dose levels, significantly decreased serum triglycerides in the 1.6 and 2.0 mg/kg/d dose groups, and significantly increased serum glucose in the 2.0 mg/kg/d dose group. Although T4 (free and total) appeared to be decreased when measured by RIA, free T4 was normal across all dose groups (dams) when measured using equilibrium dialysis. T3 was low at 1.2 mg/kg/d and above in dams but not fetuses and pups. TSH was not elevated and thyroid histology was normal. Dams in the 0.8 mg/kg/d and higher dose groups showed an increase in relative liver weight, a decrease in body weight gain, a decrease in feed consumption, and a slight decrease in the duration of gestation. Pup growth was decreased at 1.2 mg/kg/d and higher. Viability indices for pups from the 0, 0.4, 0.8, 1.0, 1.2, 1.6, and 2.0 mg/kg/d groups were 97, 98, 93, 89, and 82, 49, and 17 percent, respectively.

121 PERFLUOROOCTANESULFONATE-INDUCED PERINATAL MORTALITY IN RAT PUPS IS NOT A RESULT OF REDUCED SERUM LIPIDS.

D. Luebker[1], R. York[2], A. Seacat[1] and J. Butenhoff[1]. *[1]3M Medical Department, Corporate Toxicology, 3M, St. Paul, MN and [2]Argus Research Division, Charles River Laboratories, Horsham, PA.*

This study was designed to test the hypothesis that hypolipidemia causes perfluorooctanesulfonate (PFOS)-induced perinatal mortality in rats. Female rats were supplemented with either 500 mg/kg of mevalonic acid lactone (MAL) twice daily or 500 mg/kg cholesterol (CHOL) once daily and compared to non-supplemented controls. Dose groups consisted of Tween 80 vehicle control, CHOL/vehicle control, MAL/vehicle control, 1.6 mg/kg/d PFOS, 1.6 mg/kg/d PFOS + MAL, 1.6 mg/kg/d PFOS + CHOL, 2.0 mg/kg/d PFOS, 2.0 mg/kg/d PFOS + CHOL, and 2.0 mg/kg/d PFOS + MAL. Female rats were dosed for 42 days prior to mating to untreated males, during mating and through the end of gestation or four days of lactation. Fetuses from eight litters per dose group were taken by cesarean section on day 21 of gestation. All remaining dams were allowed to litter, and were sacrificed with litters on day 5 of lactation. For all or some of the groups, PFOS sera levels and serum lipids, glucose, and mevalonic acid were measured at both time points. For fetuses and gestation day 21 dams, all clinical chemistry parameters remained at or above control levels with the exception of triglycerides (TRIG), which were decreased in fetuses in the MAL-supplemented 2 mg/kg dose group. On lactation day 5, dams had decreased CHOL in all PFOS-treated groups and decreased TRIG in the PFOS-only and CHOL-supplemented PFOS groups. Pups in the CHOL-supplemented 2 mg/kg/d group had decreased TRIG. MAL or CHOL supplementation was unable to prevent or mitigate the perinatal mortality. Viability indices for the Tween 80 vehicle control, CHOL/vehicle control, MAL/vehicle control, 1.6 mg/kg/d PFOS, 1.6 mg/kg/d PFOS + MAL, 1.6 mg/kg/d PFOS + CHOL, 2.0 mg/kg/d PFOS, 2.0 mg/kg/d PFOS + MAL, and 2.0 mg/kg/d PFOS + CHOL were 97, 99, 98, 49, 41, 42, 17, 1, and 14 percent, respectively. Results suggest that the observed perinatal mortality is not a result of hypolipidemia in the perinatal period.

122 CADMIUM ABSORPTION AND ITS RELATIONSHIP TO DIVALENT METAL TRANSPORTER-1 IN THE PREGNANT RAT.

T. M. Leazer, Y. Liu and C. D. Klaassen. *Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

In pregnancy, the maternal gastrointestinal tract undergoes many physiological and biochemical changes to accommodate the increased demand for essential nutrient absorption and transfer to the fetus. Increased absorption of nonessential metals such as cadmium (Cd) has been reported in pregnant mice in comparison to non-pregnant mice, although the mechanism is not understood. Divalent metal transporter-1 (DMT-1) is localized on the apical membrane of the intestinal epithelial cell and has broad substrate specificity for many divalent metals including Cd. The purpose of this work was to determine whether there is increased Cd absorption in pregnant compared to non-pregnant rats, and whether this correlates with up-regulation of DMT-1 expression. Timed pregnant and non-pregnant female Sprague-Dawley rats were administered 0.4 µmol $CdCl_2$in 4 ml saline/kg (labeled with ^{109}Cd) by oral gavage on gestation day (gd)19. Tissues were collected on gd 20, weighed and assessed for ^{109}Cd content (values expressed as pmol Cd/tissue). There was greater accumulation of ^{109}Cd in duodenum than in jejunem and ileum in both pregnant and non-pregnant rats. However, the amount of Cd in all three portions of the small intestine was higher in pregnant than non-pregnant rats (duodenum 1074 *vs.* 413; jejunem 212 vs.96; ileum 244 vs.107). In addition, more Cd accumulated in the liver and kidney of pregnant than non-pregnant rats (567 *vs.* 249 and 81 *vs.* 40), respectively. The time course of duodenal DMT-1 mRNA expression was determined in pregnant rats by the branched DNA signal amplification method. DMT-1 mRNA levels were about 6-fold higher in duodenum of pregnant than non-pregnant rats. Duodenal DMT-1 mRNA levels in pregnant rats increased from gd 15 through gd 21, as compared to the non-pregnant rats. The correlation between Cd absorption and DMT-1 expression observed during pregnancy suggests the importance of DMT-1 in the absorption of Cd in pregnant rats. (Supported by NIH ES-01142 and ES-07079)

123 REGION SELECTIVE CHANGES OF N-CADHERIN EXPRESSION FOLLOWING *IN OVA* AND *IN VITRO* METHYLMERCURY EXPOSURE TO DEVELOPING CHICK BRAIN.

P. M. Dey[1] and C. P. Cifarelli[2]. *[1]Neurotoxicology and Experimental Neuropathology Laboratories, Department of Pharmaceutical Sciences, Wilkes Univ., Wilkes-Barre, PA and [2]Jefferson Medical College, Philadelphia, PA.*

Methylmercury (MeHg) exposure during embryogenesis disturbs brain development and results in decreased neurological potential. The mechanism(s) underlying these effects remain unclear. Accumulating evidence suggests that perturbation in the expression of neural adhesion molecules, several families of cell surface proteins which facilitate cellular migration and cytodifferentiation, contribute to brain dysmorphogenesis. Prominent in brain development is N-cadherin, an adhesion molecule whose developmentally-regulated expression is required for proper formation and topographic patterning of the central nervous system. To determine whether changes in N-cadherin expression occur in chick brain following developmental MeHg exposure, embryonic Day 11 chicken eggs were injected with concentrations of MeHg ranging from 0.2 to 2.0 µM and killed 48 hours later. In parallel studies, cortical and cerebellar cultures were prepared from embryonic D11 chicks, exposed to 0.2 to 2.0 µM MeHg and harvested 48 hours after treatment. Protein and RNA were extracted from cerebellar and cortical samples and analyzed for N-cadherin expression using Western blotting and RT-PCR, respectively. Semiquantitative PCR analysis revealed significant reductions in N-cadherin in both *in ova* and *in vitro* exposed chick cerebellum mRNA 48 hours post-treatment, as compared to controls. In contrast, cortical mRNA was not significantly altered in *in ova* or *in vitro*. Western blotting for N-cadherin protein in brain tissue regions was in agreement with mRNA data. The results indicate that MeHg can alter N-cadherin levels in a brain region-selective manner. Disruption of cadherin-dependent morphogenetic events may contribute to the neuroanatomical and neurological defects observed following developmental metal neurotoxicity. Supported by Wilkes University Type I and II research grants.

124 EFFECTS OF RETINOIC ACID ON CELL DEATH DURING *IN VITRO* CHONDROGENESIS.

G. E. Tillman, K. A. Agyekum, G. L. Anderson and M. A. Smith. *Environmental Health Science, University of Georgia, Athens, GA.*

Programmed cell death occurs normally in developing limbs helping to give shape and form to the digits and limb. Retinoic acid has been shown through histochemical staining and whole animal studies to affect chondrogenesis and cell death. This study examines the effects of retinoic acid on *in vitro* chondrogenesis and whether this effect is mediated by cell death of chondrocytes. Mesodermal cells from stage 25 embryonic chick limb buds were grown in micromass culture for 5 days. To determine overall effect on chondrogenesis, cultures were continuously exposed to retinoic acid concentrations ranging from 10^{-9} M to 10^{-6} M. Proteoglycan content, an indicator of chondrogenesis, was determined by fixing the cultures, staining the cells with alcian green and visualizing spectrophotometrically at 600 nm. To examine cell death, mesodermal cells from embryonic chick limb buds were grown in micromass tissue cultures and exposed to 10^{-6} M retinoic acid for 48 h beginning on day 5 and day 7 of culture. At the end of the culture period, supernatants were removed from the cultures and lactate dehydrogenase (LDH), an indicator of cell death, was measured. To determine whether cell death was a result of apoptosis, cell cultures were lysed and DNA was observed on 1.5% agarose gel for apoptotic DNA fragmentation. Retinoic acid treatment for the five-day period decreased proteoglycan content as shown by alcian green staining (49.8%, 39.3%, 28.6%, and 15.6% of vehicle control). Levels of cell death as assessed by LDH were increased in treated cultures compared to control cultures (119.3% of control at day 7 treatment). Gel electrophoresis shows that apoptotic DNA fragmentation occurs at earlier times (7 day and 9 day *versus* 14 day) when cultures are treated with retinoic acid. These results suggest that exogenous retinoic acid affects *in vitro* chondrogenesis by increasing inappropriate apoptotic cell death of chondrocytes. (Supported in part by Hatch Funds to MAS and the Interdisciplinary Toxicology Program, UGA).

125 INHIBITION OF ANGIOGENESIS BY 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) IN CULTURED EMBRYONIC HEARTS.

I. D. Ivnitski and M. K. Walker. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

It has been documented that TCDD reduces coronary angiogenesis on incubation day 10 in chick embryo hearts *in vivo*. In this study we investigated effects of TCDD on coronary vasculogenesis and angiogenesis at an earlier time point of development. Ventricles from 6-day-old control and TCDD-treated (0.3 pmol TCDD/g) embryonic chick hearts were cultured on a three-dimensional collagen gel. After 2 days of growth in normal medium and 3 days of starvation in low serum medium (0.5% fetal bovine serum), the heart explants were fixed, washed and blocked. Endothelial cells, which migrated out from the heart explants and form tubes, were identified by wheat germ agglutinin (WGA) antibody using immunohistochemistry. Three-dimensional images of tubes growing into the collagen gel were obtained by using confocal microscopy. Tube formation also was observed by electron microscopy (EM). Total length of the tubes was measured as a function of the explant's perimeter with use of Image-Pro Plus software. Confocal and EM images showed that the cells growing outward from the myocardial explants formed tubes in culture. Immunohistochemistry revealed that the cells which formed tubes in culture were endothelial in origin, based on the positive WGA staining. Vascular growth, as measured by total tube length divided by explant perimeter, was signifi-

cantly reduced in explants from TCDD-treated chick embryos as compare to explants derived from control embryos. These data suggest that TCDD may inhibit coronary angiogenesis *in vivo* by affecting vascular precursor cells present earlier in cardiac development. Future studies will use this explant culture system to elucidate the function of hypoxia in coronary angiogenesis and the relationship between hypoxia and TCDD in this event. Supported by NIH grant ES-09804.

126 MATERNAL EXPOSURE TO A MIXTURE OF POLYCHLORINATED BIPHENYLS (AROCLOR 1254) EXERTS THYROID HORMONE-LIKE EFFECTS ON NOTCH SIGNALING IN THE FETAL CORTEX.

C. T. Herzig, R. Bansal, E. I. Iannacone and R. T. Zoeller. *Department of Biology and Molecular and Cellular Biology Program, University of Massachusetts, Amherst, MA.*

Polychlorinated biphenyls (PCBs) are known to be neurotoxic in experimental animals and are associated with neurological deficits in humans. In addition, PCBs are known to reduce circulating levels of thyroid hormones in experimental animals and in humans are associated with measures of thyroid hormones. These observations have led to the hypothesis that PCBs exert at least some neurotoxic effects by reducing circulating levels of thyroid hormones during neural development. Because our Lab. has found that thyroid hormone of maternal origin can affect Notch signaling in the fetal rat brain, we tested the hypothesis that maternal exposure to PCBs can affect Notch signaling in the fetal rat brain. We used HES-1 and HES-5 mRNA expression as markers of Notch activity. Pregnant rats were given Aroclor 1254 (A1254) on a biscuit once daily from gestational day (G) 2 through G15. The doses included 0, 1, and 4 mg/kg. Fetuses were removed on G16 and prepared for measurement of HES-1 and HES-5 mRNA using *in situ* hybridization. We found that A1254 produced a dose-dependent increase in HES-1 expression in the ventricular zone of the fetal cortex, but did not significantly affect HES-5 expression. Moreover, these effects were observed in the same region of the cortex that was found to be affected by manipulating maternal thyroid status. Because HES expression is associated with differentiation of radial glia from neural precursor cells in the ventricular zone of the fetal cortex, these results suggest that PCB exposure may result in a shift toward the production of more glia and fewer neurons in the early cortex. Studies are under way to test this hypothesis and to determine whether effects persist into adulthood. Supported by ES10026 and EPA STAR Graduate Fellowship.

127 PCB-INDUCED CHANGES IN THE DNA-BINDING OF SEVERAL TRANSCRIPTION FACTORS IN THE DEVELOPING CEREBELLUM.

R. B. Mahammad[1], N. S. Braddy[2], P. S. Kodavanti[3] and N. H. Zawia[1]. *[1]Biomedical Sciences, University of Rhode Island, Kingston, RI, [2]Biology, Savannah State University, Savannah, GA and [3]Neurotoxicology Division, USEPA, Research Triangle Park, NC.*

Polychlorinated biphenyls (PCBs) are a class of persistent chemical pollutants prevalent in the environment despite the ban of their use for decades. Disturbances in brain development and cognition are among the neurotoxic manifestations of PCBs. The cellular and molecular basis for PCB-induced developmental neurotoxicity is still unclear, however, a series of *in vitro* and some *in vivo* studies have revealed that the disruption of Ca^{2+} homeostasis and Ca^{2+} mediated signal transduction play a significant role. The culminating event in a variety of signal transduction pathways is the regulation of gene expression. Therefore, we examined the DNA-binding of several transcription factors in order to identify those that are involved in signal transduction/transcription coupling in the developing brains of PCB-exposed animals. Pregnant rats (Long Evans) were exposed perinatally to 0 or 6 mg/kg/day of Aroclor 1254 (AccuStandard Inc., Lot # 124-191) from gestation day 6 through postnatal day (PND) 21. On specific PNDs viz., 7, 14, 21, and 60, the cerebellum was isolated. The DNA-binding of various transcription factors: Sp1, AP1, NF-kB and CREB was then monitored using gel mobility shift assays. While an overall transient increase in the DNA-binding of all the transcription factors was observed following birth, this period was characterized by a pronounced induction in Sp1 and NF-kB DNA-binding. The distinct changes in Sp1 and NF-kB DNA-binding suggest that they may be involved in mediating PCB-induced perturbations in gene expression that occur during perinatal brain development. (The abstract does not necessarily reflect USEPA policy).

128 DO POLYCHLORINATED BIPHENOLS INTERFERE WITH NON-GENOMIC ACTIONS OF THYROID HORMONES?

E. A. Iannacone and R. T. Zoeller. *Molecular and Cellular Biology, University of Massachusetts, Amherst, MA.*

Polychlorinated Biphenols (PCBs) are known neurotoxins. It has been suggested that PCB neurotoxicity is mediated in part by disruption of thyroid hormone action on its receptor. However, individual PCB congeners have not been shown to interact avidly with the thyroid hormone receptor. In contrast, individual PCB congeners have been shown to compete with thyroxine for binding to various blood and cellular proteins. Because specific non-genomic actions of thyroid hormone are mediated by T4, not T3, and are not mediated by the T3 receptor, we proposed that specific PCBs may affect the ability of T4 to exert these non-genomic actions. It has been reported that T4 promotes the formation of F (filamentous)-actin fibers in neonatal rat astrocyte cultures. This process is important for contact-mediated cell signaling and may mediate the effect of thyroid hormone on specific developmental events. Therefore, the goal of these studies was to test whether PCBs interfere with the T4 mediated formation of F-actin fibers in this tissue culture system. The original experimental design was to develop a simple and quantitative assay for the amount of F- and G- actin using dot blots and a standard curve derived from known amounts of purified actin. While we were successful in establishing a standard curve for the purified actin, the F-actin samples were not sufficiently soluble for use with dot blots. We are currently in the process of validating western blots to quantify actin - a requirement for testing this hypothesis. The larger significance of this work is two-fold. If we document that individual PCB congeners affect T4-mediated F-actin polymerization, it would represent a potentially important mechanism by which PCBs mediate their neurodevelopmental effects. Additionally, it would likely indicate that different congeners may exert independent effects on different elements of the thyroid system.

129 *IN UTERO* TOXICITY OF COPLANAR HEXABROMOBIPHENYL ASSOCIATED WITH PRESENCE OF THE AROMATIC HYDROCARBON RECEPTOR.

K. A. Miller[1], T. P. Dalton[1], C. V. Vorhees[2] and D. W. Nebert[1]. *[1]Environmental Health, University of Cincinnati, Cincinnati, OH and [2]Developmental Biology, Children's Medical Center, Cincinnati, OH.*

Toxicity of polybrominated biphenyls (PBBs) first became evident following the 1973 Michigan disaster in which about 1, 000 lbs of Firemaster was inadvertently added to cattle feed. Cows, chickens and pigs became sick, and thousands of farm animals were destroyed. Humans eating dairy products also manifested neurological symptoms, including a possible association with lowered I.Q. in children who were *in utero* at the time. Neonatal lethality from maternal PBB exposure has also been reported in the offspring of mink fed diets containing Firemaster. We have chosen to assess *in utero* toxicity in pregnant C57BL/6J (B6) mice (having the high-affinity aryl hydrocarbon receptor (AHR) and B6.D2-Ahrd congenic mice (having the poor-affinity AHR on a B6 background), treated at gestational day (GD)5 with 100 mg/kg coplanar 3, 4, 5, 3', 4', 5'-hexabromobiphenyl (cHBB) or non-coplanar 2, 4, 6, 2', 4', 6'-HBB (ncHBB). In controls, ncHBB-treated B6 and B6.D2-Ahrd, and cHBB-treated B6.D2-Ahrd, 100% of offspring survived birth and the weanling period. In cHBB-treated B6 mice, however, 100% of the pups died within the first 1-5 days post partum. Histologic exam of the B6 pups showed lesions in the liver with white-cell infiltrates, indicative of hepatic failure, whereas the mother's liver appeared normal. Northern blot and RT-PCR analysis confirmed CYP1A1 mRNA induction in fetal liver and brain at GD18 in cHBB-treated B6 but no other groups. The mechanism of neonatal toxicity remains unknown, but would appear to be AHR-mediated. Lower doses of cHBB and behavioral tests in surviving pups at 60 days of age are planned. ——Supported, in part, by NIH grants P30 ES06096 and R01 ES08147.

130 ANTISENSE EVIDENCE FOR NF-κB-MEDIATED SIGNAL TRANSDUCTION IN THE MECHANISM OF PHENYTOIN EMBRYOPATHIES.

J. C. Kennedy[1] and P. G. Wells[1,2]. *[1]Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada and [2]Department of Pharmacology, University of Toronto, Toronto, ON, Canada.*

The nuclear transcription factor-kappa B (NF-κB) family regulates expression of many genes, some of which have developmental roles. Excessive NF-κB activation is implicated in the pathogenesis of several diseases including cancer. NF-κB is activated by numerous stimuli, many of which increase the levels of reactive oxygen species (ROS), and activation is inhibited by some antioxidants. NF-κB may also be a downstream effector of ROS-mediated signal transduction, such as the Ras pathway. Teratogens like the anticonvulsant drug phenytoin enhance embryonic ROS formation, and embryopathies may result from oxidative damage to cellular macromolecules, and/or enhanced ROS-mediated signaling. We previously showed that phenytoin increases embryonic Ras activation, and Ras inhibition blocks phenytoin embryotoxicity. To determine the toxicological role of ROS-mediated Ras activation of NF-κB signaling, embryos were cultured with either a therapeutic concentration of phenytoin (20 μg/ml, 80 μM) or its vehicle (0.002N NaOH), with or without antisense NF-κB (p65) (2.5 - 25 μM). Gestational day 9.5 CD-1 embryos incubated with phenytoin showed decreases in anterior neuropore closure, turning, yolk sac diameter, crown rump length and somite development ($p<0.05$). Addition of antisense NF-κB to the culture medium decreased the embryotoxic effects of phenytoin on anterior neuropore closure, turning and somite development

(p<0.05), but did not protect against decreases in yolk sac diameter and crown rump length. The protective effects were not observed using sense or nonsense controls, or antisense vehicle, suggesting that NF-κB-mediated signal transduction may play a role in the mechanism of phenytoin embryopathies. (Support: Canadian Institutes of Health Research)

131 p53 MODULATION OF PHENYTOIN EMBRYOPATHIES IN p53 KNOCKOUT MICE.

A. W. Wong[1] and P. G. Wells[1,2]. [1]*Faculty of Pharmacy, Univ. of Toronto, Toronto, ON, Canada and* [2]*Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, Canada.*

The tumour suppressor protein p53 facilitates DNA repair and protects against the embryopathic effects of DNA-damaging drugs like BENZO(A)PYRENE, which enhances embryonic reactive oxygen species (ROS) formation. We previously found that p53 protected against fetal resorptions and postpartum lethality (PPL), caused by the ROS-initiating anticonvulsant drug phenytoin given on gestational days (GD) 12 and 13 (plug=GD 1). Since p53 expression declines during embryogenesis, we determined here whether its modulation of phenytoin embryopathies differed when phenytoin was given earlier in gestation. Virgin female heterozygous (+/-) p53 knockout mice were mated with p53+/- males, dams were administered phenytoin (65 mg/kg ip) or its saline vehicle on GDs 10 and 11 at 0900 hr, and resorptions and fetuses were characterized on GD 19. Compared to vehicle controls, phenytoin caused fetal body weight loss similarly in all fetal genotypes, and enhanced PPL in wild-type (+/+) and +/- fetuses (p<0.05). In phenytoin-exposed fetuses, there was a reciprocal p53 gene dose-dependent increase in fetal resorptions in +/+ (8%), +/- (18%) and -/- (23%) fetuses, although this trend was not significant. Conversely, loss of p53 alleles resulted in a gene dose-dependent decrease in PPL in +/+ (78%), +/- (48%) and -/- (30%) fetuses (+/+ *vs.* +/-, p=0.016; +/+ *vs.* -/-, p=0.008). The GD 10/11 p53-dependent resorption protection was similar to results with GD 12/13 phenytoin treatment, while the PPL enhancement by p53 was opposite. These results show that p53 differentially modulates phenytoin embryopathies in a gestationally dependent fashion, suggesting different developmental mechanisms. (Support: Canadian Institutes of Health Research)

132 MICROARRAY ANALYSIS OF DEVELOPMENTAL TOXICITY: ONTOGENETIC PROFILES OF SUSCEPTIBILITY IN THE MOUSE EMBRYONIC EYE.

K. R. Nemeth, J. H. Charlap, M. F. O'Hara, R. C. Craig and T. B. Knudsen. *Anatomy, Pathology and Cell Biology, Jefferson Medical College, Philadelphia, PA.*

The developing mouse eye is sensitive to many chemical teratogens. Microphthalmia, for example, occurs with intrauterine exposure to 2-chlorodeoxyadenosine (2CdA, D8 of gestation) or methylmercury (MeHg, D9 of gestation). Stage dependent differences in the responsiveness of the developing eye to different agents implies serial changes in genetic susceptibility during development. The purpose of this research is to profile these changes, classify them with respect to developmental patterns and biomolecular functions, and finally to analyze their behavior during critical periods following exposure to ocular teratogens. CD-1 mouse embryos, staged by somite number, were microdissected to enrich for optic pit (D8), optic vessicle (D9), and optic cup (D10). RNA isolated and labeled with fluorescein or biotin nucleotides was used for competitive fluorescent hybridization to microarray probes followed by tyramide signal amplification. Replicate analysis with dye-swapping was done for each sample. Normalized expression ratios were subjected to hierarchical clustering using a similarity metric based on standard Pearson correlation and distances computed by average linkage clustering. Genes determined to comprise the developmental core response represented approximately 3-5% of all those arrayed. At least ½ exhibited a patterned response behavior with the ocular teratogens. Potential signaling/regulatory genes that increased with eye development decreased with MeHg. Others involved in intermediate metabolism, including the lower glycolytic block, decreased with both development and MeHg. These findings may provide potential insight to the mechanism of ocular teratogenesis by MeHg and other similarly acting agents, and in doing so, elucidate measures of intervention. (Supported by grants T32 ES07282 and RO1 ES 09120 from NIH/NIEHS and STAR G9B1022 from the USEPA, but does not reflect USEPA policy)

133 ALCOHOL DEHYDROGENASE ACTIVITY FROM ZEBRAFISH LIVER AND RECOMBINANT ZEBRAFISH ADH3 PROTEIN.

A. K. Dasmahapatra[1,3], H. G. Tomasiewich[3], P. C. Lee[2,3] and M. J. Carvan III[1,3]. [1]*Great Lakes WATER Institute, University of Wisconsin-Milwaukee, Milwaukee, WI,* [2]*Pediatrics, Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI and* [3]*NIEHS Marine and Freshwater Biomedical Sciences Center, University of Wisconsin-Milwaukee, Milwaukee, WI.*

In continuation of our studies with ethanol toxicity and developmental expression of alcohol dehydrogenase (ADH) mRNA in zebrafish embryos the following studies were undertaken to identify cytosolic alcohol dehydrogenase of adult zebrafish liver that metabolize alcohols to their corresponding aldehydes. Oligonucleotide primers were used to amplify the entire coding region of ADH3 cDNA by reverse transcriptase polymerase chain reaction using total RNA prepared from adult zebrafish AB strain liver. Complete cDNA encoded a 376 amino acid polypeptide that exhibits 90% sequence identity to ADH3 from the marine fish *Sparus aurata* and 82 and 81% identity to the mouse and human sequences, respectively. Zebrafish strains show differential sensitivity to developmental alcohol exposure, and embryos also show differential expression of the ADH3 mRNA. We have expressed zebrafish ADH3, with molecular mass of 40 kDa, in *E.coli* for analysis of enzyme activity toward ethanol, hexadienal, acetaldehyde, lactic acid, and other substrates. We have also initiated the production of polyclonal antibodies against recombinant zebrafish ADH3 for immunohistochemistry and expression studies. The results will be used in conjunction with mRNA expression data and *in situ* hybridization analysis to determine the role of ADH3 in the developmental effects of ethanol exposure in zebrafish. Supported primarily by the National Institute on Alcohol Abuse and Alcoholism (NIH R03 AA12408), the University of Wisconsin-Milwaukee, UWM Marine and Freshwater Biomedical Science Center (NIH P30 ES04184) and the Medical College of Wisconsin.

134 IDENTIFICATION AND CHARACTERIZATION OF ALCOHOL DEHYRDOGENASE III (ADHIII) IN ZEBRAFISH.

M. J. Reimers and R. L. Tanguay. *Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Ethanol has been shown to be a teratogen in experimental animals and in humans. The molecular mechanism of ethanol-mediated fetal injury remains unclear. There are two proposed mechanisms of action to explain the teratogenic effects of ethanol. The first mechanism is related to ethanol's ability to directly affect development and the second requires ethanol metabolism. The focus of this work is on the indirect, or metabolism dependent, processes. We are using zebrafish as a model because they share many cellular and physiological characteristics with higher vertebrates including humans and offer many practical advantages. For example, the embryos develop externally, removing the complication of maternal/placental/fetal interactions, and are transparent so any developmental stage can be observed without interfering with normal embryogenesis. The goal of these studies is to determine if there is an association between ethanol metabolism and ethanol-mediated developmental toxicity. Here we report the isolation and characterization of a cDNA encoding a zebrafish alcohol dehydrogenase (zfADH). The 1450 bp zfADH is 78%, 72%, and 77% similar to the cod fish ADH, the human ADHIII (glutathione-dependent formaldehyde dehydrogenase), and to another zebrafish ADHIII clone (GenBank Accession AF399909) at the amino acid level, respectively. To confirm that the zfADHIII has the ability to metabolize ethanol, the protein was overexpressed in baculovirus infected SF-9 insect cells. For functional studies, the zfADHIII protein was purified to homogeneity by 5'-AMP agarose affinity chromatography. Initial kinetics indicated that this ADHIII metabolizes ethanol and a variety of other substrates. Since this protein has the ability to metabolize ethanol, *in situ* hybridization experiments were conducted to determine the temporal and spatial expression of zfADHII during zebrafish development. These studies indicate that zebrafish is a suitable model to investigate ethanol-mediated developmental toxicity. This research was supported by NIH/NIAAA grant #AA12783.

135 GESTATIONAL AND LACTATIONAL EXPOSURE TO ESTROGENIC CHEMICALS DOES NOT AFFECT MAMMARY GLAND DEVELOPMENT IN FEMALE MICE.

C. J. Fong[1], M. R. Fielden[1], S. Z. Haslam[2] and T. R. Zacharewski[1]. [1]*Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI and* [2]*Department of Physiology, Michigan State University, East Lansing, MI.*

There exist paradoxical results demonstrating opposite effects of prenatal and postnatal exposure to estrogens on mammary gland development, however, the effects of gestational and lactational exposure to estrogens has not been described. The objective of the study was to assess the effects on mammary gland morphology following gestational and lactational exposure to maternal doses of 0, 0.1, 1, and 10 µg/kg diethylstilbestrol (DES) or 0, 0.1, 0.5, 2.5 and 10 mg/kg genistein (GEN) from gestational day 12 to postnatal (PND) 21. The doses of genistein approximated human exposure levels. Body weight and anogenital distance (AGD) of female B6D2F1 offspring were measured on PND 7, 21 and 49. Mammary gland whole mounts were examined on PND 49 for epithelial growth (% of fat pad occupied by epithelium), length of mammary epithelial tree, number of terminal end buds (TEBs, undifferentiated proliferating structures) and density of alveolar buds (ABs, differentiated milk secreting lobules). Prior to analyzing female offspring, an initial study was performed to determine the time course (3, 4, 5, 7 and 10 weeks)

of mammary gland development in naïve female B6D2F1 mice. Seven weeks of age was chosen as a suitable time point to examine treatment-related changes in mammary development. There were no significant changes in body weight or AGD in female offspring of DES or GEN treated dams. Although there was a trend towards an increase in mammary gland growth and an increase in alveolar bud formation in DES-exposed offspring, the results were not significant due to large interlitter variability. We also did not detect any significant changes in mammary growth, TEBs, or ABs in GEN-exposed offspring. These results suggest that combined gestational and lactational exposure to genistein has little effect on mammary gland morphology at human exposure levels.

136 EFFECT OF *IN UTERO* AND LACTATIONAL EXPOSURE OF MICE TO RECOMBINANT HUMAN INTERLEUKIN-10.

R. C. Liu, J. Y. Rosenblum and R. E. Morrissey. *Specialized Toxicology, Schering-Plough Research Institute, Lafayette, NJ.*

Pregnant mice received daily s.c. doses of 0, 2, 4 and 8 mpk rhuIL-10 from gestation day 6 through postpartum day (PPD) 21 to investigate the effect of rhuIL-10 on fetotoxicity, offspring development, and the survival and reproductive capabilities of an F1 generation. Dam mortality (pregnant and non-pregnant) during the dosing period was 3, 9, 12 and 6% in the control, 2, 4 and 8 mpk dose groups, respectively. The deaths were not associated with abnormal clinical signs, body weights, food consumption or necropsy findings, and the majority occurred after 14 doses which, for the pregnant mice, coincided with the day of parturition. However, the timing also coincided with deaths in non-pregnant mice and male mice in other studies, which suggested that the deaths were unrelated to parturition. Although non-dose-related, the deaths were considered related to rhuIL-10; a similar pattern of mortality was seen in other studies in which the deaths coincided with the development of anti-IL-10 antibodies. Litter sizes of 11.5, 11.4, 10.1 and 9.9 liveborn pups/litter and pup mortality for PPD 0-4 of 6, 5, 18 and 17% were found in the control, 2, 4 and 8 mpk groups, respectively (mortality for PPD 5-21 was unaffected). The pup deaths (found dead / cannibalized) were not associated with abnormal clinical signs, gestation length, parturition or necropsy findings. F1 pups developed normally to sexual maturity with no effects on reproductive fertility to produce F2 pups with normal litter size, birth weight and survival. It is concluded that a combination of slightly increased resorptions (not measured but seen in a previous study), an increased number of "found deads" and possibly unobserved cannibalizations (during or immediately after parturition) contributed to the increased F1 pup mortality / litter size at birth.

137 RAPID RISE OF BLOOD LEAD IN PATIENTS WITH RETAINED LEAD BULLETS.

J. L. McQuirter[1], S. J. Rothenberg[1,2], G. A. Dinkins[1], V. S. Kondrashov[1], R. Gibbs[1], M. Manalo[1], R. Luchembe[1] and A. C. Todd[3]. *[1]Dept. Oral and Maxillofacial Surgery, Charles R. Drew University of Medicine & Science, Los Angeles, CA, [2]Center for Research in Population Health, National Institute of Public Health, Cuernavaca, Mexico and [3]Dept. of Community and Preventive Medicine, Mount Sinai School of Medicine, New York, NY.* Sponsor: M. Soliman.

Lead exposure in gunshot victims with retained lead bullets has been poorly studied, despite more than a century of published case reports and over 50,000 new cases each year in the US alone. We studied a series of nearly 300 such patients to determine the time course of blood lead concentration (PbB) for up to six months after injury and to determine the risk factors for elevated PbB. All patients in the study had retained bullets verified by x-ray. We took blood to determine PbB at the time of informed consent (mean=3.2 days after injury), again when we measured bone lead concentration (PbBone) (mean=22.4 days), at 90 and 180 days after injury. Geometric mean (range) PbB at admission, 3, 22, 90, and 180 days after admission was 2.0 (0.3-11.8), 3.4 (0.2-23.0), 5.8 (0.3-30.2), 7.3 (0.8-38.6), and 5.5 (1.7-28.4) µg/dL, respectively. Mean (range) tibia and calcaneus PbBone was 5.5 (-16.9 - 26.2) and 9.5 (-22.0 - 39.7) µg/g. Although only one patient exceeded 10 µg/dL upon admission, 10.2% and 1.8% of patients exceeded 10 and 20 µg/dL at 3 days, 28.4% and 6.8% exceeded these limits at 22 days, 38.3% and 14.8% at 90 days, and 28.9 and 7.9% at 180 days. Repeated measures analyses up to 22 days after injury revealed that PbB of patients with bone fracture increased faster and achieved higher PbB than other patients. The odds ratio of patients with bone fracture exceeding 20 µg/dL during the first 22 days was 8.9 (95% confidence interval 1.7-46.0). Over 22 days, patients with higher calcaneus PbBone and patients over 60 years had higher risk of exceeding 20 µg/dL. Continued surveillance of these patients will reveal the long term time course of PbB and the factors predicting patients who will exceed national and international norms.

138 TRABECULAR BONE LEAD CONCENTRATION INFLUENCES BLOOD PRESSURE DURING PREGNANCY IN IMMIGRANT WOMEN.

S. J. Rothenberg[1,2], V. S. Kondrashov[1], M. Manalo[1], R. Cuellar[1], J. Jiang[1], M. Garcia[1], S. Reyes[1], M. Diaz[1], B. Reynoso[1] and A. C. Todd[3]. *[1]Dept. Anesthesiology, Charles R. Drew University of Medicine & Science, Los Angeles, CA, [2]Center for Research in Population Health, National Institute of Public Health, Cuernavaca, Mexico and [3]Dept. of Community and Preventive Medicine, Mount Sinai School of Medicine, New York, NY.* Sponsor: M. Soliman.

To determine the relationship between past (bone lead; PbBone) and present (blood lead; PbB) lead exposure on blood pressure (BP) during pregnancy we analyzed prenatal (3rd trimester) and postnatal (mean≅68 days after birth) PbB and BP from over 600 immigrant women, 99% from Latin America. Geometric mean (range) prenatal and postnatal PbB was 2.0 µg/dL (0.4-38.9) and 2.4 µg/dL (0.4-51.4). Postnatal mean (range) tibia (cortical bone) and calcaneus (trabecular) PbBone (measured by *in vivo* K-shell x-ray fluorescence) were 8.6 µg/g (-33.6 - 62.2) and ll.3 µg/g (-30.1 - 66.4). Mean (range) prenatal and postnatal systolic and diastolic BP was 108.4 mmHg (84-138) and 59.4 mmHg (36-80), and 109.3 (82-136) and 69.7 (33-84). We used structural equation modeling to simultaneously account for the effects of age, body mass index, PbB, and PbBone on BP during and after pregnancy. The model indicated that of all lead measures only calcaneus PbBone was associated with BP during pregnancy, and no bone lead measure accounted for maternal BP postpartum. After controlling for the other factors influencing prenatal blood pressure, every increase of 10 µg/g in calcaneus PbBone is associated with a 0.5 mmHg increase in diastolic blood pressure. The PbBone-BP relationship in normotensive pregnant women is similar to that found between trabecular PbBone and risk for hypertension in aging women in published work from another laboratory. While the effect is small, it indicates that populations with a wide range of past lead exposure may be at increased risk for elevated blood pressure or hypertension, regardless of present exposure.

139 ASSOCIATION OF δ-AMINOLEVULINIC ACID DEHYDRATASE GENOTYPE WITH BLOOD LEAD AND ZINC PROTOPORPHYRIN LEVELS IN A MEXICAN POPULATION ENVIRONMENTALLY EXPOSED TO LEAD.

A. E. Rojas-García[1], G. García-Vargas[2], M. Rubio-Andrade[2], A. Gómez-Muñoz[1], L. López-Carrillo[3], N. Villegas-Sepúlveda[4] and B. Quintanilla-Vega[1]. *[1]Toxicología, CINVESTAV-IPN, Mexico DF, Mexico, [2]Fac. Medicina, UJED, Gómez Palacio, Dgo., Mexico, [3]INSP, Cuernavaca, Mor., Mexico and [4]Biomedicina Molecular, CINVESTAV-IPN, Mexico DF, Mexico.*

It is known that there are interindividual variations in the susceptibility to lead (Pb) toxicity. Evidence suggests that the polymorphism at certain genetic loci is known to be related to differentially inherited responses to Pb. Two polymorphic genes have been studied, the vitamin D receptor gene and the δ-aminolevulinic acid dehydratase (ALAD) gene. The polymorphism of ALAD gene ($ALAD^1$ and $ALAD^2$) has been associated with differential accumulation and distribution of Pb in blood, bone, and internal organs. Subjects who have at least one copy of the $ALAD^2$ allele have higher blood Pb (PbB) and lower zinc protoporphyrin (ZPP) levels; however, most of these studies have been done in subjects with high PbB. We investigated the potential impact of ALAD genotype on Pb toxicokinetic (PbB and ZPP) in a Mexican adult population from Northern Mexico environmentally exposed to Pb. We conducted a cross-sectional study in 191 adults (both sexes) randomly selected. The ALAD genotyping was based on the PCR method, PbB were determined by voltametry and ZPP by hematoflurometry. The $ALAD^2$ allele frequency in this Mexican population was 5.2% (0.5% $ALAD^2$ homozygote), relatively lower than the frequency reported in an infant hispanic population (Astrin et al. 1987. Ann NY Acad Sciences; 514:23-29), although this study had a selection bias. The average PbB was 9.3µg/dl, with a range from 1.2 to 37µg/dl. We found no significant differences among participants according to ALAD genotype with respect to PbB (p=0.244) or ZPP (p=0.123), even after controling by potential confounders. These preliminary results suggest that ALAD genotype may have no influence on Pb kinetics and toxicity in adults at low Pb-exposure levels. This study was supported by CONACyT-México (Grant 31024-M).

140 SPERM CHROMATIN STRUCTURE IN MEN ENVIRONMENTALLY EXPOSED TO LEAD.

B. Quintanilla-Vega[1], M. J. Solís-Heredia[1], I. Hernández-Ochoa[1], B. E. Reyes[2], E. Vera[1] and M. E. Cebrián[1]. *[1]Toxicología, CINVESTAV-IPN, Mexico DF, Mexico and [2]Biología Cellular, CINVESTAV-IPN, Mexico DF, Mexico.*

The evaluation of sperm chromatin is relevant since chromatin abnormalities may be associated with reproductive failures and offspring development. Despite the condensed structure of human sperm chromatin, it can be damaged by exposure to

toxic agents. Lead (Pb) exposure is still a public health concern in developing countries, which detrimental effects on male reproduction are not well studied. Few studies have reported Pb effects on sperm chromatin; humans occupationally Pb-exposed have shown a decreased sperm chromatin condensation, but little is known about Pb effects at low exposure levels. Therefore, we evaluated sperm chromatin in 66 semen samples from men environmentally exposed to Pb (blood Pb levels of 10.3µg/dl) by the SDS-decondensation technique (SDS-ndc) and the sperm chromatin structure assay (SCSA) by flow cytometry. Results were correlated with Pb and zinc (Zn) levels in semen compartments determined by atomic absorption spectroscopy. SDS-ncd showed that chromatin condensation significantly increased as Zn in spermatozoa (ZnSpz), in seminal liquid (ZnLS), and Pb in seminal liquid (PbLS) increased. From the SCSA parameters, only green fluorescence (GRN, accessibility to dyes) negatively correlated with SDS-dnc. Alpha-t positively correlated with ZnSpz and ZnLS, whereas Pb did not. Comp-αt (DNA denaturation) did not correlate with Zn nor Pb in any compartment. GRN negatively correlated with ZnSpz and ZnLS ($p<0.05$), but not with PbLS ($p=0.144$). In addition, positive correlations were observed between ZnSpz and ZnLS with PbLS. Taken together, these results suggest that the increase in chromatin condensation observed with Zn may be an indirect effect of Pb. Thus, these results support that the exposure to low Pb levels alters the sperm chromatin integrity, but does not damage sperm DNA. Further studies in larger populations are needed to confirm the indirect effect of Pb. This study was supported by CONACyT-Mexico (Grant 31024-M).

141 TOXIC EFFECTS OF LEAD ON OCCUPATIONALLY EXPOSED CHILDREN.

M. M. Hussain. *Zoology, Osmania University, Hyderabad, India, Hyderabad, India.* Sponsor: M. Saber Hussain, ID 4293924.

53 Children in the age group of 9 - 15, from different occupational environments and working as petrol sniffers, printing press workers, motor mechanics and working in petty shops whose shops are stationed at traffic Junctions, were chosen in this study. Blood samples of the test subjects were assayed for blood lead, total red blood cell(RBC) count, Total white blood cell(WBC) count, differential count, haemoglobin, delta amino levulinic acid dehydratase and haemsynthatase. 16 children showed blood lead more than 70 microgram/100 ml. RBC and haemoglobin significantly decreased. Basophilic stipling was prominently seen and subjects were found anemic with microcytic and hypochromic red cells. Blood lead served highly suitable and dependable indicator reflecting ill health of these children. Depleted levels of delta amino levulinic acid dehydratase and haemsynthatase were found. Genotoxity of lead was found in 15 per cent cases as shown by SCG test. 7 children showed bluish teeth, dermatitis and graying of hairs. An attempt will be made to present and discuss certain markers more specific, more reliable and suitable for assessing toxicity in occupationally lead exposed children.

142 DETERMINATION OF THE ENDOGENOUS LEAD CONTRIBUTION TO BLOOD IN CHILDREN USING A LEAD ISOTOPES APPROACH.

R. H. Gwiazda[1], C. Campbell[2] and D. Smith[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA and* [2]*Primary Care Center, The Children's Hospital of Philadelphia, Philadelphia, PA.* Sponsor: D. Smith.

The accumulation of lead (Pb) in skeletal tissues of children during Pb exposure acts as an internal Pb repository that controls the rate of decrease of blood Pb level after Pb exposure is reduced. Challenges associated with assessing the magnitude of this endogenous Pb input to blood confounds the ability to determine the efficacy of household Pb abatement practices. Here, we are implementing a novel isotopic approach to measure the endogenous release of Pb into blood in children. The Pb isotopic compositions (Pb IC) of blood, and feces (four consecutive daily collections) from children with blood Pb levels between 20 and 35 µg/dL were measured. The Pb content and Pb IC of feces were assumed to represent those of the child's Pb intake. In cases where the Pb IC of blood and the average feces were different, a household abatement was done to reduce the Pb contribution of environmental sources to blood, and to induce a shift in the Pb IC of blood towards the average isotopic composition of the endogenous Pb source(s). Two and six months after intervention, the same sampling protocol is to be repeated to obtain Pb contents and isotopic measurements of the new Pb intake and blood. Through a series of mass balance equations we will then derive the endogenous Pb contribution to blood. Preliminary results of the first round of blood and feces collection from several cases indicates that while in some cases the variability in the Pb IC of feces from consecutive collection days may be quite large, the Pb-content-weighted average isotopic composition of all collected fecal samples was significantly different than the Pb IC of blood. This indicates that in the cases examined the Pb IC of intake and endogenous sources are different, thus meeting a necessary condition required to quantify the endogenous contribution of Pb to blood post-intervention.

143 PYRROLOQUINOLINE QUINONE AS A NOVEL THERAPEUTIC CHELATING AGENT TO REDUCE TISSUE LEAD LEVELS AND TOXICITY.

J. Sheridan[1], D. Rejmanek[1], J. Loftus[1], J. Mah[2], J. Rosen[3] and D. Smith[1]. [1]*Environmental Toxicology, University of California Santa Cruz, Santa Cruz, CA,* [2]*University of Southern California, Los Angeles, CA and* [3]*Montefiore Medical Center, Bronx, NY.*

Childhood Pb poisoning continues to be a significant public health problem in the US with estimates of nearly 1, 000, 000 affected children. Recent clinical and laboratory studies have suggested that chelation treatment of subjects with blood Pb levels <40µg/dL is not efficacious for alleviating some measures of neurocognitive toxicity. Here we report data on the efficacy of a potentially novel chelating compound, the trianionic N-heteroaromatic molecule pyrroloquinoline quinone (PQQ), for reducing soft tissue Pb levels in a rodent model of human Pb poisoning. A preliminary study was conducted in which PQQ was administered *via* i.p. injection (10mg/kg/day x 5 days). The effects on tissue lead levels were evaluated in comparison to vehicle and succimer (DMSA, 25mg/kg/day x 5 days) treatments. When administered i.p., PQQ treatment significantly reduced blood ($p=0.008$) and kidney ($p<0.000$) Pb levels relative to vehicle treated animals, to an extent comparable to succimer. Brain Pb levels were reduced with both PQQ and DMSA treatment, but only the DMSA treatment reached statistical significance. A larger PQQ study is currently underway with dosing *via* oral gavage (10mg/kg/day x 14 days) to evaluate efficacy through that delivery route. These preliminary data demonstrate that PQQ shows promise as an efficacious chelating agent for the reduction of body Pb levels. These results also warrant further research into the use of PQQ as a treatment for childhood Pb poisoning, and its possible use also as a preventative agent against Pb poisoning.

144 THE RELATIONSHIP BETWEEN LEAD IN PLASMA AND WHOLE BLOOD IN WOMEN.

D. R. Smith[1], M. Hernanez-Avila[2], M. Téllez-Rojo[2], A. Mercado[2], H. Hu[3], S. Gomes[1] and R. Gwiazda[1]. [1]*University of California, Santa Cruz, CA,* [2]*INSP, Cuernavaca, Mexico and* [3]*Harvard, Boston, MA.*

Studies have suggested that plasma lead (Pb) levels may better reflect the toxicologically labile fraction of circulatory Pb that is more freely available for exchange with target tissues than do whole blood Pb levels. Here, we conducted a longitudinal assessment of the relationship between Pb in whole blood and plasma in environmentally exposed reproductive age women (n=63) living in Mexico City, Mexico. Samples were collected using trace metal clean techniques and analyzed for Pb using HR-ICP-MS. A subset of subjects provided repeated blood samples weekly for 4 weeks (n=17 subjects), or every 1 to 2 months over 9 months (n=14 subjects). Plasma Pb concentration was significantly positively associated with whole blood Pb in a curvilinear fashion over the range of blood Pb values observed here (2.13 - 39.7 mg/dL). This relationship was best described by the function: Plasma Pb = e(-2.392 + 0.0898 * blood Pb), where SEcoefficient = 0.0054, SEconstant = 0.063 (n=63 subjects, n=141 observations). Results from the short and long-term repeated collection subjects indicated that the within and between subjects variance components were not significantly different between the two subsets of subjects. The between subjects component accounts for 78% of the variance in plasma Pb levels, while the residual variance (22%) maybe attributed to other unmeasured factors. Analysis of the %plasma Pb Vs blood Pb relationship at blood Pb levels <10ug/dL suggests that relationship is neither constant or linear. This study demonstrates that plasma Pb measurements may be applied to general clinical settings, provided that established trace metal clean techniques are adopted. They also show that the relative (%) partitioning of whole blood Pb in plasma naturally varies by a factor of ~2 to 4-fold between subjects at a given blood Pb level. Overall, these data indicate that plasma Pb may provide a more meaningful measure of toxicologically available Pb that may complement whole blood Pb level measurements.

145 AN ICP-MS METHOD FOR THE DETECTION OF DEPLETED URANIUM IN BIOLOGICAL FLUIDS.

R. Gwiazda[1], K. Squibb[2], M. McDiarmid[3] and D. Smith[1]. [1]*Environmental Toxicology, University of California, Santa Cruz, CA,* [2]*Dept. of Epidemiology and Preventive Medicine, University of Maryland, Baltimore, MD and* [3]*Dept. of Medicine, University of Maryland, Baltimore, MD.*

Because of concerns about the potential adverse health effects of exposure to depleted uranium (DU) during combat, the development of a uranium (U) isotope screening method for biological fluids is a pressing need. Current methods to determine U concentration and isotope composition in urine have low precision, and are very laborious and expensive due to the difficulties to measure the very low amounts of uranium found in urine (pg/mL). We have developed an inductively coupled plasma mass spectrometry method to measure U concentration and iso-

topic ratios, with no pre-concentration steps and direct introduction into the plasma. Urines are acidified and spiked with ^{209}Bi to monitor sensitivity changes during the sample runs. The main sources of measurement error are memory effects in the sample introduction system and unsteady blanks of 235U over the course of the run. To minimize these errors, samples were run manually in self-aspiration mode in an order of increasing U concentration determined semi-quantitatively before the run. The quantification limit for U concentration is 3 pg/mL. U isotope ratio precision was evaluated as the relative standard deviation (RSD) of repeated measurements over the course of a year (10 different runs) of three types of solutions: Isotopic measurements of U concentration standards in the range 11.4 pg/mL to 122 pg/mL yielded 6% to 2% RSD (n=9), respectively; isotopic determinations of the U isotopic standard NBSU010 measured at 8.9 pg/mL yielded 3.7% RSD (n= 15), and a low U content urine spiked with NBSU010 to a final U concentration of 21.4 pg/mL had an RSD of 7.9% (n = 10). Accuracy was evaluated from measurements of the U isotopic ratio of NBS U010, which yielded a value of 99.0±0.9 (SE) (n= 15), well within the certified value of 98.6. Application of this technique to Gulf War vets verified the presence of DU in urines from vets with embedded DU shrapnel.

146 CHRONIC DOSE-RESPONSE STUDY OF LEAD TOXICITY IN RATS: ASSIGNMENT OF A LOWEST OBSERVED EFFECT LEVEL IN A DRINKING WATER STUDY.

M. H. Whittaker, M. Lipsky, G. Wang, X. Chen and B. A. Fowler. *Epidemiology and Preventive Medicine, The University of Maryland, Baltimore, MD.*

Male Sprague-Dawley rats were administered concentrations of 25, 50, or 100 ppm lead (as lead acetate) in deionized drinking water for 30, 90, or 180 days. At the 180 day timepoint, kidney/body weight ratios were 70%, 75%, and 70% that of the control value, and kidney aminolevulinic acid dehydratase (ALAD) levels were 56%, 33%, and 33% that of the control value in the 25, 50 and 100 ppm dose groups. Decreased kidney/body weight ratios at 180 days were attributed to increased terminal body weights, which ranged from 130-138% that of the control group. Significant changes in other variables were observed, but only at the 30 day and 90 day timepoints. Decreases in blood ALAD and increases in urinary protein were observed after 90 days of lead exposure. At 90 days, blood ALAD levels were 59%, 54%, and 57% that of control in the 25, 50, and 100 ppm dose groups. At this same timepoint, urinary protein was 143%, 155%, and 163% that of the control. These data suggest that some adaptation/compensation took place because these changes were not observed at 180 days. Histopathological analyses of kidney sections showed usual morphologic alterations associated with lead exposure. Compared to control animals, a larger number of mitotic figures were observed in proximal tubule cells in test animals in all dose groups after only 30 days of lead exposure. Karyomegaly along with eosinophilic inclusions in enlarged atypical nuclei were observed in proximal tubule cells among 50 and 100 ppm test animals. At 90 days, karyomegaly with inclusion bodies was observed in the 100 ppm group. At 180 days, karyomegaly with inclusion bodies was observed in the 50 ppm and 100 ppm dose groups. Cells with karyomegaly were primarily from the P3 segment. Based on changes observed at all lead concentrations, a LOEL of 25 ppm was assigned. This LOEL is currently being used in a six-month metal/metalloid mixture study. [Supported by USEPA Star Grant R827161-01-0].

147 MANGANESE TOXICITY: A COMPARATIVE REPRODUCTIVE TOXICITY IN RATS AND MICE.

M. B. Iszard, T. P. Ponnapakkam, K. S. Bailey, K. A. Graves and K. Smith. *College of Pharmacy, Xavier University, New Orleans, LA.*

The present study was designed to determine if manganese exposure caused species specific responses in rodents. CD-1 Mice and Sprague-Dawley rats were investigated for alterations in reproductive parameters after administration of manganese acetate by oral gavage. Reproductive toxicity produced in mice occurred at much lower doses than in rats. The dose-range of 50 mg/kg was determined to be toxic for mice, whereas 2500 mg/kg was toxic to rats. Rats were dosed with a sublethal concentration of 76.5, 153, 306 mgMn/kg for 63 days. Mice were dosed with 7.5, 15 and 30 mg Mn/kg for 43 days. Cross-mating was achieved between the high dose of animals of each sex with controls of opposite sex, and others were mated with their respective groups. After a 5-day cohabitation period with females, the males were separated. On day 18 of gestation, necropsy was performed and a comprehensive examination was made of reproductive organ weights. Other end points observed included uterine implantation sites, resorptions, fetus number, fetus weight and the corpora lutea. Differences in pregnancy rates, fetal weights, fetal number, resorptions and in number of *corpora lutea* were observed between the control negatives, control positives and treated groups of rats and mice. The results of the present study demonstrate that mice are more sensitive to manganese as compared to rats. In both the species, control females mated with high dose males had fewer pregnancy rates, and males were affected more than the females. Our study suggests that the pattern of response was same in both species even though it occurred at different concentrations. As a result, mice and rats may both be a valid model of toxicity testing, even though differences between the rodents exist. Supported by ATSDR #U50/ATU398948-10.

148 INDUCTION OF HEPATIC METALLOTHIONEIN BY MANGANESE IS MEDIATED BY INTERLEUKIN-6.

S. Himeno[1], K. Kobayashi[2], M. Satoh[3], C. Tohyama[3], T. Hasegawa[4], Y. Seko[4] and N. Imura[1]. [1]*Kitasato University, Tokyo, Japan,* [2]*Kissei Pharmaceutical Co. Ltd., Nagano, Japan,* [3]*NIES, Tsukuba, Japan and* [4]*Yamanashi Institute of Environmental Sciences, Fujiyoshida, Japan.*

Inducers of metallothionein (MT) include metals, cytokines, hormones and other physical and chemical stressors. Induction of MT by metals such as Zn has been shown to be mediated by a specific transcription factor, MTF1. However, the mechanism of MT induction by other transition metals including Mn has been poorly elucidated. Therefore, we investigated the characteristics of Mn-induced MT and the mechanism of MT induction by Mn. Male ICR mice were injected subcutaneously with $MnCl_2$ and sacrificed 24 h after the injection. MT concentration was increased dose-dependently in the liver by $MnCl_2$ administration, but not in the kidney. However, hepatic Mn concentration hardly increased, whereas renal Mn concentration increased dose-dependently. HPLC/ICP-MS analysis on the distribution of metals in hepatic cytosol of Mn-treated mice revealed that the major metal bound to MT-I and MT-II was not Mn, but Zn. A time-course experiment showed that hepatic Mn concentration reached the peak at 1 h after the injection and then declined quickly. Following the transient accumulation of Mn in the liver, serum interleukin-6 (IL-6) concentration reached the peak at 6 h after the injection, and then serum amyloid A, the indicator of hepatic inflammation, gradually increased. However, serum IL-1β, TNF-α, GPT or BUN did not increase after the $MnCl_2$ injection. To confirm the involvement of IL-6 in MT induction by $MnCl_2$, IL-6 null and control mice were injected with $MnCl_2$. In IL-6 null mice, no increase in hepatic MT or serum amyloid A was observed. These results suggest that the induction of hepatic MT in mice by $MnCl_2$ administration is entirely dependent on the production of inflammatory cytokine, IL-6.

149 EFFECT OF MANGANESE ACETATE ON THE SPERM PROFILE AND MATING PERFORMANCE IN SD RATS.

T. P. Ponnapakkam, K. S. Bailey, D. Magee, K. A. Graves and M. B. Iszard. *College of Pharmacy, Xavier University, New Orleans, LA.*

Manganese plays a pivitol role as a ubiquitous constituent in the environment that is beneficial or essential at low intake levels while inhalation or oral exposure to high levels can cause adverse effects. In the present study, the effect of manganese exposure on the reproductive and testicular function in Sprague-Dawley rats was investigated. Oral administration of manganese acetate was given daily to male and female Sragues-Dawley rats at 0(control/control positive), 76, 156 and 306 mgMn/kg body weight for a period of 63 days prior to mating, 5 days during mating and 17 days of pregnancy until necropsy. At necropsy, the end points of target organ toxicity examined for the treated males included; organ weights, percent sperm motility, sperm concentration in testis and caudal tissue. Crossover mating trials were accomplished between high dose animals of each sex and control rats of opposite sex. Results of the crossover were compared to mating within control positive groups to determine which sex and dose group were affected. End points for females included; organ weights, fertility assessments, total implants, and resorptions. Our data results demonstrated that there was a decrease in organ weight in both sexes. There was a significant reduction in testicular and caudal sperm counts in all groups. Sperm motility was reduced in all groups, but was significant in rats dosed at 306 mgMn/kg. Fetal observations showed lower values in pregnancy rates, uterine weights, and the number and weight of fetuses. Control positive females mated with control positive males had a pregnancy rate of 78.5% and the average resorptions of 0.33/litter. The pregnancy rate was 60% and an average resorptions were 1.33/litter in control females mated with treated males. Treated females mated with control males had a pregnancy rate of 75% and resorption of 1.08/litter. This study demonstrates manganese to affect the reproductive and fertility profile of both male and female rats, but comparatively, male rats are affected more than females. Supported by ATSDR U50/ATU398948-10

150 HEXAVALENT CHROMIUM TOXICITY IN HUMAN LUNG CELLS, CHINESE HAMSTER OVARY CELLS AND A549 CELLS: CURRENT CELL CULTURE MODELS ARE INADEQUATE.

A. Bidulescu, S. S. Wise, A. J. May, E. R. Tang, B. H. Bryant, K. R. Schumm and J. P. Wise, Sr.. *Epidemiology and Public Health, Yale University, New Haven, CT.*

Hexavalent Chromium (Cr (VI)) is a well-established human carcinogen and exposure to it is widespread. Cr (VI) induces genotoxicity and cell cycle arrest, but the specific mechanisms involved are uncertain. Most Cr (VI) studies have focused on

Chinese hamster ovary cells (CHO) or human tumor lines such as A549 cells. But these are known to have altered cell cycle machinery and may not be suitable models for such mechanistic investigations. We evaluated the cytotoxicity of Cr(VI) in these lines and in primary human bronchial fibroblasts (PHBF). We found that Na_2CrO_4 (NC) was cytotoxic to PHBF, inducing 79, 59, 18, and 0 percent survival at 1, 2.5, 5, and 10 uM, respectively. By contrast NC was less toxic to A549 cells inducing 69, 68, and 22.3 percent survival at 2.5, 5, and 10 uM, respectively. CHO cells were much more similar to PHBF with NC inducing 79, 69, 35, and 0 percent survival at 1, 2.5, 5, and 10 uM, respectively. We also found NC induced cell cycle arrest (expressed as mitotic index) in PHBF. Specifically, in PHBF, the mitotic index was 44, 46, 26 and 2% at 1, 2.5, 5 and 10 uM, respectively. There was much less arrest in A549 cells, as the mitotic index did not change significantly with dose (58, 59, 52 and 43% at 0.5, 2.5, 5 and 10, respectively). CHO cells were less sensitive than PHBF to NC-induced arrest at low doses (78% and 66% at 0.5 mM and 1 mM, respectively), but were similar at the two highest doses (19% and 4% at 5 and 10 uM, respectively). In conclusion, CHO cells and A549 cells appear to be inadequate models for investigating the mechanisms of cytotoxicity and cell cycle effects of Cr (VI) in human bronchial cells. New cell culture models are clearly needed to allow for mechanistic investigations of the cell cycle effects of Cr (VI) and other metals. Future efforts in our laboratory are aimed at assessing the utility of CHO and A549 in evaluating Cr (VI) genotoxicity and developing new human bronchial cell culture models.

151 A NEW HUMAN BRONCHIAL CELL CULTURE MODEL FOR INVESTIGATING METAL-INDUCED LUNG CARCINOGENESIS.

S. S. Wise[1], L. W. Elmore[2], P. G. Antonucci[1], S. E. Holt[2], B. H. Bryant[1] and J. P. Wise, Sr.[1]. [1]*Epidemiology and Public Health, Yale University, New Haven, CT and* [2]*Pathology, Medical College of Virginia, Richmond, VA.*

Metals are an important public health concern. Several metals are lung carcinogens and pose a significant risk for both occupational and environmental exposure. Five metals are listed in the "Top 20 Hazardous Substances" by the Environmental Protection Agency (EPA) and the Agency for Toxic Substances and Disease Registry (ATSDR), and five metals are listed as "carcinogenic to humans" by the International Agency of Cancer Research (IACR). However, the mechanisms underlying metal-induced lung cancer are poorly understood. This is largely due to the lack of adequate human bronchial cell culture models. Accordingly, we developed a new model system of human bronchial cells by introducing hTERT, the catalytic subunit of telomerase, into primary human bronchial fibroblasts (PHBF). We have isolated stable, monoclonal cell lines that demonstrate reconstitution of telomerase activity (shown by expression of ectopic hTERT using a telomeric repeat amplification protocol (TRAP)). These cell lines have been characterized as having: an extended *in vitro* life-span, a normal karyotype, anchorage dependent growth, contact-inhibited growth, and a need for exogenously supplied growth factors. Moreover, we find that both particulate and soluble hexavalent chromium induce similar amounts of cytotoxicity, clastogenicity and cell cycle delay in these lines and the parent PHBF cells. We are currently using this model to study the toxicology of hexavalent chromium, cadmium, and arsenic. Since telomerase does not compromise the function of p53 or pRB, we feel this is an excellent system for studying the cell cycle and DNA damage response of these as well as other carcinogens implicated in the development of lung cancer.

152 CYTOTOXICITY AND GENOTOXICITY OF CR(VI) IN HUMAN BRONCHIAL CELLS.

P. G. Antonucci[1], S. S. Wise[1], A. Pincavage[1], N. P. Singh[2] and J. P. Wise, Sr.[1]. [1]*Epidemiology and Public Health, Yale University, New Haven, CT and* [2]*Bioengineering, University of Washington, Seattle, WA.*

Hexavalent chromium (Cr(VI)) is a particular class of compound that is now common in the environment as a consequence of industrial pollution. Cr(VI) is widely accepted as a human bronchial carcinogen, but its carcinogenic mechanisms are poorly understood. One reason for this is the lack of information of the effects of Cr(VI) in human bronchial cells. There is only very sparse data concerning Cr(VI) and human bronchial cells. Accordingly, we investigated the cytotoxicity and genotoxicity of Cr(VI) in cultured primary human bronchial fibroblasts (PHBF). Cytotoxicity was assessed using a colony-forming assay. Using sodium chromate (SC) as a model Cr(VI) compound we found that SC induced dose dependent cytotoxicity in PHBF with 1, 2.5, 5, and 10 uM inducing 79, 59, 18 and 0 percent relative survival respectively. We also found that SC induced genotoxicity in PHBF in a dose dependent manner using the comet assay. Specifically, 0.5, 1.0, 2.5, 5.0, 10.0, and 25 uM induced a 1.4, 1.5, 2.0, 2.1, 2.3, and 2.8 fold increase in the extent of the comet relative to control. Thus we can conclude that Cr(VI) is cytotoxic and genotoxic to PHBF in a dose dependent manner. Future investigations are aimed at investigating the genotoxicity of particulate Cr(VI) compounds and understanding the time-course of damage formation and repair.

153 CHROMIUM(III) AND CHROMIUM(VI) STIMULATE cAMP-MEDIATED CELL SIGNALING IN CELL CULTURE AND *IN VIVO*.

K. K. Wolf, A. M. Davis, R. C. Kaltreider, J. C. Davey, J. P. Lariviere and J. W. Hamilton. *Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.*

Cr(III) is an essential trace element at normal dietary levels whereas Cr(VI) can be a respiratory carcinogen following chronic, high dose, occupational inhalation exposure. We had previously observed selective Cr(VI) effects on expression of the glucocorticoid receptor (GR) and cAMP-regulated PEPCK gene as well as artificial gene constructs containing GR regulatory elements (GREs) in rat hepatoma H4IIE cells. Some of these effects could be mimicked by treatment of cells with Cr(III), which does not enter cells, or by cAMP itself. Both Cr(III) and Cr(VI) also stimulated strictly cAMP response element (CRE)-driven gene expression. We have investigated the basis for these effects further both in H4IIE cells in culture and in 14 day chick embryo liver *in vivo*. In cell culture, Cr(III) was not taken up by cells, and the effects of Cr(VI) on cAMP could be completely accounted for by extracellular reduction of Cr(VI) to Cr(III). However, Cr(VI) also had effects on expression of PEPCK and other inducible genes that are independent of cAMP pathways, presumably as a result of uptake followed by intracellular reduction of Cr(VI) to Cr(III) and/or reactive intermediates. The Cr(III) stimulation of cAMP was blocked by Rp-cAMPs, a specific inhibitor of adenylyl cyclase (AC), and could be mimicked by forskolin which stimulates AC. In the chick embryo, low doses (1-50 µmol/kg) of chromium chloride or chromium picolinate stimulated cAMP in liver within 30 min, similar to effects of forskolin. Cr(VI) treatment also stimulated cAMP in liver, although at higher doses, consistent with the predicted extracellular reduction to Cr(III). Previously, Cr(III) was thought to act as an essential trace element principally by enhancing insulin receptor signaling. These results suggest that Cr(III) stimulation of cAMP signaling may also be an important physiological effect of Cr(III) — and Cr(VI) reduced extracellularly to Cr(III) — leading to alterations in cell signaling and gene expression. (NIEHS (SBRP) ES07373)

154 EFFECTS OF CHROMIUM PICOLINATE ON ANTIOXIDANT ENZYME LEVELS IN RATS.

M. Mahboob, L. McNeil, T. Tolliver and L. Ogden. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

The purpose of this study was to determine the effects of chromium picolinate on body weight, feed efficiency, lipid peroxidation (LPO) and antioxidant enzymes levels, i.e. superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx), glutathione (GSH) and glutathione reductase (GR) in the liver and kidneys of the rat. Male rats weighing 250-300 g were divided into 4 groups of three animals each and exposed orally to chromium picolinate in the doses, 0.00 (control), 2.66 (low), 5.32 (mid) and 10.64 (high) µg/kg/day respectively for 21 days. Both body weight and feed efficiency were reduced, kidney-body weight ratio increased, but, the liver-body weight ratio was unaffected in the treated groups. The liver SOD, GPx, GSH were decreased in all the treated groups and the CAT level also decreased, but only in the high dose group. The kidney SOD and CAT levels decreased in all the treated groups, similarly, GSH and GR levels were reduced in the mid and high dose treated groups. Results revealed that there was a trend towards increase in the LPO level in both the tissues in all the treated rats. This data indicated that the low level of chromium picolinate reduces the body weight and also affects antioxidant enzyme systems of the liver and kidneys in the rat.

155 MECHANISMS FOR SELECTIVE ACTIVATION OF JNK BY LOW LEVELS OF CHROMIUM(VI).

K. A. O'Hara, L. R. Klei and A. Barchowsky. *Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.*

Inhaled hexavalent chromium Cr(VI) can promote fibroproliferative disease, airway hypersensitivity, and possibly lung cancer through poorly defined mechanisms. Therefore, cultured epithelial cells were used to examine the hypothesis that nontoxic Cr(VI) exposures activate gene transcription through specific oxidant-sensitive signaling pathways. These studies demonstrated that 1-10 µM Cr(VI) increased reactive oxygen species and selectively activated JNK, relative to ERK or p38 MAP kinase. Stimulation of JNK by these levels of Cr(VI) was comparable to the effects of 1.0 mM H_2O_2. However, in contrast to H_2O_2, 10 µM Cr(VI) was only marginally toxic. JNK activation was blocked by pre-incubating the cells with either N-acetylcysteine or PP2, a selective inhibitor of the Src family of tyrosine kinases (SFKs). Treatment with rotenone to block mitochondrial respiration or with exogenous catalase only partially attenuated Cr(VI)-induced JNK activity. Neither Cr(VI) nor H_2O_2 activated JNK in SFK deficient cells. H_2O_2, but not Cr(VI) activated JNK in cells containing only Src. Transient transfection with wild type or mutant p130cas indicated that both Cr(VI) and H_2O_2 require this adapter protein

and Src substrate to activate JNK. These data suggest that Cr(VI) signals through cellular oxidation to selectively activate SFKs and downstream JNK signaling. In contrast to previous studies, these findings in pulmonary cells demonstrate mechanisms for the exclusive sensitivity of the JNK pathway to the effects of Cr(VI). *Supported by NIEHS grant ES07373 and ES10638.*

156 ADAPTIVE ANTIOXIDANT RESPONSES IN HUMAN A549 LUNG CELLS TREATED WITH HEXAVALENT CHROMIUM.

A. J. Lee, N. Lewis, N. J. Hodges and J. K. Chipman. *School of Biosciences and Institute of Occupational Health, The University of Birmingham, Birmingham, United Kingdom.* Sponsor: T. Hammond.

Hexavalent chromium (CrVI) is genotoxic and has been classified by the International Agency for Research on Cancer as a Group 1 carcinogen. CrVI is reduced intracellularly to CrIII involving the production of various intermediate species, including CrV and CrIV and accompanying the production of reactive oxygen species (ROS). The resulting oxidative stress is believed to be responsible for many of the cellular effects caused by CrVI, and may contribute to changes in gene expression. In the current study, CrVI-mediated changes in the expression of several stress-related genes were investigated in human A549 lung cells. In association with oxidative DNA damage, sodium dichromate gave a dose-dependent increase (3.4-fold increase; 100μM) in antioxidant capacity of cells at 2h as measured by the inhibition of pholasin® oxidation and bioluminescence (ABEL assay; Knight Scientific Ltd.,). There was no decline in intracellular ATP concentrations. A persistent increase in heme oxygenase (HO-1) (within 4h) and a transient elevation of cytosolic thioredoxin (TRX) (1.8-fold increase at 2h as measured by densitometry) protein levels was also seen by western blotting. Nuclease protection assays confirmed the elevation of HO-1 mRNA but also demonstrated that the mRNA for various other antioxidant systems (glutathione reductase, Mn-superoxide dismutase and NAD(P)H quinone oxidoreductase) along with the house-keeping gene glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was not elevated. In conclusion, in association with DNA damage, treatment with sodium dichromate appears to elevate selective antioxidant defences that may contribute to protective adaptation to exposure. (Sponsored by the Colt Foundation).

157 EFFECTS OF ZINC CHLORIDE ON REPRODUCTIVE PARAMETERS OF CD-1 MICE.

L. Ogden, T. Graham, M. Mahboob, A. Atkinson, M. Hammersley and N. Sarkar. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

The effects of low doses of zinc chloride ($ZnCl_2$) on the reproductive performance have not been well described. The major objective was to determine the effects of low doses of $ZnCl_2$ on reproductive performance in a mammalian species. Life stages evaluated were puberty, cohabitation, gestation, and lactation. Both males and females were exposed to either 0.00, 0.78, 1.56, or 3.125 mg/kg $ZnCl_2$ daily by oral gavage until they were terminated. Males were sacrificed after cohabitation and females after lactation. Reproductive parameters evaluated were mean litter size, pup viability index, pup litter weight, live births, clinical signs, fertility index, post partum dam body weights, food consumption and male and female body weights. Abnormal nursing and nesting behaviors were observed in the mid and high dose groups. This was characterized by hyperactivity, absence of nest building, failure to allow pups to nurse and killing pups. There were no significant differences in the F_0 male and female body weight gain or food consumption. There was a dose dependent trend toward decreased implantation efficiency. Litter size was greatest in the control group and decreased as dose increased. There was a trend toward a decrease in the number of live births in the mid and high dose groups. Also, there was a trend toward decreased numbers of live births in the mid and high dose groups. Mortalities occurred in all treatment groups but were greatest in the low group, high group and the mid dose groups, respectively. These data suggest that zinc adversely affects some reproductive parameters when mice were exposed to oral doses as low as 0.78 mg/kg. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU3922660009).

158 THE OVEREXPRESSION OF MT-3 IN THE NORMAL HUMAN BLADDER CELL LINE, UROTSA.

S. Park[1], S. H. Garrett[1], M. A. Sens[2], S. Somji[1] and D. A. Sens[1]. *[1]Urology, West Virginia University, Morgantown, WV and [2]Pathology, West Virginia University, Morgantown, WV.*

The third isoform of metallothionein (MT-3) has a limited tissue distribution, being confined primarily to neural tissue and the kidney; however, overexpression of this protein is found in many cancers of the breast, prostate and bladder. Overexpression of MT-3 has been demonstrated in bladder tumors with the levels correlating to the type and grade of the tumor, whereas MT-3 expression in the normal human bladder was undetectable. Recently a new normal bladder cell line, urotsa, was characterized as a useful *in vitro* model system of human urothelium and found not to express MT-3. The consequence of MT-3 overexpression in urotsa cells was tested by stable transfection with MT-3 under control of the CMV promoter. Twenty clones were isolated and analyzed for the expression of MT-3. RT-PCR confirmed the expression with products being identified at 25 cycles of PCR. Similar amounts of PCR products were obtained using primers for glyceraldehyde 3-phosphate dehydrogenase indicating that the level of MT-3 expression was similar to that of a common house-keeping gene. The levels of MT-3 protein were surprisingly low, however, with levels often pushing the limit of detection (0.5 ng/μg protein). Since MT-3 has been successfully overexpressed in many cell lines of the prostate, kidney, and breast, the nearly non-existent levels of MT-3 in the urotsa clones suggested that there was the potential for selection against MT-3 expression. MT-3 was then overexpressed using the regulated vector system, LacSwitch, in which stable tansfectants can be selected under MT-3 dormant conditions and then induced with the exogenous agent isopropyl β-D-thiogalactopyranoside (IPTG). Using this vector system, levels of MT-3 protein were significantly higher (average 4.13 ng/mg protein).

159 METALLOTHIONEIN ISOFORM 3 (MT-3)INHIBITS GROWTH AND INCREASES CHEMOTHERAPEUTIC RESISTANCE OF BREAST CANCER CELLS.

V. Gurel[1], S. H. Garrett[1], S. Somji[1], M. A. Sens[2] and D. A. Sens[1]. *[1]Urology, West Virginia University, Morgantown, WV and [2]Pathology, West Virginia University, Morgantown, WV.*

MT-3 is unique among the members of the metallothionein gene family in that its expression in normal cells is limited and it has a neuronal growth inhibitory activity. The present study was designed to determine if overexpression of MT-3 and 1E influences the growth and chemotherapeutic drug resistance of breast cancer cells. The cell lines MCF-7, T-47D, Hs 578T and MCF-10A were stably transfected to overexpress the MT-3 or MT-1E genes using the pcDNA3.1/Hygro (+) vector. Overexpression of the genes was confirmed in 5 independent clones by a combination of RT-PCR and immuno-blot analysis. Growth and chemotherapeutic drug resistance were determined by cell counts and colony formation assays. Overexpression of MT-3 was demonstrated to inhibit the growth rate of the breast cancer cell lines by approximately 50% compared to vector-only controls ($\alpha<0.001$ for each comparison) but to have no effect on the growth rate of non tumorigenic MCF-10A breast cells. For all cell lines, the overexpression of MT-3 resulted in increased resistance to: Cd^{+2}, cisplatin, doxorubicin, paclitaxel and methotrexate. Overexpression of the 1E isoform conferred a resistance to the above chemotherapeutic agents, but did not cause an inhibition of cell growth.

160 STIMULATION OF CYTOKINE PRODUCTION IN MACROPHAGE BY ZINC *VIA* METALLOTHIONEIN.

N. Itoh, M. Kanekiyo, A. Kawasaki, K. Matsuda, T. Nakanishi and K. Tanaka. *Pharmaceutical Sciences, Osaka University, Suita, Japan.* Sponsor: M. Cherian.

We previously reported that human cytomegalovirus major immediate-early promoter activity is controlled by intracellular zinc levels *via* metallothionein (MT)-mediated regulation of NF-kappa B activity (Antiviral Res., 47, 207-214, 2000; Toxicol. Appl. Pharmacology, 173, 146-153, 2001). This transcriptional factor is an important protein involved in expression of several cytokine genes and regulation of various cell functions. The expression of MT is easily changed in many kinds of toxicological responses. In the present study, we evaluated the effects of MT on the expression of proinflammatory cytokines in macrophages. We used peritoneal exudate macrophages (PEMs) obtained from MT+/+ or MT-/- mice. Secretion of tumor necrosis factor (TNF) stimulated by lipopolysaccharide (LPS) from MT-/- PEMs was significantly less than wild-type control. LPS-stimulated expression of TNF-alpha was decreased in MT-/- PEMs. In electrophoretic mobility shift assays, LPS-stimulated activation of the DNA-binding activity of NF-kappa B is also decreased in MT-/- PEMs. *in vivo* response was also evaluated in cell-free ascites fluid harvested 1 h after ip injection of LPS. The response of PEMs in MT-/- mice was less than in wild-type mice *in vivo* in the same manner as *in vitro*. These findings suggest that the LPS-induced production of TNF in mouse peritoneal macrophages is upregulated by MT through the modulation of NF-kappa B activity. Expression of other inflammatory cytokines, such as interleukin (IL)-1alpha and IL-6, is also downregulated in MT-/- PEMs. The function of PEMs was changed by MT deficiency in terms of LPS-induced cytokine responses. Thus, MT plays an important role in the LPS-induced activation of PEMs. Since MT is induced by various xenobiotics, it is possible that some chemicals modulate host defense system through the induction of MT.

161 THE ROLE OF METALLOTHIONEIN IN APOPTOSIS INDUCED BY ZINC IONOPHORE.

M. Takiguchi, E. Tasaki, M. Kondoh, M. Higashimoto and M. Sato. *Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Japan.*

Various cellular functions are influenced by essential trace elements such as the divalent cation zinc. It has been shown that excessively released zinc induces neuronal cell death associated with apoptosis. The metal binding protein, metallothionein (MT), is probably involved in zinc homeostasis since it typically binds large amount of zinc. Recent work has provided new role of MT in regulation of cell cycle and apoptosis. In this study, we investigated that excessive zinc accumulation in fibroblast cells induces apoptosis and necrosis depending on zinc concentration, and MT inhibits the apoptosis induced by zinc. Intercellular zinc concentrations in MT-I and -II null (MT-/-) and wild-type (MT+/+) fibroblast cells exposed with $ZnCl_2$ for 2hours were not different from non-treatment cells. The data indicate that the physiological concentration of zinc in cells is strictly controlled. Then we used Na pyrithione, zinc ionophore, and it increased the zinc concentration at 2.5 fold compared to the control, and co-existence of $ZnCl_2$ and Na pyrithione in the cell culture medium further increased the zinc concentration (7.5 fold) in both cells. MT-/- cells were more susceptible to Na pyrithione than MT+/+ cells as assessed by MTT. But sensitivity of co-exposure with $ZnCl_2$ and Na pyrithione was not different between MT+/+ and MT-/- cells. DNA fragmentation, one of the hallmarks of apoptosis, was induced by Na pyrithione, although co-treatment of $ZnCl_2$ and Na pyrithione did not induce DNA fragmentation. The DNA fragmentation by Na pyrithione in MT-/- cells was stronger than that in MT+/+ cells. These results indicate that the concentration of zinc in cells determines mode of zinc-induced cell death. MT inhibits the apoptosis induced by zinc.

162 EFFECT OF ZINC CHLORIDE ON THE HEMATOLOGICAL AND CLINICAL CHEMISTRY PARAMETERS DURING A BREEDING TRIAL OF CD-1 MICE.

T. Graham, M. Mahboob, A. Atkinson, L. Ogden, M. Hammersley, N. Sarker, A. Casimire and F. Johnson. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

The effects of low doses of zinc chloride ($ZnCl_2$) on the reproductive performance have not been well described. The major objective of this study was to determine the effects of low doses of $ZnCl_2$ on the reproductive performance in a mammalian species. A breeding trial was conducted where males and females were divided into four groups and exposed to 0.00, 0.78, 1.56, or 3.125 mg/kg of $ZnCl_2$ by oral gavage. The major objective was to determine the effects of low doses of $ZnCl_2$ on clinical pathology parameters that may adversely influence reproductive performance. The hematological parameters included WBC, RBC, HGB, HCT, MCV, MCH and MCHC. The clinical chemistries included, Na, K, Cl, PO_4, Ca, AST, ALT, Albumen, Globulin, Total Protein, Amylase, Creatinine, CK, BUN, and Glucose. Blood samples were collected at scheduled sacrifices (post cohabitation for males and post lactation for females). The most relevant changes in hematological parameters were seen in males. High dose males had decreased MCH and MCV. Although not significant, there were trends toward increased WBC counts in all $ZnCl_2$ treatment groups. Few significant changes were seen in clinical chemistries in either sex. However, creatinine was elevated in high dose males and CK was elevated in high and mid dose males. In summary, oral exposure to $ZnCl_2$ at the levels in this experiment did not alter hematological or clinical chemistry parameters to the degree necessary to influence reproductive performance. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU3922660009).

163 THE EFFECTS OF ZINC CHLORIDE ON THE ANTIOXIDANT ENZYME ACTIVITY IN F_1 MALE MICE.

M. Hammersley, L. Ogden, M. Mahboob, A. T. Khan and T. Graham. *Biomedical Sciences, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

Trace amounts of zinc are required for functional activity of several biological molecules; however, excessive amounts may be toxic to mammals. This study was conducted to determine if low levels of zinc chloride ($ZnCl_2$) given to F_0 generation affects antioxidant enzyme activity in the brain, testis, liver and kidney of the F_1 offspring. CD-1 males (70 days) and females (99 days) were exposed to 0.000 (control), 0.78 (low), 1.560 (mid), and 3.125 (high) mg/kg/day of $ZnCl_2$ *via* oral gavage. After weaning, F_1 males were weighed and sacrificed. Brain, testes, liver and kidneys were removed and assayed for the catalase (CAT), gluthathione peroxidase (GPx) and superoxide dismutase (SOD) activities. In the brain the SOD activity increased, while the GPx and CAT activities decreased in all treatment groups. Liver SOD and GPx activities increased in all treated groups, except at the low dose, in which the GPx activity decreased. CAT activity decreased in low and high dose and increased at the mid dose. The kidney SOD activity increased in all treated groups. GPx activity in the kidney increased in low and mid dose groups but decreased in high dose groups. CAT increased in all groups but decreased in low dose group. However, these values were not significant. In the testes, there was a dose dependent increase in SOD activity. The GPx increased at the low dose whereas the CAT activity decreased in all treatment groups. In conclusion this study indicates that low doses of zinc chloride alters antioxidant enzyme activity in F_1 male mice when parents were exposed to zinc.

164 IRON AUTOXIDATION AND FREE RADICAL GENERATION: EFFECTS OF BUFFERS, LIGANDS, AND CHELATORS.

K. D. Welch, T. Z. Davis and S. D. Aust. *Chemistry and Biochemistry, Utah State University, Logan, UT.*

If not tightly controlled iron can cause various toxicities as a result of its ability to mediate the deleterious oxidation of biomolecules, e.g., DNA, lipid, protein, and small molecules, such as ascorbic acid and biogenic amines. The iron-mediated oxidation of biomolecules can be accentuated by some chelators. The liganding environment of iron, including the pH of the solution and chelation, regulate its reactivity. In this study we confirmed that, in general, the rate of Fe(II) autoxidation increases as the pH of the solution is increased. However, we demonstrated that chelators which provide oxygen ligands for the iron can override the affect of pH. Additionally, the stoichiometry of the Fe(II) autoxidation reaction varied from 2:1 to 4:1, dependant upon the chelator. No partially reduced oxygen species were detected during the autoxidation of Fe(II) by ESR using DMPO as the spin trap. However, upon the addition of ethanol to the assay, the DMPO:hydroxyethyl radical adduct was detected. The oxidant formed during the autoxidation of EDTA:Fe(II) was shown to have different reactivity than the hydroxyl radical, suggesting that some type of hypervalent iron complex was formed. In addition, ferrous iron was shown to directly reduce some quinones without the reduction of oxygen.

165 DOSIMETRY OF BERYLLIUM IN AN ANIMAL MODEL BY ACCELERATOR MASS SPECTROMETRY.

M. L. Chiarappa-Zucca[1], R. C. Finkel[1], J. E. McAninch[2], R. E. Martinelli[1] and K. W. Turteltaub[1]. [1]*Lawrence Livermore National Laboratory, Livermore, CA and* [2]*Thermawave, Fremont, CA.*

A method using accelerator mass spectrometry (AMS) was developed to measure low levels (femtomoles) of beryllium in biological samples. This method provides the sensitivity to investigate macromolecular complexes formed with beryllium at low exposure doses and will provide further understanding about the molecular targets involved in beryllium disease. Berylliosis is a debilitating, progressive and potentially fatal lung disease that develops in individuals exposed to beryllium. Proof of the method was tested by administering 0.05, 0.5 and 5.0 µg 9Be and 10Be by IP injection to 30 g male ICR mice. The mice were euthanized after 24 h and blood, femurs, feces, urine, kidneys, spleen, liver, thymus and lung were prepared for AMS analysis by acid digestion. Highest levels of Be were found in the liver and the spleen (6.0 and 2.0% of whole mouse dose, respectively) while the lowest levels were found in blood, lung and thymus. Beryllium levels were dose-dependent in the spleen and liver. The detection limit of Be in tissue by this method is approximately 2 amol and the analysis was linear over 2 orders of magnitude. Possible sample size effects for measuring Be by AMS showed that similar results were obtained when using samples that were between 3.0 and 150 mg of dosed liver tissue. Precision of 8 replicates of pooled liver tissue was 5% while the variability between 8 dosed livers was 10%. These results show that routine quantification of atto- to femtomole levels of Be in tissues is possible. This method should enable future studies to understand the molecular dosimetry and mechanisms of Be toxicity in biological studies. This work performed under the auspices of the USDOE by LLNL (W- 7405-ENG-48) with support from the USDOE/OBER.

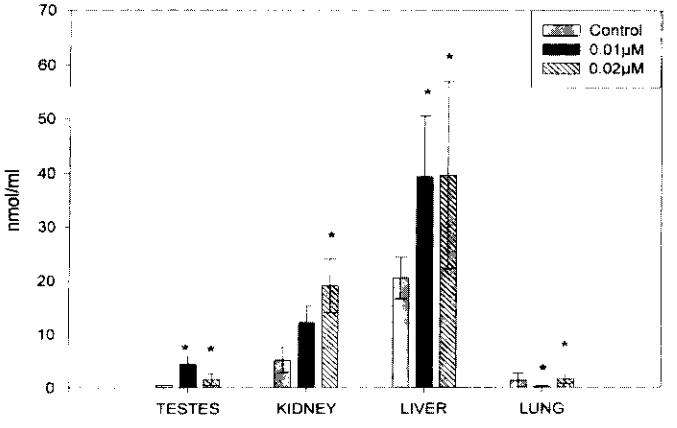
166 LIPID PEROXIDATIVE ACTIVITY OF TWO INHALED VANADIUM(V) CONCENTRATIONS (0.01M AND 0.02M) IN LUNG, TESTES, LIVER AND KIDNEY.

T. I. Fortoul, I. Sanchez, I. Lopez, I. Barenque, S. Acevedo, P. Bizarro, V. Delgado, M. I. Vega and F. Pasos. *Biologia Celular y Tisular, Facultad de Medicina UNAM, Mexico City, Mexico.*

Metals have become a problem in some countries(1). A less studied metal is vanadium -a highly oxidant metal- which could be an essential or a toxic element. One of the vanadium sources in the air is the combustion of fossil fuel products.

Mexican Maya oil has one of the highest V concentrations. Mexico City with three million circulating vehicles, has an increase in V over a thirty years period in measured in human lungs. This information made us to investigate the induction of lipid peroxidation in four organs (lung, testes, liver and kidney) in a mice model after the inhalation of V2O5. Methodology: CD-1 mice inhaled (1hr) 0.01M or 0.02M during 4 weeks twice a week. Controls inhaled only the vehicle. Mice were sacrificed after the first inhalation, and each week. Peroxides were quantified by light spectrometry using a K-assay LPO-CC. Results: Lung and testes control mice reported the lowest basal concentrations. An statistically significant increase was observed in testes at 0.01M. Kidney and liver showed an increase in lipid peroxides in a dose-dependent manner. Liver at 0.02M reported the highest lipid peroxidation concentrations. Conclusions: The inhalation of V induced lipid peroxidation in the liver and the kidney, with no differences related with the dose. Lung and testes reported almost no peroxidative activity as a consequence of V inhalation. These differences might be related with the organ content of antioxidant agents, such as glutathione, the ability to concentrate the metal, or other specific physiological characteristics of the organs which requires further anlalysis.

LIPID PEROXIDATION IN TESTES, KIDNEY,LIVER AND LUNG TISSUES AFTER VANADIUM INHALATION



* Mann Whitney U Test p<0.001vs. controls

167 GENOTOXICITY STUDIES OF TWO HISTORICAL SAMPLES OF NICKEL REFINERY DUST.

F. M. Clemens and J. R. Landolph. *Molecular Microbiology and Immunology, Keck School of Medicine, University of Southern California, Los Angeles, CA.*

The INCO nickel refinery in Clydach, Whales, U.K., was actively in operation from 1901 until the 1940's. Since 1901, there have been a total of 365 cases of cancers reported in the workers of this refinery, including 85 nasal cancers and 280 lung cancers. From 1901 to 1923, the incidence of these cancers was very high. The INCO refinery then changed the process of nickel refining after 1923 (Draper, 1994, ETP). The change in the refining process eliminated the orcelite component. The incidences of cancers were subsequently reported to be greatly reduced from 1925-1930. A refinery dust sample was taken in 1920 and another in 1929. Both samples contain primarily NiO. The main difference between the two dust samples is the presence of a nickel arsenide (Orcelite) in the 1920 sample. The arsenic content in the 1920 sample is ~10% and in the 1929 sample is only ~1%. We hypothesized that it is the nickel arsenide component of the 1920 sample that was responsible for the nasal and respiratory cancers in the refinery workers. A pure sample of the nickel arsenide (orcelite) was obtained and used for comparison. Our results show that all of the samples were taken up by the cells by phagocytosis at similar rates. both the 1920 and the 1929 samples, and the pure orcelite sample are cytotoxic to 10T½ mouse embryo cells. The LC_{50} values are (3.2 ± 0.7)µg/ml for the 1920 sample, (1.9 ± 0.2)µg/ml for the 1929 sample, and (2.5 ± 0.0)µg/ml for the pure sample of orcelite. In support of our hypothesis, we found that the 1920 sample is able to induce morphological transformation in a dose-dependent manner, with 9 foci per 20 dishes treated with the highest concentration of 7.5µg/ml. We found that the 1929 sample did not induce morphological transformation. Therefore, the data provides evidence that the 1920 sample has carcinogenic potential, consistent with induction of nasal and respiratory cancers in the refinery workers before 1923. Further investigation is in progress with the pure sample of orcelite to determine its transforming ability.

168 UTILIZING ARRAYS TO CHARACTERIZE GENERALIZED AND SPECIFIC STRESS REPONSES IN MUMMICHOGS.

N. L. Maples and L. J. Bain. *Biology, University Of Texas, El Paso, TX.*

We are using mummichogs *(Fundulus heteroclitus)* as a model organism to study the effects of generalized stress and specific contaminant stress. These estuarine minnows are a good indicator species because they have a limited home range and complete their entire life cycle in the estuary. We have been examining two estuarine sites near Charleston, South Carolina that are contaminated with a suite of toxicants. One of the sites is impacted with metals, with trivalent and hexavalent chromium being the dominant contaminants, while the other site has been contaminated with PAHs including pyrene, fluoranthene, and anthracene. To ascertain the effects of these contaminants, we exposed mummichogs to these five chemicals individually, and examined altered gene expression in their livers by differential display. We used the differentially-expressed fragments, as well as other known stress-responsive genes, to develop cDNA arrays. These additional fragments included genes involved in detoxification such as CYP1A and catalase, genes involved in the immune response including cyclooxygenase-II, iNOS, and the major vault protein, as well as other known mummichog sequences such as the CFTR gene and a sodium/potassium ATPase. Upon screening the arrays with control and trivalent chromium-exposed fish, we have found inductions in CYP2N2 and heart-fatty acid -binding protein. We hope to use this information and the cDNA arrays to develop markers of generalized toxicant stress as well as markers that are specific for a particular contaminant or class of contaminants.

169 SELECTION OF FILTER MATERIAL FOR METAL COMPOSITION ANALYSES OF AMBIENT PARTICULATE MATTER SAMPLES BY ED-XRF.

P. B. Maciejczyk and L. C. Chen. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Energy-dispersive X-ray Fluorescence (ED-XRF) is becoming a popular chemical analysis technique in large-scale air sampling campaigns. Filters or substrates used to collect ambient particulate matter (PM) for XRF analysis should have the following characteristics: (1) low mass to reduce scattering of incident radiation thus minimizing background count, (2) low concentrations of elements to be measured, and (3) low penetration of particles below the surface. Five types of commercially available filter material were analyzed for background metal content using a JVAR EX-6600 AF instrument. These filters were quartz fiber, Whatman paper, Teflon on polyolefinic ring support, Teflon on fiber support, and polycarbonate membrane. A sample of results is shown in Table 1. Quartz fiber filters were unacceptable for PM metal analysis due to high background metal concentrations and high penetration factor. Additionally, light elements such as sodium, magnesium, and aluminum could not be analyzed due to high silicon concentration. Whatman paper also had high metal concentrations in blanks although much lower than quartz fiber. Filter materials that have been found most suitable were the thin membrane type: Teflon and polycarbonate, as they have lowest background and penetration. Caution should be excercized while sampling on Teflon with fiber support as sampling on the "wrong", i.e. fiber side of the filter, is a common mistake. Supported in part by EPA R827351. TABLE 1. Selected background metal concentrations in filter material (ng/cm ^{2}).

	S	V	Fe	Ni	Cu	Zn
Quartz fiber	1074	48	1060	54	134	126
Whatman paper	200	0.77	100	4.4	85	1.3
Teflon on polyolefinic ring	15.7	1.8	19.7	4.8	27	0.60
Teflon on fiber support	16.6	3.3	19.2	2.3	25	72
Polycarbonate	15.7	1.8	9.3	2.7	7.5	1.7

170 THE EFFECTS OF AN ORGANOPHOSPHATE(OP)-CARBAMATE(CB) PESTICIDE MIXTURE ON CORE TEMPERATURE AND MOTOR ACTIVITY IN THE RAT.

C. Mack[1], C. Gennings[2], D. Herr[1] and C. J. Gordon[1]. *[1]ORD, NTD, USEPA, Research Triangle Park, NC and [2]Biostatistics, VCU, Richmond, VA.*

Pesticide risk assessment has traditionally been based on the toxicological response to single agents. Dose-additivity has been the default in risk assessment evaluations of pesticides with a common mechanism of action, but there could be supra-additive or infra-additive interactions of pesticide mixtures. We have found that rats exposed to anticholinesterase OP or CB pesticides display a transient hypothermia

followed by a delayed fever. Thus, the hypothesis of additivity of an OP/CAR mixture may be assessed using thermoregulatory endpoints. A fixed-ratio ray design was developed from single chemical dose-responses to assess the effects of a mixture of the OP chlorpyrifos (CHP) and the CB carbaryl (CAR). Adult, male Long-Evans rats were surgically implanted with radio transmitters (Data Sciences) to monitor core temperature (Tc) and motor activity (MA). After recording a 24 hr baseline of Tc and MA, rats were dosed orally with corn oil, 30 mg/kg CHP, 75mg/kg CAR, or one of the following 2:1 mixtures of CHP:CAR; 4.7:2.3, 9.3:4.7, 14.0:7.0, 18.7:9.3, or 23.3:11.7 mg/kg. Exposure to pure CHP and CAR yielded an acute, marked reduction in Tc followed by a delayed fever for at least one day post dose. The hypothermic response to the binary mixtures was diminished compared to the pure chemicals. A mixture of 23.3:11.7 mg/kg led to a hypothermic response half that of 30 mg/kg CHP (assuming dose-additivity, the hypothermic response of these two treatments should be equal). However, the CHP:CAR mixtures >14.0:7.0 mg/kg led to a delayed fever similar to that elicited by pure CHP. MA post dosing was reduced in the 30 mg/kg CHP group, whereas the mixtures did not affect MA. Overall, there is an infra-additive response to a mixture of CHP:CAR when assessed by the hypothermic response. This response is mediated through stimulation of cholinergic thermoregulatory pathways. The delayed fever, mediated by non-cholinergic systems, is unaffected by the CHP:CAR mixture. This abstract does not necessarily reflect USEPA policy.

171 *IN VITRO* INHIBITION OF RAT BRAIN AND SERUM CHOLINESTERASE BY BINARY MIXTURES OF SIX ORGANOPHOSPHATES.

J. E. Chambers[1], J. R. Richardson[1], C. A. Moore[1], S. O. Oppenheimer[2], R. L. Carr[1] and H. W. Chambers[3]. [1]*Coll. Vet. Med., Miss. State Univ., Mississippi State, MS,* [2]*Dept. Mathematics, Miss. State Univ., Mississippi State, MS and* [3]*Dept. Entomology, Miss. State Univ., Mississippi State, MS.*

Rat brain and serum were tested for cholinesterase (ChE) inhibition from binary mixtures of oxons of 6 phosphorothionate insecticides: methyl parathion (methyl paraoxon), parathion (paraoxon), azinphosmethyl (azinphosmethyl-oxon), chlorpyrifos (chlorpyrifos-oxon), malathion (malaoxon) and diazinon (diazoxon). Oxons were tested at concentrations yielding 10, 20 or 30% inhibition by the individual compounds. Serum was tested in the presence of EDTA so that A-esterases were not functional. A dose-additive model was used to predict the expected percent inhibition of the mixture; this model expressed the concentration of one oxon in the pair in terms of the concentration equivalents of the other oxon for summation. The observed percent inhibition for each of the pairs was compared to the expected percent inhibition obtained from the dose additive model. With brain preparations, the ChE inhibition observed at these low concentrations was typically similar to what would be predicted by this dose-additive model when the two compounds were added simultaneously or when the two compounds were added sequentially. More advanced mathematical modeling strategies, using ordinary differential equations, with calibrations based on the inhibition curves of the individual compounds for brain ChE, have successfully predicted the inhibition resulting from the binary mixtures. In contrast to the brain observations, the serum ChE inhibition was less readily predictable by this dose-additive model, even at very low concentrations, particularly when one of the compounds in the binary mixture was a potent carboxylesterase inhibitor, such as paraoxon. These data suggest that both anti-ChE potency and likelihood for being detoxified will need to be considered in predictive modeling of serum ChE inhibition by organophosphate mixtures. (Supported by American Chemistry Council CRAM 2a-99).

172 DEVELOPMENT OF A RESPONSE SURFACE FOR THE TOXICOLOGICAL INTERACTION BETWEEN CHLORPYRIFOS AND PARATHION USING PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING.

H. A. El-Masri[1], M. L. Yushak[2] and M. M. Mumtaz[1]. [1]*Computational Toxicology Laboratory, Division of Toxicology, Agency for Toxic Substances and Disease Registry, Atlanta, GA and* [2]*Rollins School of Public Health, Emory University, Atlanta, GA.* Sponsor: M. Mumtaz.

Chlorpyrifos and parathion are commonly used organophosphate insecticides in agricultural, household and commercial settings. In a biological system, each of these pesticides are activated by phase I (P450) reactions to their respective active forms, chlorpyrifos-oxon and paraoxon. These metabolites are potent inhibitors of the neural acetylcholinesterase. Thus, interactions between these pesticides can occur at two levels in the organism: a) the P450 enzymatic bioactivation site, and b) acetylcholinesterase binding sites. The objective of this study was to develop a physiologically based pharmacokinetic (PBPK) model to predict the joint toxicity of these chemicals in the rat. Model parameters were either calculated, obtained from published animal studies, or optimized using available data. PBPK models were developed for each chemical and its respective metabolite. The metabolite concentrations in blood were then linked to an additional model describing the kinetics of acetylcholinesterase inhibition and aging. The developed overall model was used to investigate the interactions between the parent chemicals and their metabolites with their respective biological sites. A response surface was constructed by using the overall model to simulate the response (percent of inhibited acetylcholinesterase) as a function of dose of each single chemical or various binary mixture combinations. For instance, using an oral dose of 3m/kg of each chemical, the model predicted maximum acetylcholinesterase activity inhibition at 35% and 20% of its initial level by parathion and chlorpyrifos, respectively. Although parathion produced a larger maximum inhibition, chlorpyrifos produced a longer acetylcholinesterase inhibition profile. This study illustrates the use of models to analyze toxicological interactions at dose levels that cannot be tested experimentally.

173 SARIN-INDUCED NEUROTOXICITY AND INCREASE IN BLOOD BRAIN BARRIER (BBB) PERMEABILITY ARE AUGMENTED BY STRESS AND COMBINED EXPOSURE TO PYRIDOSTIGMINE BROMIDE (PB), DEET, AND PERMENTHRIN IN RATS.

E. M. Elmasry, A. A. Abdel-Rahman, A. K. Shetty and M. B. Abou-Donia. *Pharmacology and Cancer Biology, and Surgery, Duke University Medical Center and VA Medical Center, Durham, NC.*

We studied the effect of 28 daily chemical exposures to PB (1.3 mg/kg, po, in water), DEET (40 mg/kg d, in ethanol) and permethrin (0.13 mg/kg, d, in ethanol) and stress by placing the animals in a Plexiglas restrainer for 5 min daily for 28 days on sarin (a single 50 microgram/kg, 0.5 LD50, dose, im, in saline)-induced neurotoxicity. A total of seven groups of rats underwent the following treatments: chemicals, stress, chemicals+stress, sarin, sarin+chemicals, sarin+chemicals+stress, and vehicle control. Brain acetylcholinesterase was inhibited in the cortex, midbrain and brainstem, with sarin+chemicals+stress causing most inhibition. Only sarin+chemicals+stress led to significant inhibition of plasma butyrylcholinesterase. Chemicals and sarin+chemicals increased ligand binding to m2 muscarinic acetylcholine receptor. Treatment with sarin+chemicals+stress increased uptake of [^{3} H]hexamethonium iodide by brain regions in the descending order: midbrain > brainstem > cerebellum > cortex. Increased permeability of BBB was confirmed using anti-EBA monocolonal antibodies and horseradish peroxidase. Histopathological studies with H&E stain showed much greater density of dying (degenerating) neurons in animals treated with sarin+chemicals+stress than other treatments in the cerebral cortex, hippocampus, and cerebellum, where Purkinje cells were more sensitive than molecular cells. Animals treated with sarin+chemicals+stress exhibited greatly enhanced glial fibrillary acidic protein staining, characterized by hypertrophy of astrocytic processes, that correlated with cell death recognizable with H&E stain. These results demonstrate that neurotoxiciy caused by a single sarin exposure is enhanced by combined exposure to stress, alone or with PB, DEET, and permethrin at real-life doses. Supported in part by the US Army Medical Research and Materiel command under contract DAMD 17-98-C-8027.

174 URINARY EXCRETION KINETICS OF TRICHLOROACETIC ACID (TCA) AND DICHLOROACETIC ACID (DCA) IN RATS EXPOSED TO A CHLORINATION BY-PRODUCT (CBP) MIXTURE IN DRINKING WATER.

G. Balagopal[1], F. Wu[2], K. Froese[2], S. Hrudey[2] and K. Krishnan[1]. [1]*Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada and* [2]*Dept of Public Health Sciences, University of Alberta, Edmonton, AB, Canada.*

Non-invasive biomarkers such as urinary concentrations of parent chemicals and metabolites are potentially useful for exposure assessment. Haloacetic acids, such as TCA and DCA, are potential biomarkers of exposure to CBPs in treated drinking water. However, there has not been an experimental evaluation of their urinary excretion kinetics during controlled exposure to CBP mixtures. The objective of the present study was therefore to characterize the urinary excretion kinetics of TCA and DCA in animals exposed to CBP mixtures. Male Sprague-Dawley rats (180-200 g) were provided *ad libitum* drinking water fortified with a mixture of CBPs (TCA, DCA, monochloroacetic acid, chloroform, bromoform, bromodichloromethane and dibromochloromethane) at two exposure levels for 21 days. The low exposure group received drinking water in which the CBP concentrations were similar to the highest concentrations reported in a Canadian drinking water survey, whereas the high exposure group received water fortified with ten times the highest reported environmental concentration of each CBP. Daily body weight of the rats, water consumed and the urinary output were quantified. The daily, composite urine samples from individual animals were analysed for TCA and DCA using a gas chromatograph with an electron capture detector. For the low

dose group, the daily urinary excretion of TCA varied from 0.043-0.56 mg/L and that of DCA ranged between 0.001-0.025 mg/L, whereas these ranges were 0.84-4.1 mg/L and 0.025-0.25 mg/L, respectively, for TCA and DCA in the high exposure groups. The average % dose eliminated in urine during the experimental period was 60 for TCA and 2.2 for DCA, for the low dose exposures. This controlled exposure study conducted with the rodents suggests that urinary TCA may be developed as a useful biomarker of low-level exposure to CBP mixtures.

175 A BINARY INTERACTION-BASED ALGORITHM FOR PREDICTING THE INTERNAL DOSE OF VOLATILE ORGANIC CHEMICALS (VOCS) IN MIXTURES.

K. Krishnan and M. Béliveau. *Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada.*

The objective of this study was to develop and validate a binary interaction-based algorithm for predicting the blood concentrations of VOCs in mixtures. The approach involved the calculation of the blood concentration at steady-state of one chemical (Cs) in the presence of other chemicals competing for hepatic metabolism. The following algorithm was developed: Cs = Cs-ind*(1 + Σ[Am*Ci/(K+Ci)], where Cs = concentration of substrate in the mixture, Cs-ind = concentration of substrate when present individually, Ci = concentration of the inhibitors in the mixture, Am = maximal augmentation of Cs possible in the mixture, and K = inhibition constant specific for each inhibitor-substrate combination. Cs-ind was estimated from steady-state algorithms derived from physiologically-based pharmacokinetic (PBPK) models. Both Am and K were derived from mechanistic studies with each binary mixture. Knowing the Ci measured during mixed exposures, the Cs was calculated on the basis of information on binary interaction mechanisms. The above algorithm was validated using the hepatic venous blood concentration (Cvl) of benzene (B) found in mixtures along with dichloromethane (D), toluene (T), ethylbenzene (E), and m-xylene (X). The Ci values corresponding to D, T, E and X in mixtures were obtained with a previously validated physiologically-based pharmacokinetic (PBPK) model, and were used to predict the modulation of Cvl for B during mixed exposures. The computed Cvl (μg/L) of B was 1.95 for single chemical exposure whereas it was predicted to increase to 3.97, 13.1, 26.7, 33.0, respectively, in the presence of D, D+T, D+T+E, and D+T+E+X (exposure concentrations: B = 1 ppm, D, T, E, X = 50 ppm). These values are identical to those obtained using the validated mixture PBPK model. The results presented in this study demonstrate the possibility of predicting the blood concentrations of chemicals during mixed exposures from knowledge of binary chemical interactions.

176 HEPATOTOXIC EVALUATION OF THE BINARY INTERACTIONS OF CHLOROFORM ($CHCl_3$) WITH BROMODICHLOROMETHANE (BDCM), CHLORODIBROMOMETHANE (CDBM) AND BROMOFORM ($CHBr_3$).

Y. M. Sey[1], C. Gennings[2], A. McDonald[1], L. K. Teuschler[3] and J. E. Simmons[1]. *[1]NHEERL/ORD, USEPA, Research Triangle Park, NC, [2]MCV, VCU, Richmond, VA and [3]NCEA/ORD, USEPA, Cincinnati, OH.*

Trihalomethanes (THMs) result from chlorination or chloramination of natural organic matter in water. Acute and chronic exposure to individual THMs results in target organ toxicity (hepatic, renal) and carcinogenicity. Since human exposure is to multiple chemicals, toxicity data on mixtures of THMs are needed. Three experiments were conducted to examine the binary interactions of $CHCl_3$ with the other 3 THMs. Each experiment consisted of: an aqueous control group; $CHCl_3$ alone at 0.1, 1.0 or 3.0 mmol/kg/day; either BDCM alone, CDBM alone or $CHBr_3$ alone at 0.1, 1.0 or 3.0 mmol/kg/day; 3 mixture groups of the corresponding $CHCl_3$:THM mixture at a 1:1 mixing ratio and total dosages of 0.1, 1.0 or 3.0 mmol/kg/day; and, 2 mixture groups at total dosages of 1.0 or 3.0 mmol/kg/day and varied mixing ratios (2.7:1 $CHCl_3$:BDCM; 6.5:1 $CHCl_3$:CDBM; 65:1 $CHCl_3$:$CHBr_3$) based on the average seasonal proportions of the THMs at 35 water treatment facilities (Krasner et al., 1989). Female CD-1 mice were gavaged daily for 14 days. Hepatotoxicity was assessed by serum SDH. The experimental SDH means were compared with 95% prediction intervals generated by a threshold additivity model built under an assumption of dose addition (Gennings et al., 1997). For $CHCl_3$:BDCM, the closeness of the predicted response under an additivity model and observed mean values indicated no deviation from dose additivity. For $CHCl_3$:CDBM, deviation from dose additivity was not detected for any dose level at either mixing ratio. For $CHCl_3$:$CHBr_3$ significant departure (antagonism) from dose additivity was detected only at 3.0 mmol/kg/kg of the 1:1 mixture; this result must be viewed with caution as the sample size was small in this group due to mortality. In summary, the present data indicate that the binary interactions among the THMs at these mixture dosages and mixing ratios are either additive or antagonistic but not synergistic.(This abstract may not reflect EPA policy.)

177 MICROBIAL GENOTOXICITY OF MODEL CHLORINATED ALIPHATIC HYDROCARBONS AND BINARY MIXTURES.

K. C. Donnelly[1], T. C. Hudson[2] and M. M. Mumtaz[3]. *[1]Veterinary Anatomy & Public Health, Texas A&M University, College Station, TX, [2]Environmental and Occupational Health, Texas A&M University, College Station, TX and [3]Agency for Toxic Substances and Disease Registry, Atlanta, GA.*

Human exposure typically occurs to complex chemical mixtures. This includes environmental exposures, as well as the various mixtures of chemicals in our food. This study addresses the development of *in vitro* methods for assessing the toxicity of complex environmental mixtures, and is focused on binary mixtures of chlorinated aliphatic hydrocarbons. Trichloroethylene (TCE) is one of the most common groundwater contaminants found near hazardous waste sites. The genotoxicity of these model chemicals and binary mixtures of chemicals was measured in the Salmonella/microsome mutagenicity assay. Chemicals were tested both with and without metabolic activation. TCE and dichloroethane (DCE) were tested as liquids by putting various concentrations of the chemicals in glass petri dishes and putting the dish in tedlar bags with agar plates containing the microorganisms. VC was tested as a gas by filling the tedlar bags containing the agar plates with a predetermined volume of gas ranging from 0 - 50% VC. Neither TCE nor DCE were mutagenic with activation. Vinyl chloride (VC) induced a doubling of revertants at all doses tested, with the maximum response of 341 net TA100 revertants observed at a dose of 50% VC. There were no appreciable differences in the response induced by VC alone and the response induced by binary mixtures of TCE or DCE and VC. The mixture of 30% VC and TCE induced 325 net TA100 revertants. Data from the microbial mutagenicity assay indicate that additive responses were induced by mixtures of VC with non-genotoxic chlorinated aliphatic hydrocarbons. (Supported by NIEHS SBRP Grant No. P42 ES004917 and ATSDR Grant No. TU68450502).

178 ANTIESTROGENIC ACTIVITY OF A RECONSTITUTED MIXTURE OF PCBs IN A HUMAN BREAST-CANCER CELL ASSAY.

J. Ssempebwa[1], B. Yilmaz[1], D. O. Carpenter[1] and K. F. Arcaro[2]. *[1]School of Public Health, University at Albany, Rennselaer, NY and [2]Environmental Sciences, University of Massachusetts, Amherst, MA.*

Fourteen individual polychlorinated biphenyls (PCBs) and a reconstituted mixture of the 14 PCBs were tested for their estrogenic and antiestrogenic activity in human breast-cancer cell cultures. The reconstituted mixture contained IUPAC-NOs.: 28, 77, 101, 105, 118, 126, 138, 146, 153, 156, 169, 170, 180, 187, and was prepared to reflect the pattern and concentration of PCBs frequently detected in human breast milk. The assay for estrogenic/antiestrogenic activity, the MCF-7 focus assay, is based on postconfluent cell growth and tissue restructuring measured as the development of multicellular layers or foci. The individual PCBs and the reconstituted mixture were tested at 5 concentrations between 1.6×10^{-9}M and 5×10^{-6}M. Two of the 14 PCBs (Nos.: 101 and 138) were estrogenic; they induced the formation of foci at the highest test concentration. Five of the 14 PCBs (Nos.: 28, 77, 126, 153, and 169) were antiestrogenic; they inhibited the foci induced by 1×10^{-10}M estradiol. The reconstituted mixture was antiestrogenic at the three highest test concentrations. The results are compared and discussed in relation to a published report (Hany et al., 1999, TAP 158, 231-243) in which treatment of female rats with the reconstituted mixture resulted in increased uterine wet weights of their offspring. (Supported by NIH ES049795-01A1 and TUBITAK-NATO)

179 AROMATIC FRACTION OF JET FUEL: DOSE-RESPONSE EVALUATION OF A MIXTURE AND ITS INDIVIDUAL COMPONENTS.

S. J. Baird[1], M. Hutcheson[2], S. Mahagaokar[3], D. R. Mattie[4], T. R. Sterner[5], D. J. Vorhees[1], W. H. Weisman[6] and T. Zewdie[2]. *[1]Menzie-Cura & Assoc., Chelmsford, MA, [2]MADEP, Boston, MA, [3]Pennzoil-Quaker State Co., Houston, TX, [4]AFRL/HEST, Wright-Patterson AFB, OH, [5]OpTech Corp., Dayton, OH and [6]3rd Aerospace Med. Squad., Elmendorf AFB, AK.*

Individual petroleum products are complex mixtures consisting of hundreds of individual components. The assessment of human health risk is complicated by the lack of toxicity data for the exact mixture of concern, although data are available on related components. Recently, a 90-day oral gavage toxicity study was conducted in rats and mice for the equivalent carbon $(EC)_{>8-16}$ aromatic fraction (AF) of jet fuel, containing some aliphatics (Smith *et al.*, 2000, Toxicol. Sciences. 54(1):396). Using this study, we are developing a reference dose (RfD) for the AF. In order to determine if uncertainty factor (UF) values other than the default of 10 could be used to account for subchronic to chronic extrapolation and uncertainty due to an incomplete database, we investigated which individual compounds and mixtures are relevant to the toxicological evaluation of this fraction and could support the derivation of data-derived UFs. A database was constructed using dose-response data

from published studies of chemicals within the AF including styrene, ethylbenzene, xylene, cumene, 1, 3, 5-, 1, 2, 4- and 1, 2, 3-trimethylbenzene, high flash aromatic naphtha (HFAN), naphthalene, 1- and 2-methylnaphthalene, biphenyl and AF. Dose-response data were adjusted to common dose and response metrics for comparison across endpoints grouped by target organ. Evaluation of the database suggests that components of the fraction can provide insight into the expected toxicological behavior of the fraction (e.g., dose-response relationships were similar for rats across hematological, liver and neurotoxicity endpoints for AF, biphenyl, HFAN and cumene). The availability of data for the AF mixture and for some of its components provides an opportunity to evaluate approaches for assessing the toxicity of petroleum-derived mixtures.

180 INTERACTIVE EFFECTS OF DDE AND METHOXYCHLOR ON HORMONE PRODUCTION IN BASS GONADAL CULTURES.

C. J. Borgert[1,2], T. S. Gross[2,3], P. D. Guiney[4], T. G. Osimitz[5], B. Price[6] and C. S. Wells[7]. [1]*Applied Pharmacology & Toxicology Inc., Alachua, FL,* [2]*Dept. Physiol. Sci., Univ. FL, Gainesville, FL,* [3]*USGS BRD Caribbean Sci. Ctr., Gainesville, FL,* [4]*S.C. Johnson & Son, Inc., Racine, WI,* [5]*Infoscientific, Inc., Charlottesville, VA,* [6]*Price Associates, Inc., White Plains, NY and* [7]*Gradient Corp., Cambridge, MA.*

Environmental exposures invariably involve more than one chemical. The ability to determine whether chemicals have similar modes of action has important implications for regulating pesticides and for mixture risk assessments. p', p'-DDE (DDE) and methoxychlor (MCL) were tested alone and in combination to assess the similarity of their actions on hormone production in gonadal tissue from large mouth bass, a species whose reproductive fitness has relevance to ecosystem health in Florida. Gonads were harvested from adult female bass (2-3 years of age) during the peak reproductive season, minced, and incubated in culture medium with or without test agents for 48 hours. Duplicates of each treatment were performed in each of three experiments using tissue from a different female. Testosterone was measured in aliquots of culture medium by validated RIA procedures. Dose-response relationships of individual agents were characterized over a 6-log concentration range ($1x10^{-2}$ to $1x10^{4}$ ppb). Both DDE and MCL, tested individually, produced a dose-dependent decrease in testosterone levels. Estradiol levels were unaffected. Mixtures of the agents were tested at concentrations of 0.01, 1, 100, and 10, 000 ppb in culture medium in a fractionated factorial, block treatment design. Statistical tests indicated that of 16 dose combinations tested, 15 were antagonistic and only 1 was additive based on the Loewe additivity model of "no-interaction." DDE and methoxychlor are generally recognized to have similar modes of pesticidal action, similar molecular structures and similar effects on the mammalian endocrine system. These results, however, imply that methoxychlor and p, 'p-DDE inhibit testosterone production *via* different mechanisms in bass ovaries.

181 COMPARATIVE REGULATION OF NRK-52E AND HK-2 KIDNEY CELL DEATH PATHWAYS *IN VITRO* BY ARSENIC (As3+), CADMIUM (Cd2+) AND As X Cd COMBINATIONS.

E. F. Madden, B. A. Fowler and M. Akkerman. *Toxicology, University of Maryland, Baltimore, MD.*

Arsenic and cadmium are toxic to renal proximal tubule cells but the single and combined effects of these elements on regulatory processes such as protein phosphorylation, stress protein response, and the caspase system have not been fully studied. The present studies examine the effects of As and Cd alone or in combination over concentrations of 10^{-7}M to 10^{-4}M in the rat NRK-52E and human HK-2 kidney cell lines. Preliminary TUNEL assays under these exposure conditions have shown only a minority of cells die from apoptosis. Hence, western immunoblot assays were conducted using antibodies to phosphorylated tyrosine, caspase-3, heme oxygenase, HSP 25, and HSP 27. Results showed marked increases in tyrosine phosphorylation for single and combined elements at 10^{-4}M concentrations in both cell lines. Increased heme oxygenase levels were observed to either coincide with increased tyrosine phosphorylation and/or to precede it at lower doses of 10^{-6}M or 10^{-5}M. Decreased levels of caspase-3 were generally found to coincide with increased tyrosine phosphorylation at 10^{-4}M concentrations of single and combined elements and at 10^{-5}M As x Cd. In HK-2 cells this was accompanied by decreased levels in HSP 27. In rat NRK-52E cells decreased levels in HSP 25 were observed only for 10^{-4}M of As x Cd. DNA fragmentation assays of NRK-52E cells showed no measurable positive results for apoptosis. Western immunoblot analysis of protein kinase C and tyrosine phosphatase PAC-1 in HK-2 cells showed decreased levels for 10^{-4}M doses of single and combined elements. These studies suggest single and combined mixtures of As and Cd may act in concert to inhibit essential regulatory processes leading to apoptosis and thus lead to cell death primarily *via* necrosis. Oxidative stress may play a role as evidenced by elevated heme oxygenase levels and increased levels in phosphorylated tyrosines found for higher doses of single and combined elements may be due to disruption of metabolic oxidative phosphorylation. (Supported by EPA STAR Grant# 827161 and ES 7299-06).

182 AUTOMATION OF RECOMMENDED DEFAULT METHODOLOGY FOR ANALYSIS OF EXPOSURES TO MIXTURES OF CHEMICALS IN EMERGENCIES.

D. K. Craig. *Risk Technology, Westinghouse Safety Management Solutions LLC, Aiken, SC.*

Exposures to airborne mixtures of chemicals may lead to additive, synergistic or antagonistic health effects. The objective of this paper is to describe automation of default methodology developed for use in emergency management and safety analysis within the Department of Energy complex. For individual chemicals, exposure conditions are evaluated using concentration limits such as Emergency Response Planning Guidelines (ERPGs) or Temporary Emergency Exposure Limits (TEELs). Hazard indices (e.g., HIi = Ci / Limiti, where Ci is the concentration of chemical "i") are calculated for each chemical. For exposure to mixtures, these HIs are summed unless sufficient toxicologic knowledge is available to indicate otherwise. A sum of 1.0 or less means the limits have not been exceeded. If chemicals are known to exert their toxic effect by different modes of action, they can be treated independently, i.e., their individual HIs must be less than one. Only the HIs for chemicals having the same toxic consequences need be added. To facilitate application of these recommendations for analysis of exposures to specific mixtures, chemicals are classified according to their toxic consequences. This is performed using health code numbers (HCNs) describing toxic effects by target organ for each chemical. Only HIs for chemicals having the same HCNs need be added. An Excel Workbook program has been set up to automatically apply this methodology to a user-supplied mixture of chemicals. The workbook comprises six worksheets, one of which is a lookup tabulation of HCNs and TEELs for over 1400 chemicals. These are accessed *via* the Chemical Abstract Services Registry Number (CASRN) or substitute. Only the "Input" worksheet is accessible to the user. The "Input" worksheet has room for entry of up to thirty chemicals. Individual chemical HI s, and the sums of HI s for chemicals with the same HCNs, are automatically calculated and the results are displayed on the "Output" worksheet. This occurs, after data entry is completed, when the Excel workbook is calculated.

183 ALTERNATIVE 5' SPLICING OF HUMAN MICROSOMAL EPOXIDE HYDROLASE: GENETIC LOCATION AND CHARACTERIZATION OF VARIANT EXONS.

C. Hassett[1], A. Gaedigk[2] and C. J. Omiecinski[1]. [1]*Environmental Health, University of Washington, Seattle, WA and* [2]*Division of Clinical Pharmacology & Experimental Therapeutics, The Childrens' Mercy Hospital, Kansas City, MO.*

Tissue-specific, chemical, or developmental regulation of gene expression can be directed by splicing events that result in mRNA transcripts with variant exons 1 under the control of alternative promoters. The human microsomal epoxide hydrolase (mEH) gene, important for the disposition of reactive epoxide moieties, has been reported to employ complex alternative splicing programs associated with exon 1 (which is noncoding). We have further characterized and localized these variant mEH exon 1 sequences by *in silico* analyses against the draft human genome. Each of the alternative exon 1 fragments was localized to chromosome one, in close proximity to the location of the previously characterized human mEH gene transcriptional unit (1q42.1). The alternative exon 1 sequences were positioned at distances ranging from at least 15 kbp to more than 46 kbp 5' of the previously established human mEH exon 1. Several of these mEH alternative exon 1 sequences were revealed to be homologous to a gene encoding the human signal recognition particle 9 kDa protein (SRP). In order to confirm the existence of alternative human mEH exons 1 in a variety of tissues, RNA ligase-mediated Rapid Amplification of cDNA End (RACE) reactions were performed on human liver, kidney, and small intestine samples isolated from five subjects. These RACE experiments verified the utilization of alternative mEH exon 1 sequences, but not those homologous to the SRP. Knowledge of the proximal promoter sequence information linked 5' to each mEH alternative exon 1 sequence will enable functional characterization of their gene regulation effects. (Supported by NIH grant ES-04978 and The Burroughs Wellcome Fund)

184 A ROLE FOR HIC-5 IN FOCAL ADHESION FORMATION AND IN HSP27-MEDIATED ACTIN FILAMENT STABILIZATION.

M. J. Welsh[1], R. Ransom[2], W. E. Smoyer[2] and Y. Jia[1]. [1]*Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, MI and* [2]*Pediatrics, University of Michigan Medical School, Ann Arbor, MI.*

Hsp27 is believed to stabilze actin filaments, but the mechanism is unknown. We identified hic-5, a focal adhesion protein and androgen receptor co-activator (ARA55), as an hsp27 binding protein, and have mapped the interaction to the hic-

5 C-terminal LIM4 domain and the hsp27 C-terminal domain. We observed that hic-5 inhibits the thermo-protection provided by hsp27. Hsp27 has been suggested to protect cells from heat by stabilizing actin filaments. We hypothesized that hic-5 inhibits hsp27 protection by interfering with hsp27-mediated actin filament stabilization. We analyzed the effect of hsp27-hic-5 interaction on cell polymerized actin (F-actin) using phalloidin binding assay in COS cells transiently transfected with vector only or hsp27, hic-5, hsp27 + hic-5, or hsp27 + hic-5ΔLIM4 (hic-5 mutant that does not bind hsp27) constructs. Hsp27 transfectants had greater and hic-5 transfectants had less total F-actin compared to vector transfected cells. However, coexpression of hic-5, but not hic-5ΔLIM4, with hsp27 reduced cell F-actin content. Cell fractionation studies in identically-transfected NIH 3T3 cells lysed in buffer containing 0.1% triton X-100 revealed hic-5 in the soluble fraction in hic-5 transfectants, but redistribution of hic-5 to the triton-insoluble fraction (that also contains actin cytoskeletal elements) in hsp27 + hic-5 transfectants. Immuno-staining of murine podocytes stably transfected with vector control, hsp27, or hic-5 demonstrated reduced actin stress fibers and focal adhesions in hic-5 transfectants compared to vector control or hsp27 transfected cells. We conclude that hic-5 inhibits hsp27-mediated actin filament stabilization, hic-5 may interfere with the formation of focal adhesions, and hsp27 can regulate the intracellular distribution of hic-5. Supported by NIH grants R01-ES06265, R01-ES07006 and P01-ES11188 to MJW, and K08-DK02455, R01-DK55602 and a research grant from the National Kidney Foundation of Michigan to WES.

185 EFFECTS OF OVEREXPRESSED WILD-TYPE, ATP BINDING- AND ATP HYDROLYSIS-DEFECTIVE YEAST *RAD54* ON DSB-INDUCED CELL KILLING, HR AND CHROMOSOME LOSS.

J. A. Nickoloff[1], K. S. Spitz[1] and P. M. Kim[2]. [1]*Dept. Mol.Genet. & Microbiol., UNM, Albuq., NM and* [2]*Sch. Environment Studies & Department Pharmacology Toxicol., Queen's Univ., Kingston, ON, Canada.*

DNA double-strand breaks (**DSBs**) in yeast are repaired primarily by homologous recombination (**HR**) involving several proteins including Rad51 and Rad54 which interact during heteroduplex DNA formation. Rad54 alters DNA double helix conformation in an ATP-dependent manner. We examined DSB-induced cell killing, HR, and chromosome loss in **a/α** and **a/a** diploid yeast with normal Rad54 levels, overexpressed wild-type Rad54, or overexpressed mutant versions of Rad54 defective in ATP binding or ATP hydrolysis. DSBs were introduced into *ura3* by HO nuclease. The Heyer Lab. showed that excess wild-type Rad54 reduced methylmethane sulfonate (**MMS**) resistance by 25%, while excess ATP binding or hydrolysis mutant Rad54 reduced MMS resistance by >99%. In contrast, DSB-dependent cell killing with excess wild-type or mutant Rad54 was minimal in **a/α** cells, and modest (25%) in **a/a** cells. MMS is an alkylating agent and its cytotoxic effects are probably replication-dependent, so the different effects of excess Rad54 with MMS and DSB damage may reflect differences in Rad54 function during replication (i.e., during lesion bypass at blocked replication forks by sister chromatid exchange) *vs.* replication-independent DSB repair. In **a/α** and **a/a** cells, excess wild-type Rad54 had no effect on frequencies of DSB-induced HR or chromosome loss, but excess mutant Rad54 reduced HR by 1.5- to 3-fold. In all cases, reduced HR correlated with increased chromosome loss. We reasoned that excess wild-type Rad54 might enhance Rad51-mediated heteroduplex formation and increase gene conversion tract lengths, but the opposite was observed; excess mutant Rad54 had no effect on tract lengths. Together these results suggest that excess wild-type Rad54 does not affect HR initiation but negatively affects the later step of heteroduplex formation, whereas excess mutant Rad54 blocks HR initiation (leading to chromosome loss and some cell killing) but does not affect later steps.

186 CHARACTERIZATION OF INTRINSICALLY THERMOTOLERANT (IT) SUBSTRAINS OF *C. ELEGANS* WHICH MAINTAIN THE IT STATE, SHOW INCREASED LONGEVITY, AND DISPLAY ELEVATED HSP16 LEVELS.

K. E. Stine, G. E. White, J. P. Ellwitz, K. A. McFarland, R. A. Buonpane and N. D. Smith. *Department of Biology/Toxicology, Ashland University, Ashland, OH.*

The classic heat shock or stress response has been studied in a number of organisms including the nematode *C. elegans*. We have previously demonstrated that elevated temperatures as well as exposure to the mitochondrial toxicant sodium azide have the ability to induce a stress response in this nematode, and that this response involves induction of both hsp70 and hsp16. Now, we have isolated substrains of the N2 wild type nematode which show intrinsic thermotolerance, defined as a significantly increased survival probability compared to controls when taken from either 16° or 25° C directly to 37° C for two hours. These N2ITs have maintained their intrinsic thermotolerance for well over two years, and in addition, show a significantly increased life span. Experiments have shown that the average lifespan for worms from the N2IT6 substrain grown at 25 °C is 14.5 ± 0.7 days, compared to 12.5 ± 0.5 days for N2 controls. This represents a 16% increase in average lifespan for this substrain. It was also noted that in every experiment the life span of at least 2-3 N2IT6 worms was significantly longer than the mean (typically on the order of 19 - 20 days). In terms of stress protein expression, Western blot analysis of the N2IT6 substrain indicates elevated hsp16 levels when compared to controls. To further characterize the IT state, we have designed primers and initiated RT-PCR studies from both N2IT6 and N2 controls to determine hsp70, hsp60 and hsp90 expression in these worms. In summary, we have been able to maintain N2IT substrains for over 2 years, and have discovered that these populations show significantly increased longevity compared to N2 controls. In addition, we have demonstrated that these IT substrains show elevated levels of at least one stress protein, hsp16, when compared to N2 controls. We are continuing to investigate the molecular mechanisms by which this IT state is maintained through application of RT-PCR techniques.

187 SULFUR AMINO ACID DEPRIVATION INDUCES MICROSOMAL EPOXIDE HYDROLASE, A PUTATIVE CELL SURFACE AUTOANTIGEN, IN PARALLEL WITH APOPTOTIC CELL DEATH.

K. W. Kang[1], Y. G. Kim[1], R. F. Novak[2] and S. G. Kim[1]. [1]*National Research Laboratory (MDT), College of Pharmacy, Seoul National University, Seoul, South Korea and* [2]*Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.*

Microsomal epoxide hydrolase (mEH), a detoxifying enzyme and putative cell surface autoantigen, is inducible by xenobiotics and by certain pathophysiological conditions (e.g. tumorigenesis and protein-calorie malnutrition). The present study was designed to determine mEH expression in H4IIE cells during apoptosis initiated by sulfur amino acid deprivation (SAAD) and to identify the signaling pathway for the enzyme induction. SAAD induced apoptotic cell death at 48-72 h and decreased mitochondrial permeability with cytochrome *c* release, both of which were prevented by SB203580 or by dominant-negative JNK1 [JNK1(-)] transfection. Neither caspase-3 activity nor poly(ADP-ribose) polymerase cleavage increased during SAAD-induced apoptosis, indicating that SAAD induced apoptosis independent of caspase activation. This was supported by the observation that benzyloxycarbonyl-Val-Ala-Asp-fluoromethyl ketone, a general caspase inhibitor, did not prevent apoptosis. The levels of mEH mRNA and protein were notably increased in cells under SAAD for 48-72 h. The induction of mEH occurred in parallel with apoptotic cell death. Whereas SAAD-induced apoptosis resulted from both JNK1 and p38 kinase activation, mEH induction was decreased only by JNK1(-) transfection. Immunocytochemistry revealed that mEH protein was intensely stained in apoptotic cells, cellular fragments and cell debris. The number of cells positive for surface mEH also substantially increased by SAAD, as evidenced by flow cytometry analysis. These results demonstrated that SAAD induced apoptosis with an increase in cytochrome *c* release from mitochondria, but not through caspase-3 activation, and that apoptosis induced by SAAD accompanied mEH induction, which involves JNK1, but not ERK1/2 or p38 kinase pathway. The expression of cell surface mEH by SAAD may be associated with presentation of autoantigen.

188 COVALENT BINDING OF ACTIN IS REQUIRED FOR NUCLEAR TRANSLOCATION OF NF-E2-RELATED FACTOR 2 (NRF2) AND ANTIOXIDANT RESPONSE ELEMENT (ARE) ACTIVATION.

S. J. Lee, K. W. Kang and S. G. Kim. *National Research Laboratory (MDT), College of Pharmacy, Seoul National University, Seoul, South Korea.*

Expression of phase II detoxifying genes is regulated by Nrf2-mediated activation of ARE. Phosphatidylinositol 3-kinase is involved in the translocation of cytoplasmic Nrf2 into the nucleus through rearrangements of actin in response to tert-butylhydroquinone (t-BHQ). The apparent molecular weights of cytoplasmic and nuclear proteins cross-reacting with anti-Nrf2 antibody varies according to reducing condition. The present study was initiated to determine whether Nrf2 could covalently bind with actin. The apparent molecular weight of Nrf2 was 57 kDa in both cytoplasmic and nuclear proteins fractionated from cell lysates prepared in the presence of dithiothreitol, whereas in the absence of dithiothreitol, that of the nuclear protein immunochemically reacting with anti-Nrf2 antibody was 100 kDa. The band intensity of the nuclear 100 kDa protein was increased by t-BHQ treatment. Nuclear translocation of cytoplasmic Nrf2 by t-BHQ was prevented by pretreatment of cells with dithiothreitol. Hence, it is highly likely that Nrf2 translocates into the nucleus as a complex covalently bound with a 43 kDa protein.

Western blot analysis revealed that anti-actin antibody recognized a 100 kDa nuclear protein as well as 43 kDa actin protein. The level of the 100 kDa nuclear protein, which was co-immunoprecipitated with anti-Nrf2 antibody and immunoreacting with anti-actin antibody, increased in cells treated with t-BHQ. Also, the ARE band intensity was reduced in gel-shift analysis after immunodepletion of the nuclear extract with anti-actin or anti-Nrf2 antibody. Addition of dithiothreitol and/or beta-mercaptoethanol to the nuclear fraction failed to convert the 100 kDa protein to 57 kDa Nrf2. Hence, it is unlikely that Nrf2 binds with actin through disulfide bondage. These results demonstrated that the altered cellular redox-state induced by oxidative stress causes Nrf2 to bind with actin and the actin-bound Nrf2 translocates into the nucleus prior to its ARE activation.

189 DEVELOPMENT AND APPLICATION OF AN ALLELE-SPECIFIC GENOTYPING STRATEGY FOR DETERMINATION OF *FMO2*1* FREQUENCY IN A HISPANIC POPULATION.

S. K. Krueger[1], S. R. Martin[1], J. L. Raucy[2] and D. E. Williams[1]. *[1]Environmental & Molecular Toxicology, & The Linus Pauling Institute, Oregon State University, Corvallis, OR and [2]La Jolla Institute for Experimental Medicine, San Diego, CA.*

The most common allele for the major mammalian lung isoform of flavin-containing monooxygenase, FMO2, encodes truncated inactive protein due to a C to T transition that results in a premature stop codon. The allele (*hFMO2*1*) encoding full-length protein is absent in all Caucasian and Korean individuals genotyped to date; however, it is present in 26% of African-Americans. We recently demonstrated activity of this enzyme in lung microsomes from a heterozygous organ donor. FMO metabolizes the oxygenation of many nitrogen and sulfur containing drugs/xenobiotics. The present study focused on extension of ethnic genotyping to determine the prevalence of *hFMO2*1* among Hispanics, and the screening of candidate substrates with baculovirus expressed hFMO2.1, to assess the potential relevance of allelic variation. Genomic DNA was isolated from lung, liver or blood (plasma or lymphocytes). Allele-specific forward primers, differing in length by 15 nucleotides and one common reverse primer were designed to produce a 245-bp PCR product corresponding to the allele (*hFMO2*2*) encoding truncated protein, and a 230-bp product corresponding to *hFMO2*1*. Allele-specific PCR products were identified by PAGE. DNA, from 27 individuals was sequenced including samples putatively containing the *hFMO2*1* allele, to obtain genotype verification. To date 40 Hispanic individuals have been genotyped; 5.0% have the *hFMO2*1* allele. Baculovirus expressed hFMO2.1 was active toward substituted thiourea compounds with a small cross-sectional area (≤ 4.3 Å), but was inactive toward 1, 3-diphenyl thiourea (11.2 Å), in assays following NADPH oxidation. Thioacetanilide and thiobenzamide were also good substrates. The presence of the ethnic *hFMO2*1* allele in African American and Hispanic populations indicates the potential for ethnic differences in drug and environmental toxicant metabolism. (Supported by PHS grant HL38650.)

190 APPLICATION OF THE RNA INTERFERENCE ASSAY TO INVESTIGATE THE ROLE OF Sp1 AS A TRANSCRIPTION FACTOR IN BREAST CANCER CELLS.

M. H. Abdelrahim, I. Samudio and S. H. Safe. *Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.*

Sp1 is a member of the Sp family of transcription factors that play an important role in regulating basal expression of multiple genes through interaction with GC/G-rich promoter sequences. The estrogen receptor α (ERα) interacts with Sp1 protein, and several estrogen (E2)-responsive genes are induced in human breast cancer cells through ligand-dependent activation of ERα/Sp1. This study investigates RNA interference (RNAi) through transcriptional and/or posttranscriptional gene silencing of Sp1 protein in MCF-7 cells as a probe for confirming the role of Sp1 and ERα/Sp1-mediated transactivation. For the proposed studies in subconfluent MCF-7 human breast cancer cells, we have used a double-stranded 21 nucleotide small interfering RNA (siRNA) that is homologous in sequence to the coding region 1011-1032 relative to the start codon of Sp1. Lipofectamine was used for transfection of 0.75 μg siRNA per well. Cells were then harvested after 48 hr, and Sp1 protein was examined in whole cell extracts by Western blot analysis. The results showed that immunoreactive Sp1 protein levels were decreased by 60 - 70%. In parallel studies, MCF-7 cells were transfected with a construct (pSp1) containing a single consensus GC-rich Sp1 binding motif, and reporter gene activity was determined in the presence or absence of cotransfected siRNA. The results showed that siRNA decreased Sp1-dependent transactivation by > 90%, whereas in control experiments using siRNA for lamin B, no effects on Sp1 protein levels or pSp1-dependent activity were observed. The RNAi assay is currently being used to target other Sp1- and ERα/Sp1-dependent genes/promoters to investigate contributions of Sp1 and other Sp proteins as transcription factors. (Supported by NIH CA76636 and ES09106)

191 MULTIPLE HISTONE MODIFICATIONS ARE COUPLED TO REACTIVE OXYGEN SPECIES INDUCED ONCOTIC CELL DEATH.

K. Tikoo, S. S. Lau and T. J. Monks. *Center for Molecular and Cellular Toxicology, Division of Pharmacology and Toxicology, College of Pharmacy, University of Texas at Austin, AUSTIN, TX.*

The rapid formation of DNA single strand breaks, increases in histone H3 phosphorylation, and the dephosphorylation of histone H2A, precede reactive oxygen species (ROS) induced oncotic cell death in renal proximal tubule epithelial cells (LLC-PK1) [Mol Pharmacol, 60:394-402, 2001]. Consistent with these findings, we now report that ROS, generated following the addition of 2, 3, 5-tris-(glutathion-S-yl)-hydroquinone to LLC-PK1 cells, cause the rapid ribosylation of histones H1>>H3 and H4. Histone ribosylation precedes histone H3 phosphorylation, suggesting that ribosylation of linker H1 in particular, provides subsequent access for the requisite kinase(s) to core histone H3. Moreover, ROS induced histone phosphorylation appears to be restricted to a small subset of nucleosomes that are subject to hyperacetylation/ deacetylation. Thus, triton-acid-urea polyacrylamide gel electrophoresis analysis of nuclear extracts from LLC-PK1 cells treated with the histone deacetylase inhibitor, sodium butyrate, reveals that phosphorylated histone H3 comigrates with hyper- (tetra) acetylated histone H3. The data suggest that putative histone H3 kinases selectively target nucleosomes that are also targets of butyrate sensitive histone deacetylase(s). The kinetics of the phosphorylation/acetylation coupling remains to be determined. Finally, in this model of ROS-induced oncotic cell death we fail to observe any changes in histone methylation. Because methylation of K9 and K27 in histone H3 are suggested to hinder S10 and S28 phosphorylation, the combined data indicate that specific and precise histone modifications occur during ROS induced cell death and that such selective histone modifications are supportive of the "Histone Code" hypothesis. (ES 07247, ES 07784)

192 TETRAFLUOROETHYLCYSTEINE-INDUCED ALTERATIONS TO MITOCHONDRIAL COMPLEX III ACTIVITIES *IN VITRO*.

M. L. Adams, S. D. Nelson and S. A. Bruschi. *Medicinal Chemistry, University of Washington, Seattle, WA.*

The potent nephrotoxicant tetrafluoroethylcysteine (TFEC) induces cell death by initiating damage exclusively within the mitochondrial compartment. Nonetheless, *de novo* transcription of nuclear genes is a well recognized response to TFEC treatment *in vivo* and *in vitro*. Consequently, we examined the possibility of communication from mitochondria to the nucleus, analogous to a well-characterized communication pathway in *Saccharomyces cerevisiae* ("retrograde regulation", RTG). Degenerative RT-PCR of structural motifs of the yeast RTG3 gene reproducibly yielded a 475 bp fragment identical to a segment of the mitochondrial cytochrome *b* component of Complex III (ubiquinol:ferricytochrome *c* oxidoreductase). Alterations to antimycin A-sensitive Complex III activities were examined in an accurate mammalian *in vitro* model for TFEC-induced cell death to determine the biological significance of this finding. TFEC treatment resulted in specific time-dependent decreases in Complex III activity (49.7 ± 0.8 mmol cytochrome *c* reduced/min/mg protein at 12 h v/s 79.2 ± 12.6 mmol/min/mg protein control: mean ± s.d.; n=3, p<0.001). Cell viabilities were also determined by live/dead® stain and morphological alterations by light microscopy. To determine if these changes correlated with a particular mode of cell death, antimycin A-sensitive Complex III activities were also evaluated after treatment with actinomycin D/tumor necrosis factor α, acetaminophen, or other toxicants. These results show a specific effect on Complex III activity by TFEC and suggest a mechanism by which changes to oxidative phosphorylation may be coupled to nuclear transcription *via* alterations to cytochrome *b*. *(Supported by NIH grant #GM25418 to SDN, #GM51916 to SB and P30 ES07033 to the UW Center for Ecogenetics and Environmental Health)*

193 DIFFERENCES IN METHYLATION PATTERNS OF THE ESTROGEN RECEPTOR AND AROMATASE GENES IN JAPANESE MEDAKA.

R. G. Contractor[1], K. W. Willett[1], S. F. Li[2], T. Chiang[3] and C. M. Foran[4]. *[1]Department of Pharmacology, University of Mississippi, University, MS, [2]National Cancer Institute, Bethesda, MD, [3]Tulane University, New Orleans, LA and [4]Department of Biology, West Virginia University, Morgantown, WV.*

In order to explore the potential for environmental contaminants to alter patterns of genetic imprinting, we are determining the tissue and sex specific patterns of methylation in the promoter region of the estrogen receptor and the aromatase genes of the Japanese medaka, *Oryzias latipes*. Primers were designed to span the CpG islands of the medaka promoter region where there were suspected sites of

methylation. Livers, gonads, and brains were removed from male and female medaka and the genomic DNA extracted. Samples of genomic DNA from each sex and tissue were treated with sodium bisulfite (resulting in a loss of all non-methylated cytosine residues), amplified, cloned, sequenced and compared to the genomic sequence. Cytosine residues remaining in the bisulfite-treated samples were from methylated CpG islands. In the estrogen receptor, the female liver, brain and ovary had 13 and the male liver had 15 CpG islands in the promoter respectively, all of which were methylated. The male gonad and brain only had 12 and 13 CpG islands respectively, 11 of which were methylated. Because the overwhelming majority of the CpG islands showed methylation, we had speculated that one possible mechanism for increase in transcription rates of the estrogen receptor was through a loss of methylation at these sites. However, unexpectedly, the remaining three non-methylated islands (1 from gonad and 2 from brain) were methylated in fish exposed to 500ng/L ethynylestradiol, but not in control males. In contrast to the estrogen receptor, the aromatase gene had only 5 CpG islands in the promoter region of the wild type male tissues. Further studies will look at the efficacy of other environmental contaminants in altering patterns of methylation in these two genes.

194 BIOCHEMICAL STUDIES ON THE SOLUBLE FRACTION OF HEN PERIPHERAL NERVE: SEARCHING THE TARGET OF PROMOTION OF AXONOPATHIES.

A. Nicolli, A. Moretto and M. Lotti. *Dipartimento di Medicina Ambientale e Sanità Pubblica, Università di Padova, Padova, Italy.*

Promotion of axonopathies is caused by certain esterase inhibitors such as sulfonyl halides, carbamates, thiocarbamates and phosphinates. Promotion was found to correlate with inhibition of a phenyl valerate esterase (PV) activity in the whole nerve homogenate (M200). M200 was defined as the activity resistant to 40 μM paraoxon and with an IC50 for mipafox of about 200 μM. Sephacryl S-300 chromatography of soluble proteins of peripheral nerve separated most PV activity (S-PV)in fractions corresponding to 50-70 kDa MW proteins. S-PV was found to be selectively inhibited by promoters after *in vivo* treatment with several esterase inhibitors. At least 3 proteins, as seen from SDS-PAGE, were present in such fractions. It has been reported that S-PV activities are reversibly inhibited by paraoxon (Barril and Vilanova, 1999). In fact, when S-PV activity was inhibited (77%) by paraoxon (2 μM, 20 min, 37 °C, pH 8.0), then a 78% reversibility was observed after 24 hours dialysis at 0 °C. Consequently, the S-PV IC50s for mipafox were higher in the presence of paraoxon. S-PV activity found to be sensitive to mipafox was about 90% of total, whereas that sensitive to tested inhibitors varied from 70 to 90%. The IC50s for mipafox were 20, 50 and >100 μM in the presence of 1, 8 and 40 μM paraoxon, respectively, and 1 μM in the absence. Similarly, the S-PV IC50s for several promoters were found to be lower than those of M200. These were: for PMSF 1 and 60 μM, for L(-) methamidophos 200 μM and >20 mM, for D(+) methamidophos 400 μM and 5 mM, for n-hexyl methamidophos <1 and 100 μM, and for molinate sulfone 0.01 and 1μM, respectively. In conclusion, S-PV activity displays *in vitro* sensitivity to promoters higher than that of M200. This is due to different assays which are required for either M200 or S-PV, because of the reversible inhibition of S-PV caused by paraoxon.

195 ACTIVATION OF NUCLEAR FACTOR-kappaB (NF-KB) BY CIGARETTE SMOKE CONDENSATE.

B. B. Aggarwal[1], R. J. Anto[1], A. Mukhopadhyay[1] and C. G. Gairola[2]. *[1]University of Texas M.D.Anderson Cancer Center, Houston, TX and [2]University of Kentucky, Lexington, KY.*

Cigarette smoking is a major risk factor for lung cancer and coronary artery disease. Pro-oxidant constituents of tobacco smoke have been implicated in smoking-associated disease development because of their potential role in inducing oxidative stress. We postulated that activation of redox sensitive transcription factor, NF-KB, may play a role in tobacco smoke-induced cell damage. To test this hypothesis, activation of NF-KB was examined in cigarette smoke condensate (CSC)-treated human monocytic cells (U937). The cells were treated with CSC in serum free medium for 30 min. Nuclear and cytoplasmic extracts were prepared and analyzed for NF-KB binding by EMSA and I-KBαcontent by immunoblots, respectively. Parallel experiments were carried out with TNF-α as positive control. The results showed that treatment of cells with CSC increased NF-KB -DNA binding in a dose and time dependent fashion. Analysis of the cytoplasmic extracts showed that I-KBαlevels started declining with in 15 mins of CSC treatment of cells and were significantly diminished by 60 mins. Further experiments showed that IKBαkinase was activated in cells with in 15 min of treatment with CSC. These observations indicated a potential of CSC to initiate phosphorylation and degradation of IKBα. Tests with nuclear extracts of various other CSC-treated cells of lymphoid and epithelial origin also showed increased NF-KB-DNA binding thus suggesting that CSC-mediated NF-KB activation is not cell specific. It is concluded that NF-KB activation by CSC may mediate tobacco smoke-induced cell damage (supported by NIH (P01 CA91844); Institutional Tobacco Funds, and KTRB-5-41165).

196 DUAL FUNCTIONS OF YEAST DNA POLYMERASE ζ IN DNA LESION BYPASS.

A. Guo, X. Wu, O. Rechkoblit, N. Geacintov and Z. Wang. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.*

Saccharomyces cerevisiae DNA polymerase ζ (Polζ) is required for DNA lesion bypass during replication. To gain insights into the function of Polζ in lesion bypass, we have performed *in vitro* biochemical analyses of this polymerase in response to several DNA lesions. Purified yeast Polζ performed limited translesion synthesis opposite a template (+)-trans-anti-BENZO(A)PYRENE-N^2-dG adduct and a template (-)-trans-anti-BENZO(A)PYRENE-N^2-dG adduct by preferentially incorporating G, and less frequently C. Opposite an acetylaminofluorene (AAF)-adducted guanine, purified yeast Polζ predominantly incorporated a G. This lesion, however, significantly inhibited subsequent extension DNA synthesis. Extension synthesis by yeast Polζ was more efficient when A or C was opposite the AAF-guanine. These results support the following dual-function model of Polζ. First, Polζ catalyzes nucleotide incorporation opposite (±)-trans-anti-BENZO(A)PYRENE-N^2-dG adducts and AAF-guanine with a limited efficiency. Secondly, more efficient bypass of these lesions may require nucleotide incorporation by other DNA polymerases followed by extension DNA synthesis by Polζ.

197 *IN VIVO* EXPOSURE TO IMMUNOTOXIC DOSES OF BENZO(A)PYRENE INDUCES CYTOCHROME P450 1A EXPRESSION WITHIN KIDNEY MONONUCLEAR CELLS OF FISH.

E. A. Carlson, Y. Li and J. T. Zelikoff. *Dept. of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

BENZO(A)PYRENE (BaP) is a widespread environmental contaminant and known carcinogen. In addition to its cancer promoting ability, BaP also has profound effects upon mammalian immunocompetence. Previous studies conducted in this laboratory have utilized a small teleost fish species, Japanese medaka (*Oryzias latipes*), as a laboratory model for investigating the immunotoxic potential of BaP. Similar to that observed in rodents, immune responses of medaka were suppressed following IP injection of BaP at doses that failed to affect morbidity or host survival. Specifically, BaP dose-dependently reduced antibody-forming cell (AFC) numbers. Furthermore, co-exposure to compounds that inhibit hepatic CYP1A activity ameliorated the immunotoxicity produced by exposure to BaP alone. This suggests that BaP metabolism into reactive metabolites may be required for suppression of immune function. Further studies in this laboratory have revealed that injection of BaP, at the same concentrations that suppressed AFC number, induced expression of CYP1A within a distinct subpopulation of kidney (primary site of hematopoiesis / leukopoiesis in medaka) mononuclear cells. Isolation of mononuclear cells from the kidney following *in vivo* exposure to BaP resulted in immunopositive staining of CYP1A within a small percentage of both glass-adherent and non-adherent immune cell types; little CYP1A expression was seen in isolated cells from the vehicle control. Moreover, exposure of isolated kidney immune cells to BaP *in vitro* resulted in both an induction of CYP1A expression and a concurrent decrease in AFC number following *in vitro* immunization. This later finding suggests that specific medaka immune cells are sensitive to the parent BaP compound. Since it is apparent that medaka immune cells possess inducible CYP1A, it is possible that BaP may directly alter the function of these cells *via* the production of immunotoxic BaP metabolites *in situ*. (DAMD 17-99-9011and 60-1-8109)

198 EFFECT OF RETINOIC ACID ON 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD)-INDUCED MATRIX METALLOPROTEINASE EXPRESSION IN HUMAN KERATINOCYTES.

L. A. White. *Biochemistry and Microbiology, Rutgers, The State University of NJ, New Brunswick, NJ.* Sponsor: K. Cooper.

Exposure to the environmental contaminant 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) results in an increased incidence of skin cancers. TCDD-exposure results in activation of the AhR/Arnt signaling pathway, mediating changes in gene expression through binding to XREs (Xenobiotic Response Elements). The AhR/Arnt pathway also interacts and influences other signaling pathways, including the retinoic acid (RA) pathway. Retinoids are powerful regulators of cell growth and differentiation and are widely used in the prevention and treatment of a variety of cancers in humans. Preliminary data from our laboratory suggests that interaction of these pathways alters the expression of matrix metalloproteinases (MMPs), proteases involved in tumor invasion. MMPs degrade the protein components of the extracellular matrix and the basement membrane, which is required for tumor cell migration and invasion. Northern analysis demonstrates that TCDD exposure of normal human keratinocytes results in activation of MMP expression, and that co-treatment with RA further stimulates MMP expression. The mechanism of activation of MMP-1 expression by TCDD + RA may involve binding to AP-1 sites in

the proximal promoter, or potential XREs in the distal part of the promoter. Mobility shift data demonstrates TCDD activation of binding to the AP-1 site and to the XREs following TCDD treatment. Binding to a consensus XRE is abolished following RA exposure, whereas binding to the AP-1 site appears unchanged. Future experiments will examine the role of these elements in TCDD-RA induction of MMP expression, and to determine the effect of TCDD-RA treatment on cellular migration and invasion.

199 TCDD STIMULATES ANDROGEN-RECEPTOR SIGNALLING IN LNCAP CELLS.

S. J. Barnes and A. Puga. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

TCDD, the most extensively studied aromatic hydrocarbon receptor (AHR), has a high affinity for the AHR and exhibits a broad range of toxic, biological effects in humans and laboratory animals, including tumor promotion, lymphoid involution, embryonic toxicity, epithelial hyperplasia and metaplasia, wasting syndrome, carcinogenesis, and endocrine disruption. Several mechanisms have been proposed to explain how AHR activation by TCDD interferes with steroid-regulated functions. These mechanisms include: (1) enhancement of ligand metabolism, (2) alteration of hormone synthesis, (3) down-regulation of receptor levels, and (4) interference with hormone-induced gene transcription and cell proliferation. In male rats exposed to TCDD, decreased growth of the testis, epididymis, and prostate were observed. These effects did not correlate with decreases in circulating androgen or androgen receptor (AR) levels, suggesting that TCDD does not interfere with androgen synthesis or metabolism, or with the levels of AR. Therefore, we hypothesized that TCDD interferes with AR-mediated gene expression and cell proliferation. To test this hypothesis, we utilized androgen-dependent human Lymph Node Cancer of the Prostate (LNCaP) cells to determine the effects of TCDD on androgen-regulated functions. Our studies indicate that TCDD stimulates cell proliferation in LNCaP and activates gene transcription of the human PSA (prostate specific antigen) gene promoter and of the MMTV (mouse mammary tumor virus) LTR in LNCaP as well as in African green monkey CV-1 cells, which lack AHR expression. These results point to a possible role of environmental toxicants in the androgen-independent progression of prostate cancer. Supported by NIH Grants 2RO1 ES06273 and ES05941-02.

200 DEC1 BASIC HELIX-LOOP-HELIX DIFFERENTIALLY REGULATES GENES ENCODING CARBOXYLESTERASES AND CYTOCHROME P450 ENZYMES.

Y. Li, M. Xie and B. Yan. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

DEC/STRA/SHARPs represent a new and distinct class of basic helix-loop-helix (bHLH) transcription factors. Human DEC1 is abundantly present in several normal tissues including heart, brain, placenta, lung and liver. In order to determine whether DEC1 regulates genes highly expressed in liver, transactivation and transrepresion activity towards several liver gene reporters was determined in stable transfected cell lines expressing DEC1 or a mutant (lacking the DNA binding domain). The expression levels of DEC1 or its mutant were inducibly regulated by tetracycline. The reporters were constructed to include a promoter fragment (~2 kb) from genes encoding drug-metabolizing enzymes such as carboxylesterases and cytochrome P450 (CYP) enzymes. The stable transfected lines were cultured in the presence or absence of tetracycline and then transiently transfected with a promoter reporter and the pRL-TK plasmid (transfection efficiency control). After a 24-hr incubation, the reporter activities were determined with a dual luciferase system. The activity from cells cultured in the presence of tetracycline was used to compare with the activity of cells cultured in the absence of this antibiotic. The ratio of two values was used as an indicator of DEC1-mediated effect. Among ten reporters used, four reporters including CYP2C8, 9, 19 and 3A4 were markedly repressed by DEC1 (~50%). The repression was observed only in cell line expressing full-length DEC1 but not the mutant, suggesting that repression of these reporters requires DNA binding. Factors such as cAMP and hypoxia are known to cause up-regulation of DEC1. In rats these factors are shown to down-regulate several CYP enzymes. The data presented likely provide a novel mechanism regarding the suppression of liver specific gene expression.

201 SELECTIVE MODIFICATION OF CYS186 IN RAT LIVER CARBONIC ANHYDRASE III BY ACRYLONITIRLE *IN VIVO*.

D. E. Nerland, J. Cai and F. W. Benz. *Pharmacology and Toxicology, Univ. of Louisville Medical School, Louisville, KY.*

Covalent binding of reactive chemical species to tissue proteins is a common, but poorly understood, mechanism of toxicity. Identification of the proteins and the specific amino acid residues within the proteins that are chemically modified will aid our understanding of the toxification/detoxification mechanisms involved in covalent binding. Acrylonitrile (AN) is a commercial vinyl monomer that is acutely toxic and readily binds to tissue proteins. Total covalent binding of acrylonitrile to tissue proteins is highly correlated with acute toxicity. Two-dimensional polyacrylamide gel electrophoresis and autoradiography were used to locate proteins in male rat liver cytosol that are radiolabeled following administration of [^{14}C]AN *in vivo*. Five intensely labeled proteins of approximately 30 kD were prominent in the autoradiogram. Tryptic peptide mapping by matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) mass spectrometry was used to identify all five of the proteins as carbonic anhydrase III (CA III). HPLC of the tryptic digests combined with MALDI-TOF mass spectrometry were used to localize the radiolabel to tryptic fragment T22 containing amino acids 171-187. This tryptic fragment contains two cysteine residues (Cys181 & Cys186) in the rat CA III sequence. However, using MALDI-TOF mass spectrometry, we were not able to determine which of the two residues is modified by AN. Electrospray ionization ion-trap mass spectrometry was used to sequence the peptide and establish that only Cys186 is labeled. Thus, although AN is considered to be highly reactive, our data indicate that it does not react indiscriminately with rat CA III but rather is selective for one out of five cysteine residues, namely Cys186. Rat liver CA III has previously been shown to protect cells against oxidative stress. These data suggest that CA III is also capable of scavenging reactive xenobiotics and may help prevent covalent binding to more critical macromolecules. Supported by NIEHS ES06141.

202 THE N-TERMINAL REGION OF RAT PREGNANE X RECEPTOR POTENTIATES THE TRANSACTIVATION OF THE WILD-TYPE RECEPTOR AND COREPRESSOR SUN REVERSES THE POTENTIATION EFFECT.

H. Zhang and B. Yan. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

The pregnane X receptor (PXR) is shown to interact with a wide array of dissimilar compounds and confer induction of cytochrome P450 3A (CYP3A) enzymes. The PXR is structurally divided into a DNA binding domain, a ligand binding domain and an N-terminal uncharacterized sequence. We recently isolated from a rat liver library a mutant PXR cDNA designated rPXR-2. This cDNA had an insertion in the region encoding the DNA binding domain. As a result, rPXR-2 produced at least two polypeptides: the N-terminal uncharacterized and the incomplete C-terminal ligand binding domain. Co-transfection experiments demonstrated that rPXR-2 showed no transactivation activity toward a CYP3A reporter. However, rPXR-2 was shown to potentiate the transactivation activity of the wild-type PXR (rPXR-1). Dissecting experiments showed that the N-terminal uncharacterized sequence had the potentiation activity. Such a potentiation effect, however, was reversed by corepressor SUN. These findings suggest that suggests that PXR transcription complex contains a co-repressor and increased truncated PXR levels deplete the co-repressor pool, which represents a novel signaling mechanism in regulating the expression of genes encoding drug-metabolizing enzymes.

203 1, 2-DICHLOROBENZENE MEDIATES THE PRODUCTION AND RELEASE OF FACTORS IN HEPATOCYTES THAT ENHANCE KUPFFER CELL ACTIVITY.

H. S. Younis[1], A. R. Parrish[2], J. J. Jang[1] and J. G. Sipes[1]. [1]*Pharmacology & Toxicology, University of Arizona, Tucson, AZ and* [2]*Medical Pharmacology & Toxicology, Texas A&M University, College Station, TX.*

1, 2-Dichlorobenzene (1, 2-DCB), a potent hepatotoxicant in Fischer-344 (F-344) rats, produces hepatocellular oxidative stress as a result of 1, 2-DCB bioactivation followed by a second oxidative burst mediated by activated Kupffer cells (KC). KC activation is responsible for the extensive hepatocellular necrosis associated with 1, 2-DCB. The hypothesis of this work is that KC activation, in part, is caused by cytokines and/or chemokines produced and released from compromised hepatocytes. Incubation of hepatocytes with 1, 2-DCB (3.6 umol) enhanced the production and release of cytokine induced neutrophil chemoattractant factor (CINC) by 2.2-fold and increased mRNA expression of macrophage migration inhibitory factor. These two proteins may activate KC. The production and release of CINC was not observed in hepatocytes incubated with 1, 4-dichlorobenzene (a nonhepatotoxic isomer) or L-buthionine sulfoxamine (to deplete glutathione). Interestingly, the receptor for CINC, CXC Receptor 2, was expressed on KC as determined by immunohistochemical analysis. When conditioned media from 1, 2-DCB (3.6 umol) treated hepatocytes was incubated with KC these macrophages had increased transcription factor NF-kB binding activity (4.6-fold greater than control) and enhanced release of nitric oxide (21% above control). Collectively, these data suggest that 1, 2-DCB triggers a cascade of molecular processes in hepatocytes that promote the expression and release of oxidant sensitive chemokines. These products signal the activation of KC and the upregulation of the inflammatory response leading to the progression of 1, 2-DCB induced liver damage. (Supported in part by NIEHS Grant (ES06094), The Coca-Cola Foundation and an AFPE Fellowship).

204 DIORTHO CHLORINE SUBSTITUTED PCB CONGENERS ACTIVATE MITOGEN ACTIVATED PROTEIN KINASES INDEPENDENT OF PROTEIN KINASE C ACTIVATION IN JB6 MOUSE EPIDERMAL CELLS.

B. V. Madhukar and O. Hernandez-Maldonado. *Pediatrics/Human Development, Michigan State University, East Lansing, MI.*

Polychlorinated biphenyls (PCBs) are widespread environmental contaminants that evoke a variety of toxic effects including carcinogenicity in experimental models. The co-planar PCB congeners bind with the Ah receptor (AhR) and their toxic effects are most likely mediated through the AhR. The di-ortho chlorinated non-coplanar PCBs congeners do not bind with the AhR. Their toxic effects may, therefore, occur independent of AhR. The mechanisms of their toxic interactions remain to be elucidated. In this study we examined the potential of two non-coplanar PCBs 2, 2', 4, 4'-tetrachlorobiphenyl (TCB) and 2, 2', 4, 4', 5, 5'-hexachlorobiphenyl (HCB) to activate mitogen activated protein kinase (MAPK) cell signaling cascade in JB6 mouse epidermal cells. Activation of the extracellular signal regulated kinase (ERK) group of MAPKs in JB6 cells in response to PCB exposure was assessed by western blotting using phosphorylation state specific antibodies. Treatment of the cells for one hour with 20 μM of either of these PCBs caused a six- to eight-fold increase in the activation state of the ERK-MAPKs. The activation of ERKs by these PCBs was also dose dependent and sustained for more than 12 hrs. Pre-treatment of JB6 cells with a protein kinase C (PKC) inhibitor bisindolylmaleimide (5.0 μM) attenuated ERK activation by a potent PKC activator 12-tetradecanoyl phorbol 13-acetate but not that by the PCBs. These data suggest that ortho chlorinated PCBs may cause epigenetic alterations through activation of ERK-MAPKs independent of PKC activation (supported by NIEHS Superfund grant no. ES04911).

205 THE AH RECEPTOR AND AH RECEPTOR NUCLEAR TRANSLOCATOR MEDIATE STIMULATION BY OLTIPRAZ OF THE XENOBIOTIC RESPONSE ELEMENT IN THE RAT UGT1A6 GENE.

D. J. Auyeung, F. K. Kessler and J. K. Ritter. *Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

The protective action of the chemopreventive drug, oltipraz (OTP), has been attributed in part to its selective inducing effects on phase 2 detoxifying enzymes such as glutathione-S-transferase (GST), NAD(P)H quinone oxidoreductase (NQO), and UDP-glucuronosyltransferase (UGT) isoforms 1A6 and 1A7. The mechanism of induction of GST and NQO by OTP has been reported to be mediated transcriptionally *via* antioxidant response elements (ARE), but this has not been established for UGT1A6. Previously we reported that OTP (50 μM) stimulated expression of a transfected UGT1A6-luciferase reporter plasmid in primary rat hepatocytes (PRH) and HepG2 human hepatoma cells. This effect required an intact xenobiotic-response element (XRE) located between bases -134 and -129. To confirm the role of the XRE in OTP inducibility, pGL3-promoter constructs containing 1 to 3-copies of the UGT1A6 XRE conferred responsiveness to OTP in PRH. OTP induced CYP1A mRNA as well as transfected CYP1A reporter genes, indirectly supporting the ability of OTP to induce genes under XRE control. Two lines of direct evidence support the involvement of the arylhydrocarbon receptor (AHR) and AHR nuclear translocator (ARNT) in mediating the effect of OTP on the UGT1A6 XRE. Cotransfection with AHR or ARNT expression plasmids enhanced UGT1A6 reporter plasmid induction by OTP. Electrophoretic mobility shift assays using UGT1A6 XRE oligonucleotide as probe and nuclear extracts from OTP and 3-methylcholanthrene treated HepG2 cells revealed that both agents induce specific complex formation on the UGT1A6 XRE. The specific binding was effectively competed by a CYP1A XRE oligonucleotide but not by a mutant UGT1A6 XRE oligonucleotide. Complexes were supershifted by antibodies to both AHR and ARNT. These results provide the first direct evidence that OTP may also induce biotransformation enzymes *via* an AHR-based mechanism and suggests that OTP transcriptionally activates both phase 1 and phase 2 enzymes. (Supported by ES07762 and ES078087).

206 NRF2-DEPENDENT NAD(P)H:QUINONE OXIDOREDUCTASE EXPRESSION IN MOUSE CORTICAL ASTROCYTES.

J. Lee[1,2] and J. A. Johnson[1,2]. [1]*Molecular and Environmental Toxicology, UW-Madison, Madison, WI and* [2]*School of Pharmacy, UW-Madison, Madison, WI.*

The antioxidant responsive element (ARE) mediates transcriptional regulation of NAD(P)H:quinone oxidoreductase (NQO1). Previously, we demonstrated that ARE activation depends on Nrf2 and that oxidative stress is not involved in tert-butylhydroquinone (tBHQ)-mediated ARE activation in IMR-32 human neuroblastoma cells. In this study, we report that b-zip transcription factor Nrf2 plays a major role in transcriptional activation of NQO1 in mouse cortical astrocytes. For this study, we used primary cortical astrocytes of newborn pups from a Nrf2+/- X Nrf2+/- breeding. Nrf2-/- astrocytes showed markedly decreased basal NQO1 enzymatic activity and no induction by tBHQ compared to Nrf2+/- or Nrf2+/+ astrocytes. In addition, ARE-luciferase reporter gene expression was decreased in Nrf2-/- astrocytes compared to Nrf2+/- or Nrf2+/+ astrocytes in transient transfection experiment. Finally, decreased reporter gene expression was restored by overexpression of wild-type Nrf2 in Nrf2-/- astrocytes, and ARE-luciferase gene expression in Nrf2+/- astrocytes was completely blocked by overexpression of dominant negative Nrf2. Previously we demonstrated Nrf2 nuclear translocation is the critical event for ARE activation in IMR-32 cells. Similarly, tBHQ treatment induced nuclear translocation of Nrf2 in mouse cortical astrocytes. Taken together, these data suggest that both basal and inducible NQO1expression are dependent on Nrf2 in mouse astrocytes. (Funded by ES08089, ES10042, BWF New Investigator Award).

207 INVOLVEMENT OF HEPATOCYTE NUCLEAR FACTOR-1 IN THE REGULATION OF RAT UDP-GLUCURONOSYLTRANSFERASE 1A6 (UGT1A6) GENE.

J. K. Ritter, F. K. Kessler and D. J. Auyeung. *Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

UDP-glucuronosyltransferase 1A6 (UGT1A6) facilitates the removal of phenolic compounds from the body, thereby preventing their further metabolism and subsequent toxicity. UGT1A6 exhibits a complex pattern of tissue and inducer-specific expression. A possible basis for this complex pattern was suggested in a previous study identifying a second transcription unit (class 2) giving rise to UGT1A6. The class 2 transcript utilizes an alternative promoter designated "UGT1A6P2" which, on the basis of RT-PCR and RNAse protection data, was found to be highly expressed in liver, kidney, and GI tract relative to other extrahepatic tissues. The observation that an apparent hepatocyte nuclear factor-1 (HNF1)-binding site resides in the region immediately flanking UGT1A6P2 (bases -52 to +38) suggested a possible mechanism for this profile of expression. The current study was carried out to assess the functionality of this putative HNF1 binding site. DNAse I footprinting assays suggested specific binding by nuclear extract from rat liver to this site. This binding was confirmed using electrophoretic mobility shift assays. Nuclear extracts from rat liver and HepG2 cells exhibited high binding activity, whereas Hepa1 extract exhibited no detectable binding. The specificity of binding was confirmed in competition assays. Antibodies to HNF1α and to a lesser extent HNF1β resulted in a visible supershift in mobility of the complex. The functionality of this site in liver is supported by (1) the reduced expression of a UGT1A6P2 reporter in HepG2 cells when the HNF1 site is mutated and (2) the enhanced expression from UGT1A6P2 in both HepG2 and Hepa1 cells when either HNF1α or HNF1β are overexpressed. In contrast, the UGT1A6P1 promoter does not appear to contain a consensus HNF1 site and shows lower responsiveness to overexpression of HNF1α or HNF1β. These data provide a possible basis for the high expression of the UGT1A6 "P2" promoter observed in liver and other tissues known to be enriched in HNF1. (Supported by ES07762 and ES078087).

208 COMPARISONS AMONG PERFLUORINATED COMPOUNDS OF EFFECTS ON GAP JUNCTIONAL INTERCELLULAR COMMUNICATION.

J. P. Giesy[1], W. Y. Hu[1], P. D. Jones[1], B. L. Upham[2] and J. E. Trosko[2]. [1]*National Food Safety and Toxicology, Michigan State University, East Lansing, MI and* [2]*Department of Pediatrics and Human Development, Michigan State University, East Lansing, MI.*

Gap Junctional Intercellular Communication (GJIC) is the major pathway of intercellular signal transduction, thus is very important for normal cell growth and function. Studies have demonstrated the ability of some perfluorinated organics to distrupt GJIC in *in vitro* cell culture assays. Recent studies have revealed a global distribution of perfluorinated compounds, especially perfluorooctane sulfonic acid (PFOS), in the environment. Therefore, the effects of PFOS, perfluorooctanoic sulfonamide (PFOSA), perfluorohexane sulfonate (PFHS) and perfluorobutylic sulfonate (PFBS) on GJIC were studied using rat liver epithelial (WB-F344) cell line and Carvan dolphin kidney epithelial (CDK) cell line. Effects on GJIC were measured using the scrape loading dye technique. PFOS, PFOSA and PFHS were found to inhibit GJIC in a dose dependent fashion, and this inhibition occurred rapidly and reversibly. EC50s for inhibition of GJIC in rat cells were 29.96, 36.6 and 122 uM (15, 18.3 and 61 mg/L) for PFOS, PFOSA and PFHS respectively. PFBS showed no significant effects of GJIC within the concentration range tested. A structure activity relationship was established based on the four tested perfluoro compounds, and it was indicated that the inhibitory effect was determined by the length of fluorinated tail not the functional group. Since the results from two cell lines were comparable to each other, it was also suggested that the inhibitory effects of selected perfluorinated compounds on GJIC were neither species- nor tissue-specific. The inhibition of GJIC observed in *in vitro* was confirmed in rats exposed to PFOS *in vivo* with a LOEC based on liver accumulation of PFOS of 54 ppm

(108 mg/L). Because of the relatively great concentrations of PFOS accumulated in liver in the *in vivo* experiments determination of NOECs based on tissue concentrations was not possible.

209 DISULFIRAM INDUCES SKELETAL MUSCLE DEGENERATION AND BEHAVIORAL ALTERATIONS IN LONG EVANS RATS.

K. J. Voigt-Blum and L. D. Trombetta. *St. John's University, Jamaica, NY.*

Disulfiram is a drug from the family of reactive compounds known as Dithiocarbamates. It is used clinically, industrially and agriculturally. It is established that these compounds promote the chelation of metals, interact with sulfhydral groups, enhance oxidative reactions, inhibit many metal-dependent and sulfhydral enzyme systems and adversely affect the CNS and PNS. Disulfiram has been shown by transmission electron microscopy to cause skeletal muscle degeneration in rats after 9 weeks of oral treatment with 1500 mg/kg, characterized by ultrastructural changes including disintegration and disorientation of myofilaments characterized by fiber splitting and ultimate loss of cross striations, vacuolization and necrosis. In this study, male Long Evans rats treated by oral intubation with Disulfiram at 750 mg/kg in a polyethylene glycol 400 vehicle or treated with vehicle alone, 3x/week were sacrificed at 1, 3 and 6 weeks. Skeletal muscle (vastus medialis) was dissected and fixed in Bouin's fixative followed by 10.0% neutral buffered formalin (pH 7.4). Sections were stained with hematoxylin and eosin (H&E), Mallory's phosphotungstic acid hematoxylin (PTAH) and Masson's trichrome methods. Additional samples were used for determination of malondialdehyde (MDA) and 4-hydroxyalkenals (4-HNE) using a lipid peroxidation assay. Behavioral studies included the open field test and hind-limb splay angle. In all rats given Disulfiram for 6 weeks, a focal subacute myofibrillary degeneration was observed characterized by swollen and disrupted fascicles. Treated animals showed alterations in locomotor activity associated with increased excitability as measured by number of squares traversed and number of rears. Decreased body weight gain as compared to controls was seen. Preliminary results showed no changes in lipid peroxidation among groups.

210 MERCURY INDUCES CYTOTOXICITY, AND TRANSCRIPTIONALLY ACTIVATES STRESS GENES IN HUMAN LIVER CARCINOMA ($HEPG_2$) CELLS.

P. B. Tchounwou[1], D. Sutton[1], N. Ninashvili[1] and E. Shen[2]. [1]*Molecular Toxicology Research Laboratory, Jackson State University, Jackson, MS and* [2]*Xenometrix Research Laboratory, Xenometrix, Inc., Boulder, CO.*

Mercury is a non-essential element that exhibits a high degree of toxicity to humans and animals. Exposure to mercury has been associated with a significant number of adverse health effects including: cardiovascular disease, anemia, developmental abnormalities, neurobehavioral disorders, kidney and liver damage, and cancer in some cases. In several studies, the toxicity of mercury has been attributed to its high affinity to protein-containing sulfhydryl groups. However, little is known regarding the molecular mechanisms by which mercury exerts its toxicity, mutagenesis, and carcinogenesis. This research was therefore designed to assess the cellular and molecular responses of human liver carcinoma cells following exposure to mercury. Cytotoxicity was evaluated using the MTT-assay for cell viability, while the gene profile assay was performed to measure the transcriptional activation of stress genes in thirteen different recombinant cell lines generated from HepG2 cells. Cyctotoxicity experiment yielded a LD_{50} value of 3.5 ± 0.6 ug/mL upon 48 hours of exposure, indicating that mercury is highly toxic. A dose-response relationship was recorded with respect to gene induction. Overall, nine out of the thirteen recombinant cell lines tested showed inductions to statistically significant levels ($p<0.05$). At 2.5 ug/mL of mercury, the average fold inductions were 5.2 ± 0.9, 21.4 ± 3.9, 7.0 ± 6.2, 6.8 ± 1.1, 2.7 ± 1.0, 4.5 ± 2.0, 7.5 ± 6.0, 2.2 ± 0.7, and 2.5 ± 0.3, for GSTYa, HMTIIA, *c-fos*, HSP70, CRE, *p*53RE, GADD153, GADD45, and GRP78, respectively. These results indicate the potential of mercury to undergo biotransformation in the liver (GSTYa), and to cause protein damage (HMTIIA, HSP70 and GRP78), cell proliferation (*c-fos*), metabolic perturbation (CRE), growth arrest and DNA damage (GADD153, GADD45), and apoptosis (p53RE). No significant inductions ($p>0.05$) were observed for CYP1A1, XRE, NF*k*BRE, and RARE. (Research supported by NIH-RCMI Grant No. 1G12RR13459).

211 PHOSPHATIDYLINOSITOL 3-KINASE REGULATES ACTIN-MEDIATED NUCLEAR TRANSLOCATION OF NF-E2-RELATED FACTOR 2 (NRF2) FOR RGSTA2 INDUCTION BY *TERT*-BUTYLHYDROQUINONE.

S. G. Kim, K. W. Kang, J. W. Park, S. J. Lee and H. J. Kim. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Expression of phase II detoxifying genes is regulated by Nrf2-mediated antioxidant response element (ARE) activation. We previously showed that phosphatidylinositol 3-kinase (PI3-kinase) plays an essential role in ARE-mediated rGSTA2 induction by oxidative stress. In view of the fact that the signaling pathways of platelet-derived growth factor (PDGF) β receptor tyrosine kinase (RTK) and PI3-kinase control microfilaments and translocation of actin-associated proteins, the current study was designed to investigate the role of these kinases in the rise of $[Ca^{2+}]i$ and actin-mediated translocation of cytoplasmic Nrf2 to nucleus. tert-Butylhydroquinone (t-BHQ) phosphorylated PDGF β receptor, and stimulated a rise in $[Ca^{2+}]i$ and nuclear translocation of Nrf2 in H4IIE cells, which were prevented by pretreatment of the cells with PDGF RTK or PI3-kinase inhibitors (AG1295; wortmannin / LY294002). Chelation of $[Ca^{2+}]i$ suppressed Nrf2 migration and rGSTA2 induction. t-BHQ relocalized Nrf2 in concert with changes in actin microfilament architecture, as visualized by superposition of immunochemically stained Nrf2 and fluorescent phalloidin-stained actin. Furthermore, t-BHQ increased the level of nuclear actin, co-immunoprecipitated with Nrf2, which returned to that of control by pretreatment of the cells with PI3-kinase inhibitors. Cytochalasin B, an actin disruptor, alone stimulated actin-mediated nuclear translocation of Nrf2 and ARE-dependent rGSTA2 induction. The ARE band intensity was decreased by anti-Nrf2 or anti-actin antibody. In contrast, phalloidin, an agent that prevents actin filaments from depolymerization, inhibited Nrf2 translocation and rGSTA2 induction by t-BHQ. Thus, PI3-kinase signaling pathway regulates a rise in $[Ca^{2+}]i$ and rearrangement of actin microfilaments in response to t-BHQ. Also, depolymerization of actin causes actin-bound Nrf2 to translocate into nucleus and stimulates binding of the complex to ARE for rGSTA2 induction.

212 TRANSCRIPTIONAL ACTIVATION OF STRESS GENES, AND CYTOTOXICITY IN HUMAN LIVER CARCINOMA (HEPG2) CELLS EXPOSED TO PENTACHLOROPHENOL.

W. C. Dorsey[1], P. B. Tchounwou[1], A. B. Ishaque[1] and E. Shen[2]. [1]*Molecular Toxicology Research Laboratory, Jackson State University, Jackson, MS and* [2]*Xenometrix Research Laboratory, Xenometrix, Inc., Boulder, CO.*

Pentachlorophenol (PCP) is a biocidal chemical with several industrial, agricultural, and domestic applications. There is accumulating evidence indicating that PCP is highly toxic to humans, with major target organs including the lung, liver, kidneys, heart, and brain. Evidence of PCP-induced mutagenicity, and carcinogenicity has also been demonstrated in recent studies. However, little is known regarding its molecular mechanisms of toxicity. This research was therefore designed to assess the cellular and molecular responses of $HepG_2$ cells following exposure to PCP. Cytotoxicity was evaluated using the MTT-assay for cell viability, while the CAT-Toxicology (L) assay was performed to measure the transcriptional activation of stress genes in thirteen different recombinant cell lines generated from $HepG_2$ cells. The cyctotoxicity experiment yielded a LD_{50} value of 23.4 ± 5.6 ug PCP /mL upon 48 hrs of exposure, indicating that PCP is acutely toxic. A dose-response relationship was recorded with respect to gene induction. For example, fold inductions of CYP1A1 were 1.0 ± 0.0, 1.0 ± 0.0, 1.3 ± 0.5, 6.3 ± 4.3, and 22.5 ± 3.5 for 0, 6.2, 12.5, 25, and 50 ug PCP /mL, respectively. Overall, five out of the thirteen recombinant cell lines tested showed inductions to statistically significant levels ($p<0.05$). At 50 ug PCP /mL, the average fold inductions were 22.5 ± 3.5, 52.8 ± 2.5, 8.4 ± 1.9, and 12.5 ± 6.8, for CYP1A1, XRE, HMTIIA, *c-fos*, and GADD153, respectively. These results indicate the potential of PCP to undergo Phase I biotransformation in the liver (CYP1A1, XRE), to cause cell proliferation (*c-fos*), growth arrest and DNA damage (GADD153), and to influence the toxicokinetics of metal ions (HMTIIA). Marginal inductions were recorded for HSP70, CRE, RARE, GADD45, and GRP78. Within the dose range (0-100 ug/mL) tested, no significant inductions ($p>0.05$) were observed for GSTYa, NF*k*BRE, and p53RE. (Research supported by Title III Grant No. PO31B990006).

213 UNRESTRICTED BASE PAIRS WITHIN THE ARE/EpRE CORE SEQUENCE OF *c-Ha-ras* CONFER UNIQUE PROTEIN BINDING SPECIFICITY IN VASCULAR SMOOTH MUSCLE CELLS.

K. P. Miller and K. S. Ramos. *Faculty of Toxicology and Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

BENZO(A)PYRENE (BaP)-induced oxidative stress activates nuclear protein binding to human *c-Ha-ras* antioxidant/electrophile response element (ARE/EpRE) in vascular smooth muscle cells. The minimal consensus sequence of the ARE/EpRE has been defined as 5'-GTGACNNNGC-3'. Using a 27 base pair (bp) oligonucleotide containing the core *c-Ha-ras* ARE/EpRE sequence in genomic context (hHaras27), two specific DNA:protein complexes of variable inducibility are resolved in electrophoretic mobility shift assays in response to BaP and its metabolites, and shown to be of different protein composition. Flanking sequences to the ARE/EpRE core of *c-Ha-ras* participate in the regulation of nuclear protein complex assembly. The studies presented here were conducted to evaluate the site speci-

ficity of proteins binding to the *c-Ha-ras* ARE/EpRE core. Nuclear protein binding to hHaras27 was absent upon incubation of nuclear extracts with the same oligonucleotide containing a fully mutated ARE/EpRE core region (hHaras27WOUC). Low molecular weight proteins (p23 and p25) previously shown to interact with the ARE/EpRE core of *c-Ha-ras* were not detected upon UV crosslinking of nuclear protein to this mutated sequence, implicating these proteins in core sequence binding. UV crosslinked binding of p23 and p25 to an oligonucleotide comprising only the core *c-Ha-ras* ARE/EpRE sequence (hHaras10) could not be competed by 10bp ARE/EpRE core sequences of human NQO_1 and rat GSTA1 genes, indicating that recognition by these proteins may be unique to the *c-Ha-ras* ARE/EpRE. The only difference in sequence between these ARE/EpRE cores is the "NNN" sequence of the consensus site, suggesting that p23 and p25 bind specifically to the core *c-Ha-ras* ARE/EpRE, and that unrestricted base pairs in the consensus sequence may confer both specificity and uniqueness of protein binding to the ARE/EpRE core. (Supported by NIH grants ES04849 and ES09106 to KSR. KPM is a predoctoral fellow on NIEHS Training Grant ES07273).

214 UPREGULATION OF CYTOKINE RELEASE BY SULFUR MUSTARD EXPOSURE IS MEDIATED BY THE p38 MAP KINASE SIGNALING PATHWAY.

J. F. Dillman, K. L. McGary, J. H. Clark, C. R. Braue and J. J. Schlager. *Applied Pharmacology, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (SM) is a potent alkylating agent that induces skin vesication after cutaneous exposure. Previous work has revealed that SM induces a significant increase in the production of inflammatory cytokines, including IL-8, IL-6, TNF-α, and IL-1β, in cultured keratinocytes and skin. The p38 MAP kinase signaling pathway is activated in response to cellular stress and has been implicated in the upregulation of cytokines in response to inflammatory stimuli. We investigated whether the p38 pathway mediates inflammatory cytokine upregulation in response to SM exposure. A dose-response study in cultured human epidermal keratinocytes (HEK) revealed that p38 is phosphorylated at SM concentrations that are considered to be vesicating doses (≅100 μM) but not at lower doses, which result in DNA damage but not vesication. A time course at the 200 μM exposure revealed that p38 phosphorylation is induced by 15 minutes post-exposure, peaks at 30 minutes and is sustained at peak levels until 8 hours post-exposure. Examination of MKK3/MKK6, which are two closely related kinases that activate p38, revealed a slightly faster rate of phosphorylation of MKK3/MKK6 compared with phosphorylation of p38. Assay of the SM-exposed HEK culture media for cytokines revealed that exposure to 200 μM SM increased IL-8, IL-6, TNF-α, and IL-1β beginning at two hours post-exposure, but had little effect on IL-10 or IL-12(p70). When cells exposed to 200 μM SM were treated with the p38 inhibitor SB203580, the levels of IL-8, IL-6, and TNF-α were decreased ~80% and the levels of IL-1β were decreased ~60% when compared with cells that were not treated with SB203580. These results show that the p38 MAP kinase signaling pathway is an important mediator of SM-induced cytokine production and suggest that directly targeting this signaling pathway with pharmacological inhibitors may alleviate the profound inflammatory response elicited by cutaneous SM exposure.

215 CLONING AND CHARACTERIZATION OF THE ATLANTIC KILLIFISH RETINOBLASTOMA TUMOR SUPPRESSOR cDNA AND INTERACTION WITH THE ARYL HYDROCARBON RECEPTOR.

R. R. Merson, S. I. Karchner and M. E. Hahn. *Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.*

The retinoblastoma tumor suppressor gene product (pRB) controls the cell cycle by repressing transcription of genes necessary for S-phase entry, interacting with the p53 apoptosis pathway, and facilitating terminal differentiation. Recent work on mammals has demonstrated that pRB interacts with the aryl hydrocarbon receptor (AHR), a member of the bHLH-PAS family of transcription factors. The AHR mediates the toxic effects of TCDD (2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin) and related compounds, but the endogenous ligand and the physiological role of the AHR have yet to be revealed. The Atlantic killifish *Fundulus heteroclitus* expresses two paralogs of the AHR (AHR1 and AHR2), whereas mammals express only one AHR. It is likely that the pleiotropic functions of the one mammalian AHR are partitioned into the two fish paralogs. We hypothesize that *Fundulus* AHR1 and AHR2 differ in their ability to interact with pRB and regulate the cell cycle. In support of this hypothesis, *Fundulus* AHR1 contains the LXCXE-motif and the glutamine-rich region that interact with mammalian pRB, whereas *Fundulus* AHR2 has neither pRB-binding site. We report here the cDNA cloning of *Fundulus* RB by RT-PCR with degenerate primers and RACE. The *Fundulus* RB cDNA (2739 bp) encodes a 913 amino acid protein with a predicted weight of 103.5 kDa. The *Fundulus* pRB amino acid sequence is 50% and 75% identical to the human and medaka pRB sequences, respectively. The A and B pockets (combined) of *Fundulus* pRB are 67% and 81% identical to human and medaka pRB, respectively, and the putative LXCXE-binding backbone is absolutely conserved among these three proteins. Experiments are underway to test interactions between pRB and the two killifish AHR paralogs. Supported by NIH Grants 1F32ES05935, ES07381 (Superfund), and ES06272, and by a grant from the Donaldson Charitable Trust.

216 RUBRATOXIN B INDUCED THE SECRETION OF CYTOKINES IN CULTURED CELLS.

H. Nagashima, K. Nakamura and T. Goto. *National Food Research Institute, Tsukuba, Japan.* Sponsor: F. Matsumura.

Rubratoxin B is a potent hepatotoxic and teratogenic mycotoxin produced by certain *Penicillium* fungi. To date, biochemical, cytological and serological changes have been reported, however, the mechanism of its toxicity remains unclear. In this study, induction of cytokine secretion by rubratoxin B was investigated using cultured cells. Tumor necrosis factor (TNF)-α and interleukin (IL)-8 were secreted from 40 and 80 μg/ml rubratoxin B-treated HL60 cells. In 20 and 40 μg/ml rubratoxin B-treated HL60 cells, monocyte chemotactic protein (MCP)-1 was released. These rubratoxin B-induced cytokines are known to promote liver myelocytic cell infiltration, and activate cytokine-recruited cells. As a result, recruited myelocytic cells are considered to contribute to hepatic injury. Since tyrosine kinases are known to play pivotal roles in signal transduction, we investigated the effects of tyrosine kinase inhibitors genistein and emodin. Genistein reduced the release of all three cytokines from rubratoxin B-treated HL60 cells. Likewise, emodin diminished the secretion of MCP-1. Alternatively, emodin reversed on the secretion of TNF-α, and the release of IL-8 was not affected. Since emodin did not impede rubratoxin B-caused TNF-α and IL-8 secretion in HL60 cells, they appeared to be regulated differently from MCP-1 secretion, suggesting that rubratoxin B exerts its toxicity using two or more signal transduction pathways. Other than HL60 cells, HepG2 cells were investigated. Rubratoxin B induced the secretion of IL-8 in HepG2 cells. However, not like the case of HL60 cells, neither TNF-α nor MCP-1 was detected in rubratoxin B-treated HepG2 cells. These results suggest that HepG2 cells are regulated differently from HL60 cells in the secretion of cytokines.

217 A 13 WEEK ORAL TOXICITY STUDY OF SENNA-MIS IN THE ALBINO RAT WITH AN 8-WEEK RECOVERY PERIOD.

J. M. Mitchell[1], S. McPherson[2], U. Mengs[3], T. Gregson[2] and J. Tigner[1]. *[1]NDSE, Purdue Pharma, Ardsley, NY, [2]Toxicology, CTBR, Montreal, PQ, Canada and [3]Toxicology and Pathology, Madaus, Koln, Germany.*

Senna, a known laxative derived from plants, was administered by oral gavage to Sprague-Dawley (Crl:CD®(SD)BR) rats once daily at dose levels of 0, 100, 300, 750 or 1500 mg/kg/day for up to 13 consecutive weeks followed by an 8-week recovery period for selected animals. Dose and treatment-related clinical signs included abnormal feces (abnormal consistency and color) which were seen to varying degrees from animals from all treated groups. Animals receiving 750 or 1500 mg/kg/day had significantly reduced body weight gain and increased water consumption. Notable changes in electrolytes were seen in both serum (increases in sodium, potassium and chloride) and urine (decreases in sodium and increase in potassium and chloride levels). Darker urine was also seen in these groups. At both the terminal and recovery necropsies, an increase in absolute and relative kidney weights (relative to both body and brain weights) was seen for male and female animals receiving 750 and/or 1500 mg/kg/day. Dark discoloration of the kidneys was observed in animals receiving 300 mg/kg/day or above. Histopathological changes following 13-weeks of treatment were seen in the kidneys of animals receiving 300 mg/kg/day and above (slight to moderate, tubular basophillia and tubular pigment deposits). In addition, for all treated groups, minimal to slight hyperplasia in the colon and rectum and minimal hyperplasia of the squamous epithelium of the stomach were recorded. Following 8 weeks of recovery, with the exception of the brown pigment in the kidney, these pathological findings were not evident. Thus, the biochemical and histopathological changes seen after 13 weeks of treatment with Senna, significantly reversed following 8 weeks of recovery.

218 DECREASED GLUTATHIONE LEVELS AND CELL VIABILITY IN NEURONAL AND GLIAL CELLS EXPOSED TO FUMONISIN B1.

H. D. Stockmann-Juvala and K. M. Savolainen. *Dept of Industrial Hygiene and Toxicology, Finnish Institute of Occupational Health, Helsinki, Finland.*

Fumonisin B1 (FB1) is a toxin produced by the fungus *Fusarium verticillioides* (= *F. moniliforme*). FB1 is commonly present in *Fusarium* infected corn, but it is thought that FB1 also could be present in buildings with moisture and mold problems. FB1

is known to cause for example leukoencephalomalacia in horses, pulmonary oedema in pigs and liver cancer in rats. The aim of this study was to try to clarify the mechanisms whereby FB1 affects neuronal and glial cells. Four different cell lines were used: human SH-SY5Y neuroblastoma cells, human U-118MG glioblastoma cells, mouse GT1-7 hypothalamic cells and rat C6 glioblastoma cells. All cell lines were grown in Dulbecco's Modified Eagle Medium in bottles and exposed to FB1 at concentrations of 0.1, 1, 10, 30 and 100 μM for 0-144 h in 6- or 48-well plates. Changes of intracellular glutathione (GSH) levels, cell viability and caspase-3 activity were measured with fluorescent probes, monochlorobimane, propidium iodide and a fluorescent caspase-3 substrate, respectively. Decreased GSH levels were observed in all cell lines after exposure to 100 μM FB1 for 144 h. In U-118MG, GT1-7 and C6 cells decreased GSH levels were also seen at earlier time points. Cell viability of all cell lines exposed to FB1 (1-100 μM) for 144 h was lower than controls. The viability of cells was not affected at earlier time points. Increased caspase-3 levels were observed in GT1-7 cells exposed to 10, 30 and 100 μM FB1 for 72 h. No caspase-3 activation was seen in the other cell lines. The decreased levels of GSH in all cell lines exposed to FB1 for 144 h indicate that long term exposure to FB1 may harm neuronal and glial cells, and the lowered cell viability at this same time point confirms this observation. The activation of caspase-3 in GT1-7 cells suggests that cell death may occur by apoptosis in this cell line. Supported by the Academy of Finland, Finnish Research Programme on Environmental Health.

219 ANALYTICAL METHOD VALIDATION OF KAVA KAVA POWDERED EXTRACT DOSED IN CORN OIL.

H. A. Weber[1], A. E. Hodges[1], S. M. Barnes[1], S. L. Weilert[1], R. K. Harris[1], A. P. Clark[1], D. Overstreet[2] and C. Smith[2]. [1]*Midwest Research Institute, Kansas City, MO and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

Kava kava powdered extract (kava) is an herbal supplement that has been selected for toxicological evaluation by the NIEHS. A method was validated for the analysis of kava in corn oil formulations. Neat kava and corn oil dosed with kava were extracted under ambient conditions and the extracts were analyzed using an isocratic HPLC method with UV detection at 220 nm. A method validation was performed over a dose range of ∽ 5 to ∽ 500 mg kava/mL corn oil. Solvent standards containing between ∽ 5 and ∽ 500 mg of kava were extracted by sonicating for 60 minutes at ambient temperature with 50 mL of methanol, corresponding to an analytical concentration of ∽ 0.1 to ∽ 10 mg kava/mL methanol. Spiked corn oil standards containing ∽ 5 mg kava/mL corn oil and ∽ 500 mg kava/mL corn oil (analytical concentration of ∽ 0.1 to ∽ 10 mg kava/mL methanol) were extracted in the same manner. All samples were diluted to a final analytical concentration of ∽ 0.1 mg kava/mL methanol. Kavain, one of the major kavalactones, was used to prepare quantitation standards (∽ 3 to ∽ 393 μg/mL) to determine the weight percentages of kavain in kava solvent and spiked corn oil standards. The kavain quantitation standards proved to be linear ($r \geq 0.9999$) and accurate (%RE ≤ 2%). The extraction of kavain from kava solvent and spiked corn oil standards proved to be linear ($r \geq 0.9999$) and precise (%RSD ≤ 1.7%). The average % kavain extracted from the kava in the solvent standards was 6.61 ± 0.11 (s)% (n=10). The average % kavain extracted from the kava in the spiked corn oil standards was 6.65 ± 0.10 (s)% (n=10). The average extraction recovery for kavain from corn oil dosed with kava was 100.8 ± 1.5(s)%.

220 COMPARATIVE METABOLISM OF BREVETOXINS BY RAT AND HUMAN LIVER MICROSOMES.

J. M. Benson[1], T. S. Poet[2] and D. G. Baden[3]. [1]*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM,* [2]*Chemical Dosimetry Group, Battelle Pacific Northwest Laboratories, Richland, WA and* [3]*Center for Marine Science Research, University of North Carolina, Wilmington, NC.*

Karenia brevis produces a series of neurotoxic cyclic polyethers known as brevetoxins (PbTxs). Recent evidence suggests that the respiratory tract, hemopoietic, and immune systems are potential targets for PbTx toxicity following repeated exposure. We have investigated the comparative cytochrome P450-mediated metabolism of PbTx2 and PbTx3 by Sprague-Dawley (SD) rat, Fischer rat, and human liver (pool of 15 males) microsomes. Brevetoxin 2 (0.25 to 10 μg/ml incubation mixture) was incubated (37°C) with microsomes from each strain and species under conditions of linearity with respect to protein concentration and time. Control incubations were conducted with inactivated microsomes. Extent of metabolism was quantitated by determining the loss of PbTx m+1/z ion in the incubation mixture extracts by LC-mass spectrometry (LCMS). The molecular weights of possible metabolites were also determined by LCMS. The affinity of the cytochrome P450s for PbTx2 (K_m) and maximum velocity of the metabolic breakdown (V_{max}) were calculated. The V_{max}s (mean ± sem; n=3), for PbTx2 metabolism by SD rat, Fischer rat, and humans were 1.72 ± 0.42, 2.02 ± 0.47, and 1.15 ± 0.03 nmole/mg/min, respectively. The K_ms for SD rat, Fischer rat, and human microsomes were 3.80 ± 0.62, 4.98 ± 1.52, and 4.40 ± 0.55 μM, respectively. Potential metabolites, with (m+1)/z = 759, 783, 807, and 832 were found for both species. Brevetoxin 3 did not appear to undergo metabolism. Results to date suggest that rates of cytochrome P450-mediated metabolism of PbTx 2 by two strains of rats and humans are similar on a mg protein basis. Further work is needed to identify and characterize the toxicities of the metabolites. Research funded under NIH P01-ES10594ZES.

221 FLORIDA'S RED TIDE *DINOFLAGELLATE KARENIA BREVIS* MAY MODULATE ITS POTENCY BY PRODUCING A NON-TOXIC COMPETITIVE ANTAGONIST.

A. J. Bourdelais[1], J. Kubanek[2], J. Wright[1] and D. G. Baden[1]. [1]*Center for Marine Science, UNC Wilmington, Wilmington, NC and* [2]*Dept of Biology, Georgia Tech Univ, Atlanta, GA.*

Florida red tides are the result of blooms of the unarmoured *dinoflagellate Karenia brevis*. K. brevis produces 9 different highly potent polyether brevetoxins (PbTx) that bind with high affinity to site 5 of the VSSC. The relative profile of toxins produced by K. brevis depends on growth phase and strain. These two findings may explain the variable potency of individual red tide blooms. A naturally-produced competitive antagonist for brevetoxins is described. The antagonist is found at low concentrations in rapidly-growing K. brevis cells but increases to 20% of the total toxin biomass in senescent cells. The antagonist has low potency in fish bioassay (1ug/mL (n=10) and 2 ug/ml (n=5) produced no 24 hr deaths), and in 1ug/mL combination with PbTx-2 prolonged time until death by 2.5-fold. The antagonist cross-reacts in PbTx-ELISA, indicating an intact H-K ring. Low resolution ESI gave an M + 1 peak, m/z of 657.5. High resolution FAB mass spectroscopy gave a molecular ion, m/z 656.90. Proton NMR of the antagonist indicates that the C-2, C-27 and C-28 hydrogens are no longer unsaturated, and there appears to be additional sites of unsaturation within the molecule. The exomethylene hydrogen unsaturation is also missing, but there appears to be an endomethylene in conjugation with the terminal aldehyde. The structure of the antagonist appears to be similar to the hemibrevetoxins in that it has an abbreviated PbTx-2 backbone composed of at least the H-K rings and most likely include the E-K or F-K rings with further points of unsaturation on side chains. The A-ring activity region is absent. This is the first report of a competitive non-toxic ligand produced by K. brevis, and may explain the rapidly decreasing potency of red tides during their terminal phases in natural environments. It also represents an additional antagonist for nerve membrane study of marine toxins, and joins synthetic antagonists alpha- and beta-naphthoyl brevetoxins.

222 SILYMARIN DOSE-DEPENDENTLY MODULATES IMMUNE FUNCTION IN BALB/c MICE.

V. J. Johnson, Q. He, M. F. Osuchowski and R. P. Sharma. *Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Silymarin, a mixture of bioactive flavanoids isolated from Milk Thistle (*Silybum marianum*), has been used for centuries as a natural remedy and is now effectively used in the treatment of liver toxicity and disease in humans. *in vitro* studies show that silymarin can inhibit the production and damage caused by tumor necrosis factor α (TNFα). It is also a potent antioxidant both *in vitro* and *in vivo*. These studies suggest silymarin may impact the immune system but little information exists following *in vivo* exposure. Therefore, we tested the hypothesis that exposure to silymarin will modulate the inflammatory immune response. Male BALB/c mice (6/group) were treated intraperitoneally once daily for five days with 0, 10, 50 or 250 mg/kg of silymarin. Splenic cultures were stimulated with 1 μg/ml of LPS for 6 hrs following which gene expression was analyzed by reverse transcriptase-polymerase chain reaction. Silymarin exposure did not produce any signs of overt toxicity or any changes in relative organ weights. Functional examination of secondary lymphoid tissue revealed that phytohemagglutinin-induced T-lymphocyte proliferation was increased in the lowest dose group only. B-lymphocyte blastogenesis induced by lipopolysaccharide was increased following exposure to 10 and 50 mg/kg of silymarin. Flow cytometric examination of splenic lymphocyte populations showed that the absolute number of $CD3^+$ T-lymphocytes was reduced in the 10 mg/kg group only. A concomitant decrease in the $CD4^+$ T-helper cell population was evident in this group. Similarly, the expression of interleukin (IL)-2 and IL-4 were decreased in the 10 mg/kg group only. In contrast, expression of TNFα, inducible nitric oxide synthase, IL-1β and IL-6 mRNA were increased dose-dependently. The results indicate that *in vivo* exposure to silymarin results in suppression of T-lymphocyte function at low doses and stimulation of inflammatory processes at higher doses. Further studies investigating the effects of silymarin on the immune system are warranted. (Supported in part by NIH TW01009)

223 EFFECTS OF SILYMARIN ON REGIONAL BRAIN NEUROTRANSMITTER LEVELS IN BALB/c MICE.

M. F. Osuchowski[1], V. J. Johnson[2], Q. He[2] and R. P. Sharma[2]. [1]*Animal Anatomy, University Warmia and Mazury, Olsztyn, Poland and* [2]*Physiology and Pharmacology, The University of Georgia, Athens, GA.*

Natural antioxidant silymarin is a recognized remedy widely used in the treatment of liver pathologies. The effect of this flavonoid mixture upon the central nervous system is unknown. Brain amine metabolism was studied after silymarin treatment. BALB/c mice were intraperitoneally administered 0, 10, 50 or 250 mg/kg of silymarin per day in the course of 5 days. Mice were sacrificed 24 hours following the final treatment and brains were dissected into seven regions: cerebellum, medulla oblongata, hypothalamus, striatum, thalamus, hippocampus and cortex. There were no differences in brain region weights between treatment groups. High performance liquid chromatography coupled with electrochemical detection was performed to determine concentrations of norepinephrine (NE), dopamine (DA), dioxyphenylacetic acid, homovanilic acid, 5-hydroxytryptamine (5-HT) and hydroxyindoleacetic acid in discrete regions. Analysis showed changes of brain amines levels in two brain regions, the cortex and cerebellum, while no alterations in remaining regions were evident. Exposure to silymarin increased 5-HT level in cortex in a dose-dependent manner. In cerebellum elevated levels of DA and NE were detected; however, increases were only noted in animals exposed to the highest concentration (250 mg/kg) of silymarin compared to the control group. No response was observed in the striatum and hypothalamus, regions known for highest NE and DA activity. Results indicated that the overall effects of silymarin treatment upon brain amine metabolism are minor. The increases observed at the highest dose level, although significant, remained within physiological levels. It may be concluded, that silymarin is safe regarding brain amine homeostasis up to the doses employed under the present experimental conditions. (Supported in part by NIH TW01009)

224 SILYMARIN ALTERS THE EXPRESSION OF CYTOKINES IN MOUSE LIVER.

Q. He[1], M. F. Osuchowski[2], V. J. Johnson[1] and R. P. Sharma[1]. [1]*Physiology & Pharmacology, The University of Georgia, Athens, GA and* [2]*Animal Anatomy, University of Warmia and Mazury, Olsztyn, Poland.*

Silymarin is a flavanoid mixture extracted from *Silybum marianum* (St. Mary's thistle), and its main components consist of silibinin, isosilibinin, silicristin, and silidianin. It has been shown to be protective in various forms of liver diseases including alcohol- and drug-induced problems, and acute and chronic hepatitis. Silymarin may be hepatoprotective due to its antioxidant activity, increase in cellular glutathion content, membrane stabilizing effect, and increase of protein synthesis by RNA polymerase activation. The present study investigated the effect of silymarin on expressions of hepatic cytokines and factors involved in inflammatory reactions and cell growth. BALB/c mice (6-7 weeks old) were randomly divided into 4 groups of 6 mice each and treated with 5 daily intraperitoneal injections of silymarin at 0, 10, 50, or 250 mg/kg body weight. Cytokine gene expression was analyzed by reverse transcriptase-polymerase chain reaction. Silymarin treatment resulted in dose-dependent but insignificant decreases in plasma alanine aminotransferase and aspartate aminotransferase. Silymarin caused dose-dependent increases of the transforming growth factor β1 (TGFβ1) and c-*myc* expression in liver; significant differences were observed at 250 mg/kg group. Dose-related insignificant increases were noted in the expression of hepatocyte growth factor and interferon-γ. Silymarin treatment did not change the expression of tumor necrosis factor-α or class II major compatibility complex in the liver. It has been reported that TGFβ1 is fibrogenic in liver, and c-*myc* can induce cell proliferation or apoptosis under different conditions. Results suggest that long-term, high dose administration of silyamrin may prevent or induce hepatic damage due to a persistent disruption of TGFβ1 and c-*myc* expression. (Supported in part by NIH TW01009).

225 ASSESSMENT OF CYTOTOXICITY OF INDIGENOUS COSMETIC INGREDIENTS IN VERO CELLS.

S. H. Inayat-Hussain[1], M. H. Helan[2], O. B. Annuar[3], N. Shahab[2] and P. Hashim[2]. [1]*Dept. of Biomedical Science, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia,* [2]*Chemical and Industrial Biotechnology Center, SIRIM Berhad, Shah Alam, Malaysia and* [3]*Dept. of Microbiology, Universiti Kebangsaan Malaysia, Bangi, Malaysia.* Sponsor: D. Ross.

There is an increase in the application of natural products in cosmeceutical industries worldwide. In an attempt to assess the cytotoxicity of the local Malaysian plant products, an *in vitro* cytotoxicity study was carried out using a mammalian Vero monkey kidney cells. The uptake of the vital dye neutral red (NR) into the lysosomes/endosomes and vacuoles of living cells were used as a quantitative indication of cell number and viability. Indigenous cosmetic ingredients of two essential oils of Citronella (Cymbopogon nardus, also known as serai wangi) and Tea tree (Melalleuca sp.), and a commercially available natural surfactant namely Plantacare 1200 were assessed using this method. The IC_{50} value, defined as the concentration of compound that caused a 50 % reduction in the uptake of NR when compared to the controls was determined. Our results show that Citronella oil's IC_{50} value is 108.6 ± 13.2 µg/ml which is comparable to tea tree oil's IC_{50} of 113.7 ± 6.3 µg/ml. The IC_{50} of Plantacare 1200 is 79.6 ± 4.5 µg/ml, which is relatively more toxic than our two indigenous plant ingredients. In conclusion, we have demonstrated that the cytotoxicity of Citronella and Tea tree oil extracted from our local sources are relatively safe as compared to the commercially available surfactant which is used in the formulation of the cosmetics. (This study was funded by IRPA grant no. 09-01-01-0021)

226 INHIBITION OF INDUCIBLE NITRIC OXIDE SYNTHASE EXPRESSION BY SILYMARIN IN LPS-STIMULATED MACROPHAGES.

J. Kang[1], Y. Jeon[2], H. Kim[3] and K. Yang[1]. [1]*Department of Biological Sciences, Korea Advanced Institute of Science and Technology, Taejon, South Korea,* [2]*Department of Pharmacology, Chosun University, School of Medicine, Kwangju, South Korea and* [3]*Biopotency Evaluation Laboratory, Korea Research Institute of Bioscience and Biotechnology, Taejon, South Korea.*

Silymarin, a polyphenolic flavonoid antioxidant, has been shown to have anti-inflammatory, hepatoprotective, and anticarcinogenic effects. In the present study, we report the inhibitory effect of silymarin on nitric oxide (NO) production and inducible nitric oxide synthase (iNOS) mRNA expression in macrophages. *in vivo* administration of silymarin attenuated NO production of peritoneal macrophages in lipopolysaccharide (LPS)-treated mice. Silymarin also produced dose-dependent suppression of LPS-stimulated production of NO in isolated mouse peritoneal macrophages and macrophage cell line RAW264.7. Moreover, treatment of RAW264.7 with silymarin inhibitied LPS-stimulated expression of iNOS mRNA in a dose-related manner. To further investigate the mechanism responsible for reduced iNOS gene expression, we investigated the effect of silymarin on LPS-stimulated activation of NF-κB/REL, which regulates various genes involved in immune and inflammatory response. LPS-stimulated DNA binding of NF-κB/REL was inhibited by silymarin, and this effect was mediated through inhibition of phosphorylation and degradation of IκBα. NF-κB/REL-dependent reporter gene expression was also suppressed by silymarin. Collectively, these data suggest that silymarin may inhibit NO production and iNOS mRNA expression *via* inhibition of NF-κB/REL activation.

227 PBPK MODEL FOR UPREGULATION OF THE THYROID DUE TO PROLONGED PERCHLORATE EXPOSURE.

E. A. Merrill[1], R. A. Clewell[2], J. M. Gearhart[3] and P. J. Robinson[3]. [1]*OpTech Corp., Wright-Patterson AFB, OH,* [2]*Geo-Centers, Inc, Wright-Patterson AFB, OH,* [3]*Mantech Environmental Technology Inc., Wright-Patterson AFB, OH and* [4]*Mantech Environmental Technology Inc., Wright-Patterson AFB, OH.*

A preliminary model was developed to account for upregulation of thyroidal iodide (I^-) uptake after subchronic perchlorate (ClO_4^-) exposure. A previous physiologically based pharmacokinetic (PBPK) model was capable of predicting ClO_4^- induced inhibition of I^- uptake at the sodium iodide symporter (NIS) after acute perchlorate exposure, but did not account for upregulation by thyroid-stimulating hormone (TSH). Naive thyroid follicular Vmax values (approximately1.5 and 0.7 mg/hr/g tissue for I^- and ClO_4^-, respectively) were estimated by visually fitting radioiodide uptake data at baseline TSH levels (prior to ClO_4^-). TSH upregulates the thyroid by stimulating an increase in NIS synthesis, thereby increasing iodide transfer into the thyroid. In this model the increase in NIS as a result of prolonged perchlorate exposure is estimated by adjusting the thyroid follicular Vmax. A mathematical equation was derived that is capable of expressing changes in Vmax, which are dependent upon circulating serum ClO_4^- levels and perchlorate's affinity to NIS. In addition, the "upregulated" Vmax is expressed as a time dependant function. Utilizing this method, the model predicts the time and dose dependant behavior of I^- uptake in the rat thyroid during 14 days of ClO_4^- exposure.

228 TOWARDS A BBDR MODEL FOR 5-FLUOROURACIL EMBRYOTOXICITY: ADDING A PBPK MODEL AND A SUBMODEL FOR THE TIME DELAY IN THYMIDYLATE SYNTHETASE INHIBITION.

R. S. DeWoskin and R. W. Setzer. *USEPA/ORD/NHEERL, Research Triangle Park, NC.*

5-Fluorouracil (5-FU) is a widely used chemotherapeutic drug for the treatment of solid tumors, and is a known teratogen in a variety of test species. 5-FU has an extensive literature and was chosen as a prototypic toxicant to construct a biologically

based dose-response (BBDR) model for developmental toxicity (Shuey et al., 1994). Setzer et al. (2001) developed the BBDR model using a mechanistic framework for 5-FU's embryotoxicity and dose-response data provided by Lau et al. (2001). The proposed mode of action is as follows: 1. distribution of parent 5-FU to the fetus -> 2. anabolism to fluorodeoxyuridylate (FdUMP) -> 3. FdUMP inhibition of the DNA pyrimidine forming enzyme, thymidylate synthetase (TS) -> 4. depletion of the TS product, thymidine triphosphate (dTTP), and nucleotide pool perturbation -> 5. altered cell cycle and cell replication -> 6. fetal weight deficits, cell death, and dysmorphogenesis. The initial BBDR model consisted of semi-empirical submodels for steps 1-4, and parameter values derived from the dose-response data. Simulation results adequately explained the TS inhibition response, but an unexplained time delay between peak 5-FU levels and peak TS inhibition was modeled empirically. To incorporate more of the underlying physiology, the original three compartment kinetic model was replaced with a multicompartment pregnant rat PBPK model (O'Flaherty et al., 1991) that simulated the distribution of 5-FU based upon its pKa and the pH of tissues, and that accounted for growth in the maternal tissues and fetus throughout the pregnancy. The empirical model for the TS inhibition time delay was replaced with a model of the kinetics for the FdUMP-TS-folate complex formation and competition from the naturally occurring TS substrate, deoxyuridylate (dUMP). These more physiologically realistic models improved the simulation of the TS inhibition dose-response, and the utility of the model to predict effects from different dosage regimens or in different species including humans. [This abstract does not necessarily reflect EPA policy.]

229 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL PARAMETER ESTIMATION AND SENSITIVITY AND VARIABILITY ANALYSES FOR ACRYLONITRILE DISPOSITION IN HUMANS.

L. M. Sweeney[1], G. L. Kedderis[2], D. E. Strother[3] and M. L. Gargas[1]. [1]*The Sapphire Group, Dayton, OH,* [2]*CIIT Centers for Health Research, Research Triangle Park, NC and* [3]*BP, Arlington, VA.*

A physiologically based pharmacokinetic model of acrylonitrile (ACN) and cyanoethylene oxide (CEO) disposition in rats was developed (Kedderis et al., 1996) and extended to humans (Kedderis, 1997; Kedderis and Held, 1998). This work further refines previous models by refining the approach to scaling metabolic parameters from rat to human using *in vitro* data, incorporating an *in vitro-in vivo* correction factor (calculated from the rat) and reflecting species differences in liver size, enzyme content, co-factor (glutathione) concentrations, and body weight. Estimated human biotransformation rates *in vivo* were generally increased 3- to 7-fold from previous estimates. For a given exposure concentration, refined model predictions of rat and human tissue or blood CEO concentrations were generally found to be similar. Sensitivity and variability analyses were also conducted on the refined model. While many parameters contribute to the estimated variability of the model predictions, reaction rate of CEO with glutathione, hydrolysis rate for CEO, and blood:brain partition coefficient of CEO were the parameters that made the greatest contributions to variability. Improved estimates of these parameter values and their variability present an opportunity to improve the understanding of human blood and tissue dosimetry following acrylonitrile exposure.

230 A PHYSIOLOGICAL PHARMACOKINETIC MODEL BASED ON TISSUE LIPID CONTENT FOR SIMULATING INHALATION PHARMACOKINETICS OF HIGHLY LIPOPHILIC VOLATILE ORGANIC CHEMICALS.

C. Émond and K. Krishnan. *Groupe de Recherche en Toxicologie Humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada.*

The highly lipophilic volatile organic chemicals (HLVOCs) are distributed almost uniquely in the neutral lipid fraction of tissues and blood. As suggested by their high *n*-octanol:water partition coefficient (>8000), their solubility in water fraction of tissues and blood is negligible. Hypothetically then the kinetics of HLVOCs can be simulated solely with the consideration of their solubility and distribution in neutral lipid-equivalent (NLE) fractions of the tissues and blood. The objectives of the present study were therefore: (i) to develop a physiological pharmacokinetic model based on NLE content of tissues and blood, and (ii) to apply this model framework for simulating the inhalation pharmacokinetics of HLVOCs (i.e., *d*-limonene, α-pinene, 1, 2, 4-trimethylbenzene and *n*-hexane) in rats and/or humans. The PBPK model developed in this study consisted of tissue compartments that represented only their NLE content. All biological parameters, except alveolar ventilation rate, were expressed on the basis of their NLE content. Tissue:blood partition coefficients were not used since the solubility of HLVOCs in tissue neutral lipids and blood neutral lipids is considered to be the same. The NLE-based physiological pharmacokinetic model developed in this study described adequately the uptake and disposition kinetics of α-pinene, *d*-limonene and 1, 2, 4-trimethylbenzene in humans and that of *n*-hexane in rats. The NLE-based model framework developed in this study represents an original, mechanistic tool for simulating the lipid concentrations and pharmacokinetics of HLVOCs without the use of tissue:blood partition coefficients.

231 PREDICTABILITY OF THE PERMEATION-AREA CROSS PRODUCT FOR SIMULATING TISSUE UPTAKE OF CHEMICALS IN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELS.

A. Archer and K. Krishnan. *Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada.*

In PBPK models, the tissue uptake of non-ionized organic chemicals (NIOCs) is described as a perfusion-limited process. Conceptually, this process reflects passive diffusion of chemicals across capillary membranes according to Fick's law. For calculating chemical flux as per Fick's first law, diffusion coefficient (D), membrane thickness (T), and area of the membrane (A) should be known. In physiological models, chemical flux is calculated with the knowledge of permeation-area cross product, i.e., PA(=DxA/T) as well as tissue blood flow rate (Qt) according to the equation: PAxQt/(PA+Qt). When the PA value is very large compared to Qt, the latter (i.e., Qt) is used as the determinant of chemical flux between tissues and blood. Actually, PBPK models for NIOCs use Qt as the determinant of chemical flux without any knowledge of PA. The objective of the present study was to develop an approach for predicting PA for various tissues of human PBPK models, and to compare them with Qt, using styrene as the example. For computing the values of PA of chemicals, the D values were obtained using the relationship, log D=-3.20234 logMolWt+1.974, whereas the T for capillaries was set to 0.001 cm and the values of A (x1000 cm^2) for capillaries in various tissues were obtained following a review of the literature (liver: 98, adipose tissues 200, slowly perfused tissues: 402, richly perfused tissues: 300). The results of this study suggest that, for chemicals with PA values greater than 230, 310, 980 and 1100 L/hr, Qt is the limiting factor of tissue uptake in the adipose tissue, slowly perfused tissues, liver and richly perfused tissues. Further, using the tissue-specific PA values calculated for styrene, the present study showed that the perfusion-limited PBPK model is in fact appropriate for this chemical. This study represents the first attempt to predict PA values and provides the basis for determining the appropriateness of the use of perfusion-limited description of tissue uptake of chemicals in PBPK models.

232 MAGNITUDE OF INTERSPECIES DIFFERENCES IN TISSUE:AIR PARTITION COEFFICIENTS USED IN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELS OF VOLATILE ORGANIC CHEMICALS.

K. Sokoloff and K. Krishnan. *Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada.*

Tissue:air partition coefficient (P_{ta}) corresponds to the ratio of solubility or equilibrium concentration of chemicals in two matrices. A common default approach in PBPK modeling is to assume that P_{ta} is species-invariant. Neither the validity of this assumption nor the magnitude of the interspecies differences in P_{ta} is known. The objective of the present study was to estimate the magnitude of interspecies differences (rat vs human; mouse vs human) in tissue:air partition coefficients (PCs) of organic chemicals. The approach involved the calculation of the species-specific P_{ta} for several chemicals with n-octanol:water PC (P_{ow}) values ranging from 0.01 to 10000, and dividing the human P_{ta} with the animal P_{ta}. The computation of chemical-specific P_{ta} required data on lipid and water contents. These data for the various rat, mouse and human tissues were obtained from the literature. The results of this study suggest that the maximal value of human/rat ratio is about 3 for muscle:air PCs whereas this ratio is near unity for adipose tissue:air and liver:air PCs. The calculated maximal value of human/mouse ratios for muscle:air and liver:air PCs are 1.4 and 0.4, respectively. These results suggest that adipose tissue:air and liver:air PCs determined using rat tissues can be used directly in human PBPK models whereas the muscle:air PC should preferably be determined using human tissues. Alternatively, if the P_{ow} of a chemical is known, the factors developed in the present study can be used to estimate the animal-human adjustment factors applicable for the tissue:air PCs. The present study for the first time has estimated the magnitude of rodent-human differences in tissue:air partition coefficients of organic chemicals based on tissue composition data.

233 AN APPROACH FOR ESTIMATING THE HEPATIC EXTRACTION RATIO OF VOLATILE ORGANIC CHEMICALS (VOCS) FOR HUMAN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELS.

M. Béliveau and K. Krishnan. *Groupe de recherche en toxicologie humaine (TOXHUM), Université de Montréal, Montréal, PQ, Canada.*

The metabolism rate constants (V_{max}: maximal velocity for metabolism; K_m: Michaelis affinity constant) or alternatively the hepatic extraction ratio ($E = CL_{int}/[Ql + CL_{int}]$ where $CL_{int} = V_{max}/K_m$ and Ql = liver blood flow rate) for PBPK

modeling are obtained from *in vitro* or *in vivo* studies. Validated *in silico* approaches for predicting V_{max}, K_m or E are yet to become available. The objective of this study was to develop an approach for estimating the hepatic extraction ratio (E) using the steady-state blood concentration (Cb_{ss}) of chemicals in humans. The approach consisted using experimental values of Cb_{ss} of toluene (T), *m*-xylene (X) and ethylbenzene (E) in order to estimate their apparent blood:air partition coefficient (P_{ba}). Knowing the fraction of blood flow to the liver (Ql_c) and the blood:air partition coefficient (P_b) of the chemical, it was possible to estimate E (0.75 T; 0.85 X; 0.73 E) according to the following algorithm: $P_{ba} = P_b/(1+Ql_cEP_b)$ derived from the PBPK model. The relationship between the P_{ba} and the P_b of several (19) volatile organic chemicals was also investigated. A log-linear relationship ($\log P_{ba} = 0.6897 \log P_b - 0.1167$) was found to adequately reflect the quantitative relationship between P_{ba} and P_b, and this relationship indicates the feasibility of predicting E from knowledge of P_b of VOCs. The results of this study demonstrate the adequacy of using blood concentration data and P_{ba} for estimating E for human PBPK models of VOCs.

234 A SPECIALIZED COMPARTMENTAL MODEL FOR THE DISPOSITION OF FAT-ACCUMULATING XENOBIOTICS IN ADIPOSE TISSUE: APPLICATION TO A SYSTEMIC PBPK MODEL FOR TRICHLOROETHYLENE (TCE).

L. K. Potter[1,2], H. T. Banks[3], M. V. Evans[2] and R. A. Albanese[4]. *[1]Curriculum in Toxicology, UNC, Chapel Hill, NC, [2]ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC, [3]CRSC, NCSU, Raleigh, NC and [4]Brooks AFB, San Antonio, TX.*

Large numbers of xenobiotics are known to accumulate in fat tissue, including many organochloride pesticides, PCBs, dioxins and volatile organic compounds. This accumulation in the fat has a major effect on the overall pharmacokinetics of such compounds, including blood and target tissue concentrations. The purpose of this research was to develop a PBPK model for the disposition of the fat-accumulating solvent TCE, with a focus on better describing fat concentrations. Preliminary efforts indicated that the standard PBPK models were not able to capture the dynamics of TCE concentrations in the fat tissue of adult male Sprague-Dawley rats exposed to 50 ppm TCE *via* inhalation for up to 2 hours (unpublished data). Moreover, the assumptions of the standard PBPK models were inconsistent with variations in fat cell size, lipid distribution, and blood flow within a fat depot. These physiological characteristics and the preliminary modeling results led to the development of a specialized compartmental model for TCE in fat tissue based specifically on the physiology. This spatially-varying model included capillary, interstitial fluid and fat cell subcompartments that were based directly on the structure of fat tissue. A dispersion-type term was used to account for the heterogeneities in the fat, and the resulting model was coupled with standard compartments for the blood and remaining tissues to create a systemic PBPK model for TCE. Parameter values were from a PBPK model for TCE (MV Evans, unpublished results) or were based on known physiological properties. Model simulations suggested that the specialized fat compartmental model was best able to capture the dynamics of TCE within the fat. In summary, a dispersion-type fat model is a promising tool in PBPK modeling for accurately describing the disposition of fat-accumulating compounds. (This abstract does not reflect EPA policy).

235 THE IMPORTANCE OF STRAIN-SPECIFIC METABOLIC PARAMETERS IN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELS: CARBON TETRACHLORIDE AS AN EXAMPLE.

C. R. Eklund, M. V. Evans and J. E. Simmons. *USEPA, ORD/NHEERL, Research Triangle Park, NC.*

The goal was to determine effects of physiological parameters on our ability to estimate metabolic parameters for a model volatile organic compound (VOC), such as carbon tetrachloride (CCl4). Using a published PBPK model for CCl4, we estimated maximum metabolic rate (Vmax) and affinity of CCl4 for the metabolic enzyme (Km) for two rat strains, Sprague-Dawley (S-D) and Fischer 344. Of nine strain-specific physiological parameters, five parameters were changed, since four were approximately identical. The five parameters unique for each strain were: alveolar ventilation rate, cardiac output, percent muscle volume, percent blood flow to liver, and percent blood flow to muscle. We performed optimizations against the same set of experimental data to evaluate the difference in Vmax and Km estimates due to the combined influence of these parameters. The resulting estimates for Vmax and Km were only slightly different. Once these metabolic estimates were determined, we repeated the simulations with the new Vmax and Km estimates and compared chamber concentration (Cp) and liver concentration (Cl) for each rat strain. Simulations incorporating strain-specific physiological and updated metabolic parameters produced a difference in both model outputs. The percent difference (Fischer Cl minus S-D Cl divided by S-D Cl) was larger for liver concentration compared to chamber concentration at all initial concentrations. At the lowest simulated concentration (25 ppm), the maximum percent difference was 32% for liver concentration compared to 10% for chamber concentration. At the highest simulated concentration (1000 ppm), the maximum percent difference was 50% for liver concentration compared to 7% for chamber concentration. Since accurate metabolic parameter estimates for VOCs are necessary for dose-response assessment, this research indicates the importance of including strain-specific values in PBPK models for similar chemical compounds. (This abstract does not necessarily reflect EPA policy.)

236 CORRELATION OF HEPATIC DAMAGE AND TARGET DOSE USING A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR CHLOROFORM AND BROMODICHLOROMETHANE.

M. V. Evans[1], J. R. Morin[2], C. R. Eklund[1] and J. E. Simmons[1]. *[1]USEPA, ORD, Research Triangle Park, NC and [2]DESE, UNC, Chapel Hill, NC.*

Chloroform (CHCl3) and bromodichloromethane (BDCM) are members of the trihalomethane family of disinfection by-products resulting from chlorination of source water. The application of PBPK modeling has been long proposed to estimate target dose for specific chemicals. The purpose of this research was to use PBPK models for both chemicals to estimate measures of liver dose and to correlate these results with serum liver damage markers following an oral gavage exposure in aqueous media. Oral gavage was conducted using Fischer 344 male rats approximately 90 days old. Two published data sets were combined to include the following dose range: 0, 0.125, 0.19, 0.25, 0.5, 0.75, 1, 1.5, 2, and 3 mmoles/kg. Serum alanine aminotransferase (ALT), a marker of hepatic damage, was measured 24 hours after exposure. Physiological and age specific values for Fischer 344 male rats were used with previously published PBPK models for both chemicals. The models were structurally similar except for differences in partition coefficients and metabolic parameters. The correlation of several predicted dose metrics with serum ALT was evaluated. The model predictions used for comparison were: peak rate of amount metabolized, total amount metabolized, and peak liver concentration of the parent chemical. Two of these dose metrics correlated well with ALT for both chemicals: total amount metabolized and peak liver concentration. However, it is currently believed that the hepatic toxicity of CHCl3 and BDCM require metabolic activation in order to induce damage. The model simulations presented here, coupled with metabolic activation, and recently published mechanistic data for CHCl3, all suggest that total amount metabolized is a useful metric when describing hepatic damage. In summary, PBPK modeling was shown to be a useful tool for suggesting potential mechanisms of action for two related volatile chemicals. (This abstract does not reflect EPA policy).

237 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR ARSENIC.

E. M. Kenyon, M. V. Evans and M. F. Hughes. *ORD/NHEERL/ETD, USEPA, Research Triangle Park, NC.*

Risk assessment for arsenic is uniquely complex due to both the variety of toxicologically active forms and uncertainty concerning their relative roles in the causation of arsenic-induced cancer and non-cancer health effects. We have developed a PBPK model for arsenic to provide an integrated framework for hypothesis testing and experimental design with the ultimate goal of linking this model to the biological cascade of events leading to arsenic-induced health effects. The model development strategy is based on use of data from our pharmacokinetic studies in mice with each of the major stable forms of arsenic - arsenate (AsV), arsenite (AsIII), monomethylarsonic acid MMA(V) and dimethylarsinic acid DMA(V). The model development strategy has involved sequential separate development of each of four submodels working backwards from dimethylarsenic (DMA) thru monomethylarsenic (MMA), AsIII and AsV. The models are linked by reduction and subsequent methylation steps with urinary and fecal excretion in each of the submodels. All of the submodels include the following compartments representing relevant organs and tissues: arterial and venous blood, lung, liver, kidney, bladder, and residual body. Estimates for partition coefficients were derived from previously published studies using numerical methods. In general distribution into tissues was modeled assuming blood flow limited kinetics in plasma. The notable exception to this was the inclusion of a "deep lung" compartment in the DMA submodel to account for prolonged retention of DMA in lung whether given as parent compound or as AsV or AsIII. Good visual fits were obtained for much of the data used to evaluate the model; however, liver was often a notable exception. Sensitivity analysis suggests that binding and methylation parameters are particularly influential in this regard. Our modeling efforts point to the need for additional species-specific *in vitro* studies to provide a robust mechanistic basis for cross-species extrapolation. (This abstract does not necessarily reflect EPA policy).

238 ESTIMATING PREVIOUS SERUM TCDD CONCENTRATIONS IN AN OCCUPATIONALLY EXPOSED COHORT USING A PBPK MODEL.

D. A. Dankovic[1] and M. E. Andersen[2]. [1]*Risk Evaluation Branch, NIOSH, Cincinnati, OH and* [2]*Dept. of Environmental Health, Colorado State University, Fort Collins, CO.*

This study estimated previous serum concentrations of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) in 134 male workers involved in producing sodium trichlorophenol or a derivative. These workers conceived children either during or after this employment. The estimated TCDD concentrations at the time of conception of children were used in a male reproductive health study (in press). Serum TCDD concentrations were estimated with a PBPK model. Available data were serum TCDD level at the end of the study, dates of employment in dioxin-related processes, and body mass index (BMI) at the end of the study and an earlier time point. A linear regression model estimated missing BMI values for 23 workers who had only one measured BMI. Each worker was assumed to have constant "background" exposure to TCDD, estimated from measured serum TCDD values in 79 controls. Individual occupational TCDD exposure rates were estimated for each worker based on final measured serum TCDD concentration and dates of exposure in TCDD-related processes. TCDD elimination in the PBPK model is proportional to hepatic TCDD concentration; the major site of storage is the fat compartment. The hepatic elimination rate constant for TCDD in this model was previously estimated from the Air Force Ranch Hand study. Although the instantaneous elimination rate of TCDD in the model is first-order, changes in body fat composition over time lead to non-linear kinetics. Unlike other simple first-order models, the volume of distribution of TCDD varies as BMI changes over time. The major conclusions are: (1) the retrospective serum TCDD concentrations are highly dependent on changes in body fat; and (2) data on individual body weight changes, as well as on TCDD exposures, should be gathered when modeling the long-term pharmacokinetic behavior of TCDD in humans. Use of this BMI-linked PBPK model for TCDD permits the investigator to distinguish between plasma kinetics and the whole-body kinetics of TCDD.

239 TISSUE DOSIMETRY BASED ANALYSIS OF SPECIES-SPECIFIC DIFFERENCES IN PULMONARY TOXICITY FROM STYRENE EXPOSURE: A PBPK MODEL-BASED APPROACH.

G. Cruzan[1], R. Sarangapani[2], J. Teeguarden[2], H. J. Clewell[3] and M. E. Andersen[4]. [1]*ToxWorks, Bridgeton, NJ,* [2]*K.S. Crump Group, Research Triangle Park, NC,* [3]*K.S. Crump Group, Ruston, LA and* [4]*Dept. Environment Health, Colorado State U., Fort Collins, CO.*

Chronic rodent studies demonstrate species specificity in the pulmonary carcinogenic response to inhaled styrene (ST). Increased incidences of bronchioloalveolar tumors was observed in mice, but not in rats. Although the data are not definitive with regard to a target cell, ST-induced lung tumors in mice could be from Clara cells in the respiratory epithelium lining the terminal bronchiole. Clara cells metabolize ST to styrene-7, 8-oxide (SO), which is cytotoxic and weakly genotoxic. Rodent species show marked differences in density and distribution of Clara cells and their metabolic capacity. A physiologically based pharmacokinetic (PBPK) model was developed to predict the concentration of ST and SO in the respiratory tract tissues. The model incorporated a multi-compartment description of the respiratory tract, including species specific quantitative information on respiratory tract physiology and metabolic capacity. The model was validated against multiple data sets. The PBPK model predicts a 10 fold lower SO concentration in the terminal bronchioles in rats compared to mice, which is consistent with the observed species sensitivity to the development of respiratory tract neoplastic lesions. Furthermore, model-estimated SO concentration in the terminal bronchioles of mice show a close correlation to the incidence of neoplastic lesions. However, blood SO concentration do not correlate to the neoplastic lesions data, indicating that the carcinogenic response in rodent lung is controlled by local metabolism rather than systemic delivery.

240 ROUTE-SPECIFIC DIFFERENCES IN DISTRIBUTION CHARACTERISTICS OF OCTAMETHYLCYCLOTETRASILOXANE IN RATS: A PHYSIOLGICAL MODEL BASED ANALYSIS.

K. P. Plotzke[1], R. Sarangapani[2], J. Teeguarden[2] and M. E. Andersen[3]. [1]*Dow Corning Corporation, Midland, MI,* [2]*The K. S. Crump Group, Research Triangle Park, NC and* [3]*Colorado State University, Ft. Collins, CO.*

Octamethylcyclotetrasiloxane (D4) has unusual pharmacokinetics resulting from its unique combination of low blood:air and high fat:blood partition coefficients. To understand the determinants of the pharmacokinetics of D4, a multi-route physiologically based pharmacokinetic (PBPK) model has been developed to characterize the retention, distribution, and elimination of D4 following inhalation, dermal, oral and intravenous (IV) exposures in the rat. Concentrations of D4 in plasma, D4 exhalation rates, and elimination rates of D4 metabolites in urine, measured following inhalation, dermal, oral or IV dosing, form the basis for the model. In addition to liver, lung, blood, richly and poorly perfused tissues; the PBPK model contains deep-compartments for the liver and lung, a blood-lipoprotein pool, and multiple fat compartments. The PBPK model only provided good fits to pharmacokinetic data from the multiple routes of exposure when the dose routes were treated as if the D4 entered the circulation in different pools for the different routes. The disposition of D4 following both inhalation and dermal exposure were similar and appear to be governed by direct delivery of free molecular D4 into the blood. In contrast, disposition of D4 following oral exposure appears to be governed by uptake into the blood-lipoproteins and subsequent sequestration in various lipid pools. Similarly, pharmacokinetics following IV administration was also best described by a model structure with delivery of D4 directly into the deep blood compartment, indicating that the microemulsion form of D4 never becomes readily available as a free form of the compound. Unexpectedly the physical form of D4 delivered varied among dose routes. These dose route-route differences in pharmacokinetics need to be considered in human exposure assessments and in Dose-Response modeling. Supported in part by Silicones Environmental, Health and Safety Council of North America.

241 HUMAN INHALATION PHARMACOKINETICS OF OCTAMETHYLCYCLOTETRASILOXANE (D4): EVALUATION WITH A PHYSIOLOGICAL MODEL.

M. B. Reddy[1], I. D. Dobrev[1], M. J. Utell[2], P. E. Morrow[2], K. P. Plotzke[3] and M. E. Andersen[1]. [1]*Quantitative & Computational Toxicology Group, CETT, Colorado State University, Ft Collins, CO,* [2]*University of Rochester, Rochester, NY and* [3]*Dow Corning Corporation, Midland, MI.*

D4, a lipophilic, volatile liquid, is used as a reaction intermediate and is found in industrial and consumer products. Workers and consumers may be exposed to D4 by inhalation or dermal routes. A human inhalation pharmacokinetic (PK) study (Toxicology Sciences, 44:206-13, 1998) and a physiologically based pharmacokinetic (PBPK) model for D4 inhalation in rats (Toxicology Sciences, 60:214-31, 2001) were recently published. The rat PBPK model showed that D4 is eliminated rapidly from the body after exposure due to its low blood:air partition coefficient, Pb (~ 1), and its relatively high metabolic clearance. Some D4 was present in blood in a form that was not readily exhaled, presumably bound to lipids. From the human PK study, data from 12 subjects exposed by inhalation to 10 ppm D4 for 1 hour with alternating periods of rest and exercise were analyzed with the PBPK model. The human data required a Pb of about 0.9. Human metabolism and fat partitioning constants remain to be determined more accurately (i.e., they could not be estimated from the data). When values for these parameters were based on those of the rat study, the model matched observations in the human PK study very well. The PBPK model results were also consistent with the decreased retention with increased alveolar ventilation seen in humans. While the human data set is less extensive than the rat data set, similar PK behaviors were noted including rapid clearance by exhalation and longer persistence in plasma than expected based on the Pb and the rate of metabolism. Many of the conclusions reached in PBPK modeling of D4 inhalation kinetics in rats appear valid for human kinetics of D4. Thus, a similar model structure, with a key feature of D4 sequestration in blood lipids, is required in both species. Supported in part by Silicones Environmental, Health and Safety Council of North America and by NIEHS T32 ES07321 for M. Reddy.

242 ASSESSING THE METABOLISM OF HEXAMETHYLDISILOXANE USING GAS UPTAKE METHODS AND PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING.

I. D. Dobrev[1], K. P. Plotzke[2], M. B. Reddy[1] and M. E. Andersen[1]. [1]*Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Department of Environmental Health, Colorado State University, Fort Collins, CO and* [2]*Health and Environmental Sciences, Dow Corning Corporation, Midland, MI.*

Gas uptake methods have been successfully used to assess the metabolism of a wide variety of volatile organic chemicals. The technique works best with compounds of moderate blood:air and relatively low fat:blood partitioning, and little propensity to adsorb onto chamber surfaces. We extended these techniques to evaluate the *in vivo* metabolism of hexamethyldisiloxane (HMDS), a low molecular weight volatile siloxane. The studies utilized a static atmosphere closed chamber system designed by Filser and colleagues (Arch. Toxicol. 42: 123-136, 1979). Soda lime, used to prevent accumulation of exhaled CO_2 in the system, adsorbed a substantial part of HMDS thus limiting the interpretation of the kinetic data. Soda lime was replaced

by 3.5N NaOH providing acceptable background loss rates of less than 2% per hour. After resolving these technical issues, a series of gas uptake experiments were initiated to evaluate the metabolism of HMDS. In each experiment, two rats (Fischer 344, male, 8-9 weeks old) were exposed to initial concentrations of HMDS ranging from 500 to 5000 ppm and the chamber concentration was monitored over a period of 8 hr. Families of curves for rates of loss of HMDS from the chamber atmosphere were modeled with a four-tissue PBPK model. Excellent fits were obtained incorporating a single saturable metabolic pathway (Vmax=98 μM/hr; Km=86 μM) restricted to the liver. Blood:air and fat:blood partition coefficients were 1.5 and 230. The availability of a PBPK model for HMDS will provide the means to quantitatively characterize the retention, distribution, metabolism and elimination of this material, and support risk assessment extrapolations across dose, dose route, and species. Supported in part by Silicones Environmental, Health and Safety Council of North America.

243 PBPK MODELS OF KEPONE, MIREX, HEXAFLUOROACETONE AND ACETONE SUGGEST BINDING TO HEPATIC TISSUE.

C. K. Belfiore, M. E. Andersen, M. Lohitnavy, O. S. Lohitnavy and R. S. Yang. *CETT, Quantitative and Computational Toxicology Group, Colorado State University, Fort Collins, CO.*

The structures of the pesticides Kepone® and mirex differ only by the presence of a ketone group in Kepone in place of two chlorines in mirex. Both compounds are extremely lipophilic, with log Kow values of 5 to 6. In spite of their physicochemical similarities, their distribution in the body differs markedly: Kepone concentration is highest in the liver; mirex concentration is highest in fat. We have noted a similarly anomalous distribution for hexafluoroacetone (HFA) and acetone: acetone distributes evenly throughout body tissues; HFA accumulates in liver. These two compounds are equally hydrophilic, having low Kow values of 0.6 (HFA) and -0.24 (acetone). Neither Kepone nor HFA is metabolized in rat. Physiologically based pharmacokinetic models have been designed to examine factors contributing to unusual distribution of Kepone and hexaflouroacetone compared to their respective counterparts. The Kepone/mirex model was constructed using blood, fat and liver concentrations of mirex in monkeys, determined after intravenous or oral administration of pesticide (Drug Metab. Dispos. 4:281, 1976). Blood:tissue distribution ratios calculated from the data determined distribution among tissues. Blood, fat and liver concentrations of Kepone in rats, determined after oral administration (Drug Metab. Dispos. 6:91, 1978) were effectively represented by this model only when liver binding parameters for maximal binding (Bmax) and binding affinity (Kd) were 5000 nmol/liver and 0.1 μM. Similarly, the HFA/acetone model was constructed using partition coefficients and metabolic enzyme constants appropriate for acetone (Occup. Environment Med.. 52:344, 1995). Blood and tissue concentrations of HFA in rats following subcutaneous dosing (Toxicol. Appl. Pharmacology 73:23, 1984) were adequately modeled with Bmax = 1200 nmol/liver and Kd = 18.1 μM. Liver sequestration may be a common characteristic for ketones with electron withdrawing substituents. (Supported by NIEHS grants ES05901 and P42 ES05949.)

244 DOSE DEPENDENT RATES OF MANGANESE (Mn) UPTAKE AND BILIARY ELIMINATION: COMPARTMENTAL ANALYSIS OF DIETARY AND GAVAGE DOSING STUDIES IN THE RAT.

J. G. Teeguarden[1], H. J. Clewell[2], R. Sarangapani[1] and M. Andersen[3]. *[1]The K. S. Crump Group Inc., of ICF Consulting Inc., Research Triangle Park, NC, [2]The K. S. Crump Group Inc., of ICF Consulting Inc., Ruston, LA and [3]Department of Environmental Health, Colorado State University, Fort Collins, CO.*

Tissue concentrations of the essential element Mn are regulated predominantly by control of gastrointestinal uptake and biliary elimination. Understanding of the comparative uptake, elimination and tissue distribution of Mn following oral or inhalation exposure to Mn is central to the development of quantitative tools for risk assessment of inhaled Mn. A three-compartment pharmacokinetic model consisting of the gut lumen, gut tissues and the liver was used to examine dose dependencies for absorption and elimination by simulating several dietary or gavage exposure studies in rats. Fitted rate constants provided excellent fits to true and apparent uptake of Mn following dietary exposure at concentrations of 1.5 μg/g and 100 μg/g. The first order rate constants for uptake decreased by a factor of 20 and the first order elimination rate increased approximately 100 fold across the dose range; the rate constant for elimination tended toward saturation at dietary levels greater than 35 μg/g Mn. The model was then compared with two additional dietary exposure studies, and provided good fits to reported bile elimination rates and liver concentrations. Combined dietary (45 μg/g) and oral gavage (0.2-10 mg Mn) appeared to exceed the capacity of uptake control, resulting in compensatory increases in elimination. These empirical representations of the important control processes for regulation of tissue Mn concentrations are necessary for incorporating dose-dependencies into physiologically based pharmacokinetic models describing tissue disposition following combined oral and inhalation exposure to Mn or Mn-containing byproducts of combustion. This work was supported by Ethyl Corporation.

245 SPECIES SPECIFICITY OF PLASMA PROTEIN BINDING OF TRICHLOROACETIC ACID AND ITS EFFECT ON TISSUE BIOAVAILABILITY USING PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING.

M. H. Lumpkin[1], J. W. Fisher[2], J. V. Bruckner[1] and C. E. Dallas[1]. *[1]Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA and [2]Environmental Health Science, University of Georgia, Athens, GA.*

Exposure to trichloroacetic acid (TCA) is widespread, either as a by-product of drinking water purification or as a metabolite of chlorinated solvents such as tri- and perchloroethylene. TCA has been shown to cause liver tumors in mice and is considered a probable human carcinogen. Physiologically-based pharmacokinetic (PBPK) modeling has important utility in examining species-related differences in chemical metabolism and distribution. A better understanding of the role of plasma protein binding for important metabolites like TCA and its influence on their bioavailability to liver and other tissues is needed for human risk assessment. However, there is a paucity of data. Mathematical expressions for plasma protein binding of TCA in several species were generated experimentally and included in PBPK models to predict species-specific differences in the bioavailability of TCA to the liver. Plasma protein binding of TCA in mouse, rat, and human plasma was determined *in vitro* using equilibrium dialysis. The resulting binding parameters and subsequent mathematical expressions of free and bound fractions of TCA were incorporated into PBPK models for each species. Information on the free fraction proved useful in making more accurate model predictions of liver bioavailability over a wide range of TCA plasma concentrations. Comparisons of species-specific differences in liver bioavailability as a function of TCA plasma concentration were thus demonstrated to be feasible, which can have significant utility in using PBPK modeling to assess human health risks. (This research was funded by Department of Energy Grant # DE FC02 98CH10902)

246 PHARMACOKINETIC MODELING OF THE PHYTOESTROGEN GENISTEIN IN RATS: SIMULATING THE LAG IN BILIARY EXCRETION.

M. G. Zager[1,2], H. T. Tran[2] and P. M. Schlosser[1]. *[1]ERDT, CIIT Centers for Health Research, Research Triangle Park, NC and [2]Mathematics, North Carolina State University, Raleigh, NC.*

Phytoestrogens are endocrine-active compounds naturally occurring in some food crops, resulting in human dietary exposures. The phytoestrogen genistein, a significant component of this exposure, is mainly found in soy foods with high concentrations in tofu and soy infant formula. Genistein is believed to have a range of effects, from possible breast and prostate cancer prevention in humans to observed reductions in weight and ano-genital distances of rodents at birth. We seek to develop physiologically based pharmacokinetic (PBPK) models to estimate the internal dosimetry of genistein in rats and humans. Dosimetric data from the literature indicate that genistein undergoes enterohepatic circulation and that there is a genistein concentration-dependent lag in biliary excretion. The ordinary differential equations used in typical PBPK models are unable to capture the dynamics of this observed delay. In this research effort, we developed state-dependent delay differential equations (DDE) to model the lag in genistein biliary excretion. The values of the unknown kinetic parameters were obtained by fitting the model to the biliary excretion data. Model predictions of the data using the resulting optimized parameters are better than predictions without using the DDE. However, though the delay observed in the data is present in the DDE model simulations, the model does not adequately reproduce the true dynamics. Therefore, options for developing a more biologically motivated model to capture the delay dynamics more accurately will be explored. Such work may lead to insight into the underlying biological mechanism of the delay, which is currently unknown. These developments allow for quantification and extrapolation of any exposure-response relationships observed in experimental studies of genistein. Further, these models may be used as templates for modeling compounds with similar pharmacokinetics. This research was supported in part by the American Chemistry Council.

247 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING OF DICHLOROACETIC ACID.

R. D. Stenner[1] and I. R. Schultz[2]. *[1]Battelle PNL, Richland, WA and [2]Battelle PNL-MSL, Sequim, WA.*

Halogenated acetic acids (HAs) are by-products of drinking water disinfection. Dichloroacetic acid (DCA) is a commonly identified by-product that causes liver tumors in rodents. Because of the possible link to human cancer, EPA has set standards permitting a combined total of 60 mg/L of five common HAs in drinking

water with the eventual goal of eliminating DCA from drinking water under stage I regulations. Thus, understanding and predicting the pharmacokinetics of HAs associated with drinking water disinfection is critical to assessing associated risks to the public. Recently, we characterized the low dose pharmacokinetics and oral bioavailability of DCA in F344 rats. Important features of DCA kinetics are: the pronounced non-linearity in its elimination and the complex plasma-time profiles observed after oral dosing with secondary peaks appearing well after the initial absorption phase. The secondary peaks were not caused by enterohepatic recirculation (bile flow independent). The elimination of DCA is controlled primarily by liver metabolism, mediated through a novel class of GST isoenzyme, GST-zeta. An interesting feature of the GST-zeta pathway is the loss in enzyme activity and decreased metabolism that occurs following exposure to DCA. To aid in the risk assessment of HAs, we have been developing a physiologically based pharmacokinetic (PBPK) model for DCA that incorporates key aspects of DCA disposition identified from past experimental studies using both naïve rats and rats treated to deplete GST-zeta enzyme levels. The DCA model to be presented includes a multi-compartment description of the gastrointestinal system to account for the observed discontinuous absorption of DCA. The model also describes liver metabolism using the dispersion model that is better able to account for the saturable metabolism and resultant non-linearity in DCA elimination. Model predictions were validated against previously characterized plasma-time profiles for DCA and selected tissue concentration-time profiles obtained for this study. Supported by EPA STAR grant R825954.

248 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC MODEL FOR CHLOROBENZENE IN F344 RATS.

M. R. Kania[1], A. D. Woodstock[2], C. Timchalk[2] and K. D. Thrall[2]. *[1]US Department of Energy Pre-Service Teacher Program, University of Washington, Seattle, WA and [2]Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA.*

Chlorobenzene is an industrial solvent used in the manufacture of pesticides, resins, inks, and paints. To better understand the dose-dependent and route-specific kinetics of chlorobenzene, this work focused on development and validation of a physiologically based pharmacokinetic (PBPK) model to describe the absorption, distribution, metabolism and elimination of chlorobenzene in rats. Partition coefficients were experimentally determined in rat tissues and blood samples using a vial equilibration technique. These solubility ratios were in agreement with previous reports. The *in vivo* metabolism of chlorobenzene was evaluated using groups of 3 F344 male rats exposed to 80-6750 ppm chlorobenzene in a closed, recirculating gas uptake system. Michaelis-Menten metabolic constants were optimized from the family of gas uptake curves using the PBPK model, and indicated a high affinity (Km) and high capacity (Vmax) for chlorobenzene metabolism. At the highest chamber concentration, the uptake curve could not be modeled without the addition of a first-order (Kfo) metabolic pathway. Pretreatment of animals with pyrazole, an inhibitor of oxidative microsomal metabolism, completely abolished uptake. The completed PBPK model was validated against real-time exhaled breath data collected from rats administered 400 mg/kg chlorobenzene in corn oil by oral gavage or intraperitoneal (IP) injection. Absorption rates were optimized from the exhaled breath profile from one animal per exposure route, and used to simulate the remaining data sets. Development of a comprehensive PBPK model for chlorobenzene in rats is the first step toward future extrapolations to apply to humans (Supported by the US Department of Energy under Contract DE-AC06-76RLO 1830).

249 DEVELOPMENT OF A PBPK MODEL FOR METHYL ETHYL KETONE IN F344 RATS.

K. D. Thrall, J. J. Soelberg, K. K. Weitz and A. D. Woodstock. *Molecular Biosciences, Battelle, Pacific Northwest Division, Richland, WA.*

Methyl ethyl ketone (MEK) is an industrial chemical commonly encountered in a wide variety of paint products. A PBPK model to describe the absorption, distribution, metabolism and elimination of methyl ethyl ketone (MEK) in rats was developed. Partition coefficients were experimentally determined in rat tissues and blood samples using a vial equilibration technique. These solubility ratios were in agreement with previous human-based estimates that MEK is uniformly soluble within all tissues. Both saturable (Km = 0.63 mg/L; Vmax = 5.44 mg/hr/kg body weight) and first-order (Kfo = 4.1 hr-1) metabolic rate constants for rats were derived from the optimization of a series of *in vivo* gas uptake curves conducted at various initial chamber concentrations. Pretreatment with pyrazole, an inhibitor of oxidative microsomal metabolism, decreased the slope of the uptake curve, but did not abolish metabolism. Optimal model fit to the gas uptake curve from pyrazole-pretreated animals was achieved with Km increased 50 times the value determined from naïve rats. The completed PBPK model was validated against real-time exhaled breath data collected from rats administered an intravenous (IV) injection of MEK. Model simulation of the IV-treated animals required alveolar ventilation to be reduced 30% in order to match the data. Exhaled breath profiles from animals treated with MEK by oral gavage or intraperitoneal (IP) injection exposures were evaluated, and absorption rates determined. Development of a comprehensive PBPK model for MEK in rats is the first step toward future extrapolations to apply to humans (Supported by NIOSH 1-RO1-OH03658-01A2).

250 PBPK MODEL FOR THE EFFECT OF GESTATIONAL EXPOSURE TO PERCHLORATE ON IODIDE KINETICS IN THE RAT AND EXTRAPOLATION TO HUMAN GESTATION.

R. A. Clewell[1], E. A. Merrill[2], H. J. Clewell[3] and J. M. Gearhart[4]. *[1]Geo-Centers, Inc., WPAFB, OH, [2]OpTech, Corp., Beavercreek, OH, [3]ICF Consulting, Ruston, LA and [4]Mantech Environmental Technology, Inc., WPAFB, OH.*

Perchlorate (ClO_4^-) disrupts endocrine homeostasis by competitively inhibiting the transport of iodide (I^-) into the thyroid. Therefore, the possibility of developmental effects from ClO_4^- induced iodide deficiency during gestation is cause for concern. Fetal development relies on maternally supplied I^- for hormone synthesis within the fetal thyroid. Though ClO_4^- passes through the placenta, the extent of inhibition in the fetus is unknown. A physiologically-based pharmacokinetic (PBPK) model was developed in the pregnant rat to predict ClO_4^- exposure and the resulting effect on iodide kinetics. Tissues with active uptake were described with Michealis-Menten (M-M) kinetics to simulate saturable transport. Physiological and kinetic parameters were obtained from literature and experiment. Systemic clearance, placental-fetal transport and M-M uptake parameters were obtained by fitting simulations to experimental data in the pregnant and fetal rat. The rat model is able to predict iodide kinetic data in the dam and fetus over 5 orders of magnitude (0.36 to 33, 000 ng/kg $^{131}I^-$), ClO_4^- distribution over 3 orders of magnitude (0.01 to 10 mg/kg-day ClO_4^-), and inhibition of maternal thyroid I^- uptake. The successful rat model served as the basis for a description of the corresponding human kinetics. Physiological parameters and species kinetic differences were obtained from literature and previously developed adult male rat and human ClO_4^- models. Kinetic parameters were scaled allometrically from the rat gestation model, except the parameters with significant species differences, which were obtained from the male human model and literature. The resulting model successfully describes maternal serum, urine, placenta, and thyroid, as well as fetal thyroid, kidney, stomach, serum and total fetal iodide in the human from several studies through gestation (weeks 6 to 40).

251 EVALUATION OF THE POTENTIAL IMPACT OF AGE- AND GENDER-SPECIFIC PHARMACOKINETIC DIFFERENCES ON TISSUE DOSIMETRY.

R. Gentry, J. Teeguarden, R. Sarangapani, T. Covington, G. Lawrence, T. McDonald, A. Shipp and H. Clewell. *KS Crump/ICF Consulting, Ruston, LA.*

Physiologically based pharmacokinetic (PBPK) modeling provides a means for quantitatively determining the impact of age- and gender-related changes in pharmacokinetics on chemical risk estimates. Specifically, these models provide a quantitative structure for estimating the effect of pharmacokinetic variability on the relationship between environmental exposures and biologically effective target tissue exposures. Three case studies were performed to support the development of a methodology that incorporates PBPK modeling to assess the likelihood that a chemical or class of chemicals may present an age- or gender-specific risk. The first case study focused on physiological and biochemical determinants of systemic toxicity, and tested the hypothesis that many of the pharmacokinetic differences observed across age and gender may be attributed to natural changes in physiological properties. The second case focused on the impact of differences in lung morphology and ventilation rate on both local and systemic toxicity as a function of the properties of the chemical. The third case study focused on the perinatal period, using PBPK models to evaluate *in utero* exposure *via* placental transfer *versus* exposure *via* lactational transfer to demonstrate critical periods of exposure from a pharmacokinetic perspective. These studies were exercised using parameters representative for multiple classes of chemicals to provide information on pharmacokinetic behaviors for each class of chemical. In general, variations in pharmacokinetic dose metrics for a chemical over a lifetime were within a factor of 2; however, in early childhood, exceptions were observed in which the dose metrics varied by approximately an order of magnitude. This work was supported by the Risk Assessment Methods Technical Implementation Panel of the American Chemistry Council.

252 ASSESSING DOSE- DEPENDENT GSH DEPLETION AND CHLOROTRIAZINE METABOLITE DISPOSITION AFTER ATRAZINE TREATMENT WITH A PHYSIOLOGICAL MODEL.

J. M. Ruble, T. S. McMullin and M. E. Andersen. *Environmental Health, Colorado State University, Fort Collins, CO.*

Atrazine (ATRA), a water-soluble chlorotriazine herbicide, is used throughout the United States. High doses of ATRA impair the pre-ovulatory LH surge in female Sprague-Dawley rats, presumably due to actions in the hypothalamus. This response is related to ATRA and its three chlorinated, dealkylated CYP450 metabolites. Non-chlorinated triazines appear inactive. Both ATRA and the dealkylated metabolites undergo GSH conjugation with elimination of processed conjugates in feces and urine. We have modified a physiologically based pharmacokinetic (PBPK) model developed for radiolabeled disposition studies with atrazine (McMullin et al., The Toxicologist, 60, 150) to describe blood time-course of individual chlorinated triazines measured after derivatization (see Cranmer et al., this meeting) and to include the depletion of GSH during their metabolism. To evaluate GSH depletion, we used model predictions to design an experiment in which groups of rats received very high doses of these compounds, 800 mg ATRA/kg in 1% methylcellulose, or similar doses of the dealkylated metabolites or di-amino-chloro-triazine (DACT). Rats were sacrificed at 8 hours - the predicted time for maximal GSH depletion from the original model for radiolabeled ATRA. Liver, brain and various other tissues were analyzed for GSH concentrations and blood for individual chlorotriazines. Unexpectedly, DACT caused significant GSH depletion in liver (3.8 ± 0.2 mM), compared to control rats (5.2 ± 0.3 mM), but no depletion was observed at this time with ATRA (5.2 ± 0.4 mM). These apparent differences among these chlorotriazines in GSH reactivity, now incorporated into the PBPK model, emphasize the value in refining the original radiolabeled ATRA PBPK model to accurately account for the formation and especially for the GSH-related clearance of all four chlorotriazines. This research was funded by EPA STAR grant (R-828610-01-0).

253 THE EFFECTS OF SMOKING ON HUMAN HEALTH.

K. Rodgers and B. Freed. *Ob/Gyn, USC, Los Angeles, CA.*

Recent court settlements between the cigarette industry and state health agencies has renewed interest in the effects of smoking on human health. While the association between smoking and lung cancer has been known since the 1930s, only recently have the immunosuppressive effects of smoking been appreciated. Smoking represents the most potent and widespread immunosuppressive agent with human exposure. Both marijuana and tobacco smoking render patients more susceptible to respiratory tract infections. Certain inflammatory lung diseases, such as hypersensitivity pneumonitis and sarcoidosis, are actually attenuated by the immunosuppressive effects of smoking. Recent studies have clearly identified several immunosuppressive compounds in smoke that act locally (hydroquinone, catechol, acrolein and crotonaldehyde) or systemically (cannabinoids and nicotine). This symposium will explore the molecular mechanisms by which these components of smoke affect signaling pathways, gene expression and cell cycle progression in T lymphocytes and neutrophils.

254 INHIBITION OF G_1 AND S PHASE T CELL CYCLE EVENTS BY CIGARETTE SMOKE.

B. M. Freed. *Allergy and Clinical Immunology, Univ Colorado Health Sciences Center, Denver, CO.*

Cigarette smoke is a potent immunosuppressive agent that completely blocks T and B lymphocyte responses in the lungs. We have identified several compounds in both the tar and gas phases that inhibit distinct events associated with T cell activation and proliferation. Hydroquinone (HQ), catechol and phenol represent the three major phenolic components in cigarette tar. They are present in cigarette smoke at concentrations that are directly proportional to tar content. Hydroquinone and catechol inhibit lymphocyte proliferation by interfering with two different stages of the cell cycle. When added to resting T cells prior to mitogenic activation, they permit many early activation events, such as IL-2 production, expression of CD25 and CD69. However, they cause an aborted blastogenesis by blocking progression from G_1 to S phase of the cell cycle. This phenomenon is associated with inhibition of Rb and transferrin receptor expression. When added to proliferating lymphocytes, HQ and catechol cause an immediate cessation in DNA synthesis by quenching the tyrosyl radical in ribonucleotide reductase. Phenol has no effect on any of these events. Acrolein and crotonaldehyde are thiol-reactive α, β-unsaturated aldehydes present in the gas phase of cigarette smoke. Unlike HQ and catechol, they are present even in ultra low-tar cigarettes. At doses found in a single cigarette, they inhibit the production of several proinflammatory cytokines, including IL-1β, IL-2, TNF-α and IFN-γ. The immunosuppressive effect can be completely abrogated by N-acetylcysteine, suggesting that they function by reacting with thiols. Acrolein and crotonaldehyde inhibit cytokine production by blocking NF-κB and AP-1 DNA binding activity, thereby preventing expression of genes that are regulated by these transcription factors.

255 EVIDENCE FOR CB1/CB2-DEPENDENT AND -INDEPENDENT MECHANISMS OF CANNABINOID-MEDIATED MODULATION OF LEUKOCYTE FUNCTION.

N. E. Kaminski, B. F. Kaplan, T. R. Jan and G. K. Rao. *Michigan State University, East Lansing, MI.*

Over three decades of studies have unequivocally demonstrated that the immune system is sensitive to modulation by cannabinoids, a family of structurally-related congeners derived from the marihuana plant. In fact, marihuana smoke contains over 60 different cannabinoids, the majority of which have not been investigated for biological activity. For those cannabinoids that have been investigated, the mechanism responsible for their biological activity remains poorly understood. Their effects on the two primary target organs, the central nervous system and the immune system appear to be mediated, at least in part, *via* G-protein coupled cannabinoid receptors, CB1 and CB2. A major focus of this laboratory has been the elucidation of the molecular mechanism by which cannabinoids modulate the T cell-derived cytokines, interleukin (IL)-2 and IL-4. One major signal transduction pathway we have recently identified that is disrupted by cannabinoids and which is critical for T cell function is the calcium-mediated activation of the nuclear factor of activated T cells (NF-AT). NF-AT DNA binding, which is essential for the transcriptional regulation of IL-2 and a number of other T cell-derived cytokines, is disrupted by immunosuppressive cannabinoids. Cannabinoid treatment was also found to induce a rapid and sustained rise in $[Ca^{+2}]_i$ which was concentration responsive and of a magnitude similar to that produced with 500 nM ionomycin. The rise in $[Ca^{+2}]_i$ by cannabinol and Δ^9-tetrahydrocannabinol was attenuated by pretreatment of splenocytes with the CB1 (SR141716A) and CB2 (SR144528) antagonists, in combination, and in thymocytes with SR144528 alone. Interestingly, neither SR141716A nor SR144528 alone or in combination attenuated cannabinoid-mediated inhibition of IL-2 gene expression. Collectively, these studies suggest that cannabinoid-mediated modulation of IL-2 is mediated in part *via* a disruption of $[Ca^{+2}]_i$ through a cannabinoid receptor-dependent mechanism as well as through cannabinoid-receptor-independent pathways.(Supported by NIH Grant DA07908).

256 NEUROIMMUNE COMMUNICATION IN NICOTINE-INDUCED IMMUNOSUPPRESSION.

M. L. Sopori. *Respiratory Immunology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Chronic exposure of rats and mice to nicotine (NT) decreases the antibody-forming cell response and Con A-induced proliferation of T cells. This immunosuppression is accompanied by impaired antigen receptor-mediated signaling in T cells, including constitutive activation of Fyn and other protein tyrosine kinases. Similar changes in the immune response were also observed after intracerebroventricular administration of NT, which were reversed by simultaneous administration of the nicotinic acetylcholine receptor (nAChR) antagonist, mecamylamine, indicating that NT affected the immune system *via* the nAChRs in the central nervous system. The immunosuppressive effects of NT were also seen in adrenalectomized rats, but not in animals pretreated with ganglionic blockers. Thus, the effects of chronic NT exposure on the immune system are independent of the hypothalamus-pituitary-adrenal axis but dependent on the autonomic nervous system. Surgical sympathetic denervation of the spleen or treatment of animals with the muscarinic antagonist, atropine, did not reverse the effects of NT on the immune system. Therefore, it is likely that the parasympathetic but not the sympathetic pathway transmits signals from the brain to nAChRs on T cells. In this regard, our recent data suggest the presence of α7-containing nAChRs on T cells. Interestingly, following chronic NT treatment, animals exhibited enhanced expression of IL-1βmRNA in the brain that was kinetically correlated to the induction of immunosuppression. Moreover, unlike the control wild-type mice, IL-1β receptor KO mice did not exhibit immunosuppression in response to NT exposure. These results suggest that the neuroimmune effects of NT are mediated through the parasympathetic pathway and that IL-1β may play an important role in the neuroimmune modulation by chronic NT treatment. Supported in part by grants from the NIH (DA04208, DA04208-13S1, HD38222).

257 MODULATION OF NEUTROPHIL REACTIVE OXYGEN SPECIES PRODUCTION BY CIGARETTE SMOKE EXTRACT.

K. A. Stringer[1] and B. M. Freed[2]. *[1]Pharmacy Practice, School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO and [2]Allergy and Clinical Immunology, School of Medicine, University of Colorado Health Sciences Center, Denver, CO.*

The production of reactive oxygen species (ROS) by neutrophils appears to play a central role in the pathogenesis of cardiovascular and respiratory diseases induced by cigarette smoke (CS). In particular, neutrophils initiate and maintain the inflammatory process, primarily *via* their ability to generate ROS. However, a number of studies have produced conflicting results in regard to the effect that CS has on neutrophil ROS production. Furthermore, there are data that suggest that CS may prime neutrophils resulting in enhanced ROS production following exposure to an inflammatory mediator such as tumor necrosis factor-α (TNF-α). We have evaluated the effect of varying concentrations of CS extract on neutrophil ROS production and priming followed by exposure to inflammatory mediators (e.g., interleukin-1) known to be elevated in cigarette smokers. Data from our work will be presented.

258 NEURORECEPTORS AS THE BASIS FOR INSECTICIDE RESISTANCE AND SELECTIVE TOXICITY.

T. Narahashi. *Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL.*

The resistance of insects to insecticides and the selective toxicity in mammals and insects are among the most striking and important features of insecticides. Insecticide resistance is one of the most serious problems in using and developing insecticides, and their selective toxicity is one of their most important characteristics. Whereas diverse mechanisms underlie these two different features of insecticides, many, if not all, such cases have been shown to be ascribed to factors at the target site, specifically the sensitivity of target neuroreceptors to insecticides. There have been profound developments in the cellular and molecular mechanisms that underlie these phenomena during the past several years owning to the development of advanced eletrophysiological, molecular biological and genetic techniques. For example, insect resistance to dieldrin and the pyrethroids is due in many cases to the markedly reduced sensitivity of GABA receptors and sodium channels, respectively, which are in turn ascribed to mutations of single amino acids in the target receptor/channel. Similarly, the selective toxicity between mammals and insects is also due to differential target site sensitivities as has been shown for the pyrethroids.

259 POINT MUTATIONS IN THE INSECT PARA SODIUM CHANNEL ALTER THE CHANNEL SENSITIVITY TO PYRETHROIDS.

K. Dong[1], J. Tan[1], Z. Liu[1], T. Tsai[2], S. M. Valles[3] and A. L. Goldin[4]. *[1]Entomology, Michigan State University, East Lansing, MI, [2]Pharmacology, Pharmacia Corp., Kalamazoo, MI, [3]USDA-ARS, Gainesville, FL and [4]Microbiology and Molecular Genetics, University of California, Irvine, CA.* Sponsor: T. Narahashi.

Pyrethroid insecticides are used worldwide to control insect pests of agricultural and medical importance. Pyrethroids exert toxic effects on insects by binding to a unique, but undefined site on the voltage-gated sodium channel and thereby altering sodium channel gating properties. Multiple sodium channel point mutations have been found in several pyrethroid-resistant insect species. The mutations, located in IS6, IIS6, the linker connecting IIS4-S5, and the linker connecting the domains I and II, have been shown to reduce the sodium channel sensitivity to pyrethroids. In this talk, I will review the effects of these sodium channel mutations on the gating and pyrethroid-sensitivity of the German cockroach Para sodium channel. In addition, we recently identified two Para alternative splice variants, which differ greatly in their sensitivities to pyrethroids. Further analysis of these two splice variants will reveal additional amino acid residues involved in sodium channel interaction with pyrethroids.

260 INSECTICIDE RESISTANCE: OLD PROBLEMS OR NEW SOLUTIONS?

R. H. ffrench-Constant. *Biology and Biochemistry, University of Bath, Bath, United Kingdom.* Sponsor: T. Narahashi.

Overuse of insecticides has often led to resistance in insect populations. Our laboratory has focused on how an understanding of the molecular basis of resistance can a) help us understand how resistance has evolved, b) help us identify the receptors/enzymes involved and c) help us understand if resistance can be avoided, or at least delayed, in the future. We will discuss two specific examples, resistance to cyclodienes and fipronil mediated *via* an altered GABA receptor gene (Resistance to dieldrin or Rdl) and P450 mediated resistance to DDT and the neonicotinoids. In each case we will examine central questions. 1) How many genes are involved? 2) What mutations are involved? 3) How have these mutations spread in natural populations? 4) What levels of cross-resistance are conferred by these genes and to what compounds? 5) Will resistance go away if we stop spraying? 6) Can we predict resistance to novel compounds that are yet to come to market? These questions will be examined both in an academic (receptor biology and resistance evolution) and industrial (implications for the design and introduction of new compounds) context.

261 NEONICOTINOID INSECTICIDES: MECHANISM OF SELECTIVITY FOR INSECT *VERSUS* MAMMALIAN NICOTINIC RECEPTORS.

M. Tomizawa and J. E. Casida. *Department of Environmental Science, Policy and Management, Environmental Chemistry and Toxicology Laboratory, University of California, Berkeley, Berkeley, CA.* Sponsor: T. Narahashi.

The last decade opened the era of neonicotinoids (represented by imidacloprid) as a major new class of highly effective and widely used insecticides for crop protection and veterinary pest control. The favorable selective toxicity of neonicotinoid insecticides for insects *versus* mammals is not shared by their *N*-unsubstituted imine metabolites and analogs or by nicotine or epibatidine. The same selectivity profile is evident at the target site level, i.e., the insect nicotinic acetylcholine receptor (nAChR) *versus* mammalian nAChR subtypes (α1, α3, α4 and α7). The insect-selective compounds are not protonated with a nitroimine, cyanoimine or nitromethylene substituent and the mammalian-selective compounds are ionized at physiological pH. We propose that the negatively-charged tip of the nitro or cyano group interacts with a putative cationic subsite of the insect nAChR. This contrasts with the mammalian nAChR subtypes where the iminium cation of *N*-unsubstituted imine metabolites or analogs of neonicotinoids or ammonium nitrogen of nicotine and epibatidine interacts with the anionic subsite. Further, only minor structural changes in neonicotinoids confer differential subtype selectivity for mammalian nAChRs. Chronic exposure to neonicotinoids, metabolites and analogs up-regulates the α4β2 nAChRs in M10 cells as initiated by receptor-compound interaction and followed by intracellular events.

262 TARGET SITE SELECTIVE TOXICITY TO INSECTICIDES IN MAMMALS AND INSECTS.

T. Narahashi. *Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL.*

Most insecticides are more toxic to insects than to mammals, and the selective toxicity of certain insecticides has been shown to be ascribed to the higher target site insecticide sensitivity in insects than in mammals. The major primary target of pyrethroids is the sodium channel, and the neuronal sodium channel of cockroaches were much more sensitive than that of rats. For example, allethrin was approximately 1000-fold more potent on the cockroach sodium channel than on the rat dorsal root ganglion (DRG) tetrodotoxin (TTX)-sensitive sodium channel based on the measurement of the percentages of sodium channels modified by the pyrethroid. Fipronil blocks the GABA receptor, and was more potent on the cockroach GABA receptor than on the rat DRG $GABA_A$ receptor. Indoxacarb and its metabolite DCJW have been shown to act on multiple target sites. Both blocked the sodium channels with a higher potency in cockroaches than in rats. They acted on the α7-type and α 4 β2-type nicotinic acetylcholine (nACh) receptors of rats in a complex manner: indoxacarb stimulated the α 4 β2 receptor but inhibited the α 7 receptor, while DCJW had no effect on the α4β 2 receptor with slight inhibition of the α7 receptor. The cockroach nACh receptor, which had characteristics different from either the rat α 7 or α4 β2 receptor, was inhibited by indoxacarb. A marked difference was found in the response of GABA receptors: the rat $GABA_A$ receptor was totally insensitive to indoxacarb or DCJW, whereas the cockroach GABA receptor was strongly inhibited by indoxacarb. In summary, the mechanisms of selective toxicity to pyrethroids, fipronil and indoxacarb reside in the differential sensitivity of target receptors between mammals and insects. Supported by NIH grant NS14143.

263 SELECTIVE ACTIONS OF INSECTICIDES ON LIGAND-GATED ION CHANNEL SUBTYPES.

V. L. Salgado. *Insecticide Biochemistry, Aventis CropScience, Frankfurt am Main, Germany.* Sponsor: T. Narahashi.

Nicotinic receptors and chloride-channel-gating GABA and glutamate receptors, all members of the cys-loop superfamily of ligand-gated ion channels, are important insecticide target sites. Recent electrophysiological studies on these receptors in insect neurons show the presence of subtypes of each of these receptor types, with large differences in sensitivity to insecticides and other drugs. Additionally, compounds that act allosterically on these receptors, as modulators or channel blockers, can act on more than one type of receptor in this superfamily. For example, the effects of avermectins on GABA receptors were studied long before the inhibitory glu-

tamate receptor were recognized as target sites, and more recently, fipronil, which has long been known to block GABA-gated chloride channels, has been found to also block glutamate-gated chloride channels. Similarly, spinosad, whose primary mode of action is modulation of nicotinic receptors, has also shown effects on GABA receptors. Thus, a complete understanding of the insect toxicology of these compounds requires an understanding of their interactions with a multiplicity of receptors. New comparative studies of the actions of neonicotinoids, spinosyns and fiproles on subtypes of nicotinic, GABA and Glutamate receptors help to clarify our understanding of the action of insecticides on these important target sites, and provide important new insights into resistance mechanisms and insect selectivity.

264 THE POTENTIAL FOR BIOLOGICAL MODELING TO IMPROVE CHILDREN'S RISK ASSESSMENT.

G. P. Daston[1] and R. A. Corley[2]. [1]*Miami Valley Labs, Procter & Gamble, Cincinnati, OH and* [2]*Pacific Northwest National Lab., Richland, WA.*

Fundamental differences between animal and human development create unique challenges for assessing the risk of pharmaceutical or chemical exposures to children's health. This challenge can be met by integrating the basic biology of animal and human development with chemical-specific mechanisms or modes of action through the development of quantitative, biological models of target tissue dose and/or response. Starting from a single cell and growing over a billion-fold by birth, developing embryos can become targets for toxicity when the mother is exposed during specific windows of susceptibility. Neonatal exposures to certain chemicals continue to be mediated by the mother *via* lactation. Similar to the progress made in cancer risk assessments, biological models (physiologically based pharmacokinetic [PBPK] and biologically based dose-response [BBDR]) have increasingly been used to describe target tissue dose and response in animals during pregnancy and lactation. However, significant issues remain in the ability to extrapolate from animals to humans given the unique changes that occur in maternal, embryo, fetal and neonatal biology. Unlike most PBPK or BBDR models, models of pre- and postnatal development must deal with the dynamics of rapid growth (maternal and embryonic), changes in the state of differentiation of developing structures, uniquely expressed or uniquely functioning signal transduction or enzymatic pathways, and unusual routes of exposure (e.g., lactation). Our understanding of the dynamics of normal development at a molecular level, and of mechanisms of developmental toxicity, are increasing at a rapid pace, making BBDR models of developmental toxicity more feasible, although there are still important gaps in our knowledge. The symposium will lay out basic issues in, and examples of, PBPK modeling in the pregnant mother and fetus, and early childhood, along with progress and challenges in BBDR modeling of adverse events in structural and functional development.

265 PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING OF PRENATAL GROWTH AND EXPOSURES.

R. H. Luecke. *Chemical Engineering, Univ. of Missouri, Columbia, MO.* Sponsor: G. Daston.

Physiologically based pharmacokinetic (PBPK) models have recently been developed to include description of organ growth and physiological changes in the maternal and embryo/fetal environments. These pregnancy models include physiological data and growth equations for humans, monkeys, rats and mice and may be extrapolated to other species. Drug or chemical concentrations are calculated in both maternal and fetal organs. The models have also been partially extended with growth equations for neonates. Since accidental human exposure may involve more than one incident and more than one route, the model accommodates simultaneous and/or sequential exposures involving multiple routes. Following exposure to a single chemical, a second compound can be simultaneously modeled as a metabolite. Comparative simulations using pharmacokinetic data for methyl mercury as reported in the literature for 12 mammalian species were used to elucidate the impact of species-specific response differences. A mathematical approach is also outlined for use in conjunction with PBPK models to simulate a window of susceptibility for teratogenic sensitivity during pregnancy. The procedure is illustrated with an example based on literature data.

266 DEVELOPMENT OF BIOLOGICALLY BASED DOSE-RESPONSE (BBDR) MODELS FOR DEVELOPMENTAL TOXICITY.

J. M. Rogers[1], C. Lau[1], R. W. Setzer[2], M. L. Mole[1], J. E. Andrews[1], D. L. Shuey[3] and R. J. Kavlock[1]. [1]*Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC,* [2]*Experimental Toxicology Division, U.S. EPA, Research Triangle Park, NC and* [3]*Safety Assessment, Dupont Pharmaceuticals, Newark, DE.*

As a prototype BBDR model, we have developed a mechanistically-based model for the well-studied teratogen 5-FU, which is known to interfere with DNA synthesis *via* inhibition of thymidylate synthetase (TS) and consequently impede DNA synthesis and cell replication. Our model is based on the sequence: target (embryo) dose → TS inhibition → altered nucleotide (dNTP) pools → reduced DNA synthesis → reduced tissue growth → dysmorphogenesis. These events have been quantified experimentally in rat litters after maternal s.c. dosing with 0-40 mg/kg 5-FU on day 14 of gestation, which produces developmental toxicity including reduced fetal weight and limb defects. Measurements of dose-response for mechanistic endpoints include TS enzyme activity, embryonal nucleotide pool sizes, cell cycle distribution, DNA content, cell death, limb bud development and limb dysgenesis have been carried out, and quantitative linking of these endpoints indicates that the model based on TS inhibition can predict the Dose-Response for limb defects and fetal weight. A mathematical model linking TS inhibition to dNTP pool perturbations has been developed. Similar dosing with another TS inhibitor, the folate analog tomudex, produces most, but not all, of the effects of 5-FU, supporting the TS-based model. The severity of tomudex toxicity *in vitro* and *in vivo* are inversely correlated with embryonal folate supply.

267 PHARMACOKINETIC CONSIDERATIONS IN CHILDREN'S RISK ASSESSMENT.

G. L. Ginsberg[1], D. Hattis[2] and B. Sonawane[3]. [1]*Dept. of Public Health, St. of Connecticut, Hartford, CT,* [2]*Clark Univ., Worcester, MA and* [3]*USEPA, Washington, DC.*

Pharmacokinetic processing of xenobiotics can differ widely between children and adults due to physiological differences and immaturity of enzyme systems and clearance mechanisms. This makes extrapolation of adult dosimetry estimates to children uncertain, especially at early ages. While there is very little PK data for environmental toxicants in children, there is a wealth of such data for therapeutic drugs. Using published literature, a Children's PK Database has been compiled comparing child and adult PK parameters for 44 drugs. This has enabled comparison of child and adult PK function across a number of cyp pathways and certain Phase II conjugation reactions and renal elimination. The across age group differences seen *in vivo* with drugs are consistent with *in vitro* liver bank studies and present a PK developmental profile relevant to environmental toxicants. Variability analysis points out key periods of rapid development where children's responses appear particularly heterogeneous. The manner in which this PK information can be applied to the risk assessment of children includes qualitative approaches (e.g., adjustment of uncertainty factors) and quantitative approaches (PBPK modeling). PBPK parameter values need to be specific to physical characteristics (body mass; compartment size and blood flow; water and lipid content; cardiac output and ventilation rate; partition coefficients) as well as to metabolic and renal elimination rate constants that pertain to children. Development of rate constants is aided by the Children's PK Database in that it provides case studies against which models can be calibrated and validated with respect to specific CYPs or other metabolism/ elimination pathways. Such validated children's models could then be used to adapt adult PBPK models for environmental toxicants to children and thus bring PBPK modeling into the risk assessment process for children. The views expressed are those of the author(s) and do not necessarily reflect the views or policies of the State of CT or USEPA.

268 MODELING ENDOCRINE ACTIVE COMPOUNDS (EACS) ACROSS LIFE STAGES.

H. A. Barton[1], J. G. Teeguarden[2], L. K. Potter[1,3] and R. W. Setzer[1]. [1]*Pharmacokinetics Branch, ETD, USEPA/ORD/NHEERL, Research Triangle Park, NC,* [2]*ICF Consulting, Research Triangle Park, NC and* [3]*Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC.*

Questions about the potential for endocrine disruption have focused upon differential sensitivities across life stages and the potential that dose-response behaviors would vary across these periods. Some hormone-mediated changes in gene expression are "organizational" during development (e.g. establishing system set points) *versus* "activational" changes in adults (e.g. altering the current level of expression). Biological modeling of the impact of exogenous compounds on hormonally mediated events should ultimately address both pharmacokinetic and pharmacodynamic differences. Physiologically-based models of the pharmacokinetics of EACs during pregnancy, lactation, through puberty and into adulthood have accounted for factors such as changes in compartment size, blood flows, and serum binding proteins. Use of such models to estimate tissue dosimetry is dependent upon information about the mode of action including the window of vulnerability, the active form of the compound, and the biology of the endogenous signaling system. Models have been constructed for adult hormone-mediated processes, notably central axis function in rats and humans. Models of receptor-mediated processes have described *in vitro* and *in vivo* data, e.g. uterine receptor occupancy and positive feedback loops in regulatory phenomenon. While such models may help to understand the pharmacodynamics of EACs in adults, understanding their effects during *in utero* development may require describing morphogen-like gradients of endogenous hormone

as well as receptor-mediated responses to circulating hormones. These efforts at pharmacokinetic and pharmacodynamic modeling for EACs at different life stages are designed to assist in evaluating questions of dose-response behavior and cross-species extrapolation. (This abstract has been subjected to Agency review and approved for publication. LKP was funded by the EPA/UNC Toxicology Research Program, Training Agreement CT827206.)

269 PROGRESS IN DEVELOPMENT OF EMBRYOLOGICALLY BASED DOSE-RESPONSE MODELS.

R. J. Kavlock. *Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC.*

The goal of researchers working in the area of developmental toxicology is to prevent adverse reproductive outcomes (early pregnancy loss, birth defects, reduced birth weight, and altered functional development) in humans due to exposures to environmental contaminants, therapeutic drugs, and other factors. To best achieve that goal, it is important that relevant information be gathered and assimilated in the risk assessment process. One of the major challenges of improved risk assessment is to better use all pertinent biological and mechanistic information. This may be done qualitatively (e.g., demonstrating that the experimental model is not appropriate for extrapolation purposes); semi-quantitatively (using information to reduce the degree of uncertainty present under default extrapolation procedures), or quantitatively (formally describing the relationships between exposure and adverse outcome in mathematical forms, including components that directly reflect individual steps in the overall progression of toxicity). With particular reference to developmental toxicity, the quantitative models almost invariably encounter a "black box" in translating a particular biochemical perturbation into a morphological alteration. This presentation will review recent progress in generating dynamic models of tissue and organ development (e.g., the formation of somites which ultimately differentiate into the axial skeleton) that can one day be coupled with pharmacokinetic and biochemical models to fully understand the pathogenesis of adverse pregnancy outcomes.

270 INTRODUCTION TO THIOREDOXINS AND THIOREDOXIN REDUCTASES: CENTRAL ROLES IN TOXICITY AND CANCER.

L. P. Kehrer. *Pharmacology and Toxicology, The University of Texas at Austin, Austin, TX.*

Thioredoxins (Trx) and thioredoxin reductases (TrxR) are components of widely distributed and highly conserved thiol redox systems with diverse functions in redox signaling, detoxification, repair and proliferation. Both Trx and TrxR contain dithiol motifs, that undergo cyclical oxidation/reduction during catalytic turnover. These thiols are reactive with alkylating agents, making the proteins susceptible to inactivation by reactive electrophiles and oxidative stress. Trx expression is increased in response to oxidative stress and its distribution between cytoplasm and nucleus is altered in response to DNA damage. Mitochondria contain distinct forms of both Trx and TrxR. This initial overview will provide a brief review of the structure and enzymology of the system and make some comparisons to the glutathione system. As a whole, this symposium will provide a perspective on how Trx and TrxR are important to consider in terms of cellular responses to toxicologic insults.

271 STRUCTURE AND FUNCTION OF THE THIOREDOXIN-THIOREDOXIN REDUCTASE SYSTEMS.

A. Holmgren. *Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.* Sponsor: J. Kehrer.

Thioredoxins are present in all cells and are the main disulfide reduction enzymes with a large number of functions. Reduction of the active site disulfide in thioredoxin (Trx) by NADPH is catalyzed by thioredoxin reductases (TrxR). Mammalian TrxR are very different from the small enzymes present in bacteria and have a broad substrate specificity including lipid hydroperoxides and selenite. The rat enzyme contains a glutathione reductase scaffold elongated by 16 residues and a C-terminal conserved sequence: Gly-Cys-Sec-Gly, where Sec is selenocysteine. We have expressed the rat enzyme in E.coli by changing the TGA codon for Sec498 to Cys or Ser, or a stop codon. The mutant enzymes were purified to homogeniety in high yield and contained one mol of FAD per subunit. Only the Sec to Cys mutant enzyme was active in reduction of thioredoxin with a 100-fold decrease in Kcat compared to the wild type Se-containing enzyme. The pH-optimum for the Cys mutant enzyme was 9 as opposed to 7 for the Sec-containing wild type enzyme, consistent with Se involvement in catalysis and explaining why this trace element is required for cell growth. The oxidized enzyme contained a unique selenenylsulfide bridge which is reduced to a selenolthiol in the reduced enzyme by electrons from the dithiol in the second subunit. The Cys mutant enzyme has been crystallized and the three-dimensional structure and the mechanism of the enzyme based on a 3 Å resolution map will be presented.

272 THIOREDOXIN IN CANCER DEVELOPMENT AND TREATMENT.

G. Powis. *Arizona Cancer Center, University of Arizona, Tucson, AZ.* Sponsor: L. Kehrer.

Mammalian thioredoxins (Trxs) are small redox proteins that undergo reversible oxidation and reduction by NADPH dependent selenocysteine containing flavoprotein thioredoxin reductases. Trx-1 is found in the cytoplasm, nucleus and is secreted by cells. Trx-1 reduces Cys residues on proteins including the transcription factors NF-kB and HIF-1alpha to increase their DNA binding and transactivating activity. Trx-1 also binds directly to proteins to regulate their activity including apoptosis signal regulating kinase-1 (ASK1) and the tumor suppressor PTEN. Nuclear targeted Trx-1 transforms cells. Trx-1 is also a potent cell survival factor and inhibitor of apoptosis. The stable transfection of mouse WEHI7.2 lymphoma cells with human Trx-1 inhibits apoptosis induced by a variety of agents. When inoculated into scid mice the Trx-1 transfected WEHI7.2 cells form tumors that grow more rapidly and show less spontaneous apoptosis than vector-alone transfected cells, and that are resistant to growth inhibition by dexamethasone. A catalytic site redox inactive mutant Trx-1 acts as a dominant negative to promote apoptosis of WEHI7.2 cells in culture and to inhibit MCF-7 human breast cancer tumor growth in mice. Trx-1 expression is significantly increased in a number of human primary cancers including lung, colon, gastric, cervix, liver, pancreatic and squamous cell cancer. Human primary colorectal cancer increased Trx-1 is associated with decreased patient survival. Trx-1 is a target for cancer drug development and PX-12, an inhibitor, of Trx-1, is soon to enter Phase I clinical trial.

273 REDOX OF THIOREDOXIN IN OXIDANT-INDUCED APOPTOSIS.

D. P. Jones and W. H. Watson. *Department of Biochemistry, Emory University, Atlanta, GA.*

Two major thiol-containing systems exist that modulate cellular redox balance as well as protect against oxidative stress; one utilizes the tripeptide glutathione (GSH) and the other uses the small protein thioredoxin (Trx). These systems have similar NADPH-dependent reductases and have overlapping functions and activities. Our recent research shows that the redox state of the GSH pool is maintained over a narrow range in cells and varies in association with cell proliferation, differentiation, redox signaling of gene expression and apoptosis. To determine whether the redox state of Trx similarly varies in association with changes in cell function, we have developed a Western blot technique that involves separation of oxidized and reduced forms of Trx based upon the carboxymethylation of thiols. Disulfides do not undergo carboxymethylation and consequently oxidized forms of Trx can be separated from reduced forms by PAGE under native conditions. Each form is detected by Western blotting using an antibody which detects both oxidized and carboxymethylated forms. Elution of the corresponding bands from the gels and analysis by MALDI-mass spectrometry has been used to confirm the identity of the reduced and oxidized Trx species. The results show that Trx is oxidized during oxidative stress and that redox varies independently of the GSH pool under different growth and toxicologic conditions. Application of the method to nuclear and cytosolic fractions further shows that redox in the nuclear compartment is distinct from that in the cytoplasm. (Supported by NIH grant ES09047).

274 REGULATION OF THIOREDOXIN-DEPENDENT PEROXIDASE PEROXIREDOXIN.

S. Rhee. *Laboratory of Cell signaling, National Heart, Lung, and Blood Institute, NIH, Bethesda, MD.* Sponsor: D. Jones.

Recent evidence suggests that H2O2, produced in response to stimulation of a variety of receptors, serves as an intracellular messenger. Timely elimination of second messengers after completion of their mission is critical for receptor signaling.This would seem especially true for H2O2, which is readily converted to deleterious hydroxyl radicals. Peroxiredoxin (Prx)is a family of peroxidases that exist in multiple isoforms in a variety of cells. The four mammalian members, Prx I, II, III, IV, contain two conserved cysteines that correspond to Cys52 and Cys 173 of human Prx I. They exist as a head-to-tail dimmer. The oxidized intermediates of Prx I-IV pro-

duced in the presence of H2O2 are dimmers containing intermolecular disulfide between the two conserved cysteines and the disulfides are reduced by thioredoxin but not by glutaredoxin or glutathione. Cytosolic Prx enzymes (Prx I, II, and IV) participate in receptor signaling by eliminating H2O2. Prx enzymes may participate passively by removing H2O2 molecules that diffuse away from the sites of production or participate actively by being subjected to spatiotemporal regulation. Our recent studies suggest that the latter is likely the case. Prx I and II are mainly cytosolic but are also found in nuclear fractions. The amount of Prx I and II in the nuclear fraction increases in response to serum stimulation and decreases in response to treatment with H2O2 or UV. PrxI and PrxII, which contain a consensus site [TP(K/R)K] for phosphorylation by cyclin dependent kinase (CDK), are phosphorylated by several CDKs in cells. Phosphorylation by CDK abolished peroxidase activity. When experiments were carried out with HeLa and NIH3T3 cells synchronized at various cell cycles, the highest level of Prx I phosphorylation was detected in G2/M phase arrested with nocodazole. When the cells were released from nocodazole block, the levels of Prx I phosphorylation gradually decreased as the number of mitotic cells diminished. These results suggest that Prx I and II play important roles in regulating H2O2 concentration in nucleus.

275 THE FIELD OF TOXICOLOGY-NEW CENTURY, NEW CHALLENGES.

B. A. Schwetz. *Office of the Commissioner, FDA, Rockville, MD.*

The field of toxicology is driven by issues that relate to safety of consumer products, occupational exposures, human exposure from substances in the environment, as well as the effect of chemicals on environmental species. In the coming years, toxicology will face new types of issues, ones that will require new types of expertise to deal with them effectively. Although toxicology will continue to be central as the basis for making good decisions, we must plan ahead now so that we have the right types of expertise to make future decisions. How will new technology be different from the recent past? While large molecular weight substances are still composed of chemical units, there will be less emphasis in the future on traditional chemicals, particularly those of low molecular weight. We will be faced with high throughput, large volume data systems. This capability will present challenges to the field of toxicology that we have not experienced before. As we move away from traditional chemical-driven questions to issues related to products of new technology, some parts of our previous experience will be less useful than they have been in the past. As a consequence, our experience in traditional risk assessment will also be less valuable than in the past, partly because there will be no historical experience for many of the types of molecules that we will be dealing with in the future. With the anticipated change in toxicological issues, there are important questions about the future of toxicology. Will we as a field be prepared to handle these issues? Are we training scientists in areas to be responsive to these issues? How do we avoid shortages of scientists in certain critical areas and, perhaps, more important, how do we avoid creating an excess of scientists in less critical areas? Who will train people in these required areas of expertise? Most importantly, how will we attract these people to help us with questions in the field of toxicology? We need to begin to evaluate our strategy so that newly-trained toxicologists will be prepared to meet the future demands of our field.

276 IMMUNOLOGY/MICROBIOLOGY-BRIDGING A LINK TO TOXICOLOGY.

K. L. White. *Dept. of Pharmacology & Toxicology, Virginia Commonwealth University, Richmond, VA.*

One of the most challenging activities facing an educator today, including those teaching toxicology, is selecting what information will be taught in a course or included in a study program. This is particularly challenging when the area of study spans multiple disciplines. The field of immunotoxicology is an example of an area which requires training in multiple areas, including toxicology, pharmacology, immunology and microbiology. How these disciplines are bridged or merged together varies from institute to institute. Most of the young scientist entering the field of immunotoxicology come from one of two backgrounds. There are those which have received their primary training in the field of toxicology, either from a program which specializes in toxicology or from departments of Pharmacology and/or Toxicology. These students take additional courses in immunology and microbiology in order to focus on the immune system as their area of expertise. The other major pathway produces students with in-depth training in immunology and/or microbiology who take courses in toxicology and/or pharmacology to learn basic concepts of toxicology. Regardless of the pathway followed, a strong background in the fundamentals of toxicology is necessary when conducting immunotoxicology research. With the explosion of new information in the various fields of immunology and toxicology, the balance between training toxicologist to meet future needs and the duration of toxicological training programs is becoming a critical issue. This situation will continue to be a growing concern as we attempt to include additional training in the areas of genomics and proteomics in our toxicology programs in order to meet the toxicological needs of the future.

277 BIOENGINEERING-BRIDGING A LINK TO TOXICOLOGY.

W. E. Bentley. *Dept. of Chemical Engineering, University of Maryland, College Park, MD.* Sponsor: B. Schwetz.

According to the NIH, "Bioengineering integrates physical, chemical, or mathematical sciences and engineering principles for the study of biology, medicine, behavior, or health. It advances fundamental concepts, creates knowledge for the molecular to the organ systems levels, and develops innovative biologics, materials, processes, implants, devices, and informatics approaches for the prevention, diagnosis, and treatment of disease, for patient rehabilitation, and for improving health". This paper will highlight the integration of molecular biosciences with engineering to optimize objective functions commonly found in many engineering disciplines, specifically for the creation of new or better products and manufacturing processes. New diagnostic tools including fiber optic sensors and gene arrays, and protein synthesis systems, such as bacteria that utilize cell-to-cell communication and self-optimizing insect larvae enable new and more efficient pathways to products that are biologically based. As chemical-based products are replaced with biological-based products, so grows the interface between bioengineering and toxicology that will ensure that processes and products are developed in the context of end-use performance and safety.

278 MODELING CELL SIGNALING IN RESPONSE TO TOXICANTS.

M. A. Davis. *School of Medicine, Dept. of Pathology, University of Maryland, Baltimore, MD.*

Unlike growth factors, toxicants or pharmacological agents may utilize signaling pathways to exert adverse or desired organ responses in unique ways. The new demands in toxicology studies for cellular and molecular modeling will require that toxicologists have an appreciation for the complex series of events that occur in most cell signaling pathways. In addition, pharmacological agents are becoming more and more targeted to particular signaling proteins; therefore, new toxicologists will need to be more knowledgeable about signal transduction for proper toxicological evaluation of these targeted therapies. The response of an organ to low level toxicant exposure is often related to molecular responses elicited at the cellular level. Generation and evaluation of "new age" compounds designed for specific protein targets may likely require approaches that encompass understanding and profiling of specific molecular events that provide evidence of target specificity or potential mechanisms for observed toxicities. Indeed, the toxic effect of a chemical may be mechanistically related to its interaction with intracellular protein targets and subsequent alterations in cellular function. In this section, the potential contribution of cell signaling in mediating an organ's response to a toxicant will be discussed. Using a few specific examples, interactions between toxicants and cellular signaling proteins will be presented. These interactions will be presented in context of the cellular response and the potential to predict organ toxicity. Experimental approaches that can be used to examine specific or global effects on cellular proteins or cell signaling will also be presented. Lastly, *in vivo* models that may be appropriate for examining the relevance of a cell signaling protein to the toxicity of components will be presented. The overall goal of this section is to discuss scientific approaches that may be useful to academic discovery or regulatory scientists involved in mechanistic research or risk assessment.

279 BIOINFORMATICS-BRIDGING A LINK TO TOXICOLOGY.

W. B. Mattes. *Predictive & Mechanistic Toxicology, Pharmacia & Upjohn, Inc, Kalamazoo, MI.*

In some circles it might seem that any computer application outside of word processing and spreadsheets is "bioinformatics". A proper definition of the word, however, might be " the intersection of computer science, information technology, and biology." While classically, bioinformatics involves analysis of genetic and protein sequence data, it is often used to described statistical analysis of biological data, database construction and maintenance, database mining, and automated capture of biological data. But what does any of this have to do with toxicology? Consider that in five years or less databases WILL exist containing the mRNA and protein responses to select environmental changes (e.g. chemical treatments) for various experimental systems. But what exactly does the increase in a signal for one probe set

in a given experiment mean for human safety? How will expression responses in rats be correlated with those in dogs, monkeys or humans? How do certain transcript changes statistically correlate with chemical dose or with traditional endpoints such as clinical chemistry or histopathology. How do pathways and genes compare across species? Finally, does a given probe actually measure a given transcript, a splice variant, or even closely related sequences? These questions are in the language of toxicology, but require the tools of bioinformatics, where the sequence and computer rule, and while NDR1 and CAP43 ARE the same gene, c-src and Src are not. Toxicologists unfamiliar with these tools and concepts will be a great disadvantage in the coming decades, and the challenge of training programs is to incorporate this knowledge for both faculty and students alike.

280 THE ROLE OF THE SOCIETY OF TOXICOLOGY IN PROFESSIONAL TOXICOLOGY EDUCATION IN THE FUTURE.

D. L. Eaton. *Dept. of Environmental Health, University of Washington, Seattle, WA.*

As the largest professional organization of toxicologists in the world, SOT must provide a leadership role in fostering necessary change in toxicology education. The discipline of toxicology remains highly relevant as a basic biomedical field of study, but must be able to keep pace with rapidly changing technologies and workforce demands. The Council of the SOT recently evaluated our Long Range Program and Strategic Objectives (strategic plan). Fifteen key areas of importance were 'rank ordered'. The top priority was the strategic objective to "Provide tools and resources to members that will enhance their professional and scientific development." Indeed, imbedded throughout SOT's stragetic plan is the recognition that SOT must provide direction and leadership to ensure that toxicologists of the future are properly trained in the diverse array of new tools and technologies that are changing biomedical sciences in general. Genomics, proteomics, metabolomics (and whatever the new '-omic' the future might hold!), along with computational tools of bioinformatics and the exciting possibilities of nanotechnology will become routine 'tools of the trade' in the next decade in many aspects of toxicology and risk assessment. However, it is imperative that we ensure that the fundamental concepts of toxicology are not lost in the glamour of new technologies. Although a detailed understanding of the molecular mechanism of action of a toxicant is certainly a worthwhile goal, we must ensure that the 'biology' in molecular biology is not left behind in our zeal to become more molecular. The response of the whole organism, and the many complicated interactions that occur at the 'whole animal' level, are afterall, what toxicology is all about. Through our annual meeting activities, and the new 'Current Concepts in Toxicology' focused meetings, SOT will continue to provide opportunities for all toxicologists to 'broaden their horizons' to meet the changing demands for effective product safety evaluation and risk assessment of chemical hazards.

281 DISTINCT ISOFORMS OF CALCIUM-INDEPENDENT PHOSPHOLIPASE A_2 (iPLA$_2$) ARE RESPONSIBLE FOR APOPTOSIS OF ENDOTHELIAL CELLS INDUCED BY 1-METHYLANTHRACENE (1-MA) AND PHENANTHRENE (PA).

P. K. Tithof[1], M. Elgayyar[1], K. P. Lu[2] and K. Ramos[2]. [1]*University of Tennessee, Knoxville, TN and* [2]*Texas A&M University, College Station, TX.*

Smokers demonstrate a significant increase in endothelial cell (EC) injury when compared to non-smokers, a response associated with apoptosis. Specific components of cigarette smoke that induce apoptosis have not been identified. 1-MA and PA are polycyclic aromatic hydrocarbons present in high concentrations in cigarette smoke. This study was conducted to test the hypothesis that 1-MA and PA induce apoptosis of cultured human coronary artery ECs (HCAECs). HCAECs were grown to 90% confluence and treated with 30 μM 1-MA, PA or vehicle for various times. Apoptosis was detected by confocal microscopy of Annexin V/Propridium iodide staining and by Western analysis for cleavage of poly(ADP)ribose polymerase. Apoptosis was evident after 1 hour of treatment with 1-MA or PA, but not vehicle. Given that apoptosis of many cell types involves iPLA$_2$ activity, subsequent experiments were conducted to evaluate the role of PLA$_2$s in EC apoptosis. ECs were labeled for 24 h with 0.25 μCi/ml ^{3}H-arachidonic acid (AA) and release of ^{3}H-AA into the medium was used as a measure of PLA$_2$ activity. Gene expression for various iPLA$_2$ isoforms was evaluated by reverse transcription-polymerase chain reaction (RT-PCR). Both 1-MA and PA induced concentration- and time-dependent release of ^{3}H-AA that preceded the onset of apoptosis. Furthermore, the inhibitor of Group VI iPLA$_2$, bromoenol lactone (BEL), inhibited ^{3}H-AA release and apoptosis induced by 1-MA, but not PA. Conversely, the inhibitor of acidic iPLA$_2$, MJ33, significantly attenuated ^{3}H-AA release and apoptosis in response to PA, but not 1-MA. RT-PCR experiments demonstrated that the genes for these two enzymes are expressed in HCAECs. Collectively these data suggest that 1-MA and PA induce apoptosis by activating distinct isoforms of iPLA$_2$. This effect may be relevant for the mechanism by which cigarette smoking causes EC injury. (Supported by American Heart Association Grant #0160264B).

282 STATIN INDUCED APOPTOSIS IN DIFFERENTIATED RAT SKELETAL MUSCLE CELLS.

T. E. Johnson, D. R. Umbenhauer and J. F. Sina. *Merck Research Labs, West Point, PA.*

Statins are prescribed with increasing frequency due to their proven actions on treating hypercholesterolemia and their potential to lower cardiovascular disease risk . This drug class is well tolerated by most individuals, but in < 1% of the population, they cause myopathy and very rarely, rhabdomyolysis. Myopathy incidence increases with statin dose and with the coadministration of some drugs, but the mechanism is poorly understood. One fundamental question that has not been adequately addressed is how statins cause myotoxicity. Using an *in vitro* rat model of differentiated skeletal muscle, we investigated the ability of a statin to induce apoptosis in this system. L-6 myoblasts were cultured in matrigel-coated 6-well plates, in differentiation medium for six days. During this period, myoblasts formed myotubes by about Day 4 and expressed maximal levels of intracellular creatine phosphokinase, a muscle differentiation marker, by Day 6. The myotube cultures were then treated with Compound A (lactone form), Compound B (open acid form of A) or Compound C (epimer, inactive against HMG-CoA reductase). Apoptosis was assessed over a timecourse by TUNEL and by activated caspase-3 staining. The lactone (10 μM) caused a time-related increase in TUNEL positive nuclei, from 3 to 8 fold over control at 7 and 24 hr, respectively. Caspase-3 activation was induced by about 3 fold at 3 hr and increased to about 8 fold at 24 hr. Apoptosis was detected at minimum doses of 1 μM at 7 hr and 50 nM at 72 hr. Similar results were seen with the open acid. In contrast, the epimer, at a 100 fold higher concentration, induced a 3 fold increase in apoptosis, only after 48 hr. The statin induced-apoptotic response could be inhibited by 50 μM mevalonate and by a specific caspase 3 inhibitor (Z-DEVD-FMK). Taken together, these results suggest that statins induce apoptosis in differentiated rat skeletal muscle cultures through a mechanism that involves inhibition of HMG-CoA reductase and activation of caspase-3. Until substantiated, these *in vitro* studies might not reflect the process that occurs *in vivo* (animals or humans).

283 ROLE OF FAS-FASL INTERACTIONS IN ESTRADIOL-INDUCED THYMIC ATROPHY AND APOPTOSIS.

Y. Do[1], S. Ryu[1], M. Nagarkatti[1] and P. S. Nagarkatti[2]. [1]*Microbiology and Immunology, Medical College of Virginia, Richmond, VA and* [2]*Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA.*

Previous studies from our laboratory have demonstrated that ©¬-estradiol-17-valerate (E2) induces apoptosis in thymocytes leading to thymic atrophy. In the current study we investigated the role of Fas-FasL interactions in E2-induced thymic atrophy and susceptibility to apoptosis using C57BL/6 wild-type (+/+), Fas-deficient (C57BL/6-*lpr/lpr*) and FasL-deficient (C57BL/6-*gld/gld*) mice. The +/+/, *lpr* and *gld* mice were treated with various concentration of E2 such as 75, 25, 5, 1, or 0.1mg/kg body weight or vehicle. The thymi from these mice were harvested on days 1, 4, and 7 following treatment and cellularity and apoptosis were determined. Treatment with E2 caused a decrease in thymic cellularity at all doses except 0.1mg/kg, in all three groups of mice, particularly on days 4 and 7. Interestingly, however, the degree of thymic atrophy in *lpr* and *gld* mice was significantly less than that seen in wild-type mice. When thymocytes were analyzed for apoptosis, cells from *lpr* and *gld* mice showed decreased levels of apoptosis. Moreover, cDNAarray analysis of gene expression revealed that treatment with E2 upregulated several genes involved in apoptosis including FasL, caspases, and TRAIL. At higher doses, E2 caused a decrease in cellularity of the spleen in wild-type mice. Also, E2 treatment decreased the proliferative response of T cell to the superantigen, SEA. Together, the current study suggests that estrogen may cause immunosuppression in activated T cells by inducing FasL gene and triggering apoptosis through paracrine or autocrine pathways (supported in part by NIH grants- ES 09098, HL 58641 and AI 01392).

284 DIETHYLSTILBESTROL INDUCES APOPTOSIS IN LYMPHOMAS AND LEUKEMIAS: ROLE OF FAS LIGAND UPREGULATION.

N. C. Brown[1], M. Nagarkatti[1] and P. Nagarkatti[2]. [1]*Microbiology and Immunology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA and* [2]*Pharmacology and Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA.*

Endocrine disrupting compounds like estrogens have the ability to alter the immune system. One such compound is a synthetic nonsteroidal estrogen, diethylstilbestrol (DES). Studies from our Lab. have demonstrated that estrogen induces

thymic atrophy by triggering apoptosis. In the current study, we investigated the ability of DES to induce apoptosis *in vitro* in murine lymphomas, LSA and EL-4 as well as human lymphomas and leukemias, Jurkat, Sup T1, HUT 78 and Molt-4. For this purpose, tumor cells were cultured with DES (50, 25, 10, 1 microM) in serum-free medium. Twenty four hours later, the cell numbers were enumerated by trypan blue dye exclusion and apoptosis was detected by TUNEL staining. Studies demonstrated that DES at concentrations of 10-50microM induced varying levels of apoptosis in all the cell lines tested. Inasmuch as Fas-Fas ligand (FasL) interactions play a crucial role in induction of apoptosis, further studies were performed to assess the level of expression of these molecules on the cells following treatment with DES. It was observed that while Fas expression was not altered, there was significant upregulation of FasL. The induction of apoptosis by DES was inhibited by treatment with caspase inhibitors including z-VAD-fmk, z-WEHD-fmk, z-VDVAD-fmk and z-IETD-fmk. Together, these studies demonstrated that DES-induced apoptosis of tumor cells may involve the death-receptor pathway (Supported in part by grants from NIH: ES09098 and HL58641).

285 LIGATION OF CANNABINOID RECEPTORS LEADS TO INDUCTION OF APOPTOSIS IN TRANSFORMED IMMUNE CELLS.

C. A. Lombard[1], R. J. Mc Kallip[1], M. Nagarkatti[1] and P. S. Nagarkatti[2]. [1]*Microbiology and Immunology, Medical College of Virginia/Virginia Commonwealth of Virginia, Richmond, VA and* [2]*Pharmacology and Toxicology, Medical College of Virginia/Virginia Commonwealth of Virginia, Richmond, VA.*

Exposure to delta 9-tetrahydrocannabinol (THC), an active component of marijuana can lead to suppression of the immune response although the mechanism remains unclear. In the current study, we tested the hypothesis that cannabinoids induce toxicity in lymphoid cells by triggering apoptosis. To this end, we screened a large number of murine and human transformed cells of immune origin for the expression of cannabinoid receptors and their susceptibility to apoptosis induced by THC and other cannabinoid receptor agonists. RT-PCR and Western blot analysis revealed that murine tumor cell lines EL-4, LSA, and P815 expressed both the CB1 and CB2 receptors. Exposure of EL-4, LSA, and P815 cells to THC led to a significant reduction in cell viability and increase in apoptosis. Exposure of EL-4 tumor cells to the synthetic cannabinoid, HU-210 also led to significant induction of apoptosis, while exposure to WIN55212 was less effective. Treatment with THC *in vivo* led to a significant reduction in the number of viable tumor cells and an increase in tumor cell apoptosis. Examination of a number of human leukemias and lymphomas revealed that unlike the murine tumors, Jurkat, Molt-4, and Sup-T1 cells express only CB2 receptors. Exposure of these tumor cells to 5 μM THC or HU-210 led to significant induction of apoptosis. The induction of apoptosis by THC in tumor cells was mediated through the cannabinoid receptors inasmuch as it was inhibited in the presence of CB1 and/or CB2 receptor antagonists, SR14176 and SR144528. Together, these data demonstrate that ligation of cannabinoid receptors can induce apoptosis in transformed immune cells. Thus, cannabinoids may induce immunotoxicity by triggering apoptosis in lymphoid cells through cannabinoid receptors. These studies also suggest that cannabinoid receptor agonists may serve as anticancer agents (Supported in part by grants NIH DA14885, ES09098 and HL58641)

286 DIFFERENTIAL INVOLVEMENT OF THE MITOCHONDRIAL/CASPASE-9-DEPENDENT APOPTOTIC PATHWAY IN HYDROQUINONE TREATED HL-60 AND JURKAT LEUKEMIA CELLS.

S. H. Inayat-Hussain[1] and D. Ross[2]. [1]*Department of Biomedical Science, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia and* [2]*Department of Pharmaceutical Sciences, University of Colorado Health Sciences, Denver, CO.*

Hydroquinone (HQ), a benzene metabolite induces apoptosis in hematopoietic cells and is believed to be involved in the pathophysiology of benzene-induced aplastic anemia. Here, we investigated the involvement of mitochondria and activation of the apical caspase-9 in HQ induced apoptosis in myeloperoxidase (MPO)-rich HL-60 and MPO-deficient Jurkat T cell. Treatment of HL-60 and Jurkat cells with HQ (75μM and 50μM respectively) resulted in comparable apoptosis as assessed by flow cytometric and biochemical changes, including phosphatidylserine (PS) exposure, loss of mitochondrial membrane potential (MMP) and caspase-9 cleavage. In HL-60 cells, pretreatment with the pan-caspase inhibitor benzyloxycarbonyl-Val-Ala-Asp-fluoromethylketone (ZVAD) did not inhibit PS exposure and the loss of MMP was relatively unaffected. Interestingly, activation of caspase-9 was only inhibited to the p37/35kDa subunits without any intact protein observed. In marked contrast, in HQ-treated Jurkat cells, ZVAD significantly abrogated PS exposure and loss of MMP with caspase-9 remained in its zymogen form. These data suggest that in HQ-treated HL-60 cells, the event(s) leading to mitochondrial alteration occurs *via* a ZVAD insensitive mechanism suggesting for a caspase-independent pathway in HQ treated HL-60 cells. In contrast, in HQ-treated Jurkat cells, the event(s) leading to the participation of mitochondria/caspase-9 occurs in a ZVAD sensitive manner indicating a caspase-dependent process in this apoptotic death. These differential effects may be attributed to MPO-catalyzed activation of HQ to highly reactive quinones and reactive oxygen species in HL-60 cells, and, as a result, specific death pathway is recruited. (Supported in part by ES 09554)

287 MITOCHONDRIAL SUPEROXIDE DISMUTASE INHIBITS MITOCHONDRIAL OXIDATIVE STRESS AND APOPTOSIS IN CULTURED RAT HEPATOCYTES AFTER TUMOR NECROSIS FACTOR-α (TNFα).

T. Qian and J. J. Lemasters. *Cell & Developmental Biology, University Of North Carolina at Chapel Hill, Chapel Hill, NC.*

Onset of the mitochondrial permeability transition (MPT) is a key event signaling TNFα-induced apoptosis in cultured rat hepatocytes. Previously, we showed that pre-exposure to non-toxic oxidative stress sensitizes hepatocytes to the TNFα-induced MPT and apoptosis. In the current study, we tested whether expression of cytosolic and mitochondrial superoxide dismutase (SOD1 and SOD2, respectively) inhibits the MPT and apoptosis promoted by TNFα plus oxidative stress. Rat hepatocytes were infected with an adenovirus (Ad5IkB, 30pfu) for 2 hours to induce I?B superrepressor. Some hepatocytes were also infected with adenoviruses (30 pfu) expressing SOD1 or SOD2 for 3 hours. Afterwards, the hepatocytes were exposed to 1 μM t-butylhydroperoxide (t-BuOOH), and TNFα (30 ng/ml) was added 2 h later. Cell viability and cellular oxidative stress were determined by propidium iodide (PI) and dichlorodihydrofluorescein (DCF) fluorometry, respectively. Mitochondrial reactive oxygen species (ROS) formation (DCF), mitochondrial membrane potential (tetramethylrhodamine methylester) and mitochondrial inner membrane permeabilization (DCF leakage) were monitored by confocal microscopy. In t-BuOOH pretreated cells, TNFα accelerated ROS formation, as indicated by a 387% increase of DCF fluorescence over 3h. In hepatocytes expressing SOD2, ROS was inhibited to 182%. SOD2 also inhibited TNFα-induced cell killing from 68% after 12 h to 25%. Expression of SOD1 did not protect against cell killing. Confocal microscopy showed increased mitochondrial ROS generation, mitochondrial depolarization and mitochondrial membrane permeabilization, which began 4 h after TNFα plus t-BuOOH. SOD2 expression suppressed mitochondrial ROS, depolarization and permeabilization even after 8 h. In Conclusion, mitochondrial superoxide generation sensitizes cultured rat hepatocytes to TNFα-induced apoptosis by promoting onset of the MPT. Expression of mitochondrial but not cytosolic SOD blocks this apoptotic signaling.

288 PEROAXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA ENHANCES SUSCEPTIBILITY TO APOPTOSIS INDUCERS IN MOUSE LIVER.

S. Xiao, R. Bahnemann, A. Laughter, A. J. Stauber and J. C. Corton. *Biochemistry and Molecular Genetics, CIIT Center for Health Research, Research Triangle Park, NC.* Sponsor: J. Corton.

Peroxisome proliferators (PP) are a large class of structurally dissimilar chemicals that induce hepatocellular proliferation and peroxisome proliferation through the nuclear receptor family member peroxisome proliferator-activated receptor alpha ($PPAR_\alpha$). We performed gene expression profiling to examine differences in gene expression between untreated wild-type and $PPAR_\alpha$-null mice. $PPAR_\alpha$-null mice exhibited altered expression of a number of genes that play roles in apoptosis, favoring decreased susceptibility to apoptosis. We hypothesized that $PPAR_\alpha$ activation positively influences induction of apoptosis in the liver. Wild-type and $PPAR_\alpha$-null mice were treated in separate experiments with two apoptosis inducers: Jo-2 antibody, which induces the Fas-dependent death pathway, and conconavalin A (ConA), which induces apoptosis through an unknown pathway. Mice were pretreated with and without the PP, WY-14, 643 (WY). Wild-type mice treated with WY were more sensitive to induction of apoptosis by Jo2 antibody than untreated wild-type mice or untreated or WY-treated $PPAR_\alpha$-null mice. After exposure to Jo2, morbidity and mortality were significantly higher in the presence of WY in wild-type mice and paralleled increases in hepatocyte apoptosis and necrosis. Wild-type mice treated with WY were also more sensitive to the apoptotic effects of ConA. We examined the expression of a number of gene products in the liver that influence apoptosis including those found to be altered by gene expression profiling. In the absence of apoptosis-inducer treatment, wild-type mice treated with WY exhibited increases in the activated form of caspase-9 which paralleled the decrease in the anti-apoptotic protein Mcl-1, a member of the Bcl-2 family. These data demonstrate that $PPAR_\alpha$ activation can significantly enhance the sensitivity of apoptosis inducers in the mouse liver possibly through alteration in the expression of proteins that regulate apoptosis.

289 S-(1, 2-DICHLOROVINYL)-L-CYSTEINE (DCVC)-INDUCED CHANGES IN EXPRESSION OF GENES RELATED TO APOPTOSIS AND CELL GROWTH IN HUMAN PROXIMAL TUBULAR CELLS.

L. H. Lash, S. E. Hueni and D. A. Putt. *Pharmacology, Wayne State University Sch. Med., Detroit, MI.*

DCVC, the cysteine conjugate of trichloroethylene, is a potent nephrotoxicant. Using a broad range of concentrations, including environmentally relevant ones (10 to 500 μM), we showed that DCVC induces necrosis, apoptosis and cell proliferation in a time- and concentration-dependent manner in primary cultures of human proximal tubular (hPT) cells. Significant apoptosis was observed with as low as 10 μM DCVC at 1 hr, using cell cycle analysis with propidium iodide staining or annexin V staining and flow cytometry. Maximal apoptosis occurred with 50 μM DCVC at 4 hr incubation. Similar time course was observed for enhanced cell proliferation, as assessed by cell cycle analysis with flow cytometry and incorporation of radiolabeled dTTP. In contrast, significant increases in necrosis (as assessed qualitatively by morphology and quantitatively by release of lactate dehydrogenase) did not occur until later incubation times (≥ 24 hr) and higher DCVC concentrations (≥ 100-200 μM). To gain more insight into the regulation of these responses, we measured protein expression of several genes that are related to apoptosis and cell growth regulation. Primary cultures of hPT cells were incubated with 10, 50, 100, 200, or 500 μM DCVC for 0.5, 1, 2, 4, 8, or 24 hr and protein expression was determined by Western blot analyses. Expression of several proteins related to apoptosis were altered, including αBax (decrease), Apaf1, Bcl2 and caspase-9 (all increase), and αPARP (increase in low molecular weight fragments). cJun increased only at low DCVC concentrations, whereas expression of Hsp27, NF-κB p65 subunit, and P53 all showed modest to large increases that were clearly dependent on DCVC concentration and exposure time. These results are consistent with the prominence of apoptosis at low concentrations of DCVC and with a role for oxidative stress and changes in regulation of cell growth in the response of hPT cells that are exposed to DCVC. (Supported by NIEHS Grant ES08828.)

290 ACTIVATION OF THE RAS/MAPK PATHWAY PROTECTS HYPOXIC TUMOR CELLS AGAINST P53-DEPENDENT APOPTOSIS.

A. L. Nieminen, L. Li, G. Mo and F. Agani. *Department of Anatomy, Case Western Reserve University, Cleveland, OH.*

Tumor hypoxia develops in most solid tumors because of inadequate vasculature or abnormal vascular architecture. Frequently, these hypoxic cancer cells resist radiation and chemotherapy. The aim of this study was to characterize the roles of p53 and the Ras/MAPK pathway in apoptosis to hypoxic tumor cells. p53+/+ and -/- mouse embryonic fibroblasts (MEF) transformed with proto-oncogenes Ras and E1A were exposed to hypoxia for 7 h. Hypoxia caused 29 ± 4.2% and 4 ± 1.2% apoptosis in p53+/+ and -/- MEF, respectively, as assessed by changes in nuclear morphology. Hypoxia had no effect on p53+/+ and -/- MEF without Ras and E1A. Surprisingly, the specific inhibitor of mitogen-activated protein kinase kinase (MKK1), PD98059 (50 μM), accelerated hypoxia-mediated apoptosis (85 ± 4.6%) in p53+/+ but not p53-/- MEF. PD98059 alone caused 45 ± 8.8% apoptosis in p53+/+ MEF. To investigate whether apoptosis induced by inhibition of MKK1 was mediated by activation of procaspase-8, we measured caspase-8 activation by fluorogenic assay and Western blot. Both methods showed that 4 h exposure to hypoxia or PD98059 alone did not activate caspase-8. However, the combination of hypoxia and PD98059 caused a 2-fold increase of caspase-8 activity in p53+/+ MEF but not in p53-/- MEF. To determine whether caspase-8 activation caused translocation of Bid from the cytosol to mitochondria, we transiently transfected p53+/+ MEF with cDNA Bid-GFP. Before hypoxia the pattern of Bid-GFP fluorescence was diffuse indicating a cytosolic localization. After hypoxia Bid-GFP fluorescence became punctate in the presence of PD89059 and colocalized with MitoTracker Red. Collectively, our results indicate that p53 sensitizes MEF to hypoxic apoptosis. Since inhibition of the Ras/MAPK pathway sensitizes hypoxic cancer cells to caspase-8-activation and apoptosis, we conclude that the Ras/MAPK pathway provides a survival signal against p53-mediated hypoxic apoptosis. MAPK inhibitors may therefore be useful as an adjunct chemotherapy for hypoxic solid tumors. Supported by NS39469.

291 ALTERED APOPTOTIC RESPONSE IN 4-HYDROXYEQUILENIN-TREATED MCF-10A CELLS.

J. Yao, E. Pisha, X. Liu, Y. Li, L. Yu and J. L. Bolton. *Department of Medicinal Chemistry and Pharmacognosy, University of Illinois at Chicago, Chicago, IL.*

Excessive exposure to synthetic and endogenous estrogens has been associated with the development of cancer in several tissues including the breast. 4-Hydroxyequilenin (4-OHEN), a major metabolite of equine estrogens present in Premarin® estrogen replacement formulation, has been shown to induce DNA damage and apoptosis in human breast cancer cells. It also has the potential to be a tumor promoter and complete carcinogen *in vitro*. To further understand the mechanism(s) of estrogen carcinogenesis, we have used human non-tumorigenic breast epithelial MCF-10A cells to study the toxic effects of 4-OHEN. We observed cytotoxicity in MCF-10A cells induced by 4-OHEN; LC_{50} for 18 h-treatment was 10.7 ± 1.9 μM. 4-OHEN also caused dose-dependent increases in apoptosis and DNA damage as measured by the DAPI nuclear screening assay and the Comet assay, respectively. In the present study, we found that treatment with 100 nM 4-OHEN biweekly for 2 weeks induced cellular transformation in these human breast epithelial cells. Interestingly, after the treatment of cells with 100 nM 4-OHEN biweekly for 4 weeks, the treated MCF-10A cells were resistant to 4-OHEN- or cisplatin-induced apoptosis. The mechanism of cellular resistance to apoptosis is currently under investigation. Our data indicated that long-term low-level estrogen exposure could induce DNA damage and initiate cells that become resistant to apoptosis, which could contribute to the mechanism(s) of equine estrogen carcinogenesis. (Supported by NIH grant CA73638).

292 THE SEROTONERGIC NEUROTOXICITY OF α-METHYLDOPAMINE THIOETHERS REQUIRES THE SEROTONIN TRANSPORTER-DEPENDENT GENERATION OF REACTIVE OXYGEN SPECIES.

D. C. Jones, S. S. Lau and T. J. Monks. *Center for Molecular & Cellular Toxicology, University of Texas at Austin, Austin, TX.*

We have previously shown that thioether metabolites of 3, 4-methylenedioxyamphetamine (MDA) and 3, 4-methylenedioxymethamphetamine (MDMA, ecstasy), 5-(glutathion-S-yl)-α-methyldopamine (5-[GSyl]-α-MeDA) and 2, 5-*bis*(GSyl)-α-MeDA, are selective serotonergic neurotoxicants. Using primary cell cultures derived from the striatum (ST) and hippocampus (HP), and the serotonergic JAR cell line, we examined the mechanism(s) involved in α-MeDA-thioether-mediated toxicity. Immunohistochemical staining indicated that both 5-(GSyl)-α-MeDA and 2, 5-*bis*(GSyl)-α-MeDA produced a significant loss in serotonin (5-HT) positive cells in HP, ST, and JAR cell cultures. HP cell cultures, which contain a higher proportion of 5-HT-positive cells, were more sensitive to toxicity than primary cultures of ST cells. TUNEL staining indicated that cell death in all three models was apoptotic. Although the 5-HT transport inhibitor, fluoxetine (FX), attenuated 5-(GSyl)-α-MeDA and 2, 5-*bis*(GSyl)-α-MeDA mediated cell loss, the dopamine transport inhibitor, nomifensine, had no effect on cell death. Subsequent uptake experiments revealed 5-(GSyl)-α-MeDA and 2, 5-*bis*(GSyl)-α-MeDA significantly inhibited 5-HT uptake in HP, ST, and JAR cells. This effect was potentiated with FX. Interestingly, in HP cells, and to some extent, in JAR cells, 5-(GSyl)-α-MeDA and 2, 5-*bis*(GSyl)-α-MeDA *increased* dopamine uptake, an effect that was blocked by FX. Finally, in all cell types, 5-(GSyl)-α-MeDA and 2, 5-*bis*(GSyl)-α-MeDA induced a significant increase in the generation of reactive oxygen species (ROS). Pretreatment with FX attenuated ROS production while nomifensine had little effect, suggesting that the 5-HT transporter is important for the production of ROS. These results are consistent with the view that MDA and MDMA induced serotonergic neurotoxicity are mediated *via* the formation of thioether conjugates capable of generating ROS in a manner dependent upon the 5-HT transporter.

293 TRICHLOROETHYLENE (TCE) ELICITS TOXICITY IN THE MALE REPRODUCTIVE SYSTEM.

P. G. Forkert[1], L. H. Lash[2], V. Nadeau[3] and R. Tardif[3]. [1]*Anatomy and Cell Biology, Queen's University, Kingston, ON, Canada,* [2]*Pharmacology, Wayne State University, Detroit, MI and* [3]*Environmental & Occupational Health, University of Montreal, Montreal, PQ, Canada.*

We have tested the hypothesis that TCE is metabolized by CYP2E1 and elicits toxicity in the male reproductive system. We have exposed mice to TCE by inhalation (1000 ppm) for 6 h per day for 5 days per week for a total of 1 to 4 weeks. Internal exposure to TCE was monitored by measuring urinary levels of the TCE metabolites, trichloroacetic acid (TCA) and trichloroethanol (TCOH). We have determined CYP2E1 expression in epididymis and testis by i) immunohistochemical staining, ii) immunoblotting, and iii) measurement of p-nitrophenol hydroxylase activity. We have also determined formation of chloral in incubations of microsomes from epididymis and testis and in microsomes preincubated with a CYP2E1 antibody. Our results showed that urinary levels of TCA and TCOH increased between the first and second week, and remained elevated thereafter. CYP2E1 is localized in epithelial cells of the epididymis and Leydig cells of the testis. Immunoblots of CYP2E1 showed that the protein was present at higher levels in epididymis than in testis. This finding coincided with the 2-fold higher level of hydroxylase activity detected in epididymis *vs.* testis. Formation of chloral in incubations of microsomes from epididymis and testis was time- and concentration-dependent. Peak levels were detected at 60 min of incubation time at a concentration

of 3.0 mM of TCE. Chloral formation by microsomes from epididymis was significantly higher than by those from the testis. Levels were significantly inhibited in epididymal microsomes preincubated with a CYP2E1 antibody. These metabolic parameters correlated with structural changes that were most evident in the epididymal epithelial cells of mice exposed to TCE by inhalation. These results showed that TCE metabolism in the male reproductive system leads to adverse consequences that are manifested to the greatest extent in the epididymis. Supported by Health Canada/Environment Canada and NIEHS RO1-ES08828.

294 FORMATION OF FREE RADICALS FROM METABOLISM OF 1, 1-DICHLOROETHYLENE (DCE) IN MURINE AND HUMAN LUNG AND LIVER.

M. Mombourquette[1], T. Bray[3], E. Ho[3], T. Boileau[3], C. R. Hille[4], C. Hemann[4], K. Collins[2] and P. G. Forkert[2]. *[1]Chemistry, Queen's University, Kingston, ON, Canada, [2]Anatomy & Cell Biology, Queen's University, Kingston, ON, Canada, [3]Human Nutrition, Ohio State University, Columbus, OH and [4]Molecular & Cellular Biochemistry, Ohio State University, Columbus, OH.*

DCE produces lung and liver toxicity upon exposure. The toxic response has been ascribed to formation of reactive intermediates from CYP2E1-mediated metabolism of DCE. Here, we have tested the hypothesis that, in addition to formation of reactive metabolites, free radicals are also produced by DCE exposure. We have used a microsomal incubation system and α-phenyl-*t*-butylnitrone (PBN) as a trapping agent. The PBN spin adducts were detected by electron paramagnetic resonance spectroscopy. Free radicals generated through DCE metabolism were determined in incubations of lung and liver microsomes from mice and humans. The role of CYP2E1 in free radical production was investigated in incubations containing CYP2E1-expressed β-lymphoblastoid microsomes. The potential of glutathione (GSH) to inhibit free radical formation was determined in microsomal incubations supplemented with GSH. Microsomes were incubated with DCE (2-4 mM) in the presence of NADPH and PBN. The PBN adducts were extracted with benzene and subjected to EPR analysis. Free radicals were formed from DCE in incubations containing NADPH, and were not detected in the absence of NADPH. Their formation in lung and liver microsomal incubations was time- and dose-dependent. The amounts of free radicals generated by human microsomes were similar to those in mice. Free radicals were also detected in incubations containing CYP2E1-expressed lymphoblastoid microsomes. Levels of the radicals were decreased in incubations supplemented with GSH. Analysis of hyperfine splitting constants indicated formation of an oxygen-centered radical. These results showed that free radicals are formed from P450-mediated metabolism of DCE, and implicates CYP2E1 as being involved. Supported by Grant MOP 11706 from Canadian Institutes of Health Research.

295 RELATIONSHIP OF THE SINGLE-ELECTRON REDUCTION POTENTIAL OF QUINONES TO THEIR ABILITY TO UNDERGO REDOX CYCLING MEDIATED BY RAINBOW TROUT MICROSOMAL FLAVOPROTEINS.

S. Carney[1], J. Serrano[2], P. K. Schmieder[2] and T. R. Henry[3]. *[1]Biotechnology Training Program, University of Wisconsin, Madison, WI, [2]Mid-Continent Ecology Division, USEPA, NHEERL, Duluth, MN and [3]Experimental Toxicology Division, USEPA, NHEERL, Duluth, MN.*

Exposure to quinones can result in cytotoxicity due to electrophilic arylation or redox cycling *via* enzymatic reduction to the semiquinone radical with subsequent transfer of an electron to molecular oxygen to form superoxide anion radical ($O_2^{\cdot-}$)and subsequent regeneration of the parent quinone. To assess the relationship between the redox cycling ability of quinones in rainbow trout and their single-electron reduction potentials (E^1), the production of $O_2^{\cdot-}$ by a series of quinones with potentials ranging from -348 to +671 mV was determined using two assays. Rainbow trout liver microsomes, containing NADPH cytochrome P450 reductase and NADH-cytochrome b5 reductase, were exposed to quinones in the presence of NADH or NADPH. Generation of $O_2^{\cdot-}$ was measured as O_2 consumption and acetylated cytochrome c reduction. The reduction of acetylated cytochrome c is a more sensitive indicator of $O_2^{\cdot-}$ production. The peak and lower limit for acetylated cytochrome c reduction were E^1 of-36mV and -348mV with NADPH cofactor and E^1 of -203mV and -348mV with NADH cofactor. A narrower range of redox activity was observed with the O_2 consumption assay. The peak rate for oxygen consumption was observed at the same E^1 as for the acetylated cytochrome c assay and the lower limit for reduction was E^1 of -348mV with both NADPH and NADH. These redox windows for rainbow trout microsomes are comparable to those reported for NADPH cytochrome P450 reductase and NADH-cytochrome b5 reductase in rat hepatocytes. In both rats and rainbow trout the peak reduction occurs at a more positive E^1 with NADH cofactor as compared to that with NADPH cofactor. In contrast to rat flavoproteins, the peak rate of quinone redox cycling facilitated by rainbow trout flavoproteins occurred with NADH as the cofactor rather than NADPH. This abstract does not necessarily reflect EPA policy.

296 MASS SPECTRAL CHARACTERIZATION OF DICHLOROACETIC ACID-MODIFIED GLUTATHIONE TRANSFERASE ZETA.

W. B. Anderson[1], D. C. Liebler[2], P. G. Board[3] and M. W. Anders[1]. *[1]Pharmacology & Physiology, University of Rochester, Rochester, NY, [2]Pharmacology & Toxicology, University of Arizona, Tucson, AZ and [3]Molecular Genetics Group, Australian National University, Canberra, Australia.*

Glutathione transferase zeta (GSTZ) is broadly distributed in eukaryotic species. Four polymorphic variants of hGSTZ1-1 have been described. GSTZ is identical with maleylacetoacetate isomerase, which catalyzes the cis-trans isomerization of maleylacetoacetate. GSTZ also catalyzes the biotransformation of a range of α-haloalkanoic acids, including dichloroacetic acid (DCA), which inactivates and covalently modifies the enzyme. The objective of the research was to determine the partition ratio for the inactivation of hGSTZ1a-1a and -1c-1c, the stoichiometry of [1-^{14}C]DCA binding to hGSTZ1c-1c, and the labeling of C16A hGSTZ1c-1c by [1-^{14}C]DCA and to characterize DCA-inactivated hGSTZ1c-1c by MALDI-TOF MS and ESI/MS/MS. The partition ratios for the DCA-induced inactivation of hGSTZ1a-1a and -1c-1c were 2.23 ± 0.27 x 10^3 and 5.7 ± 0.5 x 10^2, respectively. hGSTZ1c-1c incorporated an estimated 0.45 mol [1-^{14}C]DCA/mol enzyme. C16A hGSTZ1c-1c was resistant to inactivation by DCA and incorporated less [1-^{14}C]DCA than hGSTZ1c-1c: 11% incorporation was observed relative to hGSTZ1c-1c. MALDI-TOF MS and ESI/MS/MS characterization of DCA-inactivated hGSTZ1c-1c revealed 2 adducts on the active site-containing tryptic peptide (14)SSCSWR(19) (M+H$^+$ *m/z* 725.4). One modified peptide (M+H$^+$ *m/z* 1030.4) was characterized as the peptide/GSH mixed disulfide. The other modified peptide (M+H$^+$ *m/z* 1088.4) contained both GSH and the carbon skeleton of DCA, presumably in a dithioacetal linkage. These data support a mechanism of inactivation whereby GSH displaces the first chlorine atom of DCA and cysteine-16 in the enzyme active site displaces the second to result in a covalently modified and inactivated enzyme. (Supported by ES03127, ES10056, and ES06694).

297 1, 1-DICHLOROETHYLENE (DCE) ELICITS MITOCHONDRIAL DYSFUNCTION IN MURINE LIVER.

E. J. Martin[1], J. W. Card[2], W. J. Racz[2] and P. G. Forkert[1]. *[1]Anatomy & Cell Biology, Queen's University, Kingston, ON, Canada and [2]Pharmacology & Toxicology, Queen's University, Kingston, ON, Canada.*

Hepatotoxicity induced by DCE, a chemical used in the manufacture of plastics, is ascribed to cytochrome P450-dependent metabolism to reactive intermediates. We have tested the hypothesis that mitochondria are a primary target of toxicity by investigating dose- and time-dependent effects of DCE on mitochondrial respiration. We have also determined the effectiveness of *N*-acetyl-L-cysteine (NAC) to increase glutathione levels and to protect against or decrease potential mitochondrial respiratory perturbations. Liver mitochondria were isolated 2 h after DCE (50, 75, 100, 125, and 150 mg/kg) treatment. Glutamate (complex 1)- and succinate (complex 2)-supported mitochondrial respiration was assessed by measurement of state 3 (ADP-stimulated) and state 4 (resting) rates of oxygen consumption. The corresponding respiratory control ratios (RCR: state 3/state 4) and ADP:O ratios were then calculated. A DCE dose of 125 mg/kg significantly inhibited state 3 respiration at complex I and II. This inhibition led to a significant reduction in corresponding RCRs and ADP:O ratios. Respiration at complex I and II was completely uncoupled with doses of 150 mg/kg or higher. State 3 respiration rates and RCRs for glutamate-supported respiration were significantly decreased at 20, 30, 60, 90, and 120 min after DCE (125 mg/kg) treatment, while those for succinate-supported respiration were significantly decreased at 90 and 120 min. ADP:O ratios for glutamate-supported respiration were significantly decreased at 60, 90, and 120 min, whereas those for succinate-supported respiration were significantly decreased at 120 min after DCE exposure. Pretreatment with NAC (1200 mg/kg) reduced the DCE-induced impairment of mitochondrial respiration, suggesting a role for glutathione depletion in the development of toxicity. These results indicated that DCE exposure produces mitochondrial dysfunction in murine liver. (Supported by Grant MOP 11706 from the Canadian Institutes of Health Research).

298 ALTERATION OF THE RETINOBLASTOMA PATHWAY IN BENZENE-INDUCED THYMIC LYMPHOMAS FROM P53+/- MICE.

S. E. Boley[1], J. Rose[1], J. E. French[2] and L. Recio[1]. *[1]Chemical Carcinogenesis, CIIT Centers for Health Research, Research Triangle Park, NC and [2]Laboratory of Environmental Carcinogenesis/Mutagenesis, NIEHS, Research Triangle Park, NC.* Sponsor: L. Recio.

Exposure of C57BL/6-Trp53 haploinsufficient (N5) mice (p53+/- mice) to inhaled benzene induces a high frequency of thymic lymphomas. Loss of p53 function is a common feature of human cancer and we have previously shown that loss of the

functional p53 allele was a common feature of the benzene-induced tumors supporting the use of these mice to examine the molecular mechanisms of cancer. We then examined the benzene-induced tumors for altered expression of genes involved in the retinoblastoma (Rb) pathway since this pathway is also commonly altered in human tumorigenesis. Real-time quantitative RT-PCR and Western blot analysis were used to determine the levels of genes involved in the Rb pathway (p15INK4b, p16INK4a, p19ARF, Rb, cyclin D1, cyclin D2, and E2F-1) in 18 benzene-induced thymic lymphomas from p53+/- mice. Virtually all genes showed decreased mRNA levels in the tumors, however all tumors showed increased levels of p16INK4a mRNA and protein compared to normal thymus, suggesting that increased levels of p16INK4a mRNA can be used as a biomarker for benzene-induced transformation. Bisulfite DNA sequencing showed that the tumors exhibited reduced methylation at specific CpG sites within the promoter region of p16INK4a suggesting that altered methylation contributed to the p16INK4a mRNA increases. Our data show that benzene-induced thymic lymphomas from p53+/- mice exhibited alterations common to certain human cancers, providing further support for the use of these mice as a model to examine the mechanisms involved in human carcinogenesis.

299 PROGRESSIVE ALTERATIONS IN DNA METHYLATION DURING TUMORIGENESIS.

R. E. Watson[1], G. M. Curtin[2], D. J. Doolittle[2] and J. I. Goodman[1]. [1]*Pharmacol. and Toxicol., Michigan State Univ., E. Lansing, MI and* [2]*Toxicol. Div., R. J. Reynolds Tobacco Co., Winston-Salem, NC.*

DNA methylation (DNA-Me), 5-methylcytosine content of DNA, is an epigenetic process involved in transcriptional control. Typically, there is an inverse relationship between the level of DNA-Me and the degree of transcription. Multiple alterations in DNA-Me occur in precancerous and cancerous tissue, e.g., human colon cancer, suggesting that aberrant patterns of DNA-Me may be a cause of the abnormal transcription of genes involved in carcinogenesis. DNA-Me patterns in tumor tissue are often characterized by a decrease in overall, or global, methylation with a concurrent increase at specific GC-rich regions, e.g., CpG islands, in the 5'-flanking, promoter region of genes. Increased DNA-Me may silence tumor suppressor genes while decreases may facilitate expression of oncogenes. In this study, we employ a two-stage, initiation/promotion, skin tumor model of carcinogenesis. SENCAR mice were initiated with 75 mg dimethylbenz(a)anthracene and promoted with 27 mg of cigarette smoke condensate administered thrice weekly for 29 wk. DNA-Me status was assessed using both an *SssI* methylase assay and an arbitrarily primed PCR procedure to measure global and GC-rich region methylation, respectively. Methylation in GC-rich regions in both tumors and promoted non-tumor skin tissue increased as compared to controls. However, global methylation was decreased only in tumor tissue. Thus, we conclude that an increase in methylation at GC-rich regions may be an early event that occurs in initiated cells that proliferate in response to promoter-treatment. With continued promotion, a subpopulation of these cells that exhibit a global decrease in methylation, while maintaining selected regions of hypermethylation, expand clonally and progress to tumors. The skin tumor initiation/promotion model offers the potential to discern the role that particular alterations in DNA-Me play at specific stages of carcinogenesis. Additionally, methylation status may serve as a useful endpoint in the safety assessment of tumor promoters.

300 EFFECT OF ENVIRONMENTAL CARCINOGENS ON THE METHYLATION OF IGF-II AND C-MYC GENES IN RODENTS.

S. Yang, L. Li, W. Wang, Y. Li, M. Edelbrock, P. M. Kramer, M. A. Pereira and L. Tao. *Pathology, Medical College of Ohio, Toledo, OH.*

Dichloroacetic acid (DCA), trichloroacetic acid (TCA), dibromoacetic acid (DBA), bromodichloromethane (BDCM), methylene chloride (MC) and arsenic (As) are non-genotoxic carcinogens in various organs. DNA methylation as 5-methylcytosine (5-MeC) is a mechanism to regulate the transcription of mRNA. Hypomethylation of DNA and of genes including insulin-like growth factor 2 (IGF-II) and the c-myc protooncogene has been proposed to be an epigenetic mechanism for non-genotoxic carcinogens. We determined the effect of DCA, TCA, DBA, BDCM, MC and As on methylation in the promoter of the c-myc gene and in the differential methylation region 2 of the IGF-II gene. B6C3F1 mice were administered in their drinking water 3.2 mg/l DCA or 4.0 mg/l TCA for 24-96 hours and for 28 days or were administered DBA (1000 and 2000 mg/l) and DBCM (350 and 700 mg/l) for 2-28 days. Methylene chloride was administered to mice by inhalation at 1.04, 3.48 and 10.44mg/liter for 5 days. Mice received by gavage dimethylarsinic acid (DMA) at 600 mg/kg for 5 days. Fisher 344 rats were administered for 2-28 days, DBA (1000 or 2000 mg/l) and BDCM (350 or 700 mg/l) in drinking water or were administered BDCM (50 and 100 mg/kg) by gavage. Methylation of the two genes was determined using the bisulphite-modified DNA sequencing procedure. Methylation in the IGF-II and c-myc genes was decreased in the liver and kidney of BDCM, DMA and MC-treated mice, in the kidney of BDCM and DMA-treated mice, in the skin of DMA-treated mice, in the bladder with DCA, TCA and DBA-treated mice, in the lung of MC-treated mice and in the liver of BDCM and DBA-treated rats. Hypomethylation of the genes was observed after exposure of at least 96 hours and was maintained for 28 days. These findings suggested that hypomethylation of DNA and of genes is an epigenetic activity of non-genotoxic carcinogens so that it could be involved in their mechanism

301 HYPOMETHYLATION OF GENES IN CHEMICAL CARCINOGEN-INDUCED RODENT TUMORS.

L. Tao, Y. Li, S. Yang, W. Wang, P. M. Kramer and M. A. Pereira. *Pathology, Medical College of Ohio, Toledo, OH.*

DNA methylation at the 5-position of cytosine in CpG dinucleotides (CpG sites) or CpNpG trinucleotides (CpNpG sites) appears to play an important role in regulating gene expression. Many human and some animal tumors have been reported to have decreased methylation (hypomethylation) of DNA and of different genes. This includes our previous demonstration that mouse liver tumors initiated by MNU and promoted by either DCA or TCA contained hypomethylation of DNA and of the c-myc gene. The methylation of two protooncogenes, c-myc and IGF-II were chosen as indicators of the methylation status of tumor DNA. Methylation of the c-myc gene was determined by Hpa II-digestion followed by Southern blot analysis and methylation of the IGF-II gene was determined by the bisulfite-treated DNA sequencing procedure. Lung tumors were induced in strain A mice by vinyl carbamate and benzo(a)pyrene [B(a)P] and colon tumors were induced in C3H mice and F344 rats by azoxymethane (AOM). In colon, liver, and lung tissue from untreated mice, 21-24 of the 28 CpG sites (75-86%) and none of the three CpNpG sites were methylated in the probed region of the IGF-II gene. In DCA- and TCA-promoted liver tumors, in vinyl carbamate and B(a)P-induced lung tumors and in AOM-induced colon tumors the level of methylation in this region of IGF-II gene was reduced to less than 25% of the CpG sites. Similar hypomethylation of the c-myc gene was also found in these tumors. These findings support the suggestion that hypomethylation of DNA and of genes is a common molecular event in rodent tumors. Furthermore, since we have found that short-term treatment with non-genotoxic carcinogens induced similar hypomethylation of genes prior to the occurrence of tumors it is proposed that hypomethylation of DNA is involved in the activity of these carcinogens.

302 EXPRESSION OF THE ARYL HYDROCARBON (AH) RECEPTOR AS A MARKER OF HUMAN BREAST CANCER PROGRESSION.

X. Yuan[1], H. M. Gao[1], C. R. Jefcoate[2] and S. E. Eltom[1]. [1]*Pharmacology, Meharry Medical College, Nashville, TN and* [2]*Pharmacology, University of Wisconsin, Madison, WI.*

The Ah receptor (AhR), a ligand-activated helix loop helix transcription factor, binds environmental polyaromatic hydrocarbons (PAH) such as dioxin, and mediates their toxic effects. This study was designed to investigate the expression of AhR and its possible role in breast carcinogenesis, using the Sager's 21T human breast carcinoma (HBC) cell lines series. The 21T series are closely matched pairs of mammary carcinoma cell lines derived from a single patient and are characterized by exhibiting a gradient order of malignancy (21MT> 21NT> 21PT), in addition to a normal mammary epithelial cell line (H16N2), derived from the same patient. The 21MT lines showed the highest expression of AhR protein and mRNA (~20 fold higher than H16N2), and 21NT was medium between 21MT and 21PT. Although TCDD treatment of H16N2 and 21PT have resulted in substantially lower levels of AhR protein, the 21NT and MT cell lines were less responsive to that effect of TCDD. While plasminogen activator inhibitor-2 (PAI-2) levels in 21T series were inherently high in all three lines and less sensitive to TCDD treatment, its levels and the levels of urokinase plasminogen activator (u-PA) receptor expressed in these cells were proportional to their malignancy in direct correlation to the AhR levels. In conclusion, these data identify the AhR as a key regulator in breast cancer progression, and establish a positive correlation between the AhR expression and components of uPA system. While the AhR activation by TCDD is associated with induction of some components of u-PA system, the lack of this response in the advanced tumorigenic 21NT and 21MT lines suggests that the receptor over-expression and its PAH-dependent activation are probably different pathways.

303 CONNEXIN PLAQUE EXPRESSION IN RELATION TO PROLIFERATIVE RESPONSE TO NON-GENOTOXIC CARCINOGENS.

A. Mally, C. Cowles and J. K. Chipman. *School of Biosciences, The University of Birmingham, Birmingham, United Kingdom.* Sponsor: T. Hammond.

Gap junction intercellular communication (GJIC) is thought to play an important role in maintaining tissue homeostasis by influencing cell growth and cell death. Disruption of GJIC *via* down-regulation of connexin (Cx) proteins has been sug-

gested as a potential mechanism involved in the action of many non-genotoxic carcinogens. We have investigated the time- and dose-dependent effects of non-genotoxic carcinogens on connexin plaque expression and cell proliferation in target and non-target tissues. Rats were treated with TCDD (0.0025, 0.025, 0.25 μg/kg), Wy-14, 643 (50 mg/kg), chloroform (18, 90, 180 mg/kg) and *p*-dichlorobenzene (DCB) (30, 150, 300 mg/kg) for 3 and 28d. Tissue sections were immunolabelled for Cx26, Cx32 and PCNA. Treatment with Wy-14, 643 led to a significant increase in PCNA-labelled hepatocytes (indicative of proliferation) and reduction in the number and total area of Cx-labelled plaques, quantified in random regions. Similarly, administration of TCDD resulted in decreased Cx expression in both liver and thyroid, but without changes in cell replication. No effects were seen in kidneys (non-target organ) of TCDD and Wy-14, 643 treated animals. In contrast, a dose-dependent reduction in Cx32 and Cx26 levels was detected in cortical epithelial cells of rats treated with the male rat kidney carcinogens chloroform and DCB at both time points, while changes in proliferation were seen only following 3d treatment with 180 mg/kg chloroform and 28d treatment with 300 mg/kg DCB. In the liver (not target organ), chloroform and DCB led to a transient increase in proliferation without effects on Cx expression. In summary, modulation of Cx expression was observed in target organs following short-term treatment with non-genotoxic carcinogens. No changes were seen in non-target organs analysed. While aberrant expression of Cx plaques did not correlate with proliferative response to carcinogen treatment, the interaction of both processes may be important in non-genotoxic carcinogenesis and determination of threshold effect levels.

304 QUANTITATIVE PROTEOMIC ANALYSIS OF MOUSE LIVER RESPONSE TO THE PEROXISOME PROLIFERATOR DIETHYLHEXYLPHTHALATE (DEHP).

N. Macdonald[1], S. Chevalier[2], R. Tonge[3], M. Davison[3], R. Rowlinson[3], J. Young[3], S. Rayner[3] and R. A. Roberts[1]. *[1]HAES Research, Syngenta CTL, Macclesfield, United Kingdom, [2]Pfizer, Discovery Support, Amboise, France and [3]AstraZeneca, Pharmaceuticals, Macclesfield, United Kingdom.*

Peroxisome proliferators (PPs) are a diverse group of chemicals that cause hepatic proliferation, suppression of apoptosis, peroxisome proliferation and liver tumours in rodents. The biochemical response to PPs involves changes in the expression of peroxisomal β-oxidation enzymes and fatty acid transport proteins such as acyl CoA oxidase (ACO) and liver fatty acid binding protein (L-FABP). The response to PPs is mediated by the peroxisome proliferator activated receptor α (PPARα) and the livers of PPARα null transgenic mice do not develop tumours in response to PPs. In order to identify the molecular pathways underlying the adverse effects of PPs in rodent liver, we carried out 2D differential gel electrophoresis (2D-DIGE) to provide quantitative proteomic analyses of diethylhexylphthalate (DEHP) treated wild type or PPARα null mouse livers. Since tumourigenesis is both PP and PPARα dependent, analyses were focused on these changes. Fifty nine proteins were identified where altered expression was both PPARα and PP-dependent. In addition, 6 proteins regulated by the deletion of PPARα were identified possibly indicating an adaptive change in response to the loss of this receptor. The proteins we identified as being regulated by PPARα are known to be involved in lipid metabolism pathways, but also in amino acid and carbohydrate metabolism, mitochondrial bio-energetics and in stress responses including several genes not previously reported to be regulated by PPARα. These data provide novel insights into the pathways utilised by PPs and may assist in the identification of early markers rodent nongenotoxic hepatocarcinogenesis.

305 CHARACTERIZING THE MOUSE LIVER TUMOR RESPONSE THROUGH EXPRESSION PROFILE ANALYSIS.

P. D. Cornwell[1], S. P. Anderson[2], G. V. Bobashev[3] and J. C. Corton[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC, [2]GlaxoSmithKline R&D, Research Triangle Park, NC and [3]Research Triangle Institute, Research Triangle Park, NC.*

Human carcinogen risk is commonly assessed in the B6C3F1 mouse strain, a cross between a hepatocarcinogen-resistant (C57BL/6) and a hepatocarcinogen-sensitive (C3H/He) strain. Other mouse strains are known to vary in their hepatocarcinogen sensitivity as well. Although a number of hepatocarcinogen sensitivity/resistance (hcs/hcr) loci have been mapped, the molecular basis for these sensitivity variations is unknown. We hypothesize that expression differences of key genes in these loci are responsible for some of the observed strain variation. Hepatic transcript profiles of 7 mouse strains (A/J, AKR/J, B6C3F1, C3H/HeJ, C57BL/6J, C57BR/cdJ, DBA/2J) and profiles of chemically (DEN, Wy-14, 643) induced hepatic adenomas were obtained using the Atlas Mouse Cancer 1.2 array (Clontech). The Phenotypic Trait Value (PTV) method, which correlates phenotypic data with gene expression levels, was used to analyze these data. Identified in the analysis were 144 genes related to hepatocarcinogen sensitivity, 45 genes related to the rate of appearance of hepatic foci (conversion rate), 138 genes related to the rate of increase in hepatic foci size (propagation rate), 264 genes related to DEN-induced adenomas and 144 genes related to Wy-14, 643-induced adenomas. Of these genes, 78 are located near hcs/hcr loci and may play a role in differential tumor susceptibility. In addition, many of these genes fall into classes of genes related to malignant transformation (e.g., cell cycle regulators). In summary, we used multiple data sources to focus on genes whose expression most likely explains the differences between resistant and susceptible mouse strains at the molecular level. Knowing how these differences determine sensitivity to a chemical carcinogen will lead to a better understanding of the mechanisms of hepatocarcinogenesis in mice and a better understanding of the relevance of the mouse liver tumor response in human risk assessments.

306 ACRYLONITRILE EFFECTS ON GENE EXPRESSION IN RAT BRAIN AND GLIAL CELLS.

Z. Jiao, L. M. Kamendulis, Y. Xu and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Chronic exposure to acrylonitrile induces astrocytomas in rats. While the mechanisms for acrylonitrile-induced carcinogenicity are not completely understood, previous studies have shown an induction of oxidative stress in acrylonitrile treated rat brain and rat glial cells. In the present study, we investigated gene expression changes in rat brain following treatment with 200 mg/kg acrylonitrile for 14, 28, and 90 days and in glial cells treated with 25, 50 or 75 mg/ml acrylonitrile for 24 hours. Using cDNA array technology, an up-regulation in several genes associated with cell growth regulation (c-myc, c-jun, egr-1, p27kip2, IL-2 and gadd45 protein) were observed in rat brain following treatment with acrylonitrile for 14 days. After 28 and 90 days of treatment with acrylonitrile, expression of these genes was lower than that seen at 14 days and gene expression of c-fos and c-jun was lower than control. An elevation in NF-κB pathway was seen at all time points. In acrylonitrile-treated glial cells, an increase in expression of genes involved in NF-κB signaling were up-regulated while gene regulation of cell proliferation pathways were down-modulated and genes involved in the apoptotic pathway were up-regulated at 24 hours. Since NF-κB activation is regulated post-transcriptionally, by translocation of the transcription factor from the cytoplasm to nuclei, a minor change in mRNA proteins may represent a significant usage (or activation) of NF-κB early after acrylonitrile treatment. Activation of NF-κB by acrylonitrile was therefore confirmed in glial cells with a reporter gene assay utilizing glial cells transfected with an NF-κB plasmid. The results provide important information on the genes modulated in the brain by treatment with acrylonitrile. Since many of the observed modulated genes are regulated by reactive oxygen species, it is likely that these changes in gene expression are due to acrylonitrile-induced oxidative stress.

307 ALTERED GENE EXPRESSION ASSOCIATED WITH FURAN INDUCED CHOLANGIOFIBROSIS IN THE RAT.

J. M. Hitchcock[1,2], K. C. Hickling[2,1], V. Oreffo[2], J. K. Chipman[1], R. Coleman[1], C. Kind[2], J. G. Evans[2] and T. G. Hammond[2]. *[1]School of Biosciences, The University of Birmingham, Birmingham, United Kingdom and [2]Safety Assessment, AstraZeneca R&D Charnwood, Loughborough, United Kingdom.*

Cholangiocarcinoma (CC) is the most common primary hepatic malignancy in humans after hepatocellular carcinoma, comprising 15% of liver neoplasms. Human intrahepatic CC is a usually fatal malignant neoplasm thought to originate from biliary epithelium and associated cholangiofibrosis. We have studied gene expression changes to help characterise stages in the development of CC in the rat. Rats were dosed with furan at 35mg/kg daily for 3 months and also with 1 month 'off-dose' prior to necropsy to characterise persistent changes. Lesions with an elevated proliferating cell nuclear antigen (PCNA)-labelling index, and associated cell populations with increased wild type p53, phosphorylated c-jun and cdk-1 protein expression, were compared to livers of control rats using the Affymetrix Rat Genome U34A Array. 310 genes were over-expressed in both 3 and 3+1 month livers compared to control. 105 genes showed a reduced expression compared to control. A number of these changes clearly reflect the shift in major cell type and fibrosis associated with the lesion. However a sub-population of genes with established roles in proliferation was altered in expression. These are currently being studied further using real time quantitative PCR (TaqMan) in conjunction with Laser Capture Microdissection (LCM) to establish those gene expression changes that distinguish the hyperplastic and metaplastic regions from normal biliary epithelium.

308 MALIGNANT TRANSFORMATION BY MNNG AND ANTITRANSFORMATION BY ARSENIC OR METAL MIXTURE IN KERATINOCYTES.

D. Bae[1], J. S. Rhim[2], R. J. Handa[3], R. S. Yang[1] and J. A. Campain[1]. *[1]Environmental Health, Colorado State University, Fort Collins, CO, [2]Center for Prostate Disease Research, Rockville, MD and [3]Anatomy & Neurobiology, Colorado State University, Fort Collins, CO.*

In order to evaluate the carcinogenic potentials for chemicals such as arsenic (As) and other metals, we have identified molecular markers potentially involved in the process of carcinogenesis in keratinocytes. We have demonstrated that treatment

with MNNG enhanced transformation of the immortal human keratinocyte cell line, RHEK-1. In contrast, As alone or in mixtures of As, Cd, Cr, and Pb inhibited this process. Microarray analysis showed unique gene expression patterns in RHEK-1 cells treated with the chemicals/mixtures. To explore markers that may be involved in the enhancement or inhibition of malignant conversion, 9 genes commonly affected by the MNNG and As/mixture treatments were examined for expression in more detail by kinetic PCR. These 9 genes were mitogen-responsive phosphoprotein DOC2, vimentin, superoxide dismutase 1(SOD1), macrophage inhibitory cytokine 1(MIC1), glutathione (GSH) synthase, bikunin, multiple tumor suppressor 1(MTS1), UV excision repair protein RAD23A, and bone morphogenetic protein 4(BMP4). Four genes were altered in their expression in a manner consistent with a role in the transformation process. MIC1, which was induced 8-fold by MNNG and suppressed up to 12-fold by both As and the mixture, encodes a TGFβ-like protein and may be involved in malignant process. Two tumor suppressor genes, bikunin and MTS1, and TGFβ-like BMP4 were suppressed by MNNG; these same genes were induced by both As and the metal mixture. GSH synthase, SOD1 and RAD23A were all induced ≥ 2-fold by chronic treatment of RHEK-1 with As and the mixture; these changes are likely a stress response to oxidative or DNA damage. We are currently analyzing gene expression changes in RHEK-1 transformed by other agents such as dioxin or X-ray. Identification of a common battery of genes altered during progressive transformation of RHEK-1 should aid in a mechanistic understanding of this process.

309 GENOMIC INSTABILITY AND GENE COPY NUMBER CHANGES IN THREE CELL LINES COMMONLY UTILIZED IN TOXICOLOGICAL STUDIES.

V. S. Venkatraj[1], P. H. Rao[2], T. M. Cho[1], I. Sumudio[1], S. H. Safe[1], J. R. Wild[1] and E. Tiffany-Castiglioni[1]. [1]*Anatomy and Public Health, Texas A & M University, College Station, TX and* [2]*Baylor College of Medicine, Houston, TX.*

Most cancer lines are genetically unstable and undergo changes in gene expression and genomic copy number. This study examines genetic alterations in these cells, that are linked to tumor progression. We performed comparative genomic hybridization (CGH) on three cell lines commonly employed in cancer biology and toxicological studies. CGH is a molecular cytogenetic assay that screens for DNA copy number changes globally within a complete genomic complement and maps these changes onto normal chromosomes. This technique is based on the simultaneous hybridization of differentially labeled (fluorescent labeled) total genomic tumor DNA and normal reference DNA onto human metaphase chromosomes. Image analysis generates a "copy number karyotype" for the cell line, indicating relative gains and losses of segments along the length of each chromosome. MCF-7 and 47-D represent a well-established system for studying the biology of breast cancer cells, whereas SY5Y cells typifies a neuronal system. The copy number karyotype found in T47-D and SY5Y cells were identical in passages 7 and 34 and 27 and 87 respectively. Whereas in MCF-7 cells there were clear differences in genomic copy number changes between passage number 30 and 85. The genomic gains > 3copies in p85 as when compared to p30 include chromosome region 7q22, 8q21-23, 14q23-24, 17q22-23, 20q13, 22q and the genomic losses include -5p, -8p, -13q. Several of these loci harbor oncogenes and tumor suppressor genes, for example, HTK-hepatoma transmembrane kinase, BRCA1-familial breast cancer predisposition gene, BCAS1-breast cancer amplified sequence1, cadherin and Rb. Genetic alterations in these or other genes in these loci may contribute to tumor progression. Further characterization of these loci by complementary molecular approaches will help elucidate the genes involved in tumor progression in this cell line.

310 TEMPORAL CHANGES IN THE LEVELS OF XENOBIOTIC-METABOLIZING ENZYMES AND ALIPHATIC HYDROCARBONS IN RATS EXPOSED TO A PETROLEUM CRUDE OIL.

A. A. Khan, R. W. Coppock, L. M. Geleta, M. M. Schuler, M. M. Dziwenka and M. N. Hiltz. *Toxicology, Alberta Research Council, Vegreville, AB, Canada.*

In Alberta, Canada, some agricultural land sites are also used for petroleum production. This study was done to assess the temporal effects of Pembina Cardium crude oil (PCCO) in rats. Pair-wise groups of rats (6/group) were exposed to either PCCO or potable water (control) by gavage at 2.5 ml/kg on days 0, 7, and 14. The paired groups were then sacrificed on post-exposure days 1, 7, 10, 14, 21 and 28, and selected tissues were analyzed for biochemical parameters, and aliphatic hydrocarbons (n-alkanes). Temporal assessment of cytochrome P450 (CYP)-linked monooxygenases in both groups showed that on day 1 of post-exposure, the PCCO-exposed rats had a marked induction of ethoxyresorufin-O-deethylase (EROD), a CYP 1A1-linked enzyme, (15-20 fold), and pentoxyresorufin-O-dealkylase (PROD), a CYP 2B-linked enzyme, (5-8 fold) in liver. In lungs, the EROD activity was also greatly elevated (5-7 fold), but the activity of PROD was markedly reduced (50-60%). In the subsequent period, these enzymes activity in PCCO-exposed rats gradually returned to levels observed in the control rats. Exposure to PCCO also caused a marked increase in the total concentration of n-alkanes (C_{10} - C_{19})in body fat (3-5 fold). The post-exposure decrease in the levels of n-alkanes from the body fat was gradual in nature; however, their levels in liver decreased markedly in the early post-exposure phase. The differential systemic responses of CYP-linked enzymes and n-alkanes in PCCO-exposed rats indicated a close link between the levels of hydrocarbon compounds and the related monooxygenases.

311 TRANSLOCATION OF BIOMARKER CHEMICALS INTO SHEEP TISSUES AFTER ORAL EXPOSURE TO CRUDE OIL.

R. W. Coppock[1], A. A. Khan[1], L. Geleta[1], M. M. Dziwenka[1], P. N. Nation[2] and M. N. Hiltz[1]. [1]*Toxicology, Alberta Research Council, Vegreville, AB, Canada and* [2]*Health Sciences, University of Alberta, Edmonton, AB, Canada.*

Food safety is a high priority in Alberta, Canada. The landscape in Alberta is often shared by the petroleum and livestock industries providing opportunity for ruminants to be exposed to oilfield substances. The implications of petroleum ingestion on food safety do not appear to be known. Sheep (n=11) were administered 10 mL of Pembina cardium crude oil (PCCO)/ kg body weight or 10 mL of potable water on study days 0, 14, 28 and 42. Blood for clinicopathology was collected across study days. The sheep were necropsied on study day 43 and fat, brain, liver, kidney and skeletal muscle were collected for hydrocarbon analyses. The n-alkanes (C_{10} to C_{19}) were extracted from tissues and identification and quantification were made by gas chromatography - mass spectrometry techniques. The total concentration of the C_{10} to C_{19} n-alkanes found in tissues were omental fat 61.3±5.37 (SE) ppm, perirenal fat 70.2±7.08 ppm, tailhead fat 60.1±6.67 ppm, bone marrow fat 41.4±5.90 ppm, liver 4.7±0.43 ppm, brain 0.6±0.08 ppm, and kidney 0.1±0.08 ppm. The C_{10} to C_{19} n-alkanes were below detection level (<0.1 ppm) in skeletal muscle. Clinicopathologic observations include a leucocytosis primarily due to a neutrophilia. Lesions were observed in the lungs during necropsy. This study showed that oral exposure of sheep to crude oil has potential of being a food safety issue.

312 TOXICOPATHOLOGY AND IMMUNOTOXICOLOGY OF MULTIPLE EXPOSURES TO DIESEL AND CRUDE OILS IN CATTLE.

M. M. Dziwenka[1], R. W. Coppock[1], P. N. Nation[2], C. J. Field[3], A. A. Khan[1] and M. N. Hiltz[1]. [1]*Toxicology, Alberta Research Council, Vegreville, AB, Canada,* [2]*Health Sciences, University of Alberta, Edmonton, AB, Canada and* [3]*Agriculture, Food and Nutritional Sciences, University of Alberta, Edmonton, AB, Canada.*

The study being reported was part of a large study on the subchronic toxicology of crude and refined petroleum in cattle. Forty cattle (n=8/group) were gavaged on study days 0, 7, 14, 28 and 42 with 10 mL potable water (PW)/kg body weight (BW), 5 mL winter diesel oil No. 2 (WDO-2)/kg BW, or Pembina cardium crude oil (PCCO) at 2.5, 5 and 10 mL/kg. Repeated clinicopathology and immunologic determinations were done from study days -14 to study day 48. The cattle were necropsied at 22±7 days after the last dose. Statistical analyses showed differences between control (PW treated animals) and animals treated with PCCO or WDO-2. Significant hematologic changes were a decrease in Hct, Hb and differential counts for lymphocytes, basophils and eosinophils as well as significant increases in platelet numbers, the neutrophil/lymphocyte ratio and in differential counts for neutrophils. Significant changes were also observed in serum iron, LDH, AP, GGT, albumen, creatinine, glucose, bilirubin, cholesterol, triglycerides, Ca and Mg. Oil treatments stimulated neutrophil random migration, and specific neutrophil chemotaxis was increased after the first oil treatment but reduced after dose 4. Compared to pre-dosing levels, oil treatment (at dose 3) resulted in a higher proportion of CD3+, CD2+, CD4+ and CD25+ cells and lower proportion of δγ T cells, CD14+ and B cells in peripheral blood, suggesting immune activation and recruitment of some cell types to peripheral sites. Macro- and microscopic tissue lesions linked to treatment with WDO-2 and PCCO were not observed. Repeated oral exposure to petroleum products induced significant changes in both clinicopathologic and immunopathologic parameters without producing significant macro- or microscopic tissue lesions.

313 MAMMALIAN TOXICITY OF NAPHTHENIC ACIDS DERIVED FROM THE ATHABASCA OIL SANDS (AOS).

V. V. Rogers[1], M. Wickstrom[1], K. Liber[1] and M. D. MacKinnon[2]. [1]*Toxicology Centre, University of Saskatchewan, Saskatoon, SK, Canada and* [2]*Syncrude Canada Ltd., Edmonton, AB, Canada.* Sponsor: K. Wallace.

The mammalian toxicity of naphthenic acids isolated from AOS tailings was investigated by orally administering these compounds to female Wistar rats. Naphthenic acids are natural constituents of petroleum, and can represent an important waste

contaminant generated during petroleum processing. Naphthenic acids are known to be highly toxic to aquatic organisms, but effects on terrestrial animals are largely unknown. Subchronic toxicity testing revealed a number of significant effects were associated with a dosage of 60 mg/kg/d naphthenic acids for 90 d. Dosed animals had significantly lower (-9%) body weights than controls throughout the test, despite comparable food consumption. Some terminal organ weights were higher in this dose group, particularly that of liver, which was 36% higher than in controls. Plasma biochemistry was significantly affected, with total cholesterol of dosed (60 mg/kg/d) animals 43% lower than controls. In contrast, this dosage caused amylase to rise 33% above control values. Reproductive toxicity testing demonstrated dramatic effects on female fertility at an oral dosage of 60 mg/kg/d naphthenic acids during pre-breeding, breeding, and gestation. While control and low dose (6 mg/kg/d) animals achieved 93 and 100% reproductive success, respectively, only 7% of females dosed at 60 mg/kg/d successfully bore a litter. Total cholesterol of the latter group was 30% lower than controls. Mating and ovulation were comparable amongst control and dose groups, while fetal malformations were not apparent in any offspring. Results suggest that the dose-related infertility may be associated with poor embryonic implantation, an effect that might be secondary to depressed sex hormone production requiring cholesterol as a precursor. Current research is evaluating this mechanism, and whether naphthenic acids, structurally similar to cholesterol metabolites, directly alter the rate of cholesterol biosynthesis *in vivo* by means of a possible allosteric effect.

314 A COMPARISON OF THE EFFECTS OF SHORT TERM ORAL EXPOSURE TO 2, 4, 6-TRINITROTOLUENE (TNT), 1, 3, 5-TRINITRO-1, 3, 5-TRIAZINE (RDX) AND CYCLOTETRAMETHYLENE-TETRANITAMINE (HMX) IN NORTHERN BOBWHITE QUAIL *(COLINUS VIRGINIANUS).*

R. M. Gogal[1], C. T. Larsen[1], M. S. Johnson[2], D. Jones[1] and S. D. Holladay[1]. *[1]Biomedical Sciences, Virginia Tech, Blacksburg, VA and [2]Health Promotion and Preventive Medicine, US Army, Aberdeen, MD.* Sponsor: S. Holladay.

Potential risk to wildlife from exposure to the explosives, 2, 4, 6-trinitrotoluene (TNT), 1, 3, 5-trinitro-1, 3, 5-triazine (RDX) and cyclotetramethylene-tetranitamine (HMX) has been a concern throughout numerous military installations where it has been found in the soil. To date, limited data have been generated on the effects of oral exposure to TNT and no data have been generated for RDX and HMX in an avian species. Acute oral exposure and sub-acute dietary exposure to TNT, RDX and HMX was therefore evaluated in a species commonly found at military installations, the Northern Bobwhite *(Colinus virginianus).* Adult male and female quail (N = 1/ sex/dose) were given acute oral doses of each of the compounds at 4782, 3188, 2125, 1417, 945, 630, 280 187, 125 mg/kg and evaluated for 14 days duration. Acute lethal toxicity was observed at 2125 mg/kg with TNT for both genders. RDX doses of 280 mg/kg and 187 mg/kg were acute lethal doses in the male and female, respectively. Interestingly, HMX failed to induce an acute lethal dose during the initial ALD study. Even in a repeated study with concentrations as high as 10, 760 mg/kg, acute lethal toxicity to HMX could not be determined. Blood analysis with HPLC showed a strong correlation between acute toxicity and quantity of compound found in the blood. This suggests that these compounds varied in their ability to be absorbed into bird's blood stream. Additionally, fecal analysis of the compounds showed an inverse correlation to the severity of toxicity. Further, fasting status of the birds also seemed to impact the absorption. These data suggest that Northern Bobwhite appear to be less sensitive than mammals to acute oral exposures of TNT, RDX and HMX.

315 CYTOCHROME P450 MODULATION AND ANTIOXIDANT MITIGATION OF 2, 4, 6-TRINITROTOLUENE TOXICITY.

J. A. Steevens and J. G. Houston. *Environmental Laboratory, U.S. Army Engineer Research and Development Center, Vicksburg, MS.*

Toxicity of 2, 4, 6-trinitrotoluene (TNT) and three of it's degradation products, 2, 4-diamino-6-nitrotoluene (DANT), 2-amino-4, 6-dinitrotoluene (2-ADNT), and 1, 3, 5-trinitrobenzene (TNB) was determined utilizing two aquatic invertebrates. Differential toxicity of the degradation products was observed in two organisms, Neanthes areanceodentata, a marine polychaete, and Hyalella azteca, a freshwater amphipod. Implications of the differential toxicity in these aquatic organisms derive specific challenges when conducting an ecological risk assessment. To gain a better understanding of the mechanisms responsible for the changes in toxicity, investigations were conducted through a series of toxicity experiments focusing on oxidative stress and metabolism by cytochrome p450. These mechanisms were studied by exposing the organisms to TNT in combination with a cytochrome p450 inducer and inhibitor and two antioxidants. Toxicity of TNT was increased in a time and concentration dependent manner following exposure to clotrimazole, suggesting inhibition of cytochrome p450 decreases the metabolism and elimination of TNT. BNF modified the toxicity of TNT in a U-shaped dose and time dependent manner. BNF at 0.125 mg/l significantly decreased the toxicity of TNT suggesting that increased cytochrome p450 activity increases the elimination of TNT. Ascorbic acid and tocopherol mitigated the toxicity of TNT to H. azteca. Pre-exposure to ascorbic acid (0.13, 0.44, 0.88, and 1.32 mg/L) significantly decreased mortality associated with a 96-hr exposure to 3.0 mg/L TNT. Pre-exposure to tocopherol decreased mortality in a U-shaped dose-dependent trend; mortality was the lowest at 0.125-mg/L tocopherol and 3 mg/L TNT. Based on these data it is suspected that TNT elicits its toxicity through oxidative stress. These results demonstrate the sensitivity of aquatic invertebrates may be the result of differences in metabolic capacity (cytochrome p450 activity) and antioxidant capacity of the organism.

316 QUANTIFICATION OF ATRAZINE (ATRA) AND DIAMINOCHLOROTRIAZINE (DACT) IN RAT WHOLE BLOOD UTILIZING GC/MS/SIM.

B. K. Cranmer, J. M. Ruble, J. D. Tessari and M. E. Andersen. *Environmental Health, Colorado State University, Ft. Collins, CO.* Sponsor: M. Andersen.

Atrazine (ATRA) is a selective chloro-s-triazine herbicide for broadleaf and grassy weed control in corn, sorghum, sugarcane, and other crops. Diaminochlorotriazine (DACT) is the major urinary metabolite seen (64-67% of total) in *in vivo* studies utilizing radiolabeled ATRA administered orally. We are developing a suite of analytical methods to assist pharmacokinetic model development in rodents and humans, to assess human exposures *via* examination of urine metabolites, and to assess protein binding of these compounds in blood and hair [refer to Ruble et al, UTILIZATION OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL TO PREDICT DOSE-DEPENDENT GSH DEPLETION AFTER ATRAZINE TREATMENT, 41ST Annual SOT National Meeting poster session]. In this work, we have developed methods to measure ATRA and DACT in blood. Rat whole blood was spiked with ATRA and DACT and cleaned up with solid phase extraction (SPE). The SPE eluate and standards were derivatized with methyl iodide and tetra-butyl ammonium hydroxide (TBAOH), yielding the dimethyl derivative of ATRA and the tetra-methyl derivative of DACT. Derivatization is not needed for ATRA but is necessary for accurate quantification of DACT by removing undesirable column interactions and thus improving peak symmetry. Samples and standards were analyzed with Gas Chromatography/Mass Spectrometry (GC/MS) in Specific Ion Monitoring (SIM) mode. Results showed excellent recoveries of ATRA and DACT with detection limits near 100 ppb. These methods have also been employed to determine time course concentrations of chloro-s-triazines in blood following dosing in rats. This work was supported by STAR grant R-828610-01-0 and HICAHS grant U07/CCU807121-10.

317 DOES BINDING TO ALBUMIN MODULATE THE BIOLOGICAL EFFECTS OF PERFLUOROOCTANE SULFONIC ACID?

P. D. Jones, W. Y. Hu, W. DeCoen and J. P. Giesy. *National Food Safety and Toxicology, Michigan State University, East Lansing, MI.* Sponsor: R. Roth.

Perfluorooctane sulfonic acid (PFOS) has been demonstrated to accumulate in the liver and blood of exposed organisms. The potential for these detergent-like molecules to interfere with normal ligand/protein interactions in blood is of concern given the importance of many of these interactions, particularly those involving the transportation and action of hormones. Due to concern over any compounds that might modulate the endocrine system, PFOS binding to serum proteins was investigated. The ability of PFOS to displace a variety of steroid hormones from their specific binding protein sites in serum was measured. PFOS had only a weak capacity to displace the steroid hormones estrogen and testosterone from carp serum steroid binding proteins. The effects on corticosterone binding globulin in bird species (chicken and bald eagle) occurred at the least PFOS concentrations. Corticosterone displacement potency increased with increasing chain length and sulfonic acid compounds were more potent than those with a carboxylic acid functional group. The estimated PFOS concentrations to cause these effects were 320]1M or greater, equivalent to a serum concentration of greater than 160 ppm. Using mass spectrometry and *in vitro* binding assays, PFOS was demonstrated to bind strongly to bovine serum albumin (BSA). The combined results from these studies demonstrate that BSA binds only one or two PFOS molecules per protein molecule. This binding ratio is relatively low compared to the known 8 - 11 binding sites for other ligands such as fatty acids. Concentrations of PFOS required to saturate this binding would be in excess of 50 to 100 mg/L. Therefore, based on current environmental concentrations it is extremely unlikely that PFOS would cause significant displacement of hormones from their serum binding proteins in wildlife.

318 ONE FISH, TWO FISH, RED FISH, BLUE FISH: THE FISH QUALITY INDEX AS A RISK COMMUNICATION TOOL.

D. D. Petersen. *Office of Research and Development, USEPA, Cincinnati, OH.*

Many people, but particularly subsistence fishermen, are at high risk for methyl mercury toxicity because of their consumption of contaminated fish. Often health risks of Persistent Bioaccumulative Toxicants (PBT) such as methyl mercury, PCBs or Dioxins are underestimated because of their amplification in the food chain resulting in toxicity even though ambient levels of these PBT are within acceptable limits. Two concerns have developed from this situation (1) most of the affected groups have not been identified, and (2) means of effectively communicating the possible risk to the affected groups do not readily exist. We are defining regions and specific lakes and rivers that have high levels of consumption of fish, and where high PBT concentrations in water can occur. We are also identifying populations of subsistence fishermen or other high-risk groups who consume large quantities of fish from these waters. The final product will be a user-friendly risk communication tool (the Fish Quality Index), which is a color-coded pictogram for various fish species (for example; green ones are safe to eat, even at subsistence consumption levels, yellow fish are safe once a month while red ones are safe only if eaten less than once a year). This map-based tool transcends language and literacy boundaries and should inform anglers of the relative health risks according to the species of fish that they regularly consume in an easy to understand format. It has the benefit of steering people toward safer lakes and streams and safer species of fish. In most lakes we've examined, there are safe species of fish and unsafe species of fish in the same lake, depending mostly on the trophic level of the fishes food supply. A pilot of the fish quality index has been developed for several New England States, and is currently being tested by several groups. It will eventually be available on the internet, and on CD-ROM, but the individual maps shown at the presentation can be printed in wallet-size or larger formats.

319 EXPOSURE AND HEALTH EFFECTS OF INHALED FLORIDA RED TIDE BREVETOXINS ON HUMANS DURING A RED TIDE EVENT.

D. Baden[1], W. Abraham[2], L. Backer[3], J. Benson[4], G. Bossart[5], S. Campbell[1], Y. S. Cheng[4], R. Clark[6], L. Fleming[7], D. Johnson[6], B. Kirkpatrick[8], J. Naar[1], R. Pierce[8] and R. Weisman[9]. *[1]HABLAB, UNC Wilmington, Wilmington, NC, [2]Mount Sinai Hospital, Miami Beach, FL, [3]CDC, Atlanta, GA, [4]Lovelace Respiratory Research Institute, Albuquerque, NM, [5]Harbor Branch Oceanographic Institution, Fort Pierce, FL, [6]FL Department of Health, Tallahassee, FL, [7]NIEHS MFBS Center, Univ of Miami, Miami, FL, [8]Mote Marine Laboratory, Sarasota, FL and [9]Florida Poison Information, Miami, FL.*

The toxigenic marine dinoflagellate *Karenia brevis* is responsible for red tides in the Gulf of Mexico. The neurotoxic agents produced in red tides, the brevetoxins, cause asthma-like symptoms in beach-going populations. During the Fall of 2001, an extensive Florida Red Tide was studied off the coast of Sarasota Florida. Environmental data including K. brevis counts in the water and the amount of toxin present, toxin in aerosols transported on-shore, subsequent exposure of humans through respiration, and both throat swab and epidemiologic data on occupationally-exposed individuals were collected. These data were supported by GPS and meteorological measurements. Brevetoxin enzyme-linked immunoassays (ELISA) quantified total toxin on-site, and ELISA and LC-coupled mass spectrometry were used in the Lab. . During the 5-day study, toxin concentrations were measured at six different locations and ranged from 20 ng/mL to 400 ng/mL. K. brevis cell counts ranged from 1, 000 to 15 million cells/L. Impact air sampler filters collected 80-467 ng/sq cm toxin in airborne particles. Human symptoms of sneezing, eye irritation, and coughing were experienced by the lifeguard subjects and scientists. Toxin levels and symptoms were inversely correlated with distance from the shoreline. The severity of symptoms correlated with the measured concentrations of toxin from personal and high volume air samplers. Throat and nasal swabs of both subjects and environmental scientists revealed increased numbers of inflammatory cells. Phagocytic cells stained by brevetoxin ELISA were inconclusive.

320 PARALYTIC SHELLFISH TOXINS: INTERACTIONS WITH MAMMALIAN DETOXIFICATION ENZYMES.

H. Hong[1], P. K. Lam[2], W. Wang[1] and D. P. Hsieh[1]. *[1]Biology, Hong Kong University of Science and Technology, Kowloon, Hong Kong and [2]Biology & Chemistry, City University of Hong Kong, Kowloon, Hong Kong.*

Paralytic shellfish toxins (PST) are important marine phycotoxins associated with paralytic shellfish poisoning which is a significant food safety problem due to consumption of seafood contaminated by this suite of toxins. In Hong Kong, the C1 and C2 toxins (C1/2) and gonyautoxins 2 and 3 (GTX2/3) are prevalent members of PST found in its coastal waters. Although much detail is known about the mechanism of action of PST as sodium channel blockers, little is known about their metabolism/detoxification in mammalian systems. Studies were undertaken to examine the interaction of PST with mammalian detoxification enzymes. Incubation of these toxins with enzyme preparations containing Phase I and Phase II enzymes from rat and mouse livers resulted in no observable changes to these toxins. However, administration of these toxins to mice followed by assaying for various detoxification enzymes resulted in the reduced activity of ethoxyresorufin-O-deethylase (EROD), penthoxyresurofin-O-depenthylase (PROD), superoxide dismutase (SOD) and glutathione peroxidase (GPx). No change in activity was found for glutathione-S-transferase (GST), catalase (CAT) and glutathione disulfide reductase (GR). These results indicate that although the investigated PST are not metabolized, they can suppress some critical detoxification enzymes and may have adverse effects on mammalian physiology. (Supported by HKUST6102, RGC)

321 IMMUNE FUNCTION OF CRYO-PRESERVED AVIAN PERIPHERAL WHITE BLOOD CELLS: A POTENTIAL BIOMARKER OF CONTAMINANT EFFECTS IN WILD BIRDS.

M. E. Finkelstein[1], K. A. Grasman[2], D. A. Croll[1], B. R. Tershy[1] and D. R. Smith[1]. *[1]Environmental Toxicology, University of California, Santa Cruz, CA and [2]Department of Biological Sciences, Wright State University, Dayton, OH.*

There is a need to develop sensitive biological markers of contaminant-induced effects in wildlife. Immune function may prove a useful marker for toxic effects because its complexity renders it sensitive to contaminant exposure. However, there are limitations of collection and transport of immune cells in the field. Here we report the development of methods to assess immune function in wild birds, using cryo-preserved chicken peripheral white blood cells (WBCs). We determined that cryo-preservation caused a slight but measurable decrease in cell viability (99% +/-.2SE for fresh cells and 84%+/-2SE for cryo-preserved cells (n=8)). There was no reduction of viability between cells that were cryo-preserved for less than 10 days (88%+/-4SE) and greater than 50 days (89%+/-1SE) (n=6). Importantly, cryo-preserved cells responded well to tests of immune cell function (mitogen-induced cell proliferation and macrophage phagocytosis). To validate the use of cryo-preserved white blood cells to assess contaminant effects, we used these tests on cells exposed *in vitro* to the poly aromatic hydrocarbon 9, 10, Dimethyl-1, 2-Benz-anthracene (DMBA), a well-known immuno-suppressant. We found that DMBA significantly ($p<0.05$) reduced the ability of cells to proliferate and ingest yeast. We tested the applicability of these methods on wild American Coots *(Fulicia americana)* by cryo-preserving WBC for a period of up to 10 months (average viability of 75% +/-11SD, n=10) and performed immune function tests (proliferation response ranged from 224 to 583% above the non-stimulated cells and the phagocytic ability of macrophages ranged between 15-88%). This research is valuable because it provides a technique to collect samples non-lethally with a single blood sample, as well helping to establish the use of immune function for the assessment of contaminant exposure.

322 DEVELOPMENT OF ANTIBODIES TO SATRATOXINS AND APPLICATION TO ENZYME-LINKED IMMUNOSORBENT ASSAY.

J. J. Pestka[1,2,3], Y. Chung[1,2], B. B. Jarvis[4] and H. Tak[4]. *[1]Food Science and Human Nutrition, Michigan State University, East Lansing, MI, [2]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI, [3]Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI and [4]Department of Chemistry and Biochemistry, University of Maryland, College Park, MD.*

Although macrocyclic trichothecene mycotoxins produced by *Stachybotrys chartarum* have been associated with numerous outbreaks of indoor illness, no simple method exists for the detection of these toxins in environmental samples. The goal of this study was to produce specific antibodies to the macrocyclic trichothecene mycotoxin, satratoxin G (SG), and employ these in an enzyme-linked immunosorbent assay (ELISA). SG was derivatized to its hemisuccinate and coupled to bovine serum albumin (BSA-SG) for use as an immunogen. Three rabbits were immunized by intradermal injections of the immunogen followed by a single booster injection at week 18. SG-specific antibodies were detected as early as 4 wks of immunization and high titers still detectable 38 wks later. A direct competitive ELISA employing microtiter well-adsorbed SG antibodies and SG-hemisuccinate coupled to horseradish peroxidase (HRP-SG) was developed and it could detect as little as 0.1 ng/ml of SG. The concentrations of SG, satratoxin H, isosatratoxin F, roridin A, and verrucarin A causing 50% inhibition of HRP-SG conjugate binding were 1.3, 5.4, 3.2, 25.1, and 52.5 ng/ml, respectively, indicating that the antibodies were most specific for SG. Assay sensitivity was largely unaffected by methanol content up to 20% in toxin diluents suggesting that the assay could be applied to methanol extracts of environmental samples. The ELISA was applicable detection of satratoxins

in *S. chartarum* spore extracts. SG antibodies should be useful for identifyinging the toxigenic S. chartarum isolates as well as the rapid detection of SG and other satratoxins in environmental samples from buildings contaminated with this fungus.

323 COMPARISON OF GC/MS AND GC/μECD METHODS ON THE ANALYSIS OF HEXACHLOROBENZENE (HCB) IN RAT BLOOD AND LIVER.

J. W. Algaier[1], Y. A. Shan[1], C. J. Lee[1], R. L. Mathias[1], B. A. Canham[1], K. D. White[1], V. M. Abraham[1], R. K. Harris[1], A. P. Clark[1] and D. Overstreet[2]. [1]*Life Sciences, Midwest Research Institute, Kansas City, MO and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

Hexachlorobenzene (HCB), a persistent environmental pollutant, was once used widely as a fungicide but has been banned since the 1970s. However, because of its accumulation in the food chain and in lipid deposits of animals and man, HCB has been selected for toxicological evaluation by the NIEHS. In the analysis of HCB from rat blood and liver samples from a toxicokinetic study, methods were validated using GC/MS and GC/μECD. For blood, sample preparation of a 100 μL aliquot included homogenization by Polytron, if clotted material was present, followed by hexane extraction. For liver, samples of 0.1, 0.3 and 0.5 g were homogenized by Polytron followed by hexane extraction. For both matrices, HCB concentrations were determined using the peak area ratio, PAR, (Isodrin, 2 μg/mL, internal standard) compared to a spiked matrix standard curve. The GC/MS methods compared the J & W DB-5 to the DB-5MS capillary column (30 m x 0.32 mm, 1 μm film), with the DB-5MS showing less baseline noise. Comparison of GC/MS and GC/μECD separation and detection parameters allowed for the used of GC/μECD for routine analysis of samples in a cost-effective manner. The GC/μECD method used a Restek RTX-5 analytical column (60 m x 0.25 mm, 0.25 μm film). The blood HCB methods were validated using GC/MS at ~1 to 400 ng/mL and for GC/μECD at ~20 to 5000 ng/mL. For liver HCB, methods were validated using GC/MS at ~ 1 to 10, 000 ng/g and for GC/μECD at 4 to 10, 000 ng/g. Actual blood samples from the toxicokinetic study ranged in HCB concentration from 20 to 160, 000 ng/mL, while actual liver samples ranged from 8 to 460, 000 ng/g.

324 4-NONYLPHENOL INHIBITS INOS GENE EXPRESSION IN LPS-STIMULATED RAW 264.7 CELLS BY BLOCKING NF-KB ACTIVATION.

S. J. Park and H. G. Jeong. *Pharmacy and Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

4-Nonylphenol (NP) is a degradation product of a widely used non-ionic surfactant group, alkylphenol polyethoxylates that are mainly found as an intermediate in the chemical manufacturing industry. In this study, we investigated the effect of NP on the regulation of inducible Nitric Oxide Synthase(iNOS) in murine macrophages. NP alone did not affect the expression of iNOS; in contrast, suppressed the LPS-induced gene expression of iNOS, in a dose-dependent manner as determined by RT-PCR analysis. NO production was assessed by measurement of nitrites in the medium. The level of NO was found to correlate well with a decrease in transcripts of iNOS. Since the promoter in iNOS gene contains binding motifs for NF-kB, the effect of NP on the inactivation of this transcripts factor was determined by transient transfection assay. Employing a transfection and reproter gene expression system with p(NF-kB)3-Luciferase, the treatment of NP produced a dose-dependent inhibition of luciferase activity in RAW 264.7 murine macrophages cell line. These results suggest that suppression of iNOS gene expression by NP might be mediated by the inhibition of NF-kB activation [This work was supported by KFDA Grant (ED 2000-33) and RCPM].

325 EFFECTS OF THE HORMONAL GROWTH SUPPLEMENT TRENBOLONE ON REPRODUCTIVE ENDOCRINOLOGY OF THE FATHEAD MINNOW.

G. T. Ankley[1], K. M. Jensen[1], M. D. Kahl[1], E. A. Makynen[1], M. W. Hornung[1], J. J. Korte[1] and L. E. Gray[2]. [1]*Mid-Continent Ecology Division, USEPA, Duluth, MN and* [2]*Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

As part of an ongoing effort to develop and validate a fathead minnow (*Pimephales promelas*) assay to detect chemicals that affect processes controlled by estrogens and androgens, we determined the effects of trenbolone on reproductive endocrinology of the fish. Trenbolone is a synthetic androgen receptor agonist commonly used as a growth supplement in beef cattle. Reproductively-active animals were exposed for 21 days *via* the water to nominal trenbolone concentrations of 0, 5, 50, 500, 5000 and 50, 000 ng/L. During this time, reproductive performance (fecundity, fertility, hatch) of the fish was monitored daily. At conclusion of the assay, a number of parameters related to endocrine function (plasma steroid and vitellogenin concentrations, gonadal condition) were assessed in the animals. Reductions in fecundity of the fish, and masculinization of the females were observed at concentrations of 50 ng trenbolone/L and greater. Masculinization was expressed as induction of nuptial tubercles, structures normally observed only on the heads of reproductively-active males. While these data demonstrate that trenbolone is a potent androgen in fish under laboratory conditions, an assessment under relevant field conditions would be required to evaluate whether or not the observed responses might occur in wild populations of fish. *This abstract does not necessarily reflect EPA policy.*

326 EFFECTS OF THREE STEROIDAL ESTROGENS ON REPRODUCTIVE PARAMETERS IN A FISH, *TAUTOGOLABRUS ADSPERSUS.*

L. J. Mills, R. E. Gutjahr-Gobell, D. J. Borsay Horowitz and G. E. Zaroogian. *Atlantic Ecology Division, USEPA, NHEERL, Narragansett, RI.*

Estradiol (E_2), ethynylestradiol (EE_2) and estrone (E_4) are steroidal estrogens that are released into the aquatic environment in sewage treatment effluent. To determine whether these estrogens impact reproductive parameters in a model fish species, actively-reproducing cunner (*Tautogolabrus adspersus*) were exposed in the laboratory by implanting estrogen subcutaneously in a slow-release matrix. Four tanks with 3 females and 2 males each were used per treatment. Treatments were control (matrix only) and 0.05, 0.5 or 2.5 mg/kg of each estrogen. Egg production (per gram female), viability and fertility were determined daily. Pre-exposure egg production was not significantly different among experiments, averaging 283 eggs/day. Pre-exposure egg viability ranged from 17-20%, while egg fertility ranged from 25-52%. In fish exposed to E_2, egg production in the high treatment was 108±22 compared with 174±46 in control, but this difference was not significant. In fish exposed to EE_2, egg production in the high treatment (28±22) was significantly lower than in control (107±28). E_4 treatment gave no significant differences in egg production, although egg production in the high (99±82) and medium (104±56)treatments was lower than low (188±46) or control (184±104) treatments. Neither mean %viability nor %fertility was significantly different than control in any estrogen treatment. Although GSI was lower in females treated with the 2.5 mg/kg concentration of all estrogens than in other treatments, the decrease was not significant. Average concentrations of vitellogenin (vtg) in control males from the three experiments ranged from 0.0 to 0.5 mg/ml plasma. In males from the highest concentration of EE2, average concentration of plasma vtg (480 mg/ml) was approximately forty times that in the high E_2 treatment (12 mg/ml) and nine times that in the high E_4 treatment (53 mg/ml). Overall, only EE_2 significantly affected mean daily egg production of female cunner. All estrogens elevated plasma vtg in males, but EE_2 notably more so than the others.

327 ALTERATION OF P-GLYCOPROTEIN (PGP) EXPRESSION IN CATFISH BY SELECT ENVIRONMENTAL TOXICANTS.

K. M. Kleinow, P. Uppa, E. Holmes and Y. Zhang. *Comparative Biomedical Sciences, School Veterinary Medicine, Louisiana State University, Baton Rouge, LA.* Sponsor: M. James.

Pgp has been shown to modulate xenobiotic bioavailability and facilitate excretion by efflux transport. Although Pgp in aquatic species is known to be up and down regulated in the environment the etiology of these changes have not been clearly defined. These studies examined Pgp protein expression in catfish following exposure to chemical agents eliciting endocrine disruption, and oxidative stress as well as representative polyaromatic hydrocarbons and flavonoids. Separate groups of catfish were dosed IP daily for 6 days with 2mg/kg of nonylphenol ethoxylate (NPE), quercetin (Q), hydrogen peroxide (HP), methoxychlor (MC) or control vehicle(C). Plasma membranes of liver and intestinal sections were prepared by selective differential centrifugation methods and subjected to electrophoresis, western blotting and immunostaining with the Pgp C219 monoclonal. Pgp was visualized and then quantitated by densitometry. Hepatic Pgp concentrations were significantly higher than controls for NPE and were significantly lower for the HP treated fish. These changes represented 46 % higher and 59 % lower values than controls, respectively. Treatment with Q or MC did not result in significant changes in Pgp for the liver. Enriched brush border membranes of the proximal and distal intestines demonstrated significantly lower Pgp levels (13.2-211 fold) than livers for all treatments including controls. No significant differences in proximal and distal intestine Pgp concentrations were noted for all treatments. These results demonstrate a differential expression of Pgp between the liver and intestine as well as suggest that select xenobiotics or conditions they elicit may alter expression of catfish Pgp, particularly in the liver. (supported by P42 ES07375).

328 EFFECTS OF THE SELECTIVE SEROTONIN REUPTAKE INHIBITOR, PROZAC, ON THE REPRODUCTION OF JAPANESE MEDAKA.

J. J. Weston[1], D. B. Huggett[1], C. M. Foran[2] and M. Slattery[1]. [1]*Environmental Toxicology Research Program, University of Mississippi, University, MS and* [2]*Department of Biology, West Virginia University, Morgantown, WV.* Sponsor: K. Willett.

The occurrence of pharmaceutical products in municipal wastewater has recently received considerable attention; for the most part, potential aquatic impacts are unknown. Prozac (fluoxetine) is a pharmaceutical agent primarily used to treat neurological disorders. Because of the potential for neuro-endocrine interactions of Prozac in aquatic organisms, Japanese medaka were exposed to aqueous nominal concentrations of Prozac (0, 0.5, 1 and 100 ug/L) with subsequent assessment of reproduction. After 14 days pre-reproductive exposure and 14 days reproductive exposure, an increase in the mean total number of eggs produced was observed at the 0.5 ug/L concentration. Also, there was a decrease in the mean total number of eggs produced at the 100 ug/L concentration. Similar trends were observed in the mean number of fertilized eggs at each concentration, as well as the percentage of fertilized eggs that hatched at each concentration. In addition, there was a trend toward an increased incidence of developmental abnormalities. These reproductive trends were not statistically significant, however, observed trends warrant further studies. Recently Prozac has been identified in wastewater effluent from the United States at concentrations in the ng/L range. Future studies will determine the effect of environmentally realistic Prozac concentrations on reproductive parameters in medaka, as well as commonly used reproductive biomarkers (vitellogenin, plasma steroids, etc).

329 A POTENTIAL WHITE STURGEON HEPATIC CYTOCHROME P450 3A WAS CORRELATED WITH LIVER P, P'-DDE AND PLASMA TESTOSTERONE IN WILD WHITE STURGEON.

E. Foster[1], M. Fitzpatrick[1], G. Feist[2], M. Webb[2], C. Schreck[2], A. Maule[3], W. Gale[3], D. Buhler[4], D. Gundersen[5], J. Paar[5], M. Bernal[5] and J. Vavra[5]. [1]*Water Quality Division, Department of Environmental Quality, Portland, OR,* [2]*Oregon Cooperative Fishery Research Unit, Oregon State University, Corvallis, OR,* [3]*Columbia River Research Laboratory, USGS-BRD, Cook, WA,* [4]*Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR and* [5]*Environmental Science, Pacific University, Forest Grove, OR.*

White sturgeon *(Acipenser transmontanus)* are experiencing poor reproductive success in some portions of the Columbia River Basin (USA)which may be related to organochlorine contaminants. Previous studies by our group showed that liver 1, 1-dichloro-2, 2-bis(p-chlorophenyl) ethylene (p, p'-DDE) concentrations were inversely related to plasma androgens in reproductively immature male white sturgeon. This study examined the relation between the putative white sturgeon hepatic cytochrome P450 3A, liver p, p'-DDE, and plasma androgens in reproductively immature male white sturgeon collected from the Columbia River, USA. Liver and plasma were collected from reproductively immature male white sturgeon commercially caught in the Columbia River. Individual levels of chlorinated pesticides and PCBs were measured in liver by GC-ECD, plasma androgens were measured by RIA, and the putative white sturgeon hepatic cytochrome P450 3A was measured in microsomes by western blotting using a polyclonal antibody generated against rainbow trout LMC5 (3A27). Of the organochlorines measured, p, p'-DDE, was detected most frequently and at the highest concentrations. The putative cytochrome P450 3A was positively correlated with p, p'-DDE. Plasma androgens were inversely correlated with p, p'-DDE and the putative cytochrome P450 3A. These data indicate the existence of a cytochrome P450 3A in white sturgeon and that, p, p'-DDE may induce the putative white sturgeon hepatic cytochrome P450 3A and reduce plasma androgen concentration *via* increased metabolism. However, additional studies are needed.

330 RELATIONSHIP BETWEEN LIVER OIL INFRARED SPECTRA AND FISH HEALTH.

I. Olivero, H. Arnedo, I. Jimenez, Z. Blanco and A. Goenaga. *Environmental and Computational Chemistry Group, University of Cartagena, Cartagena, Colombia.*

Pathophysiological problems in organisms might be derived from changes in multiparametric metabolic responses that can be monitored using spectroscopic methods. The metabolic nature of the liver makes this organ suitable to study alterations in metabolism associated with the spectroscopic features of the liver oil. The aim of this study was to test the hypothesis that fish liver oil content and its infrared (IR) spectroscopic profile is affected by environmental contamination conditions. Mugil incilis (Lisa) was chosen as a test species because it is one of the most common fish in the Atlantic coasts of Central and South America, and usually searches for food in the sediment where pollutants are concentrated. Fish samples were monthly caught in Cartagena Bay, a waterbody that receives multiple polluted effluents, and from Totumo marsh, a low contaminated site, both located at the North of Colombia, South America. After collection, fish size and length were measured and specimens examined for parasites. Liver oils were obtained by soxhlet extraction with dichloromethane and analyzed by IR spectroscopy. Measured condition indexes for fish from Cartagena were statistically lower than those obtained from the control site, and correlated inversely with the number of nematode parasites found in the liver and muscle. Livers from fish captured at Cartagena Bay had approximately 25% less oil content than those from Totumo Marsh. IR spectra were significantly different among sites particularly in the aliphatic, carbonyl and finger print region. These changes in spectroscopic properties were dependent on the sampling season. This study established that the IR spectroscopic profile of fish liver oil can be used to successfully discriminate between the different metabolic and health status of fish caught from sites with varied degree of contamination.

331 ISOLATION AND CLONING OF A MAJOR HEPATIC GLUTATHIONE S-TRANSFERASE FROM LARGEMOUTH BASS (*MICROPTERUS SALMOIDES*).

A. M. Doi, R. T. Pham and E. P. Gallagher. *Physiological Sciences, University of Florida, Gainesville, FL.*

A full-length glutathione S-transferase (GST) cDNA was obtained from largemouth bass (*Micropterus salmoides*) liver total RNA using 5' and 3' systems for rapid amplification of cDNA ends (5' RACE and 3' RACE). The full-length GST cDNA was 957 base pairs (bp) in length and contained an open reading frame of 666 bp, encoding a polypeptide of 222 amino acids. The bass liver GST exhibited high homology to a theta-like GST (GST-A) previously isolated from plaice (*Pleuronectes platessa*) with high catalytic activity towards 4-hydroxynonenal (4HNE), a cytotoxic and mutagenic breakdown product generated during the peroxidation of polyunsaturated fatty acids. Northern blotting analysis of largemouth bass liver RNA revealed strong expression of a GST-like hybridizing band of approximately 1 kb. In addition, affinity-purified bass hepatic cytosolic fractions displayed high catalytic activity toward 4HNE. In summary, the presence of a highly expressed GST isozyme in bass with extensive sequence homology to plaice GST-A is suggestive of a role of GST in protecting against oxidative damage in this freshwater species. Supported by NIH P42 ES07375.

332 ENVIRONMENTAL INDUCTION OF CYP1A- AND CYP2K1-LIKE PROTEINS IN TWO TROPICAL FISH SPECIES BY PRODUCED FORMATION WATER ON THE NORTHWEST SHELF OF AUSTRALIA.

M. L. Haasch[1], M. F. Johnston[2] and S. Codi[3]. [1]*Environmental Toxicology Research Program, Environmental Community Health Research, Research Institute of Pharmaceutical Sciences, Department of Pharmacology, The University of Mississippi, University, MS,* [2]*University of Kansas, Kansas City, KS and* [3]*Australian Institute of Marine Science, Townsville, Qld, Australia.*

Little or no information is available regarding hydrocarbon exposure of tropical fish species inhabiting the waters near oil and gas platforms on the Northwest Shelf of Australia. In 1998, a pilot study was funded by Apache Energy Pty Ltd to evaluate the use of sub-lethal stress indicators in fish to assess exposure to produced formation water (PFW). Tropical fish, the Gold-spotted Trevally (*Carangoides fulvoguttatus*) and the Bar Cheeked Coral Trout (*Plectropomus maculatus*), were obtained from two sites impacted by PFW discharge, Harriet A (near field) and Harriet C (far field) and a non-impacted reference site, the Montebello Islands. Microsomal fractions from both Trevally and Coral Trout, each had one immunodetectable CYP1A- and one CYP2K1-like protein. CYP1A-like protein was expressed in a gender-specific manner with male Trevally from the reference site expressing a 3.5-fold higher level compared to reference site females. Only female Trevally had significantly higher CYP1A-like protein levels at both platform sites compared to the reference site females. Gender-specific induction of CYP2K1-like protein occurs in the Gold-spotted Trevally as PFW-exposed males express higher levels than PFW-exposed female Trevally. Both male and female Coral Trout showed increased (not significant) levels of CYP2K1-like proteins at the impacted sites as compared to the reference site. These data suggest possible PFW contamination near the platforms that produces induction of both CYP1A- and CYP2K1-like proteins. While induction of CYP1A is considered to be the most sensitive response to exposure to petroleum hydrocarbons, increases in CYP2K1-like proteins in fish have not previously been described as a consequence of environmental petroleum hydrocarbon exposure.

333 ENVIRONMENTAL RISK ASSESSMENT OF DULOXETINE HYDROCHLORIDE.

A. Nimrod-Perkins, S. D. Banks, J. S. Teeter and R. D. Meyerhoff. *Environmental Science, Eli Lilly and Company, Greenfield, IN.* Sponsor: L. Buckley.

The present work was conducted to assess environmental risk from the therapeutic use of duloxetine hydrochloride, a serotonin/norepinephrine reuptake inhibitor. Specifically, consequences of exposure to the environment *via* patient use and subsequent discharge from sewage treatment plants were evaluated. Environmental chemistry studies were conducted to determine the disposition of duloxetine hydrochloride in the environment. The water solubility of duloxetine hydrochloride is 21.6, 2.74, and 0.331 g/L at pH 4, 7, and 9, respectively. The log octanol/water partition coefficient is 0.781, 1.54, and 3.35 at pH 4, 7, and 9, respectively, suggesting that there is little potential for bioconcentration. The organic carbon sorption coefficient measured in sludge ranged from 2893 to 4296 indicating the potential for removal from the aqueous compartment *via* sorption to biosolids. Other minor depletion mechanisms include hydrolysis (half-life is 1.5 to 3.5 months) and aerobic biodegradation (no significant degradation after 8 days in simulated sewage treatment). To assess the effects of duloxetine on environmental organisms, standard toxicity tests were conducted. The 3-hr EC50 for inhibition of respiration in sewage microorganisms is 36.5 ppm duloxetine. The 96-hr LC50 of duloxetine in rainbow trout and the 48-hr EC50 in *Daphnia magna* are 1.3 ppm and 2.4 ppm, respectively. Algae were the most sensitive aquatic species in acute toxicity tests with duloxetine. The EC50 and NOEC in a 72-hr test with *Pseudokirchneriella subcapitata* were 0.064 and 0.011 ppm duloxetine, respectively. The chronic toxicity of duloxetine was determined in a full life-cycle test with *D. magna*. The most sensitive endpoint was reproduction, with EC50 and NOEC values of 0.28 and 0.011 ppm duloxetine, respectively. Based on these data and predicted environmental concentrations, the therapeutic use of duloxetine hydrochloride is not considered to pose a significant risk to the environment.

334 HOW ARE PCB CONGENERS DIFFERENT IN FILLETS OF FISHES AROUND LAKE MICHIGAN?

D. V. Singh[1], C. Chen[2], A. O. Chiu[3], N. H. Chiu[4], J. Beaubier[5], R. Nalesnik[6], W. Tehseen[7] and J. Riebow[8]. *[1]NCEA/ORD/8623D, USEPA, Washington, DC, [2]NCEA/ORD/8623D, USEPA, Washington, DC, [3]OST/OW, USEPA, Washington, DC, [4]OPPTS, USEPA, Washington, DC, [5]NCER/ORD, USEPA, Washington, DC, [6]NCEA/ORD/8623D, USEPA, Washington, DC, [7]HED/OPPTS, USEPA, Washington, DC and [8]Env Epid Div/Bureau Lab, Mich Department Comm. Health, Lansing, MI.* Sponsor: D. Singh.

How different are PCB congeners in fillets of various fishes around Lake Michigan in the last decade? DDT has adversely affected songbird reproduction. With amelioration of DDT pollution, clutch size of eggs in a bird's nest increases. PCB disrupts endocrine-system functions leading to increase in endometriosis, fetal abortion, glomerulonephropathies, osteoporosis, and a decline in the population, Helle-Bergman-Olsson's hyperadrenocorticism associated with environmental exposure to PCB/DDT". To protect the environment and human health, prevention from exposure to PCB along the food chain is of paramount importance. It is not only importan to measure PCB in the abiotic environment, but especially along the entry point into the food chain, the fish fillets. PCB concentrations in 14 different fish species (brown trout, carp, chinook salmon, coho salmon, lake trout, northern pike, rainbow smelt, rainbow trout, lake sturgeon, longnose sucker, walleye, white sucker, whitefish, yellow perch) around Lake Michigan were examined in the last decade with capillary gas chromatography and electron capture technique. It is noted that fishes, such as the carp with longer life spans and a dependence on feeding detritus accumulated more PCBs. This combined with the environmental/biological half-lives of PCB congeners led to a higher concentration and more varieties in carp in comparison with fillets of the salmon, trout and whitefish. These differences may have contributed to different problems in human health.

335 MAXIMALLY PERSISTENT PCB CONGENERS IN FISHES AND HUMANS.

A. O. Chiu[1], N. H. Chiu[2], J. Beaubier[3], D. V. Singh[4], S. Gerstenberger[5], J. Riebow[6] and H. Humphrey[7]. *[1]NCEA/ORD, USEPA, Washington, DC, [2]NCEA/ORD, USEPA, Washington, DC, [3]OPPTS, USEPA, Washington, DC, [4]NCEA/ORD, USEPA, Washington, DC, [5]Dept Env Studies, U Nevada, Las Vagas, NV, [6]Bureau of Lab, Mich Department Comm. Health, Lansing, MI and [7]Dept Env Sci, Mich State Univ, Lansing, MI.*

We analyzed PCB tissue burdens in humans with intermittent links to PCB contaminated fish. Pattern recognition by principal components analysis was applied to data on Ojibwa native Americans, Great Lake fishermen and non-great lake USA gamefishermen as well as PCB contaminated fish fillets determined by electron-capture-gas chromatography. Fish consumption data were obtained through questionnaires. Local-area-microenvironment PCB congeners pattern is the principal determinant factor in PCB human-contaminant-serum-patterns. Among PCB congeners, ortho position is the most frequent position regardless whether they are the gamefishermen or the Ojibwa Indians. The penta and hexachlorinated isomers are the most prevalent. The combination of these characteristics, the ortho-chlorination, the penta and hexachlorinated isomers determine not only the olubility/bioavailability, but also the bioaccumulation/ biomagnification in all organisms including fish consuming humans. 336 BIOASSAY-BASED FRACTIONATION OF AN ANDROGENIC PULP MILL EFFLUENT FROM THE FENHOLLOWAY RIVER IN FLORIDA.

E. J. Durhan[1], C. Lambright[2], V. Wilson[2], L. E. Gray[2], L. J. Guillette[3] and G. T. Ankley[1]. *[1]Mid-Continent Ecology Division, USEPA, Duluth, MN, [2]Reproductive Toxicology Division, USEPA, Research Triangle Park, NC and [3]University of Florida, Gainesville, FL.*

Pulp mill effluent samples from the Fenholloway river in Florida were collected and tested using a bioassay-based fractionation approach, to attempt to identify the causative agent(s) responsible for observed androgenic effects in female fish from the system. Androgenic activity of the effluent and subsequent fractions was "tracked" through the process using CV-1 cells transfected with a human androgen receptor -MMTV-luciferase promoter-reporter system (Parks et al. 2001. Toxicol. Sciences. 62:257). The goal of the approach was to separate biologically-active components from non-active components of the complex effluent matrix to facilitate the identification of the chemical(s) responsible for androgenic activity. Initially organic chemicals were isolated from the effluent using a C_{18} solid phase extraction (SPE) cartridge, which was subsequently eluted with graded concentrations of methanol in water. SPE fractions which exhibited *in vitro* androgenic activity were then fractionated further using high pressure liquid chromatography (HPLC) into twenty five discrete fractions. In these studies, multiple HPLC fractionation steps were required to adequately simplify samples for chemical identification. The HPLC fractions displaying activity in the CV-1 cell assay were then analyzed using gas and liquid chromatography linked with electron impact, or chemical ionization (both positive and negative ion) mass spectrometry. Androstenedione, a steroid previously identified by other researchers as responsible for androgenicity of this effluent, was found in the effluent sample but not in the active HPLC fractions. Additional mass spectrometry results to date indicate the presence of many steroidal compounds, as well as a few halogenated chemicals in the active fractions. *This abstract does not necessarily reflect EPA policy.*

337 IDENTIFICATION OF ENVIRONMENTAL ESTROGEN-LIKE CHEMICALS IN INDUSTRIAL WASTEWATER BY GC/MS.

Q. H. Felty and D. Roy. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

Alkylphenols and phytosterols possess estrogen-like activity. Exposure to these chemicals has been implicated in the development of adverse health effects such as abnormal reproductive tract development, sterility, and cancer. Alkylphenol polyethoxylates (APEs) are used as pitch dispersants, wetting agents, and as drainage and deresinating aids in the pulp and paper industry. Alkylphenols are degradation by-products of APEs and b-sitosterol, a phytosterol, can leach out of pine trees that are used in the pulping industry. The goal of this study was to develop a gas chromatography/mass spectrometry (GC/MS) based method to detect individual estrogenic chemicals from industrial wastewater samples in a single run. Water samples were collected from an anonymous pulp mill in the state of Alabama by grab sampling in front of a discharge pipe, which transports wastewater from a settling pond to a river. The concentrated extracts from the water samples were derivatized with N, O-bis(trimethylsilyl)trifluoroacetamide (BSTFA), and analyzed for trimethylsilyl (TMS) derivatives by GC/MS in select ion monitoring mode (SIM). Known estrogenic chemicals 4-nonylphenol (4-NP), 4-tert-octylphenol (4-t-OP), 4-octylphenol (4-OP), and b-sitosterol were used as standards. Detection limits for 4-t-OP, 4-NP, 4-OP, and b-sitosterol were 0.020 mg/L, 0.027 mg/L, 0.046 mg/L, and 1.25 mg/L, respectively. Sample recovery of 4-t-OP, 4-NP, and b-sitosterol was 69%. Using this method we detected 4-t-OP, 4-NP, and b-sitosterol in the effluent at concentrations of 3.45, 6.62, and 19.92 mg/L, respectively. Thus, our study indicates that this GC/MS method is highly efficient to detect environmental estrogen-like chemicals in contaminated water sources and to monitor the quality of water.

338 KINETICS AND BINDING OF FUMONISIN IN A MODEL SOIL SYSTEM.

L. D. Williams[1,2], C. W. Bacon[2], J. L. Showker[2], F. I. Meredith[2], A. J. Franzluebbers[2], M. A. Smith[1], R. D. Wyatt[1] and R. T. Riley[2]. *[1]Environmental Health Sciences, University of Georgia, Athens, GA and [2]USDA/ARS, Athens, GA.*

Fumonisin B_1 (FB_1) is a water soluble, carcinogenic mycotoxin produced by the fungus *Fusarium moniliforme*, which is parasitic to corn plants. It can be found in the ear, roots, and stalks of plants. It is estimated that 90% of the FB_1 consumed by

livestock is excreted unmetabolized. The objectives of this research are to determine 1) the kinetics of FB_1 interaction with soil constituents, and 2) if FB_1 is chemically modified in the soil. Leachate columns were used to determine the movement of FB_1 through soil matrices comprised of washed sand and 0%, 50%, 75%, or 100% Cecil sandy loam soil. The movement of FB_1 was compared to that of bromophenol blue (Bb), a dye that moved freely through the soil columns. FB_1-contaminated corn screenings or extracts containing FB_1 were placed on the surface of the soil columns. When corn screenings were used as the source of FB_1, a rain simulator was attached to the top of the column and water was allowed to saturate the corn screenings (extracting the FB_1) and percolate through the column eluting the FB_1. The 100% sand columns slightly retarded the efflux of FB_1 relative to Bb but did not appear to chemically alter the FB_1. The recovery of FB_1 decreased with increasing concentrations of Cecil sandy loam soil. At 0%, 50%, 75% and 100% Cecil sandy loam, approximately 80%, 60%, 50% and 20% of the FB_1 was recovered in the column leachate, respectively. The FB_1 retained on the 100% Cecil sandy loam column was tightly bound as evidenced by the fact it could not be extracted using acetonitrile:water (1:1). However, approximately 40% of the retained FB_1 was extractable using 5% formic acid:acetonitrile (1:1) indicating that the nature of the interaction was probably ionic. The result of this study indicate that FB_1 is probably stable in the soil environment and suggests that while some is tightly bound, under certain environmental conditions FB_1 could be released, become biologically available and possibly contaminate the water supply.

339 INCUBATION WITH TOP SOIL ENHANCES SOLUBILIZATION OF RA FROM OIL AND GAS PRODUCTION SCALE AND SLUDGE SAMPLES.

J. C. Matthews[1], S. Li[1], C. T. Swann[2] and R. L. Ericksen[3]. *[1]Pharmacology and Division of Environmental Health Res., Univ. of Mississippi, University, MS, [2]Mississippi Mineral Resources Inst., Univ. of Mississippi, University, MS and [3]Mississippi State Board of Registered Professional Geologists, Jackson, MS.*

Large quantities of formation waters (brines) are co-produced with hydrocarbons from oil and gas wells. Dissolved solutes from the brines precipitate forming scale in and on production equipment and sludge in storage tanks. Ra is one of the solutes that may precipitate rendering the scales and sludges radioactive. One method under consideration for disposal of scale and sludge wastes is land spreading in which the material is spread on the ground, tilled into the top few centimeters of soil, and then covered over with a layer of "clean" soil such that the radioactivity is below governmental action levels, and the site can be considered uncontaminated. One of the assumptions that this method of disposal is based upon is that the Ra and other inorganic components of the scales and sludges are highly insoluble, relatively immobile in the environment, and low in biological availability. To test this assumption the leaching of Ra from radioactive scale and sludge samples was examined for the scale and sludge samples alone and after mixing and incubating them under moist conditions with top soils. It was found that incubating the samples with top soils increased the leaching of Ra from them by several fold. This finding is remarkable in light of the finding that soil complexes most of the soluble Ra added to it and soils mixed with scale or sludge complex even greater proportions of the soluble Ra added to them. Even though the complexed Ra is difficult to extract from the soil it is expected to be much more biologically available and mobile in the environment than in its original insoluble form. The indication is that incubation of scales and sludges with top soils, such as with land farming, might result in significant enhancements of the environmental mobility and bioavailability of the Ra that they contain.

340 NATURAL AND ANTHROPOGENIC PROCESSES THAT CONCENTRATE MN IN RURAL AND URBAN ENVIRONMENTS OF THE LOWER MISSISSIPPI RIVER DELTA.

H. W. Mielke, C. R. Gonzales, E. Powell and A. Shah. *College of Pharmacy, Xavier University of LA, New Orleans, LA.*

Natural processes of Mn accumulation and the legacy of Pb additives in fuel for predicting Mn in the environment are the topics of this study. Data is from alluvia and sediments of the lower Mississippi River Delta and a soil metal survey of metropolitan New Orleans. The "railroad manganese," "industrial manganese" and "dynamic aquifer-stream transfer of Mn" hypotheses were tested. The results support the proposal that friction between Mn-rich steel wheels and rails contribute Mn to the environment. Sediment loads of Mn upstream and downstream from the LA industrial corridor were similar (P-value = 0.77) and this data does not support the industrial manganese hypothesis. Data medians of the alluvium surface (59 mg/kg), the aquifer (159 mg/kg) and the riverbank (513 mg/kg) where Mn-rich clay precipitates during aquifer discharge support the aquifer-stream transfer hypothesis. Soils along rural and urban roads exhibit respectively, medians of 216 and 85 mg/kg for Mn, and 17 and 212 mg/kg for Pb. The survey of metropolitan New Orleans indicates an increase from rural to interior urban communities by a factor of 4 for Mn and nearly 3 orders of magnitude for Pb. Assuming 1999 US on-road fuel use, at 8.3 mg of Mn per L, 5 thousand metric tons of Mn would be consumed. If 13% of the Mn added to fuels were emitted, 650 metric tons of Mn would become aerosols annually, and 87%, or 4, 350 metric tons would remain in the engine. The 1999 TRI for Mn shows 108 metric tons as stack releases and 370 metric tons as total emissions. In 1999, 60.5% of vehicle travel occurred in urban and 39.5% occurred in non-urban areas. Annually, Mn in fuel would emit 390 and 260 metric tons respectively in urban and non-urban areas. Mn would mimic the pattern for Pb. Release of Mn aerosols into communities currently polluted with Pb infringes on Executive Order 12898 concerning Federal redress of environmental justice in minority and low-income populations. Funded by ATSDR/MHPF cooperative agreement #U50/ATU398948 to Xavier University of LA.

341 REDUCTION OF THE TOXICOLOGIC EFFECTS OF PROLONGED HYDROCARBON VAPORS INHALATION IN CONTAMINATED BUILDINGS BY BIOREMEDIATION.

E. I. Kozliak and M. K. Beklemishev. *Chemistry, University of North Dakota, Grand Forks, ND.* Sponsor: S. Pyle.

Contamination of building structural elements which may be a result of fuel oil spills, catastrophic flooding etc., results in the release of chemicals into the air over the course of years. An efficient method of reducing the human exposure to the hydrocarbons is suggested based on bioremediation, i.e. application of live microorganisms on polluted building materials, such as wood and concrete. The purpose of this bench-scale study was to evaluate the feasibility of bioremediation for the removal of hydrocarbons using naphthalene and n-hexadecane as model pollutants. Radiolabelled hydrocarbon was applied on standard pieces of building materials followed by the adsorption of bacteria. Then pollutant degradation efficiency was monitored by scintillation counting. Two kinds of experiments were conducted: shaking the samples with biomass in mineral medium (shaking flask procedure) and attaching the building material samples on the agar medium where the biomass has been grown (overlay procedure). The observed similarity of pollutant removal kinetics for shaking flask and overlay procedures indicated that the rate-limiting step appears to be diffusion of the hydrocarbon within the pores of a building material. Moisture content of the samples had a critical influence on the degradation efficiency. Water was shown to hinder the diffusion of hydrocarbons in wood and concrete. This effect was used to accelerate the pollutant removal by adjusting the protocols for biomass application. Among the factors influencing hexadecane removal efficiency, the following conditions of biomass growth (prior to their application) were found to be critical: the time and temperature of cultivation, composition of nutrient medium, and the regime of re-inoculations. Preventing the biomass starvation resulted in a significant increase of pollutant removal. For 6-mm thick wood and one-gram concrete samples, maximum hexadecane removal achieved without applying new biomass was 85-95%, which required ca. 2 weeks.

342 MINERALOGICAL AND GEOCHEMICAL VARIATIONS AMONG ASBESTOS STANDARDS.

T. L. Ziegler[1], P. J. Lamothe[1], S. J. Sutley[1], G. P. Meeker[1], I. K. Brownfield[1], H. Lowers[1], N. N. Sun[2], T. K. Hinkley[1], G. S. Plumlee[1] and M. L. Witten[2]. *[1]US Geological Survey, Denver, CO and [2]University of Arizona, Tucson, AZ.*

It is well known that exposure to asbestiform mineral dust is associated with lung diseases such as asbestosis, malignant mesothelioma, and bronchogenic carcinoma. Past attention primarily focused on human exposure and health effects of commercial asbestos. In recent years, there has been renewed recognition of the potential deleterious health effects of asbestos that occur as accessory minerals in rocks (i.e.;serpentinite, a common rock in US) and in some mineral commodities used commercially (i.e.;vermiculite, talc). Within the past decades, many *in vitro* and *in vivo* studies have shown asbestos to be cytotoxic and mutagenic, yet the mechanisms responsible are not fully understood. These questions can be best answered through continued and increased collaborative research between the earth science and health-related communities. One example of this is the mineralogical and geochemical characterization of individual asbestos family members. The USGS has assembled 5 sets of asbestos standards, which have been previously used in toxicological studies (Standard sets:5 amosites, 4 anthophyllites, 6 chrysotiles, 5 crocidolites, 4 tremolites). Presently, we have identified the mineralogical and geochemical characteristics for each set of asbestos standards. Chemical analyses indicate that elemental (i.e.;Al, Ca, Co, Cr, Fe, Ga, Li, Mg, Mn, Ni) content varies between the different asbestos minerals. Variations within the standards of the same asbestos mineral sets are present. X-ray diffraction and SEM also indicate differences in asbestos habit (crystal shape, cleavage pattern) and the presence of other minerals as contaminants between different asbestos standards and within the sets of asbestos standards. These variations between the asbestos standards or those within the sets

of the same asbestiform mineral may be responsible for conflicting toxicological results, ultimately inhibiting mechanistic identification. Toxicity studies utilizing each group of standards are in progress.

343 DILUTED DIESEL EXHAUST EMISSIONS DO NOT INDUCE CHANGES IN PERIPHERAL BLOOD MICRONUCLEI LEVELS IN SUBCHRONICALLY EXPOSED MALE AND FEMALE A/J MICE.

M. D. Reed. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Focus has been directed toward the cancer risk associated with diesel emissions' contribution to air pollution in both occupational and environmental settings. As one component of the National Environmental Respiratory Center's long-term goal to assess the carcinogenic potential of many anthropogenic source emissions, we determined the clastogenic ability of subchronic exposures of diesel emissions to induce peripheral blood micronuclei in the strain A/J mouse. One hundred male and one hundred female A/J mice (10 male and 10 female mice per exposure concentration) were exposed (whole body, Hazelton H2000 chamber) to log doses of diesel emissions generated from one of two 2000 Cummins B series engines operated on the heavy duty test cycle with EPA certification diesel fuel. Chamber concentrations were determined by diesel exhaust particulate matter and maintained at 0, 30, 100, 300 and 1000 $\mu g/m^3$ respectively. Exposures were conducted for 6h/day, 7 days a week, for a period of six-months. Micronuclei were assessed in heparinized peripheral blood from each animal by flow cytometry (~20, 000 reticulocytes counted per animal). Levels of micronuclei in clean air-exposed, 6-month old mice were consistent with previously published reports in juvenile and age-matched A/J mice (within 3 standard deviation of the mean). As analyzed by one-way ANOVA and the Student t test for pair wise comparison to control, there were no differences between the mean levels of micronuclei in control and exposed mice ($P \leqq 05$). These findings indicate that exposure of A/J mice to diesel emissions diluted up to $1000 \mu g/m^3$ does not induce clastogenic changes in micronuclei levels as measured in peripheral blood. Research conducted by the National Environmental Respiratory Center (NERC) with support from multiple government and industry sponsors, including the USEPA. This abstract is not intended to represent the views or policies of any NERC sponsor

344 USING THE MOUSE LYMPHOMA TK ASSAY TO COMPARE THE MUTAGENICITY OF MAINSTREAM SMOKE CONDENSATE FROM RESEARCH CIGARETTES.

H. Schramke, F. J. Tewes and E. Roemer. *PRM, INBIFO GmbH, Cologne, Germany.* Sponsor: R. Solana.

The mouse lymphoma TK assay - microtiter version - has been established and optimized to quantitatively determine the *in vitro* genotoxicity of mainstream smoke condensate (MSC) in order to complement our existing testing battery. The assay was validated with the positive control substances methyl methanesulfonate and benzo(a)pyrene and MSC from the Reference Cigarette 1R4F with and without a metabolic activation consisting of the postmitochondrial (S9) fraction of the livers from rats treated with Aroclor 1254. Reproducible responses - with a coefficient of variation of less than 20% - were found for the positive control substances and for the 1R4F-MSC. To test whether the assay is able to discriminate different cigarette types, MSC from five research cigarettes containing different tobacco blends was prepared and assayed. Positive responses were obtained for all cigarettes, with concentration-related increases in the mutant frequency. To compare the mutagenicity of the cigarettes, the dose-response curve for the mutant frequency was calculated by nonlinear regression analysis. From each dose-response curve, the effective concentration for a 3-fold increase over the spontaneous mutant frequency was calculated and compared. The comparison showed that without S9, the activity of MSC from a 100% Burley blend cigarette was lower than that of the other blends; with S9 a similar trend was seen. This is different from the results seen in the S. typhimurium reverse mutation assay in strains TA98 and TA100 with S9, where the Burley cigarette was more active than the 100% Bright blend cigarette. This supports the need for a genotoxicity testing battery of complementary assays for the comprehensive testing of cigarette smoke. INBIFO is a Philip Morris research laboratory.

345 GENOTOXICITY OF NICKEL-CONTAINING SAMPLES IN 10T1/2 MOUSE EMBRYO CELLS: PREDICTIONS OF CARCINOGENIC POTENTIALS AND IMPLICATIONS FOR MECHANISMS OF CARCINOGENESIS.

R. Verma, F. Clemens, L. Kaspin, M. Merwally and J. R. Landolph. *Depts. of Mol. Micro/Immunol, Path, and Mol Pharm/Tox, USC/Norris Cancer Center, Cancer Research Lab, University of Southern California, Los Angeles, CA.*

Long-term inhalation exposures of workers to mixtures of some insoluble and soluble nickel compounds in specific nickel refinery operations in the past were associated with excess lung and nasal cancer. For example, nickel subsulfide induced tumors in rats by inhalation. Animal data by relevant routes of exposure are not available for all nickel compounds, metallic nickel, or nickel-containing alloys. *in vitro* studies can directly evaluate genotoxicities of new nickel-containing substances relative to nickel compounds that are well-characterized in animal studies. We therefore determined relative genotoxicities of nickel-containing samples in short-term *in vitro* assays, and used these relative genotoxicities to rank samples for their predicted carcinogenic potentials and prioritize samples for *in vivo* testing. Previously, we have shown that two nickel subsulfide samples (< 10μm diameter) induced strong, dose-dependent morphological transformation in 10T1/2 cells. Spherical particles of elemental nickel samples (ENi-1, average diameter of 2.3 μm and ENi-3-7 average diameter 11 μm) and two stainless steel samples (3.5 μm and 8.5 μm average diameter) did not induce morphological transformation. The order of cytotoxic potency of a new set of samples (LC_{50} values in parentheses) was: Ni_3S_2 (1.35 μm)(0.35 ± 0.2 μg/ml) > Ni (UF) (0.45 ± 0.3 μg/ml) > $Ni(OH)_3$ (powdered form) (2.96 ± 2.4 μg/ml) > $NiCO_3$ (4.08 ± 3.8 μg/ml) >> SS (<3.0 μm) (455 ± 26.1 μg/ml). Particles of stainless steel < 3.0 μm were not taken into and did not induce morphological transformation in, 10T1/2 cells. Small particles of nickel subsulfide (Ni_3S_2, 1.35μm) were phagocytosed in a dose-dependent manner (67.7% of the cells at 1.0 μg/ml). Spherical particles of ultrafine metallic nickel (UF) were phagocytosed (60.5% of cells at 5.0 μg/ml), induced chromosome breakage and morphological transformation.

346 OXIDANT-INDUCED DNA DAMAGE BY QUARTZ AND HYDROGEN PEROXIDE IN ALVEOLAR EPITHELIAL CELLS.

R. P. Schins, A. M. Knaapen, G. D. Cakmak, T. Shi, C. Weishaupt and P. J. Borm. *Particle Toxicology, Institut für Umweltmedizinische Forschung (IUF), Düsseldorf, Germany.* Sponsor: K. Driscoll.

Studies with respirable quartz using naked DNA as a target suggest that hydroxyl-radical formation by the particle itself may play a role in the DNA-damaging properties of quartz. However, it is not known whether this pathway is important for DNA damage in alveolar epithelial cells which are considered as target cells for quartz carcinogenesis. Therefore, we determined DNA damage by quartz or hydrogen peroxide in A549 human and RLE rat alveolar epithelial cells using the alkaline comet-assay. The hydroxyl radical generation capacity of the quartz was analysed by electron spin resonance (ESR), and by immunocytochemical analysis of the hydroxyl radical-specific DNA lesion 8-hydroxydeoxy-guanosine (8-OHdG) in the epithelial cells.Quartz particles as well as hydrogen peroxide were found to cause a dose-dependent increase in DNA strand breaks in both cell lines. DNA damage by quartz was significantly reduced in the presence of the hydroxyl-radical scavengers mannitol or DMSO. The involvement of hydroxyl radical was also demonstrated by ESR measurements, and by the ability of the quartz to induce formation of 8-OHdG in both cell types. In conclusion, our data show that quartz elicits DNA damage in human and rat alveolar epithelial cells, and indicate that these effect are driven by intrinsic hydroxyl-radical generating properties of the particles.

347 AGE, GENDER, AND SPECIES DEPENDENT MUTAGENICITY IN T-LYMPHOCYTES FROM MICE AND RATS EXPOSED TO 1, 3-BUTADIENE BY INHALATION.

Q. Meng[1], R. F. Henderson[1], M. Bauer[2] and V. E. Walker[1]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]School of Public Health, State University of New York at Albany, Albany, NY.*

To determine the effects of age, gender, and species on the mutagenicity of 1, 3-butadiene (BD), male and female B6C3F1 mice and F344 rats (4-5 or 8 week-old) were exposed to 0 or 1250 ppm of BD for 2 weeks by inhalation (6 h/day, 5 day/week). The mutation manifestation curves were defined by measuring the Hprt mutant frequencies (Mfs) in splenic T-lymphocytes at multiple time points after BD exposure using a T-cell cloning assay, and the mutagenic potencies of BD were calculated as the differences of area under the manifestation curves of treated *versus* control animals. The mutagenic potency of BD in 4-5 week-old female mice (69.6, with a 95% confidence interval of 61.1 and 78.7) was not significantly different from that in 8 week-old female mice (57.0, with a 95% confidence interval of 44.7 and 71.5); but, the maximum BD-induced Mfs were observed at 5 weeks post exposure in younger mice *versus* 8.5 week post exposure in older mice, with the peak values in BD-induced Mfs in 4-5 week old mice ($17.8 \pm 6.1 \times 10^{-6}$) being 2.2–fold greater than that in 8 week-old mice ($8.0 \pm 1.0 \times 10^{-6}$). Thus, while shape of the mutant T-cell manifestation curves for spleens of BD-exposed 4-5 week-old and 8 week-old mice were different, the mutagenic burden was the same for both age groups. BD-induced Hprt Mfs in female mice ($17.8 \pm 6.1 \times 10^{-6}$) were 2.3-fold greater than those in male mice ($7.7 \pm 3.3 \times 10^{-6}$) at 5 weeks post exposure, while BD-induced Hprt Mfs in female rats ($7.2 \pm 5.5 \times 10^{-6}$) were 1.9-fold greater than those in male rats ($3.9 \pm 2.8 \times 10^{-6}$) at 4 weeks post exposure. The results of these

species and gender evaluations demonstrate that the overall pattern for mutagenic susceptibility in BD-exposed rodents is female mice > male mice > female rats > male rats, consistent with the current knowledge of species and gender differences in metabolism and carcinogenic susceptibility.

348 NONHOMOLOGOUS END JOINING IS NOT A SIGNIFICANT PATHWAY FOR REPAIR OF BENZENE-INDUCED DNA DOUBLE STRAND BREAKS.

B. Faiola, A. K. Bauer, L. Pluta, V. Wong, K. Roberts and L. Recio. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Benzene is a genotoxic carcinogen that induces chromosomal breaks as a primary mode of genotoxicity in the bone marrow (BM). We showed that chronic exposure to inhaled benzene induced a p53-regulated DNA damage response in mouse BM. We investigated the nonhomologous end joining (NHEJ) pathway of DNA double strand break (DSB) repair in benzene genotoxicity. Quantitative RT-PCR was used to determine Ku80 mRNA levels in the BM of C57BL/6 mice exposed to inhaled benzene (100 ppm) for 15 wk., hypothesizing that benzene would induce expression of genes, such as Ku80, involved in NHEJ. However, Ku80 mRNA levels in benzene-exposed mice were not significantly altered. Next, we compared the genotoxic effects of inhaled benzene on C57BL/6 and 129/SvJ mice which differ at the *Prkdc* locus encoding the catalytic subunit of DNA-PK (DNA-PKcs) that binds to the Ku70/Ku80 heterodimer during NHEJ. C57BL/6 mice have a wild-type allele at *Prkdc* while 129/SvJ mice have a *Prkdc* functional polymorphism that leads to diminished DNA-PK activity and enhanced apoptosis in response to radiation-induced damage. We expected mice with deficient DNA-PK activity to be more susceptible to the genotoxic effects of inhaled benzene. Mice were exposed to 0, 10 or 100 ppm benzene for 6 h/day, 5 days/week for 2 weeks. Both strains had decreased WBC and lymphocyte counts in the blood with increasing dose of benzene. Flow cytometric cell cycle analysis on BM cells stained with propidium iodide revealed no G1 arrest in either strain at any dose of benzene. Genotoxicity was assessed by a flow cytometry assay that distinguishes micronucleated mature normochromatic erythrocytes (MN-NCE) from micronucleated reticulocytes (MN-RET) in blood. We observed comparable increases in MN-NCE and MN-RET populations in both C57BL/6 and 129/SvJ mice following benzene exposure, suggesting the difference in *Prkdc* alleles does not affect benzene-induced genotoxicity. The data indicate that NHEJ, mediated by the Ku heterodimer and DNA-PKcs, is not a significant pathway in the repair of benzene-induced DSB.

349 GENETIC SUSCEPTIBILITY TO BENZENE-INDUCED TOXICITY: ROLE OF NAD(P)H:QUINONE OXIDOREDUCTASE-1 (NQO1) AND MICROSOMAL EPOXIDE HYDROLASE (mEH).

A. K. Bauer[1], B. Faiola[1], D. J. Abernethey[1], R. Marchan[1], L. J. Pluta[1], V. A. Wong[1], K. Roberts[1], A. K. Jaiswal[2], F. J. Gonzalez[3] and L. Recio[1]. *[1]CIIT Centers for Health Research, Research Triangle Park, NC, [2]Baylor College of Medicine, Houston, TX and [3]NCI, Bethesda, MD.* Sponsor: L. Recio.

Chronic benzene is hematotoxic, genotoxic, and carcinogenic in humans and rodents, causing a variety of hematopoietic disorders. The enzyme systems involved in activation and detoxication reactions of benzene metabolism are likely genetic determinants of individual variability and risk in response to benzene. NQO1 catalyzes the detoxication of 1, 4-benzoquinone, proposed as an ultimate toxic benzene metabolite. mEH metabolizes benzene oxide to dihydrodiol, which can then be converted to catechol or trans, trans-muconaldehyde, both of which can lead to genotoxic metabolites. Our hypothesis is that the NQO1 and mEH pathways are critical to benzene-induced toxicity. We exposed NQO1-/- and mEH-/- mice to inhaled benzene (10 or 100 ppm) for 2 weeks and then determined the hematotoxicity and genotoxicity relative to the 129/SvJ (wild-type;WT) mice. Micronucleated (MN) polychromatic erthyrocytes (PCE; immature RBC) assessed manually in the bone marrow and by flow cytometry in the blood were used as a measure of genotoxicity. In preliminary studies, WT mice were almost twice as sensitive to benzene-induced genotoxicity (2.7% MN-PCE, $p<0.01$) compared to NQO1-/- mice (1.3% MN-PCE, $p<0.01$). mEH-/- mice were not sensitive to benzene (0.3% MN-PCE) compared to WT mice (3.5% MN-PCE, $p<0.01$). p21 mRNA gene expression measured by quantitative RT-PCR in bone marrow was used as a genotoxic biomarker of the p53 DNA damage response pathway. WT and NQO1-/- mice had a >7-fold increase at the 100 ppm dose over unexposed controls in p21 expression in response to benzene compared to a 1.4-fold in mEH-/- mice. p21 induction in WT and NQO1-/- mice suggests the p53 pathway is activated. These preliminary results suggest that NQO1 deficiency does not lead to increased benzene-induced genotoxicity and that mEH deficiency results in protection against benzene-induced genotoxicity.

350 INDUCTION OF MICRONUCLEI BY PHENOL IN MOUSE BONE MARROW IS ASSOCIATED WITH TREATMENT-INDUCED HYPOTHERMIA.

P. J. Spencer[1], T. A. Hammond[1], J. M. Waechter[1], R. Gingell[2], S. S. Dimond[3], B. J. Dunn[4] and J. H. Butala[5]. *[1]Toxicology & Environmental Research and Consulting, The Dow Chemcial Company, Midland, MI, [2]Shell Chemical Company, Houston, TX, [3]GE Plastics, Pittsfield, MA, [4]Honeywell, Morristown, NJ and [5]Consultant to Sunoco, Pittsburgh, PA.*

Asanami and coworkers have reported an association between hypothermia and micronuclei (MN) formation in mice (Mutat. Res. 413, 1997). Since previous studies have shown weak positive responses in the mouse micronucleus test (MNT) following intraperitoneal (i.p.) doses of phenol at or near the LD50, the current study evaluated the capability of phenol to cause hypothermia in mice and the association of MN formation and phenol-induced hypothermia. CD1 mice received a single i.p. dose of a vehicle control or phenol ranging from 0–500 mg/kg. Body temperatures (BT) of all mice were monitored at baseline and at multiple times post-dosing using subcutaneous digital transponders. Phenol at 300 mg/kg caused a significant and prolonged hypothermia in mice (up to 7°C drop in BT). BT were not significantly altered at doses below 300 mg/kg, while lowered BT and marked lethality occurred at 400 & 500 mg/kg. In the MNT, male and female CD1 mice (0, 30, 100 or 300 mg/kg phenol, single dose, i.p.) and a positive control group (cyclophosphamide (CP), 120 mg/kg p.o.) were evaluated for MN formation at 24 & 48 hr. BT were monitored in phenol-treated animals as described above. Treatment with CP induced a significant increase in MN formation. Phenol at 300 mg/kg induced a significant and prolonged hypothermia in both male and female mice as well as increases in the MN formation in bone marrow harvested at either 24 or 48 hours post-dosing. Data available to date indicate that neither BT nor MN values were affected at the lower doses of phenol in male mice. It thus appears that the induction of MN by phenol is a threshold phenomenon and the induction of MN at the maximum tolerated doses may be causally related to the induction of hypothermia. Sponsored by the American Chemistry Council's Phenol Panel, Arlington, VA.

351 CHARACTERIZING MUTATIONS INDUCED BY BENZIDINE AND BENZIDINE-RELATED COMPOUNDS USING BASE-SPECIFIC SALMONELLA TESTER STRAINS AND REDUCTIVE METABOLISM.

L. D. Claxton[1], T. J. Hughes[1] and K. T. Chung[2]. *[1]Environmental Carcinogenesis Division, USEPA, Research Triangle Park, NC and [2]Biology Department, University of Memphis, Memphis, TN.*

Benzidine (Bz), 4-aminobiphenyl (ABP), 3, 3'-dichlorobenzidine HCl (DCBz), 3, 3'-dimethylbenzidine (DMBz), 3, 3'-dimethoxybenzidine (DMOBz) and the benzidine congener-based dye trypan blue (TB) produce primarily frameshift mutations in Salmonella typhimurium. However, the base-substitution strain TA100 also responds to these compounds when S9 is present. DNA sequence analysis by other investigators shows that ABP induces frameshift, base-pair, and complex mutations. Also, an uninduced hamster liver S9 preparation with glucose-6-phosphate dehydrogenase, FMN, NADH and 4 times glucose 6-phosphate gives a stronger mutagenic response than the conventional plate incorporation with a rat S9 activation mixture for all the compounds tested. Using the base-specific tester strains of S. typhimurium (TA7001 - TA7006) with the above reductive metabolic activation system, we surveyed these compounds for the ability to produce specific base-pair substitutions after reductive metabolism. Bz was weakly mutagenic in TA7005 (0.04 revertants/μg). ABP was mutagenic in TA7002 (1.4 revertants/μg), TA7004 (0.6 revertants/μg), TA7005 (2.98 revertants/μg), and TA7006 (0.4 revertants/μg). DCBz was weakly mutagenic in TA7004 (0.01 revertants/μg). It was concluded that benzidine induced some CG–>AT transversions in addition to frameshift mutations. ABP induced TA–>AT, CG–>AT, and CG–>GC transversions as well as GC–>AT transitions. DCBz induced only GC–>AT transitions. Because DMBz, DMOBz and TB were not mutagenic in this base-substitution mutagen detection system, their mutagenic activity was attributed strictly to frameshift mechanisms. This is an abstract of a proposed presentation and does not necessarily represent the views of the USEPA.

352 EVALUATION OF THE GENOTOXIC POTENTIAL OF POLYVINYL ALCOHOL IN A SHORT-TERM BATTERY OF TESTS.

C. C. DeMerlis[1], K. Adams[2] and C. M. Kelly[3]. *[1]Colorcon, West Point, PA, [2]Huntingdon Research Centre, Cambridge, United Kingdom and [3]Huntingdon Life Sciences, East Millstone, NJ.*

Polyvinyl Alcohol (PVA) is a water soluble synthetic polymer prepared from the polymerization of vinyl acetate and the subsequent hydrolysis of polyvinyl acetate. PVA is used as a polymer for film coating pharmaceutical and dietary supplement

tablets where moisture barrier/protection properties are required. A special grade of PVA was used for these studies that is produced to meet global pharmaceutical standards using appropriate good manufacturing practices (GMP's). The PVA grade is characterized by both compendial and proprietary specifications. The impurities are strictly monitored by process controls, stringent specifications and analytical methods developed by the manufacturer. PVA was tested in a battery of short-term genotoxicity assays. A bacterial reverse mutation assay was conducted using S. typhimurium strains TA98, TA100, TA1535, TA1537 and E.coli strain WP2 uvrA in the presence and absence of Arochlor-induced rat liver S9. PVA, when tested in water up to 5000 µg/plate, showed no evidence of mutagenicity in these assays. An *in vitro* mammalian cell mutation assay based on detection and quantitation of a forward mutation in a subline of mouse lymphoma L51789Y cells at the thymidine kinase locus was conducted. PVA did not demonstrate mutagenic potential in this assay at concentrations up to 5000 µg/mL. In a bone marrow micronucleus test for cytogenetic damage using male and female mice, PVA was administered orally by intragastric gavage at doses of 500, 1000 and 2000 mg/kg/day. PVA did not show any evidence of causing chromosome damage or bone marrow toxicity at doses up to 2000 mg/kg/day. Results from these studies indicate that PVA was devoid of any genotoxic potential based on a standard genotoxicity testing battery.

353 INDUCTION OF DNA DAMAGE AND REPAIR BY THE MYCOTOXIN OCHRATOXIN A IN DIFFERENT CELL TYPES.

S. Lebrun and W. Foellmann. *In Vitro Toxicology, Institute for Occupational Health, Dortmund, Germany.* Sponsor: K. Golka.

In domestic and laboratory animals the mycotoxin Ochratoxin A (OTA) is nephrotoxic, immunosuppressive, and carcinogenic. Additionally, it is suspected to be responsible for urinary tract tumours in patients suffer from Balkan Endemic Nephropathy. In this study the induction of DNA damage by OTA and the subsequent DNA repair was investigated with the Comet Assay. Several cell types with different metabolic competence were used: primary cultured porcine urinary bladder epithelial cells (PUBEC), Madin-Darby canine kidney cells (MDCK), and the human urothelial cell line 5637. The experimental protocol was varied using different incubation times for OTA in the presence and absence of an external metabolizing system (S9) and by using inhibitors of DNA repair (cytosine arabinose araC, and hydroxyurea HU). In MDCK and 5637 cells OTA induced single strand breaks (ssb) in a concentration dependent manner, while PUBEC cells showed weaker effects. When S9-mix was added, the genotoxic effect was significantly stronger in all cells. When DNA repair was inhibited the tail length increased dramatically and all treated cells showed ssb. A further culture of the damaged cells in the absence of any supplement resulted in a complete repair of the DNA within two hours. These results demonstrate that OTA induce ssb *in vitro* and that the damaged DNA can be repaired more effectively in PUBECs compared to cells of celllines (MDCK, 5637).

354 GENOTOXIC EFFECTS OF SOY ISOFLAVONES AND TWO MAJOR OXIDATIVE METABOLITIES.

S. E. Kulling[1], C. E. Ruefer[2], A. Hartwig[2] and M. Metzler[2]. *[1]Institute of Nutritional Physiology, Federal Research Center for Nutrition, Karlsruhe, Germany and [2]Institute of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany.*

The isoflavonoid phytoestrogens daidzein (DAI), genistein (GEN) and glycitein (GLY) are major dietary components of soybeans. There is a growing scientific interest in phytoestrogens due to their potential beneficial properties for human health. Isoflavonoid intake seems to be inversely associated with the incidence of hormone-dependent diseases, e.g. breast cancer. Recently, the oxidative metabolism of DAI and GEN was investigated in our Lab.. Both isoflavones are converted by cytochrome P450 enzymes to several catechol metabolites, e.g. 6, 7, 4'- and 7, 3', 4'-trihydroxyisoflavone (6, 7, 4'-IF, 7, 3', 4'-IF), which may represent a metabolic activation process. Using the comet assay, we have investigated the potential of these compounds which may cause DNA damage. The extent of DNA strand breaks (SB) and oxidative DNA modifications (recognized by the purified bacterial repair enzyme formamidopyrimidine-DNA glycosylase, Fpg) was assessed in HeLa-S3 cells. As expected from results of the literature DAI does not cause any DNA damage in contrast to GEN, which leads to high amounts of SB. GLY induces a small number of SB. 6, 7, 4'-IF and 7, 3', 4'-IF cause small amounts of SB with a maximum after 2 h incubation time (as GEN and GLY) and high amounts of Fpg-sensitive sites at the end of incubation (24 h). The DNA-damaging potential of GEN is probably associated - as described in the literature - with the inhibition of topoisomerase II. 6, 7, 4'-IF and 7, 3', 4'-IF cause oxidative DNA damage and SB probably by generating reactive oxygen species *via* "redox cycling" and forming DNA adducts, respectively. Supported by Deutsche Forschungsgemeinschaft (Grant Ku 1079/5-1).

355 GENETIC TOXICOLOGY PROFILE OF INACTINE PEN110.

J. Chapman[1] and B. E. Butterworth[2]. *[1]V.I. Technologies, Inc., Watertown, MA and [2]Butterworth Consulting, Raleigh, NC.*

The V. I. Technologies process for the purification of blood involves removal of lymphocytes followed by inactivation of viruses, bacteria, protozoa and residual lymphocytes with the compound PEN110. PEN110 achieves pathogen inactivation by modification of nucleic acid bases to disrupt replication of the genome by polymerase enzymes. During incubation of red blood cells, PEN110 has the ability to inactivate free, cell associated, and integrated HIV. Red blood cells are then extensively washed to remove PEN110 and plasma proteins. The genetic toxicology profile studies presented here are a key segment of the work to assure that exposures to any residual PEN110 will be without adverse effects. PEN110 is positive without metabolic activation in the rat hepatocyte *in vitro* unscheduled DNA synthesis (UDS) assay, in Ames base pair substitution strains TA1535 and TA100, and in the mouse lymphoma assay. The spectrum of genotoxic activity of PEN110 is, however, narrow, apparently producing only base pair mutations and showing no activity in chromosomal assays or the whole animal. PEN110 was negative in the *in vivo-in vitro* UDS assay, in the Ames frame shift strains TA98, TA1537 and WP2uvrA, in the chromosomal aberration assay in CHO cells, and in inducing chromosomal aberrations in freshly drawn human blood peripheral lymphocytes. No response was seen in the *in vivo-in vitro* UDS assay by i.v. administration at a dose giving an initial nominal blood concentration of over 250 times that which had been demonstrated to respond in culture. This indicates the presence of a rapid, effective detoxification pathway that clears PEN110 before it can modify the liver DNA. PEN110 was negative in the *in vivo-in vitro* UDS assay at a dose approximately 12, 000 fold over the anticipated human dose following a 1 unit transfusion. These quantitative genetic toxicology studies indicate that the trace amount of residual PEN110 in purified blood products represents an insignificant risk to the patient.

356 THE INDUCTION OF FRAMESHIFT AND BASE-SUBSTITUTION MUTATIONS BY EPIRUBICIN AND IDARUBICIN IN *SALMONELLA TYPHIMURIUM*.

W. J. Mackay and J. Brumfield. *Biology and Health Services, Edinboro University, Edinboro, PA.* Sponsor: W. Mackay.

Clinical use of the natural anthracyclines (daunomycin and adriamycin) in chemotherapy has been limited due to cardiotoxicity and acute myleosuppression. Epirubicin and idarubicin are two recently developed anthracyclines that are used in cancer treatments. In spite of intensive investigations, the events leading to cell death and differential cytotoxicity in the presence of these antineoplastic compounds are not totally understood. A great many short-term tests have been developed that allow compounds to be screened for potential gentotoxicity. The first such assay to be optimized for convenience and sensitivity is called the *Salmonella* Mutagenicity Test. Previous studies have shown that daunomycin and adriamycin can induce frameshift and base-substitution transition mutations in prokaryotic and eukaryotic cells. While daunomycin can induce GC to AT and AT to GC events, adriamycin induces only GC to AT mutations. In this study, we show that both epirubicin and idarubicin can also induce frameshift (approximately 15 to 20 fold) and base-substitution transition mutations (approximately 3 to 8 fold) in *Salmonella*. Thus, it appears that these two compounds, like daunomycin and adriamycin, can induce a wide array of mutational events in the cell.

357 THE POTENTIAL GENOTOXICITY OF BRIVUDIN.

J. Brightwell. *Research Toxicology Centre, Pomezia, Italy.*

Brivudin [(E)-5-(2-Bromovinyl)-2'-deoxyuridine, BVDU] is a nucleoside analogue with selective activity against varicella zoster virus (VZV) and herpes simplex virus type 1 (HSV-1). It has recently received marketing approval in Germany for the early treatment of VZV infections. Brivudin is selectively phosphorylated to the mono- and diphosphate by viral enzymes. This leads to accumulation of brivudin within virus infected cells. The diphosphate is further phosphorylated to the triphosphate by cellular enzymes. The triphosphate interacts with viral DNA-polymerase acting either as a substrate for or an inhibitor of the enzyme. Although no brivudin incorporation into non-virus infected cells has been detected, the mechanism of anti-viral action does suggest scope for some mutagenic or clastogenic potential. A comprehensive battery of *in vitro* and *in vivo* genotoxicity studies has been performed. Data are presented from the following *in vitro* assays: a *Salmonella typhimurium* reverse mutation (Ames) test; an HGPRT test in CHO cells; two chromosome aberration studies in human lymphocytes and an unscheduled DNA synthesis (UDS) study. Brivudin was consistently negative for gene mutation and did not induce UDS. Clear increases in the frequency of chromosome aberrations were seen in human lymphocytes after 44 hours of continuous treatment in the absence of metabolic activation only. Data are also presented from the following *in*

vivo assays: a UDS assay in the rat (this also included assessment of replicative DNA synthesis); two micronucleus studies in mice and a spot test in mice. These assays were all negative for genotoxicity, although a treatment related increase was seen in replicative DNA synthesis. The data indicate that brivudin has no potential for mutagenic activity. The increase in chromosome aberrations is concluded to be of no biological significance for the human safety assessment of brivudin. In addition, the data support the argument that a non-genotoxic mechanism is responsible for the reported induction of liver tumours in rats, following oral administration of brivudin for 1 year (Semler, *et al*, 1987. *J Am Col Toxicol* **6**, 557).

358 DEVELOPMENT OF INDICATOR CELLS FOR DETECTION OF GENOTOXIC COMPOUNDS: EXPLOITATION OF THE CELLULAR p53 RESPONSE.

P. J. Duerksen-Hughes and M. Filippova. *Biochemistry and Microbiology, Loma Linda University, Loma Linda, CA.*

Our laboratory has previously developed a mammalian, *in vitro* assay for genotoxins based on the ability of cells to increase their level of p53 in response to DNA damage. Cultured cells are treated with the test substance, and at defined times following treatment, are harvested and lysed. The lysates are then analyzed for p53 by ELISA. An increase in cellular p53 following treatment is interpreted as evidence for DNA damage, and a lack of such an increase is interpreted as evidence of no significant DNA damage. To determine whether this system would work in cultured human cell lines, as well as in mouse lines, we tested several human cell lines known to express wild-type p53 for their ability to increase their p53 levels following DNA damage. Five such cell lines, U87, WI38, ZR 75-1, MCF-7 and U2OS were identified. To increase the speed and economy of this assay and to improve its ability to function in a high throughput application, we then developed indicator cells that can identify DNA damage without the need for cell lysis. Plasmids coding for the p53-responsive element fused to the gene coding for the reporter protein secreted alkaline phosphatase (SEAP) were stably transfected into human U2OS cells. Several individual clones were then isolated and characterized. When treated with the genotoxin mitomycin C, these cells increased both their intracellular level of p53 and the level of SEAP by several-fold, confirming their usefulness as indicator cells.

359 THE EVALUATION OF AGE-DEPENDENT DNA DAMAGE IN RATS BY A COMET ASSAY.

K. Hashimoto, A. Hyogo, T. Hagiwara and S. Manabe. *Medicinal Safety Research Labs., Sankyo Co., Ltd., Fukuroi, Japan.*

Various environmental factors can be a cause of DNA damage, and accordingly it is conceivable the damage is accumulated with age particularly in the organs exerting high function in the body, i.e. the liver and kidney. This study examined the correlation between aging and DNA damage in the rat kidney. In addition, the vulnerability of DNA to a chemical carcinogen in the kidney was compared between young and aged rats. The detection of DNA damage was conducted with a comet assay (single cell gel electrophoresis). Male F344 rats at 9 weeks and 9 months old were treated with a vehicle (0.5% carboxymethylcellulose sodium: CMC) or chemical carcinogen (methyl methanesulfonate: MMS at 80 mg/kg). Three hours after dosing, the kidney was homogenized to make cell suspension and specimens were prepared. The specimens were electrophoresed under alkaline conditions for lysing and unwinding DNA and then stained with ethidium bromide. Fifty nuclei from one specimen per animal were observed under a fluorescence microscope to measure DNA migration as an index of DNA damage. The average values of DNA migration were statistically compared. In the vehicle control groups, DNA migration in the 9-month-old rats was 16.73 ± 1.80 μm which was statistically greater than the DNA migration (7.56 ± 0.74 μm) in the 9-week-old rats. In the MMS-treated groups, DNA migration in the 9-week-old rats was 29.46 ± 3.28 μm, whereas DNA migration in 9-month-old rats could not be determined due to severe DNA damage. The comet image in the MMS-treated group at 9 months old was similar to a typical image of apoptosis. The present study suggests that spontaneous DNA damage and vulnerability of DNA to a chemical carcinogen in the rat kidney increase with age. The higher vulnerability in the 9-month-old rats may be attributable to an age-dependent increase in accumulated oxidative damage of DNA.

360 MUTATGENICITY EVALUATION OF BIOPHARMACEUTICALS USING AN AMES-MODIFIED METHOD BY DENATURING HIGH PERFORMANCE LIQUID CHROMATOGRAPHY (DHPLC) (WAVE).

L. R. Wing, J. A. Adams and C. D'Silva. *Biopharmaceuticals, Transgenomic, Inc., San Diego, CA.*

The Ames Test evaluates the mutagenic potential of test chemicals by analyzing their effect on histidine (his) requiring strains of Salmonella typhimurium. Salmonella strain TA102, which causes a base substitution mutation, has its his gene located on a multicopy plasmid, pAQ1. After strain TA102 was exposed to the oxidative mutagen, ethylene oxide, pAQ1 was isolated (Miniprep kit, Quiagen) and the his gene was extracted from the plasmid by restriction digest(Stratagene). The restriction fragments containing the his gene were analyzed by denaturing HPLC (Transgenomic WAVE system), and mutations were detected based on the ability to visualize the formation of heteroduplexes. When a sample contains one uniform sequence of dsDNA, a single molecule is formed as the two complementary strands anneal (homoduplex). However, a sample containing two dsDNA molecules that differ by as little as a single nucleotide, can result in the formation of two homoduplexes and two heteroduplexes. Denaturing HPLC separates these molecules with the heteroduplexes eluting first. If both samples are identical in sequence, no heteroduplex will form and only one peak will be detected. Analysis of the digests of the pAQ1 plasmid by electrophoresis indicated that after 1h, 37oC, the 322bp fragment could be detected. Samples from each of the mutants were mixed with the wild type at a ratio of 1:1 and incubated at 95oC for 4 min followed by a cooling period at 25oC for 45 min. The fragments were subjected to a temperature titration (50-62oC) and were analyzed on the WAVE system. The wild-type fragments (homoduplexes) as well as the mutant fragments (heteroduplexes) were detected. Both the hetero-and homoduplexes eluted at the predicted time based on the method for mutation detection using the WAVE software. These modified Ames assay can be used to detect mutagens using a high throughput, accurate and inexpensive procedure. Evaluation of other Salmonella strains, genomic DNA and PCR products are studies which are currently in progress.

361 COMPARISON OF THE REGULATORY AMES TEST WITH THE SOS/UMU ASSAY AS PART OF LEAD OPTIMISATION SCREENING.

J. Kitching, M. G. Wing, G. Clare, K. May and C. K. Atterwill. *Experimental Biology, Huntingdon Life Sciences, Huntingdon, United Kingdom.*

Regulatory genetic toxicology produces 20-25% *in vitro* positive results per year. We compared the SOS-umu assay as a mutagenicity screen with the corresponding Ames result. The umu assay uses S.typhimurium strain TA1535/pSK1002 in which lac-Z is under the control of the SOS repair genes. Compounds were tested up to 1 mg/ml (approximately equal to the maximum dose in the Ames test, 5 mg/plate). The Ames test was performed using standard regulatory methods with S.typhimurium strains TA1535, TA1537, TA98 and TA100 and E.coli strain CM891. A number of mutagens (Aflatoxin B1, 4-nitroquinoline oxide, methyl methane sulphonate, 2-aminoantharcene, nitrofurantoin, BENZO(A)PYRENE, methyl nitro-nitrosoguanidine, daunamycin, 2-aminofluorene, 9-aminoacridine, 2-nitrofluorene and sodium azide) were tested along with non-mutagenic toxic compounds (DMSO, ampicillin, tetracycline, amphotericin B, pen/strep and gentamycin), together with 12 proprietary compounds concluded as regulatory Ames mutagens. All were tested in the presence and absence of rat liver S9 mix. The data correlated well with the Ames test, with all 12 of the classic mutagens tested were detected and no false positives found. Of the 12 proprietary compounds the umu assay detected 9. Those that were not detected were weakly positive in the Ames test and two of them in CM891 which will detect certain types of mutation that do not induce the SOS repair pathway. On the whole the umu ranking correlated well with that for the Ames test. However, one anomaly was a proprietary compound that was weakly positive in the Ames test with CM891 but strongly positive in the umu assay. There did not appear to be any difference in sensitivity of the umu assay between frameshift and base pair substitution mutations. It is concluded that it is possible screen out the majority of genotoxins at a very early stage in development. This will give vital information, which if integrated with data from other lead optimisation screens will improve the process of lead candidate selection.

362 AUTOMATION AND VALIDATION OF THE YEAST DEL ASSAY THAT DETECTS CARCINOGENS.

R. H. Schiestl[1] and R. J. Brennan[2]. [1]*Pathology and Environmental Health, UCLA, Los Angeles, CA and* [2]*OSI Pharmaceuticals, Uniondale, NY.*

DEL assays in yeast, human cells and *in vivo* in mice quantify potentially carcinogenic DNA deletion events and detect a wide variety of carcinogens, many of which are negative in other short-term genotoxicity tests. The yeast DEL assay also differentiates correctly between carcinogen / non-carcinogen structural analogs. Of 62 chemicals of known carcinogenicity tested, the yeast DEL assay correctly identified 85%. In comparison, the widely used Salmonella reverse mutation assay correctly classified only 33%. The yeast DEL assay is under development as an automated robotic screen. We have adapted the assay to a liquid, microtiter plate format using optical density growth detection. Pilot studies, focused on the parameters of cell density and growth kinetics in microtiter plates showed the feasibility of such a format. Refinement and further development allowed the detection of two-fold differences in DEL frequency, and dose-dependent effects of carcinogens on deletion frequency are detected. Protocols for running the screen using readily available

robotics and instrumentation have been developed and pilot automated screens with small numbers of positive and negative controls have shown promising results. We are validating the automated assay with a set of coded chemicals of known carcinogenic activity. Automated, higher throughput and highly predictive genotoxicity screens like the DEL assay will assist in the identification of undesirable compound characteristics earlier in the drug discovery process, improving pharmaceutical companies' ability to make fast, scientifically-based decisions on early drug leads. More widespread adoption of validated yeast or mammalian cell DEL assays may reduce the number of animals used in carcinogenicity testing of novel pharmaceuticals, and its high predictive value may reduce the failure rate of promising drug candidates due to unanticipated carcinogenic potential.

363 CONSTRUCTION OF CHINESE HAMSTER OVARY CELL LINES EXPRESSING SINGLE COPY OF HUMAN N-ACETYLTRANSFERASE 2.

S. Zhao, M. A. Doll, J. C. States, Y. Zang and D. W. Hein. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Acetylation is important in the bioactivation and deactivation of aromatic and heterocyclic amine carcinogens in the diet, cigarette smoke, and the environment. These acetylation reactions are catalyzed by N-acetyltransferase-1 (NAT1) and N-acetyltransferase-2 (NAT2) that exhibit a genetic polymorphism in humans. We constructed a Chinese hamster ovary (CHO) cell system possessing human NAT2 to investigate the role of this enzyme polymorphism on aromatic and heterocyclic amine genotoxicity. Since the level of gene expression in the stable mammalian cell lines may vary due to the unpredictable integrity and chromosomal integration site of transferred cDNA and/or copy number of the cDNA, it is critical to control for these variables. Since the Flp-In expression system (Invitrogen) allows integration and expression at a specific genomic location, we selected it to express NAT2 into CHO cells. pcDNA5/FRT containing human *NAT2*4* was co-transfected with pOG44 plasmid into Flp-In-CHO cells containing an integrated Flp recombination target (FRT) site. Cells were selected for Hygromycin B resistance. Integration of the pcDNA5/FRT construct into the FRT site was tested by polymerase chain reaction (PCR) using forward and reverse primers specific for *NAT2*4* and *lacz* gene, respectively. The possibility of pcDNA5/FRT construct integration into a second genomic site was excluded by the observation of the absence of PCR product using forward and reverse primers specific for *NAT2*4* and *Hygromycin* gene. Cells that were Hygromycin-resistant with *NAT2*4* integrated into the FRT site exhibited measurable sulfamethazine NAT2 activity whereas untransfected Flp-In CHO cells did not. Integration and expression of a single copy of *NAT2*4* in CHO cells makes this Flp-In system useful for functional comparison of genetic variants of human NAT1 and NAT2 alleles. Partially supported by USPHS grant CA-34627 from the National Cancer Institute.

364 FLOW CYTOMETRIC ANALYSIS OF MICRONUCLEUS FORMATION IN RAT PERIPHERAL BLOOD: INTEGRATION WITH SUBCHRONIC DOSING STUDIES TO REDUCE ANIMAL USAGE.

D. K. Torous, S. D. Dertinger, N. E. Hall and C. R. Tometsko. *Litron Laboratories, Rochester, NY.*

Incorporating genotoxicity endpoint(s) into subchronic toxicology studies can potentially reduce animal usage. Recent data suggests that rat peripheral blood may be a sensitive compartment for highlighting chemical-induced cytogenetic damage expressed as micronuclei (MN). Many of these experiments have utilized conventional microscopy-based inspection to score MN events. An experiment was conducted to evaluate whether a method for scoring MN by high-speed flow cytometry (FCM) provides information of equal utility as that achieved by microscopy. This FCM method utilizes an immunochemical reagent (anti-CD71-FITC), RNase, and propidium iodide to differentially stain four cell populations: normochromatic erythrocytes, normochromatic erythrocytes with MN, reticulocytes and reticulocytes with MN (commercially available as MicroFlow®PLUS). For this experiment, rats were treated with vehicle (saline) or a range of methyl methanesulfonate (MMS) concentrations 5 days per week for 4 weeks. Blood samples were drawn initially on Day 0 and then on Days 2, 3, 4, 11, 18 and 25. MN frequencies were determined by analyzing 20, 000 young reticulocytes per blood sample. Instrumentation and calibration procedures utilizing rat bone marrow and a biological model were employed, and are described. Vehicle treatment showed no change in MN-RET frequency over the experimental timeframe, irrespective of scoring methodology. For MMS treated animals, the MN-RET frequency increased in a time and dose-dependent manner. While the average MN-RET values were similar for both scoring procedures, less variation was evident with the FCM-based measurements. Note that the FCM-based data acquisition was achieved in a fraction of the time (1/10) of the microscopy-based measurements.

365 FLOW CYTOMETRIC SYSTEM FOR SCORING MICRONUCLEATED RETICULOCYTES IN HUMAN BLOOD SAMPLES.

S. D. Dertinger, D. K. Torous, N. E. Hall, F. G. Murante, S. E. Gleason and C. R. Tometsko. *Litron Laboratories, Rochester, NY.*

Micronucleated reticulocytes (MN-RET) in the peripheral blood circulation of humans may represent a valuable endpoint of cytogenetic damage. However, the human spleen is capable of sequestering and removing micronucleus-containing erythrocytes from peripheral blood circulation. Consequently, the rarity of MN-RET has made it difficult to score these events, or to effectively evaluate the sensitivity of the endpoint. Here, we describe a single-laser flow cytometric system for enumerating the incidence of micronuclei in the youngest subset of reticulocytes. The procedure is based on an immunochemical reagent specific for the transferrin receptor (CD71). When fixed cells are treated with phycoerythrin-conjugated anti-CD71, RNase, and SYTOX Green dye, the fluorescent resolution of four erythrocyte populations is achieved (i.e., young reticulocytes and mature erythrocytes, with and without micronuclei). In addition to these minimal staining requirements, the system benefits from one additional immunochemical reagent, anti-glycophorin A-CyChrome. Anti-glycophorin A labeling of erythroid cells helps ensure that debris does not adversely impact the analysis. Instrument calibration procedures utilizing malaria-infected rodent erythrocytes have also been developed, and are described here. With this system, blood samples from ten healthy non-splenectomized human volunteers were analyzed for micronucleus frequencies with a single-laser flow cytometer. Additionally, blood from three healthy splenectomized volunteers was also evaluated. The resulting data suggest that micronuclei can be quantified in the most immature fraction of human reticulocytes with a single-laser flow cytometer. This high throughput system is potentially important for evaluating the value of the MN-RET endpoint in human populations.

366 ENZYMATIC ACTIVITIES OF WERNER SYNDROME PROTEIN ON A TELOMERE TYPE SUBSTRATE.

S. Theodore and D. K. Orren. *Graduate Center For Toxicology, University Of Kentucky, Lexington, KY.* Sponsor: M. Vore.

Werner Syndrome (WS) is a hereditary disorder that is characterized by early onset of aging symptoms and increased frequency of age-related diseases including cancer and atherosclerosis. WS is caused by mutations in a gene that codes for the Werner protein (WRN) that contains both DNA unwinding (helicase) and exonuclease activities suggesting a role in DNA metabolism. WRN belongs to the RecQ family of helicases that are involved in maintaining genomic stability. Consequently, defects in WRN lead to increased genomic instability characterized by chromosomal deletions, insertions, translocations and the accelerated loss of telomeres, the protective repeating sequences at the ends of chromosomes. In this context, WS serves as a good model for examining the relationship between accumulation of genetic changes induced by endogeneous and environmental agents during lifetime and the degenerative processes that occur during normal aging. In most normal somatic cells, telomeres shorten with each round of cell division, eventually leading to cessation of cell division known as cellular senescence. In WS cells, telomeres shorten at a much faster rate, leading to premature cellular senescence and suggesting a possible role for WRN in telomere length maintenance. Recent studies indicate that each chromosome forms a specialized structure known as T loop in which the 3'single-stranded telomeric end is inserted back into the double-stranded telomeric region. We have constructed model DNA substrates that mimic the T loop structure of telomeres and have carried out experiments to study the activities of WRN on these substrates. DNase I footprinting indicates that WRN binds specifically to the T loop structure. This binding appears to mediate disruption of the T loop structure by WRN helicase activity. In addition, WRN has a very efficient exonuclease activity on the 3' end of our T loop substrate. Our findings suggest a potential role for WRN in processing T loop structures during telomere metabolism.

367 GENOMIC INSTABILITY OF PUN GENE IN MOUSE ENBRYONIC CELLS WITH N-ETHYL-N-NITROSOUREA.

T. Shibuya, T. Morimura, S. Suzuki, H. Matsumoto, W. Endo, H. Sui, T. Hara and H. Ono. *Hatano Research Institute, FDSC, Hadano, Japan.*

Genomic instabilty (GI) by various chemical substances are regarded to play important roles in toxicology such as carcinogenesis, teratogenesis and germ cell mutagenesis. Therefore, detection of GI *in vivo* mammals is very important to evaluate the toxicity of chemical substances to human health. We recently adapted Pun mice to detect GI of the pun gene in embryonic somatic and germ cells. The embryonic mouse cell systems observed in this study were melanocytes (MLC) for somatic cells and primordial germ cells (PGC) for germ cells. The experimental systems used were mouse spot test and mouse specific locus test on P gene. We observed recessive mutations (RM) of P gene and intragenic recombinations (IGR) of pun gene. The

pun gene is composed of duplicated exons of P gene and it is easily reverted to wild type P gene through IGR. Homozygous pun males and heterozygous pun/P female were mated and transplacentally treated to N-ethyl-N-nitrosourea (ENU) at day 10.5 of development. The spontaneous frequencies of RM on P gene and IGR on pun gene in embryonic somatic cells are relatively high but they are very low in germ cells. ENU induced IGR and RM with high frequency in embryonic somatic cells and the frequency of IGR is much higher than that of RM. The male mice (Fo) obtained were mated with non-treated homozygous pun females and obtained the next generation (F1) to detect IGR in PGC with ENU. In F1 mice, IGR in PGC are observed with extraordinary high frequency with dose-dependency and mosaic mice were obtained. But the frequencies of IGR in MLC of F1 mice were decreased to the control level. These results demonstrate that delayed mutagenesis is occurred in the embryonic germ cell line of the mouse pun genes with ENU.

368 THE EFFECT OF DIFFERENT DNA DAMAGING AGENTS ON P53 AND MDM2 PROTEINS IN CANCER CELL LINES AND MOUSE SKIN.

L. Laatio[1], R. Serpi[1], U. Puistola[2] and K. H. Vahakangas[1,3]. *[1]Department of Pharmacology and Toxicology, University of Oulu, Oulu, Finland, [2]Department of Obstetrics and Gynecology, University Hospital of Oulu, Oulu, Finland and [3]Department of Pharmacology and Toxicology, University of Kuopio, Kuopio, Finland.* Sponsor: K. Savolainen.

The product of p53 gene is a transcription factor for several known cell cycle regulation-linked genes. Wild type p53 protein is increased, probably by stabilization, in response to various cellular stress signals, e.g. chemically induced DNA damage. The increase of p53 is thought to be a consequence of disrupted binding of p53 to Mdm2, which is mainly responsible for the degradation of p53. The aim of this study was to find out whether Mdm2 is the cause of p53 increase after treatment with different DNA damaging agents. We used MCF-7 breast adenocarcinoma and A-549 lung carcinoma cells and an *in vivo* C57BL/6 mouse skin model to study the effects of benzo(a)pyrene, cisplatin, docetaxel and azidothymidine (AZT) on p53 and Mdm2 proteins. The amount of p53 and Mdm2 proteins were studied by Western blotting using antibodies DO7 and CM5 for p53 (human and mouse, respectively) and H-221 for Mdm2 (both human and mouse). p53 was induced by benzo(a)pyrene in both cell lines and in mouse skin. Cisplatin also induced p53 in both cell lines, while docetaxel was studied only in MCF-7 cells, and was found to induce p53. Mdm2 was generally increased along with p53. AZT, however, had no clear effect on p53 or Mdm2 in either cell lines. In conclusion, because p53 was induced by three different DNA damaging agents in these models, but not with AZT, AZT probably did not cause DNA damage, although evidence of the carcinogenicity of AZT have been presented. Increase of Mdm2 indicates that the induced p53 is in functional form and that changes of Mdm2 are not the reason for p53 induction.

369 TRP-P-1 AND TRP-P-2 MODULATE THE ACTIVITY OF POLY(ADP-RIBOSE) SYNTHETASE *IN VITRO.*

K. Ueda[1], M. Banasik[1,2], T. Stedeford[1] and D. J. Price[3]. *[1]Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan, [2]Institute of Environmental Engineering, Polish Academy of Sciences, Zabrze, Poland and [3]Dept. of Environmental Management, Pinellas County Air Quality Planning and Analysis, Clearwater, FL.*

Heterocyclic amines (HAs) are produced by pyrolysis of amino acids or proteins in fried, broiled, or grilled meats. These compounds are potent mutagens that increase rates of colon, mammary, and prostate tumours in rodent bioassays. The carcinogenic effect of these compounds is elicited from metabolic activation by the cytochrome P450 enzyme system to reactive metabolite(s). Interestingly, the P450 catalytic cycle has the absolute requirement *in vivo* of NAD(P)H. Here we report the effects of six groups of HAs on the activity of poly(ADP-ribose) synthetase (PARS), an enzyme implicated in several important biological processes, such as DNA repair, apoptosis, or necrosis. PARS activation results in an immediate decrease in available NAD+ and may limit the activity of enzymes requiring this cofactor. Our results show that 3-amino-1, 4-dimethyl-5H-pyrido[4, 3-b]indole (Trp-P-1) causes a 91% and 94% decrease at 1 and 5 mM, respectively (IC50 = 0.22 mM). In contrast, 3-amino-1-methyl-5H-pyrido[4, 3-b]indole (Trp-P-2) at 1 mM causes a 134% increase in PARS activity *versus* a 93% decrease in the activity at 5 mM (IC50 = 2.2 mM). In all other compounds tested, only an inhibitory effect was observed. The biological significance of these findings remains to be studied; however, it is possible that by inhibiting PARS, the available pool of NADH/NAD+ allows for increased activation of these compounds to toxic metabolites. (Supported by the Japan Society for the Promotion of Science)

370 THE EFFECT OF ETHANOL, METHANOL, AND DIMETHYL SULFOXIDE ON POLY(ADP-RIBOSE) SYNTHETASE ACTIVITY.

M. Banasik[1,2], T. Stedeford[1], A. S. Persad[3] and K. Ueda[1]. *[1]Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan, [2]Institute of Environmental Engineering, Polish Academy of Sciences, Zabrze, Poland and [3]Dept. of Epidemiology and Biostatistics, University of South Florida, Tampa, FL.*

The inherent toxicity of a compound can be masked by the choice of solvent used to deliver the chemical of interest. The purpose of this study was to determine the effect of three organic solvents [ethanol, methanol, or dimethyl sulfoxide (DMSO) and water mixtures] at modulating the activity of poly(ADP-ribose) synthetase (PARS), a key enzyme in the repair of damaged DNA. A dose-response was performed with each of the respective solvents. A 112% and 75% increase in activity above baseline was observed with 15% ethanol and 10% methanol, respectively. However, a near 20% decrease in activity was observed with 4% DMSO. Our results show an activating effect on PARS activity when ethanol or methanol is used at low concentrations, compared to the inhibitory effect of DMSO. PARS activity can deplete intracellular NAD+ and subsequently intracellular ATP, thereby causing necrotic cell death, if the capacity to replenish ATP is overcome. In constrast, apoptosis is associated with PARS cleavage and inhibition. Our data indicates that the interpretation of studies obtained when using common organic solvents may be dramatically skewed, either exaggerating the inherent toxicity of the compound or masking its potential for damage. (Supported by the Japan Society for the Promotion of Science)

371 MECHANISM INVOLVED IN TOPOISOMERASE IIα INHIBITION BY PHOTOACTIVATED BAY Y3118.

C. E. Perrone and G. M. Williams. *Department of Pathology, New York Medical College, Valhalla, NY.*

Topoisomerase inhibition has been proposed as a possible mechanism involved in the photochemical toxicity and mutagenicity of fluoroquinolone antibiotics (FQs). We report here that some photochemically mutagenic FQs, but not all, inhibit the human topoisomerase IIα enzyme *in vitro* following UVA (365nm) irradiation. We studied Bay y3118 (y3118) and lomefloxacin, which are highly photoactive, ciprofloxacin which is weakly photoactive and lomefloxacin, which is photostable. The degree of inhibition at 360 mJ/cm2 was as follows: Bay y3118, 15%; ciprofloxacin, 5%; lomefloxacin, 0% and moxifloxacin, 0%. The nature of the UV-FQ-mediated inhibitory effects on the topoisomerase IIα was further examined using the photoinhibitory y3118. Topoisomerase IIα inhibition required the simultaneous presence y3118; DNA and enzyme in the UVA irradiated reaction mixture indicating the possible formation of a ternary structure. UVA-FQ-mediated topoisomerase IIα inhibition also correlated with the increased binding of y3118 to DNA:topoisomerase complexes and was not prevented by the antioxidant TEMPO suggesting that reactive oxygen species were not involved in the inhibition. We conclude that some photochemically genotoxic FQs inhibit the human topoisomerase IIα (i.e. Bay y3118) possibly by UV-induced affinity of FQs to DNA:topoisomerase complexes, but that inhibition of topoisomerase IIα does not account for the photochemical activity of others FQs (i.e. lomefloxacin). Supported by the NIH Grant CA 86056.

372 RESISTANCE TO SILICA-INDUCED LUNG FIBROSIS IN SENESCENT RATS: ROLE OF ALVEOLAR MACROPHAGES AND TUMOR NECROSIS FACTOR-ALPHA (TNF).

E. Corsini, A. Giani, S. Peano, M. Marinovich and C. L. Galli. *Pharmacological Sciences, University of Milan, Milan, Italy.*

PURPOSE: We have previously demonstrated in rat alveolar macrophages (AM), that aging was associated with a progressive decline in the ability of these cells to produce TNF 1. The purpose of the present study was to investigate the effect of aging on silica-induced lung toxicity, for which it has been demonstrated the requirement of TNF for the development of silica-induced pulmonary fibrosis2. SUMMARIZED DESCRIPTION: Sprague-Dawley rats 3 and 18 month old were intratracheally instilled with 30 mg of silica or saline as control. Two weeks following instillation, rats were analysed for bronchoalveolar lavage fluid (BAL) parameters (total protein, LDH, TNF and cellularity), total lung hydroxyproline, as measurement of collagen deposition, and lung histopathology. RESULTS: In young animals, as expected, silica induced a significant increase in BAL protein, TNF, LDH as well as in cell numbers, which correlate with increased collagen deposition and silicotic nodules formations. In old rats, however, no changes in BAL or lung parameters were observed following silica instillation. These *in vivo* results were also confirmed *in vitro*, where silica failed to induce TNF release in AM obtained from old animals. This defective response to silica could be explained with the defective

protein kinase C translocation, due to a reduction in its anchoring protein RACK-1 in old rats. Use of RACK-1 antisense oligonucleotide reduced the response of young macrophages to silica, supporting the idea that age-associated alterations in AM signal transduction pathways contribute to decreased sensitivity to silica-induced lung fibrosis.

373 THIOL ANTIOXIDANTS INHIBIT THE ADJUVANT EFFECTS OF AEROSOLIZED DIESEL EXHAUST PARTICLES IN A MURINE MODEL FOR OVALBUMIN SENSITIZATION.

M. J. Whitekus[1], M. Zhang[2], N. Li[2], M. Horwitz[3], S. K. Nelson[4], N. Brechun[4], D. Diaz-Sanchez[2] and A. Nel[2]. *[1]Pathology and Lab. Med., UCLA, Los Angeles, CA, [2]Division of Clinical Immunology and Allergy, UCLA, Los Angeles, CA, [3]Division of Infectious Disease, UCLA, Los Angeles, CA and [4]Webb-Waring Antioxidant Research Institute, UCLA, Los Angeles, CA.*

Although several epidemiological studies indicate a correlation between exposure to ambient particulate matter (PM) and adverse health effects in humans, there is still a fundamental lack of understanding of the mechanisms involved. We set out to test the hypothesis that reactive oxygen species are involved in the adjuvant effects of diesel exhaust particles (Department) in a murine ovalbumin (OVA) sensitization model. First, we tested six different antioxidants, N-acetylcysteine (NAC), bucillamine (BUC), silibinin, luteolin, trolox (vitamin E) and ascorbic acid, for their ability to interfere in Department-mediated oxidative stress *in vitro*. Of the six agents tested only the thiol antioxidants, BUC and NAC, were effective at preventing a decrease in intracellular GSH/GSSG ratios, protecting cells from protein and lipid oxidation, and interfering with HO-1 expression. We therefore selected the thiol antioxidants for testing in the murine OVA inhalation exposure model. Our data demonstrate that NAC and BUC effectively inhibited the adjuvant effects of Department in the induction of OVA-specific IgE and IgG1 production. Furthermore, NAC and BUC prevented the generation of lipid peroxidation and protein oxidation in the lungs of OVA + Department exposed animals. These findings indicate that NAC and BUC are capable of preventing the adjuvant effects of inhaled Department, and suggest that oxidative stress is a key mechanistic component in the adjuvant effect of Department. Antioxidant treatment strategies may therefore serve to alleviate allergic inflammation and may provide a rational basis for treating the contribution of PM to asthmatic disease. (Supported by US Public Health Service Grant AI34567, EPA Southern California Particle Center, and by NIAID AI07126).

374 THIOL AND IMMUNE EXPOSURE DEPENDENT RESPONSE TO OVALBUMIN IN SENSITIZED RATS.

N. H. Al-Humadi[1,2], P. D. Siegel[1], D. M. Lewis[1], M. W. Barger[1], J. Y. Ma[1], D. N. Weissman[1] and J. K. Ma[2]. *[1]ASB, NIOSH, Morgantown, WV and [2]School of Pharmacy, West Virginia University, Morgantown, WV.*

Brown Norway rats were exposed 30 min to the antigen, ovalbumin (OVA) at 7.2, 68, 93, 111 or 156 mg/m3 on days 1, 8, 15, and 29. Tissue was collected one day after the last exposure. Cysteine (CYSH), glutathione (GSH), and markers of inflammation in bronchioalveolar lavage fluid (BALF) were measured. Alveolar macrophage (AM) and pulmonary associated lymph node lymphocyte (PALNL) were isolated and assessed for CYSH and GSH concentrations. Specific IgG and IgE, and lung tissue IFN-gamma, IL-4, and TNF-alpha mRNA levels (standardized with G3PDH) were the immunological endpoints studied. Rats were immunologically sensitized as evident by exposure related increases in all immunological parameters and OVA challenge induced increases in BALF albumin, protein and lactate dehydrogenase. In addition, OVA caused a modest elevation at low OVA challenges, but sharp reduction in AM thiols at higher OVA challenges. Concomitantly, OVA exposure dependent increases in BALF CYSH and GSH were observed. CYSH, but not GSH was elevated in PALNL of OVA challenged rats. In summary, antigen exposure dose dependent alteration of thiol and immune parameters were demonstrated *in ova* sensitized and challenged rats.

375 PROTEASE ENHANCEMENT OF IGG1 AND IGE ANTIBODY RESPONSE TO HEMICELLULASE IN MOUSE MODELS OF ALLERGY.

K. Sarlo, E. D. Clark and J. S. Parris. *Central Product Safety, The Procter & Gamble Co, Cincinnati, OH.*

The mouse intranasal (MINT) and mouse aspiration (MaspT) tests are being developed as replacements to the guinea pig intratracheal (GPIT) test used to assess the allergenic potential of protein allergens. Protease enzymes have been shown to enhance the IgG1 antibody response to non-protease enzymes in guinea pigs exposed to mixtures of protease and non-protease enzymes (Sarlo, et.al. JACI, 1997, 100:480). The shift in the antibody response to enzyme mixtures in the GPIT test is used to adjust occupational exposure guidelines. To replace the GPIT test, we must show similar shifts in antibody responses to enzyme mixtures in the mouse models. BDF1 mice were exposed *via* intranasal (IN) instillation to protease, hemicellulase or a mixture of protease + hemicellulase on days 1, 3, 10, 17 and 24; sera were collected on day 29. Similarly, mice were exposed to the same enzymes *via* aspiration (ASP) instillation on days 1, 3 and 10; sera were collected on day 15. IgG1 and IgE antibody to each enzyme were measured by ELISA. IgE titers were randomly confirmed by the rat passive cutaneous anaphylaxis (PCA) test. The protease shifted the IgG1 antibody response to the hemicellulase ~3x in IN and ASP dosed mice. The shift was dependent upon the amount of protease in the mixture - the lower the protease levels in the mixture, the smaller the shift. The protease also shifted the IgE antibody response to the hemicellulase in IN and ASP dosed mice. The enhancement was greater for IgE than for IgG1. The antibody response to protease was not altered by the presence of the hemicellulase. Testing of the protease + hemicellulase mixture in the GPIT test also showed a 3x to 4x shift in IgG1 antibody to the hemicellulase. Therefore, there is consistency between the guinea pig and mouse models. Continued work with mixtures of enzyme allergens is needed to develop the mouse model as a full replacement to the GPIT test.

376 RESPIRATORY PHYSIOLOGICAL RESPONSES TO AN EXTRACT OF *Stachybotrys chartarum* IN BALB/C MICE.

M. E. Viana[1], N. Haykal-Coates[2], S. H. Gavett[2], M. J. Selgrade[2] and M. D. Ward[2]. *[1]APR CVM, NCSU, Raleigh, NC and [2]NHEERL ORD, USEPA, Research Triangle Park, NC.*

Exposure to *Stachybotrys chartarum* has been associated with the development of serious health problems in humans, including asthma. Previous studies by our group demonstrated respiratory exposure to a pool of *S. chartarum* extracts caused biochemical and immunological responses indicative of a respiratory allergic response. The goal of this study was to assess the ability of this extract to cause alterations in respiratory physiological responses similar to those observed in human allergic asthma. Five isolates of *S. chartarum* obtained from wallboards in water-damaged houses were grown and combined in approximately equal weight amounts, extracted using Hanks' Balanced Salt Solution (HBSS) + Tween-80, and filter sterilized to form a crude antigen preparation (SCE-1). Female BALB/C mice were anesthetized and exposed to 4 aspirations of 50 µl volume containing 10 mg of SCE-1, BSA as a non-allergenic protein, or HBSS over a 4-week period. Barometric whole-body plethysmography was performed to measure enhanced pause (PenH) 10 minutes prior to (baseline) and 1 hour following each aspiration exposure to assess immediate respiratory responses. Additionally, airway hyperresponsiveness to nebulized methacholine (MCh) was assessed on days 1 and 3 following the 4th aspiration exposure. Exposure to HBSS or BSA did not alter baseline PenH values, PenH following the aspiration exposures, or airway responsiveness to MCh. Exposure to SCE-1 resulted in a 4.7-fold increase in PenH over baseline after the 3rd exposure, increasing to 5.6-fold after the final exposure, and increased responsiveness to a 32 mg/ml MCh aerosol challenge. We conclude respiratory SCE-1 exposure causes respiratory physiological responses similar to those observed in human allergic asthma. However, BSA does not generate the respiratory physiological responses expected of an allergenic protein when administered by aspiration. (Supported by NCSU/EPA Cooperative Training Agreement CT826512010.) (This abstract does not reflect EPA policy.)

377 PATHOLOGIC AND CYTOKINE RESPONSES IN THE RESPIRATORY TRACT OF A/J MICE AFTER INTRANASAL SENSITIZATION AND CHALLENGE TO TOLUENE DIISOCYANATE.

A. K. Farraj, J. R. Harkema and N. E. Kaminski. *Pharmacology and Toxicology and Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.*

Occupational asthma is the most frequently diagnosed respiratory disease in the workplace and is often linked to low molecular weight chemicals (LMWC) such as toluene diisocyanate (TDI) that sensitize the respiratory tract. Occupational asthma is characterized by smooth muscle hypertrophy, mucus hypersecretion, epithelial desquamation and an inflammatory influx consisting of lymphocytes, eosinophils, and neutrophils in the airways. Many experimental models have linked the Th2 phenotype to LMWC-induced occupational asthma. Most murine models of occupational asthma, however, use systemic administration (e.g., dermal) to sensitize mice. The present study was designed to test the hypothesis that intranasal sensitization and challenge to TDI will induce the immunologic (cytokine and IgE) and pathologic responses in the lung that are characteristic of LMWC-induced occupational asthma. Only mice that were intranasally sensitized and challenged to TDI exhibited an increase in lung derived IL-4 mRNA. IL-4 mRNA expression in these animals reached 8-fold the level of control 24 hours after exposure and waned to 4-fold the control levels by 96 hours. In addition, only TDI sensitized and challenged animals exhibited an increase in total serum IgE. The total serum IgE levels

in these animals were 4-fold the level of control 24 hours after exposure and persisted at that level by 96 hours after exposure. No pulmonary lesions were found in mice of any group. TDI-exposed mice did have an acute rhinitis with associated epithelial necrosis and exfoliation. This study is the first to demonstrate that intranasal administration to an LMWC is an effective method of sensitization and results in an upregulation of a critical mediator of allergic airway disease, IL-4, within the lung after challenge (Supported in part by American Chemistry Council Grant # 0051).

378 CHARACTERIZATION OF IGE INDUCING PROTEINS FROM EXTRACTS OF *METARHIZIUM ANISOPLIAE.*

L. B. Copeland, C. A. Manuel, M. K. Selgrade and M. D. Ward. *USEPA Agency, Research Triangle Park, NC.*

We have previously demonstrated BALB/C mice exposed to *Metarhizium anisopliae* crude antigen (MACA) develop immune and pulmonary responses typical of allergy and asthma. Soluble factors from the fungal components (mycelium, conidia, and inducible proteases and chitinases) were combined in equal protein amounts to form the crude antigen. The fungal allergens were identified by SDS-PAGE/western blot analysis using IgE containing hyper-immune mouse serum as the source of primary antibody and traditional chromogenic enzyme substrate for detection. India ink staining detected more than 50 proteins in MACA. Of these 4-5 induce an IgE response and comprise approximately 12-15% of the MACA proteins by densitometric analysis of the India ink stained blot. When the MACA component extracts were examined individually, we determined that 4 of these proteins were detectible in the mycelium extract, and 2 were detectable in the inducibles extract (1 homologous by MW to a mycelium protein identified and 1 unique protein). However, there were no IgE inducing proteins detected in the conidia extract. We have begun to re-assess these extracts using a chemiluminscence detection system that is more sensitive. The IgE-inducing proteins in the mycelium extract identified as *met a* I, *met a* II, *met a* III, and *met a* IV have apparent molecular weights of 127.6 kDa, 114.7 kDa, 89.7 kDa, and 52.6 kDa, respectively. Furthermore, we have determined the isoelectric points of the allergen proteins by isoelectric focusing (IEF) and confirmed the apparent molecular weights by two-dimensional gel analysis. Using SDS-PAGE/western blot analysis we have also found batch-to-batch variability in our fungal extracts. Although we have found there are apparent changes in the concentration of the allergenic proteins in different extract batches, there do not appear to be differences in the proteins detected. (This abstract does not reflect EPA policy.)

379 EFFECT OF ORGANIC PARTICLE EXPOSURE ON ALLERGIC AIRWAY DISEASE IN MICE.

A. K. Hubbard[1,3], J. B. Morris[1,3], S. Mowbray[1], M. Thibodeau[1], L. Puddington[2,3] and R. S. Thrall[2,3]. *[1]Pharmaceutical Sciences, University of Connecticut, Storrs, CT, [2]Medicine, University of Connecticut, Farmington, CT and [3]Pulmonary Research Consortium, University of Connecticut, Farmington, CT.*

Past studies have documented the adjuvant effect of diesel exhaust and carbon black (CB) particles on allergic airway disease (AAD) in mice immunized to elicit a TH2 lymphocyte phenotype. However, few studies have examined the effect of particle exposure on reversing the normal hyporesponsive state in animals immunized to elicit a TH1 lymphocyte phenotype. To investigate if CB exposure will alter the hyporesponsive TH1 phenotype to a responsive TH2 phenotype, mice were exposed to CB by intranasal (IN) instillation during the challenge phase of ovalbumin (OVA) induced AAD. Mice were immunized with either OVA-ALUM (TH2 phenotype) or OVA-CFA (TH1 phenotype) and then challenged with OVA aerosol (1 hr/day) for 3 days. Mice received 200ug CB IN 4 hrs prior to each OVA aerosol challenge. Animals were killed 24 hrs later and evaluated for BAL cell number and type. Mice expressing a TH1 response to OVA demonstrated significantly fewer eosinophils than mice expressing a TH2 phenotype (50% *versus* 87%) confirming the hyporesponsive state. Contrary to expectations, administration of CB to TH1 mice decreased total BAL cell number with no change in % eosinophils (50% *versus* 51%). Administration of CB to TH2 mice also decreased total cell number and proportion of eosinophils from 87% to 48%. These data suggest that CB exposure decreases the pulmonary allergic response in both TH1 and TH2 phenotype mice. (Funded by ES NIH09433)

380 OXAZOLONE-INDUCED DIRECT PLNA REACTIONS ARE SUPPRESSED IN MICE ORALLY PRETREATED WITH OXAZOLONE.

F. Bouzahzah[1], B. W. Gutting[1], P. Kong[1], L. W. Updyke[2], D. E. Amacher[2] and J. E. Craft[1]. *[1]Yale University Schoo! of Medicine, New Haven, CT and [2]Pfizer Global Research and Development, Groton, CT.*

There is a need for preclinical assays that can identify low molecular weight compounds (LMWCs) with the potential to cause systemic hypersensitivity (SH). One such assay being examined is the rodent popliteal lymph node assay (PLNA). Based on >80 LMWCs, in general, only LMWCs associated with SH cause PLN reactions in rodents. However, despite this preliminary success, there are fundamental questions that remain unanswered. One such question is concerned with false positives. For example, it is hypothesized that contact sensitizers (CS) will produce strong PLN reactions but are not expected to cause SH following oral administration due to oral tolerance. The objective of this study was to examine the immunomodulating potential of the CS oxazolone (OX) and DNCB in the BALB/c PLNA, and to examine what effect oral pretreatment with OX had on the reactions. In naïve mice, both CSs induced strong PLN reactions. OX induced dose-dependent increases in PLN weight, cellularity, the % of CD4+ T cells, and the % of B cells, with a concomitant decrease in the % of CD8+ T cells. Next, the PLNA was conducted in mice gavaged 3 times with OX. Mice gavaged with OX had suppressed PLN reactions following the injection of OX (decreased PLN size, weight and cellularity), as well as a decrease in the % of CD4+ helper T cells. Oral treatment with OX had no observable effect on the PLN reaction induced by DNCB. Finally, adoptive transfer studies were conducted to examine the mechanism of PLN unresponsiveness. It was found that unfractionated splenocytes isolated from mice gavaged with OX adoptively transferred (iv) PLN unresponsiveness to naïve mice. Collectively, these observations demonstrate that OX is a potent immunostimulator in the PLNA. As importantly, these results demonstrate that the immunostimulating potential of OX is significantly decreased in mice orally exposed to the drug, possibly due to the presence of a cell-mediated mechanism of oral tolerance.

381 CHARACTERIZATION OF THE SENSITIZING POTENTIAL OF A STRONG DERMAL IRRITANT USING AN ENHANCED LOCAL LYMPH NODE ASSAY.

M. S. Wragg[1], S. A. Signs[1], M. Raffray[2], P. L. Lawson[3], E. J. Yurkow[4] and G. L. DeGeorge[4]. *[1]Lubrizol Corporation, Wickliffe, OH, [2]FMC Toxicology, Basildon, Essex, United Kingdom, [3]Akzo Nobel Surface Chemistry LLC, Chicago, IL and [4]MB Research Laboratories, Spinnerstown, PA.*

Strong irritants can give ambiguous results in animal models used for predicting dermal sensitization potential. An enhanced LLNA protocol was devised to better characterize the sensitization potential of a long chain alkylamine (LCAA), a strong dermal irritant that had previously given conflicting results in other sensitization assays. In this study, groups of five CBA mice were treated by topical application of LCAA (0.1, 0.3, 1.0% v/v) once daily to the dorsum of each ear for three consecutive days. Additional groups were treated with the known sensitizers DNCB (0.25% w/v) or HCA (50% v/v), or the non-sensitizing irritant SLS (25% w/v). Five days after the initial dose, the mice were injected (i.p.) with 5-bromo-2'-deoxyuridine (BrdU) to label proliferating cells. Auricular lymph nodes were isolated and the number of BrdU+ cells was determined for individual animals by flow cytometry. Immunophenotype analysis of the nodal cells was conducted using the marker combinations B220/CD3 and IA/CD69 to determine the B:T cell ratio and the activation state of the nodal lymphocytes respectively. Ear thickness was also evaluated for all animals. LCAA caused a significant increase in ear thickness and a dose-dependent increase in lymph node cell proliferation with a maximum Stimulation Index (SI) of 125.9 (EC3 < 0.1%), while the known sensitizers DNCB and HCA gave a SI of 104.6 and 30.1 respectively. Both positive control substances and higher dose levels of LCAA also caused a significant increase in the B:T cell ratio and the % IA+/CD69+ cells. Treatment with SLS resulted in significant ear swelling and an SI of 3.2 but no increase in cellular markers. Despite the significant irritant response induced by LCAA, the magnitude of the proliferative response and the activation state of cells localized in the nodes of treated mice identify LCAA as a potential dermal sensitizer.

382 RELEVANCE OF HUMAN CYP450 1A1 AND 1B1 IN THE METABOLISM OF FRAGRANCES.

B. Blomeke, A. Helmer, C. Skazik and H. F. Merk. *Dermatology, University Hospital, Aachen, Germany.*

Fragrances are widely encountered in our daily environment and are known to be a common cause of allergic contact dermatitis. Such small molecular compounds usually need binding to high molecular weight compounds in order to become antigenic. The knowledge about the metabolic activation is still limited. Recently, we found that the proliferative responses of lymphocytes of fragrance-allergic patients were increased in the presence of human liver microsomes or recombinant CYP1A1 (Sieben et al., 2001). In addition, we found that eugenol but not isoeugenol produced a 20-fold increase in CYP1A1 steady state mRNA levels in human primary keratinocytes (Al Masaoudi et al., 2001). With the aim of providing further insights into the mode of action of eugenol (4-allyl-2-methoxyphenol) and the structurally related compound isoeugenol (4-propenyl-2-methoxy-phenol) in human skin cells, we studied whether CYP1B1, AhR and ARNT are also involved in the activation of these compounds. We found, that eugenol additionally produced a 4-fold increase in CYP1B1 steady state mRNA levels but no induction

of the AhR gene battery. In contrast, incubation of the cells with isoeugenol increased CYP1B1 and AhR mRNA levels in keratinocytes. Our results indicate that keratinocytes can activate small haptens such as fragrances. This work was supported by the BMBF (IZKF BIOMAT, G11) and the European Community.

383 ELUCIDATING CHANGES IN SURFACE MARKER EXPRESSION OF DENDRITIC CELLS FOLLOWING ALLERGEN TREATMENT.

B. C. Hulette, C. A. Ryan and G. F. Gerberick. *Procter & Gamble, Cincinnati, OH.*

Dendritic cells (DC) are specialized antigen-presenting cells (APC) located in many non-lymphoid tissues, and Langerhans cells (LC), a specialized form of DC, are found in the skin. LC play a critical role in the induction of contact dermatitis and therefore have become a focal point for development of *in vitro* cell-based methods for contact sensitization testing. Because of the low abundance of skin-derived LC, cultured DC from peripheral blood (PB) are used as LC surrogates to study the effects of sensitizing chemicals on APC. It has been reported that chemical allergens induce changes in the expression of various DC surface markers. For the work presented here, DC were derived from the KG-1 cell line (KG-1 DC) or were differentiated from human PB (PBMC-DC). The phenotype of these DC was measured by flow cytometry after 48 hr treatment with the chemical allergens dinitrofluorobenzene (DNFB) and methylchloroisothiazolinone/methylisothiazolinone (MCI/MI), the irritant sodium dodecyl sulfate (SDS), lipopolysaccharide (LPS), and tumor necrosis factor-α (TNFα). It was found that only MCI/MI upregulated CD86 expression in KG-1 DC, whereas TNFα upregulated CD54 and slightly upregulated CD80 and CD86 expression. In PBMC-DC, MCI/MI and DNFB induced a slight upregulation of class II major histocompatibility expression (HLA-DR), whereas LPS and TNFα significantly upregulated CD54 and slightly upregulated CD80 and HLA-DR expression. SDS had no effect on surface marker expression in either KG-1 DC or PBMC-DC. Changes in surface marker expression in PBMC-DC treated with chemical allergens were detected in 2 of 5 donors, suggesting a limited sensitivity of PBMC-DC under these culture conditions. Futhermore, the presence of cytokines during allergen treatment masked the ability to detect changes in surface marker expression. Our data suggest that, under these culture and treatment conditions, measurement of surface marker changes using PBMC-DC or KG-1 DC does not provide a sensitive method with sufficient dynamic range for assessing the contact sensitization potential of a chemical.

384 DIVERGENT IMMUNOLOGICAL RESPONSES FOLLOWING GLUTARALDEHYDE EXPOSURE.

S. Azadi, L. F. Butterworth and B. J. Meade. *Health and Human Services, NIOSH, Morgantown, WV.*

Glutaraldehyde (Glut) is a potent contact sensitizer, additionally numerous cases of occupational asthma related to Glut exposure have been reported in recent years. The purpose of this study was to examine the Dose-Response relationship between Glut exposure and the development of Th1 *vs.* Th2 responses using a murine model. Initial evaluation of the sensitization potential was conducted using the standard Local Lymph Node Assay in CBA mice. Female BALB/c mice (N=5-8 per group) were used for all other studies. The IgE inducing potential was evaluated by phenotypic analysis of IgE+B220+ cells in lymph nodes draining the site of topical exposure and measurement of total serum IgE levels. The Mouse Ear Swelling Test (MEST) was used to evaluate the potential of Glut to elicit urticaria (30 min post challenge) and contact hypersensitivity (24 and 48 hrs post challenge). A dose dependent increase in lymphocyte proliferation as measured by 3H-thymidine incorporation and the %B220+ cells was observed following exposure to 0.1, 0.75, and 2.5% Glut with a positive response (SI>3 in LLNA) being observed at all concentrations tested. The MEST demonstrated an immediate response (Th2) in animals induced and challenged with 2.5% Glut, whereas animals induced with 0.1 or 0.75% and challenged with 2.5% exhibited a delayed response (Th1) at 48 hrs. post challenge. In agreement with the MEST results, only the 2.5% dose group had a significant increase ($p<0.01$) in serum IgE levels and % IgE+B220+ draining lymph nodes cells. The results of these studies indicate that the induction of a Th1 *vs.* Th2 response following dermal exposure to Glut is at least in part mediated by the exposure concentration. These studies were supported in part by NIEHS intra-agency agreement #Y1-ES-0001-01.

385 RANKING OF ALLERGENIC POTENCY OF LATEX CHEMICALS IN A MODIFIED LOCAL LYMPH NODE ASSAY.

F. M. Van Och, W. H. De Jong, R. J. Vandebriel, C. F. Den Hartog Jager, W. Slob and H. Van Loveren. *Immunobiology and Haematology, RIVM, Bilthoven, Netherlands.*

A modified local lymph node assay (LLNA) with *ex vivo* tritium thymidine (3H-TdR) labelling of the proliferating lymph node cells was used for determination of the allergenic potency of chemicals used in the production of latex medical gloves. Fifteen chemicals, known to induce allergic contact dermatitis in man, including various thiuram, carbamate, and benzothiazole compounds and one amine were tested. The EC3 (effective concentration inducing a threefold increase in proliferation of lymph node cells (Stimulation Index, SI=3)) was calculated with non-linear regression analysis, including a bootstrap method for determination of the 5%-95% confidence interval of the EC3 value. The compounds tested were thiurams: TMTM (tetramethylthiurammonosulfide), TMTD (tetramethylthiuramdisulfide), TETD (tetraethylthiuramdisulfide), TBTD (tetrabutylthiuramdisulfide), PTD (dipentamethylenethiuramdisulfide), and PTT (dipentamethylenethiuramtetrasulfide); carbamates: ZDMC (zinc dimethyldithiocarbamate), ZDEC (zinc diethyldithiocarbamate), ZDBC (zinc dibutyldithiocarbamate), ZPC (zinc pentamethylenedithiocarbamate); benzothiazoles: MBT (2-mercaptobenzothiazole), MBTS (2, 2-dibenzothiazyldisulfide), ZMBT (zinc mercaptobenzothiazole), and MBI (mercaptobenzimidazole); and DEA (diethylamine). This procedure identified 14 out of the 15 chemicals tested as sensitiser, while for one chemical, ZDBC, no EC3 could be calculated due to low responses and a lack of a Dose-Response relationship in the data obtained. The ranking order of the chemicals with increasing EC3 values (and thus decreasing allergenic potency) was found to be: ZDEC, TMTD, TETD, ZPC, ZDMC, MBTS, PTD, TMTM, MBT, MBI, PTT, ZMBT, TBTD, DEA, and ZDBC. Our results indicate that the chemicals of choice for use in latex production would be for the thiuram compounds TBTD, for the carbamates ZDBC and for the benzothiazoles ZMBT. However, one has to be aware that besides potency also the total amount of residual chemical present in the final product is important for allergy induction.

386 STUDY TO DETERMINE THE PRESENCE OF ANTIPOLYMER ANTIBODIES IN A GROUP OF DUTCH WOMEN WITH A SILICONE BREAST IMPLANT (SBI).

W. H. De Jong, M. Kallewaard, C. A. Goldhoorn, J. W. Bijlsma, J. S. Schouten and H. Van Loveren. *Immunobiology and Haematology, RIVM, Bilthoven, Netherlands.*

Recently the presence of antipolymer antibodies (APA) has been reported to be correlated with the disease status in silicone breast implant (SBI) recipients (and fibromyalgia patients. A cross sectional study was conducted in a population of Dutch women with SBI and self reported severe complaints. SBI recipients (n=42) were clinically examined and blood samples were obtained. In the APA assay the binding of immunoglobulins to acrylamide polymer-coated strip (2) was demonstated after incubation with secondary antibodies and visualization by a colorimetric method. In 12 of 42 SBI recipients an increase in the level of polymer binding immunoglobulins was detected compared to a negative reference sample, 3 of these 12 showing a positive and 9 a weakly positive response. In 3 out of 12 non-SBI recipients, included for control on the performance of the APA assay, an increased level of polymer binding immunoglobulins was demonstrated, 2 of these 3 showing a positive and 1 a weakly positive response. In the general population in 5 out of 80 women a positive APA was found, and one of 80 showed a weakly positive response. The study population of SBI recipients was categorised in severity subgroups (limited, mild, moderate, advanced) based on the functional capacity and the physicians general assessment of pain and disease activity. Most (34 of 42) SBI recipients belonged to the limited severity subgroup. In conclusion, we did not find a high prevalence of polymer binding immunoglobulins (APA) in a group of Dutch SBI recipients with self reported severe complaints. A discrepancy was present between the self-reported severe complaints and the observed mild clinical symptoms. SBI exposure (mean 17 years) did not result in induction of polymer binding immunoglobulins in this minimal symptomatic study group. Antigen strips for the APA assay were kindly provided by Dr R.B. Wilson, Autoimmune Technologies, L.C.C., New Orleans, LA, USA.

387 EXPOSURE TO SINGLE OR TERTIARY MIXTURES OF N, N-DIETHYL-M-TOLUAMIDE (DEET), PYRIDOSTIGMINE BROMIDE (PYR), JP-8 JET FUEL AND STRESS IN AUTOIMMUNE PRONE MICE.

G. S. Gilkeson, M. M. Peden-Adams, J. G. EuDaly, S. Dabra, A. EuDaly, R. Hayes, L. Heesemann, J. Miller, J. Smyth and D. E. Keil. *Medical University of SC, Charleston, SC.*

Exposures to chemicals such as DEET, PYR, and JP-8 jet fuel (JP-8) are common in military environments, as well as in some occupations. During the Gulf War, military service personnel were exposed to PYR, DEET, JP-8, and stress. Previous studies determined the lowest adverse effect level of immunological parameters to be 15.5 mg/kg DEET, 2 mg/kg PYR, 500 mg/kg JP-8, and 20 minutes exercise stress for 14 days. To investigate the contribution of these agents in accelerating or exasperating autoimmune disease, a strain of autoimmune prone mice, MRL lpr/lpr, were exposed for 14 days at age 12 weeks. At 18 weeks of age, immunological parameters in mice were assessed. No remarkable changes occurred in complete

peripheral blood counts, spleen and thymus total cellularity and CD4/8 flow cytometry, except for a decrease in thymic CD4-/CD8+ cells after exposure to JP-8 only. Furthermore, macrophage nitrite production or splenic lymphocyte proliferation after exposure to concanavalin A or lipopolysaccharide was not significantly different. Proteinuria was also assessed in these mice at 14, 16 and 18 weeks. By 18 weeks of age, MRL-lpr/lpr female mice had an expected time-dependent increase in proteinuria. Following single exposure to either PYR or exercise stress, an increase in proteinuria was noted over controls. Single exposures to DEET or JP-8 minimally affected the development of proteinuria as compared to controls. Furthermore, mice exposed to the stress mixture (20 min of exercise + 15.5 mg/kg DEET + 2 mg/kg PYR) or JP-8 mixture (500 mg/kg JP-8 + 15.5 mg/kg DEET + 2 mg/kg PYR) demonstrated increased proteinuria over control values, but this change was not typically greater than levels achieved after single exposure to PYR or stress. Thus far, these data suggest that several immunological endpoints were not remarkably exacerbated in an autoimmune mouse model, however proteinuria may be accelerated.

388 THE POSSIBLE ROLE OF THE GUT IN D-PENICILLAMINE-INDUCED AUTOIMMUNITY IN THE BROWN NORWAY (BN) RAT.

M. Masson and J. P. Uetrecht. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.*

In male Brown Norway rats, high dose D-penicillamine (D-Pen; 20mg/day) induces an autoimmune syndrome in =70% of animals within 6 to 8 weeks that is similar to drug-induced lupus in humans. The gut is believed to be central to the induction of oral tolerance. Low doses induce tolerance, while high doses induce autoimmunity. In the Brown Norway model, a tolerance-producing regimen consisting of a two-week period of low dose D-pen (5mg/day) followed by high dose D-pen results in none of the animals developing lupus. The hypothesis to be tested is that gut immunostimulation by high dose D-Pen treatment could provoke the development of autoimmunity. Male Brown Norways (n=3) were given 20 mg/day of D-Pen for periods of 0, 48 hrs and 1 week. Immunohistochemistry was performed on frozen sections of the caecum and the large intestine to examine the expression of ED1+ macrophages and B7.2, a major costimulatory molecule involved in initiating immune responses. These early time periods were chosen as changes in the distribution of ED1+ and B7.2+ cells will reflect changes in response to the drug, rather than simply reflecting signs of disease. In the caecum, both B7.2+ and ED.1+ expressing cells start to infiltrate the gut after only 48 hours of exposure to high dose D-Pen. By one week, large areas of infiltration are apparent in all sections. In the large intestine, similar findings are apparent. Interestingly, exposure to D-Pen results in the expression of B7.2 by epithelial cells. These data indicate a possible role of the gut in initiating D-Pen-induced autoimmunity.

389 PENICILLAMINE INDUCED LUPUS-LIKE SYNDROME: INVESTIGATING THE ROLE OF COVALENT BINDING *IN VIVO*.

B. Seguin, C. Ju, L. Pohl and J. Uetrecht. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.*

BACKGROUND: Idiosyncratic drug reactions are often explained by the Hapten Hypothesis, i.e. covalent binding of a drug or its metabolite to proteins leads to an immune response. We used an animal model, penicillamine-induced autoimmunity in the Brown Norway rat, to study the relationship between covalent binding and the mechanism of an idiosyncratic reaction. METHODS: Antibodies against penicillamine were induced in rabbits by injecting an penicillamine-KLH antigen. Using ELISA, the rabbit serum showed specificity for penicillamine at dilutions as high as 1/100 000. RESULTS: Male Brown Norway rats were given penicillamine (20 mg/day in water). When animals developed evidence of autoimmunity, the animals were killed and the spleen, liver and skin tissues were analyzed by immunohistochemistry and western blotting. Immunohistochemical analysis revealed low binding in spleen and liver of sick rats, but much higher binding was observed in collagen fibers of the skin. Western blot analysis under reducing conditions revealed no specific binding, but under non-reducing conditions, we identified several protein species that were covalently bound by penicillamine. This indicates that the binding involved a disulfide linkage. The molecular weight of the proteins bound by penicillamine ranged between 48 and 94 KDa. Attempts at finding autoantibodies against collagen were unsuccessful because of high background binding of the rat serum. DISCUSSION: It has been reported that penicillamine can bind aldehydes on collagen and cause fragility of bones, skin and delay wound healing. Due to the chemical structure of penicillamine, we expected that binding would occur with all sulfydryl-containing proteins and not just collagen. We suspect that penicillamine is being removed enzymatically or non-enzymatically. The high degree of binding to collagen may be because enzymes that catalyze an exchange are mostly intra-cellular. The role of binding of penicillamine to collagen in the pathogenesis of this idiosyncratic reaction is currently under investigation.

390 EVALUATION OF AN ENVIRONMENTAL CONTAMINANT, CADMIUM, ADMINISTERED IN DRINKING WATER IN THREE AUTOIMMUNE MODELS.

E. K. Leffel and K. L. White, Jr.. *Pharmacology & Toxicology, Virginia Commonwealth University, Richmond, VA.*

The etiology of autoimmune disease is largely unknown. However, there is evidence that there are genetic factors that predispose some individuals. When these people are assaulted with environmental triggers such as drugs, viruses, or chemicals, then autoimmune disease can result. The purpose of these studies was to determine if cadmium (Cd) was a potential candidate for producing autoimmune disease (AD) in genetically predisposed individuals. NZB/W and MRL/lpr mice (exacerbation models) and Brown Norway (BN) rat (induction model for systemic lupus erythematosus) were utilized. NZB/W: Mice were exposed to Cd in the drinking water at concentrations of 0 to 10, 000 ppb for 31 wks. At 15 wks of exposure, the Cd treated groups showed onset of AD, i.e. proteinuria, compared to 27 wks for tap water controls. Anti-nuclear antibody (ANA) levels were increased after 31 wks of exposure in the 30 and 300 ppb groups. Splenocytes cultured from mice in the long-term study showed increases in IgG2a & IgG3 antibodies. In the serum, a similar trend was observed. MRL/lpr: Mice were exposed to 0 to 10, 000 ppb Cd for 11 wks. Cd-treated groups developed proteinuria 3 wks earlier than the vehicle group and a larger percentage developed ANA. Deposition of immune complexes in the glomerulus was confirmed by electron microscopy. BN: Rats were exposed to 0 to 300, 000 ppb Cd for nine wks. Increases in the number of rats positive for ANA were observed in the Cd dose groups. The level of urinary Cd was significantly increased in the high dose group; notably, the level is 500-times lower than that reported to produce renal lesions from Cd. Based on the development of ANA, and the low levels of Cd in the urine, Cd may be capable of inducing autoimmunity in the BN. The findings from these rodent models suggest low levels of Cd in drinking water have the potential to exacerbate AD. Supported in part by NIEHS contract 05454.

391 MERCURY ACCELERATES AUTOIMMUNE DISEASE IN THE GRAFT *VERSUS* HOST DISEASE (GVHD) MODEL.

E. K. Silbergeld[1], D. Hoover[2,1], P. Nguyen[3], I. Silva[4,1], M. Lustberg[1] and C. Via[3,1]. *[1]Dept Epidemiology, University of Maryland Med. Sch, Baltimore, MD, [2]Dept of Neurobiology, University of Maryland Med. Sch, Baltimore, MD, [3]Dept of Medicine, University of Maryland Med. Sch, Baltimore, MD and [4]IBCM, University of Porto, Porto, Portugal.*

Mercury (Hg) is immunotoxic in many species, and has been shown to elicit immunologicaland physiological effects similar to lupus, an autoimmune disease, in inbred rodent strains. We have utilized GVHD, a well characterized model for lupus-like autoimmune disease, in which lymphocytes from a DBA/2 parent are injected into a C57Bl6xDBA/2-F_1 offspring host. This model, an alloantigen driven *in vivo* anti-host response, permits evaluation of Th1 and Th2 mediated responses in the development of disease. In this study, both donor and recipient mice were pretreated on alternate days, for 3 wks, by s.c. injection of $HgCl_2$ at either 20 or 200 µg/kg. This treatment does not affect body weight or survival, but has been shown to alter Th1/Th2 signalling without affecting splenocyte subsets. WIthin 5 days after the last Hg treatment, lymphocyte transfer was done and disease then assessed by monitoring prteinuria, antibody levels, and mortality. Four groups of female mice were studied: control C57BL6xDBA/2-F_1 animals; GVHD animals; GVHD+20 µg/kg Hg; and GVHD+200 µg/kg Hg. Mercury pretreatment significantly increased risks of early mortality in the GVHD model. At 4 months after disease initiation, 4 Hg animals had died (2 in the high group, followed by 2 in the low group) as compared to none in either control group. Also, Hg treatment significantly increased the likelihood of early and more severe proteinuria, as compared to the controls or the untreated GVHD group. No changes were observed after 8 weeks in serum autoantibody (anti-ssDNA IgG) levels; however further analyses will be conducted to measure specific autoantibodies. The results indicate that Hg may accelerate or worsen clinical autoimmune disease in susceptible populations. *Support from the Heinz Family Foundation and the Maryland Chapter of the Arthritis Foundation.*

392 SILICA ACCELERATED SYSTEMIC AUTOIMMUNE DISEASE IN LUPUS PRONE NEW ZEALAND MIXED MICE.

J. M. Brown, J. C. Pfau and A. Holian. *Department of Pharmaceutical Sciences/SPAHS/Center For Environmental Health Sciences, The University of Montana, Missoula, MT.*

The genetic backgrounds of lupus-prone murine models are a valuable resource for studying the influence of environmental exposure on autoimmune diseases in sensitive populations. Genetic predisposition may be a prerequisite for the develop-

ment of spontaneous autoimmune disease, such as systemic lupus erythematosus (SLE), but the incomplete concordance of SLE in twins suggests that exogenous or environmental factors are also important. Epidemiological studies have shown associations between silica exposure and several autoimmune diseases, including scleroderma and ANCA-associated small-vessel vasculitis. To determine whether long-term silica exposure exacerbates systemic autoimmunity in genetically predisposed animals, New Zealand mixed mice were intranasally instilled with saline or saline suspensions of 1 mg silica. Biomarkers of autoimmune disease were measured every two weeks by ELISA. These included circulating immune complexes, autoantibodies to nuclear antigen (ANA), histone, and double stranded DNA. ANA levels measured by ELISA were significantly higher in silica treated animals compared to saline treated animals (0.444 ± 0.17 *vs.* 0.293 ± 0.03, $p < .05$) 10 weeks post-exposure. Autoantibodies to histone were also significantly elevated after 10 weeks in silica treated animals compared to saline treated animals (0.587 ± 0.24 *vs.* 0.334 ± 0.045 $p < .05$). Autoantibodies to dsDNA were significantly elevated after 8 weeks in silica treated animals compared to saline treated animals (1.117 ± 0.305 *vs.* 0.593 ± 0.231 $p < .05$). Circulating immune complexes were seen in 6 of 8 silica treated mice, while none were seen in the saline treated mice at 10 weeks following exposure. Therefore, although NZM mice are susceptible to SLE, silica exposure significantly elevated levels of autoantibodies to nuclear antigens, including histone and dsDNA, as well as increasing circulating immune complexes, suggesting an exposure-induced exacerbation of the course of disease. This work was supported by NIH grant ES-04804.

393 ASCORBIC ACID AND GLUTATHIONE REDUCE 2-AMINO-4, 5-DICHLOROPHENOL (2A45CP) TOXICITY IN RENAL CORTICAL SLICES FROM MALE FISCHER 344 RATS.

M. A. Valentovic, J. G. Ball, H. Sun and G. O. Rankin. *Dept. of Pharmacology, Marshall University School of Medicine, Huntington, WV.*

2A45CP is an aromatic ring hydroxylated metabolite of 3, 4-dichloroaniline. 3, 4-Dichloroaniline is nephrotoxic with primary damage located within the proximal tubules. This study assessed the *in vitro* toxicity of 2A45CP in renal cortical slices and second, determined the effect of antioxidants and sulfhydryl containing agents on the severity of 2A45CP toxicity. Renal tissue was isolated from male Fischer 344 rats (190-22 g). Renal slices were rinsed 3 times for 3 min each in 5-ml renal Krebs buffer. Tissues were incubated for 90-120 min with 0-1 mM 2A45CP. In a separate series of experiments, the slices (50-100 mg) were preincubated for 30 min with 1 mM dithiothreitol (DTT), glutathione (1 mM) or 2mM ascorbic acid prior to exposure to 0, 0.05, 0.1 or 0.25 mM 2A45CP. 2A45CP produced a concentration and time dependent increase in LDH leakage from renal cortical slices. Total glutathione levels were diminished by 0.5 mM 2A45CP within 60 min. Renal slices incubated for 60 and 120 min with 0.05 and 0.1 mM 2A45CP had lower malondialdehyde levels than control. Pretreatment with DTT did not alter 2A45CP toxicity. 2A45CP toxicity was reduced by pretreatment with GSH and ascorbic acid. These findings indicate that 2A45CP is directly toxic to renal cortical slices and that cytotoxicity is at least partially mediated by a reactive intermediate. (Supported by NIH Grant ES08834).

394 NEPHROTOXIC EFFECTS OF THE R- AND S-ENANTIOMERS OF N-(3, 5-DICHLOROPHENYL)-2-HYDROXYSUCCINIMIDE (NDHS) AND ITS SULFATE CONJUGATE.

G. O. Rankin, D. K. Anestis, H. Sun, T. W. Crislip, A. S. Casto, J. G. Ball and M. A. Valentovic. *Pharmacology, Marshall University, Huntington, WV.*

The agricultural fungicide N-(3, 5-dichlorophenyl)succinimide (NDPS) induces nephrotoxicity characterized by polyuric renal failure and proximal tubular necrosis. Recent findings suggest that NDPS nephrotoxicity is mediated, at least in part, through sulfate conjugates of oxidative NDPS metabolites. We have also shown that the stereochemistry of NDPS metabolites may also be an important determinant for NDPS nephrotoxicity. The purpose of this study was to determine if stereochemistry is a factor in the nephrotoxicity induced by an NDPS metabolite N-(3, 5-dichlorophenyl)-2-hydroxysuccinimide (NDHS) *in vivo* or the O-sulfate conjugate of NDHS (NSC) *in vitro*. Male Fischer 344 rats (4/group) were administered R- or S- NDHS (0.05, 0.1 or 0.2 mmol/kg) or vehicle ip. Renal function was then monitored for 48 hr. R-NDHS (0.1 or 0.2 mmol/kg) had little effect on renal function, with only minor changes in glucosuria, proteinuria and elevated blood urea nitrogen (BUN) noted at the higher dose level. In contrast, S-NDHS induced minor renal effects at 0.05 mmol/kg, but marked nephrotoxicity at 0.1 mmol/kg. The nephrotoxic potential of R- and S-NSC (0.5, 0.75 or 1.0 mM) was determined using freshly isolated renal cortical cells (3-4 million cells/ml) from untreated male Fischer 344 rats. Cytotoxicity was determined by measuring lactate dehydrogenase (LDH) release at the end of a 60-min incubation. R-and S-NSC-induced LDH release was similar at all concentrations tested, with R-NSC increasing LDH release slightly more than S-NSC at the 1.0 mM level. These results support the conclusion that stereochemistry is a factor for NDPS metabolite nephrotoxicity and that the role of stereochemistry occurs outside the kidney for nephrotoxic sulfate conjugates. Supported by NIH grant DK31210.

395 METALLOTHIONEIN ISOFORM 3 AND PROXIMAL TUBULE VECTORIAL ACTIVE TRANSPORT.

D. kim[1], S. H. Garrett[1], M. A. Sens[2], S. Somji[1] and D. A. Sens[1]. *[1]Urology, West Virginia University, Morgantown, WV and [2]Pathology, West Virginia University, Morgantown, WV.*

Metallothionein isoform 3 (MT-3) has been shown to be expressed in the proximal tubule cells of the human kidney. The goal of the present study was to further characterize the basal expression of MT-3 in the proximal tubule and to determine if MT-3 participates in the maintenance of proximal tubule cell function. Expression of MT-3 mRNA was determined in the intact proximal tubule using microdissection and RT-PCR. MT-3 mRNA was detected in the proximal tubule of the *in situ* kidney with relative expression in excess to that of the beta-actin housekeeping gene. The mortal HPT cells were shown to express both MT-3 mRNA and protein and to form domes, while the immortal proximal tubule cell line HK-2, was shown to have no expression of MT-3 mRNA and protein and did not form domes. The stable transfection of MT-3 in the HK-2 cells restored MT-3 expression and dome formation in these cells. These results demonstrate that MT-3 mRNA is present in the human proximal tubule and suggest that MT-3 expression is involved in the transport function of a human renal cell line that retains properties of the proximal tubule.

396 DIFFERENT EFFECTS OF OCHRATOXIN A AND B ON ENZYME ACTIVITY *IN VITRO*.

D. R. Dietrich[1], M. E. Stack[2] and K. Stemmer[1]. *[1]Environmental Toxicology, University of Konstanz, Konstanz, Germany and [2]USFDA, Washington, DC.*

Ochratoxin A is a toxic secondary metabolite produced by several Aspergillus and Penicillium species. It has been reported to be primarily nephrotoxic and causally related to urinary tract tumors. Effects in the liver have also been reported. Several studies have shown the influence of OTA on hepatic glycogen levels but with contradicting results. On the one hand OTA has been demonstrated to cause hyperglycemia *in vivo*, while on the other hand, other groups have observed decreased activity of glycogenolytic enzymes *in vitro*, following OTA exposure. The glycogen content of the kidney is suggested to play an important role in the provision of energy, especially under the anaerobic conditions of the inner medulla. Thus, an influence of OTA on renal glycogen levels could be involved in its nephrotoxic action. Nothing is known about the influence of the less toxic analogue, OTB on either renal or hepatic carbohydrate metabolism. As the muscle phosphorylase is predominant in the rat kidney and also dominant in the kidneys of several other species, the influence of OTA on this isozyme was studied. OTA and OTB were covalently coupled to horseradish peroxidase (HRP) and used similarly to an antibody for dot blot analysis of glycogen phosphorylase binding. Enzyme-binding was observed for both substances. Phosphorylase itself cannot be measured directly thus, activity was measured using a combined optic test with glucose-6-phoshate-dehydrogenase (Glu-6-PDH) as indicator enzyme. Inhibition of the enzyme reaction was observed only with high (>75µM) OTA concentrations. This "inhibition" was however, actually due to inhibition of the indicator enzyme Glu-6-PDH. In contrast, Glu-6-PDH was not inhibited by OTB. The findings of this study yield no clear evidence of a specific influence of OTA on kidney carbohydrate metabolism but suggested OTA to be able to influence enzyme-activity in general. Moreover they support the strict structural requirements for OTA and OTB activity, implying either a weaker binding to, or faster dissociation of OTB from the enzyme.

397 SEX- AND AGE-SPECIFIC EFFECTS OF OCHRATOXIN A IN PRIMARY HUMAN KIDNEY CELLS (HKC).

P. Wolf[1], E. O'Brien[3], A. H. Heussner[1], M. E. Stack[2], R. Thiel[3] and D. R. Dietrich[1,4]. *[1]Environmental Toxicology, University of Konstanz, Konstanz, Germany, [2]USFDA, Washington, DC, [3]Urology, Klinikum Konstanz, Konstanz, Germany and [4]EUREGIO Ecotoxicology Laboratory, EESL, Konstanz, Germany.*

OTA has been demonstrated to be nephrotoxic and carcinogenic in rodents and nephrotoxic in pigs, with distinct species- and sex-differences in susceptibility. Chronic dietary intake of ochratoxin A (OTA) *via* contaminated food, leading to serum concentrations in the nM range, has also been associated with increased incidences of urothelial tumors (UT) and nephropathy in humans (e.g., Balkan Endemic Nephropathy, BEN). Epidemiological studies of the regions endemic for

BEN and UT have suggested that women are slightly more affected than men. Previous results in our laboratory have indicated OTA to disrupt the cell cycle of primary porcine renal epithelial cells. Therefore, to investigate the mechanism(s) of OTA-induced nephropathy and cancer in humans, the antiproliferative and cell cycle effects of exposure to OTA (18 and 48 hrs) were investigated in primary human male and female renal epithelial cells (HKC). To assess potential age- and sex-related differences in sensitivity to OTA, cells from both sexes and from several age groups were investigated. Average donor ages were 65.8 ± 9.6 (n=4) and 62.5 ± 13.6 (n=4) for male and female respectively. A further sample was obtained from a 14 year-old male donor. Following cell preparation from biopsy material and characterization for epithelial origin, the antiproliferative effects of OTA were determined using a standard nuclei counting procedure (crystal violet). First statistically significant proliferative arrests were found after 48 hrs at concentrations as low as 10 nM (female) and 50 nM (male) OTA. HKC obtained from the 14 year-old boy were more sensitive than those from all other male donors, showing first effects at 10 nM OTA. These results imply female HKC to be slightly more sensitive to OTA than their male counterparts and furthermore, suggest that children may be more susceptible to the toxic effects of OTA.

398 CYTOTOXICITY OF OTA AND OTB IN HUMAN AND PORCINE RENAL CELLS AFTER REPEATED EXPOSURE.

A. Heussner[1], E. O'Brien[2], M. Stack[3], R. Thiel[4] and D. R. Dietrich[1,2].
[1]Environmental Toxicology, University of Konstanz, Konstanz, Germany, [2]EUREGIO Ecotoxicology Laboratory, EESL, Konstanz, Germany, [3]USFDA, Washington, DC and [4]Urology, Klinikum Konstanz, Konstanz, Germany.

Ochratoxins induce porcine nephropathy (PMN) and are thought to be responsible for a similar human disease, namely Balkan Endemic Nephropathy (BEN).Various mechanisms of toxic action have been proposed. Due to previous *in vitro* observations, showing that even after exposure to high concentrations of ochratoxins (≧ 10 μ M) a certain number of cells always survive, one thesis proposes that normal renal epithelial cells may be converted to fibroblasts following repeated exposure to ochratoxins. The aim of the study was to characterize the differences of these "resistant" cells compared to control cells.Thus, primary human and porcine renal epithelial cells were repeatedly exposed to acutely toxic concentrations of ochratoxin A (OTA) and its structural analogue ochratoxin B (OTB). For comparison with previous results, human (IHKE) and porcine (LLC-PK1) continuous cell lines were tested in parallel. Repeated (x3) exposures of ≧ 96 hours ensured survival of only the most resistant cells. These were used for further investigations and compared with untreated control cells.The morphology, growth behavior and protein constitution of all cells were subsequently characterized. In all cell types tested, cytotoxicity in control and resistant cells following exposure to OTA and OTB (nM - μ M), was assessed *via* the endpoints of MTT reduction (MTT), neutral red uptake (NR) and cell number analysis (CN).Using MTT or CN as endpoint, resistant cells displayed a cytotoxic response similar, but slower in onset to control cells. Interestingly, NR experiments showed that intracellular dye trapping was tremendously increased in resistant cells, suggesting these cells have undergone considerable changes with respect to an increase in acidic compartments and/ or altered membrane function. Our results support the aforementioned hypothesis that renal epithelial cells are fundamentally altered following chronic ochratoxin exposure.

399 SPECIES COMPARISON OF RENAL [^{3}H]OCHRATOXIN B PROTEIN BINDING AND UPTAKE *IN VITRO*.

E. O'Brien[1], A. H. Heussner[2], M. E. Stack[3], R. Thiel[4] and D. R. Dietrich[2,1].
[1]EUREGIO Ecotoxicology Laboratory, EESL, Konstanz, Germany, [2]Environmental Toxicology, University of Konstanz, Konstanz, Germany, [3]USFDA, Washington, DC and [4]Urology, Klinikum Konstanz, Konstanz, Germany.

The mycotoxins ochratoxin A and B (OTA, OTB) are known food and feed contaminants produced by certain Aspergillus and Penicillium strains. Chronic dietary intake has been associated with increased incidences of Porcine Mycotoxic Nephropathy, (PMN) and also of urothelial tumors (UT) and nephropathies in humans (Balkan Endemic Nephropathy, BEN). OTA has also been shown to be carcinogenic in rodents with distinct species and sex-differences. OTB, which differs from OTA only in the substitution of an H-group for a Cl-group, has been shown to be significantly less toxic than OTA both *in vivo* and *in vitro*. This fact raises the question whether structure-based differential binding to certain protein structures and/or differential transport mechanisms play a role in ochratoxin toxicity. The aims of this study were to investigate protein binding and uptake of OTB in both sexes of relevant species for comparison with OTA. Such differences could at least in part explain the observed variability in toxicity. [^{3}H]OTB uptake was measured in primary and continuous renal lines from the same species. Similar uptake patterns were apparent as previously noted for [^{3}H]OTA. Protein binding to renal cortex tissue homogenates from both sexes of four species (human, pig, rat and mouse), was assessed *via* a [^{3}H]OTB competitive assay. Specific saturable binding of OTB was observed to be consistently lower than that of OTA in both capacity and affinity. The same binding rank order was determined for both substances : human > rat > pig > mouse. Substances which have been demonstrated to inhibit OTA protein binding in a concentration-dependent manner such as BSP, indomethacin and furosemide, also inhibited OTB binding, however competition patterns differed from those of OTA.

400 COMPARISON OF OCHRATOXIN BINDING TO HUMAN, PORCINE AND RAT RENAL PROTEINS *IN VITRO*.

K. Stemmer[1], A. Heussner[1], M. Stack[2], R. Thiel[3] and D. R. Dietrich[1,4].
[1]Environmental Toxicology, University of Konstanz, Konstanz, Germany, [2]USFDA, Washington, DC, [3]Urology, Klinikum Konstanz, Konstanz, Germany and [4]EUREGIO Ecotoxicology Laboratory, EESL, Konstanz, Germany.

Ochratoxin A and B are found as contaminants in foodstuff and suspected of being one of the etiological agents responsible for Balkan endemic nephropathy (BEN) and urinary tract tumors. The dechloro- analogue, OTB is less toxic than OTA in animal studies, suggesting strict structure-activity requirements for toxicity. Ochratoxin A has previously been shown to bind to serum albumin and is also suspected to bind to cellular proteins of the kidney, which could be a prerequisite for toxicity. To detect these renal proteins, OTA and OTB were coupled covalently to horseradish peroxidase (HRP) and were used similarly to an antibody in Western Blot analysis. With this method it was investigated if variations in OTA and OTB binding to renal proteins could explain the observed structure- species- and sex- differences. Several proteins from rat, pig and human kidney as well as from proximal human kidney cells (HKC) were detected using OTA-HRP as staining method and displayed large intensity differences. Comparison of Ponceau S stained membranes with the signal obtained using OTA-HRP, showed that only a few of these proteins had an "above-average-binding" for OTA. This implies certain proteins to have a higher affinity for OTA binding than others.Proteins of approx. 33, 40, 63 kDa, which displayed this characteristic, were detected in all samples tested (male and female). Additional binding-proteins of 20 and 72kDa were detected in rat and human tissue respectively. HKC from both sexes displayed additional proteins of 105 and >250kDa. Similar, but weaker signals were detected with OTB. Addition of 15mM sulphobromophthalein (BSP), a substance previously shown to inhibit OTA binding, extinguished both the OTA-HRP and OTB-HRP signals. Phenylalanine or aspartame given separately at 15mM or in combination at 15mM, weakened the binding of both conjugates to human kidney proteins and to HKC but not to rat or porcine proteins.

401 DISRUPTION OF GLOMERULAR MESANGIAL AND VISCERAL EPITHELIAL CELL INTERACTIONS *IN VITRO* BY BENZO(A)PYRENE.

K. S. Ramos, N. F. Alejandro and J. K. Kerzee. *Center for Environmental and Rural Health, Texas A&M University, College Station, TX.*

Previous studies in this laboratory have shown that the adaptive response of rat glomerular cells to benzo(a)pyrene (BaP), a prototypical polycyclic aromatic hydrocarbon, is characterized by mesangial cell injury and unregulated proliferation of visceral epithelial cells (i.e. podocytes) *in vitro* and *in vivo*. These phenotypic profiles implicate disruption of critical glomerular mesenchymal/epithelial interactions following hydrocarbon challenge. To test this hypothesis, cytochrome (CYP) 1a1 and 1b1 gene expression and cellular proliferation in mesangial/podocyte co-cultures, or in response to conditioned medium, candidate mesenchymal-derived inhibitors of proliferation, including transforming growth factor beta 1 (TGFb1), prostaglandin E2 (PGE2), and nitric oxide (NO), and matrix cross plating experiments were conducted in clonal populations of mesangial cells (SCC1) and podocytes (SCC4E) challenged with 3μM BaP. Differential constitutive and inducible CYP gene expression and activities were observed in SCC1 and SCC4E treated with BaP, a pattern consistent with differences in susceptibility to BaP injury. SCC 4E proliferation was inhibited by SCC1 in direct and indirect co-culture. Denatured conditioned media also inhibited SCC4E proliferation, but no difference between control and BaP groups was observed. TGFb1 (0.01-0.5 nM), PGE2 (0.02-2μM) and NO (0.01-1 mM) did not influence SCC4E proliferation. Cross plating experiments demonstrated that the matrix deposited by SCC1 inhibited SCC4E proliferation. We conclude that disruption of mesenchymal/epithelial interactions by BaP may contribute to the loss of selective permeability induced by BaP *in vivo*. These alterations are reminiscent of the aberrant proliferation of podocytes observed in several forms of human glomerular disease. (Supported by ES 04917 and ES 09106).

402 SYSTEMIC UPTAKE OF INHALED ARSENIC IN RABBITS.

B. D. Beck[1], T. M. Slayton[1], C. H. Farr[2], D. W. Sved[3], E. A. Crecelius[4] and J. F. Holson[3]. [1]*Gradient Corporation, Cambridge, MA,* [2]*Atofina Chemicals, Philadelphia, PA,* [3]*WIL Research Laboratories, Ashland, OH and* [4]*Battelle Marine Sciences Laboratory, Sequim, WA.*

Human occupational exposure to sufficiently high levels of arsenic in air has been associated with lung cancer, but generally not other types of cancer. Thus, a better understanding of the relationship between airborne arsenic exposures and systemic uptake is essential. In this study, rabbits were exposed to one of four levels of arsenic trioxide in air for eight weeks (0.05, 0.1, 0.22, or 1.1 mg/m^3). Plasma levels of inorganic arsenic, monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA) were measured following the last exposure. Statistically significant increases in mean inorganic arsenic levels in plasma were observed only in male rabbits exposed to 0.22 mg/m^3, and in both males and females exposed to 1.1 mg/m^3. Mean inorganic arsenic levels in plasma in males and females exposed to 0.05 and 0.1 mg/m^3, and females exposed to 0.22 mg/m^3, were not significantly elevated compared to controls. These results suggest that arsenic inhalation has a negligible impact on body burden of inorganic arsenic until air levels are significantly elevated. Based on plasma measurements of inorganic arsenic, the two lowest exposure levels in this study (0.05 and 0.1 mg/m^3) are indistinguishable from background. These results have significant implications for risk assessments of inhaled arsenic. To the extent that an exposure has no discernible impact on body burden, attributing an incremental risk or directing risk management actions toward such an exposure would be inappropriate.

403 INORGANIC ARSENIC BIOTRANSFORMATION AND MITOCHONDRIAL TOXICITY IN HK-2 HUMAN PROXIMAL TUBULAR CELLS.

M. A. Peraza, M. J. Kopplin, D. E. Carter and A. J. Gandolfi. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Arsenic is an environmental toxicant and a human carcinogen. The kidney is a known target organ and is critical for both *in vivo* arsenic biotransformation and elimination. Thus the toxicity and metabolism of inorganic arsenic was investigated in an immortalized human proximal tubular epithelial cell line, HK-2. Subcytotoxic concentrations of arsenite (<10 μM) and arsenate (<100 μM) were determined by leakage of LDH from cells exposed for 24 hr. The threshold concentration of arsenite (1-10 μM) and arsenate (<25 μM) on the mitochondria was found by evaluating the metabolism of MTT. Biotransformation of inorganic arsenicals was determined in cells exposed to either arsenite or arsenate at the pre-determined subcytotoxic concentrations. Arsenic metabolites were detected in cell culture media and cell lysates using HPLC-ICP-MS, with a limit of detection of 0.5 ppb. No metabolites were detected in lysates or media following 6-hr exposures to either arsenical, indicating that metabolism of inorganic arsenic in these cells may be a slow event. A 24-hr exposure to arsenite resulted in minimal oxidation to arsenate in media (~5%), and only arsenite was detected in lysates. Exposure to arsenate resulted in its reduction to arsenite (~25%), with both inorganic metabolites detected in the media, and only arsenite detected in lysates. Pentavalent methylated arsenicals were not detected in media or lysates following exposure to either inorganic arsenical. However, the arsenic metabolites associated with the protein fraction of cell lysates or media have not been determined, and it is possible that some trivalent methylated metabolites may be present in that fraction. From these results it appears this human renal cell line is capable of biotransforming inorganic arsenic compounds, primarily reducing arsenate to arsenite. In addition, even at low concentrations, the mitochondria are a primary target for toxicity. (NIH ES04940)

404 DOSE-DEPENDENT BIOTRANSFORMATION OF ARSENITE IN RATS - NOT S-ADENOSYLMETHIONINE (SAM) DEPLETION IMPAIRS ARSENIC METHYLATION AT HIGH DOSE.

I. Csanaky, B. Nemeti and Z. Gregus. *Dept Pharmacol, Univ of Pecs, Med. School, Pecs, Hungary.*

Arsenite (AsIII) is eliminated by excretion and methylation. Monomethylarsonous acid (MMAsIII) is the most toxic metabolite of arsenic (As), while dimethylarsinic acid (DMAsV) produced in the next step is relatively atoxic. Methylation of As is carried out by SAM-dependent methyltransferases, which are inhibited by AsIII *in vitro*. Since the role of methylation in the toxicity and elimination of inorganic As is unclear, we have examined *in vivo* how excretion and tissue retention of AsIII and its metabolites change with increase of AsIII dose. Rats were injected iv with 20, 50, 125 μmol/kg AsIII and As metabolites in bile, urine and tissues were analyzed by HPLC-hydride generation-atomic fluorescence spectrometry. It was found that the excretion of AsIII *via* bile and urine and its tissue concentration increased proportionately or more to the dose, whereas the excretion and tissue concentrations of methylated metabolites (MMAsIII, monomethylarsonic acid, DMAsV) increased less than the dosage, or it even decreased after injection of the largest dose of AsIII. To elucidate the mechanism of the dose-dependent decrease of methylation, we dosed rats iv with 0, 20, 50, 125 μmol/kg AsIII and quantified SAM, S-adenosylhomocysteine (SAH), total glutathione (GSH), ATP, ADP and AMP in the liver 1 hr later. AsIII decreased in a dose-dependent manner the hepatic concentrations of GSH and ATP and the energy charge, but increased the level of SAM and SAH. Thus, the decrease of As methylation after injection of a large dose of AsIII cannot be due to SAM shortage, but may be caused by the concentration-dependent inhibition of the participating methyltransferases by AsIII. It appears that exhausted elimination capacity of AsIII, which results in AsIII retention in tissues, rather than MMAsIII produced from AsIII, is a main contributing factor in the acute toxicity of AsIII. After GSH depletion, the retained AsIII can increasingly inhibit SH-enzymes, thus causing ATP depletion and energetic disorder. (Supported by OTKA and the Hungarian Ministry of Health)

405 MITOCHONDRIA WORK AS REACTORS IN REDUCING ARSENATE TO ARSENITE.

I. Schweibert, B. Nemeti and Z. Gregus. *Dept of Pharmacology, University of Pecs, Medical School, Pecs, Hungary.*

Arsenate (AsV) is a structural analogue of phosphate (Pi), yet its toxic effect is likely due to its reduction to the more toxic arsenite (AsIII). The cellular and molecular mechanisms of this process are still unclear. Since mitochondria take up AsV like Pi, we studied whether these organelles reduced AsV to AsIII, and if they did so, what the characteristics of this process were. Rat liver mitochondria were isolated and incubated with AsV. AsV and its metabolites were then quantified by HPLC-hydride generation-atomic fluorescence spectrometry analysis of the deproteinized incubates. We found that mitochondria rapidly reduced AsV. Among the substrates supporting the citric acid cycle glutamate enhanced the reduction most effectively. ADP increased, whereas AMP and ATP decreased the AsIII formation. These effects could be prevented by atractyloside, an inhibitor of adenine nucleotide translocator. Electron transport inhibitors (rotenone, antimycin A, azide) and uncouplers (CCCP, dicumarol) abolished AsIII formation. ATP synthase inhibitors (oligomycin, aurovertin B) strongly but incompletely inhibited AsIII formation. Phosphate decreased AsIII formation in a concentration-dependent manner. Inhibitors of mitochondrial Pi transporters (mersalyl, N-ethyl-maleimide and butylmalonate) abolished AsIII formation. Compounds transported by the also Pi-moving dicarboxylate carrier (sulfate, sulfite and thiosulfate) caused partial inhibition. AsIII was recovered completely from the supernatant of the mitochondrial incubate, suggesting that mitochondria exported all of the formed AsIII. Upon solubilization of mitochondria their AsV reducing activity was practically lost. Summarizing, our findings support the view that mitochondria work as reactors: they take up AsV, rapidly reduce it to AsIII and export this metabolite. Chemical impairment of the mitochondrial function or disruption of structure inhibits the biotransformation of AsV into AsIII in this organelle. (Supported by OTKA and the Hungarian Ministry of Health)

406 RAT LIVER CYTOSOL REDUCES ARSENATE TO ARSENITE IN THIOL- AND PURINE NUCLEOSIDE-DEPENDENT MANNER.

B. Nemeti and Z. Gregus. *Dept Pharmacol, Univ of Pecs, Med. School, Pecs, Hungary.*

As liver mitochondria reduce arsenate (AsV) to the more toxic arsenite (AsIII) (see the poster of Schweibert, Németi and Gregus), we examined if other cell fractions also carried out this process. Postmitochondrial supernatant (PMSN) was isolated from rat liver and incubated with AsV. AsV and its metabolites were analyzed by HPLC-HG-AFS. We observed that PMSN reduced AsV to AsIII only in the presence of a thiol. Dithiothreitol (DTT) supported the reduction much more effectively than glutathione. Membrane solubilising detergents enhanced AsIII formation. PMSN was separated into microsome and cytosol and AsV reducing activities of these fractions were measured. Only the cytosol reduced AsV. Phosphate (Pi) inhibited the cytosolic AsV reducing activity in a concentration-dependent manner. Mercurial thiol reagents also inhibited the process, indicating the involvement of a Pi-utilizing SH-enzyme. On searching for a reduction partner, it was found unexpectedly that oxidized pyridine nucleotides (NAD or NADP), but not their reduced forms, increased AsIII formation. Some other purine nucleotide derivatives, but not pyrimidine nucleotides, also increased the rate 2-3 fold. Examination of the effect of nucleosides and nucleobases on AsV reduction yielded dramatic results: purine nucleosides (inosine or guanosine) increased the rate 80-100 fold, whereas purine bases (hypoxanthine or guanine) decreased it 85-95%. Although the retentate obtained by ultrafiltration of cytosol was inactive, its AsV reductase activity could be regained by adding the filtrate or inosine or guanosine to the retentate, indicating that endogenous purine nucleosides were essential for AsV reduction by the cytosol. Thus, rat liver cytosol is able to reduce AsV to AsIII. The reduction requires the presence of an appropriate thiol as well as a purine nucleoside (inosine or

guanosine) and is inhibited by thiol reagents, the AsV analogue phosphate and purine bases. Identification of the cytosolic AsV reductase is presented in the accompanying poster (Gregus and Németi). (Supported by OTKA and the Hungarian Ministry of Health)

407 PURINE NUCLEOSIDE PHOSPHORYLASE (PNP) AS A CYTOSOLIC ARSENATE REDUCTASE.

Z. Gregus and B. Nemeti. *Dept of Pharmacology, University of Pecs, Medical School, Pecs, Hungary.*

The findings of the accompanying poster (Németi and Gregus) indicated that the arsenate reductase (AsVR) activity of rat liver cytosol is due to an SH-enzyme that uses phosphate (or its analogue arsenate, AsV) and a purine nucleoside (guanosine or inosine) as substrates. Such an enzyme is PNP that catalyses the phosphorolytic cleavage of 6-oxopurine nucleosides according to the following scheme: guanosine (or inosine) + phosphate « guanine (or hypoxanthine) + ribose-1-phosphate. Therefore, we tested the hypothesis that PNP is responsible for the thiol- and purine nucleoside-dependent reduction of AsV to AsIII by rat liver cytosol. AsIII formed from AsV was quantified by HPLC-hydride generation-atomic fluorescence spectrometry analysis of the deproteinized incubates. The following findings support the conclusion that PNP reduces AsV to AsIII, using AsV instead of phosphate in the reaction above: 1. Specific PNP inhibitors (CI-1000, BCX-1777) at a concentration of 1 μM completely inhibited cytosolic AsVR activity. 2. During anion-exchange chromatography of cytosolic proteins PNP activity perfectly coeluted with the AsVR activitiy, suggesting that both activities belong to the same protein. 3. PNP purified from beef liver catalyzed reduction of AsV to AsIII in the presence of dithiothreitol (DTT) and a 6-oxopurine nucleoside (guanosine or inosine). 4. AsVR activity of purified PNP (like cytosolic AsVR activity, see Németi and Gregus) was inhibited by phosphate (the substrate of PNP competing with AsV), guanine and hypoxanthine (products of PNP favoring the reverse reaction), mercurial thiol reagents (non-specific inhibitors of PNP) as well as CI-1000 and BCX-1777 (specific PNP inhibitors). Thus, PNP is responsible for the AsVR activity of rat liver cytosol in the presence of DTT. Further research should clarify the mechanism and the *in vivo* significance of PNP-catalyzed reduction of AsV to AsIII. (Supported by OTKA and the Hungarian Ministry of Health)

408 ARSENIC INDUCES ABERRANT GENE EXPRESSION DURING LUNG DEVELOPMENT: APPLICATION OF TOXICOGENOMICS.

J. S. Petrick[1], F. M. Blachere[2], O. Selmin[3], R. B. Runyan[4,5] and R. C. Lantz[4,5]. *[1]Department of Pharmacology and Toxicology, The University of Arizona, Tucson, AZ, [2]Department of Pediatrics, The University of Arizona, Tucson, AZ, [3]Department of Nutritional Sciences, The University of Arizona, Tucson, AZ, [4]The Center For Toxicology, The University of Arizona, Tucson, AZ and [5]Department of Cell Biology and Anatomy, The University of Arizona, Tucson, AZ.*

Arsenic is a known human carcinogen and exposure has been correlated with an increased incidence of lung cancers. Such studies strongly suggest that the lung is directly targeted by arsenic. Those exposed to arsenic through contaminated food and drinking water include pregnant women, with unknown developmental consequences in the fetal lung. We hypothesize that *in utero* exposure to inorganic arsenic causes altered gene expression leading to molecular and physiological changes in the lung. Pregnant Sprague-Dawley rats were exposed to 500 ppb sodium arsenite in the drinking water, from embryonic days one to eighteen. Subtractive hybridization of embryonic lung cDNA from control and treated day 18 embryos yielded 248 differentially expressed cDNA clones. Of 154 clones screened thus far, 93 are confirmed differentially expressed by Southern dot blot hybridization and have been sequenced. Dose and time dependent effects of arsenite on gene expression patterns in developing rat lung will be evaluated using a custom cDNA microarray, including the 248 clones from the subtractive hybridization. This custom microarray is also to include an additional 112 rat cDNA clones. Clones showing differential expression by cDNA microarray will be sequenced, and the expression of selected clones will be validated using Northern blotting and PCR. The effects of altered gene expression on lung development will then be assessed using specific probes to show localization of gene and protein expression. (Supported in part by the NIEHS Superfund Basic Research Program Grant P42 ES04940).

409 GENE EXPRESSION PROFILE OF ARSENITE-INDUCED SKIN TOXICITY: MECHANISTIC IMPLICATIONS FOR CARCINOGENICITY.

H. K. Hamadeh[1], K. J. Trouba[2], R. P. Amin[1], D. Germolec[2] and C. A. Afshari[1]. *[1]Intramural Microarray Center, NIEHS, Research Triangle Park, NC and [2]Laboratory of Toxicology, NIEHS, Research Triangle Park, NC.*

Human exposure to arsenic is associated with an increased incidence of cancer, in particular, skin cancer; however, mechanism(s) associated with AsIII-mediated toxicity and carcinogenesis at low levels of exposure remain elusive. Modulations in cell proliferation, oxidative damage, and DNA-repair fidelity have been implicated in AsIII-mediated toxicity, but the concomitant occurrence of these major events has not been demonstrated in response to arsenic exposure. We hypothesized the involvement of these alterations in arsenic-mediated human toxicity and investigated the time- and dose-dependent effects of arsenite (0.005-5μM, 1-24hr) in normal diploid human epidermal keratinocytes by performing cDNA microarray analysis to elucidate AsIII-mediated global gene expression changes. In addition, we examined biochemical (DNA synthesis) and physiological (cellular mitoses) changes in the proliferative response of NHEK to AsIII exposure in order to better correlate alterations in gene expression with cellular function. Our results indicate that AsIII exposure decreased transcripts associated with DNA repair (e.g. p53 and MSH5), and increased transcripts indicative of cellular response to oxidative stress (e.g. SOD1 and NAD(P)H oxidoreductase). AsIII modulated the expression of transcripts indicative of increased cell proliferation (e.g. FGFR4 and PKC), oncogenes, and genes associated with cellular transformation (e.g. Gro-1 and V-yes). These observations correlated well with DNA synthesis and mitotic measurements as AsIII treatment resulted in a dose-dependent increase in cellular mitoses at 24 hr and an increase in DNA synthesis at 48 hrs of exposure. The data presented here shows that arsenic results in gene expression indicative of decreased DNA repair, increased cell proliferation and oxidative stress. Many of the gene expression alterations reported here are indicative of novel pathways perturbed by AsIII which we hypothesize to play a major role in its mechanism of carcinogenesis.

410 ACTIVATION OF AP-1 IN UROTSA CELLS BY METHYLATED TRIVALENT ARSENICALS.

Z. Drobna[1], L. Jaspers[2], D. J. Thomas[3] and M. Styblo[1]. *[1]Pediatrics, UNC, Chapel Hill, NC, [2]Center for Environmental Medicine and Lung Biology, UNC, Chapel Hill, NC and [3]NHEERL, USEPA, Research Triangle Park, NC.*

Chronic exposures to inorganic arsenic (iAs) increase risks of various types of cancer in humans. However, mechanisms by which iAs causes cancer are unknown. Biomethylation is the major pathway for iAs metabolism in humans. Both trivalent and pentavalent iAs and methylated arsenicals are intermediates or final products in this pathway: iAsV -> iAsIII -> MAsV -> MAsIII -> DMAsV -> DMAsIII. Recent reports have shown trivalent methylated metabolites, methylarsonous acid (MAsIII) and dimethylarsinous acid (DMAsIII), to be more cytotoxic, genotoxic and more potent enzyme inhibitors than either iAsV or iAsIII, indicating that methylation increases toxic and carcinogenic potency of iAs. To further characterize the role of trivalent methylated metabolites in the toxicity and carcinogenicity of iAs, we have examined effects of iAsIII, MAsIII and DMAsIII on nuclear levels of proto-oncogenes c-jun and c-fos and on the activation of AP-1 in UROtsa cells, an SV-40 immortalized human urothelial cell line. Short-time (0.5 to 2 h) exposures to 0.1 to 5 μM iAsIII, MAsIII or DMAsIII significantly increased nuclear levels of p-c-jun and DNA-binding activity of AP-1. Western blot and EMSA/supershift analyses indicated that c-fos was not involved in activation of AP-1 by these arsenicals. Notably, MAsIII and DMAsIII were considerably more potent inducers of c-jun phosphorylation and AP-1 activation in UROtsa cells than was iAsIII. Western blot analyses of the MAPK enzyme family in cells exposed to trivalent arsenicals showed a significant increase in p-ERK but not in p-JNK or in p-p38 levels. The increase in p-ERK levels was more profound in cells exposed to MAsIII and DMAsIII and correlated with increased levels of p-c-jun. These results indicate that MAsIII and DMAsIII, toxic intermediates of arsenic metabolism, activate AP-1 in human urothelium and affect AP-1-dependent gene transcription. (This abstract does not necessarily represent policy of the USEPA.)

411 CARCINOGENICITY OF INORGANIC ARSENIC IN MICE: TUMORS AND PROLIFERATIVE LESIONS OF THE LIVER, ADRENAL, OVARY, UTERUS AND OVIDUCT IN MICE EXPOSED TO SODIUM ARSENITE DURING GESTATION.

M. P. Waalkes[1], J. M. Ward[2] and B. A. Diwan[3]. *[1]NCI at NIEHS, Research Triangle Park, NC, [2]NCI, Frederick, MD and [3]SAIC, Frederick, MD.*

Arsenic (As) is a known human carcinogen, but development of rodent models of inorganic As carcinogenesis has been problematic. Since gestation can be a period of high sensitivity to chemical carcinogenesis, we performed a transplacental carcinogenicity study in mice with inorganic As. Groups (n = 10) of pregnant C3H mice received drinking water containing As (as sodium arsenite; $NaAsO_2$) at 0 (control), 42.5 and 85 ppm As *ad libitum* from day 8 to18 of gestation. These doses where well tolerated. Dams were allowed to give birth, and offspring were weaned at 4 weeks and then randomly put into separate groups (n = 25) of males and females according to maternal dose. Offspring were observed for up to 104 weeks. A complete necropsy was performed on all mice and tissues were microscopically examined. In male offspring, there was a marked, dose related increase in hepatocellular carci-

noma incidence (control, 3 carcinoma/24 mice at risk; 42.5 ppm, 8/21; 85 ppm, 14/23) and in liver tumor multiplicity (tumors/organ; 5.6-fold over control at 85 ppm). A dose related increase in adrenal tumor incidence (control, 9/24; 42.5 ppm, 14/21; 85 ppm, 21/23) and multiplicity (2.2-fold over control at 85 ppm) and a dose related trend for increased lung tumor incidence also occurred in males. In females, dose-related increases occurred in incidence of ovarian tumors (control, 2/25; 42.5 ppm, 6/23; 85 ppm, 9/24), uterine proliferative lesions (moderate to severe cystic hyperplasia plus tumors; control, 4/25; 42.5 ppm, 13/23; 85 ppm, 15/24) and hyperplasia of the oviduct (control, 0/25; 42.5 ppm, 3/23; 85 ppm, 6/24). A dose related trend also occurred for increased lung tumor incidence. This study shows that inorganic As, as a single agent, induces tumors at multiple sites after transplacental exposure, and establishes inorganic As as a complete carcinogen in mice. The liver and lung are both target sites of As carcinogenesis in humans.

412 DIFFERENTIAL SENSITIVITY OF HUMAN AND MURINE KERATINOCYTES TO SODIUM ARSENITE: EFFECTS ON CELLULAR VIABILITY AND PROLIFERATION.

K. J. Trouba and D. R. Germolec. *NIEHS, Research Triangle Park, NC.*

Arsenic is a toxicant and carcinogen that poses a significant health risk in humans. Although the mechanisms contributing to arsenic-induced skin cancer are not completely understood, the generation of oxidative stress is thought to be central to the carcinogenicity of this agent. Based on evidence that arsenic has different biological effects on human, mouse, normal and transformed cells, this study addressed the hypothesis that arsenic-induced toxicity and cell proliferation are differentially modulated in normal human epidermal keratinocytes (NHEK) and immortalized keratinocytes (human HaCaT and mouse HEL30). To test this hypothesis, cellular viability was determined by quantifying neutral red uptake, and cell proliferation quantified by measuring [3H]-thymidine incorporation into DNA following short-term sodium arsenite exposure. The effect of glutathione depletion/enhancement on viability following arsenite exposure also was evaluated by addition of L-buthionine-[s, r]-sulfoximine (BSO) or *N*-acetyl cysteine (NAC) to culture media. Results indicate the LC_{50} for arsenite in NHEK, HaCaT, and HEL30 keratinocytes is approximately 5-10 μM. 3 μM arsenite enhances DNA synthesis > 100% in NHEK as compared to control (no arsenite) but has little effect on immortalized keratinocyte DNA synthesis. BSO increases arsenite-mediated cytotoxicity by reducing the LC_{50} to approximately 1-3 μM in all cell types examined, whereas NAC attenuates the viability enhancing effects of low concentrations of arsenite in NHEK. These data suggest that endogenous glutathione modulates the negative and positive effects of arsenite on cellular viability. Taken together, these findings indicate that normal human and immortalized human/mouse keratinocytes have differential sensitivities to arsenite-induced DNA synthesis but similar cytotoxicity profiles. These data further suggest that NHEK may provide an accurate *in vitro* model in which to study the role of oxidative stress in arsenic-induced skin cancer.

413 CHRONIC INORGANIC ARSENIC EXPOSURE IN MICE INDUCES HEPATIC GLOBAL DNA HYPOMETHYLATION AND OVER EXPRESSION OF THE ESTROGEN RECEPTOR GENE ALONG WITH REDUCED METHYLATION OF ITS PROMOTER REGION.

H. Chen[1], S. Li[2], J. Liu[1], B. A. Diwan[3], J. C. Barrett[2] and M. P. Waalkes[1]. *[1]NCI at NIEHS, Research Triangle Park, NC, [2]CCR, NCI, Bethesda, MD and [3]SAIC-Frederick, Frederick, MD.*

Inorganic arsenic (As) is a human carcinogen that targets the liver, but its mechanism is unknown. Many species, including humans, methylate As, consuming cellular methyl groups, which may perturb normal methylation. We find global DNA hypomethylation occurs during As-induced malignant transformation *in vitro* in rodent liver cells. DNA hypomethylation can increase gene expression, particularly when occurring in promoter region CpG sites, and may be a non-genotoxic mechanism of carcinogenesis. Thus, we extended our work to an *in vivo* system by exposing 129/SV male mice (6/group) to 0 or 37.5 ppm As (as $NaAsO_2$) in the drinking water for 48 weeks. Liver samples were examined for global DNA methylation, generalized aberrant gene expression, specific gene expression, and specific gene promoter region methylation. Exposure to As induced global DNA hypomethylation, as assessed by 5-methylcytosine content or methyl acceptance assay. Microarray analysis showed As induced a 2.5-fold increase in estrogen receptor-α (*ER*) gene expression. RT-PCR and immunohistochemistry confirmed As-induced increases in hepatic *ER* transcript and translation product, respectively. Estrogens can be carcinogenic, with tissue sensitivity linked to *ER* expression, and *ER* expression can be controlled by methylation. When the 13 CpG sites in the *ER* gene promoter region from hepatic DNA were examined by methylation specific PCR, all showed less methylation after As, and this was significant ($p < 0.01$) in 8/13 sites. Overall, 28.3% of the *ER* promoter region CpG sites were methylated in controls, but only 3.2% were methylated after As exposure. Thus, chronic As exposure *in vivo* can induce global DNA hypomethylation and hypomethylation of the promoter region of the *ER* gene. This likely increases *ER* expression and, as estrogens can be hepatocarcinogens, may be an early event in As carcinogenesis, at least in the liver.

414 ARSENIC IS AN ENDOCRINE DISRUPTOR, BLOCKING HORMONE-MEDIATED GENE REGULATION BY THE ESTROGEN AND GLUCOCORTICOID RECEPTORS *IN VIVO*.

J. W. Hamilton[1], J. E. Bodwell[1,2], R. C. Kaltreider[1], A. M. Davis[1], J. C. Davey[1], L. A. Kingsley[1] and J. P. Lariviere[1]. *[1]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH and [2]Physiology, Dartmouth Medical School, Hanover, NH.*

Arsenic (As) is an environmental agent of considerable human health concern in the US and around the world. Exposure to elevated drinking water As has been associated with increased risk of several cancers, vascular disease, diabetes, and reproductive / developmental problems. These risks have been shown to be elevated in populations with drinking water arsenic in the range near the current USEPA drinking water standard found in many areas of the US We previously reported that As(III) can act as an endocrine disruptor, almost completely blocking hormone-mediated activation of gene expression by the glucocorticoid receptor (GR) in cultured H4IIE rat hepatoma cells. We investigated these effects further in the current work. At the cell physiological level, As was shown to block GR hormone-mediated control of H4IIE cell growth. As was found to bind preferentially and nearly stoichiometrically to GR at extremely low (nM) doses using $^{73}As(III)$. Using various GR mutants in a GR deficient H4IIE-derived cell line, we also observed that the effects of As on GR signaling most closely mapped to the central DNA-binding domain of GR, which is highly conserved among steroid hormone receptors in the nuclear receptor superfamily. Based on this, we then examined whether As would disrupt estrogen receptor (ER)-mediated gene regulation. In cultured H4IIE rat hepatoma cells, 0.1-3 μM As(III) (4-18 hr) supressed estradiol induction of both native and artificial ER binding element (ERE)-containing genes. As(III) at non-overtly toxic doses (50-100 μmol/kg) also strongly suppressed ER-mediated estradiol induction of vitellogenin gene expression in 14 day chick embryo liver *in vivo*. These results indicate that As(III) targets both GR and ER, and possibly other steroid receptors, at doses that are directly relevant to elevated As levels in US drinking water. (NIEHS (SBRP) ES07373)

415 ARSENITE INDUCES MITOTIC ARREST AND APOPTOSIS IN SV40-TRANSFORMED HUMAN SKIN FIBROBLASTS.

J. C. States[1], J. J. Reiners, Jr.[2], J. G. Pounds[3], D. J. Kaplan[2], S. C. McNeely[1], B. D. Beauerle[1], P. A. Mathieu[2] and M. J. McCabe, Jr.[4]. *[1]Pharmacology & Toxicology, U. Louisville, Louisville, KY, [2]Environmental Health Sciences, Wayne State U., Detroit, MI, [3]Molecular Biosciences, Pacific Northwest National Laboratory, Richland, WA and [4]Environmental Medicine, U. Rochester, Rochester, NY.*

Chronic arsenic ingestion causes skin, bladder and liver cancer by an unknown mechanism. Arsenite is known to delay transit through M-phase in normal diploid human fibroblasts (NDHF). Compared to cycling or quiescent NDHF, continuously cycling SV40-transformed human fibroblasts (STHF) were observed to be hypersensitive to arsenite toxicity and the mechanism of this hypersensitivity was investigated. Five - 20 μM $NaAsO_2$ induced cytostasis in cycling NDHF but was not obviously toxic to non-cycling NDHF. Higher concentrations were overtly cytotoxic to both cycling and quiescent NDHF. Concentrations as low as 3 μM were cytotoxic to STHF. Phase microscopy of $NaAsO_2$-treated STHF suggested concentration-dependent accumulation of cells in mitosis undergoing apoptosis. Toxicity measured using AlamarBlue indicated the $NaAsO_2$ LD50 was 24.1 μM in cycling NDHF and 3.5 - 4.3 μM in the two STHF lines tested. Arsenite treatment of STHF with 0 - 10 μM $NaAsO_2$ induced concentration-dependent inhibition of cell proliferation, accumulation of cells with G2/M DNA content, and increased mitotic index. Induction of apoptosis was indicated by membrane blebbing observed by phase microscopy, by annexin V binding and by electron microscopy showing highly vacuolated cells containing chromosomes surrounded by intact blebbed cellular membranes. These results indicate that SV40 transformation sensitizes cells to arsenite induced mitotic arrest and induction of apoptosis in the mitotic cells. Supported NIH grants R25 RR12242, P30ES06639, R01 ES06460, R01 ES09392 and Commonwealth of Kentucky Research Challenge Trust.

416 TOXICITY OF PENTAVALENT AND TRIVALENT ARSENICALS IN HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS: ROLE OF PH.

W. A. Pott, S. A. Benjamin and R. S. Yang. *Center for Environmental Toxicology & Technology, Colorado State University, Fort Collins, CO.*

Chronic exposure to low levels of arsenic (As) in the environment has been associated with disorders of vascular endothelial cells (ECs) and a variety of cancers, including hepatic angiosarcoma, in which the cell of origin is the hepatic sinusoidal EC. The mechanisms underlying As-induced EC dysfunction and its carcinogenic effects remain unresolved. Under both physiological and pathological conditions, ECs can be exposed to an acidotic microenvironment, which is known to influence the progression of many diseases, including cancer. To investigate whether an acidotic microenvironment mediates the toxic effects of As in ECs, we evaluated, under conditions of normal physiological pH and acidosis, the toxicities of trivalent and pentavalent inorganic As and pentavalent methylated As metabolites. Human umbilical vein endothelial cells (HUVECs) were exposed to arsenate [As(V)], arsenite [As(III)], methylarsenate [MAs(V)], or dimethylarsinic acid [DMAs(V)] at concentrations in the milli- and micromolar ranges for 24 hours under conditions of 5% CO_2 or 20% CO_2, to achieve a culture medium pH of 7.4 or 7.0, respectively. HUVEC viability was assessed using the MTT assay. Preliminary results indicate that at pH 7.4, As(III), with an LC_{50} of 30 μM, was more toxic to HUVECs than As(V), MAs(V), or DMAs(V), with LC_{50}s of 7, 25, and 50 mM, respectively. At pH 7.0, the LC_{50}s of As(V), MAs(V), and DMAs(V) were similar to those at pH 7.4 (10, 15, and 75 mM, respectively). However, at pH 7.0, the LC_{50} of As(III) was 125 μM, approximately four times higher than at pH 7.4. These results suggest that acidosis may modulate the toxicity of trivalent As species in HUVECs. Evaluation of the toxicity of trivalent methylated As metabolites is also planned. This project is funded by the NCI (K08 CA72396-05) and ATSDR(U61/AT11881475).

417 POTENTIAL CELLULAR MECHANISMS FOR ARSENITE-INDUCED VASCULAR DISEASES.

N. V. Soucy[1], A. Barchowsky[1], L. R. Klei[1], J. W. Hamilton[1] and M. A. Ihnat[2]. *[1]Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH and [2]Cell Biology, University of Oklahoma Medical School, Oklahoma City, OK.*

Chronic, low level exposure to arsenite increases the incidence of proliferative vascular diseases, such as arteriosclerosis and ischemic heart disease. Arsenic-associated changes in blood vessels may contribute to the vascular components of diabetes and tumor growth. Angiogenesis is fundamental to most of these pathological changes and may underlie the vascular actions of arsenic. In support of this hypothesis, arsenite (0.033-1.0 μM) significantly increased blood vessel growth in an *in vivo* chicken embryo model. Above 1.0 μM, arsenite inhibited blood vessel growth. To examine potential mechanisms for these vascular effects, expression of the angiogenic genes, vascular endothelial cell growth factor (VEGF) and plasminogen activator inhibitor-1 (PAI-1), was examined in porcine aortic smooth muscle cell (SMC) cultures. Concentrations of up to 50 μM arsenite caused SMC to proliferate. Release of VEGF protein increased following a 24 h exposure to 5-25 μM arsenite. By 48 h, 1 μM arsenite caused significant VEGF release. Dose and time dependent changes in VEGF and PAI-1 mRNA levels were consistent with the changes in protein levels. However, VEGF expression continued to increase above 5 μM arsenite, while PAI-1 mRNA levels peaked at 2.5 μM arsenite and dropped to control levels by 10 μM. Arsenite levels increased hypoxia inducible factor (HIF) protein levels in a manner consistent with enhancement of the VEGF and PAI-1 promoter activity. Inhibitor studies demonstrated that arsenite stimulated oxidant formation and kinase cascades to increase HIF levels and angiogenic gene expression. Microarray analysis in human airway epithelial cells, demonstrated that exposure to arsenite (5 or 50 μM) for 4 h increased HIF mRNA levels by 1.8-3 fold. These data suggest that arsenite causes specific, dose-dependent effects on cell signaling that promote angiogenic responses, which contributes to pathologic vascular changes. *Supported by ES07373.*

418 EVALUATION OF *IN VIVO* ACUTE IMMUNOTOXICITY OF AN INORGANIC ARSENICAL, SODIUM ARSENITE, USING MURINE MODELS.

T. Sakurai and K. Fujiwara. *School of Life Science, Tokyo University of Pharmacy and Life Science, Tokyo, Japan.* Sponsor: M. Waalkes.

It has been well known that inorganic arsenicals are potent toxicans and carcinogens in humans and most animals. However, immunotoxic effects of them have not been well studied. In this study, we observed *in vivo* acute immunotoxicity of an inorganic arsenical, arsenite, using murine models. Sodium arsenite was administered intraperitoneally to male CDF1 mice aged 4 weeks at doses of 1.25-8.0 mg/kg (body weight) on day 0 and multiple immune functions of these mice were assessed until day 16. As results, a half numbers of mice were died when 8 mg/kg of arsenite were administered. The mice body weights were decreased significantly by arsenite in a dose dependent manner at doses of 1.25-4.0 mg/kg on days 1-2, and it returned to the control level on day 4. Administered arsenite was distributed to various organs, including spleen, thymus, liver, lung, kidney and heart, with similar kinetic changes determined by AAS; the maximum arsenic concentrations were detected on day 1 and they dropped slowly to the control level during 16 days. The weights of immune organs, spleen, thymus and liver, were significantly decreased by arsenite at doses of 1.25-4 mg/kg on days 1-2, and they returned to the control levels on day 4. However, it did not affect on lung, kidney, heart and Peyer's patch weights. 4-mg/kg arsenite also decreased significantly the numbers of splenocytes, thymocytes, peritoneal exude cells, peripheral blood leukocytes and erythrocytes of mice temporary on day 1, but it did not affect on alveolar macrophage and Peyer's patch lymphocyte numbers. Cellular lysosomal enzyme activity and nitric oxide production of peritoneal macrophages, and blatogenesis of splenocytes and thymocytes were inhibited by 4-mg/kg arsenite on day 1 although the functions of alveolar macrophages, Peyer's patch lymphocytes and bone marrow cells were not changed. Taken together, arsenite has significant *in vivo* immunotoxicity both quantitatively and qualitatively, and the immune organs are very sensitive to arsenic inhalations.

419 ARSENIC-INDUCED SELF-TOLERANCE AFTER CHRONIC EXPOSURE IN HUMAN PROSTATE EPITHELIAL CELLS.

E. Brambilia[1], W. E. Achanzar[1], M. M. Webber[2] and M. P. Waalkes[1]. *[1]NCI at NIEHS, Research Triangle Park, NC and [2]Michigan State University, East Lansing, MI.*

While acquired self-tolerance to arsenic (As) has been shown in many rodent cell lines, acquisition of As resistance in human cells appears difficult to induce. Acquired As tolerance is linked to As efflux, probably mediated by increases in glutathione (GSH) levels, glutathione S-tranferase (GST) activity and the participation of efflux pumps such as MRP and MDR. Thus, we studied chronic As exposure of a human prostate cell line (RWPE-1) and development of As tolerance. RWPE-1 cells were continuously exposed to 0 or 5 μM arsenite (As^{+3}) for 18 or more weeks. Acute toxicity of As^{+3} (0-100 μM; 48 h) was then assessed using the MTS assay. The acute LC_{50} of As^{+3} in chronic As exposed prostate epithelial (CASE-PE) cells was 43.8 ± 2.3 μM *versus* 17.6 ± 2.9 μM in control cells, a 2.5-fold increase. CASE-PE cells grown in As-free medium for 5 weeks retained As-resistance, indicating a stable change in phenotype. As accumulation over 24 h in cells exposed to 10 μM As^{+3} was markedly reduced in CASE-PE cells (5.4 ng As/10^6 cells) compared to control cells (66.6 ng As/10^6 cells). When As-loaded cells were placed in As-free media for 2 h, the rate of As efflux was 2.6-fold greater in CASE-PE cells than control. CASE-PE cells showed increased GSH levels (4.9-fold) and increased GST activity (1.4-fold). GSH depletion with buthionine sulfoximine or inhibition of GST with ethacrynic acid both abolished As tolerance in CASE-PE cells. Although As-tolerant cells did not show changes in *MRP* or *MDR* gene expression at the transcription level, probenecid and PSC833 (specific inhibitors of MRP and MDR, respectively) both abolished As-tolerance. Thus, human prostate epithelial cells chronically exposed to As acquire tolerance to As. The mechanism of this tolerance appears to involve increases in GSH levels and GST activity, but not increases in *MRP* or *MDR* gene expression, although the functionality of these pumps is key to maintaining resistance.

420 IS THERE A SPECIAL SENSITIVITY OF CHILDREN TO INORGANIC ARSENIC?

T. M. Slayton[1], T. A. Lewandowski[2], C. Petito Boyce[2] and B. D. Beck[3]. *[1]Gradient Corporation, Waunakee, WI, [2]Gradient Corporation, Mercer Island, WA and [3]Gradient Corporation, Cambridge, MA.*

For some chemical exposures, the period of early childhood represents a stage of development characterized by increased sensitivity. There has been recent interest in the possibility of enhanced child susceptibility to the toxic effects of arsenic. This work evaluated the available evidence addressing this concern. While metabolic differences between children and adults have been noted, the evidence is contradictory. For example, while a study in Northern Argentina observed some differences between children and adults, a study of children in Washington State did not observe age-related differences in arsenic metabolite patterns. Studies of the health effects of arsenic in children *versus* adults provide a more relevant basis for discerning age-related differences in susceptibility. In a Chilean population of children exposed to high levels of arsenic, dermal effects (i.e., hyperkeratosis, leuko-melanoderma) were associated with an estimated daily arsenic intake of 0.063 mg/kg-day. This dose-effect level lies within the dose range derived from studies reporting similar effects in adults, i.e., 0.01 to 0.1 mg/kg-day. Other findings of specific health effects in children, including hearing changes and neurological deficits, are inconsistent. These studies also have limitations which preclude determining a definitive role for

arsenic. Thus, the available data do not clearly demonstrate children have a special sensitivity to the toxicity of arsenic, particularly at the low levels of arsenic exposure typically found in the US.

421 THE PROTECTIVE EFFECTS OF ASCORBIC ACID AND FOLIC ACID ON ACUTE ARSENIC TOXICITY IN CULTURED MOUSE FIBROBLASTS.

L. Z. Crandall[1], R. H. Finnell[2] and R. L. Vorce[1]. [1]*Pharmacology, University of Nebraska Medical Center, Omaha, NE and* [2]*Institute of Biosciences and Technology, The Texas A&M University System Health Science Center, Houston, TX.*

The acute cytotoxic effects of arsenic can be modulated by a number of factors, including folic acid supplementation, glutathione status, and prior exposure to this metalloid. Based on the hypothesis that protective factors reverse arsenic-induced oxidative stress and/or alterations in cellular methyl metabolism, this study was designed to determine if the nutritional factors ascorbic acid (AA) and folic acid (FA) protect cultured cells against arsenic toxicity. Using the neutral red cytotoxicity assay, it was found that the antioxidant ascorbic acid at 10 and 30 μM significantly decreases the toxicity of 3 and 6 μM sodium arsenite (As) in C3H10T1/2 mouse fibroblasts. To determine if arsenic toxicity is influenced by the folic acid transporter Folbp2, primary fibroblast cell lines were created from Folbp2 +/+, +/-, and -/- embryos; the genotype of each cell type was corroborated by PCR screening. When exposed to As for 24 hours, Folbp2 null fibroblasts exhibit slightly more cytotoxicity than do wild type or heterozygous fibroblasts. The addition of 30 μM FA to Folbp2 null cells did not afford protection against arsenic toxicity. In contrast, the toxicity of sub-lethal concentrations of As was attenuated by FA in wild type cells. These results corroborate our earlier finding that FA protects SWV/Fnn fibroblasts from acute arsenic toxicity. In addition, it appears that this protective effect is dependent upon a functional Folbp2 gene. Because Folbp2 null mice exhibit an increased susceptibility to arsenic-induced neural tube defects, it is proposed that compromised Folbp2 function is a risk factor for arsenic-dependent toxicity secondary to compromised uptake of FA. Because exposure through drinking water and food is a major problem in many countries whose populations commonly are deficient in FA and AA, it is proposed that supplementation of these two nutrients might protect against As toxicity.

422 HEPATOPROTECTIVE EFFECTS OF *SEMISULCOSPIRA LIBERTINA* AND GARLIC ON THE LIVER DAMAGE INDUCED BY CARBON TETRACHLORIDE IN RATS.

T. W. Jeon[1], E. S. Lee[1], K. J. Kim[2] and H. J. Kim[1,2]. [1]*Efficacy and Safety Research Center for Traditional Oriental Medicines, Life Resources Center of Oriental Medicine, Kyungsan University, Daegu, South Korea and* [2]*College of Oriental Medicine, Kyungsan University, Daegu, South Korea.*

Semisulcospira libertina (Korean freshwater snail) has been used as a folk medicine for the treatment of various diseases such as jaundice, stomachache, dyspepsia, and diarrhea in the Eastern Asia. Also, garlic has many medicinal properties. This study was designed to investigate the hepatoprotective effects of *S. libertina* and garlic on the acute hepatotoxicity of carbon tetrachloride (CCl_4). Male Sprague-Dawley rats weighing 200-220 g were pretreated with dehydrated powder of *S. libertina* (2.1 g/kg, *po*; SL) and dehydrated powder mixture of *S. libertina* and garlic (3 g/kg, 7:3 ratio, *po*; SG) once daily for 3 consecutive days, given a single toxic dose of CCl_4 (1 g/kg in 5 ml/kg corn oil, *po*) and liver function determined 24 hr later. Liver damage was assessed by quantitating serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), sorbitol dehydrogenase (SDH), and alkaline phosphatase (ALP) activities as well as by histopathological examination. Pretreatments with SL and SG significantly decreased CCl_4-elevated ALT (48 %, 61 % respectively), AST (32 %, 47 %), and SDH (51 %, 76 %) activities, but had no effect on ALP. SL and SG have revealed hepatoprotective effects against CCl_4-induced histopathological changes such as severe necrosis, inflammatory cell infiltration and congestion in the central zone of hepatic lobule. SG enhanced the hepatic content of glutathione by 106 % compared with CCl_4 group, but SL increased to a somewhat lesser extent (65 %). These findings demonstrate that SL and SG have the hepatoprotective effect on CCl_4-induced liver damage.

423 HEPATOPROTECTIVE EFFECTS OF *SEMISULCOSPIRA LIBERTINA* AND GARLIC ON ACETAMINOPHEN-INDUCED LIVER DAMAGE IN MICE.

T. W. Jeon[1], E. S. Lee[1], Y. S. Lee[1], O. K. Han[1], K. J. Kim[2] and H. J. Kim[1,2]. [1]*Efficacy and Safety Research Center for Traditional Oriental Medicines, Life Resources Center of Oriental Medicine, Kyungsan University, Daegu, South Korea and* [2]*College of Oriental Medicine, Kyungsan University, Daegu, South Korea.*

Semisulcospira libertina (Korean freshwater snail) has been used as a traditional drug for the therapy of various diseases such as jaundice, stomachache, dyspepsia, and diarrhea in the Eastern Asia. Since the legendary medicinal properties, garlic has attracted scientific interests for several decades. The purpose of this study was to investigate the hepatoprotective effects of *S. libertina* and garlic on liver damage induced by acetaminophen (AA). Male ICR mice weighing 30-32 g were pretreated with dehydrated powder of *S. libertina* (3.5 g/kg, *po*; SL) and dehydrated powder mixture of *S. libertina* and garlic (5 g/kg, 7:3 ratio, *po*; SG) once daily for three consecutive days, given a single toxic dose of AA (450 mg/kg in saline, *ip*) and liver function determined 18 hr later. Liver damage was assessed by quantitating serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), and sorbitol dehydrogenase (SDH) activities as well as by histopathological examination. Pretreatments with SL and SG dramatically lowered AA-elevated ALT (94 %, 97 % respectively), AST (88 %, 89 %), and SDH (93 %, 93 %) activities. SL and SG have revealed hepatoprotective effects against AA-induced histopathological changes. SG enhanced the hepatic content of glutathione by 43% compared with control animals. The gene expression of TNFα mRNA on AA-induced liver damage was determined by RT-PCR. SL and SG markedly decreased the gene expression of TNFα mRNA induced by AA in mice. These findings demonstrate that SL and SG have the hepatoprotective effect on AA-induced liver damage.

424 EXTRACT OF *ASTRAGALI RADIX* DECREASES ACETAMINOPHEN-INDUCED HEPATOTOXICITY IN MICE.

Y. S. Lee[1], O. K. Han[1], T. W. Jeon[1], E. S. Lee[1], K. J. Kim[2] and H. J. Kim[1,2]. [1]*Efficacy and Safety Research Center for Traditional Oriental Medicines, Life Resources Center of Oriental Medicine, Kyungsan University, Kyongbuk Technopark, Daegu, South Korea and* [2]*College of Oriental Medicine, Kyungsan University, Daegu, South Korea.*

Astragali radix (AR) is one of the oldest and most frequently used crude drug for traditional medicine in many Asian countries. This study designed to investigate the hepatoprotective effects of the hot water-extracted AR against acetaminophen (AA)-induced hepatic damage in ICR mice. AA at the dose of 450 mg/kg *ip* produced liver damage in ICR mice. Pretreatment with AR significantly decreased serum enzyme activities of alanine aminotransferase, aspartate aminotransferase, and sorbitol dehydrogenase. However, concentration of hepatic glutathione did not show a significant change between the tested groups. We also investigated TNFα mRNA gene expression on AA-induced liver damage by RT-PCR. AA drastically induced TNFα mRNA gene expression in ICR mice. Pretreatment of mice with AR led to a marked decrease of TNFα mRNA gene expression. These data indicate that the protective effect of AR against AA-induced hepatotoxicity in mice appears to be related to the regulation of TNFα mRNA gene expression as well as biochemical alterations.

425 OLEANOLIC ACID INCREASES INOS AND TNF-A GENE EXPRESSION IN MACROPHAGES BY NF-KB ACTIVATION.

C. Y. Choi[1], J. Y. Kim[1], S. J. Park[1], K. J. Lee[2] and H. G. Jeong[1]. [1]*Pharmacy and Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea and* [2]*Biology, Cheonnam National University, Kwangju, South Korea.*

Oleanolic acid (OA), a pentacyclic triterpene acid, is reported to have anti-tumor activities; however, the mechanism underlying its anti-tumorigenic effects is poorly understood. To further determine the mechanism of OA, we investigated the effects of OA on the release of NO and TNF-a, and on the level of iNOS and TNF-a gene expression in mouse macrophages. We found that OA elicited a dose-dependent increase in NO and TNF-a production. Reverse-transcription polymerase chain reaction showed that the increased NO and TNF-a secretion were due to an increase in iNOS mRNA and TNF-a mRNA, respectively. Since iNOS and TNF-a transcription has recently been shown to be under the control of the NF-kB transcription factor, the effects of OA on NF-kB activation were examined using a transient transfection assay and an electrophoretic mobility shift assay (EMSA). Transient expression assays with NF-kB binding sites linked to the luciferase gene revealed that the increased level of iNOS mRNA and TNF-a mRNA induced by OA were mediated by the NF-kB transcription factor complex. Using DNA fragments containing the NF-kB binding sequence, OA was shown to activate the protein/DNA binding of NF-kB to its cognate site as measured by EMSA. These results demonstrate that OA stimulates NO and TNF-a release and is able to upregulate iNOS and TNF-a expression through NF-kB transactivation, which may be the mechanism, whereby OA elicits its biological effects.

426 ALPHA-HEDERIN AUGMENTS NITRIC OXIDE PRODUCTION AND GENE EXPRESSION IN MURINE MACROPHAGES.

H. G. Jeong. *Pharmacy and Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea.*

Alpha-Hederin (HD), a triterpene saponin, is reported to have antitumor activities; however, the mechanism underlying its therapeutic effects is not known. In this study, we examine the effects of HD on the release of nitric oxide (NO) and the

level of inducible nitric oxide synthase (iNOS) gene expression in mouse macrophages. HD elicited a dose-dependent increase in NO secretion. Reverse-transcription polymerase chain reaction showed that the increased NO secretion was due to an increase in iNOS mRNA. Transient expression assays with NF-kB binding sites linked to the luciferase gene revealed that the increased level of iNOS mRNA induced by HD was mediated by the NF-kB transcription factor complex. These results demonstrate that HD stimulates NO release and is able to upregulate iNOS expression through NF-kB transactivation, which may be a mechanism, whereby HD elicits its biological effects.

427 PREVENTION OF ACETAMINOPHEN-INDUCED LIVER TOXICITY BY *PLATYCODON GRANDIFLORUM* IN MICE.

K. J. Lee[1], S. J. Park[2], Y. S. Kim[3], Y. C. Chung[4], J. K. Seo[5] and H. G. Jeong[2]. *[1]Biology, Chonnam National University, Kwangju, South Korea, [2]Pharmacy and Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea, [3]Korea Research Institute of Chemical Technology, Taejon, South Korea, [4]Food Nutrition, College of Chinju, Chinju, South Korea and [5]R&D, Jangsaeng Doraji Co., Ltd., Chinju, South Korea.*

The protective effects of an aqueous extract from the roots of *Platycodon grandiflorum A.* DC (Campanulaceae), Changkil (CK), on acetaminophen (APAP)-induced hepatotoxicities and the possible protective mechanisms involved were investigated in mice. Pretreatment with CK prior to the administration of APAP significantly prevented the increase in serum alanine aminotransferase and aspartate aminotransferase activity and hepatic lipid peroxidation in a dose-dependent manner. APAP?induced hepatotoxicity was also essentially prevented as evidenced by liver histopathology. Hepatic glutathione levels and glutathione-S-transferase activities were not affected by treatment with CK alone, but pretreatment with CK protected the APAP-induced depletion of hepatic glutathione levels. The effects of CK on cytochrome P450 (P450) 1A2 and 2E1, the major isozymes involved in APAP bioactivation, were investigated. In microsomal incubations, CK effectively inhibited P450 1A2?dependent methoxyresorufin O?deethylase activities and the P450 2E1?dependent p-nitrophenol and aniline hydroxylase. The results suggest that the protective effects of CK against the APAP-induced hepatotoxicity may, at least in part, be due to its ability to block P450?mediated APAP bioactivation. [This work was supported by a grant of the Korea Health 21 R&D Project, Ministry of Health & Welfare, Republic of Korea; HMP-00-B-21600-0117]

428 THE HERBAL PRODUCT *SCHIZANDRA CHINENSIS* PROTECTS AGAINST LIPOPOLYSACCHARIDE (LPS)-INDUCED HEPATOTOXICITY IN FISCHER 344 RATS.

J. B. Ulreich, D. C. Caretto, C. R. Kundavaram, Z. M. Leibson, N. J. Young and P. Z. Nakazato. *Surgery, University of Arizona, Tucson, AZ.*

Estimates are that sales of herbal medicines exceeded $4 billion in 1999. A number of herbs are said to have beneficial effects on the liver but scientific evidence of their safety, efficacy and mechanism of action is limited or lacking. *Schizandra chinensis* (Schizandra) has traditionally been used in China for various ailments, from cough to amnesia, and has been touted as a treatment for liver disease. We previously showed that Schizandra protected precision-cut male Fischer F344 rat liver slices against chloroform toxicity *in vitro*. In this *in vivo* study, rats were gavaged daily for 7d with 500µl containing 50, 200, or 500µl of tincture of Schizandra or with 500µl saline (control). The 200µl dose is similar to doses recommended on the bottle for human usage. On day 8, each rat was given 16.66 mg/kg *E. coli* LPS *via* the tail vein along with another dose of Schizandra. After 24h, blood for preparation of serum was collected *via* heart puncture and one lobe of the liver was harvested and fixed in 10% buffered formalin. The other lobe was precision-cut and slices incubated at 37°C for 72h in a Vitron incubator. At 24, 48 and 72h, liver slices were harvested, weighed and assayed for potassium (K^+) and lactate dehydrogenase content as indices of viability. Treatment with Schizandra enhanced maintenance of viability (K^+ content) in liver slices from rats exposed to Schizandra with LPS compared to slices from rats treated with LPS alone. Potassium levels in rats treated with Schizandra and LPS were increased 31% (50 µl dose), 39%, $p<0.05$ (200 µl dose) and 20% (500 µl dose) in liver slices harvested at 48h. There were no significant differences in the weights of the rats in the different groups. These findings demonstrate that Schizandra administered *in vivo*, under the conditions tested, protected liver slices against LPS-induced hepatotoxicity. 429 INHIBITION OF 2-AMINO-1-METHYL-6-PHENYLIMIDAZO[4, 5-B]PYRIDINE (PHIP)-ASSOCIATED COLORECTAL CARCINOGENESIS BY NATURAL FOOD ANTHOCYANINS IN RATS INITIATED WITH 1, 2-DIMETHYLHYDRAZINE.

A. Hagiwara[1], H. Yoshino[1,2], M. Sano[1], S. Tamano[1], T. Koda[3], M. Nakamura[3], N. Ito[4] and T. Shirai[2]. *[1]Daiyu-kai Institute of Medical Science, Ichinomiya, Japan, [2]First Department of Pathology, Nagoya City University, Nagoya, Japan, [3]San-Ei Gen F.F.I. Inc., Toyonaka, Japan and [4]Nagoya City University, Nagoya, Japan.*

The potential of natural anthocyanin food colors, purple corn color (PCC), purple sweet potato color (PSPC) and red cabbage color (RCC), to modify colorectal carcinogenesis was investigated in male F344/DuCrj rats, initially treated with 1, 2-dimethylhydrazine (DMH) and receiving 2-amino-1-methyl-6-phenylimidazo[4, 5-b]pyridine (PhIP) in the diet. After DMH initiation, PCC, PSPC and RCC were given at a dietary level of 5.0% in combination with 0.02% PhIP until week 36. No anthocyanins-treatment-related changes in clinical signs and body weight were found. Incidences and multiplicities of colorectal adenomas and carcinomas in rats initiated with DMH (25%; 0.3) were clearly increased by PhIP (95%; 2.7). In contrast, lesion development was pronouncedly suppressed by PCC administration (30%; 0.3), and also moderately inhibited by PSPC (70%; 1.4) or RCC (50%; 1.0) treatment. Furthermore, in the non-DMH initiation groups, induction of aberrant crypt foci (ACF) by PhIP was significantly decreased by the RCC supplementation. The results thus demonstrate that while PhIP clearly exerts promoting effects on DMH-induced colorectal carcinogenesis, these can be reduced by PCC, PSPC or RCC in diet, under the present experimental conditions.

430 EFFECT OF DOSE, TIME, AND ROUTE OF ADMINISTRATION OF GENISTEIN ON RADIATION PROTECTION.

M. R. Landauer[1], V. Srinivasan[1], A. Shapiro[2], C. H. Takimoto[2], P. S. Wang[1] and T. M. Seed[1]. *[1]Armed Forces Radiobiology Research Institute, Bethesda, MD and [2]National Cancer Institute, Bethesda, MD.*

Radioprotective agents have applications in clinical and military settings, space flight, and radiation site cleanup. The estrogenic and antioxidant properties of the soy isoflavone genistein make it an ideal radioprotective candidate. This research investigated the radioprotective efficacy of genistein in CD2F1 male mice. Exp. 1: Mice were each administered a single subcutaneous (sc) dose of genistein either 1 hr or 24 hr before a lethal dose of gamma radiation (9.5-Gy cobalt-60 at 0.6 Gy/min). In both groups, mice either received saline, polyethylene glycol 400 (PEG) vehicle, or genistein at 3, 6, 12, 25, 50, 100, 200, or 400-mg/kg body weight. The 30-day survival rates in the groups treated 1 hr before irradiation were 6%, 13%, 13%, 0%, 0%, 6%, 6%, 6%, 13%, and 19%, respectively. Survival rates in the groups treated 24 hr before irradiation were 8%, 15%, 6%, 0%, 19%, 60%, 56%, 65%, 91%, and 85%, respectively. Thus, genistein did not provide radioprotection at any of the doses when given 1 hr before irradiation, doses of 25-400 mg/kg given 24 hr before 9.5 Gy afforded significant protection. Exp. 2: Mice that each received a single oral gavage of saline, PEG, or 400 mg/kg genistein 1 hr before 9.5-Gy irradiation had 30-day survival rates of 0%, 9%, and 3%, respectively; when given 24 hr before 9.5 Gy, survival rates were 3%, 9%, and 9%, respectively. Thus, a single oral dose of genistein was not radioprotective. Exp. 3: Mice received daily gavages of 100- or 400-mg/kg genistein for either 4 days before, 4 days after, or 4 days before and after irradiation at 9.5 Gy. Survival rates of mice receiving 100-mg/kg genistein were 0%, 0%, and 50%, respectively; for those receiving 400-mg/kg genistein, survival rates were 44%, 0%, and 69%, respectively; and for those receiving saline and PEG, survival rates were 0% and 19%, respectively. This research demonstrates that both a single sc dose and multiple oral doses of genistein protect mice from a lethal dose of gamma radiation.

431 SILYMARIN ATTENUATES THE HEPATOXICITY OF ALPHA-NAPHTHYLISOTHIOCYANATE.

D. A. Hill, S. Edwards, T. V. Martin, B. Gorham and Y. Hijji. *Biology, Morgan State University, Baltimore, MD.*

Silymarin, a polyphenolic flavonoid derived from milk thistle seeds, demonstrates anti-inflammatory and hepato-protective activity against certain toxicants. In rodents, the acute hepatotoxicity of alpha-naphthylisothiocyanate (ANIT) is inflammatory cell-dependent and mirrors that of drug-induced cholestasis in humans. Since silymarin has anti-inflammatory activity and recent studies suggest that it decreases the formation of ANIT-induced hepatic lesions, the hypothesis that silymarin affords protection against ANIT-induced hepatotoxicity was investigated. Male Sprague-Dawley rats were treated for 5 consecutive days with 0-50 mg/kg silymarin (oral). On day 6, the silymarin treated rats received 120 mg/kg ANIT (oral). Parameters of hepatotoxicity were determined 12 and 24 hours after ANIT

treatment. Rat livers were processed for histological analysis of zonal necrosis and plasma samples were collected for analysis of hepato-specific enzyme levels. The histopathological analysis of ANIT-induced liver injury was manifested as pronounced infiltration of neutrophils, overt necrosis to periportal parenchymal cells and injury to bile duct epithelium. In addition, ANIT treatment induces the increased expression of neutrophil associated adhesion molecules, elevated plasma levels of aspartate aminotransferase (AST, SGOT), alanine aminotransferase (ALT, SGPT), bilirubin, and decreased bile flow. The prophylactic administration of 50 mg/kg silymarin afforded hepato-protection against all parameters of ANIT-induced toxicity except bile flow. Importantly, the degree of neutrophil chemotaxis and induction of necrotic lesions was reduced. Moreover, the hepatic expression of adhesion molecules, such as ICAM-1, was decreased significantly. ANIT-induced elevation of plasma levels of ALT, AST, and bilirubin were reduced significantly by silymarin pretreatment. These data suggest that silymarin is protective against the neutrophil-dependent hepatotoxicity of ANIT by, in part, preventing the hepatic-accumulation of circulating neutrophils. (Supported by NIH Grant RR11606-05)

432 DEVELOPMENTAL EXPOSURE OF RATS TO DIETS CONTAINING PACIFIC OCEAN OR LAKE ONTARIO SALMON MODIFY LATER RESPONSES TO LPS.

N. M. Filipov[1,2], K. O. Brosch[1], Y. Xu[3], M. C. Craig-Schmidt[3], D. A. Lawrence[1] and R. F. Seegal[1]. [1]*Wadsworth Center, NY State Department of Health, Albany, NY, [2]CEHS, Basic Sci., College of Vet. Med., Miss. State University, Mississippi State, MS and [3]Nutrition and Food Sci., Auburn University, Auburn, AL.*

Fish contain fatty acids (FA), some of which (*i.e.* n-3) may be beneficial. However, there are large variations in FA content and speciation between fish species as well as in the same species from different waters. Because n-3 FA are anti-inflammatory, we sought to determine whether developmental exposure to diets containing salmon or salmon-extracted oil from either Pacific Ocean (PO) or Lake Ontario (LO) would, in the adult, modify the inflammatory response to LPS. From gestational day 6 through weaning, dams were fed diets containing 20% lyophilized PO or LO salmon, PO or LO oil derived from equivalent amounts of salmon, or control chow. Female offspring, 4 months old, were given LPS (100 µg/kg BW, *i.p.*) and blood was collected for up to 5 h. In control rats, LPS increased serum tumor necrosis factor alpha (TNF_α), interleukin 6 (IL-6), and nitric oxide (NO). However, in offspring of dams fed fish oil from either PO or LO, the TNF_α increase after LPS was diminished by 40%. At 3 h post LPS, rats fed PO oil diet had serum IL-6 lower than the rest. At 5 h, although greater than controls, serum IL-6 in rats fed PO oil was lower than in rats exposed to LO oil. Serum NO at 5 h post LPS was reduced by 70% only in the rats fed PO oil diets. Effects of PO and LO lyophilized salmon diets on serum cytokines and NO after LPS were similar, but less pronounced. FA analysis revealed that PO oil has 5-fold higher n-3/n-6 FA ratio than LO oil. In summary, PO oil is a more potent anti-inflammatory agent than LO oil due, at least in part, to the higher n-3 FA content of PO oil; these effects are long-lasting and are partially masked by other dietary constituents of fish. Thus, dietary FA manipulation early in life may alter sensitivity to inflammatory stimuli in adulthood. (Supported by NIEHS ES079102 and EPA82581201 to RFS; NIEHS ES05879 to NMF).

433 HUMAN PROSTATE CANCER CELLS TREATED WITH SAW PALMETTO EXTRACTS SELECTIVELY ACCUMULATE A BROWN PIGMENTED MATERIAL: CORRELATION WITH ALTERED CELLULAR PROLIFERATION AND MORPHOLOGY.

E. J. Yurkow, T. R. Ripper, M. G. Akbar and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

To determine the direct effect of commercially available saw palmetto berry extract on the viability and proliferation of human prostate cancer cells in culture, subconfluent cultures of the human prostate cancer cell line, LNCaP, were treated with increasing concentrations of aqueous extracts of saw palmetto oil. Cultures of a transformed human epidermal keratinocyte cell line (HaCaT) were treated in a similar manner for comparison. Following a 24-hour treatment period, the cells were labeled with bromodeoxyuridine and the viability and proliferation of the treated cells were determined using standard flow cytometric methods. Treatment of LNCaP cells with aqueous extracts of saw palmetto oil resulted in a concentration and time-dependent accumulation of a brown pigment within the cytoplasm of the cells. The appearance of this material within the cells was associated with alterations in cellular morphology and a dramatic decrease in the percentage of proliferating cells, without a major effect on the viability of these cells. The development of this pigmented material and its association with the inhibition of proliferation was much less pronounced in the HaCaT cell line, occurring at 10-fold higher concentrations. The results of the current study indicate that the beneficial effects of saw palmetto on pathological conditions of the prostate may be associated with the selective accumulation of this pigmented material in treated prostate cells and its inhibitory effect on cellular proliferation.

434 EFFECTS OF COMBINED QUERCETIN AND COENZYME Q_{10} TREATMENT ON THE OXIDATIVE STRESS PATHWAY IN NORMAL AND STREPTOZOTOCIN-INDUCED DIABETIC RATS.

J. B. Watkins, A. Coldiron and R. A. Sanders. *Medical Sciences, Indiana University School of Medicine, Bloomington, IN.*

Reactive oxygen species may be actively involved in the genesis of a number of pathological states such as ischemia-reperfusion injury, cancer, and diabtes, as well as the aging process. Our objective was to determine if combined dosing of quercetin and coenzyme Q10 (10mg/kg/day ip for 14 days) is beneficial or detrimental in the oxidative stress pathway of 30 day streptozotocin-induced diabetic Sprague-Dawley rats. Blood glucose concentrations were elevated in both normal and diabetic rats after quercetin treatment. Liver, kidney, and heart tissues were excised and the activities of catalase, glutathione reductase, glutathione peroxidase, superoxide dismutase, and concentrations of oxidized and reduced glutathione were determined. In the liver, superoxide dismutase, glutathione peroxidase, and levels of both oxidized and reduced glutathione were significantly decreased from the non-diabetic control, and these effects were not reversed when antioxidants were administered. In kidney, glutathione peroxidase activity was significantly elevated in the diabetic rats as compared to non-diabetic kidney, Antioxidant treatment did not return the enzyme activity to non-diabetic levels. In heart, catalase activity was increased in diabetic animals, and returned to normal by combined treatment with quercetin and coenzyme Q10. Cardiac superoxide dismutase was lower in quercetin and quercetin + coenzyme Q10 treated diabetic rats reversing the effect of diabetes. There were no adverse effects on the oxidative stress pathway after quercetin or coenzyme Q10 singularly or in combination. Quercetin may be effective in reversing some effects of diabetes, although the rise in blood glucose levels may limit the usefulness of therapy.

435 OXIDATIVE STRESS PARTICIPATES IN ACUTE LUNG INJURY AND ACTIVATION OF MITOGEN ACTIVATED PROTEIN KINASES (MAPK) FOLLOWING AIR POLLUTION PARTICLE EXPOSURE (PM).

E. S. Roberts[1], R. Jaskot[2], J. Richards[2] and K. L. Dreher[2]. [1]*College of Veterinary Medicine, NC State University, Raleigh, NC and [2]NHEERL, USEPA, Research Triangle Park, NC.*

Epidemiological reports suggest that PM is associated with increased rates of cardiopulmonary-related morbidity and mortality. *in vitro* studies have demonstrated insights into the mechanism of lung injury caused by PM. To further understand the mechanism of PM injury, we studied the *in vivo* effects of residual oil fly ash (ROFA) exposure on MAPK activation. The MAPK cascade regulates the activity of specific nuclear transcription factors that control genes involved in cell growth, differentiation, apoptosis, and inflammation. A 2×2 factorial arrangement of treatments was used in a randomized design (n=26 male Sprague-Dawley rats, 60-90 d of age). Factors included: 1) pre-treatment with either an intraperitoneal (IP) injection of 500 mg/kg dimethlythiourea (DMTU) or saline, thirty minutes prior to instillation (IT) and 2) IT with 0.5 mg/rat ROFA or saline. Bronchoalveolar lavage fluid was obtained at 24h for determination of cytotoxicity and inflammation. ROFA increased lactate dehydrogenase and induced neutrophilia at 24h post-exposure ($P < 0.05$). IP pre-treatment with DMTU inhibited both the cytotoxicity and neutrophilia ($P < 0.05$). Sixty-three male Sprague-Dawley rats (60-90 d of age) were then randomly assigned as previously described and whole lung samples were collected for analysis at 1h, 3h, and 24h. ROFA increased p-ERK levels at 3h and 24h ($P < 0.05$). These increases were attenuated by DMTU pre-treatment ($P < 0.01$). DMTU inhibited the ROFA induced p-ERK activity increase at 24h ($P < 0.01$). The inhibition of ROFA-induced injury, MAPK expression and MAPK activity by DMTU provides strong evidence that generation of oxidative stress is critical to ROFA-induced cytotoxicity. These data link *in vitro* and *in vivo* results and demonstrate an oxidative mechanism operating through molecular signaling pathways by which environmental factors cause lung injury. (This abstract does not reflect EPA policy.)

436 SUB-CHRONIC EFFECT OF METAL WORKING FLUIDS ON PULMONARY FUNCTIONS IN B6C3F1 MICE: ROLE OF VITAMIN E.

C. Kommineni, E. Kisin, A. Murray, C. A. Smith, T. Goldsmith, J. S. Reynolds, V. Castranova, D. G. Frazer and A. A. Shvedova. *PPRB, NIOSH, CDC, Morgantown, WV.*

Metal working fluids (MWFs) are widely used in many industries. Exposures to MWFs are known to cause a spectrum of respiratory effects like excessive cough and attendant secretary products, bronchitis and physical discomfort as evidenced

by tightness of chest. This lead us to examine if an inhalation exposure to a semi-synthetic neat MWF produces any morphological as well as functional alterations in the lungs of mice. Morphological/functional and antioxidant outcomes in lungs were studied after inhalation exposure to MWF of vitamin E deficient and sufficient mice. Mice were given vitamin E deficient or basal diets for 35 weeks. Inhalation exposure to MWF started after 18 weeks on respective diets. Mice were exposed to MWF for 85 individual exposures (17 weeks, five days a week, 6 hours a day). No morphological alterations were seen in the lungs of mice from the studied groups. However, functional deficits in breathing rate, peak inspiratory/expiratory flow, minute ventilation, and tidal volume, along with marked reduction in the lung levels of GSH, protein thiols and ascorbate were in evidence in mice maintained on vitamin E deficient diet. Mice maintained on sufficient diet and exposed to MWF had decreased tidal volume compared to respective controls. Exposure to MWF resulted in accumulation of peroxidative products, and reduction of ascorbate content in the lungs compared to vitamin E sufficient or deficient controls. The results of this study indicate that dietary vitamin E deficiency enhanced subchronic effect of inhalation exposure to MWF.

437 MECHANISMS OF UV INDUCED FREE RADICAL OXIDATIVE DAMAGE IN HUMAN SKIN FIBROBLASTS.

J. L. Matta[1], M. Morales[1], R. A. Armstrong[2] and H. D'Antoni[3].
[1]Pharmacology/Toxicology, Ponce School of Medicine, Ponce, Puerto Rico, [2]University of Puerto Rico, Mayaguez, Puerto Rico and [3]AMES Research Laboratory, NASA, Moffett, CA. Sponsor: J. Matta.

UV radiation induces the production of oxygen free radicals although there is limited understanding of mechanisms by which UV induces oxidative damage in human skin fibroblasts. We tested the hypothesis that acute exposure to environmental levels of UV radiation in Puerto Rico can cause oxidative damage to fibroblasts leading to apoptosis and necrosis. Environmental UV levels were measured over a period of two and half years and used to establish irradiation doses for human fibroblasts (CRL-2072) using an Oriel 1 KW UV Solar Simulator. Cells were irradiated with three doses: 0.28 (low dose), 0.36 (mean dose) and 0.44 (high dose=5.4 min) J/cm^2 and DNA adducts, DNA repair capacity, lipid peroxidation, apoptosis and necrosis measured. A low dose did not caused changes in guanosine and 2-deoxyguanosine (2dG). However, the mean dose resulted in increases of 407% and 43% in guanosine and 2-dG respectively. The high dose caused an increase of 331% and 34% in guanosine and 2dG, respectively and a 240% increase in lipid peroxidation. The DNA repair capacity of these cells increased after acute exposure to low and mean doses but decreased with a high UVA/UVB dose. Acute exposure to the equivalent of 1.5 hours of environmental levels of UV caused necrosis in all fibroblast cells. These results show that even a short-term, acute exposure to environmental levels of UV can cause substantial oxidative damage resulting in apoptosis and necrosis. Supported by NASA grant NAG-2-1176 to J.L.M.

438 N-ACETYLCYSTEINE PRETREATMENT DECREASES COCAINE AND ENDOTOXIN INDUCED HEPATOTOXICITY.

R. A. Labib, R. M. Turkall and M. S. Abdel-Rahman. *Pharmacology & Physiology, University of Medicine and Dentistry of New Jersey, Graduate School of Biomedical Sciences, Newark, NJ.*

Cocaine (COC) produces hepatotoxicity by a mechanism, which remains undefined, but has been linked to its oxidative metabolism. Endotoxin (lipopolysaccharide, LPS) is also a well-known cause of hepatic damage, due to glutathione (GSH) depletion and oxidative stress. Previously we have demonstrated that exposure to non-injurious doses of LPS dramatically increases cocaine mediated hepatotoxicity (CMH). N-Acetylcysteine (NAC) protects against oxidative stress and depletion of GSH. This study was conducted to investigate if NAC pretreatment inhibits LPS potentiation of CMH. For five consecutive days, male CF-1 mice were administered oral NAC (400 mg/kg) or sterile saline, followed an hour later with COC (20 mg/kg) or sterile saline. On the last day, four hours after the last COC or saline treatment, the mice were administered 12 x 10^6 EU LPS/kg or sterile saline. The mice were sacrificed 18 hours later by decapitation. For the COC alone and COC + LPS groups, NAC pretreatment, significantly decreased serum ALT and AST activities, indicating reduced liver injury. In addition, the blood GSH content in the COC alone and COC + LPS groups pretreated with NAC was 25% higher *versus* the mice pretreated with saline. Moreover, in all groups pretreated with NAC, hepatic GSH concentration significantly increased as well as the hepatic and blood glutathione peroxidase (GPx) and catalase (CAT) activities. In conclusion, the results demonstrate that NAC pretreatment exerted a protective effect against LPS potentiation of CMH.

439 AMELIORATION BY PHYSICAL CONDITIONING OF CARDIAC OXIDATIVE INJURY CAUSED BY CHRONIC NITRIC OXIDE SYNTHASE INHIBITION IN RAT.

K. Husain, T. M. Boley and S. R. Hazelrigg. *Surgery, Southern Illinois University School of Medicine, Springfield, IL.*

Many individuals with cardiac diseases undergo periodic physical conditioning with or with out medication. Therefore, this study investigated the interaction of physical training and chronic nitric oxide synthase (NOS) inhibitor (Nitro-L-Arginine Methyl Ester, L-NAME) treatment on blood pressure (BP), heart rate (HR) and cardiac oxidants/antioxidants in rats. Fisher 344 rats were divided into four groups and treated as follows: 1) sedentary control, 2) Exercise training for 8 weeks, 3) L-NAME (10 mg/kg, s.c. for 8 weeks) and 4) ET + L-NAME. The animals were sacrificed 24 hr after last treatments and hearts were isolated and analyzed. Physical conditioning resulted in a significant increase in respiratory exchange ratio (RER), cardiac NO production, NOS activity and endothelial eNOS and inducible iNOS protein expression. Training significantly enhanced cardiac GSH levels, GSH/GSSG ratio and up-regulation of cardiac CuZn-SOD, Mn-SOD, catalase (CAT) glutathione peroxidase (GSH-Px) activity and protein expression. Training also caused depletion of cardiac malondialdehyde (MDA) level, protein carbonyl content. Chronic L-NAME administration resulted in depletion of cardiac NO level, NOS activity, eNOS, nNOS and iNOS protein expression, GSH level, GSH/GSSG ratio and down-regulation of cardiac CuZn-SOD, Mn-SOD, CAT, GSH-PX activity and protein expression. Cardiac xanthine oxidase (XO) activity increased with enhanced MDA level and protein oxidation after L-NAME administration. The biochemical changes were accompanied by increased in BP and HR. Interaction of training and chronic NOS inhibitor treatment resulted in normalization of BP, HR and up-regulation of cardiac antioxidant defense system.It is concluded that physical conditioning attenuated the oxidative injury caused by chronic NOS inhibition by up-regulating the cardiac antioxidant defense system and lowering the BP and HR in rats(supported by AHA/IA grant # 0051395Z).

440 α-TOCOPHEROL OR INDOMETHACIN PRETREATMENT PREVENTS SEIZURE-INDUCED INCREASES IN F_2-ISOPROSTANES AND CITRULLINE.

D. Milatovic[1], R. C. Gupta[4], W. D. Dettbarn[2], T. Valyi-Nagy[1], J. Morrow[2,3] and T. Montine[1,2]. *[1]Pathology, Vanderbilt University, Nashville, TN, [2]Pharmacology, Vanderbilt University, Nashville, TN, [3]Medicine, Vanderbilt University, Nashville, TN and [4]Murray State University, Hopkinsville, KY.*

Free radicals, particularly the reactive oxygen or nitrogen intermediates, are thought to be involved in kainic acid (KA) toxicity, exacerbating excitotoxicity and exerting tissue damage. F_2-isoprostanes (IsoP) and F_4-neuroprostanes (NP) are highly accurate biomarkers of oxidant injury and are products of free radical-catalyzed peroxidation of arachidonic acid and docosahexaenoic acid, respectively. Activation of nitric oxide synthase (NOS), resulting in an increase of nitric oxide (NO) and citrulline, has also been suggested to be part of KA toxicity. As a measure of oxidative stress, lipid peroxidation and NOS activity, changes in IsoP, NP and citrulline levels were studied in the brain of C57Bl/6 mice exposed to intracerebroventricular administration of KA (1 nmol/5 µl). KA produced severe seizures in mice immediately after administration and a significant increase in IsoP (158%), NP (237%) and citrulline (249%) levels were seen 30 min following treatment compared to controls (100%). No significant increase in IsoP and citrulline levels were found in mice pretreated with α-tocopherol (100 mg/kg, i.p.) for 3 days or those exposed to indomethacin (inhibitor of cyclooxygenase, COX, 14 µg/ml of drinking water) for 2 weeks prior to KA treatment. These findings provide novel information about KA-induced excitotoxicity and the relationship of seizures to free radicals, COX and NO. (Supported by AG 05144, AG 16835 and ES04597).

441 IMMUNOCHEMICAL DETECTION AND LOCALIZATION OF MALONDIALDEHYDE-PROTEIN ADDUCTS IN THE SPLEENS OF ANILINE-TREATED RATS.

X. Wu, P. J. Boor and M. F. Khan. *Pathology, University of Texas Medical Branch, Galveston, TX.*

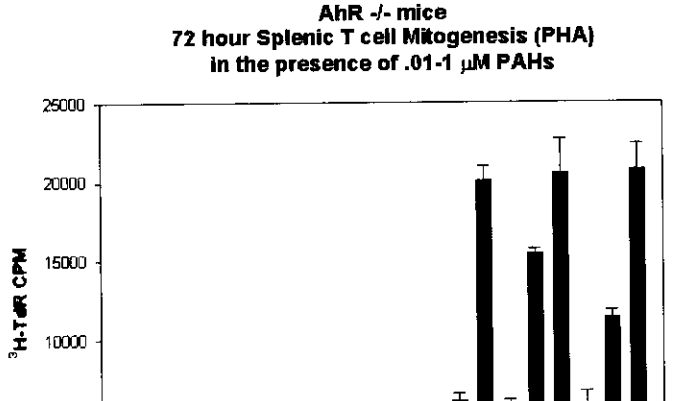
We have reported previously that aniline exposure in rats causes increased lipid peroxidation and formation of malondialdehyde (MDA)-protein adducts in the spleen. In order to further elucidate the role of MDA-protein adducts in the splenic toxicity of aniline, studies were conducted to detect and localize these adducts in the spleen. Rabbit polyclonal antisera to MDA-KLH were employed for Western blot analyses and immunohistochemical localization of MDA-protein addcuts in the spleens of aniline-treated (65 mg/kg/day aniline in the drinking water for 30 days) and control rats. Western blot analyses of splenic microsomal proteins from aniline-treated and control rats showed the presence of 13 MDA-modified proteins. However, 26, 32 and 44 kDa proteins were more prominent in the aniline-

treated rats. For immunohistochemical localization of MDA-protein adducts in the spleen, a new approach using alkaline phospharase-Fast red (red color) demonstration of bound primary antibodies was adopted, providing a sharper and increased contrast compared to horseradish peroxidase-diaminobenzidine (brown color) methodology. This new approach allowed us to differentiate the changes in aniline-treated spleens, which had extensive brownish deposits of iron. Spleens from aniline-treated rats showed intense staining for these adducts in the red pulp areas (where iron was also localized), especially within the sinusoidal macrophages. Spleens from control rats showed only mild staining. The co-localization of MDA-protein adducts with iron in the red pulp of the spleen provides a potential mechanism of splenic toxicity of aniline.

442 BENZO(A)PYRENE-QUINONES (BPQS) GENERATE REACTIVE OXYGEN SPECIES (ROS) AND ARE MITOGENIC IN LYMPHOID AND NON-LYMPHOID CELLS.

A. D. Burdick[1], K. J. Liu[1], M. K. Walker[1], M. D. Reed[2], M. Monske[1], F. T. Lauer[1] and S. W. Burchiel[1]. [1]*College of Pharmacy Toxicology Program, The University of New Mexico, Albuquerque, NM and* [2]*Lovelace Respiratory Research Institute, Albuquerque, NM.*

Previous studies have shown that quinones (diones) of benzo(a)pyrene (BaP) are formed in the presence of ultraviolet light and under the influence of various P450s and peroxidases. We have shown that BPQs are mitogenic in human lung epithelial cells (Reed et al, submitted) and human mammary epithelial cells (Burdick et al, submitted). We have also shown that BPQs generate reactive oxygen species (ROS) as detected using fluorescent ROS-reactive substrates including DCHF and DHE. In this presentation, we will compare the effects of BPQs on lung and mammary epithelial cells. In addition, we present new data indicating that BPQs are highly mitogenic in murine spleen cells, including those obtained from AhR -/- null mice. In these studies, AhR -/- spleen cells treated with 0.1-1 μM 3, 6-BPQ, 1, 6-BPQ, and 6, 12-BPQ had nearly a tenfold increase in cell proliferation in a 3-day T cell mitogen (phytohemagglutinin) culture. BaP (0.1-1 μM) was not immunosuppressive to T cell mitogenesis in AhR -/- spleen cells. The results of these studies demonstrate that mild oxidative stress in various lymphoid and nonlymphoid cells is mitogenic, perhaps owing to activation of the epidermal growth factor receptor (EGFR) in epithelial cells or other mitogenic receptors in lymphoid cells. This work was supported in part by NIH grant ES-05495, ES-07259, ES-10433, and P20 ES-09871



443 ROLE OF NITRIC OXIDE (NO) IN THE DEPLETION OF HIGH-ENERGY PHOSPHATES IN SKELETAL MUSCLES OF RATS ACUTELY EXPOSED TO DFP.

R. C. Gupta[1], D. Milatovic[2] and W. D. Dettbarn[3]. [1]*Toxicology, Murray State University, Hopkinsville, KY,* [2]*Pathology, Vanderbilt University, Nashville, TN and* [3]*Pharmacology, Vanderbilt University, Nashville, TN.*

The objective of this investigation was to determine the acute effects of the AChE inhibiting organophosphate compound DFP (1.5 mg/kg, s.c.) on citrulline (determinant of NO) and energy-rich phosphates (ATP and phosphocreatine) and their major metabolites in fast and slow skeletal muscles. Citrulline and energy metabolites were determined in perchloric acid extracts of muscles frozen *in situ* using HPLC methods. Analyses of controls revealed significantly higher levels of citrulline in the soleus (451.2±5.3 nmol/g), than in the EDL (381.3±8.2 nmol/g) or diaphragm (331.2±9.9 nmol/g). In contrast, the levels of ATP and phosphocreatine (PCr) were higher in EDL than in the soleus or diaphragm. Within 15 min of DFP exposure, with onset of fasciculations, citrulline levels were significantly elevated in all three muscles. Maximum increase in citrulline (272-288%) was noted after 60 min. At this time point, the levels of ATP, total adenine nucleotides (TAN), PCr, and total creatine compounds (TCC) were maximally reduced in all three muscles. The findings revealed that the increase in ROS (measured as increased NO synthesis) preceded the decrease of ATP in skeletal muscles. NO is known to exert neurotoxic effects primarily by depletion of cellular energy stores through multiple mechanisms, including inhibition of mitochondrial respiratory enzymes, particularly cytochrome-c oxidase, at a time when a greater utilization of ATP is necessary during muscle hyperactivity. Thus, it can be concluded that increased ROS generation may be the first step in the mechanisms involved in DFP-induced loss of energy metabolites, in addition to greater utilization of ATP, causing mitochondrial dysfunction and muscle neurotoxicity. (Supported by NIH grant, ES04597).

444 ACRYLONITRILE POTENTIATES NOISE-INDUCED HEARING LOSS: A CONSEQUENCE OF OXIDATIVE STRESS?

D. B. Rao, Z. Debebe, S. Klis and L. D. Fechter. *Center for Toxicology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Previous research from this laboratory (Rao, 2000; 2001) has shown that promotion of oxidative stress by asphyxiants + noise results in cochlea injury and auditory impairment. In this study we sought to determine whether acrylonitrile, an agent that significantly depletes glutathione would also promote noise-induced hearing loss. Acrylonitrile is commonly used in the production of plastics and synthetic fibers. It also ranks among the top 50 high volume chemicals produced in the US alone. Although acrylonitrile is a suspected human carcinogen, the neurotoxic effects are not clearly understood. In this study we determined the effects of acrylonitrile on auditory function and also on cochlear glutathione levels. Long Evans hooded rats were exposed to acrylonitrile, noise plus acrylonitrile, noise alone, and no experimental treatment (controls). Following a recovery period of three weeks, auditory thresholds were tested electrophysiologically. Results demonstrate that the auditory thresholds from animals administered acrylonitrile and exposed to noise had much higher thresholds than animals exposed to noise alone. Acrylonitrile produced no adverse effects on auditory function by itself. Spectrophotometric assay of glutathione levels in the cochlea following acrylonitrile administration demonstrates a marked reduction of glutathione compared to controls. We hypothesize that acrylonitrile potentiates noise-induced hearing loss by rendering the cochlea more sensitive to oxidative stress. Supported in part by ES08082.

445 OXIDATIVE STRESS INDUCED IN MURINE SPLENOCYTES AFTER EXPOSED TO MULTIPLE PESTICIDES *IN VITRO*.

H. P. Misra[1], C. L. Rabideau[1], F. Adeshina[2] and H. Choudhury[2]. [1]*Biomedical Sciences & Pathobiology, Virginia Tech, Blacksburg, VA and* [2]*Office of Research and Development, USEPA, Cincinnati, OH.*

The widespread use of pesticides in the environment increases the likelihood of multiple pesticide exposure, either concurrently or sequentially, over an organism's lifetime. This study examines both pro-oxidant and antioxidant status in murine (C57BL/6) splenocytes exposed to individual pesticides and pesticide mixtures, *in vitro*. The three insecticides of interest are lindane (Lin; an organochlorine), malathion (Mal; an organophosphate) and piperonyl butoxide (PBO; a synergist). These three pesticides were found to be cytotoxic to splenocytes in both concentration- and time- dependent manner. Based on minimum cytotoxicity ($\leq LC_{25}$), the following concentrations had been chosen for this study: 70μM Lind, 50μM Mal and 55μM PBO. The pro-oxidant and antioxidant statuses of the cells were monitored as indices of oxidative stress. The pro-oxidant hydrogen peroxide (H_2O_2) activity was monitored *via* the dichlorofluorescin diacetate assay. Exposure to pesticides for 15 minutes significantly increased H_2O_2 production above the controls: Mal 21.1%; Lind 10.8%; PBO 25.9%; Mal+Lind 26.8%; Mal + PBO 37.8%. The activities of superoxide dismutase and catalase levels in splenocytes were not significantly altered by these pesticides and their mixtures when exposed for 12 hrs. However, glutathione reductase (GSH-Rx) and glutathione peroxidase (GSH-Px) levels were significantly reduced when exposed to pesticide mixtures. Thus, GSH-Rx levels were found to be: control 51.7; Mal 48.2; Lind 50; PBO 52.3; Mal + Lind 40.5; Mal + PBO 42 Units/mg. The GSH-Px activity levels were found to be: control 44.9; Mal 30.2; Lind 30.6; PBO 32.4; Mal + Lind 21.1; Mal + PBO 21.1 Units/mg. These results indicate that exposure to mixtures of Mal, Lind and PBO

induces immunotoxicity, at least in part, *via* oxidative stress by both increased pro-oxidants and decreased antioxidants in cells in an additive manner compared to the individual pesticide exposures.

446 THE OXIDATIVE STRESS LEVELS OF WORKERS WHO HAVE POSSIBLE EXPOSURE TO MUNICIPAL INCINERATOR FLY ASH.

R. Yoshida[1], Y. Ogawa[1], I. Mouri[1], S. Yu[1], A. Nakata[1], R. S. Wang[1], S. Ueno[1], I. Shioji[2] and N. Hisanaga[1]. [1]*National Institute of Industrial Health, Kawasaki, Japan and* [2]*Shino-Test Corporation, Sagamihara, Japan.*

It is well known that municipal solid waste incinerator (MSWI) fly ash includes heavy metals, dioxins, polyaromatic hydrocarbons (PAH), and other organic materials. According to *in vitro* and animal studies, heavy metals and dioxins probably cause oxidative stress and PAH may also cause oxidative stress during metabolism in human body. In this study, we measured the levels of several oxidative stress markers in the blood and urine specimens of MSWIs workers and discussed whether the duration of exposure to MSWI fly ash was associated with the levels of oxidative stress markers. The subjects were 81 male workers (mean age 42.7) from four MSWIs in the same city. Written informed consents were given from all subjects. Occupational health doctors interviewed each subject about his job history, evaluated the exposure to fly ash, and calculated its total duration. The subjects were classified into four groups; those were Long duration of exposure to fly ash, Short duration of exposure to fly ash, Limited exposure to fly ash, and Control. Blood and urine specimens were obtained from subjects in the morning. The levels of 8-hydroxydeoxyguanosine (8-OHdG) in urine and in leukocytes were measured as oxidative DNA damage makers. Blood malondialdehyde (MDA) and lipid peroxides (LPO) levels, and total urinary biopyrrins level were also measured as oxidative stress markers. α-Tocopherol was measured as major antioxidant in serum. The mean levels of all markers were compared among four groups. Although the levels of all markers had no significant differences among groups, the tendency that the level of urinary 8-OHdG elevated with the increased duration of exposure to MSWI fly ash was significant. Considering this result, some chemicals contained in MSWI fly ash might have induced oxidative stress in the workers.

447 MODULATION OF PMN FUNCTION BY INCUBATION WITH HUMAN PLASMA FROM OXIDANT-CHALLENGED INDIVIDUALS.

E. Hoffer[1], A. Tabak[1], Y. Baum[1], A. Tamir[2], Y. Lerman[3] and T. Machamid[4]. [1]*Israel Poison Information Center, Rambam Medical Center, Haifa, Israel,* [2]*Dept Epidemiology, Faculty of Medicine Technion, Haifa, Israel,* [3]*Occupational Health, Sackler Faculty of Medicine, Tel Aviv, Israel and* [4]*Occupational Medicine, Kupat Holim Sick Fund, Afula, Israel.*

Polymorphonuclear leukocytes (PMN) play a fundamental role in the primary host defense against bacterial pathogens. It is possible that PMN function might be modulated by soluble immune mediators released into the blood stream due to oxidative stress. PMN from healthy volunteers were tested for the stimulated release of superoxide anions after being incubated with plasma of: 1. Welders and a matched (age and smoking habits) non-welders group 2. Smokers and non-smokers 3. Elderly and young individuals. The experiments showed that stimulated superoxide production was inhibited ($p<0.05$) by plasma from smokers as compared to that of non-smokers and by plasma from elderly individuals as compared to that of younger ones. There was no statistical difference between superoxide release from PMN incubated with plasma from welders as compared with that from an age and smoking habits non-welders matched group. These findings indicate that age and smoking induce the appearance in plasma of factors which affect neutrophil function. Determination of these factors could elucidate the mechanism of impaired immune response in elderly and oxidant-challenged individuals.

448 INDUCTION OF METALLOTHIONEIN SYNTHESIS BY MITOCHONDRIAL OXIDATIVE STRESS.

M. Kondoh, N. Futakawa, M. Takiguchi, M. Higashimoto and M. Sato. *Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Japan.*

Mitochondria is a major source of reactive oxygen species (ROS). The harmful effects of mitochondrial ROS have been implicated in the aging process and neurodegenerative diseases, but antioxidant systems against mitochondrial ROS are not fully understood. Metallothionein (MT), a cysteine-rich and metal-binding protein, is an efficient scavenger of oxygen radicals, such as superoxide and hydroxyl radicals, but the induction of MT by mitochondrial ROS have never been investigated. In this study, we examined the induction of MT synthesis by administration of mitochondrial-specific ROS generators such as antimycin A (AA), an electron transfer inhibitor, and 2, 4-dinitrophenol (DNP), an uncoupling agent. Subcutaneous administration of AA or DNP to mice significantly increased the hepatic MT concentration in a dose- and time-dependent manner. Administration of AA or DNP increased hepatic lipid peroxide production, and AA elevated mitochondrial lipid peroxide production in the liver. DNP or AA treatment elevated the hepatic lipid peroxidation and serum glutamine-pyruvate transaminase (GPT) levels. The inhibition of glutathione (GSH)Å@synthesis by L-buthionine-SR-sulfoximine (BSO) enhanced the liver injury caused by DNP or AA administration. Moreover hepatic MT concentrations of DNP- or AA-treated mice were increased by BSO-pretreatment. The intracellular accumulation of hydroperoxide by AA or DNP treatment in MT-/- fibroblast cells was higher than that in MT+/+ cells, suggesting that MT plays a role in regulation of intracellular reactive oxygen levels caused by mitochondrial stress. Taken together, these results suggest that mitochondrial oxidative stress induces MT synthesis, which may contribute to regulation of production of mitochondrial reactive oxygen.

449 GENERATION OF REACTIVE OXYGEN SPECIES IN BREAST-CANCER CELL CULTURES AFTER TREATMENT WITH CLARIFIED SLURRY OIL AND CRUDE OILS.

B. Yilmaz[1], D. O. Carpenter[1], J. Ssempebwa[1], C. R. Mackerer[3] and K. F. Arcaro[2]. [1]*School of Public Health, University at Albany, Rensselaer, NY,* [2]*Environmental Sciences, University of Massachusetts, Amherst, MA and* [3]*C&C, Consulting in Toxicology, Pennington, NJ.*

Clarified slurry oil (CSO), and two crude oil samples, Belridge Heavy Crude Oil (BHCO) and Lost Hills Light Crude Oil (LHLCO) were examined for their ability to generate reactive oxygen species (ROS) in human breast-cancer (MCF-7) cell cultures. Oil samples were prepared in DMSO resulting in extraction of virtually all of the aromatic hydrocarbons including the 3-7 ring polycyclic aromatic compounds (PACs) comprising 62.2% of the CSO, 9.0% of the BHCO, and 2.0% of the LHLCO by total weight. Generation of ROS was measured in a Coulter Epics flow cytometer using 20 μM dihydrorhodamine 123 (DHR), and cell viability was determined using 5 μM propidium iodide (PI). In the acute treatment experiments, single-cell suspensions were loaded with DHR and PI and then treated with the oil samples (1 ppm or 10 ppm). Measurements were made at 5, 15, 30, 60 and 90 minutes after addition of oil samples. In the chronic experiments, pre-confluent cell cultures were treated with oil samples for 6, 12, or 24 hours prior to preparing single-cell suspensions that were loaded with DHR and PI. Acute treatment with CSO, BHCO or LHLCO resulted in no increase in the generation of ROS as compared to the positive control, hydrogen peroxide. Chronic treatment with the CSO sample resulted in a significant increase in ROS at 24 hours. Treatment of cell cultures with a single polycyclic aromatic hydrocarbon, BENZO(A)PYRENE, resulted in a significant and concentration-dependent generation of ROS at 24 hours. (Supported by NIEHS Award RO1 ES049795-01A1 and TUBITAK-NATO).

450 OXIDATIVE DAMAGE TO RAT ERYTHROCYTE MEMBRANE LIPIDS AND SKELETAL PROTEINS BY MAQ-NOH, AN N-HYDROXY METABOLITE OF THE ANTIMALARIAL DRUG, PRIMAQUINE.

L. J. Bolchoz, D. C. McMillan and D. J. Jollow. *Dept. of Pharmacology, Medical University of South Carolina, Charleston, SC.*

We have shown previously that 6-methoxy-8-hydroxylaminoquinoline (MAQ-NOH), a potential human metabolite of the antimalarial drug, primaquine, is a direct-acting methemoglobinemic and hemolytic agent in rats. To examine the mechanism underlying the hemolytic activity, the present studies were undertaken to determine the effect of MAQ-NOH on rat erythrocyte sulfhydryl status, membrane lipids and skeletal proteins, and morphology under conditions known to commit the cells to premature removal from the circulation. Treatment of rat erythrocytes with MAQ-NOH (350-750 μM) depleted GSH with concomitant formation of glutathione-protein mixed disulfides. MAQ-NOH also induced a concentration-dependent formation of thiobarbituric acid-reactive substances and F2-isoprostanes, indicating the occurrence of lipid peroxidation. SDS-PAGE and immunoblot analysis of erythrocyte ghosts using an anti-hemoglobin antibody revealed that MAQ-NOH treatment had no effect on membrane skeletal proteins, despite a concentration-dependent increase in the content of membrane-bound hemoglobin monomer. Furthermore, scanning electron microscopy revealed that MAQ-NOH had no effect on red cell morphology. The data are consistent with the concept that MAQ-NOH induces erythrocyte membrane damage by an oxidative stress, however, the mechanism underlying its hemolytic activity may differ from that of other hemolytic N-hydroxylamines, such as dapsone hydroxylamine. Supported by NIH grant AI46424.

451 FREE RADICAL PRODUCTION AND OXIDATIVE STRESS IN CYCLOOXYGENASE-2 TRANSFECTED PC-12 CELLS.

J. F. Jiang, A. N. Osipov, I. Martin, A. A. Shvedova, R. Chen, S. H. Graham and V. E. Kagan. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Expression of cyclooxygenase-2 (COX-2) and production of prostaglandins are elevated after ischemia, while inhibition of COX-2 increases viability of neuronal cells. COX-2 has been reported to produce free radicals (e.g., arachidonic acid free radical (AA*;)), during its catalytic cycle and induce oxidative stress. Therefore, COX-2 may be a major contributor to oxidative stress during ischemia/reoxygenation. We have tested whether oxidative stress is enhanced in COX-2-transfected PC-12 cells. By spin trapping techniques, we observed and identified COX-2-dependent AA*; production. For COX-2 delivery, we incubated CHARIOT™; with recombinant COX-2 protein to yield a non-covalent complex, which was subsequently added to cells for internalization. Using Western blotting, we found that COX-2 protein amounts in PC-12 cells were significantly increased. The COX-2 activity was increased around 30-fold in transfected cells, as determined by a STAT-prostaglandin E2 EIA kit. We used the sensitive HPLC fluorescent technique based on metabolic integration of oxidation-sensitive fluorescent fatty acid, parinaric acid, into membrane phospholipids of cells to measure phospholipid peroxidation. After exposure of transfected PC12 cells to AA (50 µM, 15 min) only one phospholipid, phosphatidylserine, was preferentially oxidized. The AA-induced peroxidation could be partly blocked by a COX-2 inhibitor, NS-398, indicating that peroxidation is COX-2 dependent. To detect AA•, we used the spin trap -(4-pyridyl-1-oxide)-N-t-butylnitrone (POBN). Interaction of COX-2 and AA in the presence of POBN gives rise to an EPR-detectable pentyl radical spin adduct (with hyperfine splitting constants: aN = 15.80 Gs, aH = 2.66 Gs). This EPR signal was suppressed by a COX-2 inhibitor, nimesulide. Our observations demonstrate that COX-2 generated pentyl radicals may be responsible for oxidative stress associated with catalytic activity of the enzyme.

452 4-HYDROXYNONENAL METABOLISM IN ADULT AND PRENATAL LIVER SUBCELLULAR FRACTIONS.

E. P. Gallagher, J. L. Gardner and R. T. Pham. *Physiological Sciences, University of Florida, Gainesville, FL.*

A number of highly reactive unsaturated aldehydes are produced during cellular oxidative injury. Of these compounds, 4-hydroxynonenal (4HNE) is particularly abundant and highly cytotoxic due to its long half-life and its ability to form stable adducts with proteins and nucleic acids. In the current study, we examined the comparative metabolism of 4HNE by aldehyde-metabolizing enzymes in adult and second trimester prenatal liver subcellular fractions. The predominant biochemical pathways for 4HNE detoxification include alcohol dehydrogenase (ADH), aldehyde reductase (ALRD), aldehyde dehydrogenase (ALDH) and glutathione S-transferase (GST). The initial rates of cytosolic ALDH-catalyzed 4HNE oxidation, ALRD-catalyzed 4HNE reduction, and ADH-catalyzed 4HNE reduction were 8-, 2-, and 40-fold higher, respectively, in adult liver than in prenatal liver. Similarly, mitochondrial ALDH activities were 7-fold higher in adult liver than in prenatal liver. In contrast, affinity-purified cytosolic GST from adult and prenatal liver catalyzed the conjugation of 4HNE with glutathione at relatively similar rates. Our results suggest that second trimester prenatal liver has an overall lower ability to enzymatically detoxify 4HNE relative to adults. Furthermore, GST conjugation may be a particularly important pathway in protecting the fetus from transplacental prooxidant drugs or chemicals that generate 4HNE. Supported by NIH ES-09427.

453 RAPID ENRICHMENT OF INNER MITOCHODRIAL MEMBRANE WITH ALPHA-TOCOPHEROL FOLLOWING ACUTE VITAMIN E SUCCINATE ADMINISTRATION PROTECTS HEPATOCYTES FROM OXIDATIVE DAMAGE.

J. G. Zhang and M. W. Fariss. *Department of Pharmaceutical Sciences, Washington State University, Pullman, WA.*

Drug-induced liver injury has become the leading cause of acute liver failure resulting in the need for liver transplantation and in the withdraw of drugs from clinical use. Since scientific evidence supports mitochondria (MITO) as a critical site for the induction of oxidative stress and cell death in acute drug-induced hepatotoxicity, an attractive protection strategy would be to enrich hepatic mitochondria with the antioxidant, d-α;-tocopherol (T). Accordingly, we report that a single ip dose of d-α;-tocopheryl succinate (TS) can rapidly enrich MITO and inner mitochondria membranes (IMM) of rat liver with protective levels of T in contrast to acute T or tocopheryl acetate (TA) administration. The enrichment of MITO with T (*via* TS administration) eliminated MITO membrane susceptibility to lipid peroxidation and protected against Fe^{2+}-induced MITO permeability transition. In addition, hepatocytes isolated from TS pretreated rats were resistant to toxic oxidative damage caused by MITO toxicants such as rotenone and thenoyltrifluoroacetone, mitochondrial complex I and II inhibitors respectively, in combination with the glutathione inhibitor, diethyl meleate. In contrast, acute T administration, at an equimolar concentration enriched liver homogenates but not MITO or IMM with T and did not protect against MITO toxicant-induced oxidative hepatocyte death, indicating that mitochondria are a critical site for oxidative damage leading to acute cell death. We suggest that TS acts as a unique delivery system for T, rapidly accumulating in MITO and IMM to prevent mitochondrial damage and cell death. We propose that the acute administration of TS may prove useful for the therapeutic treatment or prevention of oxidative stress-mediated acute liver injury. Supported by NIH grant #R01ES05452 and Gasper and Irene Lazzara Foundation

454 CYCLOOXYGENASE-2 CONTRIBUTES TO OXIDATIVE STRESS INDUCED BY TEMPORARY FOCAL BRAIN ISCHEMIA.

V. A. Tyurin, Y. Y. Tyurina, S. H. Graham and V. E. Kagan. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

Focal cerebral ischemia is associated with a local inflammatory response that participates in the progression of ischemic brain injury. Cyclooxygenase-2 (COX-2) exacerbates ischemic injury of the brain. COX-2 catalyzes the formation of prostaglandins from arachidonic acid (AA) *via* cyclooxygenase/peroxidase cycle. Peroxidase reactions can generate radicals independent of AA metabolism. Thus COX-2 may contribute to oxidative stress during temporary focal brain ischemia. We found that total antioxidant reserves of rat brain as well concentrations of ascorbate and GSH were decreased after 6 and 24h of temporary focal brain ischemia in rats. A selective COX-2 inhibitor, SC58125, prevented depletion of ascorbate and GSH in ischemic rat brain. Next, we used COX-2 null and wild type mice to investigate the role of COX-2 in the mechanism of cerebral injury. We found that MCA occlusion induced a significant decrease of ascorbate and GSH in COX (+/+) but not in COX-2 (-/-) mice. In COX (+/+) mice, ischemia produced higher steady-state concentrations of ascorbate radicals in brain homogenates then in COX (-/-) mice or controls. Addition of AA to brain homogenates resulted in additional increase of ascorbate radical EPR signal. In line with this, the ascorbate radical EPR signal was significantly lower in brain homogenates of rats pretreated with SC58125 before ischemia (SC58125 did not affect ascorbate radical in the presence of a non-specific redox catalyst, Fe2+). Overall, our data suggest that COX-2 contributes to the generation of free radicals and oxidative stress after temporary focal brain ischemia.

455 PEROXYNITRITE FORMATION PRECEDES CELL DEATH IN MIDZONAL NECROSIS DURING LOW FLOW HYPOXIA TO PERFUSED RAT LIVERS.

J. R. Blattner[1,2], R. T. Currin[2], R. Schoonhoven[3] and J. J. Lemasters[1,2]. *[1]Curriculum in Toxicology, UNC-CH, Chapel Hill, NC, [2]Developmental and Cell Biology, UNC-CH, Chapel Hill, NC and [3]Environmental Sciences and Engineering, UNC-CH, Chapel Hill, NC.*

Low flow perfusion of isolated rat livers results in early hypoxic hepatocellular necrosis at the border between normoxic periportal and anoxic pericentral hepatocytes. This midzonal region is postulated to have increased superoxide production. Nitric oxide and superoxide undergo a diffusion-limited reaction to form peroxynitrite, a potent oxidant that has been shown to be produced in ischemic heart immediately after reperfusion. Our aim was to assess peroxynitrite formation in perfused rat livers during low flow hypoxia. Rat livers were perfused *via* the portal vein with Krebs-Heinseleit bicarbonate (KHB) buffer saturated with 95% O_2/5% CO_2 at 3-4 ml/min/g of liver. After 20 min of normoxic perfusion, flow rates were decreased to 0.6 ml/min/g for varying times (30, 60 and 120 min) . Subsequently, the livers were infused with KHB containing 0.5 mM trypan blue for 10 min and then with 2% paraformaldehyde in KHB for fixation. To detect peroxynitrite generation, nitrotyrosine adducts were identified by immunohistochemistry using rabbit polyclonal anti-nitrotyrosine antibody and a peroxidase detection system. After 30 min of hypoxia, an increase in hepatocellular nitrotyrosine labeling was observed in midzonal regions. Nitrotyrosine labeling increased further at one hour and was observed in both viable and non-viable hepatocytes, as assessed by trypan blue uptake. After two hours, nitrotyrosine labeling and necrosis expanded from midzonal regions into pericentral regions. Since nitrotyrosine labeling occurred in both viable and non-viable hepatocytes, we conclude that peroxynitrite formation began prior to cell death. We also conclude that both nitric oxide and superoxide are generated at the border between anoxic and normoxic tissue, which leads to peroxynitrite formation. This peroxynitrite generation may contribute to early midzonal necrosis during low flow hypoxia in the liver.

456 DELAYED INTERACTIVE EFFECTS OF SARIN, PYRIDOSTGMINE AND EXERCISE ON THE HEPATIC ANTIOXIDANT DEFENSE SYSTEM IN MICE.

M. Mehra, K. Husain, S. Verhulst, G. Trammell and S. M. Somani. *Pharmacology, Southern Illinois University, Springfield,, IL.* Sponsor: S. Somani.

Pyridostigmine (PYR), a reversible cholinesterase inhibitor, has been employed as a pretreatment drug for possible nerve agent exposure during the Gulf war. The Gulf war veterans were exposed to risk factors such as pesticides, medical agents and possible low levels of nerve gas. Physical stress may increase hepatic ROS production, leading to oxidative tissue damage. It is hypothesized that under stressful conditions during war, PYR and/or sarin could affect the antioxidant system in liver. Hence, this study investigated the interactive effects of PYR, low-dose sarin and exercise training on hepatic antioxidant defense system in mice. Male NIH Swiss mice were divided into eight groups and treated as follows: (1) Control; (2) Sarin [0.01 mg /kg, s.c.; 1/20 LD50]; (3) Exercise training; (4) Sarin plus exercise; (5) PYR [1.2 mg/kg, p.o.]; (6) PYR plus exercise; (7) PYR plus Sarin; (8) PYR plus Sarin plus exercise. Exercise was given for 10 weeks, however PYR and sarin were administered daily during 5th and 6th weeks. The animals were sacrificed 24 hours after the last treatments and livers isolated. SOD activity significantly decreased in groups 3 and 6 compared to control. Catalase activity were reduced significantly to 70%, 53% and 71% of control in groups 3, 5, and 6 respectively. GSHPx activity significantly reduced (70% of control) in Group 6. GR activity decreased in Groups 3 and 6 compared to control. Malondialdehyde significantly increased 124% and 173% of control in Groups 3 and 5 respectively. This study suggest that exercise (physical stress) plus PYR lead to significant alteration in antioxidant enzyme activity and lipid peroxidation, which may produce oxidative injury in hepatic tissue of mice. (In part supported by US Army contract # DMAD 17-97-C-70 and SIU School of Medicine)

457 FORMATION OF OXYGEN RADICALS AND RELEASE OF NITRIC OXIDE (NO) IN RATS UPON EXPOSURE TO HIGH LEVELS OF BLAST OVERPRESSURE: IS NO A MODERATOR OF CIRCULATORY OXIDATIVE STRESS?

N. V. Gorbunov. *Respiratory Research, Walter Reed Army Institute of Research, Silver Spring, MD.*

Exposure to blast overpressure (BOP) has been previously shown to result in lung injury characterized by alveolar rupture and pulmonary hemorrhage leading to oxygen insufficiency and oxidative stress (OxS) to the circulatory and cardiopulmonary systems. These events may induce a compensatory release of endogenous nitric oxide (NO), a vasodilator and antioxidant that, in turn, would decrease the extent of OxS *via* redox interaction between NO and circulatory oxygen radicals (OxR). To further examine this hypothesis, deeply anesthetized Sprague-Dawley rats were exposed to BOP shock waves of magnitude 100±10 kPa. After exposure, blood, lung, heart, liver, and spleen samples were analyzed for OxR formation using low-temperature EPR spectroscopy. Three distinct oxygen species: peroxyl radicals (PxR) (g = 2.027), alkoxyl radicals (AxR) (g = 2.015), and low-spin ferric-peroxide complexes (FerProx) (g = 1.978), as well as semidehydroascorbyl radicals (AscR) (g = 2.005, A_H = 2 G), were observed in blood and perfused lung at 10 min following BOP exposure. Release of NO was revealed by formation of nitrosyl hemoglobin in blood (with splitting constant for ^{14}N A_z = 17.2 G), and trapping of NO with iron-(dithiocarboxy)sarcosine complexes (DTCS2-Fe) in lung (adducts with $g_\perp$ = 2.042 and $g_\parallel$ = 2.020) at 20 min following BOP exposure. The release of endogenous NO was accompanied by disappearance of EPR signals of circulatory OxR species (AxR, PxR, and FerProx) and attenuation of the EPR signal of AscR. These observations suggest that endogenously released NO may moderate BOP-induced oxidative stress *via* interaction with circulatory OxR.

458 TOXICITY AND OXIDATIVE INJURY IN PC-12 CELLS TREATED WITH MN(II) AND MN(III).

D. R. DuBose and D. S. Barber. *Physiological Sciences, University of Florida, Gainesville, FL.*

Manganese (Mn) is an essential element, but excessive exposure causes neurotoxicity with symptoms similar to Parkinson's Disease. Despite much research, the mechanism of manganese neurotoxicity is still unknown. An area that has received relatively little attention is the impact of manganese speciation on toxicity. Manganese does not exist as a single species *in vivo*, but is found as ligated ions in the +2 and +3 oxidation states. Recent work suggests that Mn(III) may be more toxic than Mn(II), but the reason for this is unclear. Manganese(III) complexes are strong oxidants when compared to Mn(II) complexes, leading to the hypothesis that Mn(III) is more toxic than Mn(II) due to increased oxidative injury. PC-12 rat pheochromocytoma cells were treated with manganese in the +2 [$MnCl_2$] and +3 [$Mn(P_2O_7)_3$] oxidation states. Release of lactate dehydrogenase (LDH) was used to determine cytotoxicity. Measurement of LDH release 24 hours after addition of manganese in the +3 oxidation state revealed an LC_{50} of approximately 400μM. In contrast, addition of the +2 oxidation state produced minimal toxicity at concentrations up to 1600μM. The extent of oxidative injury was determined by HPLC analysis of cellular glutathione and fluorimetric analysis of thiobarbituric acid reactive substances (TBARS). Treatment of cells with 100μM Mn(III) or 800μM Mn(II), approximate LC_{10}'s, significantly decreased cellular glutathione within 1 hour of addition. Four hours after addition of Mn(III), TBARS increased fourfold compared to controls (2.9 *vs.* 0.7 nmol/mg). Cells treated with an equivalent concentration of Mn(II) exhibited control levels of TBARS (0.67 nmol/mg). These data indicate that Mn(III) is more toxic than Mn(II) in PC-12 cells and suggest that Mn(III) toxicity is mediated by the production of oxidative injury.

459 OXIDATIVE STRESS TOXICOLOGY: THE DEVELOPMENT OF A PISCINE MODEL SYSTEM FOR LOOKING AT NUCLEAR FACTOR - KAPPA B RESPONSES.

E. M. Boncavage-Hennessy, H. S. Gardner and W. H. Hanneman. *Environmental Health, Colorado State University, Fort Collins, CO.*

NF-κB plays a central role in the regulation of many genes involved in cellular defense mechanisms and immunological responses (e.g. expression of cytokines). Its activation is strongly associated with both the inflammatory response (e.g. macrophage activation) and with cellular oxidative stress. Many of the genes upregulated by NF-κB exert anti-oxidative activity. NF-κB exists in the cytoplasm as a dimer in association with an inhibitory subunit, IκB. Upon activation, IκB is phosphorylated and destroyed by proteolysis, whereupon the transcriptionally active dimer (p50/p65) translocates to the nucleus where it activates transcription of specific genes. Oxidative changes that occur after exposure to chemicals can affect NF-κB. Since it is well understood that exposure to environmental chemicals occurs daily; establishing experimental paradigms for testing environmental chemicals and chemical mixtures for their effects on NF-κB is crucial. To address this issue we are studying the induction and modulation of NF-κB in a piscine cell line and a murine cell line that have been transfected with an NF-κB reporter gene construct. Transfected and control cells are plated in 96 well microtiter plates and allowed to reach 80-90% confluency. Cells are then exposed to 0, 0.001, 0.01, 0.05, 0.1 and 0.5% hydrogen peroxide concentrations alone and in the presence of 10-3-10-6M trolox. The data are consistent for both piscine and murine cell lines in that there is a dose dependent increase in NF-κB reporter gene activity with increasing concentrations of hydrogen peroxide. Moreover, the addition of trolox decreased the induction of NF-κB in a dose-dependent fashion. The findings give further merit to the development of piscine models for exploring effects of environmental chemicals and their mixtures on specific cellular responses associated with oxidative damage.

460 GENERATION OF FREE RADICALS BY INTERACTION OF IRON WITH THIOLS IN HUMAN PLASMA.

J. H. Chung, S. J. Lee and K. Y. Chung. *College of Pharmacology, Seoul National University, Seoul, South Korea.*

Oxidative stress has been associated with a number of diseases in humans. Among the sources that can generate oxidative stress, it has been reported that iron can generate reactive oxygen species (ROS) with thiol. In iron overload state, increased thiol levels in plasma appeared to be associated with human mortality. In this study we examined whether iron could interact with thiols in plasma, generating ROS. In human plasma, unlike with Fe(¥²), Fe(¥±) increased lucigenin-enhanced chemiluminescence in a concentration-dependent manner, and this was inhibited by superoxide dismutase. Boiling of plasma did not affect chemiluminescence generation induced by Fe(¥±). However, thiol depletion in plasma by pretreatment with N-ethylmaleimide (NEM) decreased Fe(¥±)-induced chemiluminescence significantly, suggesting that Fe(¥±) generated superoxide anion by the nonenzymatic reaction with plasma thiol. Consistent with this findings, albumin, the major thiol contributor in plasma, also generated ROS with Fe(¥±) and this generation was inhibited by pretreatment with NEM. Treatment with Fe(¥±) to plasma resulted in significant reduction of oxygen radical absorbance capacity (ORAC) value, suggesting that total antioxidant capacity could diminished in iron overload state. In conclusion, in iron overload state, plasma may be affected by oxidative stress mediated by nonenzymatic reaction of Fe(¥±) with plasma thiol.

461 ROLE OF OXIDATIVE STRESS IN NICKEL SUBSULFIDE-INDUCED PULMONARY ALVEOLAR MACROPHAGE DYSFUNCTION IN RATS.

S. K. Chakrabarti[1] and K. S. Subramanian[2]. [1]*Sante Environmental & Sante au Travail, University of Montreal, Montreal, PQ, Canada and* [2]*Health Canada, Ottawa, ON, Canada.*

The present study has examined the relationship between nickel subsulfide (Ni3S2)-induced reactive oxygen species, genotoxicity, and cytotoxicity (cell death) using primary cultures of rat pulmonary alveolar macrophages (PAM). Rat PAM in

cultures were exposed to Ni3S2 in suspensions at concentrations 0, 25, 50 and 125 μg/ml for various times up to 48h in the absence, or presence of phorbol myristate acetate (PMA) (1μg/ml). Rat PAM exposed to Ni3S2 demonstrated a dose- and time-dependent increase in PMA-stimulated production of superoxide anion with significant increase occurring only at 125 μg/ml of Ni3S2 at 4h. However, no such significant increase could be seen at lower concentrations of Ni3S2 used, nor at any other later time periods of exposure. Oxidative stress, measured by superoxide anion-dependent reduction of nitroblue tetrazolium, occurred before Ni3S2 at 125 μg/ml produced significant genotoxicity (measured by DNA-protein crosslinks) and cell death (measured by lactate dehydrogenase leakage) in rat PAM. Ni3S2 (125 μg/ml)-induced genotoxicity and cell death were partially prevented by cotreatment with superoxide dismutase (SOD) and somewhat greater protection was shown by concurrent treatment with SOD plus catalase, with concomitant decrease in oxidative stress. Similar partial prevention of Ni3S2-induced genotoxicity and cell death was also noticed due to cotreatments with dimethylthiourea, mannitol and N-acetylcysteine, with concomitant reduction of Ni2+ uptake by rat PAM. The results suggest that reactive oxygen species, such as superoxide anion, hydrogen peroxide and hydroxyl radical may be important mediators of Ni3S2-induced DNA-protein crosslink formation and cell death in isolated rat PAM.

462 S-ADENOSYL METHIONINE (SAM) AND S-ADENOSYL HOMOCYSTEINE (SAH) METABOLISM UNDER VARIOUS STATES OF OXIDATIVE STRESS.

M. I. Panagiotidis[1], S. Stabler[2] and C. White[1]. [1]*Pediatrics, National Jewish Hospital, Denver, CO and* [2]*Medicine, University of Colorado Health Sciences Center, Denver, CO.* Sponsor: V. Vasiliou.

Oxidative stress in lung cells can alter SAM/SAH ratio. This can profoundly affect cell function and survival. The aim of the study was to determine the effect of various oxidants on SAM/SAH and other sulfur amino acids in A549 cells. Near confluent cells were challenged with sub-lethal oxidants: 1) mM H2O2, 2) enzymatic generation of H2O2 by glucose oxidase (G/GO;5U/ml), 3) 10 mM t-butyl hydroperoxide (t-butylOOH) and 1-5 days exposure to 95% O2 (oxy). Liquid chromatography–mass spectrometry (LC/MS) of SAM and SAH revealed a consistent and marked increase of intracellular SAM under all forms of oxidative stress. SAH was also increased (thus maintaining intracellular SAM/SAH ratio) except after acute treatment with 10 mM t-butylOOH or 5 days oxy, where it was decreased, leading to an increased SAM/SAH ratio (methylation index). Measurement of intracellular cystathionine and cysteine (transsulfuration metabolites) as well as methionine (transmethylation metabolite) by gas chromatography–mass spectrometry (GC/MS) revealed a significant increase under oxidative stress, except with t-butylOOH or 5 days oxy where they remained at control levels. Elevation of SAM was due to an increased activity of methionine adenosyl transferase (MAT) by 2.5- and 3-fold after treatment with t-butylOOH and 5 days oxy, respectively. Under these conditions, DNA methylation status was either unchanged (t-butylOOH) or decreased (5 days oxy). Preservation of SAM/SAH ratio (H2O2, G/GO and 1-4 days oxy) is associated with elevation of metabolites of the transsulfuration pathway which provides cysteine for glutathione synthesis, needed for adaptation to oxidants. By contrast, severe oxidative stress (t-butylOOH and 5 days oxy) caused elevation of SAM/SAH associated with decreased cystathionine and cysteine, indicating decreased utilization of SAM and toxicity.

463 UNCONVENTIONAL FREE RADICAL-DEPENDENT LIGANDS FOR PROSTANOID RECEPTORS.

T. J. Weber and L. M. Markillie. *Molecular Biosciences, Battelle Pacific Northwest Division, Richland, WA.*

Prostanoid receptors are members of the heptahelical G-protein coupled receptor superfamily. The conventional ligands for the known prostanoid receptors have been characterized in detail and are the products of arachidonic acid metabolism. However, experimental evidence suggests that certain oxidized lipids, broadly referred to as the isoprostanes, may also be ligands for the prostanoid receptors. In the present study, we have investigated whether two prototypical isoprostanes (8-iso-$PGF_2\alpha$ and 8-iso-PGE_2) were ligands for the human TP receptor. Two alternatively spliced forms of the human TP receptor, termed the platelet (TP-P) and endothelial (TP-E) type receptors were investigated. Activator protein-1 (AP-1)-luciferase activity (AP-1-Luc) in a transient transfection assay was used as a molecular readout of TP receptor activity. AP-1-Luc activity was increased by a known TP receptor agonist (U46619) in Chinese Hamster Ovary cells (CHO) transfected with the TP-P and TP-E receptors, but not in vector control cells. U46619-mediated AP-1-Luc activity was inhibited by known TP receptor antagonists (ISAP, SQ 29, 548) as expected. Treatment of CHO TP-P and TP-E cells with 1-100 nM 8-iso-$PGF_2\alpha$ was not associated with increased AP-1-Luc activity. In contrast, AP-1-Luc activity was increased in a concentration-dependent fashion by 1-100 nM 8-iso-PGE_2 in TP-P and TP-E cells, and this response was inhibited by cotreatment of cells with a TP receptor antagonist (SQ 29, 548). Cyclooxygenase and thromboxane synthetase inhibitors did not reduce 8-iso-PGE_2-mediated AP-1-Luc activity. Interestingly, AP-1-Luc activity was increased by low (nM) 8-iso-PGE_2 concentration in a TP antagonist independent fashion in naive CHO cells. Collectively, these observations suggest that 8-iso-PGE_2 may be a ligand for multiple receptors and support the notion that oxidized lipids may be unconventional prostanoid receptor ligands (DE-AC06-76RLO to TJW).

464 SPECIES DIFFERENCES IN HEMATOTOXICITY OF N-HYDROXY-4-(DIFLUOROMETHOXY)ANILINE *IN VITRO*.

R. A. Kemper, B. Shertz, B. Robinson and D. Nabb. *Biochemical Toxicology, Haskell Laboratory for Health and Environmental Sciences, E.I. DuPont de Nemours & Co., Newark, DE.*

Hemolytic anemia and methemoglobinemia are common hematologic findings in animals exposed to arylamines or their metabolic precursors. It is generally accepted that hematologic effects of arylamines are mediated by their *N*-hydroxylated metabolites, which participate in redox cycling in erythrocytes leading to oxidative stress. *N*-Hydroxy-4-(difluoromethoxy)aniline (DFMA-NOH) is a model compound for halomethoxylated *N*-hydroxyarylamine metabolites of agrochemicals. The hematotoxicity of DFMA-NOH was investigated in erythrocytes (RBCs) of rats, dogs, and humans *in vitro*. Methemoglobin (metHb) formation was measured directly, while total oxidized glutathione (GSSX), a biomarker for intracellular oxidative stress was used as an index of hemolytic potential. Concentration-dependent metHb formation was observed in RBCs from all three species over the range 1-150 μM. In the rat, peak metHb levels were observed within 15-30 min, and were maintained for the duration of the experiment (120 min). In contrast, metHb levels increased more gradually in human and dog RBCs, and were still increasing in the dog after 120 min at all DFMA-NOH concentrations tested. The rank order species sensitivity to metHb formation was dog > rat ≅ human, based on area under the response vs time curve (AUC) corrected for vehicle controls. GSSX concentration in RBCs exposed to DFMA-NOH also increased in a concentration-dependent manner in all three species. Peak GSSX concentrations were observed within 15 min after exposure and generally declined throughout the course of the experiment. The decline of GSSX levels was somewhat slower in dog RBCs compared to rat and human RBCs. Based on corrected AUC, the rank order species sensitivity to GSSX formation was dog > rat > human. The results suggest that human RBCs may exhibit equal or lower responsiveness to the hematotoxic effects of halomethoxylated arylamines than common laboratory species used in routine toxicity testing.

465 ALTERED EXPRESSION OF OSTEOPONTIN, ALPHA-1 INTEGRIN SUBUNIT, AND ALPHA-SMOOTH MUSCLE ACTIN IN VASCULAR TISSUE IN RESPONSE TO OXIDATIVE INJURY.

C. R. Partridge[1], E. Wilson[2], G. Meinger[2], E. S. Williams[1] and K. S. Ramos[1,2]. [1]*Center for Enviromental and Rural Health, Texas A&M University, College Station, TX and* [2]*Texas A&M University System Health Science Center, Texas A&M University, College Station, TX.*

Allylamine (AAM) has been used experimentally to model human atherosclerosis. Metabolic activation of this aliphatic amine to acrolein and hydrogen peroxide by a vascular-specific amine oxidase is associated with oxidative stress and activation of vascular smooth muscle cells (vSMCs). The adaptive response to repeated cycles of AAM injury involves extensive vascular remodeling and vSMC hyperplasia. vSMCs isolated from AAM-treated rats exhibit proliferative (i.e. atherogenic) phenotypes characterized by increased synthesis and deposition of osteopontin (OPN), altered expression of several integrin subunits, and vSMC dedifferentiation. OPN binds integrin receptors and initiates signaling cascades involved in inflammation, proliferation and migration. Because changes in OPN and surface integrins may represent *in vitro* adaptations of injured vSMCs, studies were conducted to evaluate OPN and integrin expression following repeated cycles of AAM injury *in vivo*. In the present study, six week-old, male Sprague-Dawley rats (175-180g) were treated with AAM (35 mg/kg/day and 70 mg/kg/day) once daily for 20 days to induce atherosclerotic-like lesions in large to medium sized vessels. Immunohistochemical evaluation of frozen sections of rat arteries showed that OPN expression is selectively upregulated at sites of vascular injury/stress. The expression of alpha-1 integrin subunit was also increased in injured vessels. These alterations correlated with marked reduction of alpha-smooth muscle actin staining, consistent with loss of differentiated vSMC phenotypes and extensive cell death. These data are consistent with the hypothesis that OPN and associated adhesion molecules participate in vascular remodeling during episodes of oxidative stress *in vivo*. (Supported by NIH grant HL 22863, HL 62539 and ES 09106).

466 POTENTIAL MECHANISMS OF OXYGEN TOLERANCE IN HUMAN CELLS.

J. Li and J. W. Eaton. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.* Sponsor: D. Hein.

An oxygen tolerant strain of Hela cells which proliferates even under 80% oxygen, termed 'Hela-80', was derived from wild-type Hela cells ('Hela-20') by selection for resistance to stepwise increases of oxygen partial pressure. We have analyzed these two cell types to determine mechanisms involved in the oxygen tolerance of the Hela-80 cells. Antioxidant defenses such as superoxide dismutases, catalase, reduced glutathione, glutathione reductase and glutathione peroxidase do not differ between the two cell types. We therefore focused on possible differences in intracellular generation of reactive oxygen species (ROS), especially of mitochondrial origin (known to be enhanced by hyperoxia). Intracellular oxidant production, detected *via* oxidation of dichlorofluorescein (DCFH) under normal (20%) and high oxygen (80%) concentrations was significantly (~2-fold) higher in Hela-20 cells compared to Hela-80 cells suggesting that Hela-80 cells produce less ROS. The source of ROS is evidently mitochondrial because in both Hela-20 and Hela-80 cells, the mitochondrial uncoupler carbonyl cyanide m-chloro phenylhydrazone almost totally inhibited ROS production as did the combination of rotenone (complex I) and thenoyltrifluoroacetone (complex I and II inhibitors). These data raise the question of what changes in mitochondrial metabolism might have occurred in the Hela-80 cells to cause this diminished ROS production. We have ruled out major differences in lactic acid production but have preliminary evidence that, paradoxically, Hela-80 cells may have elevated cytochrome C oxidase activity. We are considering two main possibilities: (1)Overall mitochondrial metabolism may be lower in Hela-80 cells. (2)Mitochondrial metabolism may be similar in Hela-20 and Hela-80 cells but the Hela-80 mitochondria may be more tightly "coupled", with a lesser tendency to generate ROS from the electron transport chain. Our preliminary data indicating an elevated cytochrome C oxidase activity in Hela-80 cells may provide some support for tighter coupling of electron transport as a potential mechanism for oxygen tolerance.

467 FREE RADICAL SCAVENGERS PROTECT CULTURED CELLS FROM HYDROGEN SULFIDE EXPOSURE.

C. R. Goodwin and D. Julian. *Zoology, University of Florida, Gainesville, FL.* Sponsor: N. Denslow.

Hydrogen sulfide (H_2S) is well-known as a metabolic toxin that inhibits mitochondrial cytochrome *c* oxidase at micromolar concentrations. However, an accumulating body of evidence suggests that H_2S may exert other toxic effects, and that exposure to H_2S concentrations that are currently considered safe may have long-term deleterious effects on human health. The mechanism for these effects is unknown. Recently, metal-catalyzed H_2S oxidation in seawater has been shown to produce free radicals. If free radicals are also produced by H_2S oxidation in tissues, then free radical damage could be an important factor in H_2S toxicity. To test this, we exposed C6 rat glioma cells in culture to various concentrations and durations of H_2S gas, both in the absence and in the presence of three free radical scavengers: dimethyl thiourea (DMTU; 0.01-1.0 mM), N-mercaptoproprionyl-glycine (NMPG; 0.01-10 mM), and reduced glutathione (GSH; 0.1-50 mM). We found that NMPG and GSH, but not DMTU, protected cells in a dose-dependent manner from a 12-hour exposure to 1 mM H_2S followed by a 12-hour recovery, as indicated both by increased cell survival (quantified using the MTT and neutral red assays) and decreased apoptosis (quantified histologically). Furthermore, H_2S toxicity was enhanced by 10 μM Fe^{2+}, which catalyzes H_2S oxidation, but probably also increases radical production. In the absence of scavengers, the dose-response curve assayed by the MTT assay was left-shifted compared with the neutral red assay, suggesting that mitochondria are specifically affected. GSH in particular may protect cells both by scavenging free radicals and by decreasing ambient H_2S, since glutathione in its oxidized form (GSSG) promotes H_2S oxidation. We propose that reduction of GSSG to GSH can be linked with H_2S oxidation *in vitro*, with GSH scavenging the resulting free radicals, regenerating GSSG.

468 NOVEL MECHANISMS OF SUBLETHAL OXIDANT TOXICITY.

T. K. Dilley[1], G. T. Bowden[2] and Q. M. Chen[1]. *[1]Pharmacology, University of Arizona, Tucson, AZ and [2]Radiation Oncology, University of Arizona, Tucson, AZ.*

Aging is the highest risk factor for cancer. Although oxidants are thought to contribute to both aging and cancer, the interplay between oxidative stress, aging and cancer has not been well studied. Human diploid fibroblasts (HDFs) undergo premature senescence in response to mild doses of H_2O_2. Since senescence is relevant to aging *in vivo*, we hypothesize that senescent or senescent-like HDFs function as a tumor promoter. We have employed a classical *in vitro* skin tumor promotion model, which involves measurement of colony formation of 308 initiated mouse keratinocytes. 308 cells form colonies when co-cultured with normal HDFs only in the presence of the tumor promoter TPA. TPA induces an average of 5.75±1.15 colonies formed with an average size of 1.96±1.01 mm^2. When co-cultured with H_2O_2 treated HDFs, 308 cells form 30.3±5.50 colonies with an average size of 8.87±0.73 mm^2. To understand the mechanism behind this phenomenon, we tested whether HDF extracellular matrix (ECM), density of HDFs, the contact between keratinocytes and HDFs, or conditioned medium of HDFs play a role in 308 cell colony formation. The ECM alone was not able to induce 308 cell colony formation. Increasing the density of normal, but not senescent, HDFs was inhibitory to the growth of 308 cells. Contact with normal HDFs, but not senescent HDFs was inhibitory to the growth of 308 colonies. The conditioned medium from prematurely senescent cells results in more 308 cell colony growth compared to that from normal HDFs. We are currently exploring the possibility of gap junctions as an inhibitory factor in the growth of 308 cells by normal HDFs. In conclusion, senescent or senescent-like fibroblasts not only lose contact inhibition on the growth of initiated keratinocytes, but also increase production of secreted factors to enhance the growth of 308 keratinocytes. Proteomics techniques will allow us to determine these factors that may play a role in cancer related to aging.

469 THE DISTINCT ROLES OF MAPKS AND PI 3-KINASE IN OXIDANT INDUCED CARDIOMYOCYTE HYPERTROPY.

V. C. Tu and Q. M. Chen. *Pharmacology, University of Arizona, Tucson, AZ.*

Cardiac hypertrophy develops under many types of pathological conditions. Although it is initially beneficial, sustained hypertrophy is often a transition to heart failure. Oxidants have been shown to play a role in heart disease. However, the molecular events induced by oxidants in cardiomyocytes have not been well defined. Our previous studies have shown that isolated rat cardiomyocytes can survive low or mild doses of oxidants but later increase cell volume and protein content. Oxidants are able to activate phosphatidylinositol 3-kinase (PI3K) and p70 S6 kinase (p70 S6K). Here we tested whether H_2O_2 activated AP-1 transcription factor and the relationship between MAPKs, PI3K and P70 S6K in AP-1 activation and hypertrophy induced by oxidants. Gel shift assays showed that AP-1 binding increased at 30 min and reached a maximum at 4 hrs after treatment. AP-1 luciferase activity increased at two hrs, was sustained for at least 6 hours and returned to basal level 24 hours after a 30 min H_2O_2 exposure. Phosphorylation (activation) of p42/p44ERK, p38 and JNK was induced by H_2O_2 within 10 min. The ERK inhibitor, PD98059 but not the p38 inhibitor SB202190 prevented the AP-1 binding and activation of AP-1. Inactivating PI3K with LY294002 partially inhibited JNK activation but did not affect the activation of ERK, p38 or AP-1. Although PD98059 was able to inhibit H_2O_2 induced phosphorylation of p70 S6K or cell enlargement, SB202190 had a partial inhibitory effect on p70 S6K activity and cell enlargement induced by H_2O_2. Our study indicates while ERKs contribute to AP-1 activation, PI3K and p38 are upstream of p70 S6K and regulate cell enlargement.

470 AMIODARONE AND N-DESETHYLAMIODARONE-INDUCED CYTOTOXICITY IN FRESHLY ISOLATED HUMAN LUNG CELLS.

M. W. Bolt[1], G. B. Smtih[1], W. J. Racz[1], J. F. Brien[1] and T. E. Massey[1,2,3]. *[1]Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada, [2]Medicine, Queen's University, Kingston, ON, Canada and [3]Environmental Studies, Queen's University, Kingston, ON, Canada.*

Amiodarone (AM), a potent antidysrhythmic agent, can cause serious adverse effects including potentially life-threatening pulmonary toxicity. Vitamin E has been shown to decrease AM-induced pulmonary toxicity in both *in vivo* and *in vitro* animal models. In the present study, we investigated the cytotoxicity of AM and its major metabolite N-desethylamiodarone (DEA), as well as the ability of vitamin E to decrease cytotoxicity of AM and DEA in enriched preparations of alveolar macrophages and alveolar type II epithelial cells freshly isolated from peripheral human lung. Following incubation for 36 h, 100 μM AM and 50 μM DEA significantly decreased ($p<0.05$) mean viability (0.5% trypan blue exclusion) in cell digest as well as in enriched macrophage and type II cell preparations (by 31, 33 and 37 % respectively). Enriched preparations of alveolar type II cells demonstrated AM- and DEA-induced loss of viability earlier (i.e. after 24 h) than macrophages and isolated, unseparated cells (cell digest) (36 h). Also, susceptibility to AM and DEA-induced cytotoxicity differed substantially in cells from different patients. Vitamin E decreased toxicity of AM and DEA by 5 - 10% in cells from two of five different patients. Following incubation for 24 h, intracellular levels of AM and DEA did not differ between preparations enriched in macrophages and type II cells or cell digest, and were not altered by vitamin E. AM-treated alveolar type II cell preparations from two patients produced marginally detectable amounts of an analyte which co-eluted with DEA, suggesting the possibility that human type II cells can biotransform AM to DEA. The results demonstrate that toxicity of AM and

DEA in human lung cells is similar to that observed previously in hamster and rat pneumocytes, and that vitamin E has a slight cytoprotective action in the human cells (Supported by CIHR Grant No. MT-13257).

471 INDUCTION OF FACIT COLLAGENS XII AND XIV DURING BLEOMYCIN-INDUCED PULMONARY FIBROSIS.

D. R. Gerecke, B. Liu, L. A. Morio, P. Zhou, R. A. Hahn, A. Sahota, J. Tischfield and E. G. Tzortzaki. *Pharmacology & Toxicology, Rutgers University, Piscataway, NJ.*

Pulmonary fibrosis is a severely debilitating lung disease that is initiated as a result of many types of severe lung injury. The etiology of the disease includes a thickening of the alveolar wall and a decrease in airspace due to an increase in lung extracellular matrix, particularly type I collagen. Collagens XII and XIV sit on the surface of collagen I fibrils and project outward to interact with other molecules of the extracellular matrix. Recent evidence suggests that these collagens play a role in organizing collagen fibrils and assisting in the maintenance of uniform fibril size. In the present studies we characterized collagen XII and XIV production during bleomycin induced pulmonary fibrosis. We speculate that alterations in the expression of these collagens contributes to the disease. Fibrosis was induced by 4 i.p. injections of bleomycin (1 Unit) every other day into female C57BL mice. Lung samples were collected 2, 4, 8, and 12 weeks after bleomycin or saline (control). The extent of fibrosis was determined microscopically after H & E staining. Tissue expression of collagens I, XII, and XIV was quantified by *in situ* hybridization and immunohistochemistry. A time-dependent increase in collagen I protein was observed in the lungs following bleomycin administration which was first evident after two weeks. Expression of collagens XII and XIV was weak until the onset of fibrosis (4 weeks after treatment). At this time their expression dramatically increased. Whereas collagen XII expression decreased between 8 and 12 weeks after treatment, collagen XIV expression persisted throughout the treatment. Our results are consistent with the idea that collagens XII and XIV play an important role in the organization of the lung extracellular matrix during fibrosis. (Supported by NIH grant HL67708 and NJ Thoracic Society).

472 ANTI-FIBROTIC ACTIVITY OF PIRFENIDONE IN A HAMSTER MODEL OF AMIODARONE-INDUCED PULMONARY TOXICITY.

J. W. Card[1], W. J. Racz[1], J. F. Brien[1], S. B. Margolin[2] and T. E. Massey[1]. [1]*Pharmacology and Toxicology, Queen's University, Kingston, ON, Canada and* [2]*Marnac Inc., Dallas, TX.*

Pirfenidone is an agent with demonstrated beneficial effects in some animal models of pulmonary fibrosis and in human fibrotic lung disease. Potentially life-threatening pulmonary fibrosis can be caused by the antidysrhythmic drug amiodarone (AM). We investigated the ability of dietary pirfenidone to ameliorate AM-induced pulmonary damage in the hamster. Intratracheal AM administration (1.83 µmol) increased pulmonary hydroxyproline content (by 22%) and histological disease index values (by 127%), indicative of fibrosis, 21 days post-dosing. Dietary supplementation with pirfenidone (0.5% (w/w) in pulverized rodent chow) for 3 days prior to and continuously after intratracheal AM administration, resulted in pulmonary hydroxyproline content and histological disease index values similar to those for control (water-treated) hamsters. In contrast, starting the pirfenidone supplementation one week after AM administration only partially prevented the pulmonary injury assessed at 21 days post-dosing. The effect of dietary pirfenidone on mitochondrial dysfunction produced *in vitro* by incubation with AM or its primary metabolite, *N*-desethylamiodarone (DEA), was investigated as a possible mechanism of protection. However, the respiratory inhibition and membrane potential disruption of isolated lung mitochondria caused by *in vitro* exposure to AM or DEA were not altered by *in vivo* dietary pirfenidone treatment. These results demonstrate that pirfenidone is beneficial against AM-induced pulmonary fibrosis in the hamster model, but that it does not attenuate the adverse mitochondrial effects of AM or DEA that have been proposed to play an initiating role in AM-induced pulmonary toxicity. (Supported by Canadian Institutes of Health Research (CIHR) grant number MT-13257, and a CIHR Doctoral Research Award to JWC)

473 INHALATION AND INTRAVENOUS PLASMA KINETICS OF VERAPAMIL IN CYNOMOLGUS MONKEYS.

J. Borlak[2], M. Walles[2], H. Windt[2], W. Koch[2], T. Appelqvist[1] and R. Forster[1]. [1]*CIT, Evreux, France and* [2]*Fraunhofer Institut Toxikologie und Aerosolforschung, Hannover, Germany.*

Administration of drugs by inhalation can result in rapid and efficient absorption, and there is currently great interest in this route as an alternative to parenteral administration. The cynomolgus monkey is generally considered to be a good animal model for man because of its phylogenetic proximity, and because it shows similar metabolism of drugs. In this study we have examined the pharmacokinetics of a model compound after inhalation administration to cynomolgus monkeys. The calcium antagonist verapamil was administered to 2 male and 2 female monkeys by inhalation and by intravenous injection in a cross-over design. For inhalation the drug was administered by mask as a nebulised solution in air at 100 mg/m^3 over a period of 60 minutes, which was estimated to result in a total dose of 1 mg/kg. For intravenous administration, 1 mg/kg was given as a bolus injection. Blood samples were taken before administration and 10, 20, 40, 60, 120, 240 and 480 minutes after the start of inhalation exposure or injection. Plasma levels of verapamil were determined by solid phase extraction and LC-MS-MS as detailed elsewhere (Walles et al., 2001). The pharmacokinetic behaviour of verapamil was modelled on the basis of a two compartment model. The fit to the data revealed the same clearance constants for both application routes: 0.05 [1/min] for compartment 1, and 0.009 [1/min] for compartment 2. These figures are almost identical to those found in a similar study performed with minipigs (Koch et al., 2001). These results support the interest of the inhalation route of administration for pharmaceutical applications and the value of the monkey model.

474 EFFECT OF ACETAMINOPHEN ON NITRIC OXIDE PRODUCTION BY RAT ALVEOLAR MACROPHAGES AND TYPE II PNEUMOCYTES *IN VITRO*.

S. Dimova[1,2], D. Uzunova[2], P. H. Hoet[1] and B. Nemery[1]. [1]*Laboratorium voor Pneumologie, K.U.Leuven, Leuven, Belgium and* [2]*Institute of Physiology, Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Nitric oxide has been implicated in the pharmacological and toxic effects of acetaminophen (APAP). Although recent studies support the hypothesis that APAP may affect the lung, little is known about the mechanism by which this occurs. Because nitric oxide plays a key role in the regulation of pulmonary function and diseases, we have studied the effect of APAP on constitutive and lipopolysaccharide (LPS) - induced nitric oxide production in rat alveolar macrophages (AM) and type II pneumocytes (TII) *in vitro*. Extracellular nitrite levels (a breakdown product of nitric oxide) were measured after 24h culturing in the absence or presence of APAP. Rat alveolar macrophages and type II pneumocytes synthesized significant quantities of nitrite in culture (63 ± 41 and 35 ± 11 nmol/mg/24h, respectively, n=5). A concentration-dependent decrease of this presumably constitutive nitrite production occurred in AM and TII exposed for 24h to APAP (0.1 and 1 mM). Nitrite production decreased by 19 and 25% in AM, and by 20 and 38% in TII, at 0.1 and 1 mM APAP, respectively. LPS (1 µg/ml) stimulated nitrite production in AM (231 ± 31 nmol/mg/24h, $p<0.01$), while TII were less responsive (80± 51 nmol/mg/24h, $p=0.07$). The LPS-stimulated nitrite production in AM and TII was not affected by 0.1 mM APAP, but a significant reduction (by 18%) was observed in AM at 1 mM APAP. Measurements of cell viability (MTT-test) verified that the effects observed were not due to cell toxicity. These observations have demonstrated that APAP decreased the constitutive nitrite production in AM and TII *in vitro*. Because of the important and dual role of nitric oxide in the regulation of pulmonary homeostasis and host defense mechanisms, the relevance of these findings has to be studied in humans. (This work was supported by the European Respiratory Society, FWO-Vlaanderen, and Bulgarian Academy of Sciences.)

475 DETECTION OF m-TOLUALDEHYDE IN TISSUE AND ITS INHIBITION OF PULMONARY CYTOCHROME P450 ISOZYMES.

A. Vaidyanathan and R. A. Schatz. *Toxicology, Northeastern University, Boston, MA.*

The xylenes are amongst the top 50 chemicals involved in industry exposures in the United States. Commercial xylene is a mixture of three isomers, m-, p-, and o-xylene with m-xylene constituting approximately 44% of the total mixture. While the xylenes are not considered particularly toxic, they have been shown to inhibit CYP450 activities in respiratory tissue after i.p. or inhalation exposure. This selective (lung vs.liver) inhibition of CYP450 has been attributed at least partly to m-tolualdehyde (m-ALD), a metabolite of xylene. m-ALD has been detected after intraperitoneal administration of m-xylene or its metabolites concurrent with inhibition of CYP450's 2B1 and 2E1 in lung. The purpose of this study was to determine if m-ALD is detectable in tissues after inhalation exposure to m-xylene or m-ALD. Following exposure, tissues were prepared for extraction using a 2, 4 dinitrophenylhydrazine (DNPH) assay and quantified on reverse phase HPLC using a standard curve of m-ALD. Exposure to 300ppm m-xylene yielded hepatic, pulmonary, blood and nasal mucosa concentrations of 65, 107, 45, and 317-ng/g tissue of m-ALD, as well as CYP450 inhibition. A lower exposure level of m-ALD was used due to the previous observation that this metabolite was more toxic than the parent compound, m-xylene. Following m-ALD exposure at 100ppm, levels of m-ALD in liver, lung, blood, and nasal mucosa were 258, 588, 92, 283-ng/g tissue of m-ALD respectively. Inhalation of m-ALD inhibited pulmonary CYP2B1 and

CYP2E1 as did inhalation of the parent compound m-xylene. The data indicate that the metabolite m-ALD is detectable after inhalation exposure to m-xylene or m-ALD coincident with inhibition of pulmonary CYP450 activity.

476 VANILLOID RECEPTORS MEDIATE CYTOKINE PRODUCTION AND CYTOTOXICITY IN BEAS-2B CELLS.

C. A. Reilly, B. A. Carr, D. L. Lanza and G. S. Yost. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

The vanilloid receptor type-1 (VR1), or capsaicin receptor, has been implicated as a critical component in the regulation of inflammatory and cytotoxic processes in several different cell types. We have investigated the role of VR1 in mediating the pro-inflammatory and cytotoxic effects of VR1 ligands in BEAS-2B cells. Using RT-PCR we demonstrated the endogenous expression of VR1 in BEAS-2B cells. BEAS-2B cells exposed to capsaicin exhibited dose- and time-dependent increases in their production of IL-6 and IL-8. Resiniferatoxin (RTX) also caused an increase in cytokine production, but anandamide and capsazepine did not. Maximum induction of IL-6 and IL-8 was observed at 24h with 100μM capsaicin. Production of TNFα was not observed. Production of cytokines by BEAS-2B cells was inhibited by modulators of VR1 function; capsazepine inhibited IL-6 production while EGTA, a Ca^{++} chelator, decreased IL-6 production by 43%. Exposure to capsaicin also caused a time- and dose-dependent decrease in cell viability. Similar decreases in cell viability were observed with anandamide and RTX. The LC_{50} for capsaicin, anandamide, and RTX was 100μM, 12μM, and 6μM, respectively. Substance P did not cause cytotoxicity to BEAS-2B cells even though it has been shown to stimulate IL-6 production. Capsazepine (10μM) increased the cytotoxicity of capsaicin by 23%, due presumably to the cytotoxic effect of capsazepine (LC_{50}=25μM). EGTA did not influence the susceptibility of BEAS-2B cells to cytotoxicity. Overexpression of VR1 in BEAS-2B cells also appeared to dramatically increase the susceptibility to cytotoxicity by VR1 ligands. These data suggest that the inflammatory and cytotoxic effects of VR1 ligands in BEAS-2B cells require VR1 binding, but involve separate downstream pathways. This work was supported by the Colgate-Palmolive Post-Doctoral Fellowship in *in vitro* Toxicology and by a grant from the National Institute of Standards and Technology (Contract #6NANBOD0006).

477 BIOCHEMICAL/CYTOLOGICAL CHANGES IN BRONCHOALVEOLAR LAVAGE FLUID IN THE MALE RAT AFTER INTRATRACHEAL DOSING TO 3 DIFFERENT SILICON DIOXIDE POSITIVE CONTROL MATERIALS.

G. M. Hoffman. *Safety Assessment, Huntingdon Life Sciences, East Millstone, NJ.*

This study was designed to assess the biochemical/cytological changes in bronchoalveolar lavage fluid (BALF) in the male rat after intratracheal dosing with 3 different silicon dioxide (SiO2) positive control materials (SiO2-Alfa, SiO2-HLS UK and SiO2-US Silica). These evaluations were intended to provide a comparison of the pulmonary toxicologic potential of the positive control materials in order to select the most effective material for future studies and to provide reference data for prior studies. The positive control materials were administered once to Sprague-Dawley rats (10 males/material) at a dose level of 50 mg/kg. In addition, a saline and a Titanium Dioxide (TiO2) negative control material were also administered once to rats (10 males/material) at a dose level of 50 mg/kg. BALF was collected and assayed, for enzyme levels and cytology, on 5 animals/group/interval following a 1-day or 14-day post-dose observation period. At 1 day and 14 days after dosing, changes in BALF results compared to the saline control dosed animals were seen in TiO2 and SiO2 dosed animals. At 1 day after dosing, the responses for the SiO2 dosed animals were greatest for SiO2-US Silica, were intermediate for SiO2-HLS UK and were least for SiO2-Alfa. At 14 days after dosing, the responses for the SiO2 dosed animals were greatest in SiO2-Alfa, were intermediate for SiO2-HLS UK and were least for SiO2-US Silica. The responses at 14 days after dosing were generally less than at 1 day after dosing indicating some recovery from the initial pulmonary effects. The changes in the TiO2 dosed animals were generally the least and were indicative of a nuisance dust response as expected. In conclusion, a comparison of 3 different sources of Silicon Dioxide indicated the US Silica material was most effective for an immediate response, the Alfa material was most effective for a persistent response and the HLS UK material was moderately effective at both time intervals.

478 REPEAT BRONCHOALVEOLAR LAVAGE IN LIVE CYNOMOLGUS MONKEYS.

M. Stoute, A. Viau, R. Salame and B. Dube. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

Bronchoalveolar Lavage (BAL) is routinely performed at CTBR in rats, guinea pigs, dogs and monkeys at study termination. An investigation was undertaken to assess the feasibility of repeat bronchoalveolar lavage in studies at CTBR, specifically in live cynomolgus monkeys. This procedure could be used in the detection and progression of toxic lung injury, determination of drug concentrations or provide a profile of cell populations. Performing repeat bronchoalveolar lavage on the same day on male and female cynomolgus monkeys required an anesthetic with a short duration of action and no accumulative effect. Following anesthesia, a lavage tube was inserted inside the trachea and directed into a lung until it blocked (secondary bronchia level). The lavage was performed using 0.9 % saline (approximately 5 mL), infused in the lung and then withdrawn. Approximately half of the fluid was recovered. The tube was retrieved slowly and the procedure was repeated in the other lung. Respiration of the animal was monitored and oxygen was available throughout the procedure and recovery period (approximately 2 to 12 minutes) in event of any distress. Repeat bronchoalveolar lavage, in live cynomolgus monkeys did not show significant distress to the animals. Therefore this technique was considered to be a feasible and effective assessment to be included in inhalation toxicity studies.

479 METHACHOLINE AEROSOL-INDUCED NASAL OBSTRUCTION IN THE MOUSE.

P. T. Symanowicz, A. K. Hubbard and J. B. Morris. *Pharmaceutical Sciences, Univ. of Connecticut, Storrs, CT.*

Airway hyperreactivity is often assessed by measurement of the obstructive response to graded concentrations of methacholine aerosol in intact nose-breathing animals. The current study was aimed at determining if increased nasal flow resistance was induced by a typical methacholine exposure protocol. Male C57Bl/6J mice were exposed for consecutive two minute periods to saline, 3, 10, 30, 100 or 300 mg/ml methacholine aerosol, with airway responses being monitored during a four minute period after each aerosol exposure. Intact animal exposures took place in a Buxco double plethysmograph. In intact animals, SRaw was increased by the methacholine protocol to a maximum of roughly 3-fold over the baseline value of ~ 2.4 cm H2O*sec. The response was similar in awake and urethane-anesthetized mice. Nasal responses were assessed by surgically isolating the upper respiratory tract of urethane-anesthetized mice *via* insertion of an endotracheal tube and drawing air through that site at a constant flow rate of 25 ml/min. Using the identical methacholine exposure protocol, nasal flow resistance was increased roughly 3 fold over baseline values of ~ 3 cm H20/ml/sec. The nasal responses mirrored those observed for the intact animal. Moreover, nasal responsiveness appeared to be heightened in mice with ovalbumin-induced allergic airway disease. These results suggest that nasal obstruction may contribute to measurement of airway hyperreactivity by standard protocols in intact mice. This work supported by NIEHS R01-08765 and the University. of Connecticut Pulmonary Research Consortium.

480 IMMEDIATE RESPONSES OF MOUSE NOSE TO INSPIRED IRRITANTS.

J. B. Morris and P. T. Symanowicz. *Pharmaceutical Sciences, Univ. of Connecticut, Storrs, CT.*

Previous studies have shown rats exhibit an immediate sensory nerve mediated nasal vasodilatory response to several inspired irritants including acrolein and acetic acid. The maximal response to each vapor was observed at exposure concentrations below the RD50. The response occurred in the absence of alterations in nasal flow resistance. The aim of the current study was to assess the immediate nasal responses of the C57Bl/6J mouse to these two irritants for comparison to the rat. The RD50 values for acrolein and acetic acid were first determined in this strain and were 1.85 and 450 ppm, respectively. To allow for continuous monitoring of responses, exposures were performed by drawing irritant laden air (1.1 ppm acrolein or 330 ppm acetic acid) through the surgically isolated upper respiratory tract of urethane-anesthetized mice at a constant flow rate of 25 ml/min with three parameters being monitored during exposure: nasal perfusion rate (as assessed by acetone vapor uptake), nasal flow resistance, and plasma protein extravasation (by Evans blue dye leakage). Acetone uptake rates were significantly increased during exposure to acrolein but not acetic acid suggesting a vasodilatory response to the former but not latter irritant. Both vapors caused an immediate 3-fold increase in nasal flow resistance. Nasal tissue Evans blue dye content was not increased by exposure to either vapor suggesting that tissue edemagensis did not occur. The results indicate that immediate nasal responses occur to inspired irritants in the mouse, but that the pattern of responses appears to differ slightly from those in the rat This work supported by NIEHS R01-08765

481 INTERSTRAIN DIFFERENCES IN AIRWAY RESPONSIVENESS TO METHACHOLINE CHALLENGE OBSERVED IN UNRESTRAINED, BUT NOT IN RESTRAINED, PLETHYSMOGRAPHY OF MICE.

M. P. DeLorme and O. R. Moss. *Respiratory Toxicology, CIIT Centers for Health Research, Research Triangle Park, NC.*

The measurement of airway responsiveness in laboratory animals is an essential tool to assess alterations in pulmonary physiology. Recently, an unrestrained barometric, whole-body plethysmograph (WBP) that utilizes enhanced pause (Penh) to quan-

tify airway resistance has gained widespread use as a technique to determine airway responses to aerosol challenge with bronchoconstrictive agents. However, results generated with the unrestrained WBP have come under increased scrutiny because airflow in the lung is indirectly measured. To address this problem, mice with known interstrain differences in bronchial reactivity (A/J, BALB/c, CD-1, and B6C3F1) were subject to methacholine challenge while unrestrained in a WBP and while restrained with a rubber neck collar in the widely accepted noninvasive airway mechanics (NAM) plethysmograph for measurement of Penh and specific airway resistance (SRaw), respectively. Animals were placed into the plethysmographs and were then subject to challenge with aerosols generated from isotonic saline (control) and methacholine solutions of increasing concentration (2.5 to 320mg/ml) for 3min. Measurements of airway resistance were recorded and averaged for 3min following each concentration. Methacholine challenge data for the unrestrained WBP confirmed the previously reported observation that A/J mice have enhanced airway responses to cholinergic challenge, demonstrated by a concentration of methacholine required to induce a 200% increase in airway resistance (PC_{200}) that was at least 4-fold lower than that observed in the CD-1, BALB/c, and B6C3F1 strains. In contrast, mice restrained in the NAM did not differentiate this strain difference in airway reactivity, with A/J mice demonstrating PC_{200} values were indistinguishable from those observed in the CD-1 and BALB/c mice. Thus the unrestrained WBP is a more sensitive tool than the restrained NAM in assessing airway resistance and responsiveness to bronchoconstrictive agents.

482 ADAPTATION TO STRESS INDUCED BY RESTRAINING RATS IN NOSE-ONLY INHALATION HOLDERS.

S. P. Narciso, E. Nadziejko, L. C. Chen and T. Gordon. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Nose-only inhalation studies involve restraining rodents in nose-only inhalation holders. Protocols for adapting rodents to restraint are used to minimize the stressful effects but there is limited data on the efficacy of adaptation procedures. We examined 1) whether a gradual increase in the duration of restraint facilitates adaptation, 2) how much time is needed for full adaptation when restraint is repeated daily for 4 hrs/day, and 3) whether adaptation persists when restraint is interrupted for several days. Experiments were done in 3 groups of male Sprague-Dawley rats (n = 5/group) as shown in the Table. Heart rate and body temperature were monitored as measures of stress using ECG transmitters. Restraint of rats in nose only holders caused an increase in heart rate (approx. 40 BPM, $p < 0.05$) with no significant change in temperature compared to cage controls. After the first 4 days, the restraint-induced increase in heart rate was the same in rats that were gradually exposed to restraint compared to rats restrained for 4 hours per day. There was a gradual decrease in the effect of restraint on heart rate. Full adaptation to restraint required 14 days of repeated daily restraint. Adaptation persisted even after an interruption of 4 days. In conclusion, nose only restraint for 4 hours caused a modest increase in heart rate. The rats slowly adapted to the stress of restraint with repeated daily exposure indicating that adaptation to nose-only inhalation holders is not necessary for short term exposures except when heart rate is an important factor. A gradual increase in the duration of restraint does not facilitate the adaptation process. Supported in part by EPA R827351.

Purpose	Day	Group 1	Group 2	Group 3
Gradual vs repeated restraint	1-4	cage only	increase restraint by 1 hr per day	4 hrs restraint/day
Fully adapt groups 2 + 3	5-9	cage only	4 hrs restraint/day	4 hrs restraint/day
Interupt repeated restraint	10-13	cage only	cage only	4 hrs restraint/day
Test effect of interuption	14	cage only	4 hrs restraint	4 hours restraint

483 A METHOD TO CHARACTERIZE AEROSOLS PRODUCED BY VOLUNTARY RESPIRATORY MANEUVERS.

A. Afshari, S. Azadi, T. Goldsmith and D. Frazer. *Health and Human Services, NIOSH, Morgantown, WV.* Sponsor: B. Meade.

Many respiratory diseases are associated with changes in the composition and balance of fluids within the airways. The purpose of this study was to develop a system to measure the production of aerosols generated while performing a variety of respiratory maneuvers. Results of these measurements will be used to determine if aerosol generation is associated with airway fluid composition and the development of airway diseases. The system was designed to measure airflow, expired gas volume, and aerosols generated during a variety of ventilatory procedures. It featured a small dead space and was housed in a chamber held at body temperature to reduce the effects of evaporation and condensation. The temperature and humidity of the collected gas was recorded during the course of each experiment. Prior to each measurement, the test subject breathed HEPA filtered air for two minutes to reduce the contribution of inhaled ambient particulates. The subject then voluntarily coughed or performed an exhalation procedure into a mouthpiece attached to a spirometer. The spirometer was used to characterize the airflow pattern while collecting the exhaled air and aerosol. Three types of particle analyzers (APS, GRIMM, SMPS) were used to characterize aerosol size over a range between 10 nm and 10 µm. Results show that aerosol characteristics were consistent for each test subject but varied widely between subjects. This method has potential in evaluating the toxicological effects of substances that alter airway integrity. This project is supported in part by FAA IAG 97-11.

484 CHARACTERIZATION OF RESIDENCE TIMES FOR GASES AND AEROSOLS FLOWING THROUGH CHAMBERS USED TO MEASURE RESPIRATORY PARAMETERS OF RODENTS.

B. A. Wong, M. A. Pirbhai, E. W. Tewksbury, M. P. DeLorme and O. R. Moss. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Inhalation studies commonly use two basic systems to provide respiratory information for mice and rats used in pulmonary toxicity research on airborne agents. Bronchoconstrictive agents can be characterized by measuring the enhanced pause (Penh) in the breathing pattern of an unrestrained rodent in a whole body plethysmograph (WBP). Direct measurements of airflow and volume may be made on a rodent restrained by a rubber neck collar in a noninvasive airway mechanics (NAM) plethysmograph. However, variations in aerosol concentrations in a plethysmograph were observed in a recent study [Bowen, L.E. et al., 2001. Toxicologist, 60]. This variation in aerosol concentration could be due to nonideal air flow patterns in the chamber. The uniformity of flow distribution within a chamber was characterized by the mean residence time for a step change in gas or aerosol concentration. A rat and a mouse WBP, and a rat and a mouse NAM (Buxco Electronics, Inc.,) were evaluated. An atmosphere of the airborne material was introduced into the plethysmograph chamber, allowed to reach equilibrium, and then flushed out with clean air. The mean residence time for mixing and clearance of nitrogen, ultra fine carbon black and latex particles were evaluated for the WBP and NAM chambers and compared with the mean residence times of ideal exposure units of the same volume. Results showed that nitrogen gas diffused in the rat WBP within 17.5 % and the rat NAM within 1 % of the ideal mean residence time. Introduction of ultrafine carbon black or latex particle aerosols resulted in a shorter mean residence time by more than 31 %. These shorter experimental times indicated that the aerosols were, in effect, mixing in a smaller volume of the inhalation chambers, supporting the possibility of non-uniform distribution of particles in the inhalation chambers. Similar results were obtained for the mouse WBP and NAM. Thus, the uniformity of distribution within a plethysmograph should be characterized, especially for short duration inhalation tests.

485 AIR-LIQUID INTERFACE CULTURE FOR EVALUATION OF CELLULAR EFFECTS OF COMBUSTION EMISSIONS.

J. C. Seagrave, J. D. McDonald and J. L. Mauderly. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Combustion products from mobile sources contribute to a particulate material fraction of air pollution implicated in adverse effects on human health ($PM_{2.5}$). In these studies, we have examined the effects of a major constituent of $PM_{2.5}$, diesel exhaust emissions, on cells in culture under conditions more closely representing the physiology of the intact lung than conventional submersion culture. The Cultex system allows cell exposure to a continuous flow of material at an air-liquid interface in a controlled manner. Prior to this work, no known study of the dose of material deposited from an atmosphere onto the Transwell membrane surface had been conducted. Here we present the deposition dose and deposition homogeneity for a delivered amount of PM and gases to the Cultex system. PM deposition was studied using fluorescent microspheres ranging in size from 50 nm to 5 microns. Gas deposition was measured using NO_2 and the Salzmann method. Both PM (all investigated particle sizes) and gases were homogenously distributed throughout the system. To test the biological effects of diesel exhaust on lung epithelial cells, A549 human type II-like cells were grown to confluence on Transwells and exposed to diesel exhaust at an air-liquid interface using this system. The exhaust was diluted to 1000 mg/m^3 total PM and passed over the cell surface at a flow rate of 8.3 ml/minute per Transwell. Cells were exposed to the exhaust for 1 hr, or to whole exhaust or filtered exhaust for 3 hr. The cells were then returned to conventional submersion culture conditions for 1 or 24 hr, and overt toxicity (LDH release, loss of ATP, or changes in mitochondrial tetrazolium salt cleavage), oxidant stress (glutathione content), epithelial integrity (diffusion of Evans Blue-labeled BSA across

the monolayer), and inflammatory potential (IL-8 secretion, at 24 hr only) were evaluated. These conditions resulted in little overt toxicity, but oxidant stress and increased epithelial permeability were observed. Supported by the Office of Heavy Vehicle Technology, US. Department of Energy

486 EXPRESSION OF 15-LIPOXYGENASE-2 IN THE EPIAIRWAY™ *IN VITRO* HUMAN TRACHEAL/BRONCHIAL EPITHELIAL MODEL: REGULATION BY TNFα AND INF-γ.

P. J. Hayden[1], G. R. Jackson[1], T. J. Last[1], M. Klausner[1], J. Kubilus[1] and S. B. Shappell[2]. *[1]MatTek Corporation, Ashland, MA and [2]Department of Pathology, Vanderbilt University School of Medicine, Nashville, TN.*

15-Hydroxyeicosatetraenoic acid (15[S]-HETE) is the predominate arachidonic acid (AA) metabolite produced by human tracheal/bronchial tissue. This product of the 15-lipoxygenase (15-LOX) enzyme is believed to play a significant role in human airway inflammation and respiratory diseases including cystic fibrosis and asthma. In the current work, RT-PCR and Western blotting techniques were utilized to investigate the expression of 15-LOX isozymes in EpiAirway™, a commercially available *in vitro* model of human tracheal/bronchial epithelium. The effects of IL-1β, TNFα, the TH2 cytokines IL-4 and IL-13, the TH1 cytokine INFγ and various combinations of these cytokines were examined. The previously reported expression of 15-LOX-1, as well as induction of enhanced 15-LOX-1 expression by IL-4 and IL-13, was confirmed by RT-PCR. Additionally, 15-LOX-2 message and protein were detected in the EpiAirway model. TNFα was found to induce expression of 15-LOX-2 message and protein, while the TH1 cytokine INFγ inhibited the TNFα-induced increase in both message and protein. Identical results were obtained in EpiAirway constructs derived from four separate airway cell donors, including one asthmatic donor. These results demonstrate, for the first time, 15-LOX-2 expression in human tracheal/bronchial epithelial cells. The induction of 15-LOX-2 by TNFα and inhibition by the TH1 cytokine INFγ suggest a possible important role of 15-LOX-2 in mediating human airways diseases such as asthma, which is characterized by increased TNFα and decreased TH1 (INFγ)/TH2 (IL-4, IL-13) ratios.

487 THE INFLUENCE OF RISK COMMUNICATION ON RISK PERCEPTIONS.

C. P. Tabone and R. D. Harbison. *Environmental and Occupational Health, University of South Florida, Tampa, FL.*

This study examined variations in public attitudes and perception bias toward environmental risk. Attitudes and perception are influenced by shared opinions, sometimes based on emotion and rooted beliefs. Information concerning environmental risk is delivered to the public through the media, often diluted or inaccurately portrayed as fact. The mixed messages the public receives through faulty risk communication may be conflicting, creating mistrust and confusion. This may effect the views and attitudes of the public during the process of evaluating risk and creating policies. The purpose of the study was to evaluate the public's perception of environmental risk between two target groups: laypeople and occupationally exposed workers. A survey of adults (N=300) of voting age in the Tampa Bay area was conducted to study the attitudes of the public toward environmental risk. A group of laypeople (N=150) were surveyed to evaluate the significance of fears of environmental exposure and related health risks. A group of people (N=150) who work with occupational risks, such as those employed to manage chemical or physical agents (i.e.: asbestos, radon), were surveyed. Demographic information was collected to determine if public perception of environmental risk might be correlated with specific variables. These variables are: 1) age group (Baby Boomers *versus* non-Baby Boomers), 2) education (college degree *versus* non-degree), 3) parental status, and 4) source of environmental information (news media *versus* technical information). The results of this investigation showed similar overall perceptions of environmental risk between each target group, but with demographic biases within each group. (Supported in Part by ATSDR)

488 DEFINING A METHODOLOGY TO ASSESS THE ENVIRONMENTAL HEALTH STATUS OF A COMMUNITY.

M. R. Francois, J. Studnicki and R. D. Harbison. *EOH, Univ. of South Florida, Tampa, FL.*

Evaluating the impact of environmental pollution on the health status of a community has long been a goal of public health practitioners. Recently, several databases that track health-based environmental indicators have become available. The purpose of this study was to develop a health outcome model that would be useful for evaluating the relationship between environmental pollution and disease. Once those indicators were identified, the CATCH (Comprehensive Assessment Tracking Community Health) Methodology was used to assess the environmental health status of Hillsborough County, Florida. The National Emissions Trends database was used to access the 1996 estimates of annual emissions of air pollutants from all sources for Hillsborough County. The environmental indicators selected included carbon monoxide, nitrogen oxides, particulate matter (< 10 microns), particulate matter (<2.5 microns), sulfur dioxide, volatile organic compounds, ammonia, and total industrial releases from the Toxic Release Inventory (TRI). The model compared the above indicators with morbidity data. The CATCH Methodology reveals that the majority of the indicators remain areas of concern for Hillsborough County when their levels are compared to both peer counties as well as the State. This methodology will be useful in helping communities to effectively utilize limited public health resources to formulate efficient interventions and preventive strategies. (Supported in Part by a Grant From ATSDR)

489 EXAMINATION OF HEALTH TOXICITY DATA WITH APPLICATION TO BENEFIT-COST ANALYSIS OF ENVIRONMENTAL HEALTH POLICY.

E. Y. Wong[1], S. Farrow[2], R. A. Ponce[1] and E. M. Faustman[1]. *[1]Institute for Risk Analysis and Risk Communication, Environmental Health, University of Washington, Seattle, WA and [2]Engineering and Public Policy, Carnegie Mellon University, Pittsburgh, PA.*

Health toxicity data is a key input to analysis of environmental health policies and require careful use and examination of inherent assumptions prior to application in policy analyses. Using a case study of the health benefits derived from Clean Air Act (CAA) regulations, we have focused on two key issues: the lack of transparency of the use of health measures and dose-response in the calculation of health benefits and the clarification of assumptions associated with the use of epidemiological data for benefit-cost analysis. To address the lack of transparency, we developed and applied a computerized template tool, the Fast Environmental Regulatory Evaluation Tool (FERET), to explicitly reference the studies, dose-response parameters, and default assumptions used in the CAA analysis. Calibration to existing analyses showed no difference in the key mortality drivers but differences did exist for morbidity effects. Based on these analyses, key needs in the interface of health research and benefit-cost analysis include explicit definition of the populations at risk, use of study-specific data instead of default assumptions, and increased coordination between health and economic researchers. For example, lack of consideration of multiple simultaneous causes for hospital admission may overestimate total admission estimates by 39-65%. Lack of consideration of hospital readmission may overestimate the affected population by 15-34%. As these impacts are age specific, misestimation of health impacts can be problematic for analyses of sensitive subpopulations. Thus, in this case example, not only can lack of available scientific evidence hinder the economic analysis but inappropriate use of health information can result in misestimation of health benefits associated with environmental improvement. [Funded by the Center for the Study and Improvement of Regulation at Carnegie Mellon University. and the University. of WA.]

490 A RISK/BENEFIT ANALYSIS OF PENTABROMODIPHENYL ETHER.

T. L. Long[1], A. Q. Armstrong[2] and J. A. Biesemeier[1]. *[1]Regulatory Affairs, Great Lakes Chemical Corporation, West Lafayette, IN and [2]Toxicology and Risk Analysis, Oak Ridge National Laboratory, Oak Ridge, TN.*

Brominated Diphenyl Ethers are a class of Brominated Flame Retardants (BFRs) widely recognized as effectively decreasing the risk of death and injury from fire by reducing the potential for flashover. Statistics indicate that 50–60% of residential fires flashover and spread beyond the room of origin increasing the risk of injury or death. An average of 4, 000 people die each year in residential fires and another 20, 000 suffer serious injuries. This study compares the non-cancer human health risk from environmental pentabromodiphenyl ether (PeBDPE) exposure and the reduction in the risk of injuries and death from residential fires attributed to the use of BFRs. Probabilistic risk estimates of injury and death from residential fires were evaluated using data from the US Census Bureau and the National Fire Protection Association. An estimated 45% reduction in the risk of death and injury due to residential fires can be achieved with the continued and increased usage of BFRs in household materials. An evaluation of the health risks posed by environmental exposure to PeBDPE was conducted by calculating the expected oral and dermal uptake based on concentrations measured from soil, water, sediment, and air, as well as animal tissues and human fluids. Calculated hazard quotients for residential (1.4E-3) and industrial (4.9E-3) scenarios were below 1 indicating no adverse toxic effects are predicted based on EPA recommended toxicity values (RfDs) and the potential worst-case exposure parameters. Thus, environmental exposure to PeBDPE poses no adverse health risk while the benefits of use contribute to a predicted 45% decrease in the risk of death and injury in residential fires in the US

491 DAILY WATER INGESTION IN THE US - UPDATE.

J. T. Du and H. Jacobs. *Office of Water, USEPA, Washington, DC.*

We have published a report entitled "Estimated Per Capita Water Ingestion in the United States" (EPA-822-R-00-008) which is based on USDA's 1994-1996 data on Continuous Survey of Food Intake by Individuals (CSFII), covering a total of 15, 303 individuals. Water refers to plain drinking water and water added in final preparation of beverages and foods at home, school cafeteria or in a restaurant. The data base on young children was limited. Recently, we obtained the 1998 CSFII data from USDA that focused only on children. These new data are for drinking water ingestion by more than 5, 500 children (from birth through 9 years of age) who were not included in the previous survey. We have revised our previous estimates of drinking water ingestion using the expanded sample for infants younger than 1 year old (from 359 to 1, 486) and for children 1 through 9 year-old (from 3, 986 to 8, 157). The increase in sample size for children enabled us to generate more precise estimates of water ingestion for the children, especially for the new-born to 6-month-old, and the 6-month to 1-year-old groups. We have calculated the per capita estimates of mean and percentile distributions of daily water ingestion for community, bottled, other water and water of all sources by age and gender, based on per person and per kg body weight. The opinions expressed are those of the authors and do not necessarily reflect USEPA policy.

492 HUMAN HEALTH RISK ASSESSMENT FOR n-BUTYL ACETATE.

V. Bhat, G. L. Ball, C. J. McLellan, M. C. Sanders and L. L. Bestervelt. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A risk assessment to determine acceptable levels of n-butyl acetate in drinking water was conducted according to Annex A of American National Standards Institute/NSF International (ANSI/NSF) Standard 60/61. The scientific literature was reviewed for human and animal data. No oral studies of adequate quality were identified. Thus, the critical study was determined to be a 13-week inhalation study in which rats inhaled n-butyl acetate (0, 460, 1380, or 2760 mg/kg-day in females and 430, 1290, or 2580 mg/kg-day in males) for 6 hours/day and 5 days/week. The dose-related effects in both sexes were sedation and hypoactivity during exposure, and decreased mean absolute spleen weights. At the mid dose, considered the LOAEL in both sexes, significantly decreased mean body and absolute and/or relative organ weight changes were also observed. Thus, the low dose in males, 430 mg/kg-day, was considered the NOAEL. A 14-week neurotoxicity study, employing the same doses and exposure paradigm as the critical study, provided support for the sedation, hypoactivity, and decreased body weight observed in the critical study. Since n-butyl acetate is rapidly metabolized to n-butanol in the blood and brain, the likely mediator of the sedation and hypoactivity caused by n-butyl acetate is n-butanol. Based on a total uncertainty factor of 3, 000x to account for inter- and intraspecies, and subchronic to chronic extrapolation, as well as database deficiencies, the oral RfD was calculated to be 0.1 mg/kg-day. This oral RfD compares favorably to the IRIS oral RfD of 0.1 mg/kg-day for n-butanol. The resulting Short-Term Exposure Level (STEL) is 10 mg/L. Long-term exposure levels derived include a Total Allowable Concentration (TAC) of 1 mg/L, and a Single Product Allowable Concentration (SPAC) of 0.1 mg/L. These drinking water action levels are considered to be adequately protective of human health.

493 HUMAN RISK ASSESSMENT FOR γ-BUTYROLACTONE TO DETERMINE DRINKING WATER ACTION LEVELS.

C. D. Gillilland, G. L. Ball and C. J. McLellan. *Toxicology Services, NSF International, Ann Arbor, MI.* Sponsor: M. Dourson.

A risk assessment to determine acceptable levels of γ-butyrolactone in drinking water was conducted according to Annex A of American National Standards Institute/NSF International (ANSI/NSF) Standard 60/61, since it had been detected as a product extractant. Subchronic and chronic mouse and rat oral studies were evaluated. The key effect observed in these studies was general hypoactivity, with progressively more severe neurotoxic effects observed as the doses increased. The effect was acute and occurred at a lower dose than any chronic effect. Further, the weight of evidence suggested that γ-butyrolactone was not genotoxic. γ-Butyrolactone is rapidly metabolized to γ-hydroxybutyrate. Therefore, neurotoxicity studies on this metabolite were also reviewed. From these, an acute human study in which twenty adult males were administered single oral doses ranging from 35-63 mg/kg γ-hydroxybutyrate was chosen as the critical study. Lethargy was observed at all dose levels, with coma induced in subjects treated with doses of greater than 50 mg/kg γ-hydroxybutyrate. Electroencephalographic patterns similar to slow sleep were observed, in addition to alpha rhythms, in unconscious subjects. Brief delta and theta slowing was observed in subjects who were awake. This study was chosen because it was a human study and because the neurotoxic effects induced by γ-hydroxybutyrate occurred at doses lower than those in the repeated dose animal studies with γ-butyrolactone. This ensures that the resulting action levels would be based on the most sensitive toxicological endpoint. A LOAEL of 35 mg/kg was determined. Uncertainty factors of 10x each for intraspecies variability, database deficiencies, and the LOAEL to NOAEL extrapolation were used to calculate an oral RfD of 0.035 mg/kg-day. The Short-Term Exposure Level (STEL) was calculated to be 1 mg/L, and the chronic exposure levels of the Total Allowable Concentration (TAC) and the Single Product Allowable Concentration (SPAC) were calculated to be 1 mg/L and 0.4 mg/L, respectively.

494 IDENTIFICATION OF COMMON TOXIC EFFECTS WITH COMMON MECHANISMS OF TOXICITY FOR PESTICIDES SELECTED FROM THE DRINKING WATER CONTAMINANT LIST (CCL).

T. J. Mast[1], F. Adeshina[2], N. H. Moore[1], H. Choudhury[2], A. Protzel[3] and A. Mahfouz[4]. *[1]Environmental Technology Division, Pacific Northwest National Laboratory, Richland, WA, [2]National Center of Environmental Assessment, USEPA, Richland, WA, [3]Office of Pesticide Programs, USEPA, Washington, DC and [4]Office of Water, USEPA, Washington, DC.*

The Food Quality Protection Act (FQPA) has mandated that the EPA assess the cumulative risks to human health from aggregate dietary and non-occupational exposure to pesticides and other substances with a common mechanism of toxicity. It is necessary to identify chemicals or groups of chemicals that cause a common toxic effect based on a common mechanism of toxicity before assessing the cumulative of exposure to chemical mixtures. In this study, the pesticides identified in the CCL, FR 63(40), 1998, have been evaluated as candidates for cumulative risk assessment. A literature search was performed on MEDLINE, TOXLINE, and other databases using the CAS numbers for 40 candidate pesticides or major degradation products of known toxicological concerns. The extensive volume of retrieved literature, ~ 70, 000 citations with abstracts, was entered on to PNNL's Spatial Paradigm for Information Retrieval and Exploration (SPIRE) software to identify groups of compounds with a commonality of toxic effects and mechanisms of toxicity. These groups of compounds were later sorted based on specific toxic effects, i.e. hepatotoxicity, neurotoxicity, reprotoxicity, etc. The "toxic effects groupings" were viewed with SPIRE's visualization tools to identify pesticides or degradation products likely to possess common mechanisms of toxicity. Once relevant groups were identified, the selected scientific literature associated with each group was retrieved and the information used in the formulation of a table of toxic effects and mechanisms of toxicity common to groups of compounds. This end product may be used as a basis for conducting cumulative risk assessment as needed. DISCLAIMER:The opinions expressed in this study are those of the authors and do not necessarily reflect those of EPA.

495 RISK COMPARISON OF SIX VOLATILE ORGANIC COMPOUNDS (VOCS) DETECTED IN CALIFORNIA DRINKING WATER.

P. R. Williams and P. Sheehan. *Exponent, Menlo Park, CA.* Sponsor: D. Paustenbach.

The California Department of Health Services maintains a drinking water monitoring database that consists of analytical data for more than 450 chemicals. In this paper, we evaluate the detection frequencies, average concentrations, and relative health risks of six VOCs in California drinking water that are classified as "known" or "potential" human carcinogens. Although not formally classified as a human carcinogen by the USEPA, methyl tertiary butyl ether (MTBE) is included in the analysis, given its recent controversy in California. We find that from 1995 to 2000, the percentage of drinking water sources containing at least one chemical detection is about 17% for chloroform, 9% for tetrachloroethylene (PCE), 8% for trichloroethylene (TCE), 2% for 1, 1-dichloroethylene (1, 1-DCE), 1.7% for MTBE, and <1% for benzene. Interestingly, the detection frequency for each VOC has not changed much over the last six years. Average detected concentrations from 1995–2000 are about 15 parts per billion (ppb) for PCE and TCE, 10 ppb for chloroform and MTBE, and 4 ppb for 1, 1-DCE and benzene. Average detected concentrations have also remained relatively stable over the last few years, but exceed California's Maximum Contaminant Levels (MCLs) for benzene, PCE, and TCE. To compare the relative risks posed by these VOCs in drinking water, estimates of lifetime cancer risk were also calculated for each chemical based on drinking water exposures *via* ingestion, inhalation, and dermal routes, and using average exposure parameter values and California-derived cancer slope factors. Estimated cancer risks are the greatest for 1, 1-DCE, followed by PCE, benzene, chloroform, TCE, and MTBE. When adjusted for frequency of detections, PCE accounts for the greatest risk, followed by chloroform, 1, 1-DCE, TCE, benzene, and MTBE. The results of this analysis provide useful information on the incidence and relative risks of different drinking water contaminants in California, which can be used to prioritize public health hazards and aid in the development of appropriate risk mitigation efforts.

496 DERMAL EXPOSURE TO CONTAMINANTS WHILE SWIMMING: AN ASSESSMENT OF THE RISKS AND HAZARDS ASSOCIATED WITH USEPA AMBIENT WATER QUALITY CRITERIA.

H. Ochoa-Acuna, J. K. Tolson and S. M. Roberts. *Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL.*

Currently, Ambient Water Quality Criteria (AWQC) based on protection of human health consider intake from fish ingestion and, if the water is designated as a potable water source, from direct ingestion. Intake from dermal contact while swimming is not included in the development of these risk-based criteria. In order to evaluate the impact of this omission on the protectiveness of the AWQC, risks and hazards from dermal contact while swimming in waters with chemicals at AWQC concentrations were calculated. The assessment was focused on 42 carcinogens and 27 non-carcinogens for which AWQC are calculated based only on human health risks. For each chemical, Monte Carlo simulation was used to assess the variability of intake and risks among swimmers. Body weight data from NHANES 3 were entered as a custom distribution, and surface areas were calculated from allometric scaling based on body weight. A custom distribution for swimming frequency was taken from the 1994-95 National Survey on Recreation and the Environment. Swimming duration was entered as a triangular distribution with a minimum of 10 min, a maximum of 5 h, and a most likely value of 1 h. Dermal absorption was assessed using a non-steady state approach, given the limited duration of contact per each swimming event. For carcinogens, an exposure duration of 70 yr was assumed, and cancer slope factors were corrected for body weight. Among carcinogens, risks from dermal exposure for individuals at the 95th percentile ranged up to about 10^{-3}, depending upon the chemical. For non-carcinogens, 95th percentile hazard quotients for dermal exposure ranged up to values well over 100. For some chemicals, virtually all swimmers in waters at the current AWQC would have an excess cancer risk $>10^{-6}$ or a HQ >1 from dermal exposure only. The results of this analysis suggest that dermal intake should be considered explicitly when developing surface water criteria for waters where recreational swimming occurs.

497 DETERMINATION OF A HUMAN ACUTE NO-OBSERVED-ADVERSE-EFFECT LEVEL (NOAEL) FOR COPPER IN BOTTLED DRINKING WATER: VOLUME, DOSE AND CONCENTRATION CONSIDERATIONS.

K. A. Poirier[1], M. Araya[2], L. M. Klevay[3], F. H. Nielsen[3], L. Johnson[3], J. J. Strain[4], P. Robson[4], B. H. Chen[5], S. Wei[5], H. G. Zhu[5] and S. R. Baker[6]. [1]*TERA, Cincinnati, OH,* [2]*University of Santiago, Santiago, Chile,* [3]*USDA, Grand Forks, ND,* [4]*University of Ulster, Coleraine, United Kingdom,* [5]*Shanghai Medical University, Shanghai, China and* [6]*ICA, New York, NY.*

A human, acute NOAEL for nausea was determined in a prospective, double blind controlled study. As part of an ongoing protocol, Phase II of this study recruited 70 adult females (18-60 years of age) at each of four different international sites (final pooled n = 269). The study design was a 3 x 3 factorial (volume x dose) for 100, 150, or 200 ml of bottled drinking water for 0.4, 0.8, 1.2 mg of Copper (Cu) as sulfate. Two additional doses (0 and 1.6 mg Cu) were added at the 200 ml volume to determine a Dose-Response and corroborate previously reported results. Each subject was given a blind, randomly selected concentration of Cu once a week. Following dosing, all subjects were monitored by health care personnel for 1 hour. All subjects completed a questionnaire at 0, 0.25, 1, and 24 hours post-dosing that screened for positive GI effects (nausea, vomiting, abdominal pain, and diarrhea). Nausea was the most prevalent symptom reported and was generally reported within the first 15 minutes (water volume $p < 0.032$, copper dose $p< 0.0001$ and water x copper interaction is $p<0.97$). As volume increased, the effect of Cu-induced nausea decreased; as Cu dose increased; the incidence of nausea increased. At 200 ml, a significant increase in reported incidence of nausea at 0.25 hr occurred at 0.4 (6 mg Cu/L), indicating a NOAEL of 0.8 mg Cu (4 mg Cu/L) for adult females. An acute nausea threshold of 5.3 mg Cu/L can be determined from the factorial analysis (0.8 mg Cu in 150 ml). These data confirm a previously determined human acute NOAEL for Cu and provide additional, controlled human data for determining regulatory contaminant levels of Cu for drinking water.

498 SCIENTIFIC CRITERIA FOR DERIVING OCCUPATIONAL EXPOSURE LIMITS FOR METALS AND OTHER COMPOUNDS RELATED TO MINING OPERATIONS.

A. Maier and L. T. Haber. *TERA, Cincinnati, OH.*

Despite general agreement that occupational exposure limits (OEL) play an important role in protection of worker health, significant disparities often exist in specific OEL values for a particular substance. These differences often reflect diversity in scientific criteria used among OEL-setting organizations. We investigated areas of scientific consensus and disagreement by conducting a critical evaluation of OEL documentation from various international organizations for a series of five case-study compounds: chromium, copper, lead, manganese, and silica. These chemicals served as a backdrop for evaluating key scientific criteria for setting OELs. As just one example, in the context of OELs for chromium compounds we present a decision logic for evaluating chemical speciation, demonstrate the impact of using particle dosimetry to calculate human equivalent concentrations from animal studies, and recommend approaches for considering nutritional essentially. Some issues became apparent only by comparing all of the case-study substances. For example, we found large differences in the extent of the supporting databases, but no explicit approach for documenting confidence in the resulting OELs. We also evaluated the application of uncertainty factors among various organizations and found that the rationale for their use, areas of uncertainty considered, and recommended defaults differed widely among organizations. Although in many cases we found that equally valid alternative approaches were used to address the scientific issues we explored, the one over-riding theme in our analysis was the need to increase the degree to which the OEL documentation described the selected approach. The results suggest the opportunity for greater scientific harmonization in setting OELs, with the goal of increasing transparency in OEL derivation, and enhanced sharing of resources among organizations that set OELs. Sponsored by the International Council on Metals and the Environment.

499 DEVELOPING ENVIRONMENTAL CRITERIA BASED ON THE ACUTE TOXICITY OF LEAD.

B. K. Gadagbui[1], J. G. Pounds[2], T. W. Simon[3] and S. M. Roberts[1]. [1]*Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL,* [2]*Pacific Northwest National Laboratories, Richland, WA and* [3]*USEPA, Region 4, Atlanta, GA.*

Effects from chronic lead exposure are a significant public health problem, and the development of environmental criteria for lead have understandably focused on circumstances of prolonged or repeated lead exposures. Occasionally, however, environmental problems arise where the potential for effects from acute lead exposure must be considered. Currently, no criteria are available for this type of exposure in environmental settings. In an effort to explore development of such criteria, the toxicological literature was evaluated with the objective of identifying blood lead concentrations that might serve as an upper limit to prevent acute lead poisoning. One approach to setting this limit would be to use the lower end of the range of blood lead concentrations observed in child and adult patients with symptomatic acute lead toxicity. A strength of this approach is that it deals with endpoints of obvious clinical relevance. An alternative approach would be to use the lower end of the range of lead concentrations associated with changes in heme metabolism (e.g., δ-aminolevulinic acid dehydratase, ALAD) as a sensitive endpoint. In basing the blood concentration limit on a sensitive biochemical effect of lead, this approach is likely to be protective for subtle acute effects of lead that might be missed in acutely poisoned patients. Blood concentration limits based on both approaches were compared to predictions of blood concentrations after various acute lead doses using the Leggett model. The Leggett model was used because the IEUBK model is a poor predictor of blood lead concentrations resulting from acute exposure. With the Leggett model, upper limits on lead concentrations in environmental media could be calculated such that acute-toxicity-based blood lead concentration limits are not exceeded. This technique appears to hold promise as a method for developing environmental criteria based on acute lead toxicity.

500 EVALUATING LEAD EXPOSURE AT MINING SITES WITH HETEROGENEOUS SOIL TYPES AND LEAD BIOAVAILABILITY.

M. R. Garry[1,2] and J. S. Tsuji[2]. [1]*Environmental Health, University of Washington, Seattle, WA and* [2]*Exponent, Bellevue, WA.*

Risk assessments conducted on residential areas near mining and smelting sites typically apply USEPA's Integrated Exposure Uptake Biokinetic (IEUBK) model for children to evaluate lead exposure. The model is designed to estimate blood lead levels, using input assumptions about exposure to lead from various environmental media. Soil lead concentration and bioavailability are among the parameters with the most influence on blood lead estimates. At many mining sites soils are highly heterogeneous with regard to lead concentration, soil chemistry, and the associated soil lead bioavailability. This is due to both the natural mineralization of the area and the variable enrichment from mining activities. The IEUBK model is designed to accept only single input values, usually averages, for each parameter. In heterogeneous settings, use of independent averages for lead concentrations and bioavailability in soil inaccurately reflects lead exposure from either individual samples or from the site as a whole. This study describes application of a soil lead concentration-bioavailability weighted averaging method for deriving input parameters to the IEUBK model at a mining site in comparison with results derived using independ-

ent averages or model defaults. Lead bioaccessibility testing of site soils indicated lead bioavailability ranging from less than 2.5 percent to 22.5 percent. Relative to the independent averaging method, use of the weighted averaging method resulted in a 24 percent lower estimate of geometric mean blood lead and a 70 percent lower estimate of the percent of individuals exceeding the regulatory blood lead limit of 10 micrograms per deciliter. Differences compared to the model default bioavailability factor of 30 percent were greater. Use of the soil lead bioavailability weighted averaging method provides a site-specific refinement to IEUBK model input parameters that improves the model's ability to accurately estimate lead exposure.

501 ASSESSING BIOAVAILABILITY AND OTHER PARAMETERS INFLUENCING EXPOSURES TO ARSENIC ASSOCIATED WITH CCA-TREATED WOOD.

C. Petito Boyce[1], E. M. Dube[2], C. S. Wells[2] and B. D. Beck[2]. [1]*Gradient Corporation, Mercer Island, WA and* [2]*Gradient Corporation, Cambridge, MA.*

Potential health risks associated with arsenic originating in wood treated with chromated copper arsenate (CCA) are receiving increasing regulatory, scientific, and public attention. A recent risk assessment found that incidental ingestion of arsenic that may be present on the surface of treated wood structures (termed dislodgeable arsenic) was the primary contributor to exposure associated with arsenic from CCA-treated wood. To evaluate this exposure pathway, several exposure parameters were derived that have not been frequently used in other risk assessment contexts, i.e., the concentration of dislodgeable arsenic on the wood surface (C_{da}), the relative bioavailability adjustment (RBA) factor for ingested dislodgeable arsenic, and the hand transfer efficiency (HTE) factor describing the amount of arsenic that would be removed from the wood surface and subsequently ingested. Parameter estimates were derived based on data from the published scientific literature and other relevant studies. In addition, a sensitivity analysis was conducted to examine the variability and uncertainty of each parameter and the influence of parameter choices on risk estimates. Data sources reviewed in this work included studies of arsenic loadings on hands or wipe materials, studies of arsenic bioavailability from CCA-treated wood and other solid media, information regarding the CCA wood treatment process, studies of soil adherence to hands, skin surface area data, and soil ingestion rate data. The results of the sensitivity analyses indicate that potential values for C_{da} could span the widest range (with the 5th and 95th percentile values for a wood sample differing by as much as a factor of 25). By contrast, the high- and low- end estimates of HTE values differed by a factor of 14, while those for the RBA factor differed by only a factor of 2.3. These results suggest that actual arsenic exposures and risks are more likely to be less than the best estimates calculated in the risk assessment than to exceed them.

502 EVALUATION OF HUMAN HEALTH RISKS FROM EXPOSURES TO ARSENIC ASSOCIATED WITH CCA-TREATED WOOD.

E. M. Dube[1], C. P. Boyce[2], B. D. Beck[1] and S. Schettler[1]. [1]*Gradient Corporation, Cambridge, MA and* [2]*Gradient Corporation, Mercer Island, WA.*

We performed a human health risk assessment (HHRA) to evaluate exposures to arsenic associated with chromated copper arsenate (CCA) treated wood. Central tendency exposure (CTE) and reasonable maximum exposure (RME) parameters were used to quantify exposures for a residential and a playground exposure scenario. The residential scenario included a male/female child ages 2-6 years, and a male/female child and adult ages 2-31 years. The playground scenario included a male/female child ages 2-6 and 7-12 years. Both exposure scenarios evaluated incidental ingestion and dermal contact with dislodgeable arsenic, which is arsenic on the surface of CCA-treated wood that can be removed by dermal contact with the hands. Eight different samples of treated wood were included in the evaluation. Exposure to arsenic in soil *via* incidental ingestion, dermal contact, and inhalation was also evaluated. The primary source of arsenic in soil was assumed to be a CCA-treated structure where CCA migrated *via* rainwater run-off from the treated structure to the soil below. Estimated cancer and non-cancer health risks ranged from 4.9E-07 to 5.4E-06 and 2.6E-04 to 2.8E-02, respectively using CTE parameters; and 1.4E-06 to 1.2E-05 and 6.9E-04 to 6.4E-02, respectively using RME parameters, depending on wood sample and receptor. For all of the scenarios evaluated, 80 to 90% of the risks were from ingestion and dermal exposures to dislodgeable arsenic. The highest estimated risks were for a resident exposed to a wooden structure made of CCA-treated Southern Pine with pressure-applied water repellent. Estimated cancer and non-cancer health risks from the most commonly used type of treated wood in the US (i.e., CCA-treated Southern Pine), ranged from 1.1E-06 to 6.6E-06 and 6.9E-04 to 3.3E-02, respectively, for the resident. Based on the results of the HHRA, exposures to arsenic from CCA-treated wood in both a residential and playground setting does not pose a significant health risk to children or adults.

503 THE USE OF A WEIGHT OF EVIDENCE APPROACH TO ASSESS HEALTH RISKS FROM ARSENIC EXPOSURE.

E. Sigal, C. Bacigalupo and R. Moore. *Cantox Environmental Inc., Mississauga, ON, Canada.* Sponsor: J. Daniels.

The importance of considering a weight of evidence approach when evaluating arsenic at contaminated sites became clear during two recent projects. Elevated levels of arsenic were encountered in two communities in Ontario, one near a former gold mine and the other near a sintering plant. Risk assessments, involving multi-pathway exposure assessment (air, water, soil, backyard produce, fish and market basket foods) and use of the USEPA slope factors revealed risk levels in the 1 in 1000 range. Ontario considers 1 in 1, 000, 000 to be the acceptable risk level. These elevated risk estimates raised community concerns. Answers were needed to ensure public safety and satisfy community and regulator concerns. Further investigation into the risk assessment revealed the following: (i) market basket foods were the main contributor to arsenic related risks; (ii) generic criteria in Ontario (25 ppm) result in elevated risk levels (greater than 1 in 100, 000); (iii) the contribution of soil to overall arsenic related risks was small; all other pathways were less significant; (iv) health based intervention levels, as determined by the risk assessment, proved to be economically and technologically impossible; and, (v) removal of all soil above the generic criteria would result in a 2 to 4% overall risk reduction. It became clear that information beyond that typically contained within a risk assessment was needed to complete the decision making process. Therefore, limited health status studies were conducted which considered the incidences of cancer in the communities in question. In addition, urinary arsenic studies compared the 'impacted' communities with 'control' communities. In all cases, these studies indicated that the 'impacted' communities were similar to the control communities. Only after consideration of all pieces of evidence (risk assessment, community health status, urinary arsenic study) was it possible to conclude that there were no unsafe exposures or adverse health effects associated with elevated arsenic levels in both communities.

504 COMPARISON OF THE TOXICOLOGICAL PROFILE DETERMINED IN THE SPRAGUE-DAWLEY RAT FOLLOWING DERMAL OR DIETARY EXPOSURE TO A PROSPECTIVE INSECT REPELLANT ACTIVE INGREDIENT(KBR 3023).

B. S. Wahle, S. G. Lake, L. P. Sheets, G. K. Sangha and W. R. Christenson. *Toxicology, Bayer Corporation, Stilwell, KS.*

The general toxicological profile of -(1-methyl-propoxycarbonyl)-2-(2-hydroxyethyl)-piperidine (KBR 3023), a prospective new insect repellant active ingredient intended for human use, was studied in rats using the dermal and dietary route of exposure. Dermally applied dosages of 0, 80, 200, 500, or 1000 mg/kg/day were evaluated for 13 weeks (followed by a recovery period); dermal dosages of 0, 50, 100, or 200 mg/kg/day were evaluated for 1 and 2 years. Dietary dosages of 0, 100, 150, 300, or 1, 000 mg/kg/day were evaluated for 2, 5, and 14 weeks. With the exception of lesions occurring at the dermal dose site, the toxicological response of the rat following continuous and repeated dermal or dietary exposure to the test substance for durations of up to 14 weeks, was principally characterized by structural and/or functional alterations in liver- and kidney-related endpoints. Lesions noted in the liver were indicative of an adaptive response to an increased need to metabolize and excrete an exogenous chemical. Lesions observed in the kidney were consistent with an α_{2u}-globulin-induced nephropathy, a common lesion in the male rat. By the end of the four-week recovery period that followed the 13-week dermal exposure, all changes attributable to exposure to the test substance had returned to within normal limits. Results following 1 and 2 years of continuous dermal exposure (excluding dose site lesions) were limited to an increased incidence of areas of cystic degeneration of the liver noted in males sacrificed at 2 years; indications of altered liver function were not observed. The same lesion was not identified histopathologically at 1 year. No evidence of a compound-induced neoplasia was suggested. A comparison of the results of these investigations indicate a very similar systemic toxicological response in the rat following exposure to KBR 3023, regardless of the route of exposure.

505 DIFFERENTIAL SPECIES SENSITIVITIES AND DURATION-SPECIFIC REFERENCE CONCENTRATIONS (RfCs) FOR HYDROGEN SULFIDE (H_2S) EXPOSURES.

T. Zewdie. *Massachusetts Department of Environmental Protection (MADEP), Boston, MA.*

H_2S is an extremely hazardous gas and is the most common cause of death in the workplace. Although information on the human toxicity of H_2S is abundant, exposure concentrations and durations are not well defined. Consequently, regulatory

agencies have had to use available animal data to derive RfCs. A subchronic mouse inhalation study resulted in a LOAEL of 111 mg/m^3 and a NOAEL of 42 mg/m^3 for respiratory effects. Both MADEP and the USEPA derived a chronic RfC of 1 µg/m^3 from the above mouse study using the NOAEL. A subchronic RfC of 10 µg/m^3 can be developed using the same data. Because of the emergence of short-term human exposure data acute RfCs were developed and compared with the RfCs based on mouse data. Mild asthmatics exposed to 2.28 mg/m^3 H_2S for 30 minutes sensed odor, and experienced nasal and pharyngeal dryness, bronchial obstruction and headache. This acute human LOAEL is 40 times lower than the mouse subchronic LOAEL (111 mg/m^3) identified in the study that was used to derive the chronic RfC. A 30-minute RfC of 93 µg/m^3 was developed by applying a safety factor of 30 (10 for the use of a LOAEL and 3 to protect severe asthmatics) to the LOAEL (2.78 mg/m^3). In a separate study, field workers exposed to 125 µg/m^3 H_2S for 5 hours sensed persistent odor, and experienced eye and throat irritation, headache and nausea. If this LOAEL (125 µg/m^3) is adjusted by a safety factor of 100 (10 to account for sensitive individuals, and 10 for LOAEL to NOAEL extrapolation), the 5-hour RfC will be 1.25 µg/m^3: similar to the chronic RfC and lower than the subchronic RfC. In conclusion, the emerging data suggest that: (1) humans may be more sensitive than mice to H_2S toxicity; (2) the current chronic RfC may not be health protective and the interspecies extrapolation factor used to derive the chronic RfC should be reassessed to reflect current toxicity data; and (3) future H_2S toxicity studies should be conducted in H_2S-sensitive species like rabbits and guinea pigs that are identified in the literature. (Abstract may not reflect MADEP policy).

506 UTILIZING DATA FROM MULTIPLE STUDIES (META-ANALYSIS) TO DETERMINE EFFECTIVE DOSE LEVELS: EXAMPLE OF MORTALITY IN RATS AND MICE EXPOSED TO HYDROGEN SULFIDE.

K. G. Brown[1] and J. A. Strickland[2]. *[1]Chapel Hill, NC and [2]Integrated Laboratory Systems, Inc., Durham,, NC.* Sponsor: M. Stevens.

Most chemical-specific risk assessments use a single best study to identify a toxicity marker, such as a NOAEL, benchmark dose, or LD50. The objective of this exercise is to incorporate as much data as possible from multiple studies to derive a chemical-specific dose-duration response curve from which to identify toxicity markers. This has the advantage of incorporating more information than single-study assessments. The current example uses mortality for rats and mice, analyzed separately, from acute exposure to hydrogen sulfide. Methods of statistical analysis are used to determine when data from different studies can be pooled. EC01, EC10, EC50 (concentrations at which there are response rates of 1%, 10%, and 50%) are estimated with 95% confidence intervals, at durations of 5, 10, and 30 minutes, and 1, 2 4, and 6 hours. A concentration-response curve for mortality is fit to the rat data simultaneously for exposures of 5 min., 10 min., 30 min., and 1 hour, using a logistic curve additive in log(concentration) and log(duration). Separate curves are fit at 2, 4, and 6 hours. Fewer data are available for mice but fits are obtained for 30 minutes and 1 hour. The curves for rats fit the data exceedingly well and exhibit a threshold-like response followed by a steep incline as concentration increases. The response curves for mice start upward at a much lower concentration than for rats and then incline more gradually. Response is clearly more variable in mice than rats. The data on a mix of nonlethal adverse effects at the durations described above, and the observed NOAELs for mortality from individual studies, are plotted by concentration and described in the text. The NOAELs for mortality from individual studies fall within 95% confidence bounds for the EC01 (except lower at 5 minutes for rats and higher at 30 minutes for mice). Nonlethal adverse effects occur at concentrations below the lower bound for EC01 mortality at most durations.

507 THE ORAL REFERENCE DOSE FOR ETHYLENE DIBROMIDE: A NEW LOOK AT AN OLD PROBLEM.

M. Osier[1], M. Odin[1], C. Smallwood[2] and J. Swartout[2]. *[1]Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY and [2]National Center for Environmental Assessment, USEPA, Cincinnati, OH.*

Previous evaluations of the experimental toxicity data for ethylene dibromide (EDBr) have concluded that limitations of the available studies precluded the derivation of oral toxicity values. Therefore, the USEPA has no oral RfD on IRIS and ATSDR has not developed an MRL for EDBr. Upon critical re-examination of the data, however, with consideration of the strengths and limitations of the existing studies, as well as a proposed mechanism of action for the testicular effects of EDBr, a provisional oral RfD for EDBr of 9x10^{-3} mg/kg-day is presented here. A lifetime carcinogenicity study in rats and mice was performed by the NCI, but was terminated prematurely because the MTD was apparently being exceeded. Even with early termination, dose-related increases in testicular atrophy were noted histologically, as well as increased incidence of tumors of the tunica vaginalis (the serous covering of the testes). Several studies in bulls exposed orally to low doses of EDBr also showed testicular atrophy, which was reversible upon cessation of exposure. Rodent studies of 90 days and 17 months have also examined the oral toxicity of EDBr. The provisional RfD is based on testicular atrophy in rats observed in the NCI study rather than on the effects observed in bulls at lower doses. The rationale for the choice of critical study includes an allometric argument as well as a mechanistic one.

508 NOAEL/LOAEL AND BENCHMARK DOSE APPROACHES TO SETTING ACCEPTABLE HUMAN EXPOSURE LEVELS TO 1, 2-DICHLOROETHANE (ETHYLENE DICHLORIDE).

D. A. Beblo[1] and P. McGinnis[2]. *[1]Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY and [2]Environmental Science Center, Syracuse Research Corporation, Philadelphia, PA.*

Chemical risk assessment approaches other than the most common NOAEL/LOAEL approach are being considered by the EPA. The benchmark dose (BMD) approach has a number of advantages to the traditional NOAEL/LOAEL approach, including not being limited to the experimental doses, and responding to sample size and the associated uncertainty. Because EPA's IRIS database contains no reference dose for chronic oral exposure (RfD) for 1, 2-dichloroethane, multiple approaches were compared for derivation of a provisional toxicity value. The majority of 1, 2-dichloroethane released into the environment enters the atmosphere from its production and use as a chemical intermediate, solvent, and use as a lead scavenger in gasoline. Major human exposure is from urban air, drinking water from contaminated aquifers and occupational atmospheres. Animal studies point to the kidney and liver as target organs for 1, 2-dichloroethane toxicity, consistent with reported injury to these organs in humans following accidental acute ingestion. The principal study selected as the basis for RfD derivation was conducted in rats and used five concentrations in drinking water, ranging from 500-8000 ppm, and a vehicle control. The lowest exposure level was considered a minimal LOAEL for increased kidney weight. Because the principal study examined a sufficient number of exposure levels, an RfD was also calculated using a BMD approach. RfD comparisons were based on several endpoints including increased kidney and liver weights, renal and liver histopathology, and altered enzyme activities.

509 HEALTH RISK ASSESSMENT FOR TRICHLOROACETIC ACID.

D. Wong. *Office of Water, OST/HECD, USEPA, Washington, DC.*

TCA is one of the five haloacetic acids considered for regulation under EPA's proposed Stage 2 Disinfectants and Disinfection Byproducts Rule. A health risk assessment was conducted based on available studies. TCA induces systemic, noncancer effects in animals that can be grouped into three categories: alterations in intermediary carbohydrate metabolism, liver toxicity and developmental toxicity. The liver is the primary target organ for TCA toxicity. In a 104 week drinking water study in male F344 rats (DeAngelo et al., 1997), there was a significant decrease in body weight(10%), minimal histopathological changes in the liver, increased serum alanine aminotransferase level, and increased peroxisome proliferation at 364 mg/kg-day. The No-Observed-Adverse Effects-Leved (NOAEL) is 32.5 mg/kg-day. TCA increased resorptions, decreased implantations, and increased fetal cardiac malformations when administered to pregnant rats at 291 mg/kg-day on gestation days 1-22 (Johnson et al., 1998). In another study (Smith et al., 1989), decreased fetal weight and length, and increased cardiovascular malformations were observed when pregnant rats were administered 330 mg/kg-day TCA by gavage during gestation days 6 to 15. A RfD for TCA of 0.03 mg/kg-day is derived from the NOAEL of 32.5 mg/kg-day for liver histopathological changes identified by DeAngelo et al. (1997). An overall uncertainty factor of 1000 is applied to the NOAEL to calculate the RfD. Mutagenicity data have provided mixed results. TCA was reported to induce liver tumors in mice but not in rats. EPA has classified TCA as Group C: possible human carcinogen. Under EPA's Draft Guidelines for Carcinogen Risk Assessment, TCA can be described as having "Suggestive evidence of Carcinogenicity, but not Sufficient to Assess Human Carcinogenic Potential". (The opinions expressed in this abstract are those of the author and not necessarily those of EPA.)

510 RE-EVALUATION OF THE ORAL REFERENCE DOSES FOR THE BROMINATED TRIHALOMETHANES BROMODICHLOROMETHANE, DIBROMOCHLOROMETHANE, AND BROMOFORM.

L. H. Moilanen[1], B. C. Allen[2] and N. H. Chiu[3]. *[1]Environmental Science Center, Syracuse Research Corporation, Denver, CO, [2]ICF Consulting, K.S. Crump Group, Chapel Hill, NC and [3]Health and Ecological Criteria Division, Office of Science and Technology, USEPA, Washington, DC.*

The brominated trihalomethanes (BTHMs) bromodichloromethane (BDCM), dibromochloromethane (DBCM), and bromoform are by-products of drinking water chlorination. Information on the hazard, dose-response, and risk characterization

of these chemicals is being updated. Oral Reference Doses (RfDs) for BDCM, DBCM, and bromoform have previously been derived using the conventional NOAEL/LOAEL approach and are reported in the Integrated Risk Information System (IRIS). The RfDs obtained were 0.02 mg/kg-day for BDCM, based on lesions in the liver, kidney, and thyroid of exposed mice; 0.02 mg/kg-day for DBCM, based on absence of lesions in exposed rats; and 0.02 mg/kg-day for bromoform, based on absence of effects in exposed rats. For the updating process, new health effects data published between 1993 and July, 2001 were identified and evaluated. Toxicological endpoints from new and existing studies were reviewed for suitability for benchmark dose modeling. Benchmark doses (BMDs) for selected endpoints were obtained using the Benchmark Dose Modeling Software (Version 1.2) developed by the USEPA National Center for Environmental Assessment. $BMDL_{10}$ values (the 95% lower confidence limit on the BMD) were used to calculate a new RfD for each BTHM. The uncertainty factors used in derivation of the RfD values were also re-evaluated in consideration of new studies added to the databases for individual BTHMs. Using this approach, the resulting RfD values are 0.003 mg/kg-day for BDCM, based on fatty degeneration in the liver of rats; 0.02 mg/kg-day for DBCM, based on fatty changes in the liver of rats; and 0.009 for bromoform, based on hepatocellular vacuolization in the liver of rats. (This work was conducted under contract to EPA, but the opinions expressed in this abstract are those of the authors and do not necessarily represent EPA policy.)

511 UPDATED ASSESSMENT OF HEALTH EFFECTS FROM TOLUENE EXPOSURE.

P. McClure[1], M. Osier[1] and L. Flowers[2]. [1]*Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY, and* [2]*National Center for Environmental Assessment, USEPA, Washington, DC.*

Toluene is widely used in industry as a solvent, gasoline additive, and in polymer production. The present EPA assessments for toluene on IRIS were verified between 1987 and 1990. Since the verification dates, a number of new studies have been published, warranting a reconsideration of the data for toluene. The existing IRIS RfD is based on hepatic effects in rats exposed by gavage. New oral studies not described on IRIS examined hepatic, immunological, and neurological endpoints, and raise the issue of whether or not to change the critical effect for RfD derivation from hepatic effects to one based on immunological or neurological endpoints. The existing RfC is based on a LOAEL for neurobehavioral effects in a study of toluene-exposed electronics workers, but a number of new studies examining neurologic effects in occupationally-exposed humans have been published, including two identifying NOAELs. The new studies support neurological effects as the critical effect for RfC derivation and add more information about exposure-response relationships. Several methods of analysis, including NOAEL/LOAEL and benchmark dose analyses, are under consideration with regard to the derivation of a new RfC. New data are also available examining the potential carcinogenic effects of toluene. While a single oral study in rats has suggested carcinogenic effects of toluene, limited reporting of the study results confounds interpretation. Adequate inhalation bioassays in rats and mice have not demonstrated a carcinogenic effect of toluene, and the vast majority of genotoxicity evaluations of toluene have been negative. (This document does not necessarily reflect EPA policy.)

512 REFINEMENT OF REFERENCE DOSE (RFD) FOR ZINC.

L. Ingerman[1], H. Choudhury[2] and M. Osier[1]. [1]*Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY, and* [2]*National Center for Environmental Assessment, Office of Research and Development, USEPA, Cincinnati, OH*

USEPA is currently re-evaluating the RfD for zinc. Derivation of an RfD for zinc requires balancing its essentialty functions with its potential adverse effects. Essential trace elements, such as zinc, pose an additional problem of nutrient-nutrient interactions. The excessive intake of one nutrient may interfere with the toxicokinetic properties of another nutrient. Increased zinc intake has been associated with a number of adverse health effects in humans, including decreased erythrocyte Cu-Zn superoxide dismutase (ESOD) activity, hematological effects, decreases in HDL-cholesterol levels, and gastrointestinal effects. Human studies provide evidence that excessive zinc intake may primarily induce copper deficiency. Excessive dietary zinc results in the induction of intestinal metallothionein synthesis. Since metallothionein has a greater binding capacity for copper than for zinc, copper absorbed into the intestinal mucosal cells is sequestered by metallothionein and does not enter the body. Copper deficiency is the primary mechanism for a number of the effects associated with excessive zinc intake, including decreases in HDL-cholesterol levels and ESOD activity. The endpoints associated with copper deficiency appear to be the most sensitive targets of toxicity (occur at doses of Zn as low as 300 ppm). There are limited data to suggest that high zinc intake can decrease iron absorption leading to symptoms of iron deficiency. In deriving an RfD for zinc, these interactions, as well as others, must be considered to determine a level of zinc (4-40 mg/day) that would not result in a disturbance in the balance of other nutrients. (This abstract does not necessarily reflect USEPA policy).

513 RESIDENTIAL SOIL SAMPLING FOR CLEANUP DETERMINATION: COMPARISON OF FIXED-SITE LABORATORY AND FIELD PORTABLE X-RAY FLUORESCENCE (FPXRF) ANALYSIS AND SAMPLE PREPARATION.

M. L. Stifelman., *USEPA, Seattle, WA.* Sponsor: G. Diamond.

Lead and other metals released from over 100 years of smelting and mining remain a public health concern in Idaho's Silver Valley. In 1986, USEPA and Idaho Department of Environmental Quality started to remove contaminated soil from public areas located near the Bunker Hill Lead Smelter. Recently, USEPA has focused its efforts on sampling and cleanup of lead-laden soils at residences along the South Fork Coeur d'Alene River. Sampling objectives included analysis of soil for lead, arsenic, and zinc for cleanup determination as well as collecting data to test FPXRF as a predictor for fixed-site laboratory analyses (acid digestion/Inductively Coupled Plasma Spectroscopy, AD/ICP) of dried and sieved samples (< 175 micrometer size fraction). FPXRF analyses were performed using a Niton XL 723. Results of FPXRF analyses of 1) dried and sieved samples; 2) dried samples; and 3) unprepared samples (at field moisture) were compared with dried and sieved samples analyzed by AD/ICP. Linear regression models of the dependence of AD/ICP on FPXRF yielded R-square values (R^2) that varied little among sample treatments, although the slopes of the zero intercept regression lines for lead were 0.92, 1.27, and 1.64 for groups 1-3, respectively. For lead, values for R^2 were: 0.94, 0.92, and 0.92 for groups 1-3. For arsenic, the R^2 values were: 0.97, 0.96, and 0.86. For zinc, the R^2 values were: 0.94, 0.86, and 0.94. These results suggest that, for these samples, predictions of AD/ICP from FPXRF measurements would not have been highly affected by drying (moisture content) or sieving (particle size). Future sampling will use FPXRF to analyze unprepared samples with confirmatory AD/ICP analysis of sieved and dried samples when FPXRF results approach soil cleanup levels. Benefits of FPXRF and reduced sample preparation include financial and logistical gains with potential to increase sampling density. Future plans include re-examining sampling and analysis protocols to apply real time data acquisition to adaptive sampling techniques.

514 RISK ASSESSMENT OF METHYLMERCURY INTAKE FROM SPORT FISH TAKEN FROM SELECTED WATER BODIES IN THE NORTHERN SIERRA NEVADA FOOTHILLS, CALIFORNIA.

S. A. Klasing, R. K. Brodberg and A. M. Fan. *California Environmental Protection Agency, Office of Environmental Health Hazard Assessment, Oakland/Sacramento, CA.*

The United States Geological Survey collected samples of nine sport fish species from five reservoirs and 14 stream sites in northwestern Sierra Nevada watersheds affected by historical gold mining. Total mercury concentrations were analyzed in composite and individual boneless and skinless fillet samples and reported on a wet weight basis. Mercury concentrations in collected fish species ranged from 0.02 to 1.53 ppm, with the highest concentrations found in spotted bass (mean: 0.85 ppm). In October 2000, the Departments of Environmental Health of Nevada, Placer and Yuba Counties, in cooperation with the Office of Environmental Health Hazard Assessment (OEHHA), issued an interim advisory recommending that sport fishers limit their consumption of several species caught in the study area. OEHHA has since conducted a more detailed assessment to determine human exposure to mercury and the associated potential health risks from consumption of these sport fish. Sample size was sufficient ($\geq$9) for exposure characterization at four species/site combinations. Using the USEPA RfD for methylmercury ($1x10^{-4}$ mg/kg-day), results of the assessment suggest that consumption by pregnant women and young children should be limited for spotted bass from Camp Far West, largemouth bass from Lake Combie, smallmouth bass from Lake Englebright, and channel catfish from Rollins Reservoir. For other sites and/or species, data for similar species from the same water body or the same species from different water bodies were pooled to determine whether consumption should also be limited. Consumption restrictions are also recommended for all other bass species, channel catfish and bluegill from all evaluated reservoirs and brown trout and rainbow trout from the Bear River, South Yuba River, and Deer Creek sites. OEHHA, the agency responsible for issuing state fish advisories, will follow up in developing a final health advisory.

515 EVALUATION OF TEQ EXPOSURE FROM FISH CONSUMPTION RELATIVE TO AVERAGE POPULATION TOTAL EXPOSURE: IMPLICATIONS FOR PCB, PCDF, AND PCDD RISK MANAGEMENT.

N. L. Judd, W. C. Griffith and E. M. Faustman. *Environmental Health, University of Washington, Seattle, WA.*

Recognition of a common mode of action for dioxins, dioxin-like PCBs and dibenzofurans has expanded our ability to assess cumulative risk from exposure to these ubiquitous compounds through consideration of TCDD toxic equivalency (TEQ).

PCBs are the second greatest cause of fish advisories, and PCBs are often the greatest contributors to TCDD-TEQ in fish. Because fish consumption is associated with both contaminant risks and health benefits, the incremental risk from this source should be considered within the context of overall TEQ associated risk. In this study, adult TEQ exposure from fish consumption using consumption data and recent fish contaminant data from the literature is explored relative to average population exposure to these agents. Recent estimates presented by EPA suggest fish and seafood contribute just 19% of average dioxin like exposure. However, results from our study indicate that for high level consumers eating from relatively contaminated sites, TCDD-TEQ exposure from fish consumption alone may be 400% greater than the 1 pg TEQ/kg/day average estimated by EPA. This average exposure potentially carries an upper bound cancer risk of one in one thousand. Risk for other groups who consume high levels of fish and seafood from primarily commercial sources is likely less, but is far more uncertain, since data sufficiently sensitive to assess cancer risk from dioxin-like PCBs or even total PCBs, is unavailable for over 96 percent of the seafood they consume. For most adult consumers, however, fish may contribute a small incremental risk from these compounds relative to an unacceptable ambient TCDD-TEQ associated risk, indicating the need for exposure reduction through more holistic environmental efforts rather than simple dietary changes. This proposal was prepared with support of US Department of Energy, under Award No. DE-FG26 00NT40938. However, any opinions, findings, conclusions, or recommendations expressed are the author's and do not necessarily reflect the views of the DOE.

516 RISK ASSESSMENT OF POLYCHLORINATED BIPHENYLS (PCBs) IN INDOOR AIR.

B. K. Davis[1], J. F. Beach[2], M. J. Wade[1], A. K. Klein[1] and K. Hoch[2]. [1]*Toxic Substances Control, California EPA, Sacramento, CA and* [2]*Tetra Tech EM Inc., San Francisco, CA.*

In the 1970s, residences were built on a site where recent investigation found PCBs (primarily Aroclor 1260) in soil at concentrations as high as 160, 000 mg/kg. Contaminated soil was removed to a target level of 1 mg/kg, but concentrations under the residences were not removed or sampled. Though PCBs are relatively non-volatile, they are complex mixtures and there is a potential for transport of some constituents from soil through the foundation into indoor air. A screening analysis using USEPA's Johnson and Ettinger model for subsurface vapor intrusion estimated greater than 1000 ng/m3 in indoor air, corresponding to a possible cancer risk greater than 1E-5. The modeling was based on a saturation soil concentration of 168 mg/kg. Soil concentrations suggest the presence of non-aqueous phase PCBs in the soil, limiting the utility of the model. Five indoor air samples were collected in three sampling events over four months. Congener-specific analysis using GC/SIM-MS measured total PCBs in indoor air ranging from 112 ng/m3 to 234 ng/m3. The SIM-MS detector has a low detection limit for risk management requirements, but may have resulted in artifacts of sampling, preparation, and analysis. Those potential artifacts required careful analysis of the analytical data to characterize air concentrations. The congeners measured in indoor air were mostly mono-chlorinated. Cancer risk estimates for the detected concentrations range from 1E-6 to 7E-5. Conclusions: 1. The indoor air exposure pathway can be complete for low-volatility chemical mixtures in soil if they contain more volatile components and source concentrations are high. 2. Congener analysis provides information essential to evaluate exposure to PCB vapors, because the congener distribution in air can be very different from that in soil. 3. The Johnson and Ettinger model is useful in identifying potential concerns. 4. Indoor air measurements are technically difficult, but can provide critical information about actual indoor exposures.

517 HUMAN EXPOSURE AND RISK ASSESSMENT OF METHIDATHION IN GREENHOUSES.

J. Byoun[1], K. Liu[1], H. Lee[2], H. Sung[2], K. Kim[3] and J. Kim[1]. [1]*School of Agricultural Biotechnology, Seoul National University, Suwon, South Korea,* [2]*Division of Pesticide Safety, National Institute of Agricultural Science and Technology, Rural Development Administration, Suwon, South Korea and* [3]*Toxicology Research Center, Korea Research Institute of Chemical Technology, Taejeon, South Korea.* Sponsor: M. Cho.

Methidathion (S-2, 3-dihydro-5-methoxy-2-oxo-1, 3, 4-thiadiazol-3-ylmethyl-O, O-dimethyl phosphorodithioate) is a non-systemic, organophosphorous insecticide registered for control of agricultural insect and mite pests on various terrestrial food crops, such as cucumber, citrus and apple in Korea. Human health risk assessment of methidathion was evaluated in greenhouse situation for risk management and for safe re-entry interval establishment. Dermal and inhalation exposure to methidathion were measured when this chemical was mixed/loaded, applied, and during the harvest. And dermal penetration rate was estimated with *in vitro* dermal penetration test using diffusion cell. Oral ADI of methidathion is 0.002mg/kg/day and Oral NOAEL for human is 0.2mg/kg/day. The dermal penetration rate of methidathion was 13.92μg/cm2/hr. The dermal exposure from mixing/loading or application was 2.69mg/hr and 115.6mg/hr, respectively. The average dermal exposure of harvesters for 2days was found to be 1.08mg/hr. There was no significant evidence of inhalation exposure. Hazard Quotient (HQ) and Margin of Exposure (MOE) were used for short-term risk assessment of methidathion. There was no potential risk of mixing/loading, and harvest under the Personal Protective Equipment (PPE) situation

518 ESTIMATES OF ACRYLAMIDE INTAKE FROM THE USE OF PERSONAL CARE PRODUCTS CONTAINING POLYACRYLAMIDE: A MONTE CARLO ANALYSIS.

G. A. Lawrence, C. Van Landingham and A. M. Shipp. *ICF Consulting, Ruston, LA.* Sponsor: M. Friedman.

Estimates of the Lifetime Average Daily Dose (LADD) of acrylamide resulting from the use of representative personal use products containing polyacrylamide have been developed. Because each of the variables that are used to estimate intake can have a range of values and there is uncertainty as to which is the true value, a Monte Carlo analysis was conducted to make maximum use of all of the data. From these data, distributions of values were defined and used to provide a distribution of LADDs for each personal care product. Further, estimates of unit risk factors and doses corresponding to a target risk level, in this case, 1x10-5, were estimated from the bioassay data reported by Johnson et al. (1986) and Friedman et al. (1995) using those approaches typically used by the FDA, the USEPA, and proposed for use by the European Union (EU). Ratios of the estimated acrylamide intake at the median, mean and 90th percentile of the distribution of individual intake values to the lifetime dose corresponding to a target risk level of 1x10-5 were also calculated. All ratios were well below 1, indicating that all were below the target risk level. The conclusion can be drawn that the lifetime cancer risk from the use of polyacrylamide-containing personal care products, in the manner assumed in this Exposure Assessment, are well below acceptable levels. In all cases, even at the 90th percentile on the distribution of LADDs, the ratio of intake to the target dose ranged from 0.01 to 0.000002. Stated differently, use of some of these products and the resulting acrylamide intake from that use would have to increase approximately 100 times at the high end of exposure by more than 500, 000 times to reach the target risk level of 1x10-5. Even if it were assumed that an individual used all of the products together, the estimated intake would still provide a dose that was well below the target risk level.

519 ASSESSING POTENTIAL CANCER RISKS ASSOCIATED WITH INSECTICIDES USED TO CONTROL THE MOSQUITO-BORNE WEST NILE VIRUS: USE OF THE MARGIN OF EXPOSURE APPROACH.

M. R. Seeley, S. Schettler, C. Liu, R. J. Blanchet and T. S. Bowers. *Gradient Corporation, Cambridge, MA.*

The 1999 outbreak of the mosquito-borne West Nile Virus in New York City (NYC) resulted in the use of insecticides in an attempt to control mosquitoe populations. Because of the potential for human exposure to insecticides, a human health risk assessment was performed to describe and quantify the potential for health effects, including cancer, due to insecticide spraying. We evaluated cancer risks for six active ingredients in the insecticides, including the organophosphates malathion and naled, the pyrethroids permethrin, resmethrin, and sumithrin, as well as the synergist, piperonyl butoxide. With the exception of naled, there is some evidence that these active ingredients may cause cancer in humans, based on data from animal bioassays. Cancer risks are typically evaluated using a cancer slope factor (CSF). However, CSFs were only available for malathion and permethrin. Of the remaining potentially carcinogenic active ingredients, USEPA specifically recommends using a Margin of Exposure (MOE) approach for evaluating cancer risks for piperonyl butoxide, using the reference dose (RfD) as a point of departure (*i.e.*, a dose associated with a negligible increase in excess cancer). In order to fully evaluate any potential cancer risks in the absence of a CSF or other recommendations, we also used the MOE approach for evaluating cancer risks due to sumithrin and resmethrin, using their RfDs as a point of departure. This poster discusses our rationale for using the MOE approach, and presents the results of our evaluation. For sumithrin and piperonyl butoxide, the MOE is sufficiently high (*i.e.*, the exposure dose was sufficiently lower than the point of departure) as to indicate that cancer risks should be negligible. For resmethrin, the MOE indicates that although there may be some concern for increased cancer risk, excess risks are likely to be very low.

520 RISK ASSESSMENT OF A MILITARY PUBLIC GOLF COURSE SLATED FOR CLOSURE.

O. B. Hodoh[1,2], M. A. Smith[1,2] and T. W. Simon[3]. [1]*Environmental Health Sciences, University of Georgia, Athens, GA,* [2]*Interdisciplinary Toxicology, University of Georgia, Athens, GA and* [3]*, USEPA, Atlanta, GA.*

In 1993, Naval Air Station (NAS) Cecil Field was slated for closure by the Base Realignment and Closure Commission and approximately 17, 200 acres is planned for transfer to the private sector. Cecil Field is participating in the Installation

Restoration Program (IRP) under the Department of Defense, to identify, investigate, and cleanup contamination from hazardous materials. Reuse plans have been developed to assist in the property transfer and other closure activities. Anticipated future uses include public buildings and facilities, residential land use, a new runway and industrial use. A risk assessment was performed to evaluate current and future cancer risks and noncancer health hazards from human exposure to a military public golf course potentially contaminated with pesticides, herbicides, insecticides, metals and volatile organic compounds (VOCs). The reasonably maximally exposed (RME) scenarios include an on-unit maintenance worker, future excavation worker, and recreational golfer. Future residential exposures to an adult or child potentially exposed to contaminated soil due to recreational and residential activities were also evaluated. Results from the lifetime cancer risks (RME estimate) were 3E-03 for the future residential adult and 3E-04 for the recreational golfer. For noncancer health effects, the estimated HQ for the residential adult was 24.0 and the estimated HQ for the golfer was 1.5. The cancer risks and non-cancer health hazards for the exposure pathways of the other receptors were much lower. It would be interesting to compare the estimated risks at this previous military golf course to those risks estimated with soil sampling at other private and public golf courses in the southeast.

521 BIODEGRADATION *RULES OF THUMB*: A MEANS TO REDUCE UNCERTAINTY ASSOCIATED WITH PREDICTING HALF-LIVES OF TOXIC, COMBUSTOR-EMITTED CHEMICALS DEPOSITED ONTO SOILS.

D. Knaebel[1], D. Gray[1], P. Howard[1], P. McGinnis[1], E. Brady-Roberts[2] and D. Williams[2]. *[1]ESC, Syracuse Research Corp., N. Syracuse, NY and [2]USEPA, ORD/NCEA, Cincinnati, OH.*

To address the risk presented by combustor-emitted chemicals deposited onto soils, this research examined if general trends, or "*Rules of Thumb*" could be derived that describe the basic influences that soil or chemical characteristics have on biodegradation half-lives. An exhaustive search of the scientific literature was conducted to find documents that provided half-life data and appropriate soil information. Data were extracted from these reports, entered into a database, and statistically analyzed. Soil characteristics examined were pH, organic matter content, soil type, and percent sand, silt and clay. Chemical characteristics examined were formula weight, melting point, water solubility, vapor pressure, Henry's Law constant, Octanol-water partition coefficient (K_{OW}), and soil partition coefficient (K_{OC}). The database provided summary information about the chemicals, the soils in which the chemicals' half-lives were studied, and the range of half-lives observed. Statistical analyses permitted derivation of two *Rules of Thumb*. One *Rule* states that when a chemical is deposited onto a soil, its half-life will be longer in soils high in sand content compared to soils with less sand. The other *Rule* states that a chemical's half-life will be longer in soils with greater amounts of clay compared to soils with less clay. A predictive model was derived that allows estimation of half-lives for chemicals when they are deposited into different soils. The model has the form: Log(half-life)= 2.37×(log[FW]) - 0.145×(log[wat sol]) +0.012×(% sand) +0.753×(log[% clay]) - 8.018 {R^2=0.631, n=110}. Analysis showed, however, that more data are needed to apply this model to a wider range of chemical and soil types. In conclusion, the risk presented by combustor-emitted chemicals that are deposited onto a soil will depend in part on the sand and clay content of that soil. The *Rules of Thumb* capture the important elements of this relationship.

522 EUROPEAN AND USA RBCA, COMPARISON OF HEALTH RISK ASSESSMENT RESULTS FOR OIL REFINERY SITES.

R. J. Welsh. *Toxicology, URS Corporation, New York, NY.*

The potential for residential and industrial redevelopment of a large oil refinery sites were addressed using Tier 2 Risk-Based Corrective Action (RBCA) approach. Two software packages were used in the Tier 2 risk assessments: 1) Van Hall Instituut, Netherlands, RISC-HUMAN, Version 3.1, 1999; and 2) Groundwater Services, Inc.., USA, ASTM RBCA, Version 1.2, 1999. The RISC-HUMAN model is based on methodologies developed by the Netherlands National Institute of Public Health and Environmental Protection (known as RIVM). The GSI model is designed to meet the requirements of the American Society for Testing and Materials (ASTM) PS-104 Standard Provisional Guidance for RBCA. There are several key differences in the models including: 1) the default exposure routes addressed; 2) the methodologies for evaluating carcinogenic risk; 3) the default human exposure and site parameters; and 4) the chemical fate and transport algorithms. Of particular note are the differences in the models for calculating the volatilisation of contaminants from subsurface soil and groundwater to indoor air. A comparison is made between both the model methodologies and results of the risk assessment (i.e., back-calculated risk-based screening levels or RBSLs).

523 THE HEALTH SURVEY OF MUNICIPAL INCINERATOR WORKERS IN JAPAN.

Y. Ogawa[1], I. Mouri[1], R. Yoshida[1], S. Yu[1], A. Nakata[1], R. S. Wang[1], S. Ueno[1], R. Bowler[2] and N. Hisanaga[1]. *[1]National Institute of Industrial Health, Kawasaki, Japan and [2]San Francisco State University, San Francisco, CA.*

It is well known that municipal solid waste incinerator (MSWI) fly ash contains heavy metals, dioxins, polyaromatic hydrocarbons, and other organic materials. The workers at MSWIs have a certain possibility to absorb such materials chronically *via* exposure to fly ash. The purpose of this paper is to investigate the health effects of chronic exposure to fly ash on MSWI workers. The subjects were 81 male workers (mean age 42.7) from four MSWIs in the same city. Written informed consents were given from all subjects. Blood and urine samples were corrected in the morning of each study day. Occupational health doctors interviewed each subject about his job history, evaluated the exposure to fly ash, and calculated its total duration. The subjects were classified into four groups; those were Long duration of exposure to fly ash, Short duration of exposure to fly ash, Limited exposure to fly ash, and Control. Blood chemistry, oxidative stress markers, immunological markers, sex related hormones, and neurobehavioral functions were measured and compared among the groups. There were no significant difference or association between measured variables and the groups except oxidative stress markers and neurobehavioral functions. The results of oxidative stress marker are presented elsewhere in this meeting (R Yoshida). The 4 T-scores of POMS (Profile of Mood State), which are Tension-anxiety, Depression-dejection, Fatigue-inertia, and Confusion-bewilderment, increased according to the elongation of the exposure duration. Grip strength of non-dominant side and the ability of short-term memory using a portion of the Symbol Digit Modalities Test increased in Long-exposure-duration group. Although we could not conclude that a certain contaminant of fly ash was responsible to these effects, there may be neuropsychological effects on workers exposed to fly ash.

524 CHARACTERIZING THE HUMAN RISKS FROM MILITARY USE OF NON-LETHAL WEAPONS (NLWS).

J. Patterson, A. Maier and M. Dourson. *TERA, Cincinnati, OH.*

Non-Lethal Weapons (NLWs) are important assets in nontraditional military operations, such as peacekeeping missions, where the use of lethal force may not be a desired first response. Various types of NLWs are considered, including those employing chemical, electromagnetic, mechanical, or acoustic technologies. DoD directives call for these weapons to achieve an appropriate balance between the competing goals of having a low probability of causing death, permanent injury, and collateral materiel damage, and a high probability of having the desired anti-personnel or anti-materiel effects. A conceptual framework for characterizing the risks of human effects from non-lethal weapons has been developed. This framework focuses on the physiological effects caused by the weapons and utilizes tools and techniques of risk assessment, including Dose-Response and exposure information, and decision analysis to provide decision-makers with the probability of intended effects and unintended effects for the exposure scenarios of interest. Preliminary results indicate that force over distance is one unifying metric for some NLWs, and that Dose-Response curves for intended and unintended effects may be estimable for some NLWs, but not others. Field commanders and mission planners could use the resulting risk information to make informed choices with regard to which NLWs would provide the most appropriate combination of target effectiveness and risk for the particular situation or mission. This conceptual framework, and application of it to weapon systems based on various technologies, is a new application of the traditional toxicology and epidemiology based risk assessment approaches. This work was funded by Department of Defense under subcontract PO P66050-DSC0142.

525 RECYCLING WASTES IN AGRICULTURE: EVALUATION OF THE QUÉBEC CRITERIA FOR CADMIUM AND DIOXIN/FURAN BASED ON HUMAN HEALTH ASSESSMENT.

M. O. Fouchécourt and M. Beausoleil. *Institut National de Santé Publique, Montréal, PQ, Canada.* Sponsor: K. Krishnan.

In the province of Québec, Canada, municipal or industrial wastes such as biosolids or calcic amendments can be used as fertilisers in agriculture if they respect several criterias including maximal concentration of 11 inorganic elements and of dioxin/furans (D/F). The objective of this study was (i) to evaluate the exposure of highly exposed individual (HEI) to cadmium (Cd) and D/F when biosolids and calcic amendments (CA) used as a main fertilisers have a concentration of Cd or of D/F equal to the maximal allowed, and (ii) to determine if the risk level is acceptable for the public health. Mean application rates (t d.w./ha-y) of pulp and paper biosolids (1.45 and 2.45 for primary biosolid (B1) and mixed biosolid (B2), respectively) and for CA (0.525) were determined from four scenarios of fertilisation that

respect both agronomic and environmental constraints. Cd and D/F concentrations were set to 3, 10 and 24 mgCd/kg and to 17, 27-50 and 27 ng EQT/kg in B1, B2 and CA, respectively). The contamination of the soil receiving these fertilisers annually was estimated for 100 years. The levels of Cd and D/F in food produced on this soil and on control soils (background concentrations) were estimated by the same method and compared. The HEI was defined as a farmer which spend all its life in a region where soils are mainly fertilised with biosolids and CA, and which is exposed by ingestion (soil, biosolids, CA, contaminated food), inhalation (vapour, dusts) and dermal contact. The method used to estimate the dose of exposure was validated by comparison of the doses estimated from the background concentration in soil with the ones published for Canadians by other authors. Following a long term (100 y), concomitant use of biosolids and CA in the conditions described above, the dose of exposure of the HEI should exceed the reference dose for cadmium (i.e., 0.84 µg/kg-d). The contamination by D/F would lead to a 65% increase of the risk of cancer related to the background level of risk, which is already higher than 1×106

526 HAZARDOUS AIR POLLUTION: A RESEARCH STRATEGY.

M. J. Selgrade. *NHEERL, USEPA, ORD, Research Triangle Park, NC.*

The 1990 Clean Air Act Amendments list 188 chemicals/chemical classes as hazardous air pollutants(HAPs). EPA's implementation of this act includes characterizing residual risks after applying technology-based standards for sources of HAPs, and developing an understanding of risks in urban areas from a subset of 33 HAPs, as well as risks from indoor and mobile sources. Nat'l Air Toxics Assessments (NATA) will monitor progress towards EPA's goal to eliminate unacceptable risks of health problems from HAPs. The 1st NATA reveals many uncertainties. A research strategy is needed to reduce the uncertainties in risk assessment that result from lack of information. The research needed differs considerably from that needed to address the 6 criteria pollutants. The sheer number of chemicals is daunting. Thus, it is necessary to focus attention on those HAPs which pose the greatest risk to humans, and if possible group HAPs based on physicochemical properties, structure/activity, and mechanisms of toxicity, in order to increase the usefulness of information gathered on any one HAP. HAPs can pollute different media; hence, inhalation may not be the only or even primary exposure route. Research is therefore needed to consider the fate & transport of HAPs once they leave the source, to characterize personal exposures, and to consider methods for dealing with aggregate risks of exposure of multiple organ systems by more than one route. Because much of the current data come from studies using other than inhalation exposures, pharmacokinetic models are needed to facilitate route to route extrapolation. Information is also needed to deal with cumulative risk of exposures to HAP mixtures and to consider the risks of sensitive populations. Unlike the criteria pollutants, HAPs risk assessments will have to rely more heavily on animal to human extrapolation. The purpose of this symposium is to propose a multidisciplinary approach for meeting HAP research needs, provide some examples, and encourage the researchers to think outside the traditional box of one chemical, one route of exposure, one species studies. This abstract does not reflect EPA policy

527 EXPOSURE ASSESSMENT TO HAZARDOUS AIR POLLUTANTS.

C. P. Weisel. *EOHSI/ECM, UMDNJ/RWJMS, Piscataway, NJ.* Sponsor: M. Selgrade.

When Hazardous Air Pollutants (HAPs) are prioritized according to potential risk, it is critical to consider total exposure from both ambient and non-ambient emissions. Exposure to HAPs from non-ambient sources can exceed that from ambient emissions. Small sources of HAPs in close proximity to people (releases within homes and use of personal products) can dominate the inhalation exposure and HAPs have other exposure routes (dermal/ingestion). For example, inhalation exposure to formaldehyde indoors with new furnishings, ingestion exposure to PAH from charcoal cooked foods, and ingestion and dermal exposure to dust containing lead and pesticides for toddlers can exceed inhalation exposures from ambient air sources. Characterization of HAPs by source type and physiochemical properties is important because not all HAPs can be individually determined in a cost effective manner. The contribution of ambient air emissions to indoor air is a function of environmental transport and penetration factors into homes. The indoor air concentration is critical to determine since people spend the majority of their time indoors or in transit. We have measured indoor/outdoor and personal/outdoor air ratios that were greatly in excess of one for many of the HAPs, such as the VOCs, tetrachloroethyene, chloroform and 1, 4 dichlorobenzene and the aldehydes, formaldehyde and acetylaldehyde. The ratio for particulate matter mass was less than one but, individual PAHs and metals exceeded unity. Differences in exposure to HAPs across the population due to age (child vs adult), gender, socioeconomic and cultural differences exist as these factors affect the time spent in different locations and activities that alter the multi-route exposure to the HAPs. Inhalation exposure measurements are typically integrated averages of ½ to two days, but acute exposures can exist that may be of toxiciological importance. Thus, reported ambient HAP concentrations are not good surrogates for exposure, and we need to determine which HAP exposures are dominated by ambient emissions and what time scale are important for those exposures.

528 STRUCTURE-ACTIVITY APPROACHES AND DATA EXPLORATION TOOLS FOR PRIORITIZING AND ASSESSING THE TOXICITY OF HAZARDOUS AIR POLLUTANTS.

A. M. Richard and C. R. Williams. *NHEERL, USEPA, Research Triangle Park, NC.* Sponsor: M. Selgrade.

Hazardous Air Pollutants (HAPs) refers to a set of structurally diverse environmental chemicals, many with limited toxicity data, that have been grouped, not due to chemical or biological similarity, but rather due to a common route of exposure (inhalation), environmental media (air) and regulatory framework. Hence, this set of chemicals provides particular challenges to structure-activity relationship (SAR) and data mining approaches. These approaches can be productively applied to characterization and testing prioritization of HAPs chemicals, but analyses must reach beyond this set of chemicals to construct larger chemical groupings according to either common structures and mechanisms of action, or a common endpoint of concern. Commercial toxicity prediction programs can apply algorithms derived from large sets of chemicals to estimating general toxicity properties of the HAPs chemicals. Another type of SAR approach, more focused and exploratory in nature, has successfully characterized structural classifiers of activity and determinants of potency among a set of diverse volatile organics, many HAPs included, that have been evaluated for their ability to produce rat nasal histopathology. The electronic and reactivity indices identified have provided a basis for exploring associations with the sub-chronic nasal irritation endpoint for which larger data sets are available. Finally, a new initiative to enable structure-based searching and exploration of public toxicity data bases will be reported that has the potential to greatly enhance current capabilities to gather relevant data with respect to HAPs chemicals. Such tools will facilitate analogue identification and hypothesis generation with respect to characterization of HAPs spanning multiple classes and toxicity endpoints of concern. This abstract does not reflect EPA policy.

529 CONCENTRATION - DURATION RELATIONSHIPS FOR NON-CANCER HEALTH EFFECTS OF EXPOSURE TO HAZARDOUS AIR POLLUTANTS.

W. K. Boyes. *Neurotoxicology Division, NHEERL, USEPA, Research Triangle Park, NC.*

EPA is charged with assessing the risks of both acute and chronic exposures to hazardous air pollutants (HAPs). The emissions from sources of HAPs are often characterized as temporally-averaged values, however, patterns of exposure not captured in such measures may influence non-cancer toxicity. This research program examined non-cancer health effects as a function of temporal exposure patterns, with the goal of improving models to predict toxicity across exposure scenarios. Currently, temporal adjustments in risk assessment typically are based on Haber's rule ($C \times t = K$) or ($C^n \times t = K$), where C represent concentration, t time (duration) of exposure, K a constant toxic effect and n, when used, is empirically derived. Several general conclusions were derived from this work. Concentration is more important than time: where C and t were manipulated the influence of concentration predominated over time in contrast to the equal influence of C and t in the linear form of Haber's rule. Target tissue dose. Understanding the relationship between exposure and target tissue dose was better at predicting toxicity than was Haber's rule. Target tissue sensitivity changes over time: variations in target tissue sensitivity are not accounted for in standard $C \times t$ calculations. Interpretation of standard toxicity assays: standard toxicity assays do not address acute exposures during critical windows of sensitivity. Quantitative models: models with parameters reflecting physiological entities improved extrapolation across species and age as well as exposure concentration and duration. Understanding Mechanisms: having mechanistic information improved predictions across exposure conditions. These results demonstrate the importance of considering temporal exposure variations when predicting the risks of adverse non-cancer health outcomes. This abstract does not reflect EPA policy.

530 MODEL-BASED APPROACHES TO DOSE EXTRAPOLATION.

R. Sarangapani. *The K. S. Crump Group, ICF Consulting, Research Triangle Park, NC.*

The preponderance of non-inhalation route toxicological evaluations of volatile chemicals places a premium on methodologies for conducting route-to-route dose extrapolations. Such methodologies are increasingly important for industry and regulatory agencies seeking to conduct risk assessments of chemicals that pose a hazard predominantly by the inhalation route, because they facilitate the use of data from alternative dose-routes. For these compounds, a reliable capacity to perform route-to-route extrapolation increases the database for conducting risk assessments based on target tissue dosimetry. Physiologically-based pharmacokinetic (PBPK) models with route specific components link dose-routes through tissue dosimetry, and are the leading tool for conducting dose-route extrapolations. Model-based approaches to estimate dose-equivalence (in terms of mg per kg per time) for various exposure routes, such as inhalation, dermal, oral, gavage, and intraperitoneal have been computed for a few hazardous air pollutants (ex. vinyl acetate and styrene). Minimum data needs to perform adequate route specific dosimetry, and their associated advantages and limitations, have been characterized. Such models can also be used for mode-of-action hypotheses testing by correlating multiple internal dose metrics to the observed response data.

531 AIR TOXICS RESEARCH NEEDS IN THE 21ST CENTURY, SUMMARY.

A. Holian. *Center for Environmental Health Sciences, University of Montana, Missoula, MT.*

The 1990 Clean Air Act Amendments (CAAA) listed 188 chemicals and chemical classes as hazardous air pollutants (HAP). In most cases the health effect of concern for HAP exposure is cancer risk, while a limited list of HAPs are known or suspected to cause or exacerbate other diseases (e.g., asthma, fibrosis, neurodegenerative diseases, developmental effects). The complexity of working with this extensive list of HAPs arises not only from the exhaustive list, but also the certainty that exposures will be to mixtures. This is further complicated by the limited information on exposure levels as well as health effects of individual compounds, nevertheless the effects of mixtures (additive, synergistic, antagonistic). Selection of representative classes of HAPs may be useful, but will not resolve all of the issues and in the case of disease causation assumes that all of the potential mechanisms are identical. Furthermore, identification of sensitive and susceptible populations remains incomplete. The potential matrix becomes overwhelming and tactics need to be developed to focus on the most likely scenarios of exposure. One approach is to assess actual exposure that is most representative of a substantial fraction of the population and generate an appropriate mixture. Issues to review are the limitations of exposure assessment, the applicability of the resulting mixture, and the approaches that could be utilized having this information. Alternatively, in the absence of portions of this data set what would be the most scientifically plausible approach to filling the data gaps. This information will be critical to advance the study of health effects to real world exposure to HAPs.

532 TOXICOLOGICAL APPLICATIONS OF METABONOMICS TECHNOLOGY.

D. G. Robertson. *Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

Toxicants, by definition, disrupt the normal composition and flux of endogenous biochemicals in, or through, key intermediary cellular metabolic pathways. These disruptions, either directly or indirectly, alter the blood that percolates through the target tissues. The diagnostic utility of any one trace biomolecule is limited by the number of variables affecting its concentration *in situ* and by the commonality of biochemical processes disrupted by toxicants. However, if a significant number of trace molecules are monitored, the overall pattern, or " fingerprint" produced may be more consistent and predictive than any one marker. Obtaining such comprehensive biochemical information is made possible using high-field nuclear magnetic resonance (NMR) spectroscopy coupled with pattern recognition technology. Urine and serum are routinely studied, but virtually any biofluid can be used for metabonomic analysis. Magic-angle spinning NMR technology enables similar information to be garnered from tissues as well. The power of the technology lies in its ability to non-invasively assess animal physiology thus allowing temporal evaluation of the metabolic consequences of toxicity. Onset and regression of toxicity can be determined within a single animal, target organs identified, mechanistic information obtained and biomarkers of toxicity established. When coupled with genomic and proteomic technologies, metabonomics permits complete assessment of toxicity from genotype through phenotype. The objectives of this symposium are to introduce the principles of metabonomics, describe its application emphasizing both the strengths and weaknesses and to present a vision of the future for this emerging technology.

533 METABONOMIC APPROACHES TO UNDERSTANDING THE CONSEQUENCES OF DRUG TOXICITY AND GENE FUNCTION.

J. K. Nicholson. *Biological Chemistry, Faculty of Medicine, Imperial College, University of London, London, United Kingdom.* Sponsor: D. Robertson.

High frequency ^{1}H NMR spectroscopy provides a rapid method of characterizing and quantifying a wide range of metabolites in untreated biological fluids and tissues and a powerful means of exploring the biochemical effects of drug-induced toxicological processes. ^{1}H NMR spectra of biofluids are highly complex, containing signals from thousands of metabolites representing many key biochemical pathways. The ^{1}H NMR-generated biofluid metabolite profiles are characteristically changed in different toxicological conditions according to the exact site and mechanism of the lesion. Thus interrogation of the biofluid NMR data can give direct diagnostic information and aid the detection of novel biomarkers of toxic effect. Recent advances in MAS-NMR spectroscopy also allow high resolution ^{1}H data to be collected on small intact tissue samples, thus giving metabolic information that is complementary to those obtained from biofluid NMR. By use of computer pattern recognition (PR) methods, complex biofluid/tissue NMR data can be reduced and analyzed quantitatively to provide PR maps showing the physiological and toxicological effects of test xenobiotics in pre-development drug toxicity studies and the effects of genetic modification. Neural network, rule induction and other expert system approaches can also be implemented to give direct diagnostic outputs on toxicity type based on NMR input data. NMR-PR based diagnostics can be extremely sensitive for the detection of low level damage in a variety of organ systems and is potentially a powerful new adjunct to conventional toxicological procedures for lead compound selection. With the advent of flow injection NMR technology, it is now possible to analyze hundreds of biofluid samples per day using one NMR spectrometer and to use NMR as a novel tool for toxicological screening. The NMR-PR and expert system approach to rapid *in vivo* toxicological assessment of drugs will be illustrated for a wide range of drug and toxin-induced lesions in both experimental animals and man.

534 APPLICATION OF METABONOMIC EXPERT SYSTEMS TO THE STUDY OF PHYSIOLOGICAL AND TOXICOLOGICAL VARIATION.

E. Holmes. *Biological Chemistry, ICMS London University, South Kensington, London, United Kingdom.* Sponsor: D. Robertson.

One of the major applications of NMR-based metabonomic technology in the pharmaceutical industry involves advanced chemometric analysis of NMR spectra of biological matrices with a view to establishing and predicting the pharmacological and pathophysiological consequences of drug candidates. Using such technology, overt toxic insults are easily detected as perturbations in the 1H NMR spectral profiles and expert systems can be constructed for efficient classification and prediction of drug toxicities. However, many factors can be responsible for generating biochemical alterations in the baseline urinary profile including change in diet, diurnal variation, hormonal cycles, changes in temperature, poor health, level of activity, genetic drift and bacterial contamination of urine, and all of these factors may have implications on the toxicologic response of an animal. NMR-based metabonomic methods can be used to establish the degree and precise nature of normal physiological variation for a population of animals or humans. Moreover, mathematical data filtering methods can be used to deconvolve confounding physiological effects, thereby removing sources of variation that are unrelated to the class of toxicity. Sophisticated expert systems that can compensate for physiological, pharmacological and pathophysiological variation can thus be established.

535 METABONOMIC AND GENOMIC INVESTIGATION OF RENAL PAPILLARY NECROSIS (RPN).

C. E. Thomas[1], T. P. Ryan[2], H. Gao[2], A. Mockel[1], J. M. Colet[1], W. Dewe[1], A. Cauvin[1], C. Gavaghan[3], E. Holmes[3] and E. Destexhe[1]. [1]*Toxicology Projects & Investigative Toxicology, Eli Lilly & Co., Mont-Saint-Guibert, Belgium,* [2]*Investigative Toxicology, Eli Lilly & Co., Greenfield, IN and* [3]*Imperial College, London, United Kingdom.*

Metabonomics and oligonucleotide-based microarray technology were used in a comparative study with compound 393277, an experimental agent inducing RPN. Bromoethanamine (BEA) was used as a positive control. Papillary injury was evident microscopically at 4 h postdose for 393277 and 24 h for BEA. NMR showed

that 393277 treatment induced changes previously identified as typical for papillary toxicants including altered excretion of trimethylamine-N-oxide and decreases in 2-oxoglutarate and citrate. Trajectory analysis of NMR data indicated a return to 'normal' by 72 h following either single or repeat administration. In several 393277-treated animals, elevated taurine combined with lower TCA cycle intermediates suggested hepatic injury. Histologic examination revealed hepatocellular vacuolation at 48 h that resolved by 96 h. Gene expression changes in liver and kidney papilla were also maximal at 48 h with few changes persisting at 96 h. In the papilla, expression changes were noted for genes common to both compounds including immediate early genes (c-fos, jun), general stress genes (MT, HO), and inflammatory markers (gro, MIP-2). Corresponding to the observed hepatotoxicity, 393277 altered expression of more genes in the liver than did BEA. Genes associated with beta-oxidation and fatty acid metabolism were affected in both liver and kidney, consistent with the NMR data. In the ovary of 393277, but not BEA-treated animals, a marked reduction in expression of genes associated with estradiol and progesterone was observed. This finding agrees with the pathology and with data demonstrating estral cycle disruption associated with decreased levels of circulating hormones. This study documents that both metabonomics and genomics have the ability to predict target organ toxicity following acute dosing and that parallels can be drawn between the technologies.

536 METABONOMIC TECHNOLOGY AND THE PHARMACEUTICAL INDUSTRY: THE COMET CONSORTIUM.

D. G. Robertson. *Drug Safety Evaluation, Pfizer Global Research & Development, Ann Arbor, MI.*

Metabonomics technology has the potential to impact drug-development from early in the discovery process through clinical trials. The non-invasive assessment of toxicity (or efficacy) enables rapid-throughput screening while the potential for serial assessment of toxicity within a single animal minimizes drug requirements. Beyond screening, early identification of biomarkers of either efficacy or toxicity is engendered. This identification of biomarkers is more than just an alternative to traditional clinical chemistry measurements. Metabonomics enables identification of biomarkers where currently none exist. The non-invasive nature of the technique makes for ready export to the clinic. The spectrum of changes and the ease of identifying temporal responses allow for novel mechanistic information to be obtained adding significantly to the assessment of safety. The value of pattern recognition techniques to toxicological endpoints is realized only if a valid pattern is established. The role of the consortium on metabonomics (COMET) is to establish a comprehensive database that defines the chemical space encompassed by hepatotoxins and nephrotoxins. The consortium is a research endeavor of 6 pharmaceutical companies collaborating under the auspices of Imperial College in London. This presentation will provide practical examples of the application of metabonomic technology within the pharmaceutical industry. 'Lessons Learned' from the COMET consortium will be presented and cross-company validation efforts described.

537 TRANSPLACENTAL CARCINOGENESIS OF ENVIRONMENTAL TOXICANTS.

M. S. Miller[1] and L. M. Anderson[2]. [1]*Wake Forest University, Winston-Salem, NC and* [2]*NCI, Frederick, MD.*

A growing body of scientific evidence has shown that the developing fetus and neonate exhibit different sensitivities and responses to environmental chemicals than do adult organisms, and that exposure of parents before conception can alter the risk of cancer and other diseases in the offspring. Developmental and stage specific effects are often seen as a result of the dynamic nature of the developing organism, which presents a constantly changing biochemical picture as various enzyme and signal transduction systems are turned on or off during growth and maturation. The higher sensitivity of the fetus to certain carcinogens has long term implications for the regulation of potentially toxic chemicals. Several studies have suggested that the process of cancer initiation may begin *in utero* following exposure of the fetus to carcinogenic agents. Thus, the fetus and neonate are not "little adults", and further understanding of the toxic effects of chemicals at both the biochemical and molecular/genetic level are needed in order to make rational regulatory decisions, to devise chemopreventive strategies for exposed populations, and to elucidate the unique characteristics of tumors resulting from damage initiated during the early developmental stages. The first speaker will discuss recent data showing that pre-conceptional exposure of male mice to carcinogens can lead to epigenetic changes in hormones that could influence tumor development in subsequent generations. The second speaker will review alterations that occur at oncogenic loci following *in utero* exposure of mice to 3-methylcholanthrene, contrasting the differences between adult and fetal exposures. The third speaker will continue on this theme and describe the role of the *N*-acetyltransferases in determining the genotoxicity of aromatic amines in the fetus and neonate. The last speaker will demonstrate the effects of tobacco smoke exposure on 4-aminobiphenyl-hemoglobin adduct formation and mutation at the HPRT locus in human maternal and fetal lymphocytes to highlight the effects of *in utero* exposures on the fetus in the human population.

538 EPIGENETIC ASPECTS OF PERINATAL CARCINOGENESIS: HORMONAL MODULATION.

L. M. Anderson. *Laboratory of Comparative Carcinogenesis, NCI, Frederick, MD.*

Epidemiological evidence continues to implicate early life exposures as factors in cancer risk, and certain forms of childhood cancer, including leukemia, appear to be increasing. Preconceptional exposures of fathers, occupationally to chemicals such as metals, solvents, and pesticides, and to tobacco smoke, have been linked to increased risk of childhood cancers. Preconceptional carcinogenesis after exposures of fathers has been clearly demonstrated in animal models, for most categories of chemical carcinogens and for radiation. The phenomenon in animals suggests that a novel mechanism may be in play, since the incidence of effect is higher by several orders of magnitude than the rate of any known specific locus mutation, and the inheritance pattern may be non-Mendelian. Since the tumors that are increased after preconceptional exposure of animals are most often those that have a significant spontaneous incidence, we postulated that the mechanism could be epigenetic and involve changes in hormones that influence tumor development. We have pursued this hypothesis using chromium(III) as the preconceptional exposure agent. Cr(III) is a common human occupational exposure metal and a demonstrated preconceptional carcinogen in mice. After exposure of male Swiss mice to this chemical, their offspring at 10 weeks of age have been found to have marked, highly significant alterations in average levels of serum corticosterone, glucose, and insulin-like growth factor 1, compared with offspring of vehicle-treated fathers. Since all of these factors have known potential to influence tumor growth, these findings confirm the hypothesis. To determine whether the hormone alterations relate in fact to tissue changes, we have utilized microarray analysis, starting with liver. The changes in corticosterone correlated strongly with gene expression for insulin-like growth factor binding protein 1, a regulatory protein for IGF1. Such transgenerational effects on hormones in offspring may have wide implications.

539 ALTERATIONS IN ONCOGENES AND TUMOR SUPPRESSOR GENES IN TRANSPLACENTALLY-INDUCED TUMORS.

M. S. Miller and M. C. Mizesko. *Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Fetal mice exhibit differential sensitivity to carcinogens that is determined by their ability to metabolize xenotoxicants. Following *in utero* exposure to 3-methylcholanthrene (MC), the treated offspring demonstrated increased sensitivity for tumor formation compared to exposed adults. [D2 x B6D2F1]F2 and Balb/c mice develop lung tumors 6-12 months after birth, with the F2 mice also developing liver tumors. The tumor incidence correlated with expression and inducibility of *Cyp1a1*. Conversely, fetal mice were resistant to tumor induction by 2-amino-3-methylimidazo[4, 5-*f*]quinoline (IQ), probably due to the lack of *Cyp1a2* expression during gestation. MC-induced tumors from the [D2 x B6D2F1]F2 and Balb/c mice demonstrated a high incidence of mutations in Ki-*ras*, with 79% and 56% of the lung lesions exhibiting mutations in exon 1, respectively. [D2 x B6D2F1]F2 mice showed predominantly G→T transversions (84%) whereas the Balb/c mice had mostly G→C mutations (62%). In both studies, the type of Ki-*ras* mutation was associated with the histological stage of the tumors. Though no alterations were found in the *p53* gene, alterations in the *Rb/Ink4a* axis were seen. All 14 of the larger lung tumors examined from [D2 x B6D2F1]F2 mice displayed decreased levels of *Rb* RNA and protein. A low incidence of alterations at the *Ink4a* locus in both lung (15%) and liver (27%) tumors was seen. However, whereas adult lung lesions exhibited mainly promoter hypermethylation and a low incidence of homozygous deletions, mice exposed *in utero* had low incidences of both point mutations and hypermethylation. The type of alteration at the Ki-*ras* locus appeared to influence the type of damage that occurred in *Ink4a*, suggesting that the type of mutation induced in Ki-*ras* may influence tumor progression. Thus, the developing organism is more sensitive to certain carcinogens and exhibits a distinctive tumor pathogenesis relative to adults.

540 PRE- AND POSTNATAL EXPRESSION OF N-ACETYLTRANSFERASES (NAT): POTENTIAL ROLE IN AROMATIC AMINE GENOTOXICITY.

C. A. McQueen. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Children and adults often respond differently to xenobiotics. This may be due, at least in part, to alterations in the expression of biotransformation enzymes that can affect the formation of reactive and/or non-toxic products. Studies in mice have fo-

cused on NAT2, an enzyme that may be involved in regulation of folate metabolism and play a role in neural tube development. NAT2 has been detected in murine pre-implantation embryos with the NAT2 protein and associated capacity for acetylation increasing from birth to sexual maturity. Since activation of aromatic amine carcinogens involves reactions catalyzed by NAT1 and NAT2, the developmental expression of both genes is of interest. In C57Bl/6J mice, NAT1 and NAT2 mRNAs were detected at gestational day (GD) 10, the earliest time evaluated, with fetal *N*-acetylation of 4-aminobiphenyl (4ABP) measured at GD 10, 15 and 18. After birth, hepatic expression of NAT1 and NAT2, determined by quantitative RT-PCR, continued to increase with age. This trend was also observed when NAT activities were assessed. Hepatic *N*-acetylation of *p*-aminobenzoic acid, a murine NAT2 selective substrate, isoniazid, a murine NAT1 selective substrate, as well as the carcinogenic aromatic amines 2-aminofluorene and 4ABP, substrates for both isoforms, increased with increasing age. *in utero* exposure to 4ABP resulted in fetal 4ABP-DNA adducts, reflecting maternal and possibly fetal activation of 4ABP. Neonatal exposure to 4ABP resulted in levels of hepatic 4ABP-DNA adducts that were significantly lower at neonatal day 4 than in adult liver. Thus, the capacity to acetylate aromatic amine carcinogens is present pre- and postnatally. While fetal and maternal biotransformation contribute to 4ABP genotoxicity during gestation, there is sufficient neonatal biotransformation to result in 4ABP-DNA adducts. The activation of aromatic amine carcinogens and the formation of DNA adducts during development may result in critical mutations that increase risk of childhood or adult cancer. (Supported by ES 09812 and ES 10047).

541 APPLICATION AND USE OF HEMOGLOBIN AS A BIOMARKER OF TOBACCO SMOKE EXPOSURE.

S. R. Myers. *Pharmacology and Toxicology, Center for Environmental and Occupational Health Sciences, University of Louisville School of Medicine, Louisville, KY.*

Smoking during pregnancy has been linked to a variety of adverse outcomes, including low birthweight, spontaneous abortion, and infant death. Low birthweight shows the clearest and most consistent association with maternal smoking. Evidence suggests that a Dose-Response relationship exists between cigarette consumption, especially during the third trimester, and birth weight. Women who smoke during pregnancy expose themselves, as well as the fetus, to numerous carcinogens, many of which may be harmful to the fetus. Although much data concerning the effects of smoking is known, few studies have investigated the effect of tobacco smoke on the developing fetus. Three of the most widely studied carcinogens in tobacco smoke include the potent bladder carcinogen 4-aminobiphenyl, as well as the carcinogens benzo(a)pyrene and the tobacco specific nitrosamines. Numerous biological markers of exposure to tobacco smoke carcinogens have been proposed and investigated. Recently, the utilization of hemoglobin (Hb) adducts of tobacco smoke compounds have emerged as a viable biomarkers of tobacco smoke carcinogen exposure. Hb adducts will accumulate in the circulation, allowing their use as biomonitors of exposure to various agents, such as those carcinogens found in tobacco smoke. In this presentation, we will discuss a series of studies that have helped define the use of Hb as a biological marker to assess exposure to carcinogens. In addition, we will discuss the following hypotheses related to the use of Hb adducts as biomarkers of exposure assessment. These include (1) that the formation of fetal Hb tobacco smoke carcinogen adducts is proportional to maternal smoking as well as maternal Hb adducts; (2) that the formation of maternal and fetal Hb adducts are dependent on maternal and fetal genotype to glutathione S-transferase M1 (GSTM1), glutathione S-transferase T1 (GSTT1), *N*-acetyltransferases (NAT1 and NAT2), or cytochrome CYP1A1; and (3) that there is a correlation between the formation of DNA adducts and maternal and fetal Hb adducts.

542 INTRODUCTION TO PERFLUOROOCTANE SULFONATE (PFOS).

J. A. Moore. *Hollyhouse, Inc., Arlington, VA.*

Perfluorooctanesulfonate (PFOS) is a perfluorinated organic acid that has been used as a surfactant in products such as fire fighting foams. It is also formed by the environmental or metabolic degradation of other fluorochemical products used on items such as carpets, clothing, and food containers. PFOS does not appear to be further degraded by humans or environmental processes. Analytical techniques in the 1960s could identify organic fluorine in human serum at levels ~ 0.10 ppm. In the 1990s, improved methods and instrumentation allowed routine measurements of specific organofluorine chemicals in human and environmental samples at levels of ~ 0.01 ppm. PFOS has been measured at low concentrations in serum samples from human populations, in various species of wildlife, in surface waters and in other environmental media. Occupational workers have measured serum PFOS levels that averaged 2.0 ppm with highest levels at ~11 ppm. In non-occupational human samples, the upper 95th percentile serum concentration is approximately 0.1 ppm. The halflife of PFOS in the serum of retired workers is currently estimated to be several years. Environmental matrices are being examined to understand the dispersion of PFOS and other fluorochemicals in the food chain, general environment and in the vicinity of manufacturing and heavy use. Results of such studies indicate that PFOS is widely dispersed in the environment. Substantial information has been developed and continues to be developed on the possible biological effects of exposures. The mammalian toxicology database has grown rapidly. Also, several epidemiological investigations in exposed workers have been completed. Numerous acute and chronic toxicity studies involving freshwater and marine organisms also have been conducted. The aggregate data, to be summarized at this workshop, can permit a basic understanding of exposure, effects, mechanism and risk to the environment, wildlife and humans.

543 UNDERSTANDING THE GLOBAL DISTRIBUTION AND ENVIRONMENTAL EFFECTS OF PFOS.

W. J. Warren-Hicks. *The Cadmus Group, Durham, NC.* Sponsor: J. Moore.

Perfluorooctane sulfonic acid (PFOS) and its salts are fully fluorinated organic molecules produced synthetically by electrochemical fluorination or from the degradation of other fluorochemical products produced by electrochemical fluorination. As a fully fluorinated organic molecule, PFOS is very stable and resists further degradation. Substantial information related to human and environmental exposures to PFOS has been developed providing evidence of widespread distribution in humans and the environment. PFOS at very low levels has been identified in serum and tissue samples from both occupationally and non-occupationally exposed human populations, in various species of wildlife, and in surface waters and other environmental media. An extensive database has been, and continues to be, developed on the possible biological effects of these exposures. Based on the existing body of information presented here, the observed levels of PFOS from a wide variety of samples have not been associated with identifiable adverse effects on human health, wildlife, or the environment. Additional data currently under development from ongoing studies will be used in the future to refine this initial assessment. This presentation presents a comprehensive ecological risk assessment of PFOS using existing exposure and effects data. Analytical methods for the determination of exposure concentrations and toxicology of PFOS are presented. The analyses suggest that levels found in the environment and in wildlife are not associated with adverse effects. Additional research is now underway that will be used to refine this initial assessment.

544 THE HEALTH EFFECTS OF PFOS.

J. Seed. *OPPT, USEPA, Washington, DC.* Sponsor: J. Moore.

Numerous repeat-dose oral toxicity studies on PFOS have been conducted in rats and primates. In rat studies, toxicity has been observed at doses of 2 mg/kg/day and above and effects include increases in liver enzymes, hepatic vacuolization and hepatocellular hypertrophy, gastrointestinal effects, weight loss, convulsions, and death. In rhesus monkey studies, toxicity has been observed at doses of 1.5 mg/kg/day and above, and effects include anorexia, emesis, diarrhea, hypoactivity, prostration, convulsions, atrophy of the salivary glands and the pancreas, marked decreases in serum cholesterol, and lipid depletion in the adrenals, and death. At doses as low as 0.75 mg/kg/day, cynomolgus monkeys exhibited low food consumption, excessive salivation, labored breathing, hypoactivity, ataxia, hepatic vacuolization and hepatocellular hypertrophy, significant reductions in serum cholesterol levels, and death. Developmental toxicity was evident at doses of 5 mg/kg/day and above in rats administered PFOS during gestation, and at doses of 2.5 mg/kg/day and above in rabbits. In a two-generation reproductive toxicity study in rats, all F1 pups in the 3.2 mg/kg/day dose group died within a day after birth while close to 30% of the F1 pups in the 1.6 mg/kg/day dose group died within 4 days after birth. The NOAEL and LOAEL for the F2 pups were 0.1 mg/kg/day and 0.4 mg/kg/day, respectively, based on reductions in pup body weight. A subsequent cross fostering study showed that the perinatal death was due to *in utero* exposure. In addition, reductions in serum lipids and cholesterol synthesis do not appear to play a significant role in the perinatal mortality. A report on the results of a two-year feeding study in Cr1:Cd (SD) rats is expected in late 2001. This abstract does not reflect EPA policy.

545 MOLECULAR MECHANISMS OF PERFLUOROOCTANESULFONATE TOXICITY.

K. B. Wallace. *Biochemistry & Molecular Biology, University of Minnesota, Duluth, MN.*

The evidence regarding perfluorooctanesulfonate (PFOS) toxicity is strongly suggestive of a primary metabolic disorder. Early indicators of exposure to PFOS in rats include cachexia, hepatomegaly that results from expansion of the mitochondrial, endoplasmic reticulum and peroxisomal bodies, decreased serum glucose,

triglyceride and cholesterol, and the accumulation of lipid vacuoles in liver tissue. In view of the fact that PFOS is a perfluorinated fatty acid, we questioned whether its toxicity might owe to competing reactions for fatty acid metabolism in the cell. Although PFOS and its metabolic precursor perfluorooctanesulfonamides (PFOSN) do not inhibit mitochondrial fatty acid oxidation, they do interfere with mitochondrial bioenergetics. PFOS causes a nonspecific increase in permeability of mitochondrial membranes, whereas the primary and secondary sulfonamides are highly specific and extremely potent uncouplers of oxidative phosphorylation. PFOS and its sulfonamides also interfere with fatty acid metabolism in the cell by activating peroxisome proliferator activated receptor to stimulate the proliferation of hepatic peroxisomes and enhanced expression of peroxisomal enzyme activities in rats *in vivo* and in cell culture. Guinea pigs, however, are unresponsive to PFOS or PFOSN-induced peroxisome proliferation. PFOS exposure also causes a dramatic stimulation of CYP4A1 expression in rats, but not guinea pigs. In conclusion, PFOS and its sulfonamide precursors exert multiple effects to interfere with intermediary metabolism by the cell, indicating that it is quite probable that metabolic dysfunction is the basis for the generalized wasting syndrome and perinatal mortality that characterize PFOS and PFOSN toxicity in rats. However, there exists a discerning species-related difference in susceptibility to metabolic dysfunction, which raises some uncertainty whether rats provide a reliable indicator of potential adverse outcomes associated with human exposures to PFOS or its precursor sulfonamides. (This work was supported by The 3M Company.)

546 CHALLENGES OF RISK CHARACTERIZATION FOR PERFLUOROOCTANESULFONATE (PFOS): A PERSISTENT, PERVASIVE FLUOROCHEMICAL.

G. S. Omenn. *University of Michigan, Ann Arbor, MI.* Sponsor: J. Moore.

In traditional assessments used in risk characterization, external dose is generally measured or estimated in the absence of direct measurement of biomarkers of exposure in serum or other tissues. Absorption, distribution, metabolism, and excretion differences across species are often unknown; thus, generic uncertainty factors, not chemical-specific in nature, are commonly used. Such approaches can yield estimates of exposure and risk that are so widely divergent as to undermine the confidence of the scientific community. Scientific data for perfluorooctanesulfonate (PFOS) present characteristics that may permit more refined assessment approaches. PFOS has been identified in non-occupationally exposed human population serum samples at low parts per billion levels. The origin of PFOS in human sera is not clearly understood; most likely, it comes from a combination of environmental and product exposures. Because PFOS is persistent, serum levels integrate exposure over time from all sources. Furthermore, PFOS serum concentration has been shown to approximate liver tissue concentration in humans and in laboratory animals at levels observed in human populations. Using such knowledge can reduce some of the uncertainty inherent in the typical approach to risk assessment. The approach we recommend for PFOS involves comparisons of the range of serum levels documented in both epidemiological and toxicological studies of exposed populations. The presentation will examine these assumptions and discuss limitations related to the nature and extent of human exposure data, the assumption that PFOS is the sole or major toxicant, and the likelihood of genetic variation in biotransformation and in susceptibility to adverse effects.

547 EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) AND HYPOXIA ON CARDIAC VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) EXPRESSION.

M. K. Walker. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

A myocardial oxygen gradient during embryo development is thought to stimulate coronary angiogenesis and VEGF is one factor that regulates this process. Previously, we have demonstrated that TCDD inhibits the branching of coronary arteries in the developing chick embryo heart. Thus, we tested the hypothesis that hypoxia can regulate cardiac VEGF mRNA expression and TCDD can reduce cardiac VEGF mRNA expression. To determined if hypoxic incubation conditions induced the cardiac hypoxia, chicken eggs were injected with 0.9% saline (control) or ^{3}H-misonidazole (MISO, a tissue hypoxia marker) in saline on incubation days 7 or 9 (D7 or D9) and the incubated for 24 hr under 20% or 15% O_2. Misonidazole is reduced metabolically to a reactive intermediate when tissue oxygen levels are low and will bind to cellular macromolecules. Hearts were collected on D8 and D10 and analyzed for MISO binding by scintillation counting. Hypoxia induced a 155 ± 14% and 3300 ± 60% increase in MISO binding on D8 and D10, respectively. To determined if these same hypoxic incubation conditions induced cardiac VEGF mRNA, chicken eggs on D7 and D9 were incubated for 24 hr under 20% or 15% O_2. Hearts were collected on D8 and D10 and analyzed for VEGF mRNA by quantitative RT-PCR. Hypoxia induced a 169 ± 35% and 200 ± 31% increase in cardiac VEGF mRNA on D8 and D10, respectively. We then determined the effects of TCDD on cardiac VEGF expression at these same time points. Fertile chicken eggs were injected with control or 0.24 pmol TCDD/g on day 0; hearts were collected on D8 and D10, and analyzed for VEGF mRNA by quantitative RT-PCR. TCDD significantly reduced VEGF mRNA on D8 by 25 ± 1.5%, but had no effect on D10. These results demonstrate that cardiac VEGF expression during coronary angiogenesis is regulated, in part, by hypoxia and further suggest that TCDD can reduce VEGF mRNA during coronary development. Future studies will evaluate the ability of TCDD to inhibit hypoxia-induced VEGF mRNA on D8 and D10. Supported by NIH ES09804.

548 TOXICITY OF CB 126 IN METAMORPHOSING SUMMER FLOUNDER LARVAE.

B. Soffientino[1], D. Nacci[2] and J. L. Specker[1]. [1]*Graduate School of Oceanography, University of Rhode Island, Narragansett, RI and* [2]*NHEERL, Atlantic Ecology Division, USEPA, Narragansett, RI.* Sponsor: L. Mills.

The summer flounder, *Paralichthys dentatus*, is a commercially important species of flatfish found on the East Coast of the United States, from Cape Hatteras to Maine. Pelagic, stomachless larvae metamorphose into the benthic, gastric, juvenile flatfish in shallow coastal bays, lagoons and estuaries during the spring. In summer flounder, metamorphosis is regulated by thyroid hormones (TH), and chemically induced hypothyroidism inhibits metamorphosis past the very early stages. PCBs are among the major pollutants found in industrially impacted coastal ecosystems, and are known to act as endocrine disrupters by lowering blood TH levels in mammals and some fish. This project is concerned with determining the developmental effects of the dioxin-like CB 126 on metamorphosing larvae, and ultimately to understand if any of the effects are mediated by thyroidal disruption. Here we present results of the first experiments carried out 30 day-old (premetamorphic) and 39 day-old, (early metamorphosing) larvae to establish their sensitivity to CB 126. Larvae were exposed to radiolabeled CB 126 through the water, and grown out for 3 weeks to assess mortality. Cytochrome P450 IA1 immunoreactivity was measured as a marker of Aryl hydrocarbon Receptor pathway activation in liver, small intestine, stomach, and kidney. Mean metamorphic stage was calculated at the end of growout to determine if sublethal doses had an effect on metamorphosis. The younger group appeared more sensitive than the older (LD 20 = 20.9 pg/mg and 170 pg/mg, respectively). Sensitivity to CB 126 was similar to that observed in embryos of other marine fish (e.g. *Fundulus heteroclitus*). CYP1A1 induction was highest in the kidney and liver, lowest in anterior intestine, and was maximal near the LD 20 in all tissues; this pattern was in accord with observations in other species. In the younger group we observed a dose-dependent trend toward more advanced metamorphic stage, suggestive of an effect of CB 126 on developmental rate.

549 EXPRESSION OF A TRUNCATED RETINOIC ACID RECEPTOR ALPHA IN PHENYTOIN-INDUCED CLEFT PALATE.

J. Gelineau-van Waes, R. Barber, L. Starr, F. Aleman and G. Bennett. *Center for Human Molecular Genetics, University of Nebraska Medical Center, Omaha, NE.*

The anticonvulsant drug phenytoin (PHT) has been widely studied with respect to its teratogenic potential to induce orofacial clefts in the offspring of epileptic patients. The hypothesis that PHT-induced malformations involve perturbations in retinoid signalling pathways subsequent to altered gene expression, and, presumably, altered protein expression, was investigated in the current studies. Using *in situ* transcription/antisense RNA amplification techniques, and reverse Northern blots, our laboratory has previously shown that *in utero* exposure to PHT alters expression of the retinoic acid receptors (RARα, RARβ, and RARγ) in the developing embryonic palate. In the current study, alterations in expression of the RARα protein were examined immunohistochemically in the craniofacies of murine embryos following chronic *in utero* exposure to PHT. Using a commercial antibody to the C-terminal end of the RARα protein, and a custom antibody to the N-terminal end of the protein, we were able to demonstrate expression of a C-terminal truncated RARα' protein in the craniofacial region of GD 14.5 PHT-exposed embryos presenting with a cleft palate phenotype. In control embryos, cells expressing the full-length RARα protein in the region of palatal fusion were undergoing an epithelial-mesenchymal transformation. However, in PHT-exposed embryos, epithelial cells on the medial palatal shelves expressed the truncated RARα' protein and did not undergo fusion, but rather, differentiated into columnar epithelial cells. RARα transcripts expressing alternate splice-site variants were quantified in a ribonuclease protection assay, and there was a significant increase in the alternately spliced mRNA coding for the truncated RARα' protein in the palates of PHT-exposed embryos. The relative increase in expression of a dominant-negative RARα' protein following PHT exposure may affect transcriptional regulation of downstream growth factors necessary for normal craniofacial/palatal morphogenesis.

550 ROLE OF FOLATE IN FUMONISIN-INDUCED NEURAL TUBE DEFECTS.

J. Maddox, G. Bennett, L. Starr, F. Aleman and J. Gelineau-van Waes. *Center for Human Molecular Genetics, University of Nebraska Medical Center, Omaha, NE.*

The current studies investigate the mycotoxin fumonisinB1 (FB1) and its interaction with folate transport systems in the induction of neural tube defects (NTDs). FB1 is a contaminant of corn associated with a variety of diseases, and recent reports suggest it may act as a developmental toxicant. Experimental evidence indicates that exposure to FB1 adversely affects folate uptake *in vitro*, potentially compromising cellular processes dependent on this vitamin. Since maternal folate deficiency has been causally linked to NTDs, we investigated this interaction as a potential mechanism for FB1-induced NTDs in a murine model. Preliminary results using inbred strains of mice indicate a differential genetic susceptibility to FB1-induced NTDs. SWV mice were completely resistant to the teratogenic effects of FB1, whereas there was a dose-dependent increase in the incidence of NTDs in the susceptible LMBc strain. Pregnant LMBc dams injected with 20mg/kg FB1 ip on GD 7.5 and GD 8.5 had a significant number of pups present with NTDs (81%). The precise timing of exposure during gestation was also critical, since a single FB1 dose on GD 8.5 resulted in only 16% exencephaly. Folinic acid (50mg/kg) administered periconceptionally to pregnant dams by daily oral gavage was unable to provide protection and rescue the phenotype. FB1 inhibits the enzyme ceramide synthase, resulting in a decrease in biosynthesis of sphingolipids, important membrane components for GPI-anchoring of the folate receptor. Since depletion of cellular sphingolipids may disrupt folate receptor function, we examined FB1-induced alterations in folate transport by injecting pregnant dams with ^{3}H-folate and measuring folate uptake in embryos. Our results indicated that ^{3}H-folate uptake was significantly inhibited in FB1 exposed embryos compared to controls. Using ^{14}C-labeled FB1, we were also able to demonstrate that FB1 crossed the placenta, inhibiting folate uptake within the developing embryo, and suggesting folate deficiency as a mechanism for FB1-induced developmental toxicity.

551 INTERACTION BETWEEN PHENYTOIN AND RETINOIC ACID RECEPTORS.

G. D. Bennett, M. Solomon, F. Aleman, S. Heller and J. Gelineau-vanWaes. *Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE.*

Phenytoin (PHT) has been one of the most widely studied of all therapeutic agents with respect to its potential to induce congenital malformations. In general, adverse pregnancy outcomes have been observed in approximately 8 to 10% of the infants exposed *in utero* to PHT. A syndrome consisting of a well-described pattern of both major and minor congenital defects have been ascribed to *in utero* PHT exposure and have been termed the Fetal Hydantoin Syndrome (FHS). One of the well-recognized characteristics of FHS is craniofacial dysmorphia. Although well studied, the precise mechanism(s) by which PHT alters normal craniofacial development remains unknown. It has been shown that PHT alters the expression of retinoic acid receptors in the developing craniofacial tissue. In the current study we investigated whether PHT might act as a retinoic acid receptor (RARα) agonist. Using lung tissue, a rich source of RARα, from a murine strain that is susceptible to the teratogenic effects of PHT, competitive binding studies were performed using [3H]- *all trans*-retinoic acid (*at*RA). PHT competed with *at*RA in a dose dependent manner. However, PHT was more effective in the presence of liver microsomal enzymes. Additionally, if epoxide hydrolase inhibitors were added to the microsomal enzyme mixture RA binding was greatly diminished. Since this suggests that a metabolite of PHT could bind to RARα, we wanted to determine whether PHT could affect genes that are regulated by *at*RA. Using a reporter cell line transfected with a RA response element (RARE), which was linked to a *lac-Z* gene, we show that PHT could induce the *lac-Z* gene. However, if these cells were cultured in the presence of liver microsomal enzymes, the induction of the *lac-Z* gene was significantly increased in a dose dependent manner from 50–3000uM of PHT. Collectively these data suggest that a metabolite of PHT, most likely an epoxide, could act as a RA-agonist and alter the gene expression, which could lead to the observed craniofacial malformations.

552 ANTIBODY PRODUCTION INDUCED BY FOOD PROTEINS IN MICE : DOSE RESPONSES.

R. J. Dearman[1], H. Caddick[1], S. Stone[1], D. A. Basketter[2] and I. Kimber[1].
[1]*Research, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*SEAC, Unilever Colworth Laboratory, Sharnbrook, United Kingdom.*

A limited range of produce, including peanuts, tree nuts and eggs, is responsible for the majority of IgE-mediated food allergies. We have examined the ability of food proteins of varying allergenic potential to provoke IgG and IgE antibody responses following systemic (intraperitoneal; ip) exposure to BALB/c strain mice. Animals were treated with a purified peanut allergen (Arachis hypogea lectin) or with ovalbumin (OVA), a major allergenic constituent of chicken egg. Mice were also exposed to proteins derived from the potato, a foodstuff for which there is little evidence of allergenicity; to the purified lectin (Solanum tuberosum), or to a crude potato protein extract (PPE). Animals (n=5 per group) received various concentrations of protein by ip injection on days 0 and 7. Seven days later, serum samples were analyzed for specific IgG content by enzyme-linked immunosorbant assay and for specific IgE content by homologous passive cutaneous anaphylaxis assay. Administration of OVA or peanut lectin provoked vigorous IgG antibody responses and relatively high titer IgE at all doses tested. Thus, titers ranged from 1/128 to 1/16 for 0.2% to 0.02% peanut lectin and from 1/62 to 1/16 for 10% to 1% OVA. Potato lectin (10% to 1%) stimulated similar titers of IgG antibody to those induced by administration of the same concentrations of OVA, but only induced low titer (positive with neat serum only) IgE at the maximum dose tested (10%). PPE was somewhat less immunogenic over the same dose range and also failed to stimulate marked IgE responses (titer of 1/2 at 10% only). Particularly taking into account the dose responses, these food proteins display a differential capacity to provoke IgE antibody which is consistent with their differing allergenic potential in man.

553 THE SENSITIZING POTENTIAL OF DIFFERENT FOOD PROTEINS IN AN ORAL BROWN NORWAY (BN) RAT FOOD ALLERGY MODEL.

L. M. Knippels[1], A. H. Penninks[1], J. D. Astwood[2], E. Rice[2], G. Holleschak[2], R. Thoma[2] and R. E. Goodman[2]. [1]*Experimental Immunology, TNO Nutrition and Food Research, Zeist, Netherlands and* [2]*Product Safety Center, Monsanto, St Louis, MO.* Sponsor: P. van Bladeren.

Brown Norway rats were sensitized with common strong and non-allergenic proteins to evaluate the potential predictive value for allergenicity of food proteins. Natural, purified peanut Ara h1, shrimp tropomyosin, hen egg-white ovalbumin, potato patatin (the major allergenic protein in an uncommon allergen), and beef tropomyosin (a non-allergenic protein), were tested. BN rats (n=6) were either gavaged daily with 0.01, 0.1, or 1 mg protein/ml/rat during 42 days, with or without the oral adjuvant Cholera Toxin (CT), or sensitized by intraperitoneal injection (ip) with alum as a positive control. Weekly serum samples were tested for antigen specific IgE and IgG2a (a Thelper-2 mediated subclass in rats) antibody levels using a passive cutaneous anaphylaxis assay and enzyme-linked immunosorbent assay (ELISA). Although, responses to oral sensitization were not as common as to ip injection with alum, an apparent gradation of responses was observed in animals dosed with 1 mg per day without CT. Fifty percent of the animals developed specific IgE responses to the strong allergens Ara h1 and Shrimp tropomyosin, 70% to ovalbumin, and one of six animals developed a specific IgE response to patatin. No animals produced IgE responses to beef tropomyosin. Interestingly Ara h1, shrimp tropomyosin and ovalbumin are all stable in pepsin at low pH, a trait that is common for food allergens, while patatin is quite labile. Addition of CT as an oral adjuvant at day 0 and 7 during sensitization did not consistently increase the number of IgE responding animals. The reported results suggest that in the BN rat the oral route of sensitization, without the use of CT as an oral adjuvant, may be more predictive for food allergens than injection of the antigen with alum. In addition, based on the obtained results measurement of protein-specific IgG2a is not likely to be used as a stand-alone parameter for allergic sensitization.

554 PEANUT PROTEIN ELICITS T HELPER 2 CYTOKINE PRODUCTION AS DETECTED BY GENE EXPRESSION AND PROTEIN SECRETION IN MICE.

B. F. Flanagan[2], C. J. Betts[1], H. Caddick[1], R. J. Dearman[1] and I. Kimber[1].
[1]*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*University of Liverpool, Liverpool, United Kingdom.*

Sensitization to peanuts is associated usually with high titer IgE antibody, consistent with the selective activation of T helper (Th) 2 type cells. We have characterized cytokine profiles, at the mRNA and protein levels, induced by exposure of mice to a purified peanut allergen, *Arachis hypogea* lectin. Fourteen days following intradermal exposure of BALB/c mice to peanut lectin, draining lymph node cells (LNC) were isolated and cultured in the presence or absence of peanut lectin, concanavalin A (con A) or irrelevant protein for 24 to 120 hours. Control animals were untreated (naïve). Cell proliferation was assessed over the final 24 hours of the culture period. Culture supernatants were analyzed for cytokine protein secretion by Enzyme-Linked Immunosorbent Assay (ELISA) and cytokine gene expression was evaluated by ribonuclease protection assay (RPA) using probes for various Th1- and Th2-type cytokines. Treatment of control (naïve) LNC with peanut lectin (0.2 mg/ml) failed to stimulate marked proliferation, confirming that peanut lectin is non-mitogenic. Culture with con A (2 μg/ml) induced vigorous proliferation and transient expression of mRNA for the type 1 cytokines interferon γ (IFN-γ) and interleukin (IL) 2. Restimulation of LNC from peanut-primed mice with peanut

lectin and con A in each case induced vigorous proliferative responses. Culture with peanut lectin also induced the expression of high levels of transcripts for the Th2 cytokines IL-4, IL-5, IL-10 and IL-13 throughout the time course investigated. Conversely, a more Th1-type cytokine profile was observed following restimulation with con A, with high expression of IL-2 and IFN-γ after 24 hours of culture, and less vigorous production of type 2 cytokines. These expression patterns were paralleled by cytokine protein secretion profiles. These data confirm that exposure of mice to peanut allergen results in the selective stimulation of a Th2-type response.

555 DIFFERENTIAL ANTIBODY RESPONSES PROVOKED BY SYSTEMIC EXPOSURE OF MICE TO Ara h 1 AND Sol t 1.

I. Kimber[1], R. E. Goodman[2], J. D. Astwood[2], G. A. Bannon[3] and R. J. Dearman[1]. *[1]Research, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom, [2]Monsanto Product Safety Center, St Louis, MO and [3]Biochemistry and Molecular Biology, University of Arkansas Medical School, Little Rock, AZ.*

Most cases of IgE-mediated food allergy are associated with a relatively limited range of produce, including eggs, peanuts and shellfish. We have isolated and purified native patatin (Sol t 1), which represents approximately 40% of the total protein derived from the potato, a foodstuff which is recognized as a relatively rare cause of allergenicity, and vicilin from the peanut (Ara h 1). Antibody responses induced by systemic (intraperitoneal; ip) exposure of BALB/c strain mice to these proteins have been characterized. In four independent experiments, animals (n=5) received an ip injection of 0.25ml of a 1% solution of protein in phosphate buffered saline on days 0 and 7, with serum samples prepared for analysis 7 days later. Specific IgE antibody was measured by homologous passive cutaneous anaphylaxis assay and specific IgG antibody production was analyzed by enyzme-linked immunosorbant assays. In each experiment, exposure to Ara h 1 stimulated detectable IgE in the majority of animals (60% to 100%), with titers for pooled serum samples ranging from 1 in 4 to 1 in 16. Identical treatment with Sol t 1 resulted in only a minority of IgE responder mice in each experiment (0% to 40%) and pooled serum samples were uniformly IgE-negative (no detectable IgE with neat serum). In contrast, analyses of specific IgG antibody responses revealed that both Sol t 1 and Ara h 1 provoked vigorous IgG antibody production in all exposed mice with comparable titers achieved. Thus, under conditions where both proteins are of equivalent immunogenicity (with respect to IgG antibody responses), a divergent capacity to stimulate IgE antibody production is observed. The differential abilities of Ara h 1 and Sol t 1 to stimulate specific IgE antibody following systemic exposure to BALB/c strain mice are consistent with their differing potential to cause allergenicity in man.

556 CHANGES IN THE COMPLEMENT SYSTEM IN TRIMELLITIC ANHYDRIDE-INDUCED OCCUPATIONAL ASTHMA IN THE MOUSE.

I. F. Regal and M. E. Mohrman. *Department of Pharmacology, University of Minnesota, Duluth, MN.*

Trimellitic anhydride (TMA) is a small molecular weight chemical known to cause occupational asthma. Recent studies in animal models suggest that the complement system plays a role in mediating symptoms of asthma. To determine if complement changes accompanying eosinophilia into the lung differ in TMA-induced asthma compared to ovalbumin (OA)-induced asthma, parallel murine asthma models were used. BALB/c mice were sensitized as follows: days 1 and 3 intradermally with either TMA or OA in corn oil vehicle; day 12 intratracheally with either TMA conjugated to mouse serum albumin (TMA-MSA), OA, or MSA as control. To elicit the allergic response, mice were challenged intratracheally on days 19, 22, and 23 with either 30 μg or 400 μg TMA-MSA, OA or control MSA. Eosinophil infiltration and concentrations of complement component 3 (C3) or the complement activation product C5a in bronchoalveolar lavage (BAL) were assessed 72 hr later in 4 to 15 animals per group. Mouse C3 was determined by ELISA and mouse C5a by a Western blot method. Challenge of a sensitized animal with 30 or 400 μg of the corresponding antigen resulted in significant eosinophil infiltration into the lung compared to MSA challenge. After challenge with 30 μg antigen, the concentration of C3 in the BAL increased in OA challenged mice, but not in TMA-MSA challenged mice. However, with 400 μg antigen challenge, the C3 in the BAL increased after either OA or TMA-MSA challenge when compared to MSA challenged controls. A significant increase in C5a in the BAL was only apparent after challenge with 400 μg TMA-MSA compared to MSA challenged animals, with no changes observed in OA challenged mice. These data demonstrate that different antigens elicit different changes in the complement system, and suggest that the mechanism of the asthmatic response may differ with the antigen. (Supported in part by NIH ES 07406).

557 INTERLEUKIN-4 AND INTERLEUKIN-6 WERE INCREASED IN RATS SENSITIZED WITH TOLUENE DIISOCYANATE.

K. Zheng and M. Ariizumi. *Department of Preventive Medicine, University of the Ryukyus, Nishihara, Japan.* Sponsor: W. Dong.

In order to investigate the cytokine profile in toluene diisocyanate (TDI)-induced occupational asthma, we conducted a quantification of cytokine production in a murine model of respiratory hyperreactivity to TDI. Wistar rats were sensitized with intranasal application of 10% TDI and provoked with 5% TDI to induce airway hypersensitivity. The blood leucocytes were counted, and bronchoalveolar lavage (BAL) was performed and the cellular responses in BAL fluid were analysed. Lung histological examination was performed to investigate the inflammatory status in the airway. The production of IL-2, IL-4, IL-6 and IFN- in serum, BAL fluid and spleen cell were determined with ELISA kits. The cellular results demonstrated that neutrophils and eosinophils in blood were significantly increased and the total cells and each different cell, in particular eosinophils in BAL fluid were markedly increased in TDI sensitized rats. Histological analysis showed that a respiratory inflammation represented by prominent infiltration of eosinophils in central and peripheral airways was present in TDI-sensitized rats. The cytokine assays revealed that in TDI-sensitized rats, IL-4 was predominately secreted in serum, and IL-4 and IL-6 rather than IL-2 and IFN- were predominately secreted in BAL fluid and in spleen cell. These findings suggested that IL-4 and IL-6 are preferentially produced and may have an important role in occupational asthma induced by TDI.

558 SPECIES COMPARISONS AND STATISTICAL ANALYSES OF CYTOKINE FINGERPRINTING FOR CHEMICAL ALLERGENS.

R. Skinner, R. J. Dearman, E. V. Warbrick and I. Kimber. *Research, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Prolonged topical exposure of BALB/c strain mice to different classes of chemical allergen induces cytokine secretion profiles consistent with the selective development of discrete functional subpopulations of T cells. Thus, treatment with the reference contact allergen 2, 4-dinitrochlorobenzene (DNCB), which apparently lacks respiratory sensitizing potential, elicits a preferential type 1 cytokine production pattern, whereas the reference respiratory sensitizer trimellitic anhydride (TMA) stimulates a selective type 2 phenotype. We have now compared allergen-induced cytokine secretion profiles in the Brown Norway (BN) rat with those stimulated in the BALB/c strain mouse. Under conditions where TMA and DNCB induced similar levels of immune activation, divergent cytokine expression patterns are elicited. TMA-activated LNC isolated from both species elaborated high levels of the type 2 cytokines interleukin (IL)-10 and IL-13, but little of the type 1 cytokines IL-12 or interferon γ. For vigorous IL-4 production, LNC from both BALB/c mice and BN rats required restimulation *in vitro* with the T cell mitogen concanavalin A. DNCB-stimulated LNC generally displayed the converse type 1 phenotype. Cytokine secretion profiles displayed by LNC derived from BN rats were considerably more variable than those observed for LNC from BALB/c strain mice. With the exception of IL-4, statistically significant differences ($p<0.01$) between TMA- and DNCB-activated LNC were recorded for all cytokines in BALB/c mice. For the BN rat, differences reached statistical significance ($p<0.01$) only for the expression of IL-13. These data demonstrate that the intrinsic ability of DNCB and TMA to promote preferential type 1 and type 2 responses, respectively, is species-independent. However, with respect to the identification of potential chemical respiratory allergens as a function of induced cytokine secretion profiles (cytokine fingerprinting) these data suggest that the use of the BALB/c strain mouse will provide the more robust method for hazard assessment.

559 PARA-PHENYLENEDIAMINE (PPD) REDUCES MONOCYTE CHEMOTACTIC PROTEIN-1 (MCP-1) LEVELS IN PPD/BB SPECIFIC T CELL CLONES, PBMC, MONOCYTES, AND U937 CELLS.

T. Wahle, D. Laizane, D. Kunz, H. F. Merk and B. Blomeke. *Dermatology, University Hospital, Aachen, Germany.*

Para-Phenylenediamine (PPD) is very strong allergen causing allergic contact dermatitis. We recently found that CD4+ T cells are involved in PPD contact allergy. PPD/BB specific T cell clones secreted high amounts of IL-4 and IL-5. However, little is known about the impact of chemokines in PPD allergy. Chemokines may play an important role in the development and exerbation of delayed hypersensitivity reactions (Rollins, 1997). One CC chemokine, the monocyte chemotactic pro-

tein 1 (MCP-1), has been implicated in chronic inflammatory diseases such as rheumatoid arthritis as well as allergic concact dermatitis. The possible role of MCP-1 in the PPD contact allergy has not been investigated so far. We analyzed the capacity of PPD and it's autooxidation product Bandrowski's Base (BB) to modify MCP-1 levels. PPD reduced MCP-1 secretion up to 80% compared to controls while BB did not. The latter was found using PPD/BB specific T-cell clones, PBMC's, monocytes as well as in a cell line (U937). Further analyis revealed that PPD reduced MCP-1 mRNA expression and mRNA stability. These results indicate that PPD can directly influence immune surveillance. This work was supported by the BMBF (IZKF BIOMAT, G11) and the European Community.

560 CYTOKINE PRODUCTION INDUCED BY LOW MOLECULAR WEIGHT CHEMICALS AS A FUNCTION OF THE STIMULATION INDEX IN THE LOCAL LYMPH NODE ASSAY: AN APPROACH TO DISCRIMINATE CONTACT SENSITIZERS FROM RESPIRATORY SENSITIZERS.

H. Van Loveren, F. M. Van Och, W. H. De Jong and R. J. Vandebriel. *Immunobiology and Haematology, RIVM, Bilthoven, Netherlands.*

In general, contact sensitizers have been shown to selectively induce Th1 immune responses, such as IFN-gamma production, whereas Th2 responses, such as IL-4 production, were seen after exposure to respiratory allergens. However, these features are to a large extent dependent on the dose of the particular allergen. Therefore, the aim of the present study was to investigate the distinction between sensitizers and respiratory allergens, by establishing dose-dependent cytokine profiles. The contact allergens 2, 4- dinitrochlorobenzene (DNCB) and hexyl cinnamic aldehyde (HCA), as well as the respiratory allergens phthalic anhydride (PA), toluene diisocyanate (TDI), and trimellitic anhydride (TMA) were tested. For a range of concentrations, both proliferative responses and cytokine production were established. Estimated concentrations were derived at several stimulation indices (SI's). From that, IFN-gamma, IL-4, and IL-10 production as a function of estimated concentrations were calculated. All three respiratory allergens showed significantly higher IL-4 and IL-10 production patterns compared to DNCB and HCA. A positive identification of DNCB and HCA as contact allergens on the basis of IFN-gamm production, was observed only at very high stimulation indices (SI>40) for DNCB and already at low SI's (SI>7) for HCA. This approach combines potency evaluation and discrimination between contact and respiratory allergens in a single short assay. We propose that by direct linkage of proliferation and cytokine production in a dose-response manner, distinguishing contact allergens from respiratory allergens may be improved compared to present approaches.

561 AN APPROACH FOR SAFETY ASSESSMENT TO MINIMIZE POTENTIAL FOR TYPE I ALLERGY FROM PROTEINS IN PERSONAL CARE (PC) PRODUCTS.

G. M. Adamson[1], D. Weisgerber[2], G. Johnston[1] and K. Sarlo[1]. [1]*Product Safety & Regulatory Affairs, Procter & Gamble, Cincinnati, OH and* [2]*Skin Technology, Procter & Gamble, Cincinnati, OH.*

This report summarizes an approach for supporting the safety assessment of proteins in PC products (cosmetics, skin, hair care products) to minimize potential for inducing Type I allergy. There is increasing use of proteins (e.g. soya, hydrolyzed wheat, plant extracts) in PC products. Currently there are over 3000 proteins, protein extracts listed in the INCI dictionary for commercial PC product use. Proteins can induce IgE mediated Type I hypersensitivity, that may lead to symptoms like urticaria and respiratory allergy. In general, use of proteins has been shown to be safe, and levels of proteins in formulations are usually low (<1% w/w). However, exposure to some proteins has caused allergy: urticaria *via* hair products with quarternized hydrolyzed collagen (Niinimaki 1998. Allergy 53:1073-87); urticaria *via* PC products with hydrolyzed wheat (Varjonen 2000. Allergy 55:294-96). A strategy for safety risk assessments of proteins is proposed using an example of a body lotion containing a protease. Aerosol exposures were measured during showering after dermal application of this product, that showed exposures of 8-111ng/m3 of the protease. Dermal deposition studies also showed that 50% of applied protein remained intact on skin for over 24 hours. A previous report showed levels of 3-29ng/m3 of a similar protein inducted 4 of 61 panelists after 6 months of daily shower exposure (Kelling et al., 1998 J. Allergy Clin. Immunol. 101:179-87). This proposed risk assessment approach depends on; (1) innate allergenic potency of the protein; (2) structural similarity to other proteins for SAR comparison (3) exposure determination *via* relevant biologic route; (4) product application and usage habits; (5) comparisons to benchmark. For the body lotion example used here it was concluded that this product was considered unsafe for consumers.

562 EFFECTS OF MANCOZEB ON IMMUNE SYSTEM IN AGRICULTURAL WORKERS.

C. L. Galli[1], E. Corsini[1], G. De Pascale[3], S. Fustinoni[4], T. Mammone[2], S. Visentin[2], M. Maroni[2] and C. Colosio[2]. [1]*Pharmacological Sciences, University of Milan, Milan, Italy.* [2]*Intern. Ctr. Pesticide Safety, ICPS, Busto Garolfo, Italy,* [3]*Voghera District, ASL of Pavia, Pavia, Italy and* [4]*Occupational Health, University of Milan, Milan, Italy.*

Ethylenebisdithiocarbamate pesticides (EBDTCs) may have immunostimulating effects in man.The aim of this study was to investigate the immune status of agricultural workers exposed to an EBDTC fungicide (mancozeb).Twenty-six healthy subjects entered the study, 13 agricultural workers and 13 unexposed control subjects.The exposure to mancozeb was assessed through the determination of the levels of urine excretion of the main EDTCs metabolite, ethylentiourea (ETU).The study of the immune function was performed on serum and blood samples collected before and after the work shift in the workers and only once (morning samples) in controls.The following parameters were measured:complete and differential blood count, serum immunoglobulins, complement fractions, autoantibodies, lymphocyte subpopulations.As for the functional assay, we measured the proliferative response to several lymphocytes mitogens (PHA, PWM, anti-CD3 and PMA plus ionomycin) and cytokine production after stimuli (TNF, IL-4, g-INF) in a whole blood assay. We found that agricultural workers resulted significantly exposed to mancozeb (median ETU in urine, exposed:= 2.5 mg/g creatinine;range=0, 04-95.2 mg/g.Controls: median 0.25 mg/g creatinine; range: 0.02-0.25 mg/g). As for the immune testing, the post shift assay showed an increase in the proliferative responses to PHA 0, 3 % (median=85, 490, range=13, 989-137, 742 cpm vs 35, 796, range=313-117, 230) in the exposed subjects, as well as to anti-CD3 (25 ng/mL) and PWM 2%. Relatively to cytokine production, we found an increase in g-INF, while IL4 and TNF decreased, suggesting a preferential Th1 cells activation. In summary, our results confirm that exposure to mancozeb has slight immunostimulatory effects and point out the possibility to monitor and reveal immunomodifications in workers occupationally exposed to potential immunotoxic compounds using a whole blood assay.

563 ANTISENSE INHIBITION OF TRANSLATION ELONGATION FACTOR-1 DELTA REVERSES THE ONCOGENIC POTENTIAL OF CADMIUM TRANSFORMED CELLS.

P. Joseph, Y. Lei and T. Ong. *Toxicology and Molecular Biology Branch, CDC/NIOSH, Morgantown, WV.*

The molecular mechanisms of carcinogenesis induced by the human carcinogen – cadmium, were investigated. Differential display analysis of gene expression revealed the overexpression of translation elongation factor-1delta sub-unit in BALB/c-3T3 cells transformed with cadmium chloride compared with the non-transformed control cells. cDNA cloning (GenBank Accession Number AF304351), expression of the encoded protein, and functional analysis of cDNA transfected NIH3T3 cells indicated that translation elongation factor-1 delta is a proto-oncogene. In order to confirm the oncogenic potential of translation elongation factor-1 delta, BALB/c-3T3 cells transformed with cadmium chloride were transfected with the plasmid DNA expressing antisense TEF-1 delta mRNA. Expression of the antisense translation elongation factor-1 delta mRNA resulted in marked reversal of the oncogenic potential of the cadmium-transformed BALB/c-3T3 cells. This was evidenced by a significant reduction in the number of anchorage independent colonies developing from the transformed cells expressing antisense mRNA for translation elongation factor-1 delta compared with the vector alone-transfected control cells. Furthermore, sub-cutaneous injection of the antisense mRNA expressing transformed BALB/c-3T3 cells resulted in a significant reduction in the onset as well as the size of tumors in athymic nude mice. These results demonstrate that the cell transformation and tumorigenesis induced by the human carcinogen – cadmium, were due to the overexpression of translation elongation factor-1 delta - a novel cadmium-responsive proto-oncogene.

564 APPLICATION OF GENE ARRAY TECHNOLOGY TO TRANSCRIPTIONAL FINGERPRINTS OF PRIMARY RAT HEPATOCYTES EXPOSED TO CADMIUM ACETATE.

B. W. Harker[1], D. C. Rudnicki[2], K. A. Utendorf[2], S. M. Hussain[1], J. M. Frazier[2] and C. Wang[1]. [1]*ManTech Environmental Technology Inc., Dayton, OH and* [2]*Operational Toxicology Branch, Air Force Research Laboratory, Wright Patterson AFB, OH.*

Traditional toxicological testing utilizes whole animals to test potential toxicity of chemicals. These tests are expensive, time consuming, and provide little data on early low dose effects and gene expression in target cells. Gene chip technology allows the simultaneous monitoring of expression levels of thousands of genes and

can be used as a rapid and highly sensitive detector for toxicity evaluation and prediction. Cadmium (Cd) is an extremely toxic trace metal of concern to the US Air Force. Although toxic effects of Cd have been well characterized, its temporal effect on the transcriptome has not been studied. To determine the transcriptomic fingerprints of Cd toxicity, primary rat hepatocytes were exposed to Cd at 0, 1.25 and 2 μM for 2 hrs at 37 °C. Total RNA was isolated at -2 (pretreatment control), 0, 3, 6, 12 and 24 hrs post-exposure to determine mRNA expression profiles using the Affymetrix RatTox U34 array. Simultaneously, hepatocyte viability was assessed by LDH leakage and MTT reduction. Our results indicated that (1) Cd resulted in a significant time-course, dose-dependent induction of stress genes (ie., *hsp*70s, heme oxygenase, GLCLc, MT1 and NQO1); (2) the *hsp*70s displayed a differential dose-dependent up-regulation due to Cd treatment: at 3 h-76 fold/5 fold; at 6 h- 67 fold/8 fold (data are expressed relative to controls for the 2μM/1.25μM treatments); (3) 2 μM Cd down-regulated CYP450s, vimentin, and tyrosine aminotransferase at certain time points; (4) effects of Cd on gene expression profiles in rat primary hepatocytes were consistent with the results of cytotoxicity data, however, transcript responses were more sensitive. In summary, Cd-exposed primary rat hepatocytes give rise to a unique gene expression fingerprint. Modulation of gene expression will help elucidate the mechanisms of Cd toxicity and identify early biomarkers that can be used to predict human health.

565 EXPRESSION OF A HEME OXYGENASE-LUCIFERASE (HO-LUC) CONSTRUCT IN TRANSGENIC MICE FOLLOWING TREATMENT WITH DIFFERENT CHEMICALS.

S. E. Malstrom, D. J. McMullen, K. L. Steinmetz, W. Zhang and L. C. Sambucetti. *Xenogen Corporation, Alameda, CA.*

Heme oxygenase-1 (HO) is a key enzyme in the conversion of heme to bilirubin and may be involved in some cellular anti-oxidative responses. The HO gene has been previously shown to be rapidly up-regulated after treatment with chemicals or other inducers of oxidative stress. FVB mice transgenic for the luciferase gene under transcriptional control of the HO promoter (HO-luc) have been shown to express the HO-luc transgene similarly to the endogenous HO gene following the administration of HO-inducing compounds. *in vivo* tissue-specific expression of HO-luc can be visualized using a low-light imaging system (IVIS™) after i.p. injection of luciferin. The HO-luc mouse has previously been shown to express luciferase in response cadmium chloride, a potent HO inducer. In this study, compounds representing different toxicity pathways were used to evaluate the HO-luc Tg mouse as an *in vivo* screening tool for toxicology. Adult male and female HO-luc mice were treated (3-28 days) with acetaminophen (250 mg/kg, oral or ip), cadmium chloride (CdCl2, 10 μM/kg, ip), chloroform (100, 200 and 250 mg/kg oral or ip), clofibrate (500 mg/kg oral or ip), or doxorubicin (10 mg/kg intravenous). All compounds induced HO-luc expression with the greatest responses after CdCl2 or chloroform treatment, and tissue-specific pathology was confirmed. These findings suggest that the HO-luc mouse may be used as a model for *in vivo* screening of new and unknown compounds for their potential toxic effects.

566 UTILITY OF HISTORICAL DYNAMIC RANGE DATA IN MICROARRAY GENE EXPRESSION ANALYSIS.

T. D. Nolan, S. Hicken, R. Suizu, G. Farris and S. Farr. *Phase-1 Molecular Toxicology, Inc., Santa Fe, NM.*

A major difficulty in applying microarray gene expression (MGE) data to toxicity assessment is interpretation of the significance of a gene's induction or repression. One important component to the dimension of significance is the response of genes in relation to their individual dynamic ranges of expression, which can differ significantly due to both biological factors and technical limitations within microarray platforms. In this study, we assess the utility of normalizing fold induction (FI) data based on individual gene dynamic ranges in the analysis and interpretation of MGE experiments with $CdCl_2$ and other compounds reputed to exert pro-oxidant (OX) effects (clofibrate, cyclosporin A, and puromycin aminonucleoside). Historical maximum (max) or minimum (min) FI values were derived from the Phase-1 database of *in vivo* rat MGE experiments, which includes 38 well-characterized, paradigm toxicants. FI data for each gene were then converted to % max or % min values by referencing corresponding historical values. In 6 hour liver samples from experiments with 3 rats treated with a single IP injection of 1 mg/kg $CdCl_2$, the most highly induced (> 2.5 FI in at least 2 rats) genes implicated in oxidant defense (OD) were heme oxygenase-1 (HO-1) (3.3, 3.1, 4.9) and metallothionein-1 (MT-1) (9.0, 21.5, 12.5). However, when % max values were considered, the most highly induced (> 40% of max in at least 2 rats) OD genes were Cu/Zn superoxide dismutase (Cu/Zn-SOD) (13%, 88%, 74%), heme-binding protein 23 (HBP23) (23%, 63%, 83%), and thiol-specific antioxidant (TSA) (6%, 45%, 82%). Induction values for both HO-1 and MT-1 were < 25% max for all 3 rats. Additionally, historical max data showed several instances of co-induction of Cu/Zn-SOD, HBP23, and TSA in liver by the other OX compounds. The results suggest that converting MGE data to values based on historical dynamic ranges can enhance the identification of genes that show substantial participation in specific toxicological responses, as well as the compounds that elicit those responses.

567 MAP KINASE PATHWAY DECREASES THE INDUCTION OF METAL RESPONSE ELEMENT-DRIVEN LUCIFERASE ACTIVITY BY CADMIUM.

L. S. He, Y. Xia, D. W. Nebert and T. P. Dalton. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

Both cadmium (Cd++) and zinc (Zn++) activate metallothionein (Mt1) gene transcription *via* the metal response element (MRE motif), to which the MRE transcription factor-1 (MTF1) binds. In cells cultured in low Zn++, most MTF1 is localized to the cytoplasm and is inactive. However, even under these circumstances, a modest percentage of MTF1 is in the nucleus and is binding-competent. Activation of Mt transcription by Zn++ is preceded by a stoichiometric activation of MTF1 binding and its nuclear accumulation. On the other hand, Cd++ activates MTF1-dependent Mt transcription without an increase in MRE binding or nuclear translocation. Thus, a modest amount of nuclear MTF1 may acquire potent transactivation potential in the presence of Cd++. Because heavy metals appear to activate oxidative stress-signaling, we assessed the role of signaling components of mitogen-activated protein (MAP) kinase pathways in controlling the trans-activity of MTF1. Transient transfection experiments were performed in monkey kidney fibroblast CV1 cells, using a reporter construct containing 153 bp of the Mt1 promoter fused to the luciferase (LUC) gene. Cd++ treatment resulted in a dose-dependent increase in LUC activity reaching a maximal 80-fold above control. Co-transfection with constitutively active MEKK1, an upstream regulator of the MAPK kinase pathway, shifted the dose-response to Cd++ approximately 4-fold to the right and decreased to half the maximal induction. MEK1 and MKK6 are the downstream mediators of MEKK1. Co-transfection of their constitutively active forms similarly decreased the cadmium-mediated induction as MEKK1. PD98059, a generalized inhibitor of MEK, augmented Cd++ induction, either with or without MEKK1 plasmid co-transfection. Using transient transfection with MTF1-null cells, these effects were found to be MTF1-dependent. [a]Supported, in part, by NIH grants P30 ES06096 and R01 ES10416.

568 DIFFERENTIAL EFFECTS OF ARSENIC, CHROMIUM, CADMIUM, NICKEL AND MITOMYCIN C ON GENE EXPRESSION AS MEASURED BY DNA MICROARRAY.

A. S. Andrew, A. J. Warren, K. A. Temple and J. W. Hamilton. *Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.*

Examining global effects of toxins on gene expression can be useful for examining patterns of biological response, underlying mechanisms of toxicity, and identification of candidate metal-specific genetic markers of exposure and response. Using gene microarrays, we examined changes in gene expression following low dose, acute exposures of Cd, Cr, Ni, As or mitomycin C (MMC) in BEAS-2B human bronchial epithelial cells. Treatments were chosen that did not cause any overt signs of toxicity, or changes in cell survival or replication as measured by long term colony forming assays. Total RNA was isolated from cells exposed to 3 μM Cd(II) (as cadmium chloride), 10 μM Cr(VI) (as sodium dichromate), 3 μg/cm2 Ni(II) (as nickel subsulfide), 5 μM or 50 μM As(III) (as sodium arsenite), or 1 μM MMC for 4 h. Gene expression profiles in response to these treatments were measured using a Clontech Atlas Human 1.2 cDNA microarray. A signal intensity threshold ratio of 1.5 was used for Cd, Cr, Ni and MMC, but a higher threshold value of 1.7 was used for As due to the much larger number of As-affected genes. Surprisingly, only a small subset of genes was differentially expressed in response to each agent: Cd, Cr, Ni, As (5 μM), As (50 μM), and MMC each differentially altered the expression of 25, 44, 31, 110, 65, and 16 individual genes, respectively. Interestingly, only a few genes were commonly expressed among the various treatments. Only one gene was altered in response to all four metals (hsp90), and no gene overlapped among all five treatments. Only three to seven genes overlapped among any two treatments, and similarly only a few genes were common to any three treatments. We also compared low (5 μM, non-cytotoxic) and high dose (50 μM, completely cytotoxic) arsenic treatments, which surprisingly affected expression of almost completely non-overlapping subsets of genes, suggesting a threshold switch from a survival response to an apoptotic response. (NIEHS (SBRP) ES07373)

569 MICROARRAY AND DIFFERENTIAL DISPLAY ANALYSES OF BONE CELL GENE EXPRESSION EARLY AFTER CADMIUM GAVAGE TO MICE.

M. H. Bhattacharyya[1], A. Regunathan[1], D. A. Glesne[1], T. Flores[1], J. M. Vaught[1], J. E. Villarreal[1] and A. K. Wilson[2]. [1]*Argonne National Laboratory, Argonne, IL and* [2]*Benedictine University, Lisle, IL.*

We developed an *in vivo* model for Cd-induced bone loss in which mice excrete bone mineral in feces starting 8 h after Cd gavage. The bone response starts at 5 μg Cd/l blood, below US OSHA guidelines for industry. Female mice of 3 strains

[CF1; metallothionein-wildtype (MT+); MT1, 2-deficient (MT-)] were placed on low Ca diet for 2 weeks. Each mouse was gavaged with 200 µg Cd or vehicle only. Fecal Ca was monitored daily for 8 days, starting 3 days before Cd gavage, to document bone response. For CF1 mice, bones were taken from 4 groups: +/- Cd, 2h after Cd; +/- Cd, 4h after Cd. MT+ and MT- strains had only +/-Cd, 4 h after Cd. PolyA RNA was isolated from marrow-free shafts of femura and tibiae, and each +/- Cd pair was submitted to Incyte Genomics for microarray analysis. Other RNA samples (4 h after Cd) were subjected to conventional DDRT-PCR. Fecal Ca results show that the 3 mouse strains differed in amount of bone Ca excreted after Cd (CF1 0.24±0.08 mg; MT+ 0.92±0.22 mg; MT- 1.7±0.4 mg). Differential display results show that 2 of 4 cloned bands that had confirmed Cd down-regulation by Northern analysis were mitochondrial. Another was 71% identical to arg-tyr kinase (GenBank U40827); the other was 74% identical to 2 mouse cDNAs of unknown function. Microarray results show that nearly all arrayed genes were unaffected by Cd. However, MT1 and MT2 had +Cd/-Cd expression ratios >1 in all four groups, while all ratios for MT3 were essentially '1', showing specificity. Both probes for MAPK 14 had expression ratios >1, while no other MAPK responded to Cd. Vacuolar proton pump ATPase and integrin αv (osteoclast genes), transferrin receptor, and src-like adaptor protein genes were stimulated by Cd; other src-related genes were unaffected. Genes down-regulated by Cd included procollagen type IX, and RIKEN cDNA 2900017D14. Results support the hypothesis that Cd stimulates bone demineralization *via* a MAPK pathway involving osteoclast activation.

570 APPLICATION OF CDNA MICROARRAY TO STUDY SUBACUTE CD TOXICITY.

M. S. Yang. *Biology, Hong Kong Baptist University, Hong Kong, China.*

Following a single intraperitoneal injection of 2mg/kg CdCl2, there was a sequence of change in mouse liver which included a change in the level of MT-mRNA, MT protein, as well as a marked increase in the content of Zn, which was found to bind to the high molecular weight proteins fraction (Yang et al., 2000). It was suggested that the marked increase in tissue Zn might be related to events such as further subcellular damage or recovery. The aim of the present study is to identify possible role of Zn during the subacute phase of Cd induced injury by finding the genes that might be involved in the subsequent biochemical changes. Six animals were randomly paired. One of the animals in each pair was injected with 0.9% NaCl and the other with CdCl2 (2 mg/kg). The animals were sacrificed after 48 hr. The liver was removed and total RNA was extracted by TRIZOL reagent. Total RNA (100µg) from the control and treatment groups were labeled with Cy5 and Cy3 fluorescent dye, respectively. The labelled probes were hybridized with the UCLA mouse 2K cDNA chip which consists of 1920 spots at 65OC overnight. The arrays were washed with 2X SSC, 0.1% SD and 0.2X SSC buffer and scanned by the GSI Lumonics confocal laser scanner. Fluorescent signal intensities of each spot on the slide were further normalized by the total intensity normalization method. Results from different trials indicated that several genes include alpha-2-macroglobulin, ferrtin heavy chain, translocator of inner mitochondrial membrane 44, metallothionein 1, cytochrome P450 steroid inducible 3a1, N-myc downstream regulated 1 and some ESTs geneswere up-regualted. Amongst them, only alpha-2-macroglobulin were consistently induced by more than 2-fold in each case. We are in the process of confirming their statement levels by RT-PCR or Northern blot. Yang et al, (2000). Toxicology 154, 103-111.

571 METALLOTHIONEIN GENE AND PROTEIN EXPRESSION IN A HUMAN UROTHELIAL CELL LINE EXPOSED TO CADMIUM CHLORIDE.

M. A. Sens[1], M. R. Rossi[2], S. Somji[3], S. H. Garrett[3], J. Nath[2] and D. A. Sens[3]. *[1]Pathology, West Virginia University, Morgantown, WV, [2]Genetics and Developmental Biology, West Virginia University, Morgantown, WV and [3]Urology, West Virginia University, Morgantown, WV.*

Metallothionein (MT) proteins are involved in the cellular stress response to toxic insult, and many bladder disorders have an environmental basis. The goal of this study was to characterize the expression of the MT isoforms in response to the classic MT inducer/toxic agent, cadmium, in UROtsa cells. UROtsa cells are immortalized human urothelial cells that exhibit many features consistent with normal human urothelium. One such feature is the exclusive basal expression of MT-1E, -1X and -2A genes. Acute exposure of UROtsa cells to 53.4 µM cadmium chloride for four hours resulted in the induction of MT-1E, -1X and -2A genes, as well as the MT-3 and -4 genes. Other metallothionein isoforms, MT-1A, -1B, -1F, -1G and -1H were not expressed at levels detectable by RT-PCR. Simultaneous detection of MT-1 and MT-2 proteins (MT-1/2) using the E-9 antibody showed an increase in the levels of MT protein corresponding to the increase in MT-1E, -1X, and -2A mRNA. Chronic exposure of UROtsa cells to 1, 5 and 9 µM cadmium chloride over a period of sixteen days, showed an increase in MT-1/2 protein, as well as an increase in MT-1E, -1X and -2A gene expression. MT-4 was induced in cells treated with 5 and 9 µM cadmium over the 16 day time course, whereas MT-3 mRNA was not detected in any of the chronically treated cells. These results suggest that MT- 1 and -2 are induced by acute and chronic exposure to cadmium, whereas MT-3 is only induced by acute exposure to cadmium.

572 MICROARRAY ANALYSIS OF MOLECULAR CHANGES SPECIFIC TO CADMIUM-TRANSFORMED HUMAN PROSTATE EPITHELIAL CELLS.

W. E. Achanzar[1], S. Quader[2], M. M. Webber[2] and M. P. Waalkes[1]. *[1]NCI at NIEHS, Research Triangle Park, NC and [2]Michigan State University, East Lansing, MI.*

Cadmium (Cd) is a carcinogenic metal implicated as a human prostatic carcinogen based on epidemiological studies, rodent studies and *in vitro* experiments. The molecular events underlying Cd carcinogenesis remain elusive, although our recent development of a Cd-transformed human prostate epithelial cell line (CTPE) provides a model amenable to molecular dissection. We initiated molecular comparisons of CTPE with the non-tumorigenic parental line (RWPE-1) as well as *ras*- (RWPE2-W99) and MNU-induced transformants derived from the same line. The goals of this study were to identify gene expression changes specific to CTPE cells in order to shed light on the carcinogenic mechanism of Cd and identify possible biomarkers of Cd-induced prostate tumors. This analysis revealed 29 genes whose expression is specifically altered in CTPE cells, including caveolin-1 and -2, P-cadherin, IL-6 and cytokeratins 8 and 18. Western blot analyses revealed that protein levels of caveolin-1and -2 and P-cadherin were elevated in CTPE cells, confirming the array results. Caveolin-1 was present in CTPE while undetectable in the other cells and caveolin-2 levels were increased 5-fold compared to RWPE-1 and 8-fold compared to RWPE2-W9. Caveolin-1 has been proposed as a marker of prostate tumor progression and the observed increase is consistent with the invasive and metastatic nature of CTPE-derived tumors. P-cadherin protein levels in CTPE cells were 3.4-fold those in RWPE-1 and 2-fold of those in RWPE2-W99. A review of the literature revealed no reports of increased P-cadherin in prostate cancer, making it a promising candidate for a specific biomarker of Cd-induced prostate tumors. We are expanding our study in order to better define the molecular changes specific to CTPE cells and beginning to construct a molecular fingerprint of Cd-induced prostate tumors. Development of such a fingerprint would dramatically impact the ability to assess the risk of Cd-induced prostate cancer in human populations.

573 ACUTE CADMIUM EXPOSURE INDUCES STRESS-RELATED GENE EXPRESSION IN WILD-TYPE AND METALLOTHIONEIN-I/II NULL MICE.

J. Liu[1], M. Kadiiska[2], J. C. Corton[3], W. Qu[1], M. P. Waalkes[1], R. P. Mason[2], Y. Liu[4] and C. D. Klaassen[4]. *[1]LCC, NCI at NIEHS, Research Triangle Park, NC, [2]LPC, NIEHS, Research Triangle Park, NC, [3]CIIT Centers for Health Research, Research Triangle Park, NC and [4]University of Kansas Medical Center, Kansas City, KS.*

This study examined effects of acute cadmium (Cd) on stress-related gene expression and free radical generation in wild-type and metallothionein-I/II-null (MT-null) mice. Atlas Toxicology arrays showed that Cd (40 µmol/kg as $CdCl_2$, ip for 3 hr) markedly increased the expression of genes encoding heat shock proteins, heme oxygenase-1, and DNA damage/repair response genes, such as DNA-damage inducible gene GADD45 and GADD153, DNA excision repair genes ERCC1, Rad23, Rad50, DNA mismatch repair gene PMS2, MSH3 and DNA glycosylases. The expression of genes encoding cytochrome P450 enzymes, UDP-glucuronosyltransferases, Mn-superoxide dismutase and catalase, was suppressed by Cd. MT-null mice were more sensitive than wild-type mice to Cd-induced stress-related gene expression, in accord with greater activation of transcription factor AP-1 and phosphorylated c-Jun NH_2-terminal kinase (JNK1/2) and extracellular signal-regulated kinase (ERK1/2). Thus, absence of MT exacerbates Cd-induced aberrant gene expression. To evaluate free radical production, mice were simultaneously given the spin-trap agent, N-*tert*-butyl-α-phenylnitrone (PBN, 250 mg in DMSO/kg, ip) with Cd, and livers were removed 30 minutes later for PBN-trapped radicals extraction with chloroform:methanol (2:1). The PBN-trapped radicals were detected with electron spin resonance. Cd treatment caused free radical generation in the liver of both wild-type and MT-null mice. Lipid peroxidation, as determined by hepatic concentrations of malondialdehyde and 4-hydroxyalkenals, was also increased in both wild-type and MT-null mice to a similar extent. These results indicate that a deficiency in MT enhances stress-related gene expression in response to Cd, but that the effect of MT may be down-stream of radical production.

574 SIGNAL TRANSDUCTION PATHWAYS IN CADMIUM-MEDIATED METALLOTHIONEIN-1 EXPRESSION.

R. D. Watkin, R. J. Potts and B. A. Hart. *Biochemistry, University of Vermont, Burlington, VT.*

The purpose of this study was to investigate signal transduction pathways that participate in cadmium-induced regulation of metallothionein (MT), a thiol-rich metal binding protein with free radical scavenging properties. Using quantitative real-time RT-PCR, we show that *in vitro* cadmium (Cd) treatment of alveolar epithelial cells causes both time- and dose-dependent changes in steady state levels of MT-1. The expression of MT-1 was significantly elevated above control (25-fold) 4 hours after the addition of 10 μM $CdCl_2$. A maximum increase in MT gene expression (~ 100-fold) was achieved by hours. Transcript levels remained above control at 16 h (30-fold) and eventually returned to baseline levels by 24 hours. Exposure of cultures to 5, 10, or 20 μM $CdCl_2$ for 8 hours resulted in increases of MT expression of 25-, 100-, and 210-fold, respectively. Inhibitors, specific to protein kinase C (PKC), protein kinase A (PKA), ERK kinase (MEK), p38 mitogen activated protein kinase (MAPK), and tyrosine kinases, were subsequently tested to determine how each affected Cd-mediated induction of MT-1. In these experiments, alveolar epithelial cell cultures were pre-treated for 30 min with each inhibitor prior to an 8 hour treatment with 10 μM $CdCl_2$. Induction of MT by Cd was reduced by 70% when PKC activity was suppressed with the inhibitor GF190203X. In contrast, inhibition of MEK with PD90859 resulted in a 50% increase in Cd-mediated MT gene expression. Inhibitors of p38 MAPK and tyrosine kinase caused less dramatic changes in MT mRNA. In conclusion, the results of this study indicate that signal transduction pathways that include PKC and MEK as active components are of importance in the induction of MT-1 by Cd.

575 ANTISENSE-BCL-2-INDUCED SELECTIVE OXIDATION OF PHOSPHATIDYLSERINE IN NCI-H226 CARCINOMA CELLS: ROLE IN APOPTOTIC SIGNALING.

Y. Y. Tyurina, P. P. Koty, V. A. Tyurin and V. E. Kagan. *Environmental & Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

The major function attributed to Bcl-2 is its ability to confer resistance against apoptosis. We have previously shown that Bcl-2 was effective in preventing of membrane phospholipid oxidation during apoptosis induced by a number of oxidants as well as non-oxidative stimuli. In particular, phosphatidylserine (PS) was protected against apoptosis-associated peroxidation and subsequent PS-dependent signaling events such as PS externalization. To further investigate the antioxidant/anti-apoptotic role played by Bcl-2 in oxidation of phosphatidylserine during apoptosis, we decreased the expression of Bcl-2 in the lung squamous carcinoma cell line NCI-H226 using a synthetic phosphorothioate oligonucleotide targeted against bcl-2 mRNA (antisense-bcl-2). NCI-H226 cells (106) were incubated with media only or with either the antisense-bcl-2 (0.3 M) oligonucleotide or with a specificity/cytotoxicity nonsense (0.3 M) oligonucleotide control for 5 h at 37C. Incubation of NCI-H226 cells in the presence of the antisense-bcl-2 oligonucleotide resulted in a significantly increased amount of apoptotic cells as compared to controls. Using our technique to assess oxidative stress using cis-parinaric acid (PnA), we found a significant oxidation of Pn-A-PS in apoptotic Bcl-2-depleted NCI-H226 carcinoma cells. No significant differences in oxidation of PnA-labeled phosphatidylcholine and phosphatidylethanolamine between control cells and cells after treatment with both nonsense and antisense-bcl-2 was found. This selective oxidation of PS cannot be attributed to changes of phospholipid composition as our HPTLC analysis of the major phospholipid classes showed no differences in the phospholipid composition between control (untreated) cells and cells incubated in the presence of either antisence-bcl-2 and nonsense oligonucleotides. We conclude that Bcl-2 plays an important role in regulation of programmed cell death and PS oxidation during apoptosis.

576 ROLE OF APOPTOSIS INDUCTION IN DEVELOPMENT OF LUNG INJURY FROM HIGH BURDENS OF TITANIUM DIOXIDE.

R. R. Mercer, L. Wang, J. Antonini, J. F. Scabilloni and V. Castranova. *HELD, NIOSH, Morgantown, WV.* Sponsor: V. Castranova.

We previously examined the role of apoptosis in lung pathology due to silica, a highly toxic particle and demonstrated that apoptotic cells and degradation products significantly accumulate as injury develops. In this study we test the hypothesis that titanium dioxide (TiO2), a particle with no known specific toxicity, induces apoptosis and accumulation of apoptotic degradation products. To test this, male, F344 rats were given intratracheal instillations (IT) of 0.4, 4 and 40 mg of TiO2. At 1 day, 1 week and 4 weeks after instillation rats were sacrificed, lungs preserved by intra-tracheal instillation of fixative. Sections were processed for TdT labeling of apoptotic nuclei with a fluorescent indicator and counter-stained to label non-apoptotic nuclei. The number of apoptotic cell nuclei per lung was measured by morphometric methods. Additional sections were stained with Sirius Red to detect areas of collagen accumulation. Apoptotic cells in the saline instilled lungs were minimal at 1 and 4 weeks (0.2±0.2 and 0.3±0.4 million cells per lung, mean±SE). One week after IT, apoptotic cells per lung were 1.9±0.1, 4.4±0.4 and 13.3±2 million in the 0.4 mg, 4 and 40 mg groups respectively. At 4 weeks the number of apoptotic cells was increased to 5.2±0.5, 9.5±2.0 and 24.1±3.1 million in the 0.4, 4 and 40 mg TiO2 groups. Sirius Red staining of lung sections demonstrated areas with significant connective tissue accumulations in response to the IT of TiO2 in both the 4 and 40 mg TiO2 groups at 4 weeks of exposure. Sirius Red staining of collagen in saline and 0.4 mg TiO2 groups was normal at 1 and 4 weeks. Our results demonstrate that high levels of inert, non-toxic dusts produce significant numbers of apoptotic cells and products. At high levels of lung burden the induction of apoptosis is associated with development of fibrotic foci. The results suggest that injury from the accumulated apoptotic products may be responsible for injury observed in high lung burden exposures to particulates such as TiO2 which have no specific toxicity.

577 BENZO(A)PYRENE 7, 8-DIHYDRODIOL IS GLUCURONIDATED BY HUMAN UGT1A9 AND CAUSES APOPTOSIS IN HEPG2 CELLS.

S. Chen, M. Yueh, N. Nguyen and R. H. Tukey. *Dept. of Pharmacology, UCSD, La Jolla, CA.*

The human UDP-glucuronosyltransferases (UGTs) are involved in cellular detoxification and have been implicated as a mechanism to promote genoprotection. Polycyclic aromatic hydrocarbons such as BENZO(A)PYRENE (BP) are metabolized through oxidation and epoxidation to simple and complex phenols. Both phenolic and dihydrodiol metabolites have been shown to be proximate mutagens capable of being activated to ultimate forms. While most of the simple phenols are substrates for glucuronidation, little is known about the more complex dihydrodiols. Using expressed human UGTs (1A1, 1A3, 1A4, 1A6, 1A7, 1A8, 1A9, 1A10, 2B4 and 2B7), we have demonstrated that BP-*trans*-7, 8-dihydrodiol (±) (7, 8-diol) is actively glucuronidated by UGT1A9. In cells deficient in UGT1A9, such as HepG2 cells, experiments were conducted to examine the mutagenic properties of 7, 8-diol on cell viability. Annexin V analysis revealed in a dose dependent fashion that HepG2 cells were undergoing apoptosis following treatment with various concentrations of the 7, 8-diol. DNA fragmentation assays confirmed the presence of internucleosomal cleavage products consistent with the analysis of poly (ADP-ribose) polymerase (PARP) as shown by the appearance of the PARP 89 kD fragment. In Western blot analysis, HepG2 cells treated with 2.5 μM 7, 8-diol led to a two fold increase in cytosolic Cytochrome C, consistent with one of the properties of apoptosis. $Bcl\text{-}_{XL}$, an anti-apoptotic protein, decreased over 50%, while Bax, a pro-apoptotic protein, increased to 150% of that following vehicle treatment. In addition, an extensive down-regulation of xIAP (inhibitors of apoptosis) was detected which paralleled the appearance of apoptotic DNA fragments. In conclusion, HepG2 cells may be a sensitive biological tool to examine the actions of mutagens on apoptosis in addition to monitoring the genoprotective role of the human UGTs on cell viability. (Supported by USPHS grant CA79834)

578 INVOLVEMENT OF OXIDATIVE STRESS IN SDZ IMM 125-INDUCED APOPTOSIS IN RAT HEPATOCYTES.

A. Wolf[1], S. Grub[1] and W. E. Trommer[2]. *[1]Toxicology/Pathology, Novartis Pharma AG, Basel, Switzerland and [2]Department of Chemistry, University, Kaiserslautern, Germany.*

The mechanisms underlying the apoptotic activity of the immunosuppressive drug cyclosporine A and its hepatotoxic O-hydroxyethyl-D(Ser)8-cyclosporine derivative SDZ IMM125 in rat hepatocytes are not fully understood. It was the purpose of the present study to investigate the role of oxidative stress in SDZ IMM125-induced apoptosis, and to evaluate the role of caspase-3 by coincubation of anti- and pro-oxidants with rat hepatocytes. SDZ IMM 125 induced a dose-dependent increase in chromatin condensation and fragmentation, and the activation of caspase-3. Supplementing the cell cultures with the antioxidants, DL--tocopherol-polyethylene-glycol-1000-succinate and ascorbic acid significantly inhibited the SDZ IMM125-mediated increase in chromatin condensation and fragmentation, and caspase-3 activity. The reducing agent, dithiothreitol, significantly inhibited the SDZ IMM125-mediated increase in chromatin condensation and caspase-3 activity. The glutathione synthetase inhibitor, buthionine sulfoximine, significantly enhanced SDZ IMM125-mediated caspase-3 activation and increased SDZ IMM 125-mediated chromatin condensation and fragmentation. The present data suggest that SDZ IMM125-induced apoptosis is mediated by the imbalance of anti- and pro-oxidant steady state in rat hepatocytes and that the intracellular redox-state can act as a modulator of apoptosis. The results further suggest that antioxidants and pro-oxidants might act on apoptosis by modifying caspase-3 activity.

579 REVERSAL OF ACETAMINOPHEN (AAP) AND THIOACETAMIDE (TAM)-INDUCED CASPASE-ACTIVATED DNASE (CAD) AND OXIDATIVE STRESS-MEDIATED APOPTOTIC AND NECROTIC LIVER CELL DEATHS BY *MOMORDICA CHARANTIA* BIOFLAVONOIDS.

S. D. Ray, T. S. Lam, A. Dontabhaktuni, J. A. Rotolo, S. Phadke, R. R. Raje and D. Bagchi. *Molecular Toxicology Program, Division of Pharmacology & Toxicology, Arnold & Marie Schwartz College of Pharmacy and Health Sciences, Brooklyn, NY.*

Acetaminophen and Thioacetamide are well known for their liver-specific apoptogenicity. Similarly, bitter gourd or *M. charantia* extract (MCE), has been vouched nearly a century, for its anti-diabetic, antioxidant and numerous other medicinal properties. However, the influence of MCE on apoptosis-inducing signals *in vivo* remains unknown. This study investigated effects of MCE pre-exposure on AAP- and TAM- induced hepatotoxicity, and events that orchestrate apoptosis(oxidative stress and CAD-dependent genomic DNA fragmentation). Additional focus was to determine the incidence of apoptotic and necrotic deaths and the degree of cytoprotection. Male ICR mice were given orally MCE for 7 and 14 days. On 7th or 14th day, AAP (400 or 500 mg/kg) or TAM (25, 50, 100 mg/kg) was administered ip. All animals were sacrificed 24 hrs after AAP or TAM injections. Blood samples were collected to analyze serum chemistry, and liver tissues for biochemistry and histopathology. Results show that liver injuries induced by both AAP and TAM were significantly counteracted by MCE pre-exposures. In addition, apoptosis controlling events, such as orderly DNA fragmentation and oxidative stress (MDA accumulation and glutathione depletion) culminated by AAP and TAM were also significantly inhibited. Histopathological evaluation of liver sections by brightfield microscopy (X1000) revealed, both AAP and TAM caused dramatic glycogen depletion coupled with massive apoptotic cell death. Interestingly, MCE+AAP exposed tissues discerned near complete reversal of AAP-induced effects, whereas, MCE+TAM-treated sections exhibited significant protection from TAM-induced hepatotoxicosis. These findings suggest that, besides chemopreventive properties, MCE may influence drug and chemically-induced apoptogenic and necrogenic signaling mechanisms in the liver.

580 MOLECULAR MECHANISMS OF ZINC INHIBITION OF ETHANOL-INDUCED LIVER APOPTOSIS.

J. C. Lambert[1], Z. Zhou[2] and Y. J. Kang[2,1]. *[1]Pharmacology and Toxicology, University of Louisville, Louisville, KY and [2]Medicine, University of Louisville, Louisville, KY.*

Apoptosis is critically involved in the hepatic pathogenesis induced by acute alcohol exposure. This study was undertaken to test the hypothesis that zinc interferes with apoptotic signaling pathways in the liver leading to inhibition of ethanol-induced apoptosis. Male 129/Sv^{PC}J mice were injected subcutaneously with $ZnSO_4$ (5 mg/kg) in 12 h intervals for 24 h, prior to intragastric administration of ethanol (5 g/kg) in 12 h intervals for 36 h, which has been shown to represent binge drinking in humans. Ethanol-induced apoptosis in the liver was detected by a terminal deoxynucleotidyl transferase nick-end labeling assay and further confirmed by electron microscopy. The number of apoptotic cells in the zinc-pretreated livers were significantly decreased, being only 15 % of that found in the animals treated with ethanol only. Characteristic apoptotic morphological changes observed by electron microscopy were also inhibited by zinc. Importantly, zinc inhibited ethanol-induced activation of caspase-3, the primary executioner protease responsible for alcohol-induced liver apoptosis, as determined by enzymatic assay and Western blotting analysis. Immunohistochemical analysis revealed that zinc inhibited ethanol-induced endogenous hepatocyte Fas ligand activation, which is a key component in signaling pathways leading to hepatic caspase-3 activation and apoptosis. Further studies showed that zinc suppressed ethanol-induced Fas ligand protein expression, as determined by Western blotting, in the liver. These results thus demonstrate that zinc is a potent inhibitor of ethanol-induced liver apoptosis and that this inhibition occurs primarily through zinc interference with Fas/Fas ligand signaling pathway.

581 DIFFERENTIAL INFLUENCE OF STREPTOZOTOCIN (STZ)-INDUCED HYPERGLYCEMIA ON ACETAMINOPHEN (AAP)-MEDIATED APOPTOTIC CELL DEATH AND EXPRESSION OF CYTOKINES IN THE LIVER.

J. A. Rotolo and S. D. Ray. *Molecular Toxicology Program, Division of Pharmacology & Toxicol., Arnold & Marie Schwartz College of Pharmacy and Health Sciences, Brooklyn, NY.*

The diabetic condition and toxic doses of AAP are known to increase CYP2E1 levels, oxidative stress, and promote apoptotic cell death in the liver in addition to modulating cytokine levels. This study was specifically designed to investigate whether diabetic hyperglycemic state, potentiates or antagonizes AAP-induced: i) hepatotoxicity and genomic DNA fragmentation, ii) oxidative stress, iii) cytokine expression, and iv) apoptotic cell death. Hyperglycemia and liver injury were induced by i.p injections of STZ (100mg/kg/day for 8 days) and AAP (300 and 400 mg/kg for 24 hrs) respectively. Male ICR mice were administered Vehicle, STZ, AAP, or STZ+AAP. Blood was collected to evaluate glucose levels and serum chemistry, and livers for histopathology, analysis of DNA integrity, and cytokine levels. Surprisingly, results indicate that STZ-induced hyperglycemia potentiated liver DNA fragmentation, but antagonized hepatotoxicity and oxidative stress. Serum ALT activities were 3.4 and a 7.8 fold lower in STZ+AAP groups compared to AAP alone controls. Oxidative stress markers, lipid peroxidation and total glutathione contents, mirrored the serum chemistry changes. In contrast, the diabetic condition increased DNA fragmentation (Con: 100%; STZ: 206%) coupled with expressions of TNF-alpha (Con: 100%; STZ: 211%) and INF-gamma (Con: 100%; STZ: 205%). AAP exposure to diabetics did not alter cytokine levels but dramatically enhanced the AAP's potential to cause DNA fragmentation (AAP400: 302%; STZ+AAP400:542% of controls values). It appears that diabetes increases hepatocellular antioxidant status and antagonizes AAP-induced hepatotoxicity and oxidative stress but fails to interfere with DNA fragmentation-related events. Induction of CYP2E1 in diabetics may not be universal, and failure of a cause-and-effect relationship between oxidative stress and apoptotic death in the liver may be due to hyperglycemia or breakdown of signaling pathways.

582 MECHANISTIC TOXICOLOGY OF HYDRAZINIUM NITRATE IN PRIMARY RAT HEPATOCYTES.

S. M. Hussain[1], J. M. Frazier[2] and B. Brown[3]. *[1]Mantech Environmental Technology, Inc.,, Dayton, OH, [2]AFB, Dayton, OH and [3]Geo-Centers, Dayton, OH.*

Hydrazine (N2H4), a simple diamine and powerful reducing agent, has been used by the US Air Force as a fuel in aircraft and propellant in rockets. Hydrazinium nitrate (HZN), a nonvolatile form of hydrazine, is being examined as a potential replacement for hydrazine, a known hepatotoxicant. The current study was undertaken to (1) evaluate the toxicity of HZN in primary rat hepatocytes *in vitro*, and (2) investigate whether HZN toxicity is mediated by oxidative stress and/or apoptosis. The effects of short-term exposure of hepatocytes to HZN were investigated with reference to viability, biomarkers of oxidative stress and apoptosis. Viability data showed an increase in lactate dehydrogenase (LDH) leakage, and a decrease in mitochondrial activity with increasing concentration of HZN. Studies of oxidative stress biomarkers showed a depletion of reduced glutathione (GSH) and an increase in oxidized glutathione (GSSG), increased reactive oxygen species (ROS) generation, lipid peroxidation and reduced catalase activity. However, there were no changes in glutathione peroxidase and glutathione reductase activities. Depletion of GSH and catalase activity in hepatocytes by buthionine sulfoximine (BSO) and amino triazole, respectively, prior to exposure to HZN increased toxicity. It is obvious from the results obtained that HZN induced biochemical markers of oxidative stress. Further, studies of apoptosis revealed no significant change in total caspase activity, marginal increase in annexin V binding and partial evidence of DNA fragmentation in HZN treated cells. There is a decrease in mitochondrial membrane potential in HZN treated hepatocytes. In summary, the data suggest that short-term exposure to HZN is toxic to primary hepatocytes and its toxicity is attributable to oxidative stress.

583 ASSESSMENT OF APO2L/TRAIL HEPATOTOXICITY *IN VITRO*.

K. Achilles, D. Shih and B. Mounho. *Toxicology, Genentech, Inc., South San Francisco, CA.*

Recombinant soluble Apo2L/TRAIL induces apoptosis in a wide range of human cancer cell lines while sparing many types of normal cells and is currently being investigated as a candidate for cancer therapy. A polyhistidine-tagged version of Apo2L/TRAIL (Apo2L/TRAIL.HIS) was recently reported to induce substantial apoptosis in primary human hepatocytes, but not in rodent or monkey hepatocytes. To determine if clinical grade, non-tagged Apo2L/TRAIL exhibited activity similar to Apo2L/TRAIL.HIS, the induction of cell death by these versions was investigated in primary human and monkey hepatocytes using the MTT, Alamar Blue™ and Crystal Violet colorimetric assays. Hepatocytes were treated overnight with media, vehicle, Apo2L/TRAIL, Apo2L/TRAIL.HIS (0.01-10 mg/ml), or FasL (a hepatotoxicant serving as a positive control), followed by incubation with MTT, Alamar Blue™, or Crystal Violet. Using all three assays, Apo2L/TRAIL.HIS and FasL induced a marked decrease in cell survival in human hepatocytes, even at concentrations as low as 0.15 mg/ml, whereas Apo2L/TRAIL induced minimal cytotoxicity, even at concentrations as high as 10 mg/ml. While the sensitivity of the Alamar Blue™ and MTT assays was sufficient to detect decreased cell survival induced by FasL, neither assay was adequate for detecting cell death by

Apo2L/TRAIL or Apo2L/TRAIL.HIS in monkey hepatocytes. Monkey hepatocytes treated with Apo2L/TRAIL.HIS, however, showed substantial apoptotic morphology, while Apo2L/TRAIL induced only marginal morphological changes of apoptosis. Additionally, analysis of cell viability using Crystal Violet produced similar findings, with Apo2L/TRAIL.HIS inducing a moderate decrease in cell survival and Apo2L/TRAIL having little effect. The Alamar Blue™ and MTT assays are based on metabolic activity, and their inability to detect cell death in monkey hepatocytes perhaps explains why monkey hepatocytes were resistant to Apo2L/TRAIL.HIS in a previous study using only the MTT assay. Further nonclinical studies are ongoing to evaluate the safety of Apo2L/TRAIL.

584 THE NMDA ANTAGONIST MK-801 POTENTIATES APOPTOSIS IN THE NEONATAL MOUSE BRAIN, LEADING TO HYPERACTIVITY AND LEARNING DISABILITIES IN ADULT MICE.

A. Fredriksson[1] and P. Eriksson[2]. *[1]Neuroscience, Uppsala University, Uppsala, Sweden and [2]Environmental Toxicology, Uppsala University, Uppsala, Sweden.*

It is known that drugs blocking a subtype of glutamate receptors (NMDA) potentiate the natural programmed cell death (apoptosis) occurring during the synaptogenes which can affect learning and memory processes in animals. In humans, this period cover the last three months of pregnancy and first year after birth, which correspond to the first three to four weeks postnatally in rodents. Massive apoptosis during this sensitive period can induce neuropsychiatric disorders like ADHD (attention deficit hyperactivity disorder) in humans. Also, ethanol exposure during pregnancy can manifest as Fetal Alcohol Syndrome (FAS) with characteristic facial malformations, intellectual handicap and psychiatric disorders. In the present study 10-day-old mice were given the NMDA antagonist (+)-MK-801 0.5 mg/kg s.c. three times with 8 hours interval between the doses. One group of mice were killed 24 hours after the first injection and 10 µm thick brain sections were cut and stained using the Fluoro-Jade method. A second group of mice were testet at an adult age of 3 months for spontaneous- and d-amphetamine induced motor activity performance and learning ability in radial arm maze and Morris swim maze. The Fluoro-Jade staining showed a potentiated extensive hippocampal neurodegeneration, but also to a lesser extent in frontal cortex and cerebellum of MK-801 treated animals. Neonatal MK-801 treated mice showed derangement in spontaneous motor activity (hyperactivity) and spatial learning ability. These effects could be reversed when given a low dose of d-amphetamine. Further research should be addressed to investigate anesthetic drugs used in pediatric surgery and child deliveries (ketamine and laughing gas), in order to make a proper risk assessment, regarding dose/effect relationship and possible drug interactions.

585 PCBs ALTER APOPTOSIS IN PRIMARY CULTURES OF HIPPOCAMPAL BUT NOT CORTICAL NEURONS.

A. S. Howard and P. J. Lein. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Perinatal exposure to PCBs has been linked to cognitive dysfunction, however, the mechanism(s) underlying this effect are not known. During normal brain development, apoptosis occurs in a region and time specific manner and alteration of normal patterns of apoptosis are associated with deficits in neural function. Therefore, we investigated the possibility that PCBs alter apoptosis in neuronal cell types critical to cognitive function. Primary cultures of cortical and hippocampal neurons were treated for 48 hr beginning on day 5 *in vitro* with varying concentrations of Aroclor 1254 (0.1 – 10 uM), and apoptosis was assessed using the Hoechst stain. Aroclor 1254 (10 uM) significantly increased the percentage of apoptotic cells in hippocampal but not cortical cultures, suggesting that hippocampal neurons are more vulnerable to PCB induced apoptosis. To examine the role of the arylhydrocarbon receptor (AhR) in PCB induced apoptosis, we compared effects in hippocampal and cortical cultures treated with varying concentrations (0.01 to 1 uM) of either PCB 47 or 77, which bind the AhR with low and high affinity, respectively. PCB 47 (1 uM), but not PCB 77, increased apoptosis in hippocampal neurons; neither congener altered apoptosis in cortical cultures. These data suggest that the AhR does not mediate the effects of PCBs on apoptosis. Further studies indicated that the pan caspase inhibitor z-VAD-FMK (60 uM) inhibited increased apoptosis in hippocampal cultures exposed to Aroclor 1254 and PCB 47. However, fluorometric analysis of caspase-3 enzymatic activity indicates that caspase-3 is not activated in hippocampal neurons following PCB exposure, suggesting that caspases or proteases other than caspase-3 mediate PCB induced apoptosis. In summary, our data suggest that alterations in regional profiles of apoptosis subsequent to PCB exposure may be an important mechanism underlying PCB effects on cognitive development.

586 MITOCHONDRIAL EVENTS IN 6-HYDROXY-DOPAMINE-INDUCED APOPTOSIS: IMPLICATIONS FOR PARKINSON'S DISEASE.

L. Li and A. L. Nieminen. *Anatomy, Case Western Reserve University, Cleveland, OH.*

Parkinson's disease (PD) is a neurodegenerative disorder characterized by a loss of dopaminergic neurons in the substantia nigra pars compacta. 6-Hydroxy-dopamine (6-OHDA) is a neurotoxicant that mimics nigral degeneration *in vitro* and *in vivo*. The purpose of this study was to characterize mitochondrial changes occurring during 6-OHDA toxicity. Human neuroblastoma SH SY5Y cells were exposed to 6-OHDA (0-100 µM) which caused time and dose-dependent apoptotic death. After 2, 4, and 7 h exposure to 100 µM 6-OHDA, apoptosis was 3 ± 0.9%, 15 ± 4.0%, and 30 ± 2.5%, respectively, as assessed by Annexin-V staining. Loss of viability of untreated cells was 0.5 ± 0.2% after 7 h. Annexin-V staining paralleled caspase-3 activation, measured by cleavage of the fluorogenic caspase-3 substrate Ac-DEVD-AFC. To investigate the temporal relationship between changes of mitochondrial membrane potential and cytochrome *c* release, SH SY5Y cells were transiently transfected with cDNA cytochrome *c*-GFP and loaded with membrane potential-indicating fluorophore, tetramethylrhodamine methylester (TMRM, 250 nM). Confocal microscopy revealed a 30 ± 6.5% and 97 ± 1.7% decrease in TMRM fluorescence 2 and 4 h after 6-OHDA compared to untreated cells. The pattern of cytochrome *c*-GFP fluorescence was not changed after 2 h exposure to 6-OHDA, but after 4 and 6 h, the percentage of diffuse cells (cytochrome *c* redistribution from mitochondria to the cytosol) was 10% and 48%, respectively. Similar results were obtained by immunocytochemical analysis of native cytochrome *c*. These results indicate that mitochondrial depolarization is an early event in 6-OHDA-induced apoptotic death in SH SY5Y cells. Furthermore, release of proapoptotic cytochrome *c* release is likely the consequence, not the cause, of mitochondrial depolarization. Thus, manipulations to prevent mitochondrial dysfunction may protect against 6-OHDA-induced death in dopaminergic neuroblastoma cells. Supported by NS39469.

587 DIFFERENTIAL ROLE OF CELLULAR FACTORS IN THE MEDIATION OF CYANIDE INDUCED NECROTIC OR APOPTOTIC DEATH.

K. Prabhakaran, L. Li, J. L. Borowitz and G. E. Isom. *MCMP, Purdue University, West Lafayette, IN.* Sponsor: L. Li.

Cyanide, a well known neurotoxicant, damages neurons by several mechanisms including peroxide formation, elevation of intracellular calcium and blockade of oxidative metabolism. Cyanide at the concentration range of 100-400µM induced apoptotic cell death in primary cultured cortical neurons characterized by positive TUNEL staining. After the same dose of cyanide, mesencephalic (MC) cell cultures underwent necrosis as confirmed by propidium iodide staining. It was observed that generation of intracellular oxidant species and alterations in mitochondrial functions initiate both modes of cell death. A number of intracellular factors such as caspases, Bcl-2 family members and mitochondrial pro-apoptotic factors play a role in regulation of cellular responses to the toxic insult. Initial studies show that cyanide (100-400µM) in cortical cells resulted in a significant increase in caspase activity and increased cytosolic cytochrome c. No significant changes were observed in nitric oxide synthase (NOS) or superoxide dismutase (SOD) activity. Prior treatment of cells with Z-VAD (non specific caspase inhibitor) inhibited the cyanide-induced increase in caspase activity as well as the apoptosis, suggesting that caspase mediates the cell death in cortical cells. On the other hand MC cells responded with an increased NOS activity and a significant reduction in SOD activity. Pretreatment with L-NAME (NOS inhibitor) greatly reduced cyanide-induced cell death. Thus nitric oxide appears to play a significant role in cyanide-induced oxidative stress in MC cells, but not in cortical cells. Furthermore the anti-cell death factor Bcl-2 was over expressed in MC cells after cyanide treatment suggesting a role for this protein in cyanide induced necrosis. Increased levels of nitric oxide and excess Bcl-2 may favor cyanide-induced necrosis in MC cells whereas cortical cell apoptosis caused by cyanide may involve a mitochondrial pathway. (Supported by NIH grant 04140).

588 CYANIDE-INDUCED REACTIVE OXYGEN SPECIES GENERATION AND ELEVATED CYTOSOLIC CALCIUM UP-REGULATE CYCLOOXYGENASE-2 EXPRESSION IN CORTICAL CELLS.

L. Li, K. Prabhakaran, J. L. Borowitz and G. E. Isom. *MCMP, Purdue University, West Lafayette, IN.*

The role of cyanide-induced reactive oxygen species (ROS) generation in cyclooxygense-2 (COX-2) expression is unclear. COX-2 is an inducible enzyme involved in arachidonic acid metabolism, which generates ROS as side products. It has been shown that ROS up-regulates COX-2 expression. In the present study, the role of

ROS generation in cyanide-induced up-regulation of COX-2 and apoptosis was determined. After treatment with cyanide (50-300μM) there was a prompt increase of intracellular ROS generation. Inducible COX-2 expression followed ROS generation, showing that ROS regulate COX-2 expression. Pretreatment of cells with antioxidants (PBN, SOD or CAT) inhibited cyanide-induced COX-2 expression as shown by western blotting and RT-PCR. Direct stimulation of cells with H_2O_2(100-200μM) for 4h induced a dose-dependent increase of COX-2 and apoptosis (24h) similar to cyanide. Cyclosporine A, a specific blocker of mitochondrial membrane potential and permeability transition, blocked cyanide-induced ROS generation and COX-2 expression. When cyclosporine A was added at 30 min after cyanide incubation, the effect on COX-2 expression and apoptosis was abolished. Measurement of PGE_2, a metabolite of COX-2, showed that pretreatment with antioxidants (PBN, SOD or CAT) reduced cyanide-induced COX-2 activity. When added at 30 min after cyanide, antioxidants still inhibited neuronal apoptosis, indicating that ROS generation from COX-2 metabolism plays a key role in the apoptosis. The results from western blot and RT-PCR showed that Ca^{2+} is a mediator in cyanide-induced COX-2 up-regulation. Cyanide did not increase COX-2 expression when cells were incubated with cyanide in the Ca-free medium. BAPTA, a membrane permeable chelator of Ca, blocked cyanide-induced COX-2 expression and apoptosis. These results show that cyanide increases intracellular ROS and free-Ca^{2+} to mediate up-regulation of COX-2 and the sequent ROS evolving from COX-2 metabolism play a role in cyanide-induced apoptosis. (Supported by NIH grant ES 04140)

589 THE ROLE OF CASPASE III INHIBITION IN METHAMPHETAMINE-INDUCED ALTERATIONS IN P53 AND *BCL-2* EXPRESSION: CORRELATION WITH DOPAMINERGIC NEUROTOXICITY.

S. F. Ali, M. Oetinger, J. T. Skinner, W. Skikker Jr. and S. Z. Imam.
Neurotoxicology, NCTR, Jefferson, AR.

Methamphetamine (METH) is a widely used drug of abuse. It causes long-lasting reductions in dopamine (DA) content, tyrosine hydroxylase activity and dopamine transporters in the striatum. It also produces oxidative stress by generating reactive oxygen and nitrogen species. METH has been reported to upregulate p53 and downregulate *bcl-2* expression in striatum of mice after repeated doses. Caspase-3 is a downstream effector involved in the dissolution of the nucleus. Activation of Caspase-3 follows the onset of apoptosis. In the present study, we studied the role of caspase inhibition on METH-induced alterations in the expression of striatal p53 and *bcl-2* in mice. Adult male C57 mice (n=8/group) were treated with 4x10 mg/kg of METH at 2 h intervals. Another groups of mice also received a specific Caspase-3 inhibitor (CIII, 0.5 mg/kg) or a general caspase inhibitor (GC, 0.5 mg/kg) along with METH or alone. Saline treated animals served as control. Animals were sacrificed 72 h after the last dose of METH. METH administration resulted in significant up-regulation of p53 and down-regulation of *bcl-2* in mice striatum. GC failed to protect against this genetic alteration caused by METH but CIII significantly protected against METH-induced genetic changes in the mice striatum. METH also resulted in the significant depletion of DA and its metabolites DOPAC and HVA. CIII provided a significant attenuation whereas GC failed to provide any protection against dopaminergic neurotoxicity. Therefore, the present data demonstrated that METH-induced dopaminergic neurotoxicity caused genetic alterations, which can lead to the onset of programmed cell death, however, it can be protected by specifically targeting the downstream effector action of Caspase-3.

590 ROLE OF MITOCHONDRIAL BCL-2 PROTEIN AND DOPAMINE IN ENVIRONMENTAL CHEMICALS-INDUCED DOPAMINERGIC CELL DEATH.

M. Kitazawa, V. Anantharam, S. Kaul and A. G. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

Several epidemiological studies have implicated chronic exposure to certain pesticides and metals in the etiology of Parkinson's disease. Manganese and dieldrin are two prominent environmental toxicants that have been associated with Parkinson's disease. We previously demonstrated that dieldrin and methylcyclopentadienyl manganese tricarbonyl (MMT) share similar cell death signaling process and induce apoptosis in dopaminergic cells. In the present study, we have further characterized biochemical mechanisms underlying dieldrin- or MMT-induced selective dopaminergic toxicity. When exposed acutely, both dieldrin and MMT show relatively selective cytotoxicity to dopaminergic PC12 cells with EC_{50} at 142μM and 200μM, respectively. EC_{50} of dieldrin in HCN-2 cells (human cortical neuronal cells) and α-TC (pancreatic B cells) is 292μM and 351μM, respectively, and EC_{50} of MMT in striatal GABAergic cells is 577μM. The dieldrin- or MMT-induced generation of reactive oxygen species (ROS) and apoptotic cell death are significantly attenuated by pre-treatment with α-methyl-*p*-tyrosine or deprenyl, indicating that the presence of dopamine may, in part, contribute to susceptibility of dopaminergic cells to these environmental neurotoxicants. Furthermore, using Bcl-2 transfected PC12 cells, we have demonstrated that these chemicals may target mitochondria and initiate apoptotic cell death signaling cascades. Reduction of mitochondrial membrane potential, caspase-3 activation and DNA fragmentation are significantly ($p<0.01$) attenuated in Bcl-2 overexpressed PC12 cells following acute exposure to dieldrin (10-100μM) or MMT (10-200μM). Together, our results suggest that excessive dopamine release and mitochondrial dysfunction may serve as intrinsic susceptibility factors in environmental factor-induced dopaminergic degeneration. Supported by NIH grant ES10586

591 ACTIVATION OF CASPASE-3 BY DIETHYLDITHIOCARBAMATE (DDC) IN RAT HIPPOCAMPAL ASTROCYTES WITH OR WITHOUT GLUTATHIONE.

J. A. Mlockier-Audrain and L. D. Trombetta. *Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Diethyldithiocarbamate (DDC), is a carbamate derivative and potent metal chelator. It has been shown to bind and redistribute copper in a lipophilic complex to many organs including the central nervous system. We have previously demonstrated by TUNEL and DNA laddering techniques that 35μg/ml and 350μg/ml DDC induced apoptosis or programmed cell death in rat hippocampal astrocytes treated for 1hr. Caspases, also known as interleukin-1-β-converting enzyme (ICE), are cysteine proteases that have been implicated in apoptosis. The activation of the caspase cascade requires the activation of initiator caspases by a toxic insult which in turn activates effector caspases. Caspase-3 cleaves a set of vital proteins and executes the cascade of events leading to the apoptotic degradation phase. Glutathione plays a major role in the antioxidant defense system. It has been documented to participate in the detoxification of xenobiotics. It has also been documented in the literature that glutathione maintains cytoskeletal integrity by stabilizing intracellular sulfhydryl status. Previous experiments have shown that glutathione (10mM) post-treatment protects against DDC insult. The purpose of this experiment was to determine whether caspase-3 may be induced following 1hr treatment with DDC and whether glutathione prevents caspase-3 activation. Rat hippocampal astrocytes grown in Dulbecco's modified Eagle's essential media were treated with 35 and 350 μg/ml DDC at subconfluency for 1 hr. Astrocytes were then left to recover with or without 10mM glutathione in DMEM for 48 h at which time caspase-3 activity was assayed. Preliminary studies suggest that caspase-3 is activated in astrocytes treated with 35 and 350 μg/ml DDC. Glutathione post-treatment prevents the activation of caspase-3 in both treated groups.

592 CASPASE-3 MEDIATED PROTEOLYTIC CLEAVAGE OF PKCδ PLAYS A CRITICAL ROLE IN METHYLCYCLOPENTADIENYL MANGANESE TRICARBONYL (MMT)-INDUCED APOPTOTIC CELL DEATH IN MESENCEPHALIC CLONAL CELLS.

V. Anantharam, M. Kitazawa, S. Kaul, S. Ranade, M. L. Kirby and A. G. Kanthasamy. *Biomedical Sciences, Iowa State University, Ames, IA.*

The cellular mechanisms underlying selective dopaminergic degeneration in PD remains elusive. Oxidative stress has been suggested to contribute the pathogenesis of PD. Additionally, environmental exposure to certain pesticides and transition metals such as manganese have a positive association with increased incidences of PD. We characterized oxidative stress dependent cellular events by exposing an immortalized rat mesencephalic dopaminergic cell line ($1RB_3AN_{27}$) to an organic form of manganese compound, methylcyclopentadienyl manganese tricarbonyl (MMT). Expsoure of MMT (30-100 μM) resulted in a rapid increase in generation of reactive oxygen species (ROS) within 5-15 min and was followed by release of mitochondrial cytochrome C into cytoplasm. Cytochrome C then activated a proapoptotic cysteine protease, caspase-3 (6-fold) in a time- and dose-dependent manner. Interestingly, we also found that MMT exposure induces a time- and dose-dependent proteolytic cleavage of native protein kinase Cδ(PKCδ, 72-74 kDa) to yield 41-kDa catalytically active and 38-kDa regulatory fragments. Pretreatment with caspase inhibitors (Z-DEVD-FMK or Z-VAD-FMK) blocked MMT-induced proteolytic cleavage of PKCδ, indicating that cleavage is mediated by caspase-3. Attenuation of ROS generation, caspase-3 activation and PKCδ activity prior to MMT treatment almost completely suppressed DNA fragmentation. Additionally, overexpression of catalytically inactive $PKC\delta^{K376R}$ (dominant negative mutant)prevented MMT-induced apoptosis in immortalized mesencephalic dopaminergic cells. Preliminary data in *ex vivo* rat brain slices exposed to MMT indicated proteolytic cleavage of PKCδ within 3 hr of treatment. For the first time, these data demonstrate that caspase-3 dependent proteolytic activation of PKCδplays a key role in oxidative stress-mediated apoptosis in dopaminergic cells following exposure to an environmental neurotoxic agent.

593 METHYLMERCURY INTERACTS WITH MUSCARINIC RECEPTORS DURING NEURONAL DEATH IN RAT CEREBELLAR GRANULE CELLS.

S. A. Loiselle, T. L. Limke and W. D. Atchison. *Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

Cerebellar granule cells are highly susceptible to MeHg-induced neuronal death both *in vivo* and *in vitro*. One hallmark of this neuronal death is severe Ca^{2+} deregulation, which contributes to delayed neuronal death in primary cultures of rat cerebellar granule neurons. Within granule cells, the SER represents a high affinity, low capacity Ca^{2+} store which may contribute to MeHg-induced Ca^{2+} elevations by release of Ca^{2+} though inositol-1, 4, 5-phosphate (IP_3) receptors. Because this Ca^{2+} can be released through activation of M3 muscarinic acetylcholine receptors, we examined whether inhibition of these receptors is cytoprotective during MeHg exposure. We used neonatal rat cerebellar granule neurons in primary culture to measure cell viability using a calcein-ethidium homodimer live/dead cytotoxicity assay. Previous results indicated that down-regulation of muscarinic and IP_3 receptors with 24 hr bethanechol (1 mM) was neuroprotective (Martinez *et al., The Toxicologist* 60:184, 2001), suggesting a role for muscarinic and/or IP_3 receptors in MeHg-induced cell death. In our experiments, the protection afforded by bethanechol was not affected by the nicotinic receptor antagonist dihydro-β-erythroidine, indicating that protection was through the muscarinic receptors. However, application of atropine alone (10 μM) did not attenuate cell death caused by 0.2-1.0 μM MeHg. Inhibition of Ca^{2+} release through the IP_3 receptor with 1 μM xestospongin C was also not protective. Interestingly, 24 hr application of 1 μM xestospongin C or acute application of the phospholipase inhibitor U73122 (1 μM) alone caused significant cell death, highlighting the importance of SER Ca^{2+} signaling pathways in maintenance of cell viability. These results suggest that the protection afforded by 24 hr BCh treatment occurs through muscarinic receptors, and that disruption of this pathway is neurotoxic in cerebellar granule neurons. Supported by NIEHS grants R01 ES03299 and T32 ES07255.

594 THE 2-NITROIMIDAZOLE RADIOSENSITIZER CI-1010 INDUCES SELECTIVE APOPTOSIS IN THE PHOTORECEPTORS OF C57BL/6 MICE.

T. J. Miller[1], L. A. Dethloff[2] and M. A. Philbert[1]. *[1]Environmental Health Sciences, University of Michigan, Ann Arbor, MI and [2]Pfizer Global Research and Development, Ann Arbor, MI.*

CI-1010, a bifunctional nitroimidazole, produces selective apoptosis in photoreceptors *in vivo*. CI-1010 triggers opening of the mitochondrial permeability transition (MPT) pore in SY5Y neuroblastoma cells following oxidation of the intracellular space. This study investigates *in vivo* mechanisms of CI-1010-induced retinal toxicity. Adult C57BL6 mice treated with a single intraperitoneal injection (1000 umol/kg) were necropsied at 4, 12, 24, 48, 72, and 96h following treatment. Morphological evaluation by light microscopy reveals retinal degeneration by 96h localized to the photoreceptor (PRL) and outer nuclear layer (ONL) of the retina. By 12h, the PRL appears vacuolated, compressed, and poorly organized. The pattern of retinal degeneration is time-dependent and characterized by thinning of both retinal layers due to loss of photoreceptor segments and nuclei, culminating in the collapse of the PRL. Apoptotic bodies are visible in the ONL by 72h and many nuclei label with (TdT) mediated 3'-OH fluorescein end-labeling. Western blot analysis of retinal homogenates from treated mice show decreased expression of the anti-apoptotic protein, Bcl-xL, at 4h, remaining less than control at all timepoints. Bcl-xL is responsible for stabilization of the MPT pore in the closed position. Reduced Bcl-xL expression may destabilize the MPT pore in the PRL. Analysis of caspase 9 and 8 activation suggests involvement of both the mitochondrial and non-mitochondrial pathways by 24 h. Caspase 3 is active at 72h. The precise role of mitochondria and caspase activation in CI-1010-induced neuronal cell death is unknown. However, these results suggest that retinal apoptosis induced by CI-1010 is mediated by caspase-3 activation subsequent to the execution of a mitochondrial pathway of cell death.

595 BCL-XL INHIBITS LEAD-INDUCED ROD PHOTORECEPTOR APOPTOSIS BY BLOCKING THE INCREASE IN MITOCHONDRIAL CONTACT SITES.

D. A. Fox[1], G. A. Perkins[2], L. He[3], A. T. Poblenz[4], M. H. Ellisman[2] and J. B. Harris[1]. *[1]U. Houston, Houston, TX, [2]UCSD, San Diego, CA, [3]UNC, Chapel Hill, NC and [4]UT MD Anderson, Houston, TX.*

Photoreceptor apoptosis and visual deficits occur in man and animals with inherited and chemical-induced retinal degenerations, and retinal diseases and injuries. Rod-selective apoptosis is produced by developmental lead exposure in mice and by *in vitro* lead and/or calcium: the latter activates the cytochrome c-caspase cascade of apoptosis (JBC, 2000; SOT, 2001). This study used wild-type and transgenic mice overexpressing Bcl-xL in photoreceptors to examine the role of mitochondria in lead-induced rod apoptosis. Newborn mice were raised by dams drinking water (controls) or 0.15% lead acetate solution. At weaning (BPb = 26 μg%) studies of rod mitochondria were conducted in all four groups using three-dimensional electron microscopic tomography, JC-1 staining, immunoblots for cytochrome (cyt) c, caspase assays and oxygen consumption. There were no differences between the four treatment groups for 5 of 7 different measurements of rod mitochondrial substructures (crista widths, crista junction diameters, outer (OMM)-inner membrane widths, contact site widths, contact site diameters) and no physical disruptions of the OMM or swollen mitochondrial matrices. Lead-induced rod apoptosis was accompanied by calcium overload, increases in mitochondrial contact site area and density, decreases in rod mitochondrial respiration and membrane potential (depolarization), cyt c release and caspase activation. Bcl-xL overexpression completely blocked the lead-induced increase in contact sites and all apoptotic events, except calcium overload, and maintained normal rod respiration. These results suggest that Bcl-xL is located and functions at mitochondrial contact sites to block the opening of the permeability transition pore. These findings have relevance for therapies in human and animal retinal and neuronal degenerations where lead exposure, calcium overload and/or mitochondrial dysfunction occur. Supported by NIH Grants ES03183, EY07088, RR04050, NS14718, KD54441.

596 MERCURIC CHLORIDE-INDUCED PROGRAMMED CELL DEATH IN MOUSE LEYDIG CELL LINE (LFG6).

K. A. Ali, A. Atkinson, J. Johnson and Q. Cobb-Sinne. *Biomedical Sciences, College of Veterinary Medicine, Nursing and Allied Health, Tuskegee University, Tuskegee, AL.* Sponsor: R. Dalvi.

There is strong evidence that exposure to heavy metals, in general, and mercurial compounds in particular, impair the function of the male reproductive system. A multigenerational study, recently, completed our laboratory, demonstrated that mercuric chloride causes a reduction of fertility indices, reproductive indices and testosterone level. Recent studies have demonstrated that germ cell apoptosis increases after testosterone withdrawal from the testes. The present study was undertaken to determine whether testosterone reduction associated with exposure to mercuric chloride occurred due to Leydig cells death by the apoptosis. Mouse Leydig cell line (LFG6) was exposed in Dulbecco's modified Eagle's medium (DMEM) to mercuric chloride concentrations 0.0, 3.75, 7.5, 15 or 30 μM. Viability of Leydig cell was tested using trypan-blue exclusion assay after 1, 6, 12 and 24 hours of mercuric chloride exposure. Cells in control, 2.75 and 7.5 μM groups had a viability of approximately 96%, regardless of exposure time. In contrast, the viability of the cells in15 and 30 μM treatments gradually declined to approximately 85% and 60 respectively, after 24 hours of exposure. Agarose gel electrophoresis and ligation-mediated polymerase chain reaction (LM-PCR) were used to assess the presence of apoptosis. The nucleosomal DNA fragmentation was quantitated visually and by using Fluor-S Multilmager. The intensity of DNA ladder in exposed cells increased significantly in a concentration- and- time dependent manner when compared to that of the controls. These results suggested that mercuric chloride caused a significant apoptosis in a Leydig cell line and the mechanism of mercuric chloride -induced testosterone level reduction *in vivo* may be related to the induction of apoptosis.

597 EVIDENCE OF MITOCHONDRIA-ASSOCIATED SIGNALING IN TESTICULAR GERM CELL APOPTOSIS IN ADULT C57BL/6(B6) MICE AND SPRAGUE-DAWLEY RATS EXPOSED TO MONO-(2-ETHYLHEXYL) PHTHALATE (MEHP).

C. J. Giammona, P. Sawhney and J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

The Fas signaling pathway has been previously characterized as a key mediator of germ cell apoptosis, particularly after toxicant-induced Sertoli cell injury. Recent reports have indicated that cell-damaging agents can stimulate apoptosis through a "stress-induced" mitochondria-regulated signaling pathway. In stress-induced apoptosis, the release of cytochrome C (initiated by the pro-apoptotic proteins Bak and Bax) appears to be a critical event. Cytochrome C release results in the activation of caspase-9 and eventual cell death. Interestingly, caspase-8 activation has been shown to increase the release of cytochrome C by truncating Bid to tBid, which can then oligomerize with Bax or Bak causing the release of cytochrome C. We propose that the mitochondria-associated signaling system is important in the initiation of apoptosis after MEHP-induced germ cell injury and may act in conjunction with the Fas signaling system. Adult C57 mice and adult Sprague-Dawley rats were exposed to an acute dose of MEHP (1 g/kg p.o.). Western blot analyses demonstrated early increases (by 3 h post-MEHP exposure) in cytosolic cytochrome C and subsequent increases in active caspase-9 and caspase-3 in mice. Immunohistochemisty (IHC) on both frozen tissue sections and fresh testis touch

preparations revealed germ cell-specific protein expression and/or localization of Bax and caspases in rat testes. These immediate changes of stress-related signaling proteins occurred simultaneously with earlier observed increases in death receptors (e.g., Fas, death receptor 4, etc.) and caspase-8, suggesting a link or possibly cooperation between death receptor- and mitochondria-regulated apoptosis signaling pathways. (Supported by R01ES09145, Training Grant ES07247, NIEHS Center Grant 07784).

598 PULSATILLA NIGRICANS (HOMEOPATHIC DRUG) TREATMENT INCREASED APOPTOSIS AND ATRESIA IN RAT OVARIAN FOLLICLES ALONG WITH DECREASED DNA LEVELS.

Z. Nikhat, M. N. Rao, S. L. Rao and R. Tiwari. *Reproductive Physiology, Bhavan's New Science College, Hyderabad, India.* Sponsor: S. Hussain.

Pulsatilla nigricans is an age-old homeopathic drug prescribed for various reproductive ailments especially in women. The drug contains an alkaloid annemonin, annemonic acid and potassium sulphate. The mode of action of the drug and the effect of different doses (Potencies) is not well understood. Hence the present study was under taken to evaluate the effect of Pulsatilla nigricans on paracrine mechanisms involving follicular atresia along with quantification of DNA. Female albino rats of wistar strain were administered with different potencies of the drug orally on alternate days for a period of four weeks. The biochemical study revealed that 200c potency has shown a significant decline in the DNA content of the ovary. This was indicative of low rate of protein synthesis and steroidogenesis especially in the ovary. Likewise histological studies also revealed consistent follicular atresia with prolonged diestrous and metaestrous phases when treated with 200c potency. The drug with 200c potency had shown a maximum decline in the DNA levels possibly because of increased DNA fragmentation when compared with the other potencies. The same potency showed maximum follicular atresia and significant number of apoptotic cells ($P < 0.005$). Ovarian cycle in general involves a complex networking of tissue growth and differentiation of programmed cell death / atresia. In conclusion, our findings suggested that 200c potency of Pulsatilla is a strong antifertility compound, which can be used as a safe and cheaper contraceptive in the developing countries.

598A DAMAGE OF DNA IN CULTURED SKIN CELLS BY LOW DOSES OF AS(III).

L. I. Bernstam, Y. Chong and J. Nriagu. *Environmental Health Sciences, University of Micigan, Ann Arbor, MI.*

We have previously established the higher toxicity of As(III) than that of As(V) for nucleated cells including skin cells on integrity of the cell membrane, the rate of DNA, RNA and protein synthesis in primary human skin cultures. In this study we demonstrated that: a) exposure of human keratinocytes (HK) cultures to As(III) produces a dose-dependent decrease in protein concentration and shows a significant decrease at 500µg/L (over 30% of control) and 1000 µg/L (over 45% of control) within 48 hrs of exposure; b) transition of apoptotic changes to necrotic damage in artificial skin topically exposed to As(III) as determined by *in situ* DNA fragmentation analysis at the single cell level using the TdT-mediated biotin dUTP nick end-labelling (TUNEL assay); c) low doses (5-100µg/L) of As(III) cause single strand DNA breaks and alkali labile dose and time dependent damage in HK and fibroblasts (HF)). Exposure of HF to 5µg/L As(III) for 30 min results in an increase of 165% in the comet moment. At 10µg/L this increase is 195% rising to 282% at 100µg/L and 728% at 500µg/L. We used Telomerase PCR ELISA to quantitate telomerase activity in cell extracts from submerged cultures of HF, exposed to As(III). Our experiments reveal that increasing of the exposure dose to100 and 1000µg/L of As(III) from 15 min to 30 min elevated telomerase activity in both cases. The enhancement is greater at the higher (1000µg/L) As(III) concentration (>3 times) and less pronounced at the lower (100µg/L) exposure (~1.6 times) thereby reflecting the significantly greater chromosome damage produced by the higher As(III) doses. The involvement of telomerase in the regulation of cell growth and viability *via* the protection against DNA damage makes it an appropriate target for analysis of the extent of molecular damage at the genomic level produced by As exposure.

599 INDUCTION OF CYP ISOFORMS BY PESTICIDES AND DEET AS MONITORED BY THE BDNA ASSAY.

R. L. Rose[1], N. J. Cherrinton[2], J. Tang[1], Y. Cao[1], D. P. Hartley[2], C. D. Klaassen[2] and E. Hodgson[1]. [1]*Toxicology, North Carolina State University, Raleigh, NC and* [2]*Medical Center, University of Kansas, Kansas City, KS.*

Drug-drug interactions often occur when important drug metabolizing enzyme levels are altered as a result of exposure to another drug. As a consequence of this phenomenon, drugs are routinely screened for their ability to induce cytochrome P450 enzymes, one of the more important drug metabolizing enzyme families. Pesticides are also known to induce cytochrome P450 enzymes in humans. Studies of gulf war veterans suggest that pesticide-pesticide or pesticide-drug interactions may have had negative impacts on veterans. Our previous rodent studies confirm that pesticides and insect repellants such as DEET can induce enzymes important in pesticide activation and/or detoxication reactions. To determine possible pesticide interactions in humans, cultured human hepatocytes were exposed to gulf war pesticides and repellant and CYP450 mRNA levels quantified using the branched DNA signal amplification assay. Preliminary results indicate that several CYP isoforms are altered by permethrin, chlorpyrifos, and DEET. The insecticide permethrin significantly induced the CYP isoforms 2A6 and 2B6. Chlorpyrifos was surprisingly efficient in its induction of CYP1A1, 1A2, and 3A4, but also repressed 2E1. The insecticide repellant DEET induced CYP3A4, 2B6, and 2A6. Since our previous studies using human lymphoblast cell lines demonstrated the importance of human CYP2B6 in the activation of chlorpyrifos to chlorpyrifos-oxon, this work suggests that pesticides and repellants such as DEET have the potential to increase and/or decrease pesticide susceptibility.

600 FORMATION OF UBIQUITIN-CYTOCHROME P450 3A CONJUGATES IN ISOLATED MICROSOMES.

R. C. Zangar[1], A. L. Kimzey[1], J. R. Okita[2], D. S. Wunschel[1], R. J. Edwards[3], H. S. Kim[4] and R. T. Okita[2]. [1]*Pacific Northwest Nat'l Lab, Richland, WA,* [2]*Wash State Univ, Pullman, WA,* [3]*Imperial College, London, United Kingdom and* [4]*Detroit R&D, Detroit, MI.*

A novel microsome system is described that conjugates CYP3A and ubiquitin to form high molecular weight (HMW) complexes. The induction of this process in isolated microsomes appeared to be dependent upon extended *in vivo* treatment with potent CYP3A inducers. Treatment of the microsomes to remove potential contamination of cytosolic proteins did not prevent the formation of the HMW CYP3A conjugates. Immunoprecipitation of HMW CYP3A and Western blot analysis indicated that this protein was complexed with ubiquitin. Even so, the conjugation reaction did not require addition of ubiquitin, ATP, Mg++ or cytosol and, as such, was unlikely to be dependent upon the ubiquitin activating enzyme E1. Furthermore, mass spectrometric analysis of tryptic peptides strongly suggested that the HMW CYP3A was in molar excess to ubiquitin. This result suggested that the HMW CYP3A may be conjugated to itself or a diffuse pool of already ubiquitinated proteins present in the sample. CYP3A substrate blocked formation of the HMW CYP3A in the incubated microsomes. These results suggest that extended induction of CYP3A expression results in the activation of microsomal factors that catalyzed the formation of HMW CYP3A conjugates. This conjugation reaction may be related to the substrate-dependent stabilization of CYP3A observed *in vivo* but appears to be distinct from the classical ubiquitination pathway.

601 SAFETY EVALUATION OF CHRONIC DIETARY EXPOSURE TO 3, 3-DIINDOLYLMETHANE (DIM) IN SPRAGUE-DAWLEY RATS.

D. A. Leibelt[1], O. R. Hedstrom[2] and D. E. Williams[1]. [1]*Environm. & Mol. Toxicology, Oregon State University, Corvallis, OR and* [2]*College of Vet. Med., Oregon State University, Corvallis, OR.*

Indole-3-carbinol (I3C), a naturally occurring component of the human diet, is found in significant concentrations in cruciferous vegetables. In an acidic environment, such as the stomach, I3C forms condensation products, one of the most abundant of these being DIM. DIM is marketed as a dietary supplement but little is known about the safety of long-term exposure. Male and female Sprague-Dawley rats were fed either control diet, diet containing the proposed human dose of Bioresponses' DIM equaling 6.45 mg/kg/day, or diet containing ten times the proposed human dose equaling 64.5 mg/kg/day. The experiment was terminated after 3 or 12 months of exposure. Small animal chemistry panels were performed along with histopathological examination of the liver, kidneys, adrenals, and colon of all animals, the testicles, prostate, and epididymus for the males, and the uterus and overies for the females. The total cytochrome P450 (CYP) content of the liver was determined along with the levels of the specific isoforms CYP1A1 in liver and colon and CYP3A2 in the liver. No significant differences between groups were found in blood chemistry. Most notably no increases were seen in markers for liver or other tissue damage. Tissue examination yielded no observable differences grossly or histologically between groups, although a high number of hyaline casts were found throughout the kidney tissue of all animals. Total hepatic CYP levels were induced (28%) only in males. Slight induction of CYP1A1 and CYP3A2 was seen in liver and CYP1A1 in colon for both sexes. Comparison to I3C indicates that DIM is a markedly less potent inducer of CYP1A1 in the rat. Supported by the OSU Ag. Res. Fdn.

602 EVALUATION OF ALBENDAZOLE SULFOXIDE AS A PROBE FOR CYP1A1 ACTIVITY.

J. Asteinza Castro, D. M. Escobar García and J. J. Espinosa Aguirre. *Genetics and Toxicology, Universidad Nacional Autónoma de México, Mexico City, Mexico.* Sponsor: M. Gonsebatt.

Albendazole Sulfoxide (ABZSX) is the active metabolite of the anthelmintic drug Albendazole (ABZ). Previous reports on ABZ pharmacokinetics in rats (pretreated with different cytochrome P450 (CYP) inducers) suggest that ABZSX is metabolized to Albendazole Sulfone (ABZSN) by cytochrome P450 1A1 (CYP1A1). In order to test this compound (ABZSX) as a probe to evaluate CYP1A1 activity *in vivo*, three experimental groups were used: a) Control group; b) Induced group; and c) Inhibited group. All experimental groups were treated p.o. with a single dose of Albendazole Sulfoxide (20 mg/kg, suspended in corn oil). Groups b) and c) were previously treated with a CYP1A1 inducer (β-naphtoflavone) and a CYP1A1 inhibitor (α-naphtoflavone), respectively. After treatment with ABZSX, plasma levels of ABZSX and ABZSN were evaluated through 18 h by HPLC. CYP1A1 activity (Ethoxyresorufin *O*-deethylase) was measured in liver microsomes from animals belonging to each experimental group. Correlations between pharmacokinetic parameters and hepatic CYP1A1 activity will be presented.

603 QUININE METABOLISM AS A PROBE FOR THE EVALUATION OF RAT HEPATIC CYP1A1 AND CYP3A.

V. M. Mishin and P. E. Thomas. *Laboratory for Cancer Research, College of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ.* Sponsor: M. Iba.

The *in vitro* metabolism of quinine was investigated with 15 recombinant rat cytochrome P450 enzymes. It was found that the CYP3A1 enzyme produced 3-OH quinine as the major product (90% of all metabolites detected) of quinine biotransformation. The recombinant CYP3A2 was active in metabolizing quinine into 3-OH quinine but with a rate approx. 30% of that for CYP3A1. No significant formation of 3-OH quinine was found in the experiments with other 13 recombinant rat CYP. Recombinant rat CYP1A1 formed O-desmethylquinine as the major metabolite of quinine with no significant formation of 3-OH quinine. No significant formation of O-desmethylquinine was found in the experiments with either CYP3A1, CYP3A2 or CYP1A2, as well as with other 11 tested recombinant rat CYP. In liver microsomes incubated with quinine, the rates of formation of 3-OH quinine were 0.26, 0.32, 22.0 and 1.0 nm/min/mg protein for female control, MC- and DEX-induced and male control rats, respectively. Among the microsomal preparations tested the only female MC-induced microsomes were active in the production of O-desmethylquinine. Overall, the data obtained with recombinant rat cytochrome P450 enzymes are in the good agreement with the data obtained with hepatic microsomes from variously treated rats. Enzymes kinetics (Vmax, Km and Clint) determined for rat CYP1A1 and CYP3A1 indicate that both enzymes are similarly active in quinine biotransformation although each produces different metabolite. This study indicates that two different products of quinine biotransformation could be used as suitable probes for the *in vitro* and/or *in vivo* evaluation of CYP1A1 and CYP3A metabolic activities. (Supported by GM 44982 and ES 05022)

604 STRUCTURE-ACTIVITY RELATIONSHIPS (SARS) FOR *IN VITRO* INHIBITION OR INDUCTION OF AROMATASE (CYP19) ACTIVITY BY VARIOUS PESTICIDES.

J. T. Sanderson, M. Heneweer, C. Buitenhuis, J. Boerma and M. van den Berg. *Research Institute for Toxicology, Institute for Risk Assessment Sciences, Utrecht, Netherlands.*

SARs were assessed for aromatase (which converts androgens to estrogens) inhibition or induction by various pesticides in H295R human adrenocortical carcinoma cells. The effects of 13 pesticides were assessed and compared to literature data for *in vitro* inhibition or induction by structurally similar pesticides. Among the most potent aromatase inhibitors were the fungicides imazalil and prochloraz, which both contain an imidazole and chlorinated aromatic moiety. The structurally similar imidazole fungicides (in order of decreasing potency) tioconazole, clotrimazole, econazole, miconazole and isoconazole have previously been reported to be good inhibitors. Less potent inhibitors in H295R cells were the triazole containing fungicides difenoconazole, penconazole and propiconazole. The structurally similar triazole fungicides triademenol and triadimefon were also reported previously to have similar inhibition potencies. The hydroxy-containing triazoles tebuconazole, hexaconazole and paclobutrazole were almost inactive in H295R cells, as were the pyrimidine fungicides fenarimol (a known microsomal aromatase inhibitor) and nuarimol, probably due to the limited cellular uptake of these relatively more polar compounds. Enzyme kinetic analyses indicated that the imidazole fungicides were uncompetitive-, whereas the triazole fungicides were competitive inhibitors of aromatase with K_i values in the low micromolar range. The triazine herbicides atrazine, simazine and propazine, the structurally similar vinclozolin and to a lesser extent the hydroxylated triazole fungicide diclobutrazole were inducers of aromatase activity. Atrazine and vinclozolin act by increasing intracellular cAMP levels, possible through inhibition of phosphodiesterase activity, suggesting this enzyme as a target for SAR analysis of aromatase inducers in H295R cells. These SARs may be useful to identify chemicals with the potential to disturb the androgen/estrogen balance through an interaction with aromatase.

605 HYPEROXIA DIFFERENTIALLY MODULATES CYTOCHROME P450 EXPRESSION IN NEWBORN AND ADULT RATS: IMPLICATIONS FOR OXYGEN-MEDIATED LUNG INJURY.

X. I. Couroucli[1], M. E. Wearden[2], H. W. Strobel[3] and B. Moorthy[2]. [1]*Pediatrics, University of Texas-Houston Medical School, Houston, TX,* [2]*Pediatrics, Baylor College of Medicine, Houston, TX and* [3]*Biochemistry, University of Texas-Houston Medical School, Houston, TX.* Sponsor: B. Moorthy.

Supplemental oxygen is frequently administered to infants having pulmonary insufficiency. Newborn rats show increased tolerance to hyperoxic lung injury than adult rats. In this study, we tested the hypothesis that exposure of newborn or adult rats to hyperoxia would differentially regulate hepatic and pulmonary cytochrome P450 (CYP) isoforms, a phenomenon that may contribute to the increased tolerance to injury in the neonatal rats. Newborn Fisher rats or adult male rats were maintained in room air or exposed to hyperoxia ([gt] than 95% O2) for 1-7 days, and animals were sacrificed at selected time points. Pulmonary and hepatic CYP1A1, CYP1A2, and CYP4F4 mRNA expression was determined by RT-PCR. All newborn rats survived 7 days of hyperoxic exposure. On the other hand, none of the adult rats survived beyond 60 h of hyperoxia. In the newborn liver, hyperoxia markedly induced CYP1A1, CYP1A2 and CYP4F4 expression over room air controls after 2-4 days of exposure, but the expression of CYP1A1, but not CYP1A2 or 4F4, declined after 7 days. In the newborn lung, hyperoxia induced CYP1A1 and CYP4F4 expression early in the time course (1-2 days), but expression of both isoforms declined by 7 days. In adult rats, the hepatic expression of CYP1A1/1A2 and CYP4F4 was enhanced between 24-48 h of hyperoxia, followed by decline at 60 h. In contrast, pulmonary CYP4F4, was induced by hyperoxia only at 60 h. The sustained induction by hyperoxia of CYP1A2 and CYP4F4 genes in the newborn but not adult liver suggests an important protective role for these enzymes against hyperoxic lung injury. Furthermore, the augmentation of pulmonary CYP4F4 gene expression early in the time course of hyperoxic exposure in the newborn rat may contribute to the increased tolerance to oxygen-induced lung injury. (Supported in part by NIH grant ES09132 and by ALA.)

606 ALLEVIATION OF HYPEROXIC LUNG INJURY IN THE RAT BY THE CYTOCHROME P4501A INDUCER 3-METHYLCHOLANTHRENE.

B. Moorthy and W. Jiang. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Supplemental oxygen administration is used extensively in the treatment of pulmonary insufficiency that is commonly observed in in premature infants. We reported earlier that exposure of rats to hyperoxia for 48 h leads to induction of hepatic CYP1A1/1A2 enzyme activities, followed by decline at 60 h, the time point that coincides with severe respiratory distress and lung damage. In this study we tested the hypothesis that pretreatment of rats with the CYP1A inducer 3-methylcholanthrene (MC) would protect animals from lung damage caused by subsequent hyperoxic exposures. We treated adult male Sprague-Dawley rats with MC (93 μmol/kg) or vehicle only, once daily for 4 days. After 1 or 15 days after MC withdrawal, the animals were either maintained in room air or exposed to hyperoxia (> 95% oxygen) for up to 60 h. Activities of pulmonary and hepatic ethoxyresourufin-O-dethylase, which is specific for CYP1A1, were about 30-40-fold elevated in the MC-treated rats at both 1 and 15 day time points, compared to vehicle-treated controls. Seven out of 9 control rats survived 60 h of hyperoxia. On the contrary, 12/12 MC-treated animals survived 60 h of hyperoxia. This was the case for both the 1 and 15 day time points. Vehicle-treated animals exposed to hyperoxia for 60 h had severe measurable pleural effusions (~ 10.4 ± 2.0 g), which is an index of lung injury. In contrast, MC-treated animals after 60 hyperoxia had significantly lower pleural effusions, being 3.1 ± 1.2 (g) and 6.3 ± 1.7 (g), respectively, for 1 and 15 day time points. The decreased susceptibility of MC-treated animals to oxygen-induced lung damage, in conjunction with the sustained CYP1A1 expression in these animals, supports the hypothesis that CYP1A1 induction plays a beneficial role in hyperoxic lung injury. (Supported in part by NIH grant ES09132 and by ALA.)

607 UROPORPHYRIA CAUSED BY FE AND ALA IN MICE - THRESHOLD REQUIREMENTS FOR FE AND CYP1A2.

P. R. Sinclair[1,2], N. Gorman[1,2], K. L. Ross[4], H. S. Walton[1,2], W. J. Bement[1], J. G. Szakacs[3], G. S. Gerhard[1,2], T. P. Dalton[5], D. W. Nebert[5], R. S. Eisenstein[4] and J. F. Sinclair[1,2]. *[1]VA Med. Center, White River Junction, VT, [2]Biochem, Pharmacol/Toxicol, Pathology, Dartmouth Medical School, Hanover, NH, [3]VA Med. Center, Salt Lake City, UT, [4]Nutritional Sciences, Univ of Wisconsin, Madison, WI and [5]Environmental Health, Univ of Cincinnati, Cincinnati, OH.*

Previous work has implicated both CYP1A2 and Fe in experimental uroporphyrin (URO) accumulation caused by polyhalogenated compounds, 5-aminolevulinate (ALA) and Fe. In mice, strain differences in sensitivity for uroporphyria caused by ALA and Fe have been observed. We examined whether the higher sensitivity to uroporphyria caused by ALA alone in SWR compared to C57BL/6 mice was due to higher endogenous levels of hepatic Fe and CYP1A2 in SWR mice.The ALA and Fe-treated Cyp1a2 (+/-) heterozygote which has CYP1A2 protein levels about 60 % of the Cyp1a2 (+/+) wild-type, accumulated much less URO than the wild-type, whereas Cyp1a2 (-/-) mice accumulated no URO. In C57BL/6 mice treated with ALA, increasing CYP1A2 about 2-fold by a low dose of PCB126, increased URO accumulation by 6-fold, if Fe was also given. A Dose-Response study with Fe dextran in mice given PCB126 and ALA, showed that hepatic levels of Fe greater than 800 microg/g wet weight were required to cause considerable URO accumulation. Perls staining revealed that at low Fe dextran doses, Fe accumulation was mainly in Kupffer cells; with higher doses more Fe was also detected in parenchymal cells. Two indices related to the availability of iron, IRP-IRE binding and accumulation of protoporphyrin, the substrate for ferrochelatase, were decreased at much lower Fe dextran doses than those required to produce uroporphyria. We conclude that while increasing CYP1A2 increases the sensitivity of C57BL/6 mice for uroporphyria to that of SWR mice, merely increasing hepatic Fe to the same level does not. Other strain specific factors, especially in Fe metabolism may be involved. This work was supported by the VA and NIH (ES06263, ES 06321, AG14731, DK47219).

608 CYTOCHROME P450 REDUCTASE MUTANTS WITH ALTERED COFACTOR SPECIFICITY (NADPH *VS.* NADH).

C. L. Elmore and T. D. Porter. *Graduate Center for Toxicology, University of Kentucky, Lexington, KY.* Sponsor: M. Vore.

Cytochrome P450 reductase (CPR) is responsible for electron transfer from NADPH to the cytochromes P450 and other microsomal monooxygenases. CPR has an unusually high specificity for NADPH (*vs.* NADH). These two cofactors differ only in the presence of a 2' phosphate instead of a hydroxyl group (OH) on the adenine ribose of NADPH, and thus this moiety must provide the target for cofactor discrimination. We have used site-directed mutagenesis to identify several residues that discriminate between the 2' phosphate of NADPH and the 2' hydroxyl of NADH; amino acids were chosen for mutation based on the crystal structure of ferredoxin NADP+ reductase in conjunction with sequence alignments of NADH-specific enzymes. Five single mutants (S596D, R597M, E598A, K602W, and W677A) and four double mutants (S596D-R597M, S596D-K602W, R597M-W677A, K602W-W677A) were generated. Most notably, S596D, S596D-R597M, and S596D-K602W show a greater than 23, 000-fold shift in Km value from NADPH to NADH. W677A, S596D-R597M, R597M-W677A, and K602W-W677A mutants show a higher kcat with NADH than with NADPH. The W677A mutant shows the highest overall catalytic efficiency (kcat/Km) with NADH, with a $kcat^{NADH}$ of ~3000^{-1} (comparable to the wild-type enzyme with NADPH) and a Km^{NADH} of ~100 μM, but is inhibited by NADPH concentrations as low as 2.5 μM. To determine if mutations to the 2' phosphate binding region of P450 reductase might allow activity with NADH without inhibition by NADPH, we tested K602W-W677A along with the W677A enzyme in the presence of 2.5 μM NADPH. K602W-W677A retains significant activity in the presence of 2.5 μM NADPH, a concentration that causes complete inhibition of W677A. This enzyme may be suitable for use in *in vivo* applications. This research was supported by NSF Grant MCB-9808636 and NIH Training Grant ES-07266.

609 GENDER DIFFERENCES IN THE METABOLISM OF ACRYLONITRILE TO CYANIDE IN MICE: ROLE OF CYTOCHROME P4502E1 (CYP2E1) AND EPOXIDE HYDROLASE (EH).

B. Chanas[1], H. Wang[2] and B. I. Ghanayem[1]. *[1]NIEHS/NIH, Research Triangle Park, NC and [2]University of North Carolina, Chapel Hill, NC.*

Acrylonitrile (AN) is a potent toxicant and a known rodent carcinogen. AN may undergo direct conjugation with glutathione or oxidation to form cyanoethylene oxide (CEO). CEO is metabolized to yield cyanide *via* several proposed pathways including epoxide hydration. Further, male mice were reported to be more sensitive to the acute toxicity of AN than females. The objectives of this work include the study of the importance of CYP2E1 and EH in the metabolism of AN to cyanide and the role of these enzymes in the gender differences in AN-induced acute toxicity. Male and female wild-type (WT) and CYP2E1-null mice received AN at 0, 2.5, 10, 20, or 40 mg/kg by gavage. Blood and tissue cyanide concentrations were measured at 1 or 3 hr after dosing. Present results showed that cyanide levels in blood and tissues of AN-treated WT mice were significantly greater than controls and increased in a dose-dependent manner. In contrast, cyanide levels in the blood and tissues of AN-treated CYP2E1-null mice were not statistically different from those of vehicle-treated mice. Significantly higher levels of AN-derived cyanide were detected in the blood and tissues of WT male mice than in females, which may explain the higher sensitivity of male mice to AN-induced toxicity. Western blots of microsomal and cytosolic liver protein from WT male and female mice showed that while there was negligible differences in CYP2E1 expression, higher levels of EH were detected in male mice. Differences in the expression of EH may contribute to elevated metabolism of CEO to cyanide and to the greater sensitivity of male mice to AN-induced toxicity. In summary, these data demonstrated that CYP2E1 is the only enzyme responsible for the oxidative metabolism of AN, and suggest that metabolism of CEO *via* EH may play a major role in the formation of cyanide in mice. Further, gender differences in the expression of EH may explain the higher cyanide levels and the more severe toxicity observed in male *vs.* female mice.

610 DEHYDROEPIANDROSTERONE (DHEA) TARGETS MULTIPLE NUCLEAR RECEPTORS TO MODULATE CYTOCHROME P450 GENE EXPRESSION.

S. L. Ripp[1], J. M. Peters[2] and R. A. Prough[1]. *[1]Biochemistry, University of Louisville, Louisville, KY and [2]Molecular Toxicology, Penn State University, University Park, PA.*

DHEA is a C-19 steroid produced by the human adrenal gland. Administration of DHEA at pharmacological doses produces diverse biological effects, including chemoprotection in multiple cancer models, and amelioration of obesity, diabetes, and lupus in animal models and in humans. We have previously shown that in rats DHEA treatment modulates expression of multiple cytochrome P450 (CYP) enzymes. DHEA treatment increases expression of members of the CYP4A and CYP3A subfamilies and decreases expression of CYP2C11. In the current study, we examined the role of nuclear receptors in modulation of CYP expression by DHEA. DHEA is known to activate a member of the nuclear receptor superfamily, peroxisome proliferator activated receptor α (PPARα), to modulate expression of some genes, including CYP4A. PPARα-null mice were utilized to examine the role of this receptor in expression of CYP3A. In wild-type mice, DHEA-sulfate (150 mg/kg) induced CYP4A and CYP3A mRNA by 4- and 1.5-fold, respectively, compared to controls. In PPARα-null mice, induction of CYP4A by DHEA was lost while CYP3A induction was 1.5-fold, as in wild-type. Because CYP3A can be regulated by another nuclear receptor family member, the pregnane X receptor (PXR), we tested the ability of DHEA and its metabolites to activate PXR. A reporter gene containing two copies of the PXR responsive element from the CYP3A23 gene was transiently transfected into CV-1 cells in the presence or absence of PXR expression vector. DHEA and its metabolites androstenedione and androstenediol were activators of PXR in these assays. We also examined the involvement of nuclear receptors in DHEA's ability to suppress CYP2C11. In cell-based assays, DHEA suppresses CYP2C11 in a PPARα-independent manner. Taken together, these results indicate that DHEA can act through the nuclear receptors PPARα, PXR, and likely additional members of the nuclear receptor superfamily to modulate expression of CYPs. Supported by DK54774 (RAP) and F32 ES05927 (SLR).

611 CYTOCHROME P450 EXPRESSION DURING THE GASTRIC CARCINOGENIC PROCESS.

L. Ladron de Guevara, C. Castro, J. Espinosa, R. Camacho, L. Espinosa and J. Rubio. *Instituto de Investigaciones Biomédicas, Universidad Nacional Autonoma de Mexico, Mexico, D.F., Mexico.* Sponsor: M. Gonsebatt Bonaparte.

Gastric Cancer (GC) is the second most common cancer worldwide. In Mexico, gastric cancer has occupied the second and third places among neoplasm death rates for many years. GC is classified according to the histological type in intestinal and diffuse (Lauren's Classification). It is known that intestinal GC is preceded of a series of histological changes that include active and inactive chronic gastritis, atrophy and intestinal metaplasia and finally gastric adenocarcinoma. Intestinal type GC is strongly related to environmental factors and the infection caused by *Helicobacter pylori* . The gastric tract is exposed to a large amount of carcinogens. It has been proved that 90% of all xenobiotics pass throughout it, most of them subject to be bioactivated by cytochrome p450 enzyme family (CYP). Our objective is to demonstrate that there is a CYP differential expression related to inflammation in the different histological progression stages leading to intestinal type GC. We sampled 244 gastric mucosal tissue specimens from the proposed gastric carcinogenesis model stages to be analyzed by immunohistochemistry performed with CYP 2E1

and 3 A4 polyclonal antibodies . *Helicobacter pylori* status, drug intake and smoking habit information were collected. The results were assessed according to the presence or absence of immunostaining using standard light microscope. Differences in staining proportions were tested with square χ test. Briefly, we found 2E1 and 3A4 CYP expression in normal tissues. This expression decreases in active and inactive chronic gastritis. A 95% of intestinal metaplasia analysed tissued exhibited 2E1 CYP expression while only 23% was found in GC specimens. CYP 2E1 and 3A4 is inversely correlated to *Helicobacter pylori* infection.

612 CYP1B mRNA EXPRESSION IN TWO RELATED CATFISH SPECIES.

C. Metzger[1], R. T. Di Giulio[2] and K. L. Willett[1]. *[1]Department of Pharmacology, The University of Mississippi, University, MS and [2]Nicholas School of the Environment, Duke University, Durham, NC.*

CYP1B1 is a P450 gene that in mammals is involved in the metabolism of polycyclic aromatic hydrocarbons (PAHs) and estradiol to potentially toxic intermediates. This gene was recently cloned in fish (scup and plaice). The objective of our study is to characterize CYP1B in channel catfish (*Ictaluras punctatus*, CC) and brown bullhead (*Ameriurus nebulosus*, BB). These species were selected because of their established differences in sensitivity to PAH-induced carcinogenesis; BB is the more sensitive species. An 861 nucleotide sequence to the polyA tail was cloned from CC liver that was 67% similar to the human and plaice CYP1B1 protein sequences (104 of the 183 residues were shared by all 3 species). In a 459 nt sequence spanning two exons, there was only one amino acid residue different between the two catfish species. Tissue distribution was investigated in fish exposed to control and 20 mg/kg benzo(a)pyrene (BaP). RT-PCR analysis indicated a 207 nt CYP1B band in gill, blood, gonad, kidney, and liver of BB and CC. When standardized against beta-actin, there appeared to be an induction by BaP in some CC tissues but not liver where CYP1B was lowest. Complete Dose-Response curves for CYP1B mRNA induction by BaP and TCDD exposure of primary hepatocytes and gill cells are being established with real time quantitative PCR. Using semiquantitive RT-PCR, neither TCDD nor BaP caused significant induction in BB hepatocytes, however BaP caused CYP1B some induction in CC hepatocytes. Ultimately, we will compare CYP1B induction responses in BB and CC to determine if differential CYP1B activity could have a role in species differences in PAH susceptibility.

613 ASSESSING THE ROLE OF CYP3A5 AND CYP3A7 IN DRUG-DRUG INTERACTIONS.

D. M. Stresser, S. D. Turner, T. Ho and C. L. Crespi. *BD Biosciences, Woburn, MA.*

CYP3A5 is present in significant quantities in 20-60% of human livers, whereas CYP3A7 is most abundant in fetal liver. The role of these enzymes in drug interactions is not well understood. A panel of 16 compounds was tested for potential to inhibit dealkylation of 7-benzyloxy-4-trifluoromethylcoumarin (BFC) catalyzed by cDNA-expressed CYP3A5, CYP3A7, CYP3A4 and human liver microsomes (HLM). CYP1A2 was used as a non-CYP3A comparator. Three of 16 compounds exhibited 50% inhibition of CYP1A2 activity (IC50) whereas at least 13 of 16 compounds exhibited 50% inhibition of CYP3A4, CYP3A5, CYP3A7 and HLM activity. α-Naphthoflavone inhibited CYP1A2, but activated all CYP3A enzymes as well as HLM catalysis. The IC50 values for all CYP3A enzymes and HLM correlated well with each other ($r > 0.77$). We show that inhibitor specificity for CYP3A5 and CYP3A7 is similar to CYP3A4 but inhibitor potency for these enzymes is on average, 45-fold less than with CYP3A4. Since HLM is a mixture that includes at least two CYP3A enzymes, expect intermediate potency when using HLM as an enzyme source in CYP3A4 inhibition assays. Indeed, this was observed. Because of similarities in inhibitor specificity between CYP3A4 and CYP3A7, CYP3A7-mediated drug-drug interactions and/or drug-endobiotic interactions in fetus may exhibit a specificity profile similar to that of CYP3A4 in adults, however, inhibition potency appears to be at least an order of magnitude less with CYP3A7.

614 DIESEL EXHAUST PARTICLE-INDUCED ALTERATIONS OF PULMONARY PHASE I AND PHASE II ENZYME SYSTEMS.

A. Rengasamy, M. W. Barger, E. Kane, J. K. Ma, V. Castranova and J. Y. Ma. *Pathology & Physiology Res. Br., NIOSH, Morgantown, WV.*

Several environmental pollutants including polycyclic aromatic compounds induce carcinogenesis through the activation of xenobiotic metabolic pathways. The xenobiotics require bioactivation by phase I enzymes to induce carcinogenicity, while phase II enzymes contribute to resistance to chemical toxicity. The purpose of this study was to investigate the effects of diesel exhaust particle (Department) on phase I and phase II enzymes. Male rats were intratracheally instilled with saline (vehicle control) or a single dose of Department or carbon black (CB) at 5, 15, or 35 mg/kg body weight. CB was used as a control for the particulate carbon core of Department. At 1, 3, or 7 days post-exposure, lung microsomes and cytosol were prepared. The activities of CYP1A1 and CYP2B1 (Phase I enzymes) in microsomes and GST and catalase (phase II enzymes) in the cytosol were determined. Enzyme protein levels were determined by Western blot analysis. Department exposure at 5, 15, or 35 mg/kg, but not CB, significantly elevated CYP1A1 protein levels at 1 and 3 days post-exposure compared to the control. CYP1A1 activity was also increased with 15 and 35 mg/kg Department at 1 day post-exposure. On the other hand, both Department and CB exposures caused a significant decrease in CYP2B1 protein levels at 15 and 35 mg/kg with a concomitant attenuation of CYP2B1 enzyme activity. At 1 day post-exposure, both Department and CB significantly decreased the GST-Pi protein level at all doses tested with a significant attenuation in GST activity at 15 and 35 mg/kg. Catalase activity was significantly decreased by Department or CB (35 mg/kg) exposure at 1 and 7 days. These data suggest that the organic components of Department induce CYP1A1, while the carbon core attenuates CYP2B1, GST and catalase activities. The Department-induced alterations in the phase I and phase II enzyme pathways may play a significant role in pulmonary toxicity/carcinogenicity.

615 METABOLISM AND TOXICITY OF THE FUNGICIDE THIRAM AND ITS METABOLITES IN RATS.

P. S. Dalvi, T. Wilder-Kofie, B. Mares, R. R. Dalvi and L. H. Billups. *Biomedical Sciences, College of Veterinary Medicine, Nursing & Allied Health, Tuskegee, AL.*

Thiram (tetramethylthiuram disulfide) is a dithiocarbamate compound widely used as an agricultural fungicide, antioxidant in rubber/rayon industry and antibacterial agent in medicine. The objective of this study was to examine whether thiram and its two metabolites, dimethyldithiocarbamate (DMDC) and carbon disulfide, interact with hepatic cytochrome P450 (CYP) isozymes and cause hepatic damage in rats. These compounds were individually administered i.p. to rats at two equimolar doses (0.1 and 0.5 mmol/kg) and the animals were sacrificed 3 and 24 hr after treatment. At 3 hr, there was a significant inhibition of CYP1A1 caused by only the higher dose of thiram and DMDC whereas the inhibitory effect was seen with both doses of carbon disulfide. On the other hand, CYP2E1 was inhibited by all doses of all compounds. CYP2B1 was not affected by DMDC, but was inhibited by higher dose of thiram and both doses of carbon disulfide. The activity of CYP3A2 was decreased by only the higher dose of carbon disulfide and not by others. The results of 24 hr treatment indicated that CYP 1A1 and 2E1 were inhibited only by higher dose of thiram, CYP 2B1 and 2E1 were induced by higher dose of carbon disulfide and CYP3A2 remained unaffected by all doses of all three compounds. The higher dose of thiram elevated the levels of serum SDH and ALT at 24 hr. Further assessment of liver damage was done histopathologically, and only the higher dose of thiram produced mild to moderate hepatic cell necrosis 24 hr after treatment. In summary, the results suggest that these compounds are metabolized by CYP 1A1, 2B1 and 2E1, but not by 3A2, and only thiram is hepatotoxic. Supported by NIH/MBRS S06GM08091.

616 INCREASED CYP2E1 ACTIVITY AND ENHANCED SYSTEMIC OXIDATIVE STRESS AFTER ENDOTOXIN IN HUMANS.

R. T. Tosheva[1,2], P. Van Ess[3], C. R. Cunninghan[1], R. A. Blouin[3] and S. I. Shedlofsky[1,2]. *[1]Medicine, VA Hospital, Lexington, KY, [2]GCRC, Univ of KY, Lexington, KY and [3]College of Pharmacy, Univ of KY, Lexington, KY.*

Reactive oxygen species (ROS) are important toxic mediators in the pathophysiology of systemic inflammation. Previous studies have shown systemic oxidative stress in animal models of inflammation. Usually activities of hepatic P450s are decreased. However, we previously reported that CYP2E1, a P450 that leaks ROS, is not decreased in humans after LPS. To further evaluate CYP2E1 and oxidative stress in the human LPS model, human volunteers were given LPS. Methods: Six healthy, non-smoking men were given two consecutive daily injections of E. coli lipopolysaccharide (LPS) as a safe reproducible model of inflammation. In a control study each subject was monitored after saline injection. Oral and formation clearances of chlorzoxazone (CZX) as a measure of hepatic activity of CYP2E1 were assayed. Urinary F2-isoprostanes, whole blood GSH, peripheral blood leukocyte NF-κB activation, and plasma nitrate/nitrite concentration were measured as markers of systemic oxidative stress, as well as plasma TGF-*beta*1 and hyaluronic acid concentration. Results: Pharmacokinetic data of CZX clearance showed increases in the activities of CYP2E1 after LPS administration. Statistically significant two to three fold increases in urinary F2-isoprostanes were found between 0-6 hr after each dose of LPS. Plasma nitrate/nitrite concentration reached peak values of 86.0 ±36uM and 70.8 ±18uM between 3 and 6hr after first and second LPS dose respectively, while the control value was 40.1 ± 18uM. The profiles of changes in leukocyte NF-κB (p50 and p65), human plasma TGF-*beta*1 and plasma

hyaluronic acid concentrations at early time points after each LPS administration exhibited transient but significant increases that returned to normal values 24 hr after treatment. Conclusion: Our results indicate an increase in hepatic CYP2E1 activity with low-dose LPS in humans that is associated with enhanced but transient measures of systemic oxidative stress.

617 PHENYLETHYLISOTHIOCYNATE (PEITC) REDUCES 2-AMINO-1-METHYL-6-PHENYLIMIDAZO[4, 5-B]PYRIDINE (PHIP) DNA ADDUCT FORMATION BY INHIBITION OF CYTOCHROME P450 DEPENDENT METABOLISM.

J. A. West, K. H. Dingley and K. W. Turteltaub. *Biology and Biotechnology Program, Lawrence Livermore National Laboratory, Livermore, CA.*

Exposure to potent heterocyclic amine mutagens, such as PhIP, result in DNA adducts that correlate with tumor formation in target tissues of rats. Consumption of cruceferous vegetables, which contain PEITC, appear to reduce the carcinogenic potential of heterocyclic amines. The mechanism by which PEITC reduces the carcinogenic potential is unknown. To determine if chemopreventitives interfere with PhIP bioactivation, microsomes from rat liver, prostate and lung were prepared to measure the metabolism of PhIP in the presence of PEITC. In a separate experiment rats were administered PEITC prior to a PhiP exposure and DNA adducts were measured by accelerator mass spectrometry. Results: Microsomes prepared from neither rat prostate, nor lung tissue generated oxidation products of PhIP. In contrast, liver microsomes generated multiple oxidation products from PhIP, including NOH-PhIP, an intermediate that results in DNA binding. PhIP metabolism in liver was inhibited by PEITC. With particular significance PEITC abolished the production of NOH-PhIP, while less reactive metabolites were still produced. When rats were administered PEITC prior to PhIP exposure, DNA adducts were reduced. We conclude: 1) NOH-PhIP is not generated by cytochrome P450 at detectable leves in extra-hepatic tissue 2) PEITC inhibits cytochrome P450 dependent metabolism of PhIP, and 3) inhibition the metabolic activation of PhIP to reactive intermediate such as NOH-PhIP, leads to the reduction of DNA Adducts. This work was performed under the auspices of the U. S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under Contract No. W-7405-Eng-48. 618 USE OF REAL-TIME QUANTITATIVE REVERSE TRANSCRIPTION-POLYMERASE CHAIN REACTION (QRT-PCR) METHODOLOGY TO STUDY THE INDUCTION OF CYTOCHROME P450 (CYP) mRNA LEVELS IN RAT LIVER.

C. Meredith, M. P. Scott, J. L. Newcomb, A. B. Renwick, R. J. Price and B. G. Lake. *Molecular Sciences, TNO BIBRA International Ltd, Carshalton, United Kingdom.*

In this study QRT-PCR (TaqMan®) methodology has been employed to study the induction of CYP mRNA levels in rat liver and in cultured precision-cut liver slices. Fluorigenic (TaqMan®) probe/primer combinations specific for a range of CYP cDNAs were designed using Primer Express® software. The probe/primer sets were selected to span exon junctions in order to minimise the effect of any contamination from genomic DNA. Probes for CYP genes utilised a FAM reporter while the house-keeping (albumin) probe was labelled with VIC allowing duplex analysis for both CYP and albumin in the same reaction. To test the specificity of the TaqMan® probes and primers male Sprague-Dawley rats were treated with either a single 500 mg/kg ip dose of Aroclor 1254 (ARO) or four daily oral doses of 50 and 75 mg/kg/day dexamethasone (DEX) and methylclofenapate (MCP), respectively. Total RNA was extracted from liver samples from control rats and pooled samples from ARO, DEX and MCP treated rats and cDNA prepared. A series of duplex PCR amplifications was conducted using an ABI PRISM™ 7700 Sequence Detector. Compared to albumin (as a house-keeping gene) levels of CYP1A1, CYP1A2, CYP3A1, CYP3A2 and CYP4A1 mRNA were induced by 51, 44, 49, 13 and 62 fold, respectively. To assess CYP mRNA induction *in vitro*, rat liver slices (diameter 10 mm, thickness around 250 µm) were prepared using a Krumdieck tissue slicer. Liver slices were cultured in Williams medium E containing 0.1 µM insulin, 0.1 µM DEX, 2 mM L-glutamine, 50 µg/ml gentamicin and 2.5 µg/ml fungizone in a dynamic organ culture system at 37°C under an atmosphere of 95% O_2/5% CO_2. Treatment with ARO, but not MCP, for 24 hr markedly induced levels of CYP1A1 and CYP1A2 mRNA, whereas MCP induced levels of CYP4A1 mRNA. These results demonstrate the usefulness of TaqMan® QRT-PCR methodology for studying the induction of rat CYP mRNA levels *in vivo* and *in vitro*.

619 MEASUREMENT OF HEPATIC ENZYME INDUCTION AND β-OXIDATION IN RATS DOSED WITH CLOFIBRATE.

D. E. Amacher and S. E. Boldt. *Molecular and Investigative Toxicology, Groton Laboratories, Pfizer Global Research and Development, Groton, CT.*

The goals of this study were to evaluate the effects of various doses of clofibrate on inducible liver enzymes in the rodent and to assess possible increases in peroxisome proliferation at the higher doses. Groups of 5 male and 5 female [Crl:CD®(SD)BR (Sprague-Dawley)] rats received either 0, 300, 450 or 600 mg/kg/day clofibrate s.i.d. for 14 days. The animals were sacrificed, and the livers removed and frozen. Subsequently the livers were homogenized, and supernatants were prepared and later assayed for peroxisome proliferation based on cynanide-insensitive β-oxidation of palmitoyl CoA. In comparison with control animals, palmitoyl CoA oxidation increased significantly ($p < 0.01$) in both sexes at 300 mg/kg, but appeared to plateau at 450 and 600 mg/kg, indicating that a 300 mg/kg dose of clofibrate was adequate to generate an optimal response in the rat. Concurrently, liver microsomal samples were prepared from the same livers and later assayed for microsomal cytochrome P450, NADPH cytochrome c reductase, ethoxyresorufin O-dealkylase (EROD), methoxyresorufin O-dealkylase (MROD), pentoxyresorufin O-dealkylase (PROD), p-nitroanisole O-demethylase (P-NOD), p-nitrophenol hydroxylase (NP), and ethylmorphine N-demethylase (EMD) activities. For some of these endpoints, significant ($p < 0.05$) differences were found between the control means and those means obtained from animals dosed with clofibrate. In both sexes, significant elevations in PROD and P-NOD were seen at all three dose levels. Elevated cytochrome c reductase was noted in both sexes at the high dose. Both EROD and MROD were essentially unaffected in males and females. In males, elevations of total P450 were observed at 300 and 450 mg/kg. In females, EMD levels rose significantly at all three doses, and increases were also seen in NP at 300 and 450 mg/kg. Based upon results for several inducible rodent cytochromes, this study demonstrates that clofibrate is a hepatic microsomal enzyme inducer of CYP2B1 and/or CYP2B2 and CYP2E1 in both sexes and CYP3A1 in females.

620 IRON DEFICIENCY CAUSES MANGANESE ACCUMULATION IN DEVELOPING RAT BRAINS.

K. M. Erikson and M. Aschner. *Physiology and Pharmacology, Wake Forest University School of Medicine, Winston-Salem, NC.*

Iron (Fe) deficiency (ID) is a prevalent nutritional disorder affecting nearly 2 billion people worldwide. It is well known that ID represents a risk factor for toxicity due to metal exposure (e.g., aluminum, cadmium, lead). Since Fe and manganese (Mn) share similar transport mechanism(s), studies were carried out to test the hypothesis that dietary ID leads to increased Mn accumulation in the brain, potentially predisposing the central nervous system (CNS) to toxicity. Previous studies have shown that ID increases brain Mn, but specific regional changes have, as of yet, not been reported. Thus, the goal of this study was to examine the effect of ID on [Mn] in Mn-rich brain regions. Twenty-one day old male Sprague-Dawley rats were fed for 6 weeks one of three semi-purified diets (AIN-93-G), (35 mg Fe/Kg, 10 mg Mn/Kg diet, CN n=7), (3 mg Fe/Kg, 10 mg Mn/Kg diet, ID n=7) and (3 mg Fe/Kg, 100 mg Mn/Kg diet, IDMn+ n=7). After 6 weeks of dietary treatment, the rats were euthanized, and the brains dissected into seven brain regions. Brain regions were analyzed for [Mn] with neutron activation analysis (NAA), and amino acid (glutamate, aspartate, glutamine, glycine, taurine, GABA) concentrations were measured with HPLC. Both Fe-deficient diets caused significant ($p<0.05$) increases in [Mn] in six of the brain regions compared to controls (ranging from cerebellum, 31%-globus pallidus 60% increase). The hippocampus was the only brain region in which the IDMn+ group accumulated significantly more Mn than both the CN and ID groups (CN<ID<IDMn+). While multiple alterations in brain regional amino acid concentrations were observed, two significantly correlated with CNS [Mn]. In the substantia nigra, [Mn] significantly correlated with increased taurine concentration ($r=0.65$; $p<0.05$), whereas in caudate putamen [Mn] negatively correlated with decreased g-amino butyric acid (GABA) ($r=-0.54$; $p<0.05$). These data show that ID increases brain Mn in a heterogeneous fashion, and that ID is a significant risk factor for CNS Mn accumulation. (Supported by NIEHS 10563).

621 PRENATAL LEAD (PB) EXPOSURE AND SCHIZOPHRENIA: METHODOLOGY FOR EXAMINING THE POTENTIAL RELATIONSHIP.

M. G. Opler[1], A. S. Brown[2], V. Babulas[2], J. Graziano[1], W. Zheng[1], M. Desai[3], P. Factor-Litvak[2] and E. S. Susser[2]. *[1]Environmental Health Sciences, Columbia University, New York, NY, [2]Epidemiology, Columbia University, New York, NY and [3]Biostatistics, Columbia University, New York, NY.*

Schizophrenia is a mental disorder affecting approximately 2.8 million Americans, characterized by hallucinations, delusions, emotional and social withdrawal, and disorganized thinking. The causes of the disease are thought to include hitherto unspecified genetic and environmental risk factors. Prior studies suggest that disruptions in prenatal development may be risk factors. The current study was designed

to test the hypothesis that exposure to a specific neurodevelopmental disruptor (Pb) during the 2nd trimester of pregnancy might increase the risk of developing the disease. Serum samples from a cohort of 19, 044 pregnancies were collected between 1959-1966. Samples of serum were taken at each trimester and at delivery, respectively. Samples were stored at 20 C until the present day for an average storage time of 38 years. Diagnosis of schizophrenia spectrum disorder in the children born to this cohort yielded a total of 71 cases. A method to quantitate a biological marker of Pb exposure, i.e. delta-aminolevulinic acid (d-ALA) has been developed. Serum samples were processed and treated with acetylacetone and derivatized with formaldehyde to produce a fluorescent molecule. The samples were fractionated on a reverse phase C18 column and assayed by a fluorescence detector with an excitation wavelength set at 360 nm and an emission wavelength of 470 nm. Our method improves the detection limit by a factor of 10, ultimately yielding 2.4 ng/mL of d-ALA. d-ALA values greater than (and less than) 10 ng/ml agree well with BPb values greater than (and less than) 14 ug/dL. This work is currently underway on the primary study.

622 COGNITIVE EFFECTS IN LEAD EXPOSED CHILDREN FROM URBAN AREAS IN THE REGION LAGUNERA, MEXICO.

G. G. García-Vargas[1,4], M. Rubio-Andrade[1], E. Casillas[2], E. Vera-Aguilar[3] and M. E. Cebrián[3]. *[1]F. Medicina, UJED, Gómez Palacio, Dgo, Mexico, [2]E. Psicología, UJED, Gómez Palacio, Dgo., Mexico, [3]CINVESTAV-IPN, México, DF., Mexico and [4]F. Medicina, UA de C., Torreón, Coah., Mexico.*

There is known that exposure to low doses of lead can cause cognitive effects in children. This population study was based in a previous cross sectional survey, where it was demonstrated that heavy metal contamination in soil, dust, and air around a smelter site by far exceeded background levels, and that a high proportion (> 90 %) of children living in the neighborhood had lead in blood concentrations (PbB) above 10 µg/dL (J. Toxicol. Environment Health. Part A, 62:417-429, 2001). From a initial number of 394 scholar children, 285 were recruited and their parents filled a consent letter form, to be studied by psychometric tests, particularly the Wechsler Intelligence Scale for Children - Revised (WISC-R) for Mexican children in Spanish. Diet, socioeconomic status, hygienic habits, and other variables were assessed by questionnaire. Gender distribution was 151 male, and 134 female, aged 6 – 14 years. The mean (range) of PbB was 19.13 µg/dL (3.9 – 58.5 µg/dL). Same parameters for psychometric index were: IQ: 100.32 (75.0 – 134.0) and for equivalent mental age: 8.15 years (5.0 – 11.5 years). Non parametric Spearman's correlation were significant between lead and IQ (ρ = - 0.169; p = 0.004) and for lead and equivalent mental age (ρ = -0.206; p< 0.0001). Socioeconomic status and education levels were co-variables for PbB and IQ, however, when the results were adjusted by the co-variables, the relationships among PbB and IQ, and equivalent mental age remain significant. The results confirm that chronic lead exposure have cognitive effects on children, particularly in mental maturity. These results will be useful for follow-up studies and set up epidemiological surveillance programs in this population.

623 HEME BIOSYNTHESIS IMPAIRMENT IN CHILDREN CHRONICALLY EXPOSED TO LOW DOSES OF LEAD IN A SMELTER COMMUNITY IN MEXICO.

J. Ruvalcaba[1], A. Cebrián[1], P. López[2,6], J. Alatorre[3], E. Vera[4], M. Uribe[4], M. E. Cebrián[4], J. L. Rosado[2,6] and G. G. García-Vargas[1,5]. *[1]FM-UJED, Gómez Palacio, Dgo., Mexico, [2]INNSZ, Mexico, DF, Mexico, [3]F. Psicología, UNAM, Mexico, DF, Mexico, [4]CINVESTAV-IPN, Mexico, DF, Mexico, [5]FM-UA de C, Torreón, Coah., Mexico and [6]UAQ, Queretaro, Qro, Mexico.*

Metal contamination in soil, dust and air around a smelter site has resulted in increased lead body burden in children living in the vicinity of the major smelter complex in Latin America, located in Torreón, Coahuila, northern Mexico. Children with lead in blood concentrations (PbB) over 10 *micro*|g/dL (value considered as indicative of lead poisoning) are at risk of suffering adverse effects of lead. Heme biosynthesis can be disturbed by lead exposure. Several heme biosynthesis enzymes or intermediate metabolites has been used as biomarkers in lead toxicity. The aim of this work was to assess two of the main lead toxicity biomarkers related with heme synthesis, particularly we evaluate the activity of the 5- aminolevulinic dehydratase (ALA-D; assayed by HPLC) and zinc protoporphyrin (ZPP; measured by fluorescence) in 270 children aged from 6-7 years old. Children were recruited from nine primary schools, 2 km around the smelter. Diet, socioeconomic status, hygienic habits, and other variables were assessed by questionnaire. Median (range) of PbB in children was 11.18 *micro*|g/dL (3.0 – 43.82 mg/dL), whereas for ZPP was 63.0 mmol of ZPP per mol of Hb (27.0 – 452.0 mmol of ZPP per mol of Hb), and for ALA-D was 147.0 nmol PBG / mL RBC x h (28.9 – 332.9 nmol PBG / mL RBC x h). There was a significant inverse relationship [r = -0.467; p< 0.00001; equation: Log (y) = 0.869 (log x) + 3.167] between PbB and ALA-D, and a significant positive relationship between PbB and ZPP [r = 0.443; p< 0.00001; equation: $y = 2.05 (x) + 42.22$]. These relations remain significant even adjusted by hemoglobin. These results showed that heme biosynthesis biomarkers, particularly ALA-D activity and ZPP in blood are useful biomarkers of damage for lead toxicity in children exposed to low doses of the metal.

624 LOW-LEVEL POSTWEANING LEAD (Pb) EXPOSURE: ALTERATIONS IN TIMING BEHAVIOR.

B. Brockel, J. Coleman, D. Coonfield, T. Smith and C. Lubbers. *Department of Psychology, Kansas State University, Manhattan, KS.*

Several clinical and experimental studies have suggested that low-level lead (Pb) exposure produces impulsive behavior and/or delay aversion. In addition, Pb exposure is associated with deficits in temporal behaviors, i.e. fixed-interval schedules. However, no studies have been conducted to determine if these Pb effects are related to differences in timing mechanisms. To test this hypothesis, rats exposed chronically from weaning to 0, 50, or 250 ppm Pb acetate in drinking water were tested on a temporal bisection task. Rats were trained to respond on one lever after the presentation of a 4-s ("short") tone and on another lever after the presentation of a 16-s ("long") tone. Once all subjects reached a criterion of 80% correct for both the 4 and 16-s tones, intermediate tones (5.2, 6.4, 8.0, 10.0, and 12.8 s) were added to the trials procedure. For each rat, the percentage of "long" responses at each signal duration was calculated, and psychophysical functions were determined by using least squares. The point of indifference, defined as the stimulus duration at which a rat responds "long" 50% of the time and the difference limen, an estimate of the threshold to detect differences between two time lengths were calculated from the individual psychophysical functions. Pb exposure produced a decrease in the PI without altering the DL. Pb exposure had no effect on the ability to discriminate the 4 and 16-sec tones. These results indicate that Pb produced an increase in clock speed without altering threshold sensitivity or discrimination ability and support the hypothesis that alterations in timing mechanisms play a role in some Pb-related behavioral deficits. Funded by NIEHS (ES010992).

625 EFFECTS OF CHRONIC LEAD EXPOSURE ON HIPPOCAMPAL BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) CONCENTRATIONS IN RATS.

S. M. Lasley. *Biomedical & Therapeutic Sciences, Univ. of Illinois College of Medicine, Peoria, IL.*

Previous studies have established that chronic developmental lead (Pb) exposure impairs the magnitude and duration of long-term potentiation (LTP) and the amount of stimulus-evoked hippocampal glutamate release. Other evidence indicates that induction of LTP is dependent on appropriate BDNF expression and release, and BDNF also potentiates glutamatergic transmission by increasing the efficacy of glutamate release. Moreover, chronic Pb exposure has been reported to decrease neurotrophic factor gene expression (Schneider et al., 2001). This study examined the production of hippocampal BDNF protein in rats chronically exposed from birth. Pregnant Long-Evans dams were exposed to 0.2% Pb in drinking water beginning at gestational day 16 and exposure was continued throughout lactation with male offspring continued on the same solution until testing. Previous studies have shown that this exposure protocol produces blood and brain Pb values of 40 ug/dl and 378 ng/g tissue, respectively (Gilbert et al., 1999). At 8 months of age rats were sacrificed and dorsal hippocampi and parietal cortices were dissected and sonicated. Cell lysates were clarified by centrifugation, briefly acidified in phosphate-buffered saline, and BDNF quantified by a microplate-based sandwich enzyme immunoassay; signal was determined by the absorbance at 450 nm. Total protein was determined by the bicinchoninic acid method. Hippocampal expression of BDNF protein did not differ between Pb-exposed and control animals. While alterations in BDNF activity could conceivably be an important factor in the impaired LTP and diminished glutamate release observed in tetanically-stimulated or depolarized hippocampal tissue, these data suggest that such exposure-induced changes cannot be traced to alterations in the expression of BDNF protein in unperturbed animals. (Supported by the Children's Miracle Network)

626 TOXICOLOGICAL ASPECTS OF LEAD: COGNITIVE EFFECTS IN CHILDREN AND NEUROCHEMISTRY IN YOUNG ALBINO RATS.

M. Al-awady and W. Atta. *Faculty of Medicine, Zagazig Univeristy, Zagazig, Egypt.* Sponsor: L. Sultatos.

Although little is known about the mechanism of lead neurotoxicity, the hazardous effects of lead exposure on the young has long been recognized. The current study investigated the effects of lead exposure on the intelligence and cognitive abilities of

children, as well as on gamma amino butyric acid (GABA) levels in the brains of young albino rats. Three hundred children of both sexes selected from different residential areas, were investigated for their blood lead level (BLL), IQ and minimental state. The clinical study on the children revealed that there was a strong relationship between the place of residence and lead exposure. Children living in rural areas had the lower blood lead levels, while those living in the urban areas had the higher blood levels. Children living in the rural areas had higher IQs and cognitive abilities, compared to those in urban areas. Fifty four young albino rats divided into 3 equal groups were exposed to 0, 100 and 1000 ppm lead acetate in drinking water respectively for 4 weeks. BLL and GABA levels were determined at the end of 2nd, 4th, and 6th weeks. No behavioral changes were noticed upon exposure to the examined doses of lead. However, lead exposure at 100 and 1000 ppm was found to elevate GABA levels. At the end of the follow up period (the end of the 6th week), GABA levels decreased toward normal control levels at the end of the 6th week although BLL remained high.

627 DEVELOPMENTAL LEAD EXPOSURE AFFECTS NEUROCHEMICAL AND IMMUNOHISTOCHEMICAL MARKERS OF THE RAT DOPAMINERGIC AND SEROTONERGIC SYSTEMS.

E. G. Moreira[1], V. S. Vassilieff[1], I. Vassilieff[1], J. C. Florio[1], T. L. Lassiter[2] and S. Barone, Jr[2]. *[1]CEATOX, UNESP, Botucatu, Brazil and [2]NTD, USEPA, Research Triangle Park, NC.*

Recently, we have demonstrated that exposure to lead (Pb) during pregnancy and lactation induced behavioral alterations in rats on PN23 and on PN70. Considering the role that the dopaminergic and serotonergic systems play in behaviors, this study was undertaken to investigate the effects of Pb exposure on these neurotransmiter systems. Wistar rat dams received 500 ppm of Pb acetate or 660 ppm Na acetate in the drinking water during pregnancy and lactation and the pups were euthanized on PN23 or 70. Dopamine (DA) and its metabolites DOPAC and HVA, as well as serotonin (5-HT) and its metabolite 5-HIAA were determined (ng/g of tissue) in the hypothalamus, hippocampus and striatum. Coronal sections immunostained for tyrosine hydroxylase (TH) or 5-HT were used for morphometric analyses (# of cells and volume) of the ventral tegmental area (VTA), substantia nigra (SN) and dorsal raphe nucleus (DRN). Data were analyzed by three-way ANOVA (Treatment x Age x Region). Data are presented as mean±SE. Means followed by different letters are statistically different. Theese results show that low-level Pb exposure during pregnancy and lactation induce neurochemical and morphological alterations in a brain region-specific manner that may be related to the behavioral alterations previously observed.

628 PERINATAL LEAD EXPOSURE ALTERS INOSITOL POLYPHOSPHATE RECEPTOR BINDING IN DEVELOPING RAT BRAIN.

C. S. Chetry[1], G. R. Reddy[1], A. Suresh[1], B. Nykeba[1], G. Gunasekharan[4] and D. Desaiah[5]. *[1]Biology, Savannah State University, Savannah, GA, [2]Biology, Savannah State University, Savannah, GA, [3]Biology, Savannah State University, Savannah, GA, [4]Biology, Fisk University, Nashville, TN and [5]Baxter BioScience, Baxter Healthcare Corp, Glendale, CA.*

Lead (Pb), an environmental neurotoxicant is known to mimic or inhibit the actions of calcium in biological systems and alter calcium mediated cellular processes. The phosphoinositide (PI) cycle is a major second messenger system that is involved in the release and regulation of calcium.Our recent studies demonstrated that the developmental Pb-exposure decreased calcium/calmodulin dependent nitric oxide synthase (NOS) activity in rat brain. In the present study, we examined the effects of Pb and NOS-modulators, L-nitroarginine (NA), 7-nitroimidazole (NI) and sodium nitroprusside (SNP) on inositol 1, 4, 5 trisphosphate (InsP3) and inositol 1, 3, 4, 5-tetrakisphosphate (InsP4) binding to membrane receptors in the cerebellum and hippocampus of Sprague-Dawley rat brain. Pb-exposure was initiated on gestation day 6 (GD6) and continued through postnatal day 21 (PND 21) for *in vivo* studies; whereas adult brains were used for *in vitro* studies. The results showed a progressive increase in the binding of InsP3 and InsP4 in both hippocampus and cerebellum during postnatal development following Pb-exposure. The *in vitro* studies also showed similar increase in the binding by Pb or NOS inhibitors (NA and NI) in a concentration-dependent manner; however, SNP (NO-donor), significantly decreased InsP3 and InsP4 binding. These results suggest that Pb alters the PI pathway leading to alterations in intracellular calcium homeostasis and provide evidence for the interrelationship between NOS and PI cycle. (Supported by NIH/GM 60853).

629 ENVIRONMENTAL ENRICHMENT REVERSES COGNITIVE DEFICITS INDUCED BY LEAD.

C. D. Toscano, J. L. McGlothan, S. A. Weaver and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Children exposed to lead (Pb2+) exhibit long-term deficits in cognitive function. A recent study has shown that chelation therapy, the primary means of treating Pb2+-poisoned children, has no significant impact on Pb2+-induced cognitive deficits (Rogan et al., N.Eng.J.Med.. 344: 1421, 2001). Thus, finding alternative intervention strategies is imperative. We have previously described that rats exposed to Pb2+ during gestation and lactation until weaning, exhibit deficits in spatial learning as young adults (Kuhlmann et al., Neurosci.Lett. 233: 101, 1997). Using this Pb2+ exposure protocol, we set out to determine if environmental enrichment (EE) affected the learning deficits induced by Pb2+. One male rat from control or Pb2+-exposed litters was randomly assigned to standard or EE housing. The latter contained platforms, tunnels, toys, a hammock and a running wheel. Standard housing consisted of one rat per cage, while EE housing had 8 rats of the same treatment per cage. Rats were reared under these housing conditions from postnatal day 21 (weaning) until the end of the water-maze spatial learning task that started at postnatal day 50. Lead-exposed rats reared in EE cages acquired the spatial learning task to the same degree as control EE rats. On the other hand, Pb2+-exposed rats reared in standard housing conditions were markedly impaired in the acquisition of the spatial learning task. Probe test data confirmed that Pb2+-exposed rats housed in an enriched environment were able to learn the task while those in standard housing did not. No group differences were noted for body weight, swimming speed or cue-test (non-spatial). These findings demonstrate for the first time that EE initiated after developmental exposure to Pb2+ is able to totally reverse the spatial learning deficits induced by Pb2+. In summary, our studies suggest a new direction for the treatment of children with learning disabilities resulting from environmental Pb2+ exposure. [Supported by grant # ES06189 to TRG].

630 ALTERED NEUROGENESIS IN THE DENTATE GYRUS OF LEAD-EXPOSED RATS: PRELIMINARY FINDINGS.

T. Verina, C. D. Toscano, J. L. McGlothan and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University, Baltimore, MD.*

Chronic exposure to lead (Pb2+) during development diminishes spatial learning in young adult rats [Nihei et al., Neuroscience 99: 233, 2000]. Recent studies suggest that modulation of neurogenesis in the dentate gyrus (DG) can influence the ability to learn a spatial learning task. To investigate whether Pb2+-induced spatial learning deficits are associated with altered neurogenesis in the DG, we examined cell proliferation in rats chronically exposed to Pb2+ using the thymidine analog bromodeoxyuridine (BrdU). Rats were injected with BrdU (200 mg/kg or 100 mg/kg daily) and perfused transcardially (two hours or five days, respectively) at postnatal day 50. BrdU labeled cells were counted in the suprapyramidal blade (SPB), infrapyramidal blade, dentate crest, and hilus. BrdU-labeled cells localized in the subgranular zone (SGZ) of the DG were irregular in shape and frequently arranged in clusters. Within the granular cell layer, labeled cells were seen occasionally and only after five days of BrdU injection. In rats perfused two hours after BrdU injection, cell counts showed no significant differences in any DG region as a function of treatment. On the other hand, significant treatment effects on the number of BrdU labeled cells were found in animals injected for five days. Pb2+-exposed rats exhibited a lower number of BrdU labeled cells in the SGZ of the suprapyramidal blade (24.3%, $p < 0.05$) and in the SGZ and granule cell layer of the suprapyramidal blade combined (21.8%, $p < 0.05$). Total number of BrdU labeled cells in the entire SGZ were also decreased, but the difference did not reach statistical significance ($p = 0.091$).These observations suggest that chronic developmental exposure to Pb2+ decreases net neurogenesis, possibly by reducing the survival of proliferating cells in specific areas of the DG. This alteration in DG neurogenesis may reflect a novel mechanism by which developmental exposure to Pb2+ causes deficits in spatial learning [Supported by grant # ES06189 to TRG].

631 GESTATIONAL EXPOSURE TO METHYLMERCURY RETARDS OPERANT BEHAVIOR IN TRANSITION IN ADULT RATS.

M. C. Newland, P. A. Reile, J. L. Langston and E. M. Paletz. *Psychology, Auburn University, Auburn, AL.*

Evidence is growing that developmental exposure to methylmercury (MeHg) has behavioral effects that extend into adulthood and aging. To study MeHg's prolonged effects on behavioral plasticity, rats were exposed to methylmercury during gestation *via* maternal drinking water containing 0, 0.5 or 6.4 ppm Hg as MeHg. Exposure began at least four weeks before mating, and continued to post-natal day 16. Brain Hg concentrations were 0.49 and 9.8 ppm at birth in littermates of the rats described here; lactation resulted in no mercury exposure. The behavior of one- and two-year old offspring was maintained under various Concurrent Variable Interval reinforcement schedules in which pressing each of two levers was maintained by independent Variable Interval t schedules of reinforcement, and t is the average inter-reinforcer interval. During the first 30 minutes of 150 min. sessions, the reinforcement rates on both levers were equal, and the ratio of left to right (L:R) lever presses approximated 1.0. After 30 min. the left lever became rich relative to the right, the right became relatively rich, or there was no change. During sessions in which one lever became rich, responding was tracked as it transitioned to reflect the new allocation of reinforcers. Terminal reinforcer ratios (L:R) used were 9:1, 4:1, 3:1, 1:1, 1:3, 1:4, and 1:9). In controls and most exposed rats, response ratios reflected reinforcer ratios by the end of the session. The transitions of many exposed rats were retarded relative to controls, and in some transitions they went in the wrong direction. The tactic used here greatly reduced the time required to study behavior in transition from a month in previous reports to a single session here. (Supported by ES06466 from NIEHS).

632 GESTATIONAL EXPOSURE TO CHLORPYRIFOS: QUALITATIVE AND QUANTITATIVE NEUROPATHOLOGICAL CHANGES IN THE FETAL NEOCORTEX.

T. L. Lassiter[1,2], L. D. White[2], S. Padilla[2] and S. Barone[2]. [1]*Toxicology, University of North Carolina, Chapel Hill, NC and* [2]*Neurotoxicology, USEPA, Research Triangle Park, NC.*

This study investigated the qualitative and quantitative neuropathological changes that occur in the fetal brain following gestational exposure to chlorpyrifos [(O, O'diethyl O-3, 5, 6-trichloro-2-pyridyl) phosphorothionate], a commonly used organophosphorus insecticide. Two cohorts of pregnant rats were orally dosed daily with chlorpyrifos in corn oil on gestational days 14-18. Cohort A consisted of a time course study of fetuses collected at 2, 5, 10, and 24 hours after the last dose of chlorpyrifos (0 or 7 mg/kg/day). Cohort B is a replication of Cohort A and includes a Dose-Response component at 5 hours (0, 1, 3, 5, and 7 mg/kg/day of chlorpyrifos). Fetal brain total cholinesterase, acetylcholinesterase, or butyrylcholinesterase activities were 70, 75, or 53 % of control activity 5 hours after the last 7 mg/kg dose of chlorpyrifos. Fetal brain sections stained with cresyl violet for neuropathological assessments showed overt pathology in the neocortex, consisting of vascular alterations, disorganized migratory waves, ectopic cells, neuropathological holes, and qualitative thinning of the ventricular zone and cortical plate. Neuropathological changes were evident at dosages as low as 1 mg/kg/day. Stereology used to quantify the volume of the ventricular zone, subventricular zone, and cortical plate in the fetal neocortex showed limited treatment-related changes in the volume of the subventricular zone at 7 mg/kg/day but no changes in other neocortical laminae. We conclude that repeated, gestational exposure to chlorpyrifos not only inhibits cholinesterase activity in the fetal brain, but also causes neuropathological changes in the fetal neocortex. This abstract does not reflect EPA policy.

633 PRENATAL EXPOSURE TO CHLORPYRIFOS ALTERS NEUROTROPHIN IMMUNOREACTIVITY AND APOPTOSIS IN RAT BRAIN.

L. D. White[1], T. L. Lassiter[2,1], K. P. Das[2,1] and S. Barone,Jr[1]. [1]*NTD, USEPA, Research Triangle Park, NC and* [2]*Curr Toxicology, UNC-Chapel Hill, Chapel Hill, NC.*

The effects of the organophosphate pesticide chlorpyrifos (CPF) on the regional distribution of three neurotrophic factors that regulate brain development and on levels of apoptosis. Pregnant Long-Evans rats were dosed daily (*p.o.*) with CPF (0, 3, 5, 7, and 10 mg/kg) in corn oil on gestational days 14-18. Fetuses were examined at 2, 5, 10, and 24 hr after the last dose. Immunohistochemistry (IHC)showed very little nerve growth factor (NGF) immunoreactivity (IR) in the fetal brain. There was significant brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) IR in the ventricular and subventricular zones fetal brains. BDNF IR was widely and spottily distributed throughout the intermediate zone and cortical plate of the control neocortex. There was a decrease in BDNF and NT-3 IR in the brains of CPF treated fetuses. These CPF-related changes in NTF-IR are consistent with quantitative changes in whole brain BDNF and NT-3 levels determined by enzyme-linked immunoabsobent assays(ELISA)'s. The IHC demonstrates that these changes are limited primarily to proliferative zones of the forebrain. Results from cell death ELISA showed the highest level of DNA fragmentation at the 7 mg/kg/day dosage at 5 hr after the last dose. Terminal transferase dUTP nick end-labeling (TUNEL) assays of fetal brains showed increased numbers of apoptotic cells in the striatum, hippocampus and cortical plate. This apparent increase in apoptosis was localized primarily to proliferative zones in the striatum and the hippocampus. The altered pattern of apoptosis in the fetal brains of CPF-exposed rats were reciprocal to changes in BDNF and NT-3 IR in proliferative and post migratory zones. This observed increase in apoptosis could be due to the changes in neurotrophin levels. Further, these changes in regional levels of neurotrophins and apoptosis with CPF exposure suggest possible alterations in cell number and function that could persist in the adult nervous system.This abstract does not reflect EPA policy.

634 CHLORPYRIFOS ALTERS GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) IN THE DEVELOPING RAT BRAIN: DISRUPTION OF ASTROCYTE DEVELOPMENT?

S. J. Garcia, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Despite limitations recently imposed on the organophosphorus pesticide, chlorpyrifos (CPF), concerns remain regarding its potential neurotoxicological properties in the developing nervous system. CPF inhibits brain cell replication and perturbs differentiation but the specific types of cells targeted by CPF have not yet been identified. CPF affects gliotypic cells in culture. We therefore administered CPF to developing rats and examined expression of the astrocytic protein, GFAP, using immunoblotting. Prenatal treatment increased GFAP levels in fetal brain only at CPF exposures that elicited maternal toxicity (reduced weight gain), and no persistent changes were seen as late as postnatal day (PN) 30. CPF treatment on PN1-4, at doses below the threshold for systemic toxicity (1 mg/kg/day) elicited initial suppression and rebound elevation of GFAP, limited to the cerebellum of males. Bergmann glia, responsible for guiding neuronal migration, are emerging in the cerebellum at that time, and our results may thus explain the targeting of motor function in males with this treatment regimen. When we gave CPF later, during the peak of gliogenesis (PN11-14, 5 mg/kg/day), GFAP showed initial deficits across all brain regions and in both sexes; rebound elevations (PN30) were seen in all regions in males, with the largest effect in striatum (significant for both males and females). Our results indicate that CPF targets glial development *in vivo*, so that the postnatal period is a critical period of susceptibility. The region-, sex-, and time-dependent effects on astrocytes are likely to contribute to comparably selective alterations in synaptogenesis, axonogenesis, and ultimately, behavior. Glial targeting suggests that the vulnerable period for CPF neurotoxicity extends relatively late in brain development, into the phases of synaptic plasticity, myelination, and architectural modeling. (Supported by USPHS ES10356, ES10387, and an EPA STAR fellowship)

635 DEVELOPMENTAL NEUROTOXICITY OF CHLORPYRIFOS: DEFINING THE VULNERABLE PERIOD.

D. Qiao, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

There is concern over the consequences of fetal and childhood exposure to chlorpyrifos (CPF) and related pesticides. In previous work, we found that neonatal CPF produced cell damage/loss in the brain, with abnormalities of neurotransmission and attendant behavioral anomalies. We used the same biomarkers to examine prenatal treatment "windows" to define the critical periods in which neural and synaptic development show immediate effects of CPF. One group of pregnant rats received 0, 1, 2 or 5 mg/kg daily by sc injection from gestational days (G) 9-12, during neural tube formation. A second group received 0, 1, 2, 5, 10, 20, or 40 mg/kg daily on G17-20, a peak period of neurogenesis. In the G9-12 treatment group, the threshold for maternal toxicity, defined by reduced weight gain, was 5 mg/kg; however, even this was only a transient reduction. There was no reduction in the number of fetuses assessed on G17 or G21, nor were there significant changes in fetal weight, brain weight, heart weight or liver weight. When the treatment window was shifted to G17-20, the threshold for impairing maternal weight gain was slightly higher (10 mg/kg), and although a similar threshold was seen for impairment of fetal body and liver weights, both the heart and brain were spared. DNA content, a marker for cell number, was unaffected in brain regions, although reductions were seen in the fetal liver at doses exceeding the threshold for maternal toxicity. These results stand in contrast to the robust effects seen previously for im-

mediate effects of postnatal CPF treatment on brain development, where apparently subtoxic doses nevertheless elicit reductions in brain cell number. It remains possible that defects from prenatal CPF exposure may emerge later in development; we have preliminary evidence that behavioral anomalies emerge in adolescence or young adulthood. However, in terms of immediate biomarkers of neuronal damage, it appears that later stages of development are more sensitive. (Supported by USPHS ES10387 and ES10356, and by the Leon Golberg Toxicology Fellowship)

636 NEUROCHEMICAL EFFECTS OF REPEATED DEVELOPMENTAL EXPOSURES TO CHLORPYRIFOS ON THE CHOLINERGIC NERVOUS SYSTEM.

J. R. Richardson and J. E. Chambers. *Center for Environmental Health Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS.*

Neurochemical components of the cholinergic system play critical roles in the development of the nervous system. The widely used organophosphorus insecticide chlorpyrifos (CPS) has been shown to affect the levels or activities of many of these components. The effects of repeated exposures to CPS during the gestational and postnatal periods on the activities of brain cholinesterase (ChE) and choline acetyltransferase (ChAT) were studied. Pregnant Sprague-Dawley rats were orally administered CPS daily from gestation days 6-20 at doses of 0 (control; C) or 5 mg/kg/day (5). Following parturition, designated as postnatal day (PND) 0, pups were orally gavaged with CPS from PND1-21 at doses of 0 (control; CC and 5C), 0.75 (low dose; CL and 5L), or incremental doses of 0.75 to 3 mg/kg/day (high dose; CH and 5H). Pups were sampled on PND1, 6, 12, 22, and 30. ChE and ChAT activities increased about 3.3 and 11-fold from PND6 to PND30, respectively. ChE was inhibited by about 26% on PND1 in the 5C group and had returned to control values by PND6. ChE was inhibited in a dose-related manner in all treatment groups, with inhibition of about 22 and 24% on PND6 in the CL and 5L groups, respectively; and on PND12 by about 23, 51, 31, and 47% in the CL, CH, 5L, and 5H groups, respectively. ChE inhibition on PND22 was about 12, 52, 16, and 52% in the CL, CH, 5L, and 5H, respectively, and persisted in the CH (22%) and 5H (24%) groups through PND30. ChAT activity was decreased by about 11% only in the 5H group on PND22 and 30. These data suggest that exposure to CPS during the gestational and postnatal periods results in relatively persistent inhibition of ChE. In addition, exposure to CPS during the gestational period may have resulted in an increased susceptibility of these animals to decreases in ChAT activity elicited by subsequent postnatal exposures to low levels of CPS. (Partially supported by NSF EPS-9874669)

637 BEHAVIORAL EFFECTS IN TWO GENERATIONS OF RATS FOLLOWING DAILY PRE/POSTNATAL EXPOSURE TO TECHNICAL CHLORDANE.

V. V. St.Omer[1], K. M. Mizinga[2], B. C. Datiri[1], E. O. Abdalla[1], M. M. Mansour[1], F. Johnson[1] and R. D. Mosha[3]. *[1]Biomedical Sciences, College of Veterinary Medicine, Tuskegee University, Tuskegee, AL, [2]Pharmacology, University of Health Sciences, Kansas City, MO and [3]Veterinary Physiology, Sokoine University of Agriculture, Sokoine, Tanzania.* Sponsor: R. Dalvi.

Male and Female Sprague-Dawley rats were used in a two-generation study to evaluate neurobehavioral toxicities of technical grade chlordane, a mammalian toxicant and formerly used pesticide, now persistent in the environment. Adult and juvenile rats (F0, F1, F2) were exposed (in replicate-1) to continuous levels of chlordane (0.0, 0.125, 0.25 and 1.0 mg/kg) by daily oral gavage. Offspring (F1 and F2) were exposed *via* dam in-utero and *via* lactation until weaning. In the F1 generation, chlordane at 1 mg/kg body weight (bw) delayed ($p < 0.05$) male and female negative geotaxis (PND 7-10), and olfactory discrimination (PND 11), but advanced both surface righting reflex (PND 3-4) and spatial learning abilities in Morris maze (PND 77); at 0.25 mg/kg chlordane advanced female Morris maze spatial learning. For F2 generation, chlordane at 1 mg/kg/bw. delayed female olfactory discrimination and fore-limb grip strength; at 0.25 mg/kg chlordane delayed male and female surface righting reflex and male hind-limb grip strength. In general, chlordane manifested greater neurobehavioral changes in the F1 generation compared to F2. The female rats were more sensitive than the males to chlordane effects (Supported by MHPF/ATSDR # U50/ATU3922660008)

638 REPRODUCIBILITY OF DEVELOPMENTAL NEUROTOXICITY PRODUCED BY PYRETHROIDS AND DDT IN NEONATAL MICE.

D. E. Ray[1], R. D. Verschoyle[2] and B. Y. Muhammad[3]. *[1]MRC Applied Neuroscience Group, School of Biomedical Sciences, Nottingham, United Kingdom, [2]MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom and [3]Department of Pharmacology, Usumanu Danfodiyo University, Sokoto, Nigeria.* Sponsor: K. Crofton.

Eriksson et al.(1) found that mice showed persisting changes in neurochemistry and behaviour after administration of very low doses of pesticides such as pyrethroids or DDT to the neonate. We examined the reproducibility of these effects. Three trials of a single dose of DDT (1mg/kg) to 10 day old mouse pups produced small but significant decreases ($p<0.01$ or <0.001) in neocortical muscarinic receptor density at 4 months in each trial. This effect was also seen at 0.5, 5 & 100 mg/kg, and resembled that reported by Eriksson et al. (1). After daily administration of pyrethroids (bioallethrin or deltamethrin) (0.7 or 3.5mg/kg) from the 10th to the 16th postnatal day, neocortical muscarinic receptor binding at 4 months showed no consistent changes. Behavioural tests at 4 months showed significantly delayed habituation of open field behaviour in only one trial and at one DDT dose level. Neither pyrethroid produced a change in habituation. Although our baseline values for muscarinic receptor density (813-1321 fmol/mg protein) were similar to those reported by Eriksson et al. (1), we could not reproduce the rapid habituation shown by their control mice, despite the use of the same strain and similar test conditions. We can confirm the reported developmental effects of DDT on muscarinic receptors but found that those of pyrethroids were not reproducible. Reported behavioural effects were also not reproducible, although the latter may be due to baseline differences. We conclude that although neonatal exposure to DDT produces reproducible and lasting changes in neurochemistry, pyrethroids do not produce a robust effect, possibly due to their rapid disposal from the body or to a dependence on as yet undefined variables. (1) Eriksson P, Ahlbom J & Fredriksson A (1992 Brain Res. 582, 277-281

639 EFFECTS OF DEVELOPMENTAL EXPOSURE TO HEPTACHLOR ON THE CHOLINERGIC SYSTEM IN RATS.

S. Purkerson-Parker[2,1], K. L. McDaniel[1] and V. C. Moser[1]. *[1]NTD/NHEERL/ORD, USEPA, Research Triangle Park, NC and [2]Curriculum in Toxicology, UNC, Chapel Hill, NC.*

Heptachlor is an environmentally persistent cyclodiene pesticide which is a known antagonist of the γ-aminobutyric acid $(GABA)_A$ receptor. Since GABA is a trophic factor for the development of other neurotransmitter systems (Lauder *et al.*, Perspectives in Developmental Neurobiology 5:247-259, 1998) exposure to heptachlor may affect neuronal development. To determine the developmental effects of heptachlor, one group of rats was orally dosed with 0 or 4.2 mg/kg/day of heptachlor from gestational day (GD) 10 to postnatal day (PND)21, and another group was dosed with 0, 0.3, or 3 mg/kg/day from GD10 to PND42. From PND2-5 there was a delay in righting reflex ontogeny in pups exposed gestationally to 3 mg/kg/day of heptachlor. In adult rats dosed with 3 mg/kg/day of heptachlor from GD10 to PND42, there was a significant decrease in muscarinic acetylcholine receptor binding in the cerebellum, but not in the striatum or frontal cortex. In adult rats dosed with 4.2 mg/kg/day of heptachlor from GD10 to PND21, there was a decreased hypothermic response to oxotremorine. An increased response to scopolamine on motor activity was observed in adults exposed to 3 mg/kg/day from GD10 to PND42. These data suggest a functional consequence of fewer muscarinic acetylcholine receptors. Thus, exposure to heptachlor during development resulted in a developmental delay and long-lasting alterations of the cholinergic system. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

640 EFFECTS OF CHRONIC BLOCKADE OF SODIUM CHANNELS AND NMDA RECEPTORS DURING DEVELOPMENT ON THE ACQUISITION AND PERFORMANCE OF SEVERAL COGNITIVE FUNCTION TASKS IN RATS.

M. G. Paule[1], C. M. Fogle[1], R. R. Allen[1], E. Pearson[2], T. Hammond[3] and E. J. Popke[1]. *[1]Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR, [2]Peak Statistical Services, Evergreen, CO and [3]Safety Assessment, AstraZeneca, Loughborough, United Kingdom.*

The effects of MK-801 (a relatively selective NMDA receptor antagonist), phenytoin (a sodium channel blocker) and a combination of the two on the acquisition and performance of several complex, food-reinforced operant behaviors were assessed in juvenile female rats. Audio/visual discrimination (AVD), learning (LRN), and motivation (MOT) were modeled using conditioned position responding, incremental repeated acquisition and progressive ratio tasks, respectively. LO and HI doses of both drugs (0.1 and 1.0 for MK-801, 30 and 150 mg/kg/day for phenytoin, PHT) and LO and HI dose combinations (COMB) of both drugs were administered once daily, 7 days/week by oral gavage beginning on postnatal day (PND) 23. M-F behavioral assessments began on PND 27 and are ongoing (>PND 122). Over the duration of the study, HI MK-801 and HI COMB subjects exhibited decreased body weight gains and performance in all three behavioral tasks (the performance and body weight gain of all other groups was similar to that of controls). For these two affected groups, response rates were decreased in all tasks, indicating decreased motivation and/or motoric capabilities. Accuracy was decreased for both these groups in the AVD task, but only for the HI MK-801 group in the

LRN task. Thus, chronic treatment during development with LO or HI PHT, LO MK-801 or LO COMB had little or no effects, while HI MK-801 and HI COMB differentially affected accuracy of performance of two cognitive function tasks. These data suggest that, during development in the rat: blockade of sodium channels is well tolerated and that blockade of NMDA receptors alone has significant adverse consequences for the development of important cognitive functions.

641 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) IMPAIRS SPATIAL LEARNING AND ALTERS HIPPOCAMPAL MORPHOLOGY IN FEMALE MICE HETEROZYGOUS FOR THE ARYL HYDROCARBON RECEPTOR.

B. E. Powers[1], T. M. Lin[3], A. Vanka[1], J. Juraska[2], R. Peterson[3] and S. Schantz[1]. *[1]Veterinary Bioscience, University of Illinois, Champaign, IL, [2]Psychology, University of Illinois, Champaign, IL and [3]School of Pharmacy, University of Wisconsin-Madison, Madison, WI.*

Gestational and lactational exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) has been reported to alter spatial learning and memory in rats tested on a radial arm maze (RAM). TCDD is believed to exert most of its effects through binding to the aryl hydrocarbon receptor (AhR). To determine if TCDD-induced alterations in spatial learning are mediated by the AhR, we tested male and female AhR knockout ($AhR^{-/-}$), heterozygous ($AhR^{+/-}$), and wild-type ($AhR^{+/+}$) mice on the 8-arm RAM. Following testing on the maze we examined hippocampal morphology using the Timm's silver-sulfide stain. This stain permits accurate measurement of the intra- and infrapyramidal mossy-fiber field (IIP-MF), the area of which has been reported to correlate with RAM learning. $AhR^{+/-}$ males and females were timemated, the dams were dosed with 0 or 5 µg TCDD/kg body weight on day 13 of gestation and the pups were weaned on postnatal day 21. Upon maturation, male and female $AhR^{+/+}$, $AhR^{+/-}$, and $AhR^{-/-}$ mice from TCDD-exposed and unexposed litters were tested on the RAM. Following testing their brains were processed for staining. TCDD-exposed female $AhR^{+/-}$ mice made significantly more errors on the RAM than their respective controls and exhibited a decrease in the relative size of the IIP-MF. None of the other TCDD-exposed groups differed from their respective controls with regard to maze performance or hippocampal morphology. The reduction in IIP-MF area provides a morphological basis for the learning deficit that was observed in the female $AhR^{+/-}$ mice. The role of the AhR remains unclear, but the data suggest that the amount of receptor and sex of the animal interact in some way. Possibly, the AhR interacts with hippocampal steroid or glucocorticoid receptors and/or their pathways. (Supported by NIH Grant ES01332)

642 EVIDENCE THAT GABAERGIC NEURONS OF THE PREOPTIC AREA OF THE BRAIN ARE TARGETS OF TCDD REPRODUCTIVE TOXICITY IN ADULT AND PERINATAL RATS.

J. Laroche, L. Hays, C. Carpenter and S. L. Petersen. *Biology, University of Massachusetts—Amherst, Amherst, MA.*

Acute or chronic exposure to the arylhydrocarbon receptor (AhR) ligand, 2, 3, 7, 8-tetrachlor-*p*-dibenzodioxin (TCDD), in adulthood or during development interferes with reproductive functions. However, it has been debated whether TCDD exerts these effects directly by binding to the AhR in specific brain regions, or secondarily through effects on liver or peripheral tissues. We previously found that, in the rat, mRNAs encoding arylhydrocarbon receptor (AhR), as well as its companion proteins, arylhydrocarbon receptor nuclear translocator (ARNT) and ARNT2 are present in a number of regions important for reproductive function. In the present studies, we used *in situ* hybridization histochemistry (ISHH) to map these genes in perinatal rat brains and found that they were expressed in the same regions as in adults. Of particular importance, we found them expressed in the anteroventral periventricular/median preoptic nucleus (AVPV/MPN) region, a region known to be sexually dimorphic and to play a critical role in estradiol-dependent preovulatory luteinizing hormone (LH) surge release in females. GABAergic neurons in this region have estrogen receptors (ER) and are important for the generation of the LH surge. Therefore, we next used dual-label ISHH and found that glutamate decarboxylase (GAD; a marker of GABAergic neurons) and AhR genes are expressed in the same cells in the AVPV/MPN region, as well as throughout the brain in both adults and perinates. Furthermore, we found that a single exposure to 1 microgram/kg of TCDD on gestational day 15 and through lactation abolished sexual differences in GAD gene expression in the AVPV/MPN region in animals examined at postnatal day 3. These neuroanatomical findings support the hypothesis that GABAergic neurons in the preoptico-hypothalamic region mediate the developmental and adult effects of TCDD on fertility.

643 DEVELOPMENTAL EXPOSURE TO A BROMINATED FLAME-RETARDANT, 2, 2', 4, 4', 5, 5'-HEXABROMO-DIPHENYL ETHER (PBDE 153) AFFECTS BEHAVIOUR AND CHOLINERGIC NICOTINIC RECEPTORS IN BRAIN OF ADULT MICE.

H. Viberg, A. Fredriksson and P. Eriksson. *Envrionmental Toxicology, Uppsala University, Uppsala, Sweden.*

Flame-retardants are used to suppress or inhibit combustion processes in order to reduce the risk of fire. One class of flame-retardants, polybrominated diphenyl ethers (PBDEs), have been found to increase in the environment and in human mother's milk. In recent studies we have seen that neonatal exposure to some brominated flame-retardants, such as PBDE 47, PBDE 99 and PBDE 209, can cause permanent aberrations in spontaneous behaviour, an effect that worsen with age. PBDE 99 and PBDE 209 have also been shown to induce these effects during a defined critical phase of neonatal brain development. In view of an increasing amount of PBDEs in mother's milk and in the environment, the present study was undertaken to investigate whether PBDE 153 can induce persistent neurotoxic effects on spontaneous behaviour, learning and memory and cholinergic nicotinic receptors in mice. Mice were exposed to 0.45, 0.9 or 9.0 mg PBDE 153/kg body weight on postnatal day 10. Spontaneous behaviour was observed in 2-, 4- and 6-months-old mice, and mice exposed to 0.9 or 9.0 mg PBDE 153/kg body weight on postnatal day 10 showed significantly impaired spontaneous motor behaviour at all three testing occasions. This effect worsened with age. At 6 month of age learning and memory was assessed in a Swim maze of Morris water maze type. The ability to locate the platform was significantly impaired in animals neonatally exposed to 0.9 or 9.0 mg PBDE 153/kg body weight, compared to control animals. The mice were sacrificed at 6 months of age and analyzed for cholinergic nicotinic receptors in hippocampus using α-Bungarotoxin. There was a significant decrease in the density of specific [^{3}H]-α-Bungarotoxin binding sites in the hippocampus in mice exposed neonatally to 9.0 mg PBDE 153/kg body weight. In conclusion, neonatal exposure to PBDE 153 induces behavioural derangements in adult mice as well as defects learning and memory. In addition, the cholinergic nicotinic receptors in hippocampus were affected.

644 DEVELOPMENTAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHERS DOES NOT ALTER SYNAPTIC TRANSMISSION OR LTP IN HIPPOCAMPUS.

M. E. Gilbert and K. M. Crofton. *Neurotoxicology, USEPA, Research Triangle Park, NC.*

Polybrominated diphenyl ether (PDE) flame retardants bioaccumulate in the environment, in wildlife, and in humans. Concern has been raised over potential thyrotoxic effects of this class of xenobiotics. Severe hypothyroidism during critical periods of brain development leads to alterations in hippocampal structure and physiology and produces learning deficits. The present work examined field potentials evoked in the dentate gyrus of adult offspring of dams treated daily with 0 or 30 mg/kg of DE71, a commercial PDE mixture, from gestational day 6 to weaning at postnatal day (PND)21. This regimen produced moderate decreases (~55%)in thyroxine (T4) during the early postnatal period that returned to control levels by PND36. Triiodothyronine (T3) was unaffected. Male offspring(4-8 mon)were anesthetized with urethane and electrodes implanted in the perforant path and dentate gyrus. Input/output (I/O) functions were collected to assess the integrity of synaptic transmission. Long-term potentiation (LTP) was induced by delivering theta burst stimulation at a modest stimulus intensity of 300µA and I/O functions were re-evaluated 1 hr later. Thereafter, a second set of trains at maximal stimulus intensity (1500 µA) was administered and a third I/O collected 15 min later. No alterations in population spike, EPSP slope, or postsynaptic potential amplitudes were observed in baseline I/O recordings of DE71-treated animals relative to controls. Modest LTP was observed in both groups in response to the low intensity train stimulation, and robust LTP was induced by the higher intensity train series. No group differences in LTP magnitude were revealed. The lack of effects of PDE differs from the response to either propylthiouracil or A1254, agents that also transiently reduce thyroid hormones during development, albeit it to a greater degree. These data suggest that the modest reductions in T4 induced by this dosing regimen with DE71 were not sufficient to alter synaptic transmission in the dentate gyrus of the hippocampus. *(Does not reflect USEPA policy).*

645 INTERACTIVE EFFECTS OF METHYLMERCURY AND PCB MIXTURES ON NEURODEVELOPMENT IN MICE.

S. Lee and R. S. Yang. *Quantitative and Computational Toxicology Group, Center for Environmental Toxicology and Technology, Environmental Health, Colorado State University, Fort Collins, CO.*

To examine the effects of methylmercury (MeHg) and PCB congeners either alone or in combination on neurodevelopment, several neuronal proteins were measured in the neonatal mice at different time points. From gestation day 10 until postnatal

day (PND) 21, each group of pregnant C57BL/6 mice were exposed to control, methylmercury alone (40 ug/kg), PCB 153 alone (5 mg/kg), PCB 126 alone (5 ug/kg), the mixture of PCB 153 (5 mg/kg) and PCB 126 (5 ug/kg), the mixture of PCB 153 (5 mg/kg) and methylmercury (40 ug/kg), and the mixture of all chemicals. The mortality rate of neonatal mice in the group treated by MeHg alone was about 70 %, whereas those in the other mixture group (the mixture of MeHg and PCB 153 and the mixture of all chemicals) was under 10% suggesting antagonism toward MeHg toxicity. At PND 9, 16, 23, and 30, brains of neonatal mice from each group were collected and dissected into cerebellum, hippocampus, and cerebral cortex. Western blot analysis was performed to measure CREB, ERK 1/2, PKC, CaMK II, and CaMK IV in each brain regions. Preliminary results showed that the expression of CREB in cerebellum of the group exposed to the mixture of all chemicals increased four times higher than control at PND 9 but decreased dramatically after that, resulting in the 50 % decrease comparing with control at PND 30. The expression of CREB in hippocampus showed similar pattern, but the extent of differences in the expression was smaller than in cerebellum. The expression of CaMK IV in hippocampus of the group exposed to the mixture of all chemicals decreased comparing with control at PND 9. However, the expression of CaMK IV in cerebellum of the group exposed to the mixture of all chemicals increased comparing with control at PND. These results suggest that repeated exposure to methylmercury and PCBs *via* gestational and lactational transfer affects normal expression of neuronal proteins in a non-additive manner. (Supported by NIEHS R03 ES10116)

646 PERINATAL EXPOSURE TO A POLYBROMINATED DIPHENYL ETHER MIXTURE (DE-71) DISRUPTS THYROID HORMONES BUT NOT NEUROBEHAVIORAL DEVELOPMENT.

M. M. Taylor[1], J. M. Hedge[1], M. J. DeVito[2] and K. M. Crofton[1]. [1]*Neurotoxicology Division MD-74B, NHEERL, ORD, USEPA, Research Triangle Park, NC and* [2]*Experimental Toxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

Polybrominated diphenyl ethers (PBDEs), produced commercially as mixtures, are used as flame-retardants for numerous consumer products. Because of their lipophilicity and persistence, PBDEs have become ubiquitous environmental contaminants. Previous work in our Lab. has demonstrated that short-term (4 day) *in vivo* exposure to DE-71 in young rats (a commercial polybrominated diphenyl ether mixture containing mostly tetra- and penta-bromodiphenyl ethers) induces hypothyroxinemia. In this study, motor and auditory function were measured in offspring following perinatal maternal exposure to DE-71. Primiparous rats were orally administered DE-71 (0, 1, 10 and 30mg/kg/day) in corn oil from gestation day 6 (GD6) to postnatal day 21 (PND21). Offspring were evaluated at various ages for body weight, thyroid hormones, hepatic enzymes, eye opening, survival, motor activity development, and auditory startle response. There was no effect of DE-71 on body weight gain or survival in either the dams or offspring. There were dose-dependent decreases in thyroxine (maximal decrease of 55% on PND14), and increases in hepatic glucuronidation (3-fold). Both endpoints return to control levels by PND36. There were normal age-dependent changes in motor and sensory behaviors, but no effects of treatment. Benchmark dose (BMD) modeling resulted in BMDs of 2.3 and 5.5 mg/kg/day, and BMDLs (lower bound) of 0.9 and 3.4 mg/kg/day, for serum T4 and hepatic glucuronidation, respectively. These data suggest that DE-71 alters thyroid homeostasis during development, but does not seem to alter sensory or motor development as determined by these endpoints. *This abstract does not necessarily reflect USEPA policy.*

647 LONG-LASTING NEUROSTRUCTURAL CONSEQUENCES IN THE RAT HIPPOCAMPUS BY DEVELOPMENTAL EXPOSURE TO A MIXTURE OF POLYCHLORINATED BIPHENYLS.

R. F. Mervis[1], A. D. Bachstetter[1], G. J. Harry[2], H. A. Tilson[3] and P. S. Kodavanti[3]. [1]*Neuro-Cognitive Res. Labs, Columbus, OH,* [2]*NIEHS, NIH, Research Triangle Park, NC and* [3]*Neurotox Div., USEPA, Research Triangle Park, NC.*

The objective of the study was to assess the effects of developmental exposure to a commercial mixture of PCBs (Aroclor 1254) on neuronal dendritic morphology of hippocampal CA1 pyramidal neurons in postnatal day (PND) 22 and PND 60 male Long-Evans rats. Rat pups were born to mothers who were exposed to Aroclor 1254 (AccuStandard Inc.., Lot # 124-191; 0 and 6 mg/kg/day) from gestational day 6 through PND 21. Thus, pups were exposed to PCBs *in utero* and through weaning. Male rats (N = 5-6 per group) were sacrificed on PND 22 and PND 60. Brains were formalin-fixed for Rapid Golgi staining of tissue blocks; coded slides of hippocampus were prepared. For branching and spine analysis, 6 CA1 pyramids were randomly selected from each brain. Camera lucida drawings of the basilar dendritic tree were analyzed using the Sholl method of concentric circles. For spine analysis, counts were made along internal and terminal tip segments of 6-7 neurons from each brain. Results of the branching analysis for the PND 22 PCB-exposed rats showed that, compared to controls, there was significantly less dendritic branching in the outer 2/3rds of the dendritic tree ($p = 0.002$, Wilcoxon test). Spine analysis also showed a reduction in spines on the terminal tips segments of 22 day old PCB-exposed rats ($p=0.005$, T-test). These results suggest that perinatal exposure to Aroclor 1254 resulted in morphometric changes in hippocampus. By PND 60, spine density on terminal tip segments had returned to normal levels. However, branching analysis now showed that compared to controls there was an excessive amount of dendritic material in the distal 2/3rds of the tree ($p=0.001$, Wilcoxon test). This suggested a possible structural "hyperplasticity" in neurons damaged by PCB exposure during the developmental period with a residual long-term dysmorphic impact on hippocampal circuitry. (This abstract does not necessarily reflect USEPA policy).

648 DEVELOPMENTAL NEUROTOXICITY (DNT) STUDIES WITH TRIBUFOS (DEF) AND METHAMIDOPHOS.

L. P. Sheets, H. E. Hoss and S. G. Lake. *Toxicology, Bayer Corp., Stilwell, KS.*

DNT studies (OPPTS 870.6300) were conducted with two organophosphorus (OP) compounds in response to a data call-in notice issued by the USEPA. Each OP was administered *via* the diet at 4, 40 and 200 ppm for DEF and 1, 10 and 30 ppm for methamidophos to mated female Wister rats (n=20/level) from gestation day (GD) 0 through postnatal day (PND) 21 for the offspring. The offspring were evaluated for clinical signs, weight gain, sexual maturation, motor activity (figure-8 maze), auditory startle habituation, associative learning and memory (M-maze and passive avoidance), neuropathology and brain measurements. Whole-brain, erythrocyte and plasma cholinesterase (ChE) activities were measured in the dams on LD 21 and in the pups on PND 4 or 11 and again on PND 21. Slight ChE inhibition in the dam was the only effect at 40 ppm with DEF and 1 ppm with methamidophos. In pups, ChE inhibition occurred at the mid- and high-dietary levels of methamidophos and at the high dose only with DEF. Effects in pups at the higher doses included decreased weight gain and decreased motor activity during treatment, a reduced startle response on PND 22 and delays in vaginal patency (both OPs) and preputial separation (DEF only). With the high dose of DEF, absolute (but not relative) brain weight was reduced on PND 11 but not on PND 21 or 70. The only effect that persisted to term on PND 70-75 was a lower body weight at the high dose with DEF. Measures of cognition and habituation (motor activity and startle) were not affected and neuropathology was not evident with either OP at any dietary level. The overall NOELs in the dam and offspring were 4 ppm and 40 ppm, respectively, for DEF and <1 ppm and 1 ppm, respectively, for methamidophos. The overall NOEL in each study was based on inhibition of ChE activity in the dam. This outcome and the resulting overall NOELs are consistent with those of the two-generation reproduction studies.

649 CONTROL BEHAVIORAL DATA FROM DEVELOPMENTAL NEUROTOXICITY STUDIES (DNT)AND PERI-POSTNATAL STUDIES: IS SEXUAL MATURATION IN DNT STUDIES IMPROVED BY ANALYZING THREE PUP/SEX/LITTER?

J. R. Barnett, Jr, R. G. York, A. M. Hoberman and M. S. Christian. *Research, Argus Research a Division of Charles River Laboratories, Inc., Horsham, PA.*

Behavioral evaluations of the pup and adult rat (motor activity, acoustic startle habituation, sexual maturity) are requirements of DNT studies conducted under USEPA guidelines (OPPTS 870.6300). Learning and memory (i.e. passive avoidance and watermaze) and sexual maturity have been conducted as part of peri-postnatal studies since the mid-80s for pharmaceuticals. Relatively few DNT studies have been conducted to date, and the ranges of normal values for the various parameters have not been previously established. The behavioral values for control rats participating in nominally identical DNT and approximately 60 pharmaceutical testing studies have been compared. The results of approximately 40 studies were presented in 2000. Pregnant Sprague-Dawley rats were administered control substances orally beginning on Day 0 or 6 of gestation and continuing through Day 11 or 21/22 of lactation [Day of birth = DP 1]. Rats were tested for motor activity on DPs 14, 18, 22 and 61"2. Rats were tested for passive avoidance on DPs 24"1 and then retested one week later. Rats were tested for auditory startle habituation on DPs 23 and 61"2. Rats were tested in a watermaze on DPs 61"2 and retested one week later. Rats were evaluated for sexual maturity (female rats beginning on DP 28 and male rats beginning on DP 39). The availability of such control data for behavioral measurements will help clarify the extent to which between subject and between litter (sexual maturation) variation affects the statistical power of comparisons between treatment and control groups in DNT studies.

650 NEUROMORPHOLOGICAL EVALUATION OF CONTROL DATS FROM SEVEN DEVELOPMENTAL NEUROTOXICITY STUDIES (DNT)INCLUDING POSTIVE CONTROL DATA.

R. G. York[1], J. F. Barnett, Jr[1], A. M. Hoberman[1], M. S. Christian[1] and R. H. Garman[2]. *[1]Research, Argus Research, Horsham, PA and [2]Consultants in Vet. Path, Inc, Monroeville, PA.*

Quantitative morphological measurements of the pup and adult rat brain are a requirement of DNT studies conducted under USEPA guidelines (OPPTS 870.6300). Relatively few guideline studies of this type have been conducted to date, and the range of normal values for the various parameters has not been previously established. The morphometric values for control rats participating in seven nominally identical DNT studies will be compared. Pregnant Sprague-Dawley rats were administered control substances orally beginning on Day 0 or 6 of gestation and continuing through Day 11 or 21/22 of lactation [Day of birth = DP 1]. Brains from DP 12 pups and adult rats were weighed, and the gross anterior-posterior lengths of the cerebrum and cerebellum were recorded. Microscopic measurements of the frontal cortex, parietal cortex, hippocampal gyrus, corpus callosum and cerebellum were performed and recorded. Qualitative neuropathological evaluations were performed on the DP 12 rat brain and the adult rat brain, spinal cord, dorsal root ganglia, Gasserian ganglia and associated trigeminal nerve, and selected peripheral nerves. Morphometric measurement data, collected during a validation study, comparing Day 10 and 12 Sprague-Dawley rat pups are provided. The results demonstrate that the measurement data collected from the selected neuroanatomic areas reveal age-related developmental differences that might, therefore, be predictive of either an *in utero* neurotoxic effect or a delay in brain development. The availability of control as well as positive control data for morphometric measurements will help clarify the extent to which between-subject variation affects the statistical power of comparisons between treatment and control groups in DNT studies.

651 THE RELIABILITY AND SENSITIVITY OF HISTOMORPHOMETRIC METHODS IN DETECTING MORPHOLOGICAL CHANGES IN THE DEVELOPING RAT BRAIN.

N. Hamelin[1], J. Oberdoerster[2], G. Yipchuck[1], D. Breton[1] and P. Tellier[1]. *[1]Pathology, ClinTrials BioResearch Ltd., Senneville, PQ, Canada and [2]Toxicology, Aventis CropScience, Research Triangle Park, NC.*

In regulatory developmental neurotoxicity studies the study guidelines require that morphometric analyses be conducted on the developing rat brain. Histomorphometric evaluation is recognized as a useful tool to quantify gross changes and cellular migration in the developing brain; however, it is important to identify and examine regions of the brain that are sensitive to toxicological insult. Further, high quality sections and consistent histomorphometric techniques are essential for reliable quantitative data. The developing rat brain undergoes rapid growth during the first 2 weeks after birth and morphometric changes would be anticipated during this time. The objective of the present study was to ensure that the histomorphometric procedures employed in our laboratory are sensitive enough to detect the subtle morphological changes occurring in the developing brain. For this we compared the morphometry of various brain regions from 10 day and 13 day old rats. The brains (6/sex/age) were immersion fixed in 10% neutral buffered formalin, embedded in paraffin, and stained. Histomorphometric evaluations were made by the same operator using a BIOQUANT/TCW image analysis system (BIOQUANT-R&M Biometrics, Inc..) on one section of forebrain (left and right frontal cortex; left and right parietal cortex; corpus callosum) and cerebellum (lobule base thickness; internal and external granular layer thickness) from each animal. Significant differences between 10 and 13 day old pups were detected in the frontal and parietal cortex (males only), the thickness of the base of cerebellar lobule 6/7/8 and lobule 9 (females only), and in the internal and external granular cell layers of the cerebellum (males and females). Our results indicate that during the second week of postnatal development the internal and external granular layers of the cerebellum are the most sensitive and consistent brain regions that can be measured reliably.

652 DEVELOPMENTAL NEUROTOXICITY TESTING GUIDELINES: A QUALITATIVE RETROSPECTIVE ANALYSIS OF POSITIVE CONTROL DATA.

K. C. Raffaele[1], S. L. Makris[1], W. F. Sette[1] and K. M. Crofton[2]. *[1]Health Effects Division, OPPTS, USEPA, Washington, DC and [2]Neurotoxicology Division, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

The USEPA Developmental Neurotoxicity (DNT) Study Test Guideline calls for both functional and neuropathological assessments in offspring during and following maternal exposure. This guideline also requires data from positive control (PC) agents. Submission of these data permit evaluation of laboratory proficiency in the detection of changes in the structure and function of the developing nervous system and comparison of the sensitivity of assessments in different studies and labs. This project surveyed approaches taken in contract and industrial laboratories in generating and providing these data. Data from 24 DNT studies from 13 different laboratories were summarized by method, e.g., motor activity, for information on: age relevance, Dose-Response, gender, group size, statistics, report quality, quality assurance, age of data relative to main study, and relevance of methods to the main study. Endpoints included: developmental landmarks, FOB, motor activity, startle response, learning and memory, standard histopathology and brain morphometry. Results ranged from no PC data for two laboratories, to one laboratory which submitted 16 different reports. The qualitative range was similarly broad, from excellent to extremely poor. Various quality problems were identified including: poor report structure (e.g., copies of poster presentations), lack of individual data, inadequate methodological details, differences in methods between the PC report and the main study, submission of very old data or data from completely different laboratories, significant variance in the submitted data, use of inappropriate PC chemicals or doses that were without effect, lack of statistical analysis, use of only one sex, and use of inappropriate age animals. Preliminary analyses suggest that there were only 4 out of 13 laboratories judged to have submitted adequate PC data. *This abstract does not necessarily reflect the policy of the USEPA*

653 PRENATAL NICOTINE EXPOSURE EVOKES LONG-TERM ALTERATIONS OF CELL STRUCTURE IN HIPPOCAMPUS AND SOMATOSENSORY CORTEX.

T. S. Roy, F. J. Seidler and T. A. Slotkin. *Pharmacology & Cancer Biology, Duke University Med. Ctr, Durham, NC.*

Offspring of women who smoke during pregnancy show behavioral abnormalities including increased incidence of attentional deficit, learning disabilities and cognitive dysfunction. Animals models indicate that nicotine elicits changes in neural cell replication and differentiation, leading to deficits in synaptic neurochemistry and behavioral performance, many of which first emerge at adolescence. In this study, we evaluated cellular morphology and regional architecture in the juvenile and adolescent hippocampus and the somatosensory cortex in rats exposed to nicotine prenatally. Pregnant rats were given nicotine throughout gestation *via* minipump infusion of 2 mg/kg/day, a regimen that elicits nicotine plasma levels comparable to those found in smokers. On postnatal days 21 and 30, brains were perfusion-fixed, coronal slices were taken between the anterior commissure and median eminence, and the morphology of the dorsal hippocampus and somatosensory cortex were characterized. In the hippocampal CA3 region and dentate gyrus, we found a substantial decrease in cell size, with corresponding decrements in cell layer thickness, and increments in cell packing density. Smaller, transient changes were seen in CA1. In layer 5 of the somatosensory cortex, although there was no significant decrement in the average cell size, there was a reduction in the proportion of medium-sized pyramidal neurons and an increase in the proportion of smaller, nonpyramidal cells. Taken together with previous work on neurochemical and functional defects, these data demonstrate that prenatal nicotine exposure compromises neuronal maturation, leading to long-lasting alterations in the structure of key brain regions involved in cognition, learning and memory. (Supported by USPHS DA14247 and by a fellowship from IBRO)

654 NICOTINE AFFECTS ZEBRAFISH MOTONEURON DEVELOPMENT.

K. R. Svoboda[1], S. Vijayaraghavan[1] and R. L. Tanguay[2]. *[1]Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO and [2]Physiology and Biophysics, University of Colorado Health Sciences Center, Denver, CO.*

Nicotine is a drug of abuse that has a profound impact on society. Of great concern is the harm that is caused when a pregnant mother smokes and exposes her unborn child to nicotine. Nicotine has been shown to be a developmental toxicant in several experimental models, but the mechanism by which nicotine alters development is not well understood. It is thought that the actions of nicotine are mediated by the nicotinic acetylcholinergic receptors (nAChRs). We are utilizing zebrafish embryos to gain insight into how nicotine modulates development with a particular emphasis on nervous system development. For these studies, zebrafish embryos were exposed to 33 micromolar nicotine beginning at 22 hours post-fertilization (hpf). At this dose, embryos do not respond to touch (at 48hpf) and are functionally paralyzed. At 48 hpf, nicotine had no apparent effect on the gross morphology of the embryo. However at 66 hpf and 120 hpf, embryos exposed to nicotine were 6% and 7% shorter in length, respectively, compared to controls. The morphological deficit coupled with the behavioral deficit suggested to us that either motoneuron or neuromusculature development was altered by nicotine. In order to investigate these possibilities, we imaged living transgenic zebrafish that express green fluorescent protein (GFP) in their spinal secondary motoneurons. Embryos exposed to

nicotine had significantly fewer GFP positive neurons than stage matched controls. This effect was easily detectable at 54-60 hpf. This effect was partially reversed by 2 mm MLA, a nicotinic antagonist known to act at the alpha 7 receptor subtype. Furthermore, 20 mm DHβE, an alpha 4/beta 2 subtype specific nicotinic receptor antagonist also reversed the nicotine effects. These results demonstrate that zebrafish is an excellent vertebrate model to study nicotine developmental toxicity, and suggest that an "alpha4/bera 2 like" nAChR subtype may be involved in mediating nicotine's actions in zebrafish early life stages.

655 PHARMACOKINETICS OF SB-247083, A POTENT AND SELECTIVE ENDOTHELIN-A RECEPTOR ANTAGONIST, IN THE RAT, DOG, AND MONKEY.

K. W. Ward, L. M. Azzarano, J. A. Morgan, M. J. Gould, P. R. Souder, D. Lundberg and B. R. Smith. *DMPK, Preclinical Drug Discovery, GlaxoSmithKline, King of Prussia, PA.*

The endothelins (ET) are among the most potent vasoconstrictors identified to date, and have been implicated in such diseases as renal failure, pulmonary hypertension, atherosclerosis, and congestive heart failure. There is currently interest in developing selective antagonists of the ET-A subtype receptor, and one such antagonist is SB-247083 ((E)-[1-butyl-5-[2-(2-carboxyphenyl) methoxy-4-chlorophenyl]-1H-pyrazole-4-yl]-2-[5-methoxydihydrobenzofuran-6-yl]methyl]-2-propionic acid). This investigation was conducted to evaluate the preclinical pharmacokinetics of SB-247083. Clearance of SB-247083 was low in the rat, moderate in the monkey, and high in the dog. Clearance was linear in the rat, with modest evidence of nonlinear elimination at high concentrations in the dog and monkey. First-pass hepatic extraction was approximately 60% in the rat, and ranged from 50 to 90% in the monkey. Oral bioavailability of SB-247083 administered as a solid formulation of the free acid is good in the rat (24%), but low in the dog (1 to 8%) and the monkey (2%). Pre-administration of 0.1 N HCl to normalize the achlorhydric fasting dog stomach did not improve bioavailability. Various formulations and salt forms of SB-247083 were evaluated; the most favorable was formulation as the monoarginyl salt, which approximately doubled oral bioavailability in each species tested. These data suggest that SB-247083 may be a promising ET-A receptor antagonist, and may have utility in various ET-mediated diseases.

656 KINETICS AND LOCOMOTOR ACTIVITY FOLLOWING COCAINE AND KETAMINE ADMINISTRATION IN RAT.

H. Rofael and M. Abdel-Rahman. *Pharmacology & Physiology, GSBS, UMDNJ, Newark, NJ.*

The co-abuse of cocaine (COC) and ketamine (KET) occurs with high frequency. The presence of another active substance with COC allows the potential of various drug-drug interactions to occur. COC metabolism may play an important role in its toxicity. Benzoylecgonine (BE) has been reported to be a potent vasoconstrictor and convulsant agent. This study investigated the plasma time course, tissue distribution and locomotor activity of COC or KET alone and their combination in rat. COC (5 mg/kg i.v.), KET (100 mg/kg p.o.) or KET followed by COC (same doses and routes of administration) were utilized. KET administered concurrently with COC, significantly reduced COC area under the curve (AUC) and elimination half-life, while the total clearance was increased *versus* COC administration alone. The AUC of plasma BE was significantly increased in the combination treatment compared to COC alone. Tissue distribution study revealed that, the brain, heart and liver contents of COC and norcocaine were significantly lowered at 5, 15 and 30 min following KET administration *versus* COC alone. However in the same organs, BE was significantly higher in the combination group compared to COC alone. On the other hand, COC treatment did not affect the kinetics of KET as a parent compound. Locomotor activity study showed that, rats treated with COC and KET in combination had a significantly lower horizontal locomotor activity compared to COC treatment. The results suggest that KET increases the metabolism of COC sufficiently to alter its behavioral effects. The high plasma and tissue concentrations of BE after the combination treatment, which is potent cardiovascular and neurotoxic agent, may possibly affect the toxicological profile of COC as well. (Supported in part by the Egyptian government).

657 PLASMA PHARMACOKINETICS OF TRICLOSAN FOLLOWING REPEATED DERMAL EXPOSURE.

D. P. Davis[1], W. E. Salminen[2], P. J. Kostyniak[3] and J. R. Plautz[2]. [1]*The Dial Corporation, Scottsdale, AZ,* [2]*Ciba Speciality Chemicals Corporation, High Point, NC and* [3]*State University of New York at Buffalo, Buffalo, NY.*

Triclosan (TCS: 2, 4, 4'-trichloro- 2'- hydroxydiphenyl ether) is an anti-microbial agent that has been used for over 30 years in a variety of personal care products. This study evaluated the steady-state plasma concentration and pharmacokinetic profile of TCS following repeated dermal application. Plasma levels of TCS were followed in 13 human volunteers (7 males and 6 females) after use of a commercial hand wash containing 1% TCS, 6 times per day for 20 days. Volunteers were instructed not to use any other TCS-containing products during the course of the study. Blood samples were taken prior to first hand washing on study day 1 (baseline TCS level) and study days 5, 10, 15, and 20. Blood samples were also taken post exposure on study days 21, 23 and 30. Samples were then analyzed by LC/MS/MS for free and total (conjugated) TCS in plasma. On day 20, the subjects were sequestered for 12 hours, during which hand washing was continued every 2 hours and blood samples obtained prior to each hand wash. Pharmacokinetic analysis of the plasma concentration data supports a first order single compartment model for TCS. Steady state levels of free and total TCS were reached by study day 5. Mean (±SD) steady state levels of free and total TCS from day 5 to day 20 ranged from 5.4(±5.0) to 10.6(±11.6) ng/ml and 67.1(±34.7) to 74.9(±48.9) ng/ml, respectively. Maximum free and total TCS plasma levels during the study for any volunteer were 69.9 and 229 ng/ml. The average elimination half life and eliminate rate constant, calculated from the individual values for the study population, were 1.4 days and 0.615 day^{-1}. Overall, the study results show that TCS is absorbed through the skin and rapidly eliminated from the body. Furthermore, the data support that human exposure to TCS resulting from continued use of a hand wash containing 1% TCS is significantly below exposures associated with animal toxicity end points.

658 APPLICATION OF THE CULEX™ AUTOMATED BLOOD SAMPLER IN THE PHARMACOKINETIC STUDY OF SU006668 IN AWAKE RATS.

W. Tan, M. Van Petten, X. Yu, Q. Zhang, L. Antonian and J. Sukbuntherng. *Bioanalysis, Metabolism and Pharmacokinetics, SUGEN, Inc., South San Francisco, CA.*

Conventionally in the *in vivo* rat study of pharmacokinetics, a series of blood samples are collected manually through a dwelling intravenous catheter. A novel robotic device, Culex™ automated blood sampler (Bioanalytical Systems, Inc.., West Lafyette, IN), provides an alternative way to automatically collect blood from awake and freely moving rats. The purpose of this study was to evaluate the feasibility of the Culex™ automated blood sampler in the application of pharmacokinetic studies in rats. SU006668, an antiangiogenetic agent in Phase I clinical development for the treatment of solid tumors, was studied as a model drug for this purpose. Fifteen rats received intravenous (IV, n=7) or oral (PO, n=8) administration of the drug. For each group, the blood samples were collected up to 12 hours either by using manual blood collection method (n=4 for both IV and PO groups) or by using Culex™ automated blood sampler (n=3 for IV and n=4 for PO). The plasma concentrations of SU006668 were determined using a LC-MS/MS method. The pharmacokinetic parameters were determined by non-compartmental analysis using Winnonlin Professional Edition. The results shown below indicate that the pharmacokinetic parameters obtained from two blood sampling techniques (Culex vs Manual) were comparable (P>0.05, t-test), and consistent with the historical pharmacokinetic data on SU006668. The study suggests the feasibility of blood sampling by the Culex system for the study of pharmacokinetics.

659 CORTICOSTERONE IN DRINKING WATER ENHANCED THE ABSORPTION OF A SINGLE ORAL DOSE OF CORTICOSTERONE.

T. Pung, K. Fuhrman and M. Ehrich. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.*

Corticosteroids are stress indicators that contribute to many body functions. Effects of corticosterone exposure on corticosterone kinetics were studied in adult male Long Evans rats. Some of these were gavaged with corticosterone in corn oil at 20

mg/kg body weight (n = 4). The control rats were given only corn oil (n = 4). Each rat was bled at 0, 15, 30, 60, 120, 240, 480, and 720 minutes after the treatments. Plasma corticosterone levels rose to a peak level of 713 ± 59 ng/ml by 30 minutes after dosing. Plasma corticosterone gradually decreased until 240 minutes, when the level was similar to that of the controls. After 12 days without treatment, the rats were given either 2.5% ethanol or corticosterone 400 ug/ml in drinking water for 29 days. Ethanol 2.5% in drinking water increased the basal corticosterone levels. The corticosterone-drinking rats were then gavaged with corticosterone 20 mg/kg. Blood samples were taken as noted above. The plasma corticosterone levels of the corticosterone-drinking water rats (106 ± 71 ng/ml) were lower than the ethanol group (453 ± 71 ng/ml)), and also lower than the levels in these rats before they drank the corticosterone water (227 ± 59 ng/ml). The peak plasma corticosterone after gavage was 975 ± 71 ng/ml at 15 minutes. The corticosterone in drinking water, therefore, enhanced the absorption of a single oral corticosterone dose. This demonstrates that corticosterone in drinking water can affect corticosterone kinetics. (Supported by DAMD 17-99-1-9489.This abstract does not necessarily reflect the position or policy of the US Government).

660 CONTINUOUS INFUSION IN MARMOSET MONKEYS: FEASIBILITY OF A PORT-CATHETER TECHNIQUE.

P. Nowak, A. Wiederhold, S. Korte, B. Niggemann, G. Weinbauer, W. Mueller and F. Vogel. *Covance Laboratories GmbH, Muenster, Germany.* Sponsor: R. House.

The common Marmoset (Callithrix jacchus jacchus) can play an important role as the second species in the safety evaluation of new drugs. Hence the need occurred to evaluate the suitability of this primate as a model for continuous infusion studies. This work investigates the feasibility of a port-catheter technique in marmosets and concentrates on the technical details of the surgical implantation procedure.The right and the left thigh as well as the abdominal wall and the dorsal region of the thorax are shaved. The operation area in the upper field of the right thigh is sterilized with Betaisadona solution. Following intramuscular premedication with Ketamine, Xylazine and Atropine, anaesthesia of the marmoset is performed by inhalation narcosis with Isoflurane. During the operation process, breathing is supported using a respirator.The proximal section of the V. femoralis dexter is selected for accessing to the venous system. The silicone catheter (3 French O.D.) is placed close to the V. renalis sin., and the disconnected distal V. femoralis is used as a point of fixation. A subcutaneous pocket in the region of the upper thigh is used to connect the externally fixed titanium port (Type POPS II), placed on the animals's back, with the injection site. The external port is fixed on the skin by a patch, the silicone membrane of the port is directed cranially to inject substances easily. To protect the surgical operation area and to support wound healing, a tube-shaped wound cover is used to enclose thorax and abdominal body. The suture material is removed after 8 days. A heparine solution of 5 IU/mL is regularly used to rinse and protect the infusion system.In conclusion, a port-catheter system is feasible for marmoset monkeys since it is shown here that such a system can successfully be implanted in these very small non-human primates. First experiences confirm successful and intermittent use of the system for more than six weeks.

661 INCREASED PLASMA LEVEL OF ACETAMINOPHEN-GLUCURONIDE IS ASSOCIATED WITH INDUCTION OF MULTIDRUG RESISTANCE PROTEIN 3 (MRP3) IN LIVER.

A. L. Slitt, N. J. Cherrington, J. M. Maher and C. D. Klaassen. *Pharmacology, Toxicology, & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Previous studies report that treatment with the cytochrome P450 2B1/2 inducers phenobarbital (PB) and trans-stilbene oxide (TSO) can decrease biliary excretion of acetaminophen-glucuronide (AA-GLUC) and increase excretion of AA-GLUC into blood. The canalicular Multidrug Resistance Protein 2 (Mrp2) can transport glucuronide conjugates into bile, whereas the sinusoidal protein Mrp3 is thought to transport these conjugates into blood. Hence, it is hypothesized that Mrp2 and Mrp3 are responsible for the excretion of AA-GLUC conjugate into bile and blood, respectively. Thus, PB and TSO-induced alterations in vectoral excretion of AA-GLUC may occur *via* increased hepatic Mrp3 levels. Therefore, the goal of this study was to determine 1) whether PB and TSO, compounds known to increase plasma concentrations of AA-GLUC up-regulate Mrp3 expression, and 2) whether compounds that induce Mrp3 expression, such as diallyl sulfide (DAS) and oltipraz (OLT), can correspondingly decrease biliary and increase hepatovascular excretion of AA-GLUC. Sprague-Dawley rats were administered PB, TSO, OLT, or DAS, or vehicle for four days. To determine the effects of these chemicals on AA excretion, the carotid artery and bile duct were cannulated and blood and bile were collected at various intervals up to 90 min after AA injection into the carotid cannula. AA-GLUC content in bile and blood was quantified by HPLC and Mrp2 and Mrp3 mRNA was quantified using the branched DNA signal amplification assay. Interestingly, all of the chemicals increased the hepatovascular and decreased the biliary excretion of AA-GLUC. Furthermore, all of the compounds dramatically increased hepatic Mrp3 mRNA by at least 6 fold, but had little or no effect on hepatic Mrp2 mRNA levels. Together, these studies correlate increased Mrp3 mRNA levels with increased hepatovascular excretion of AA-GLUC and suggest that induction of Mrp3 affects the route of drug excretion. (Supported by NIH grants ES-09716 and ES-07079)

662 KINETICS OF PROPYLENE GLYCOL MONOMETHYL ETHER (PGME) AND PGME ACETATE (PGMEA) FOLLOWING INTRAVENOUS (IV) ADMINISTRATION TO MALE FISCHER 344 RATS AND THE *IN VITRO* HYDROLYSIS OF PGMEA IN RAT AND HUMAN BLOOD AND LIVER HOMOGENATE.

K. A. Brzak, J. Y. Domoradzki and C. M. Thornton. *The Dow Chemical Company, Midland, MI.* Sponsor: W. Stott.

The blood kinetics of PGMEA and PGME following iv administration to rats was conducted to determine toxicological equivalency between the two materials. The *in vitro* rates of hydrolysis of PGMEA to PGME in incubations with rat and human blood as well as liver homogenates were measured for use in a future PB-PK model for PGME. For investigation of the kinetics of PGME or PGMEA following iv administration to rats, equimolar doses of 10 mg PGME/kg or 14.7 mg PGMEA/kg and 100 mg PGME or 147 mg PGMEA/kg were used. Blood samples were drawn from the jugular vein cannula through 12 h post-dosing and analyzed for PGMEA and PGME. Plasma time course of PGME following iv administration of 10 mg PGME/kg or 14.7 mg PGMEA/kg were identical; similarly for the high dose of 100 mg PGME/kg or 147 mg PGMEA/kg. Plasma time courses of PGMEA following iv administration of 14.7 or 147 mg PGMEA/kg bw were determined and half-lives were 1.55 and 3.37 min, respectively. Incubations were conducted through 6 h at concentrations of 5 and 50 µg PGMEA/ml. Samples were analyzed *via* PCI or EI-GC/MS for determination of PGMEA and PGME in blood or liver homogenate incubations. The disappearance of PGMEA was faster in rat blood than in human blood. The hydrolysis half-lives were 36 and 34 min for the 5 and 50 µg/ml concentrations of PGMEA in human blood, whereas in rat blood the hydrolysis half-lives were 16 and 15 min, respectively. The rate of loss of PGMEA was similar in rat and human liver homogenate incubations. Hydrolysis half-lives were 27 and 30 min for the 5 and 50 µg/ml concentrations of PGMEA in human liver homogenate, whereas in rat liver the hydrolysis half-lives were 34 min for both concentrations. These data indicate that PGMEA is rapidly hydrolyzed in the body to its parent glycol ether, PGME. Once hydrolyzed the kinetics for PGME derived from PGMEA is identical to that for PGME. *Sponsored by the American Chemistry Council Glycol Ethers Panel.*

663 DISPOSITION AND ORAL BIOAVAILABILITY OF HALOACETATE MIXTURES IN F344 RATS.

S. A. Saghir and J. R. Schultz. *Battelle PNL, Richland, WA.*

Chloro, bromo and mixed bromo- chloro haloacetates (HAs) are by-products of drinking water disinfection and exhibit both carcinogenic and reproductive/developmental toxic properties in rodents. Drinking water typically contains a mixture of di- and tri-HAs. Recent toxicokinetic studies have identified significant differences in the disposition of di- and tri-HAs. It is now established that di-HAs are almost exclusively eliminated *via* metabolism that occurs as a glutathione dependent process mediated through a novel class of GST isoenzyme, GST-zeta. Di-HAs are prone to extensive first pass metabolism by the liver that can greatly reduce their oral bioavailability. The brominated tri-HAs are metabolized in the microsomal fraction of rodent and human liver tissue and are also subject to first pass liver metabolism. Recent experiments have shown that metabolism of di-HAs is greatly reduced after prolonged exposures due to suicide inactivation of the GST-zeta protein. Preliminary evidence suggests that the tri-HAs do not exert this effect. We measured the tissue distribution, in-vivo plasma/tissue partitioning and oral bioavailability of two separate HA mixtures containing both di- and tri-HAs in F344 rats before and after depleting GST-zeta activity. Results indicated the plasma/tissue partition coefficients ranged between 0.6-1. The oral bioavailability of tri-HAs was not affected by GST-zeta depletion and ranged between 67-92 %. The oral bioavailability could not be assessed for the di-HAs as the plasma area-under-the-curve was always greater after oral dosing compared to the i.v. reference dose. This phenomenon appears to be due to secondary peaks that appear in the plasma profiles of di-HAs after oral dosing. Supported by EPA STAR grant R825954.

664 STEREOSPECIFIC DISPOSITION OF BROMOCHLORO- AND CHLOROFLUOROACETATE: EFFECT OF GST-ZETA DEPLETION.

J. R. Schultz[1] and S. R. Sylvestor[2]. *[1]Battelle PNL-MSL, Sequim, WA and [2]2Washington State University-Vancouver, Vancouver, WA.*

The chloro- and bromo- haloacetates are drinking water disinfection by-products and rodent carcinogens. Chloro, bromo di-haloacetates are also mechanism based inhibitors of glutathione-S- transferase zeta (GSTZ1-1). We studied the stereospe-

cific toxicokinetics of two chiral di-haloacetates in male F344 rats: (-), (+)bromochloro-acetate (BCA), and racemic chlorofluoro-acetate (CFA), a non GST-zeta inhibiting di-haloacetate. These experiments were repeated in animals that had previously been treated with dichloroacetate (DCA) to deplete GST-zeta activity. Results indicated that in naïve rats the elimination half-life of (-)BCA was 0.07 hrs compared to 0.40 hrs for (+)BCA. A comparable difference in elimination half-life was also observed for the CFA stereoisomers (0.79 hr *vs.* 0.11 hrs). In GST-zeta depleted rats, stereospecific elimination of (-), (+) BCA was absent with both stereoisomers having an elimination half-life of approximately 0.4 hrs. This finding was in contrast to results for CFA, which still maintained the same relative difference in elimination rate between its stereoisomers although overall elimination was diminished in GST-zeta depleted rats. The AUC(0-inf) of (-), (+) BCA after oral administration differed by more than 10 fold in naïve rats but this difference was reduced considerably in GST-zeta depleted rats. The oral bioavailability varied between 20 - 67% for the different BCA stereoisomers. These results indicate (+)BCA is a poor substrate for GST-zeta and the internal dosimetry of (-), (+)-BCA will differ considerably after drinking water exposure. Supported by EPA STAR grant R825954.

665 TOXICOKINETICS OF HEXACHLOROBENZENE (HCB) IN FEMALE RATS.

E. Little[1], J. Algaier[1], R. Harris[1], A. Clark[1], T. Morton[1], E. Laille[1], D. Overstreet[2] and C. Smith[2]. [1]*Midwest Research Institute, Kansas City, MO and* [2]*NIEHS, Research Triangle Park, NC.* Sponsor: M. Cunningham.

The toxicokinetics (TK) of hexachlorobenzene were assessed after p.o. (300 µg/kg) and i.v. dosing (100 or 1000 µg/kg) to female Sprague-Dawley rats. TK parameters estimated for the p.o. group included maximum blood levels (C_{max}) and time to peak (T_{max}), elimination rate (k_e) and half-life ($t_{1/2}$), volume of distribution (V_c/F), clearance (Cl/F), dose-normalized areas under the concentration-time curve (DNAUC), and bioavailability (F). Parameters estimated for the i.v. groups were C_{max}, distribution and elimination rates (α and β) and $t_{1/2}$'s, volumes of distribution (V_c and V_{ss}), clearance (Cl), and DNAUC. Liver, fat, and lung were also analyzed for HCB. Kinetic parameters estimated included mean residence time, C_{max}, T_{max}, $t_{1/2}$, $AUC_{0\text{-}inf}$, and DNAUC. Blood levels of HCB showed linear kinetics at the i.v. doses used, and HCB given orally was completely and rapidly absorbed (F = 1.2; T_{max} = 3 hr). TK parameters estimated for the p.o. and i.v. groups were comparable except for Cl. The fact that the data collection period covered only 3 to 4 elimination half-lives, and the final portions of the blood concentration-time curves were flat may explain this. TK parameters for HCB in fat and liver behaved in a similar manner, and suggest linear kinetics over the dose range. HCB was highly concentrated in fat. TK parameters estimated for HCB levels in lung suggest non-linear kinetics. TK parameters for the oral group are consistent with those from an earlier study, where dose normalized peak blood levels (C_{max}) after a p.o. dose at 30, 000 µg/kg were of similar magnitude to those at 300 µg/kg. In the earlier study, T_{max} was at 3 hr, thus indicating linear (first-order) absorption following an oral dose of 300 to 30, 000 µg/kg of HCB. Other parameters, such as Cl/F, F, and the $t_{1/2}$'s were also similar in magnitude. Bioavailability was found to be complete (F = 1.1) for female rats receiving an oral dose of 30, 000 µg/kg, estimated using the average DNAUC from rats in these low and high i.v. dose groups.

666 DISPOSITION OF MENTHOFURAN IN F344 RATS.

E. H. Lebetkin, L. J. Chen and L. T. Burka. *Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC.*

Menthofuran is a proximate toxic metabolite of pulegone, a monoterpene constituent of pennyroyal oil, and is believed to account for a significant percentage of pulegone toxicity. Metabolism of menthofuran yields a highly reactive γ-ketoenal intermediate that covalently binds to protein. A study comparing the disposition of menthofuran to pulegone in F344 rats has been conducted as part of the National Toxicology Program initiative in herbal medicines and dietary supplements. Adult male and female F344 rats received single oral doses of ^{14}C-menthofuran (6 or 60 mg/kg) in corn oil; urine and feces were collected and the animals were sacrificed at 24 or 72 hours for tissue collection. Although menthofuran is fairly volatile, only 0.22% of the original dose was recovered as expired volatiles. Overall, 92 to 98% of the dose was recovered. Menthofuran is excreted in the urine (57 to 65% after 72 hours) and feces (19 to 28%). The highest concentrations of menthofuran-derived radioactivity were in blood and liver at 24 and 72 hours. The concentration of radioactivity in kidneys from males was 2-fold higher than those from females at 24 hours. The sex-related difference in kidney concentration is not as great as observed for pulegone, but the results may indicate that menthofuran and/or a metabolite(s) binds to α2u globulin. At 72 hours, 10 to 14% of the dose was still in the tissues. This is 3-times the residual pulegone in tissues at 72 hours at a similar dose. Menthofuran-derived radioactivity was covalently bound to liver tissue with 0.98 and 0.91 nmole-eq/mg protein in male rats dosed with 6 mg/kg menthofuran for 24 and 72 hours respectively. The extent of covalent binding to liver protein is high and is comparable to furan. The observation of higher residual radioactivity in tissues compared to pulegone and covalent binding to protein is consistent with menthofuran being a proximate toxic metabolite of pulegone.

667 THE DOSIMETRY AND MODES OF ACTION OF 2-BUTOXYETHANOL IN B6C3F1 MICE.

T. S. Poet, J. J. Soelberg, T. M. Luders, T. L. Curry, K. K. Weitz, T. J. Mast, R. A. Miller, B. D. Thrall and R. A. Corley. *Battelle, Pacific Northwest Division, Richland, WA.*

2-Butoxyethanol (BE) is a widely used solvent in industrial and consumer cleaning and coating products. An extensive toxicity and mechanistic database shows humans are considerably less sensitive than rats and mice to hemolysis, the main endpoint of toxicity. However, a recent NTP inhalation bioassay identified the forestomach and liver of mice, but not rats, as target organs for potential tumorigenicity. A series of studies were conducted to evaluate the role of dosimetry in producing lesions specifically in the forestomach. Results to date indicate that forestomach tumors appear to be produced by a chronic irritation/cytoxicity mechanism. This further questions the relevance of the forestomach tumors for humans which lack this tissue. Irritation and compensatory hyperplasia were induced in the forestomachs of mice upon oral administration of neat BE. Similar, but milder lesions were also produced by systemic administration (intraperitoneal or subcutaneous injection) of comparable doses. Salivary excretion was found to be a contributing source of BE and its metabolite, butoxyacetic acid (BAA) to forestomach tissue in female mice following intraperitoneal injection. Salivary levels of BE in the mice were nearly equivalent to blood concentrations. The elimination half-lives for BE and BAA in blood were 0.06 and 0.9 hr, respectively, which is considerably faster than rats or humans. Based upon focused kinetic and toxicity studies following inhalation, oral and intraperitoneal injection routes of exposure, sources of BE and its hemolytic metabolite, butoxyacetic acid (BAA) in the forestomachs of mice can be attributed to a combination of systemic delivery *via* the blood, elimination in saliva with subsequent oral ingestion and oral consumption due to grooming of BE deposited on the fur. Taken together, there appears to be a significant role for local tissue dosimetry in the development of forestomach cytotoxicity in mice. (Sponsored by the Ethylene Glycol Ethers Panel of the American Chemistry Council).

668 DISPOSITION OF POLYDIMETHYLSILOXANE, 10 AND 350 CST IN F344 RATS FOLLOWING A SINGLE EXPOSURE BY ORAL GAVAGE.

M. L. Jovanovic, D. A. McNett, J. M. Regan, R. H. Gallavan and K. P. Plotzke. *Dow Corning Corporation, Midland, MI.*

Disposition of two neat ^{14}C-polydimethylsiloxanes (PDMS) with viscosities of 10 and 350 cst from the GI tract was evaluated in male and female Fischer 344 rats. A single, oral dose of 1000mg/kg of body weight was administered to rats in Mass Balance (MB: 4 females and 4 males) and Whole Body Autoradiography groups (WBA: 4 females and 4 males). Rats in the MB groups were housed in Roth-style metabolism cages for collection of excreta and the assessment of the recovery of total radioactivity. At 96 hr post-dose, rats were euthanized by cardiac puncture under anesthesia and blood, liver, GI tract, kidneys, spleen, eyes, perirenal fat, and remaining carcasses were collected and processed for analysis. Radioactivity content in each sample was measured by liquid scintillation counting (LSC). Aliquots of the fecal homogenates were extracted and analyzed by HPLC with radiochemical detection using a gel-permeation chromatography column for qualitative determination of the radioactivity profile. Rats in the WBA groups were sacrificed at 12, 24, 48 and 96 hr post-dose and immediately frozen at -75°C. Sagittal sections of 40 µm in thickness were collected at various levels to include major organs and tissues and exposed to x-ray film at -80°C. Both quantitative (LSC) and qualitative assessments (WBA) showed that radioactivity was rapidly excreted through gastrointestinal tract. *in vivo* assessment of tissue distribution by WBA at 12, 24 and 48 hr post-dose showed that radioactivity was concentrated in the contents of the GI tract. No significant radioactivity was detected outside the GI tract with the exception of exterior contamination. Dose recovery from all the animals through 96 hr post-dose was > 93.6%. Virtually the entire recovered dose was excreted in feces (99.6-99.8% of recovered dose) with little, if any, absorption. The entire radioactivity recovered in feces was attributed to the unchanged PDMS, 10 or 350 cst. No detectable degradation products were present in feces. Funded in part by Silicones Environmental, Health and Safety Council.

669 CHROMIUM ACCUMULATION IN THE TISSUES OF RATS, MICE, AND GUINEA PIGS EXPOSED TO SODIUM DICHROMATE DIHYDRATE IN DRINKING WATER FOR TWENTY-ONE DAYS.

S. A. Anderson[1], J. L. Valentine[1], R. Fernando[1], C. M. Sparacino[1] and B. Collins[2]. *[1]RTI, Research Triangle Park, NC and [2]NIEHS, Research Triangle Park, NC.*

Chromium (Cr) is widely used in industry for corrosion inhibition, metal finishing, manufacturing of safety matches and production of pigments. Hexavalent chromium (VI) has been found to contaminate soil and air. This study was designed to evaluate the relationship between drinking water concentrations of Cr (VI), as sodium dichromate dihydrate (SDD), and tissue accumulation of total Cr in three species. Male Fischer 344 rats, B6C3F1 mice, and Hartley guinea pigs were exposed to SDD in tap water for 21 days at 0, 1, 3, 10, 30, 100, or 300 mg Cr/L water (0, 2.87, 8.62, 28.7, 86.2, 287, and 862 mg SDD/L; n=4/dose). On Study Day 22 until necropsy, all animals received tap water (0 mg Cr/L). Actual doses received were calculated based on twice weekly water consumption data and weekly body weights. On Study Day 24, animals were humanely sacrificed and blood, kidneys, and femurs were collected. Whole blood and tissues were analyzed for total chromium content. Water consumption remained normal throughout the course of the study for rats and mice and did not differ between dose groups (water consumption could not be calculated for guinea pigs). In mice, mean body weights were not significantly different from controls. However, for both rats and guinea pigs, mean body weights at the 100 and 300 mg/L dose levels were decreased when compared to controls. Cr levels in rat kidney were ca. 3 times higher than in mouse kidney (rat range: 0.4 – 9.1 µg/g *vs.* mouse range: 0.1 – 3.3 µg/g). Cr levels in guinea pig kidney were similar to mouse kidney (range: 0.1 – 3.1 µg/g). In all three species, Cr tissue concentrations appear to increase in a linear manner up to 80 mg Cr/L. Tissue concentrations of Cr do not appear to increase at higher dose levels. This may be due to a decrease in the bioavailability of Cr or a decrease in the uptake of Cr into specific tissues. Tissues appear to reach a saturation level at the 100 mg Cr/L dose level.

670 BIOAVAILABILITY OF PENTACHLOROPHENOL FROM DIFFERENT TYPES OF SOILS.

X. Z. Pu[1], Y. Z. Zhao[2], L. S. Lee[2], A. P. Schwab[2] and G. P. Carlson[1]. *[1]Health Sciences, Purdue University, West Lafayette, IN and [2]Agronomy, Purdue University, West Lafayette, IN.*

Pentachlorophenol (PCP) is a broad-spectrum biocide widely used as a wood preservative and is thus a ubiquitous environmental pollutant. Evidence exists that usually only a fraction of the chemicals in soil is bioavailable to organisms, and this bioavailability is influenced by chemical and soil properties. In the current study, the absolute and relative bioavailabilities of PCP from soils varying in organic carbon content, particle size and pH were examined. Four uncontaminated soils and two contaminated soils from a wood preserving industry were collected from different sites in Indiana. Uncontaminated soils were spiked with 50 and 100 mg/kg PCP. The PCP concentration in the soils from contaminated sites was approximately 200 mg/kg. Soils and corn oil containing equivalent levels of PCP were administered to male Sprague-Dawley rats (weight range 275 to 350 g) by gavage at two dose levels—100 and 200 µg/kg body weight. Equivalent doses were also given *via* intravenous injection (iv). Blood samples were obtained from the orbital sinus at 1, 3, 6, 12, 24, and 48 hours after administration. PCP concentrations in plasma were analyzed by GC-ECD. Areas under the curve (AUC) were calculated for each soil and compared to those of the iv injection and corn oil groups to estimate the absolute bioavailability (AUC of soil:AUC of iv injection) and relative bioavailability (AUC of soil:AUC of corn oil). Both absolute and relative bioavailabilities were very high for each soil at each dose with no statistical differences detected among them. Bioavailabilities decreased in one of the environmentally contaminated soils. These results indicate that PCP in soil is readily absorbed into the blood from the gastrointestinal tract and the soil properties do not have much impact on PCP bioavailability. (Supported by EPA grant CR827234).

671 TIME COURSE FOR TISSUE DISPOSITION OF DIMETHYLARSINIC ACID AFTER ACUTE ORAL ADMINISTRATION IN THE MOUSE.

M. F. Hughes, B. C. Edwards, C. T. Mitchell and E. M. Kenyon. *USEPA, ORD, NHEERL, ETD, Research Triangle Park, NC.*

The primary metabolite excreted by most mammals after exposure to inorganic arsenic is dimethylarsinic acid (DMA(V)). Recent studies have shown that DMA(V) is a multi-organ tumor promoter in rodents and a bladder carcinogen in rats. This study examined the disposition of DMA-derived radioactivity in tissues over time after acute oral administration. Adult female B6C3F1 mice (N=3-4/time point) were administered [^{14}C]-DMA(V) orally at a dose level of 0.6 or 60 mg As/kg, and sacrificed at selected time points (0.25-24 hr). Tissues were removed and analyzed for chemical-derived radioactivity (^{14}C). DMA(V) was rapidly absorbed and distributed among the tissues, as evidenced by the detection of ^{14}C in all tissues at the earliest time point (0.25 hr). Concentrations of ^{14}C (%dose/ gm tissue) in the kidney, liver, and lung were greater than in blood at this time, indicating that DMA is rapidly accumulated by tissues. The peak concentration of ^{14}C in the tissues occurred between 0.5-2 hr after administration of DMA(V) and ranged from 0.4-2.6%. The tissues with the highest concentration (2.6%) of ^{14}C were the lung for the low dose and the kidney for the high dose. There were no dose-dependent differences in peak tissue concentration of ^{14}C. By 24 hr, the tissue concentration of ^{14}C was considerably lower than observed at 0.25 hr. Approximately 0.01% of the dose/gm tissue or lower was detected in kidney, liver, or lung at 24 hr. The concentration of ^{14}C in these tissues was greater than in the blood at 24 hr. The data indicate that an acute oral dose of DMA(V) is rapidly absorbed, distributed, and excreted from the mouse. The rapid elimination of DMA(V) explains in part the low acute toxicity of this compound. (This abstract does not necessarily reflect EPA policy.)

672 THE POTENTIAL OF SELECTED CROP PROTECTION CHEMICALS TO ALTER HUMAN P-GLYCOPROTEIN ATPASE ACTIVITY.

L. G. Fox[1], R. C. Peffer[2] and J. T. Stevens[2,3]. *[1]GENTEST Corporation, Woborn, MA, [2]Syngenta Crop Protection, Inc., Greensboro, NC and [3]Wake Forest University, Winston-Salem, NC.*

P-glycoprotein (PGP, encoded by mdr1) is a member of the ABC transporter superfamily and is expressed in the capillary endothelial cells of the brain, gonads, placenta and other tissues. PGP serves as a barrier to keep toxins out of the nervous system, gonads and fetus by actively pumping substrates across the cell membrane and out of the cytoplasm; ATP hydrolysis provides the energy for active transport. Numerous drugs and crop protection chemicals (CPC) are substrates for PGP [Bain and LeBlanc, 1996, *Toxicol. Appl. Pharmacology* 141, 288-298]. The potential of selected CPC to stimulate the ATPase activity of human PGP membranes(GENTEST™ Catalog K228) was evaluated. CPC were incubated in a buffered solution containing PGP membranes and supplemented with MgATP, with and without sodium orthovanadate to inhibit PGP by trapping MgADP in the nucleotide binding site. Each CPC was assayed over a concentration range based on its solubility in DMSO up to 100 µM in 96-well microtiter plates. The herbicides, atrazine and clodinofop-propargyl, did not stimulate human PGP-ATPase activity in the concentration ranges tested nor did the insecticide, thiamethoxam. The failure of these substances to alter ATPase suggests they are not substrates of PGP. The insecticide, emamectin-benzoate, suppressed the basal activity in the PGP membranes over the entire concentration range tested, indicating an inhibitory interaction with the PGP-ATPase. Additionally, when verapamil, an established substrate of PGP was coincubated with increasing concentrations of emamectin-benzoate, the verapamil-stimulated ATPase activity was inhibited in a concentration-dependent manner. The triazine herbicide didealkylated metabolite, diaminochlorotriazine, as well as the fungicide, propiconazole, stimulated activity in a concentration-dependent manner indicating that they are substrates for PGP. This screen further supports the premise that CPC, like pharmaceutical agents, may interact with PGP.

673 DISTRIBUTION OF CHLORPYRIFOS AND ITS PRINCIPAL METABOLITE TRICHLOROPYRIDINOL IN DAM AND NEONATE TISSUES/FLUIDS.

A. E. Fuciarelli[1], H. H. Mottaz[1], J. A. Dill[1], S. W. Graves[2], V. B. Godfrey[3] and C. S. Smith[3]. *[1]Battelle Toxicology Northwest, Richland, WA, [2]Battelle Memorial Institute, Columbus, OH and [3]NIEHS, Research Triangle Park, NC.*

Pregnant Sprague-Dawley rats were administered chlorpyrifos (CPF) *via* gavage (in corn oil) at doses of 0.5, 3.0, and 5.0 mg/kg from gestational day 14 to postnatal day 7. CPF and its principal metabolite, trichloropyridinol (TCP), were assayed in the samples collected on postnatal day 7 from dams (blood, brain, liver and milk) and neonates (plasma, brains, and livers) at Battelle using gas chromatography-negative-ion chemical ionization mass spectrometry (GC-NCI/MS) methods. CPF was readily quantified in dam milk, liver, brain, and blood collected from dams administered 5 mg CPF/kg, but was not detectable in neonate plasma, liver, or brain from the 5 mg CPF/kg group. CPF was also readily quantified in liver and detectable in brain samples collected from dams administered 3 mg CPF/kg. Generally, CPF concentrations in all study samples were not detectable in samples from either the control or 0.5 mg CPF/kg groups. In those tissues/fluids where CPF was observed, the concentrations increased with increasing CPF dose and the highest CPF concentrations were observed in dam milk. TCP was quantifiable in all tissues/fluids analyzed (blood, liver, brain, milk) from dams administered 0.5, 3.0, and 5.0 mg CPF/kg. TCP was detectable in plasma, liver, and brain collected

from neonates in the 0.5, 3.0, and 5.0 mg CPF/kg groups. TCP concentrations in the dam and neonate tissues/fluids increased with increasing CPF dose. Although TCP was detected in all dam blood samples, a dam liver sample, four neonate plasma samples, and four neonate brain samples that were part of the control group, mean TCP concentrations were below the LOD, or had measurements that were suspect due to contamination. Overall, the highest concentrations of TCP were observed in dam blood and liver. TCP concentrations in neonate plasma and liver were greater than TCP concentrations in neonate brain.

674 KINETICS OF PERCHLORATE-INDUCED INHIBITION OF IODIDE UPTAKE IN TISSUES OF THE PREGNANT RAT AND FETUS.

K. O. Yu, D. A. Mahle, L. Narayanan, R. J. Godfrey, G. W. Buttler, P. N. Todd, P. N. Parish, J. D. McCafferty, T. A. Ligman, T. R. Sterner, T. R. Bausman, J. W. Fisher and D. R. Mattie. *AFRL/HEST, Wright-Patterson AFB, OH.*

Perchlorate (ClO_4^-) acts as a competitive inhibitor for iodide uptake into the thyroid gland. This results in perturbation of biosynthesis of thyroid hormones necessary for neurodevelopment in prenatal and neonatal periods. The objective of this project was to determine disposition of ^{125}I in maternal and fetal tissues of Sprague-Dawley rats, and inhibition of iodide uptake in maternal thyroids. Pregnant rats (GD20, n=6) were intravenously injected with carrier-free ^{125}I (1.87 ng/kg, control) or with 1 mg/kg ClO_4^-, then with carrier-free ^{125}I 2h later. Dams were sacrificed at 0.5, 1, 2, 4, 8, 12 and 24h post dosing. Blood, thyroid, skin, placenta, mammary gland, amniotic fluid, gastric tract (GT) and gastric contents (GC) were collected as well as fetal blood, skin and GT. Percent inhibition of iodide uptake in dam's thyroid was observed at all time points, the highest (over 85%) at 1 and 2 h, and the lowest (over 65%) at 0.5 and 24 h post dosing of iodide. Concentrations of iodide in control serum at 0.5, 1, 2, 4, 8, 12 and 24 h were 2.99, 2.52, 2.35, 1.84, 1.26, 0.36 and 0.014 pg/ml. Iodide levels in control dam's serum and skin were similar during 24h period while iodide concentrations of control fetal serum and skin at 0.5, 1, 2, 4 and 8h were 0.81, 1.08, 1.03, 1.13, 0.57 and 1.10, 2.02, 1.37, 1.36, 1.56 pg/ml, respectively. Levels of iodide in amniotic fluid were lower than fetal skin levels except 24 h. Iodide levels of control dam's mammary gland at 4, 8, 12 and 24h were 2.41, 2.19, 2.38 and 1.49 pg/ml, respectively, and these are higher than dam's serum levels. Sequestration of iodide was evident in both fetal skin and dam's mammary gland. This information was used to develop a physiologically based pharmacokinetic model to illustrate target concentrations of ClO_4^- in prenatal period. In addition, this model will be employed to address potential risk associated with ClO_4^- exposure during gestation.

675 KINETICS OF PERCHLORATE AND IODIDE IN LACTATING S-D RATS AND PUPS AT POSTNATAL DAY 10.

D. A. Mahle[1], R. J. Godfrey[1], J. D. McCafferty[2], T. A. Bausman[1], L. Narayanan[3], M. A. Parish[1], P. N. Todd[2], T. A. Ligman[2], D. R. Mattie[2] and K. O. Yu[2]. *[1]ManTech Environmental Technology, Inc., WPAFB, OH, [2]AFRL/HEST, WPAFB, OH and [3]GEO-Centers, Inc, WPAFB, OH.*

Ammonium perchlorate (NH_4ClO_4), a groundwater contaminant resulting from military and industrial use, readily dissociates to NH_4^+ and ClO_4^-. The perchlorate ion (ClO_4^-) competes with I^- for uptake into the thyroid, potentially causing hypothyroidism. Time course studies were performed to understand better the kinetics of ClO_4^- and iodide in lactating dams and nursing pups. At postnatal day (PND) 10 female Sprague-Dawley dams were intravenously (i.v.) injected with 0.1 mg/kg ClO_4^- in water and returned to their culled litters. Dam serum, thyroid, skin, mammary gland and gastric contents and pup serum, skin, gastric tract and contents were collected at 0.5, 1, 2, 4, 8 and 12 hr for ClO_4^- analysis. To investigate the inhibition of iodide uptake by ClO_4^-, lactating dams at PND 10 were i.v. injected with 1 mg/kg ClO_4^- followed 2 hr later with an i.v. injection of carrier free ^{125}I and returned to their litters. Control sets of lactating dams were i.v. injected with carrier free ^{125}I only and returned to their litters. Dam serum, thyroid, skin, mammary gland and gastric contents and pup serum, skin, gastric tract and contents were collected at 0.5, 1, 2, 4, 8 and 24 hr for ClO_4^- and iodide analysis. Perchlorate level in serum after dosing with 0.1 mg/kg ClO_4^- was 0.19 ± 0.02 mg/ml at 4hr and was not detectable at 8 hr. Both male and female pups had 0.038 ± .003 mg/ml of ClO_4^- in serum at 12 hr. Perchlorate exposure inhibited iodide uptake into thyroids of lactating dams. At 30 min the bound iodide level in dam thyroid after ClO_4^- exposure was 0.19 ± .02 ng/g whereas the level in dam thyroid after iodide only exposure was 0.08 ± .03 ng/g. The information generated from this kinetic study will support the development and validation of a ClO_4^- lactation model. A risk assessment for ClO_4^-, supported by a lactation model, will address the risks associated with ClO_4^- exposure in a sensitive population.

676 ETHYLENE GLYCOL KINETICS IN PREGNANT RATS: DIFFERENCES BETWEEN SLOW AND FAST DOSE-RATE EXPOSURES.

E. W. Carney[1], A. B. Liberacki[1], B. Tornesi[1], K. K. Weitz[2], T. L. Luders[2] and R. A. Corley[2]. *[1]The Dow Chemical Company, Midland, MI and [2]Pacific Northwest National Laboratories, Richland, WA.*

Large bolus doses of ethylene glycol (EG) are developmentally toxic in rodents. However, human occupational and consumer exposures typically involve low doses and slow dose-rates (e.g. dermal, inhalation). This study examined the impact of dose-rate on maternal and embryonic kinetics of EG and its metabolites. Pregnant CD rats were dosed from gestation days (GD) 6-16 with 1000 or 2000 mg/kg/day of EG given either as a daily subcutaneous (SC) bolus injection (fast dose-rate) or constant rate infusion (slow dose-rate) *via* an implanted pump. Rats were also dosed by oral gavage (fast dose-rate) on GD 11 at either 100 or 1000 mg/kg. EG and its developmentally toxic metabolite, glycolic acid (GA) were determined in maternal blood samples on GD 7-15 in the SC bolus injection and continuous infusion study. Detailed analysis of the kinetics of EG, GA and oxalic acid (OX) were also determined in maternal blood, urine and kidneys, as well as conceptus fluids and embryos on GD 11-12 for the oral gavage and SC infusion studies. EG levels were similar in maternal blood *vs.* maternal tissues and conceptuses within a given treatment group, while GA levels were consistently higher in tissues than maternal blood. OX levels at all dose levels were variable but similar to control levels in all samples regardless of dose. Blood levels of EG and GA were similar following the two bolus administration routes. However, peak blood levels for both EG and GA were consistently higher (~5-fold for EG and ~50-fold for GA) following bolus oral and SC dosing than following constant rate SC infusion at comparable total dose levels. The lower levels of GA observed in the slow dose-rate group corresponded with the low toxicity characteristic of slow dose-rate administration of EG, as shown in previous studies. Therefore, bolus dosing with EG appears to significantly overestimate the risk of typical occupational and consumer exposures to EG. Funded by the American Chemistry Council, Arlington, VA.

677 BISPHENOL A (BPA): THE EFFECT OF AGE AND DOSE ON THE *IN VIVO* METABOLISM AND PHARMACOKINETICS FOLLOWING ORAL ADMINISTRATION TO MALE AND FEMALE NEONATAL AND ADULT SPRAGUE-DAWLEY RATS.

J. Y. Domoradzki[1], S. C. Hansen[1], C. M. Thornton[1], T. L. Card[1], M. D. Dryzga[1], J. M. Waechter[1] and R. N. Shiotsuka[2]. *[1]The Dow Chemical Company, Midland, MI and [2]Bayer Corp., Stillwell, KS.*

A previous study demonstrated the rapid clearance of BPA from blood following oral administration to adult rats with the principal metabolite being BPA-monoglucuronide (Toxicology Sciences 54: 3-18, 2000). Since the ontogeny of certain isozymes of glucuronyl transferases (GT) differ with age, the pharmacokinetics of BPA was studied in neonatal animals. ^{14}C-BPA was administered *via* oral gavage at 1 or 10 mg /kg bw in corn oil, to rats at post-natal day (pnd) 4, pnd 7, pnd 21, and 11-week old adults. Blood was collected at 0.25, 0.75, 1.5, 3, 6, 12, 18 and 24-h post-dosing. BPA and BPA-glucuronide in plasma were quantified by HPLC with eluent fractions collected for liquid scintillation spectrometry analysis. The data indicate that neonates at all three ages metabolized BPA to its monoglucuronide. The majority of the plasma radioactivity following administration of the higher dose was BPA-monoglucuronide with concentrations about 100-fold greater than the plasma concentrations of BPA, except at the earliest times post-dosing. BPA-monoglucuronide and BPA concentrations in plasma of neonates were greater than in adults, except at 24 h. BPA was not detectable in adult female plasma, except at 0.75-h post-dosing, and by 3-h in males. At a dose of 1 mg/kg, plasma radioactivity concentrations were ~10-fold lower than at a dose of 10 mg/kg and BPA-monoglucuronide was the only metabolite observed in plasma representing 91-100% of the radioactivity present. A clear dose dependency in the metabolism and pharmacokinetics of BPA administered to neonates was observed with nearly complete metabolism of BPA to BPA-monoglucuronide at a dose of 1 mg/kg. These data suggest GTs that can metabolize BPA to its monoglucuronide develop sufficiently early in rodents to efficiently metabolize low doses of BPA to its non-estrogenic metabolite. Sponsored by: PC/BPA Global Group, American Plastics Council, Arlington, VA.

678 METABOLISM AND PHARMACOKINETICS OF BISPHENOL A FOLLOWING ORAL ADMINISTRATION TO PREGNANT SPRAGUE-DAWLEY RATS.

L. H. Pottenger[1], J. Y. Domoradzki[2], S. C. Hansen[2], M. D. Dryzga[2], J. M. Waechter[2] and R. N. Shiotsuka[3]. *[1]Dow Europe, SA, Horgen, Switzerland, [2]The Dow Chemical Company, Midland, MI and [3]Bayer Corp., Stillwell, KS.*

A previous study demonstrated the rapid clearance of BPA from blood following oral administration to rats (Toxicology Sciences 54: 3-18, 2000). However, the pharmacokinetics of BPA has not been extensively studied in pregnant animals. In

this study, ^{14}C-BPA was administered *via* gavage at 10 mg BPA/kg body weight to time-mated pregnant rats on gestation days 6, 14, 17, and to non-pregnant female rats. Blood samples were collected at selected time points over a 96-h period following oral administration. Plasma radioactivity, BPA and BPA-glucuronide were quantified in pooled plasma samples by liquid scintillation counting or radiochemical profiling using HPLC. Pooled excreta samples from selected dose groups and collection intervals were profiled by HPLC to quantify total BPA parent, BPA-glucuronide and metabolites. Structural confirmation of BPA and BPA-glucuronide were confirmed, as in a previous study, for representative plasma, urine and fecal samples. Selected tissues were collected at sacrifice and analyzed for radioactivity, parent compound and metabolites, including blood, brain, embryo/fetus, fat, liver, kidneys, ovaries, placenta, uterus, skin, and remaining carcass. BPA pharmacokinetics and metabolism did not appear to be affected by pregnancy. There was evidence of enterohepatic circulation in all groups, based on a secondary peak in the plasma radioactivity concentration-time profile. Mean tissue concentrations were either non-quantifiable or <0.25 µg-equivalents/g tissue. No apparent selective affinity of either placenta or embryo/fetus for ^{14}C-BPA-derived radioactivity was observed. Systemic exposure to parent was very low based on plasma BPA concentrations. BPA-monoglucuronide was found to be the major metabolite in both pregnant and non-pregnant rats. This study provides important evidence that the disposition of BPA is not altered by reproductive status. *Sponsored by: PC/BPA Global Group, American Plastics Council, Arlington, VA.*

679 PHARMACOKINETICS OF ^{14}C-GENISTEIN FOLLOWING I.V. ADMINISTRATION IN ADULT FEMALE SPRAGUE-DAWLEY RATS.

A. Upmeier, B. A. Elswick, H. D. Parkinson and S. J. Borghoff. *CIIT Centers For Health Research, Research Triangle Park, NC.*

Genistein is a phytoestrogen present in soy-food and virtually all rodent diets and has been reported to elicit detectable estrogenic effects in developing rodents. Understanding the placental transfer of genistein in rats as a possible route of exposure during development will be important for assessing potential effects. As a first step this study was designed to evaluate the clearance of genistein from blood of nonpregnant female Sprague-Dawley rats dosed with ^{14}C-genistein. The time profile of genistein blood kinetics was established following intravenous administration of a high dose (40 mg/kg b.w.) and low dose (4 mg/kg b.w.) of ^{14}C-genistein (10 µCi/rat; 1 ml/kg, in 65% DMSO) 48 hours following jugular vein cannulation. Blood samples were taken at 0, 5, 15, 30, 45, 60, 90, 120, 180, and 240 minutes following dosing and total radioactivity in plasma determined by liquid scintillation spectrometry. Five minutes after the administration of genistein, the plasma concentration was 130 ± 28 and 7.9 ± 2.7 µg genistein equivalents/ml plasma following high and low dose, respectively. These plasma levels rapidly declined so that by one hour the levels were 16 ± 7.1 and 0.9 ± 0.2 µg genistein equivalents/ml in the high and low-dosed animals, respectively. Fitting the plasma concentration-time curves to a 2-compartment model the initial half-life (alpha-phase) was estimated to be ~ 12 min for the 40 mg/kg b.w. dose and ~ 7 min for the 4 mg/kg b.w. dose. The terminal half-life (beta-phase) derived from the curve of the high dose was approximately 2.3 hr. Because the levels of genistein fluctuated during the terminal phase of elimination following the low dose, this half-life could not be determined. These fluctuations may be influenced by enterohepatic circulation of genistein which is known to occur in rats. These data provide the kinetic information that can be used in conjunction with a PBPK model to estimate metabolic rate constants for genistein. This study was funded in part by the American Chemistry Council.

680 DISTRIBUTION OF MANGANESE IN THE BRAIN OF STAINLESS STEEL WELDING FUME INHALED SPRAGUE-DAWLEY RATS.

I. J. Yu[1], J. Park[2], E. Park[1], S. Song[1], J. Han[1], Y. Chung[1] and H. Chung[1]. *[1]Center for Occupational Toxicology, Korea Occupational Safety & Health Research Institute, Daejeon, South Korea, [2]Dept. of Preventive Medicine, Chung-Ang University, Seoul, South Korea and [3]Dept. of Pathology, Cung-Ang University, Seoul, South Korea.*

Welders working in the confined space like shipbuilding industry have a risk of exposing a high concentration of welding fumes and of developing pneumoconiosis or other welding fume exposure related diseases. Among them, manganism caused by welding fume exposure is still controversial and no clear demonstration of manganese movement into specific brain regions. To investigate distribution of manganese in the brain of welding fume exposed rats, welding fumes generated from manual metal arc stainless steel (MMA-SS) were exposed to male Sprague-Dawley rats with concentrations of 63.6 ± 4.1 mg/m^3 (low dose) and 107.1 ± 6.3 mg/m^3 (high dose) total suspended particulates for 2 hrs per day, in an inhalation chamber for 90 days. Blood, brain, lung and liver were collected at the end of 1. 15, 30, 60, and 90 days of exposure, and the tissues were analyzed for their manganese concentrations by atomic absorption spectrophotometer. Although there were dose dependent increases of manganese concentrations in the lungs of exposed rats during 90 days of exposure, only slight manganese increases were detected in the blood during exposure period. Major statistically significant increases of manganese concentrations in the brain were detected in the cerebellum after 15-60 days of exposure. There were slight increases of manganese concentrations in the substantia nigra, basal ganglia (caudate nucleus, putamen and globus pallidus), temporal lobe and frontal lobe.

681 CELL TYPE SPECIFIC DIFFERENCES IN FORMATE TOXICITY.

J. L. Emmrich, M. M. Henry, C. M. Skumatz, J. M. Burke and J. T. Eells. *Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

Methanol is an important health and environmental concern because of the neurotoxic actions of its metabolite, formic acid. Formic acid has been hypothesized to act as a mitochondrial toxin to produce retinal and optic nerve toxicity. Studies in our laboratory using a methanol-sensitive rodent model have revealed functional, metabolic and structural abnormalities in the retina consistent with this hypothesis. The present studies were undertaken to further define the mechanism of formate toxicity by examining cell-type specific differences and cellular consequences of formate toxicity. Madin-Darby canine kidney cells (MDCK), retinal pigment epithelial cells (RPE), and a photoreceptor cell line (661W) were exposed to formate (1-100mM) over 3 time courses (10 min, 24 hrs, and 13 dys). Cellular formate concentrations, morphologic changes, and cellular ATP concentrations were assessed. Intracellular formate concentrations increased to a similar extent in all 3 cell types. In cultures exposed to 10 mM formate, concentrations increased from basal concentrations of 8.8 ± 1.1 µmoles formate/mg protein to a plateau concentration of 115.2 ± 12.5 µmoles formate/mg protein following 6 dys of exposure. In cultures exposed to 100mM formate, intracellular formate concentrations increased for 6 dys plateauing at 253.4 ± 21.4 µmoles formate/mg protein. Formate treatment produced morphologic changes in MDCK cells primarily characterized by cell swelling. No morphologic alterations were observed in RPE or 661W cells. Intracellular ATP concentrations were significantly decreased in MDCK cells and RPE cells within 24 hours. In 661W cells, ATP concentrations increased from 15 ± 2 to 26 ± 3 nmoles ATP/mg protein within minutes followed by a significant decrease in ATP concentrations to 5 ± 1 nmoles ATP/mg protein by 6 hrs. These data provide evidence of cell-type specific differences in the cytotoxic actions of formate. They further suggest that intracellular compensatory mechanisms are rapidly triggered following formate exposure. (RO1-ES06648, RO1-EY11396 and P30-EY01931).

682 ESTIMATING MINIMUM CRITERIA FOR JUDGING THE PERFORMANCE OF TOXICITY TESTS IN VALIDATION STUDIES.

J. W. Harbell[1], R. D. Curren[1] and L. H. Bruner[2]. *[1]Institute for in vitro Sciences, Inc., Gaithersburg, MD and [2]Gillette Medical Evaluation Laboratories, Needham, MA.*

It is often stated that a new toxicity test (NTT) must provide a level of protection equivalent to or better than the reference test it will replace. It is less clear how to measure the performance of a reference test in a manner that is useful for comparison with a NTT. The purpose of this report is to describe an approach used to define the predictive capacity of a commonly used *in vivo* method, the Draize eye irritation test. Data were obtained on the reproducibility of the Draize test from the scientific literature. These data were then used to define variability terms used in a computer simulation that models the predictive capacity of the Draize test. The validity of the simulations was verified by comparing actual *in vivo* data with results from the simulations. The Draize test variability is greatest for the mildest irritants. The maximum expected correlation coefficient is r = 0.84. The expected sensitivity = 0.74-0.95, specificity = 0.67-0.87, and concordance = 0.82-0.92 depending on the cutoff chosen. The width of the 95% prediction interval ranges between 16 and 93 for a predicted maximum average score of 55 on the 110-point scale. These performance statistics can be used as baseline criteria for judging the adequacy of NTT intended to replace the *in vivo* test.

683 ESTIMATION OF DNA STRAND BREAKS IN LENS EPITHELIAL CELLS: WHITE LIGHT MEDIATED GENOTOXICITY.

N. P. Singh[1], P. E. Penn[2], W. R. Pendergrass[2] and N. S. Wolf[2]. *[1]Bioengineering, University of Washington, Seattle, WA and [2]Pathology, University of Washington, Seattle, WA.*

It was hypothesized that white light induces DNA single-strand breaks/alkali labile sites in lens epithelial cells of 60 day old Brown Norway rats during the dissection process. Rats were narcotized using carbon dioxide gas and eye lenses were dissected

out either in white or red light at a distance of 3.5 inches and for a duration of approximately five minutes. Electrical input to lamps was adjusted such that the light delivered from each was approximately equal to the intensity of 100 foot candles (1076 lux). DNA single strand breaks/alkali labile sites were estimated using the alkaline microgel electrophoresis (COMET) assay. Dissection of lenses in white light induced significantly higher integrated intensity ($p=0.0216$), tail moment ($p=0.0453$), comet extent ($p= 0.0462$, tail extent ($p=0.0048$) and tail breaks ($p=0.048$) as indices of DNA single strand breaks/alkali labile sites. In addition, we investigated the DNA damaging effect of visible light in a human lymphocyte model in which cells were exposed to white, red or minimal indirect light for five minutes. Results of these experiments confirm our conclusion regarding the ability of visible light to induce DNA damage in individual, isolated cells. Our results on the ability of visible light to induce DNA single strand breaks/alkali labile sites may have numerous implications in both plant and animal cells. These findings may also relevant while conducting genotoxicity assays on cells *in vitro*.

684 VALIDATION OF A MODEL OF PHOTORECEPTOR DEGENERATION IN THE RAT.

M. Vezina, I. Tourigny, P. Gaines and G. Washer. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

A rat model of light-induced photoreceptor degeneration was validated in order to serve as an efficacy model for therapeutics directed towards prevention of retinal damage. The design included a positive control group which received an intravitreal injection of brain-derived neurotrophic factor (BDNF) in one eye and the negative control (saline) in the contralateral eye. A negative control group received the intravitreal injection of saline in one eye, while the contralateral eye served as an untreated control. Animals were housed under reduced illumination (£20 foot candles) and 12 hour light cycle, for 10 days prior to injection. Twenty-four hours following the injections, the rats were placed into housing units which ensured continuous and complete (even distribution) light exposure at approximately 200 foot candles, for 84 hours. Thereafter the animals were returned to standard caging, with a 12 hour light cycle, where they were maintained for 14 days. A series of scotopic and photopic electroretinograms (ERGs) were performed prior to the injections and again at the end of the 14 day observation period. Following termination, 5 serial sections of each eye (from inferior to superior eye, including the outer nuclear layer) were prepared and examined histopathologically. Both ERG and histopathology examinations confirmed the light exposure to have induced photoreceptor degeneration in negative control and uninjected eyes. Anticipated neuroprotective action of the positive control compared to the negative control was also evident and therefore the model was considered suitable for use in efficacy evaluations of neuroprotective agents in retinal indications.

685 ROLE OF LENTICULAR CHOLESTEROL BIOSYNTHESIS AND SMALL GTP-BINDING PROTEINS IN THE CJ-12, 918 RAT CATARACT.

D. J. Baltrukonis[1], S. Paillet[2], S. M. Kajiji[2], M. D. Alco[1] and M. E. Verdugo[1]. [1]*Drug Safety Evaluation, Pfizer Global R&D, Groton, CT and* [2]*Cancer Biology, Pfizer Global R&D, Groton, CT.*

Purpose: Alterations in cholesterol biosynthesis, either through drug inhibition (i.e. lovastatin and triparanol) or inherited genetic defects, are associated with cataract formation in animals and humans. We have previously reported CJ-12, 918 inhibits lenticular cholesterol biosynthesis before significant alterations in lenticular ATP, GSH, and γ-crystallin content, or clinical evidence of cataract formation in the rat. Rao *et al.* have demonstrated *in vitro* that lovastatin inhibits the isoprenylation of small GTP binding proteins in lens epithelial cells (LEC) and have proposed this as the main mechanism of the lovastatin *in vitro* rat and *in vivo* canine cataract. The following study investigates whether CJ-12, 918, like lovastatin, alters small GTP binding protein isoprenylation in primary LEC. Methods: Rat and canine LEC were treated with CJ-12, 918 (10-50 μM) or lovastatin (10-50 μM) for 48 hrs. RhoA/RhoB and Ras isoprenylation expression were analyzed in the membrane/cytosol fractions, and phosphorylated ERKII in the whole cell lysate by Western blot. Results: No change in rat or canine LEC isoprenylation patterns or phosphorylated ERKII was observed with CJ-12, 918 treatment. However, treatment with lovastatin decreased Ras and Rho expression in the membrane fraction with a concurrent increase in the cytosol fraction and decreased phosphorylated ERKII in the whole cell lysate. In the canine LEC, these isoprenylation changes with lovastatin treatment were shown to be concentration-dependent. The effects of lovastatin treatment (50 μM) in the rat LEC were alleviated with mevalonic acid supplementation (100 μM). Conclusions: Our data support lovastatin inhibition of small GTP binding protein isoprenylation in LEC *in vitro*. CJ-12, 918 does not inhibit small GTP binding protein isoprenylation. The major mechanism of the CJ-12, 918 cataract appears to be inhibition of lenticular cholesterol biosynthesis late in the pathway.

686 OCULAR IRRITANCY OF COMMON CONSUMER PRODUCTS USING THE CULTURED BOVINE LENS.

J. G. Sivak, W. Wong and K. L. Moran. *Optometry, University of Waterloo, Waterloo, ON, Canada.* Sponsor: L. Ritter.

In recent years, abattoir-supplied bovine lenses have been cultured to measure ocular irritancy as an alternative to the Draize Test. This approach uses cultured cells and a laser-scanning instrument to measure the optical quality of bovine lenses exposed to potentially harmful agents. Quantitative results are obtained rapidly and objectively, and with greater sensitivity, than the Draize Test or other suggested alternatives such as BCOP. We report here the results of a study, which measures the ocular irritancy caused by common semi-solid and solid materials that are partially or not transparent. The consumer products tested included 2 shampoos, 4 body washes, 2 lotions, 3 toothpastes, 3 facewashes, as well as, a deodorant and an antiperspirant; for a total of 16 products. The number of lenses tested per product ranged from 7 to 11, with a total of 153 tested lenses. An additional 28 untreated lenses were tested as controls. Each treated lens was exposed to a test material for 15 minutes at room temperature. The material was then washed off the lens with sterile salt solution and culture medium and the lens was then cultured, as before the exposure, at 37 degrees Celsius. Lens optical function was measured periodically for eight days. Lens damage, as indicated by increased focal variability (loss of sharp focus), appears between 1.7 and 123 hours after exposure. Thus, the results indicate large ranges in ocular irritability on the basis of time to induce damage. This wide range is true both between groups of products and within each group. The deodorant /anti-perspirant results indicate most damage (about 2 to 4 hours) while, on average, the shampoos and the then the body washes are least damaging (about 90 hours and 21 hours, respectively). This study supports an earlier preliminary one showing that the cultured bovine lens can be used to measure ocular irritancy of semi-solid and non-transparent substances. It also demonstrates the sensitivity needed to produce a rank order of irritancy within the various products groups.

687 INTERIM DATA FOR A NINE-MONTH LOCAL TOLERANCE AND TOXICITY STUDY OF EYE001 GIVEN BY INTRA-VITREOUS INJECTION TO BEAGLE DOGS.

D. D. Norton[1], W. M. Dairman[2,3] and C. B. Spainhour[1]. [1]*Calvert Preclinical Services, Inc., Olyphant, PA,* [2]*W. D. Associates, Marco Island, FL and* [3]*EYETech Pharmaceuticals, New York, NY.*

EYE001, an RNA oligonucleotide attached to a PEG group, inhibits angiogenesis in the retina of the eye by binding to vascular endothelial growth factor ($VEGF_{165}$). It has shown activity in Phase I clinical trails for age-related macular degeneration, a disease associated with excess choroidal neovascularization. EYE001 is unique, in that it is one of the first RNA-based products under clinical development to inhibit a mammalian growth factor. The objective of the study was to determine local tolerance and toxicity of EYE001 when administered once every 2 weeks to beagles *via* intra-vitreal injection for nine months. Animals received intra-vitreal injections of vehicle or EYE001 (0.1 ml volume at 3.0 mg/ml, 10.0 mg/ml or 30.0 mg/ml, into each eye). Dosage was calculated on the aptamer (RNA) component of the test article. While animals were under light anesthesia, an eyelid speculum was inserted to keep the eyelid open. The globe was rotated in an inferior fashion. The needle tip (27 gauge) of the syringe was placed perpendicular to the globe at a position 7 mm superior from the limbus on the scleral portion of the globe and pressure applied until the needle tip just penetrated the sclera. The angle to the orthoganol injection line was then increased (30-45°) by rotation downward to a point that facilitated administration of the material into the posterior portion of the eye. Possible toxicity was observed by eye exams using an indirect ophthalmoscope and slit lamp, fundus photography, electroretinographic and intraocular pressure measurements, daily macroscopic observation, clinical signs, body weight and food consumption determinations. Animals had blood and urine samples collected for hematology, coagulation and serum clinical chemistry profiles and semi-quantitative urinalyses prior to study initiation and at weeks 13 and 27. Through thirty weeks, the data indicate that EYE001 does not appear to cause local or systemic toxicity in the beagle dog.

688 PROTECTIVE ROLE OF THE HUMAN CORNEAL ALDH3A1 AGAINST UV-INDUCED TOXICITY.

V. Vasiliou, R. Manzer and A. Pappa. *Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Aldehyde dehydrogenase 3A1 (ALDH3A1) is a significant constituent of mammalian corneal epithelium, representing 20-40% of total water soluble protein. Several hypotheses are proposed for the role of ALDH3A1 which include: (a) metabolism of cytotoxic aldehydes formed during UV-induced lipid peroxidation, such as 4-hydroxy-2-nonenal (4-HNE), (b) direct absorbance of UV-light, and (c) generation of NAD(P)H, which has recently been assigned a UVB absorbing species. The aim of this study was to develop human corneal epithelial cell lines expressing the human ALDH3A1 at levels similar to those observed *in vivo*, and to

study the role of this enzyme against UV-induced toxicity. We have established three types of transfected cell lines expressing ALDH3A1 at high, moderate and low levels. Our data indicate that ALDH3A1 protects against 4-HNE-induced cytotoxicity. Furthermore, Western blot analysis using antibodies against 4-HNE-adducted proteins revealed that ALDH3A1 also prevents adduction of the corneal epithelial proteins by 4-HNE. Enzyme kinetics with a human recombinant ALDH3A1 showed a Km of 32 mM for 4-HNE. Finally, ALDH3A1 expression protects corneal epithelial cells against UVB and/or UVC-induced cytotoxicity. In conclusion, the human ALDH3A1 appears to be a significant factor against UV-induced toxicity. [Supported by NEI 1 R29 EY11490].

689 INDUCIBLE EXPRESSION OF GLUTAMATE-CYSTEINE LIGASE AFFECTS CARBON TETRACHLORIDE-INDUCED LIVER INJURY IN TRANSGENIC MICE.

S. Shi[1], D. Botta[1], C. C. White[1], M. J. Dabrowski[1], S. L. Srinouanprachanh[1], F. M. Farin[1], R. H. Pierce[4], C. B. Ware[2], W. C. Ladiges[2], N. Fausto[3], S. Y. Tsai[3], B. W. O'Malley[5] and T. J. Kavanagh[1]. *[1]Environmental Health, University of Washington, Seattle, WA, [2]Comparative Medicine, University of Washington, Seattle, WA, [3]Pathology, University of Washington, Seattle, WA, [4]Pathology and Laboratory Medicine, University of Rochester Medical Center, Rochester, NY and [5]Molecular and Cell Biology, Baylor University College of Medicine, Houston, TX.*

Glutathione (GSH) is a major free radical scavenger and is important in detoxification of xenobiotics such as carbon tetrachloride (CCl4). The rate-limiting enzyme in GSH synthesis is glutamate-cysteine ligase (GCL) which is composed of catalytic (GCLc) and modifying (GCLm) subunits. Transgenic mice that conditionally overexpress GCLc and/or GLCm using a mifepristone (RU486) sensitive GeneSwitchTM system have been generated, and we have demonstrated RU486-inducible expression of the transgene(s) in the liver of these animals. We examined the influence of GCLc and GCLm overexpression on the extent of CCl4-induced liver toxicity. GCL transgenic mice were less susceptible to liver injury following RU486 administration and subsequent CCl4 treatment as revealed by serum ALT activity measurements and histopathology scores of the liver. GCL transgenic mice also showed lower levels of lipid peroxidation that is an early event in CCl4-induced liver injury. In contrast, administration of RU486 in nontransgenic mice synergized carbon tetrachloride-induced liver injury.

690 REGULATION OF THE MOUSE GLUTAMATE CYSTEINE LIGASE MODIFIER SUBUNIT GENE *VIA* THE ARE AND NRF/AP1 BINDING SITES.

E. N. Hudson[1], F. Bea[2] and T. J. Kavanagh[1]. *[1]Environmental Health, University of Washington, Seattle, WA and [2]Pathobiology, University of Washington, Seattle, WA.*

We previously reported that basal and BHQ-inducible expression of the mouse glutamate-cysteine ligase modifier subunit gene (Gclm) was dependent upon regulatory elements located within 787 bp upstream of its translation start codon. This region is highly homologous to the human GCLM promoter and contains a conserved antioxidant response element (ARE). Electromobility shift assays (EMSAs) reveal constitutive and BHQ-inducible binding of mouse Hepa-1 nuclear factors to this ARE, and mutagenesis of the ARE in a luciferase reporter construct containing 1.3 kb of Gclm promoter preferentially diminished inducible expression and affected basal expression as well. EMSAs reveal constitutive and BHQ-inducible binding of nuclear factors at a putative Nrf/AP1 site 90 bp upstream of the ARE. A single base-pair substitution at this site reduced basal expression of the reporter 100-fold while BHQ induction was conserved. The transcription factor Nrf1 mediates Gclm expression as evidenced by a 10-fold reduction in luciferase reporter activity in Nrf1-deficient cells which can be partially restored upon cotransfection with Nrf1 cDNA. Deletion constructs indicate that Nrf1-responsive elements lie within the region containing the ARE and upstream Nrf/AP1 site, and inclusion of a-Nrf1 or a-Nrf2 antibodies inhibits binding and induces a subshifted band respectively in binding reactions for both the ARE and Nrf/AP1 sites. Finally, mutations of the ARE in reporter constructs diminished basal and inducible expression in wild-type MEFs but had no effect in Nrf1-deficient cells. Taken together, these data indicate regulation of Gclm by the transcription factors Nrf1 and Nrf2 *via* the ARE and upstream Nrf/AP1 binding site.

691 GLUTAMATE CYSTEINE LIGASE LEVELS IN HUMAN PERIPHERAL BLOOD LYMPHOCYTE SUBTYPES.

L. M. Bekris, A. J. Jabbour, M. J. Dabrowski, T. K. Takaro, T. J. Kavanagh and E. M. Faustman. *Environmental Health, University of Washington, Seattle, WA.* Sponsor: E. Faustman.

Glutahione (GSH) plays a role in the immune response associated with inflammation. GSH disruption has been implicated in inflammatory lung diseases such as idiopathic pulmonary fibrosis, cystic fibrosis and chronic beryllium disease. Glutamate cysteine ligase (GCL) is the enzyme catalyzing the rate-limiting step in the formation of GSH. The aim of this investigation was to determine the levels of the GCL catalytic subunit (GCLC) in human peripheral blood lymphocyte (HPBL) subtypes according to cell cycle in normal healthy individuals. PHA stimulated HPBL GCLC levels were measured by staining with a rabbit polyclonal anti-GCLC peptide antibody and a goat anti-rabbit FITC labeled secondary antibody. HPBL subtypes and cell cycle phases were determined by staining for lymphocyte cell surface markers and DNA content. Antibody binding was then analyzed on a flow cytometer and a multiparameter analysis performed utilizing Multiplus software. PHA stimulated lymphocytes were found to have similar GCLC levels as non-stimulated lymphocytes. CD8 T-cells have the highest levels of GCLC. CD14 monocytes have the lowest GCLC levels which decrease further upon PHA stimulation. CD19 PHA stimulated B-cells have intermediate levels of GCLC which increase upon PHA stimulation. Cell cycle analyses suggest G1 phase GCLC levels are highest in CD4 and CD8 T-cells. Whereas, G1 and S/G2 phase GCLC levels are similar in CD14 monocytes. G1 phase GCLC levels in CD19 B-cells are higher in the PHA stimulated B-cells than in the non-stimulated B-cells. This information will contribute to the understanding of the role of GSH and GCL in the proliferation of lymphocyte subtypes and in defining potential immunotoxicity within sensitive populations. This study was supported by the Department of Energy *via* the Consortium for Risk Evaluation with Stakeholder Participation and NIH grants P30-ES04696, P50-ES07033

692 GENERATION OF A *Gclc(ii)* INDUCIBLE KNOCKOUT MOUSE LINE, USING THE *Cre/loxP* SYSTEM.

Y. Yang, T. P. Dalton, L. Driscoll, Y. Chen, H. G. Shertzer and D. W. Nebert. *Center for Environmental Genetics, and Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Glutathione (GSH) is the most abundant nonprotein thiol in mammalian cells. Glutamate-cysteine ligase (GCL) is the rate-limiting enzyme in the glutathione (GSH) biosynthesis pathway. This holoenzyme is a heterodimer comprising a catalytic subunit (GCLC) and a modifer subunit (GCLM). Although *Gclc(-/-)* mice homozygous for the targeted disruption of the *Gclc* gene have provided insight into the developmental roles of GSH synthesis, the early embryonic lethality of these animals precludes studies of GSH during later development and organogenesis. To overcome this obstacle, we have generated an inducible knockout mouse line, whose *Gclc* gene was flanked by *loxP* sites in introns 3 and 6. Homozygous *Gclc(i/i)* mice containing the floxed *Gclc* gene have the same GSH level as *Gclc(+/+)* wild-type mice, suggesting that insertion of the *loxP* sites has no effect on *Gclc* expression. The ability of the *Cre* recombinase enzyme to cause deletion of the floxed allele was tested *in vivo* by crossing *Gclc(i/i)* mice to mice carrying a *Cre* transgene. Homozygous deletion of the floxed allele in the *Cre/loxP* progeny resulted in embryonic lethality that coincides with the phenotype observed in the conventional knockout mouse. This inducible knockout mouse line will serve as a valuable tool to investigate the role of GSH synthesis in a tissue- and temporal-specific manner.——*Supported, in part, by NIH grants P30 ES06096 and R01 AG09235.*

693 GLUTATHIONE S-TRANSFERASE EXPRESSION IN HUMAN LIVER MITOCHONDRIA.

J. L. Gardner, D. S. Barber and E. P. Gallagher. *Physiological Sciences, University of Florida, Gainesville, FL.*

The mitochondrial environment is rich in reactive oxygen species (ROS) that may ultimately peroxidize membrane proteins and generate highly reactive unsaturated aldehydes such as 4-hydroxy-2-nonenal (4HNE). Accordingly, multiple protective pathways have arisen to ensure mitochondrial function during oxidative stress. In the present study, affinity chromatography was used to isolate glutathione S-transferases (GSTs) from human hepatic mitochondria. HPLC-subunit analysis of affinity-purified liver mitochondria suggested the presence of at least two or more mitochondrial glutathione S-transferases (GSTs). Amino acid sequencing and immunologic analyses of affinity-purified GST indicated the presence of two alpha class GSTs related to hGSTA4-4 and hGSTA1/2, isozymes that protect against oxidative injury. Matrix-assisted laser desorption/ionization mass spectroscopy was used to further characterize the mitochondrial GST isozymes. Results from this ongoing investigation suggest that GST may represent an important pathway to protect the mitochondrion from the deleterious effects of ROS. Supported by N.I.H. ES-09427 and U.S.E.P.A. R-827441.

694 OVEREXPRESSION OF A MITOCHONDRIAL GLUTATHIONE TRANSPORTER IN NRK-52E CELLS.

D. A. Putt[1], L. H. Lash[1] and L. H. Matherly[1,2]. *[1]Pharmacology, Wayne State University Sch. Med., Detroit, MI and [2]Karmanos Cancer Institute, Wayne State University Sch. Med., Detroit, MI.*

The dicarboxylate carrier (DCC) of the mitochondrial inner membrane was cloned from total rat kidney RNA, expressed in *E. Coli* as a His_6-tagged protein, and shown to transport both malonate and glutathione (GSH) with properties that

were similar to what we described previously. The cloned, expressed, purified and reconstituted DCC protein exhibited saturable uptake of both malonate and GSH. Uptake of GSH was inhibited by several competitive substrates (butylmalonate, L-γ-glutamyl-L-glutamate, ophthalmic acid, malonate) and by pyridoxal 5'-phosphate and mercurials. Malonate uptake was inhibited by butylmalonate, pyridoxal 5'-phosphate, mercurials and, most significantly, by GSH. Like many immortalized cell lines, NRK-52E cells (derived from normal rat kidney cells) exhibited low, endogenous levels of many mitochondrial processes, including respiration, activities of dehydrogenases, and substrate transport. Fluorescent imaging with MitoTracker® Orange suggested, however, that these cells do contain a high density of mitochondria; we conclude that many mitochondrial processes are, therefore, down-regulated. NRK-52E cells were transiently transfected with the cDNA for rat DCC to overexpress mitochondrial GSH transport activity. Expression of the rat DCC-His_6 fusion protein was confirmed by Western blot analysis. Mitochondria from transfectants exhibited 2.1 to 6.8-fold higher activity for uptake of 5 mM GSH and 2.0 to 10.7-fold higher activity for uptake of 1 mM malonate as compared to mitochondria from normal cells. We are currently developing stable transfectants that overexpress the DCC protein and investigating the effect of higher mitochondrial GSH transport activity in the transfected cells on susceptibility to chemically induced apoptosis. Preliminary results suggest that transfectants are indeed less sensitive than normal cells to chemically induced injury. (Supported by NIDDK Grant DK40725.)

695 ALKYLATION AND INACTIVATION OF HUMAN GLUTATHIONE TRANSFERASE ZETA (HGSTZ1-1) BY MALEYLACETONE AND FUMARYLACETONE.

H. B. Lantum[1], D. C. Liebler[2], P. G. Board[3] and M. W. Anders[1]. *[1]University of Rochester, Rochester, NY, [2]University of Arizona, Tucson, AZ and [3]Australian National University, Canberra, Australia.*

Glutathione transferase zeta (GSTZ1-1) catalyzes the cis-trans isomerization of maleylacetoacetate (MAA) or maleylacetone (MA) to fumarylacetoacetate or fumarylacetone (FA), respectively. GSTZ1 also catalyzes the glutathione (GSH)-dependent biotransformation of a variety of α-haloacids, including dichloroacetic acid (DCA). This study was designed to investigate the mechanism of inactivation of hGSTZ1-1 by MA and FA and to determine the covalent modification of hGSTZ1-1 by MA and FA in the presence and absence of GSH. MA and FA (0.01-1 mM) inactivated hGSTZ1-1 in a concentration- and time-dependent manner and these effects were blocked by GSH. MA or FA did not, however, inactivate the C16A mutant of hGSTZ1c-1c. ESI-MS/MS and SALSA (Scoring Algorithm for Spectral Analysis) analyses of tryptic digests of hGSTZ1 variants revealed that the active site (SSC*SWR) and C-terminal (LLVLEAFQVSHPC*R) cysteine residues of hGSTZ1-1 were modified by Michael addition reactions. MA and FA ($HOOCCH{=}CHCOCH_2COCH_3$) adduction caused diagnostic 156 Da shifts in the masses of the modified peptide ions and in their MS-MS fragment ions. Alkylation of the active site cysteine residues, but not of the C-terminal cysteine, was relatively less intense when hGSTZ1-1 variants were incubated with MA or FA in the presence of S-methyl glutathione. These data indicate that MA and FA are substrate and product inactivators of GSTZ1-1 and covalently modify GSTZ1-1 at the active site cysteine residue in the absence of GSH. That these effects are blocked by GSH indicates that the mechanism of catalysis of GSTZ1-1 is by an obligate ordered reaction with GSH binding before MAA or MA. These data also indicate that MA and FA may covalently modify and inactivate other proteins that have accessible cysteine residues and thereby in part contribute to DCA- or hypertyrosinemia type I-associated toxicities. (Supported by NIEHS grant ES03127, ES10056, and ES06694).

696 DEPENDENCE OF CYTOLOGICAL GRADINGS OF EXFOLIATED UROTHELIAL CELLS UPON GSTM1 AND GSTT1 POLYMORPHISM IN FORMERLY BENZIDINE-EXPOSED WORKERS.

Q. J. Ma[1], G. F. Lin[1], J. G. Chen[2], J. H. Shen[1], C. Q. Xiang[2], K. Golka[3] and D. S. Zhang[2]. *[1]Sino-German Laboratory of Toxicology, Shanghai Institutes of Biological Sciences, Shanghai, China, [2]Municipal Center for Disease Prevention and Control, Shanghai, China and [3]Institute of Occupational Physiology at the University of Dortmund, Dortmund, Germany.*

The distribution of the polymorphic alleles of the genes coding for glutathione S-transferases (GSTs) M1 and T1 was compared to results of a cytological grading according to Papanicolaou of exfoliated urothelial cells in a non-diseased high-risk group formerly exposed to benzidine in the Shanghai dyestuff industry (n=317). All subjects were genotyped for GSTT1 and M1 gene polymorphism by allele-specific PCR. Individuals were stratified according to the job and duration of exposure. A subgroup of 78 cases with cytological gradings grade III or higher (according to Papanicolaou) showed a significant under-representation of the combination of GSTT1 0/0 and M1 0/0 genotypes compared to 238 subjects with a cytological classification lower than grade III (OR=0.55, 95% CI=0.31-0.98, P=0.04). These results suggest that neither the GSTM1 0/0 or GSTT1 0/0 genotypes alone nor their combination do have a clear association with cytopathological changes in exfoliated urothelial cells from individuals previously exposed to benzidine in Shanghai. This is contradictory to studies reporting that the GSTM1 0/0 genotype is associated with an increased risk for bladder cancer in the general population, mostly outside China.

697 CELLULAR GLUTATHIONE DISTRIBUTION DURING OXIDATIVE STRESS.

D. A. Lawrence and J. G. Ault. *Clin Exp Endocrinol Immunol, Wadsworth Center, New York State Department of Health, Albany, NY.*

Oxidative stress causes molecular changes within cells that can lead to cytotoxic outcomes. Glutathione, a ubiquitous thiol-reactive tripeptide, plays a major role in regulating responses to oxidants. Glutathione in its reduced form (GSH) also is suggested to assist in intracellular protein translation and trafficking. With the use of a monoclonal antibody (mouse IgG1; 8.1GSH; StressGen, Victoria) against the glutathione adduct with N-ethylmaleimide, we have determined the cellular distribution of GSH in three human leukocyte cell lines (Jurkat, T cells; Daudi, B cells, and THP-1, monocyte-like) by an immunoelectron microscopy method (gold conjugated goat anti-mouse IgG). In general, the distribution pattern was quite similar with GSH distributed in most cellular compartments, including the nucleus. The lumen of rough endoplastic reticulum was the one area with less GSH. After stress with diamide (0.1 mM), ethycrinic acid (0.1 mM), or L-buthionine-(S, R)-sulfoximine (BSO; 1 mM), the distribution patterns among the cell types demonstrated some differences. On the whole, the mitochondria maintained residual reservoirs of GSH. The THP-1 line showed a major increase in vacuoles and membrane blebbing; however, results were not consistent even within this homogenous cell line, suggesting possible cell cycle influences. In general, the immunoelectron microscopy results were similar to results by flow cytometry with regard to the amount of 8.1GSH-reactive GSH in the various cell lines after the oxidative stresses. Work support, in part, by NIEHS grant ES03778.

698 NUCLEAR GLUTATHIONE REDUCTASE ACTIVITIES ARE INCREASED DURING S PHASE OF CELL CYCLE IN CHO CELLS.

L. K. Rogers, T. N. Hansen, S. E. Welty and C. V. Smith. *Pediatrics, Children's Research Institute, Children's Hospital, The Ohio State Univ., Columbus, OH.*

Glutathione reductase (GR) is a key enzyme in the glutathione antioxidant pathway, reducing glutathione disulfide (GSSG) to the thiol form (GSH). We have previously demonstrated GR localization in the mitochondria, the nucleus, and the nucleoli of rat liver tissue. The goal of the present study was to test the hypothesis that nuclear GR activities changed in a cell cycle-dependent manner, which would suggest a role for GR in regulation of cell cycle progression and related cell responses. CHO (Chinese Hamster Ovary) cells were plated at 3×10^6 cells/plate in McCoy's media supplemented with 10% FCS and allowed to adhere for 24 h. The media was then replaced with McCoy's media supplemented with 0.1% FCS for 72 h prior to experiments allowing the cells to arrest in G0. At 0 h, the CHO cells were re-fed McCoy's media with 10% FCS and were harvested at 0, 4, 16, and 20 h. Cells from each time point were harvested for subcellular fractionation using the digitonin solubilization method of Bronfman [Anal Biochem 255:252], and nuclei and mitochondria were separated by centrifugation. Additional cells were fixed with ethanol and stained subsequently with propidium iodide for flow cytometric analysis, to determine the degree of synchrony and the stage of cell cycle. Flow cytometry indicated that 65-75% of the cells had arrested at G0 at the 0 h time point, by 16 h had moved into S phase, and by 20 h were in G2/M phase. GR activities in the whole cell homogenates, cytoplasm, and the mitochondria were not different during cell cycle progression. Nuclear GR activities, expressed as mU/mg protein, were 1.4±0.32 in G0, 3.08±1.35 in G1, 9.70±0.80 in S, and 3.92±2.17 in G2/M, indicating a marked increase in GR activity at S phase, $p<0.05$. The data indicate that nuclear GR activities change as cells progress through cell cycle and implicate a role for redox regulation of cell cycle progression. Supported by GM44263 from the NIH.

699 EFFECTS OF FASTING ON TISSUE CONTENTS OF COENZYME A AND RELATED INTERMEDIATES.

S. E. Welty, F. A. Jenniskens, K. S. Jopperi-Davis, L. C. Walters, L. K. Rogers and C. V. Smith. *Pediatrics, Children's Research Institute, Columbus, OH.*

Exposure of rats and mice to hyperoxia decreases lung coenzyme A (CoASH) contents, with a decrease of 50 % observed in adult male Fischer-344 rats exposed to >95 % O2 for 48 h. The decreases in lung CoASH levels are not accompanied by

increases in contents of the mixed disulfide with GSH (CoASSG), as might be expected of a primary oxidative stress on CoASH status. Animals exposed to hyperoxia exhibit decreased food intake, and the present studies were to test the hypothesis that fasting would decrease lung CoASH contents, thereby suggesting a mechanism for the effects of hyperoxia. Adult male Fischer-344 rats were examined after 0, 24 or 48 h of fasting (n=5, 6, 6, respectively). Fasting for 24 or 48 h did not affect (1-way ANOVA, Student-Newman-Keuls) lung CoASH levels or lung weights, despite 6 and 12 % losses in body weights. Lung GSH concentrations (nmol/g tissue) and contents (nmol/whole organ) and GSSG contents were lower in rats fasted for 48 h than in fed rats. Liver weights and GSH and GSSG contents and concentrations were lower in rats fasted for 24 or 48 h than in fed rats. Hepatic CoASH concentrations increased during fasting, but hepatic contents of CoASH remained remarkably constant. Liver protein contents (mg/whole organ) decreased after 24 and 48 h, but protein concentrations (mg/g tissue) were higher in rats fasted 48 h than in fed rats. Overall, GSH, GSSG, and protein contents in liver and skeletal muscle, decreased with fasting, but significant changes in CoASH levels were not observed. Diminished food intake in animals exposed to hyperoxia may contribute to effects on GSH and GSSG contents, but does not explain the effects of hyperoxia on lung CoASH contents. CoASH and derived thioesters participate in many cellular functions, and if CoASH depletion proves to be relevant to lung injury caused by hyperoxia, dietary supplementation or support of mechanisms needed to sustain CoA levels could be helpful in prematurely born infants as well as in adults.

700 THE NATURE OF PROTEIN DISULFIDE ISOMERASE ALKYLATION BY THE EPISULFONIUM ION DERIVED FROM S-(2-CHLOROETHYL)GLUTATHIONE.

R. S. Kaetzel[1] and D. J. Reed[2]. *[1]Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and [2]Biochemistry and Biophysics, Oregon State University, Corvallis, OR.*

Glutathione (GSH) protects cells although GSH conjugation can cause cytotoxicity by enhancing the reactivity of some xenobiotic chemicals, i.e., halogenated alkenes, quinines, and isothiocyanates. GSH conjugation to form S-(2-chloroethyl)glutathione (CEG) as a consequence of 1, 2-dichloroethane (DCE) exposure is another example of a toxication reaction. CEG can form an electrophilic episulfonium ion that can react with specific sites in DNA and proteins. Evidence indicates that mutagenicity of DCE is due to the GSH conjugate. Our experiments are based on the reactivity of this episulfonium ion with proteins of the thioredoxin family (i.e., thioredoxin (TRX) and protein disulfide isomerase(PDI)). Mammalian PDI has two thioredoxin fold active sites each containing two cysteines. When reduced, these four cysteines are expected to be the major targets of alkylation by the episulfonium ion of CEG, preferring the first cysteine in each active site sequence if PDI alkylation follows the same pattern observed with TRX. Reduced recombinant rat PDI was incubated for 90 minutes with a range of CEG concentrations from equimolar to 50-fold excess CEG. Based on ESI-MS and MALDI-MS of the whole protein before and after alkylation, 50% of the protein is either monoalkylated (38%) or bisalkylated (12%). Further increasing CEG concentrations shows a rapid decrease in native PDI to non-detectable amounts in 50 fold CEG excess. Alkylation of PDI does not correlate with an inhibition of reductase or isomerase activity as well as the alkylation of TRX. Iodoacetamide carboxy methylation of PDI inhibits activity suggesting that the CEG derived episulfonium ion may not be as accessible to the active sites of PDI as is observed with TRX. Peptide mapping of alkylated PDI and further sequencing of modified peptides by ESI-MS/MS is underway. (This work was supported by grants from the NIEHS (ES00040 and ES00210).

701 POSTEXPOSURE TREATMENT WITH 2-MERCAPTOETHANE SULFONIC ACID (MESNA) INCREASES THE SURVIVAL OF MICE FOLLOWING EXPOSURE TO PHOSGENE.

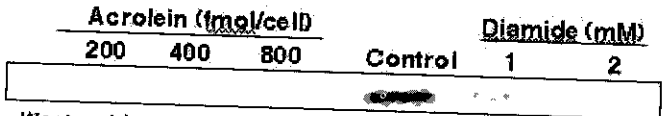
S. I. Baskin and A. M. Sciuto. *Pharmacology, USAMRICD, Aberdeen Proving Ground, MD.*

Phosgene (CG) is a highly reactive oxidizing/acylating gas used industrially as a chemical intermediate for the production of pharmaceutical drugs, pesticides, and polyfoam rubber products. CG can cause life-threatening pulmonary edema by reacting with peripheral lung conpartment tissue components. The insidiousness of CG inhalation is that there is a clinical latent phase where edema is not usually evident until 6-36 hr after exposure. Treatment modalities have primarily relied on pretreatments. This study was designed to investigate the effect of a clinically available sulfhydryl donor, MESNA. On postexposure survival rates and pulmonary edema formation (PEF) in mice. Seventy-two male mice were exposed to 32 mg/m3 (8ppm) CG for 20 min followed by room air washout for 5 min. Four groups of 18 mice each were injected i.p. at 20 min and 3 hr after exposure with 0 (saline), 5, 25, or 50 mg/kg MESNA. Within 12 hr of exposure gravimetric analysis was performed on lung tissue dry weights (DW), wet weight (WW), and wet/dry weight ratio (W/D). Survival rates (SR) were also determined at both 12 and 24 hr postexposure. Both 5 and 25 mg/kg MESNA had no positive effect on any parameter measured. However, at 12 hr the 50 mg/kg dose showed a marginal decrease in lung tissue WW compared with 0 mg/kg, 118+/-10 mg vs 135+/-9 mg ($P<0.07$), respectively. MESNA, 50 mg/kg, also significantly decreased the W/D ratio, 7.2+/-0.5, vs 0 mg/kg, 9+/- ($P<0.038$) also at 12 hr. SR for the 50 mg/kg mice was 72% at 12 hr, $P<0.07$ (chi square) compared with 44% for 0 mg/kg. The 24 hr SRs were 50% and 33%, respectively. Treatment with 50 mg/kg MESNA also significantly enhanced lung tissue protective nonprotein sulfhyudryl levels, 21+/-2 uM/kg vs 0 mg/kg MESNA, 2.9+/-0.1 ($P<0.0001$) and reduced lung tissue protein oxidation, 5.2+/-1 vs 14.8+/-1 uM($P<0.0001$), at 12 hr. We conclude that the sulfydryl donor, MESNA, may be useful as a therapeutic agent against phosgene-induced acute lung injury by ameliorating PEF and reducing tissue oxidation.

702 ACROLEIN DEPLETES GLUTATHIONE AND THIOREDOXIN IN HUMAN BRONCHIOLAR CANCER CELLS.

J. C. Kern and J. P. Kehrer. *Dept. of Pharmacology and Toxicology, College of Pharmacy, The University of Texas at Austin, Austin, TX.*

Glutathione (GSH) and thioredoxin (Trx) are important components of the cellular thiol redox system. Both play vital roles in regulating the activity of various transcription factors such as NF-κB and AP-1 that are involved in cell growth and cell death. Acrolein is a highly reactive α, β-unsaturated aldehyde commonly found in the environment, particularly as a component of smoke. Acrolein's toxicity is related to its electrophilic nature, and appears to correlate with GSH depletion. However, the effects of acrolein on other cellular thiols is less well-known. The current data demonstrate with biotin maleimide detection of free sulfhydryls on PVDF membranes that, beginning 1 h after treatment of H727 human bronchiolar cancer cells with 100fmol/cell acrolein or more, there is an overall decrease in protein thiols. In addition, treating H727 cells for 0.5 h with the same doses of acrolein depletes GSH levels in a dose-dependent manner and causes a loss in Trx protein levels. The thiol oxidant diamide also caused a loss in Trx protein. These acrolein-mediated changes in GSH and Trx are likely to disrupt the activity of various transcription factors and, in conjunction with an inhibition of caspase activities, may be important in the necrotic (not apoptotic) cell death caused by this aldehyde. (Supported by RO1 ES09791 and Center Grant ES07784.)



Western blot of thioredoxin using 50 µg of a H727 cell lysate. Treatments were for 0.5 h.

703 EFFECT OF 2, 4-HEXADIENAL ON TISSUE GLUTATHIONE AND MALONDIALDEHYDE LEVELS IN FISCHER 344 RATS.

R. R. Swezey, S. Nath, S. E. LeValley, L. Sharp, M. Ho, W. Shinn and C. E. Green. *Metabolism and Pharmacokinetics, SRI International, Menlo Park, CA.*

2, 4-Hexadienal (2, 4-HX) is an α, β-unsaturated aldehyde formed by peroxidation of unsaturated lipids that causes neoplasms in the forestomach of rats. The objective of this study was to investigate the mechanism of action of this agent. 2, 4-HX was administered orally in corn oil to male and female Fischer 344 rats for 10 days. Plasma, liver, and forestomach samples were collected and analyzed for malondialdehyde (MDA) and glutathione (GSH and GSSG) by HPLC with fluorescence detection. No mortality, clinical signs or body weight changes were noted in rats administered either 90 or 120 mg/kg/day 2, 4-HX. Marked changes in the forestomach were observed microscopically including chronic inflammation, acanthosis, hyperkeratosis, ulceration and squamous epithelial cell papilloma; the severity was dose dependent. Significant differences in MDA content of plasma, liver or forestomach were not observed in the treatment groups compared to the vehicle or untreated groups, except for plasma MDA, which was slighrly decreased in rats treated with 120 mg/kg/day. There was no apparent effect of either dose of 2, 4-HX on plasma levels of GSH. In the liver, the total amount of GSH was decreased with increasing dose of 2, 4-HX at 1 and 4 hr post-dose, but by 24 hr post-dose the total GSH levels returned to those observed in the vehicle controls. In contrast, 2, 4-HX administration increased the total amount of GSH in the forestomach, and at 1 hr and 4 hr post-dose this was largely due to increased GSSG; by 24 hr forestomach GSH levels had also become elevated. The GSH redox status in forestomach samples was decreased by administration of 2, 4-HX. In summary, 2, 4-HX treatment

for 10 days alters the tissue glutathione levels in both a target tissue, the forestomach, causing a compensatory increase in total glutathione and a decrease in the redox status, and in a non-target, the liver, in which total glutathione was significantly reduced. (This work was supported by NIEHS contract N01-ES-95437.)

704 ACUTE EFFECTS OF DIQUAT ON REDOX STATUS OF HEPATIC COENZYME A AND GLUTATHIONE IN FISCHER-344 RATS.

C. V. Smith, K. S. Jopperi-Davis, E. N. Schorr, L. K. Rogers and S. E. Welty. *Pediatrics, Children's Research Institute, Columbus, OH.*

Exposures to oxidant stresses *in vivo* frequently are characterized by measurements of glutathione disulfide (GSSG), but initiation of irreversible injury has correlated poorly with tissue concentrations of GSSG. Because 70% or more of hepatic coenzyme A is intramitochondrial and CoASH and CoASSG undergo thiol-disulfide exchange reactions with GSH and GSSG, we measured tissue concentrations of CoASH and CoASSG, to assess possible compartmental effects in the oxidant stress responses initiated by administration of diquat. Adult male Fischer-344 rats were given 0, 0.05, or 0.1 mmol/kg of diquat, i.p. After 2, 4, 6, or 24 h, the animals were anesthetized with pentobarbital, blood drawn, and livers freeze-clamped. Plasma ALT activities were measured as assessments of liver damage, concentrations of CoASH and CoASSG were measured by HPLC, and hepatic GSH and GSSG concentrations were measured by enzyme recycling methods, as we have described previously. Diquat administration produced dose-dependent increases in ALT activities, but did not decrease hepatic concentrations of CoASH (123 nmol/g of liver in controls), in contrast with the effects of hepatotoxic doses of acetaminophen [Chem Res Toxicol 13:873, 2000]. Diquat caused dose-dependent increases in hepatic CoASSG levels that showed significant correlations with plasma ALT activities (P=0.0016), also in contrast with the effects observed with acetaminophen-initiated hepatic injury; however, in no animal did the hepatic CoASSG concentrations exceed 10 % of the CoASH content. Hepatic GSSG concentrations showed dose-dependent increases and correlated with elevations in plasma ALT activities, although the mean levels in diquat-treated rats were little more than twice the levels observed in saline-treated controls. The present data document effects of diquat on hepatic CoASH/CoASSG redox status, but do not suggest marked mitochondrial compartmentalization of diquat-induced oxidant stress responses *in vivo*. Supported by GM44263 from the National Institutes of Health.

705 IMMUNOTOXICITY OF 2-BROMOPROPANE AND 1, 2-DIBROMOPROPANE IN MICE AND RATS.

T. C. Jeong[1], E. S. Lee[1], W. Chae[2], N. H. Kim[1], W. S. Koh[3], B. H. Kang[3] and S. S. Han[3]. *[1]College of Pharmacy, Yeungnam University, Kyungsan, South Korea, [2]College of Medicine, Taegu Catholic University, Taegu, South Korea and [3]Toxicology Research Center, Korea Research Institute of Chemical Technology, Taejon, South Korea.*

2-Bromopropane (2BP) is a major component of the mixture of SPG-6AR and Solvent 5200 which is a substitute of chlorofluorocarbon. In 1995, an occupational exposure to 2-BP has been a social issue in Korea. Many female workers in an electronic company were found to have amenorrhea and male workers were diagnosed with oligospermia. In the present studies, immunotoxic effects of 2-BP were investigated in male Sprague-Dawley rats and female BALB/c mice. The rats were treated po with 2-BP at 100, 330 and 1000 mg/kg for 28 days. Four days before necropsy, the rats were immunized iv with sheep red blood cells (SRBCs). The body and thymus weights were reduced by 2-BP at 1000 mg/kg. In addition, the numbers of splenic and thymic cells were decreased by 2-BP. In hematology, the number of WBCs, RBCs and platelets was reduced. Among the serum clinical parameters, chloride ion was increased by 2-BP. The antibody response to SRBCs was suppressed at 1000 mg/kg. With immunized animals, immunophenotyping of splenic and thymic cells was performed to investigate the changes of the number of macrophages, B- and T-cells in spleen and the number of $CD4^+$ and $CD8^+$ cells in thymus. The numbers of most cell types were decreased in the spleen when animals were treated with 2-BP at 1000 mg/kg. Likewise, all cell types of thymus were decreased by 2-BP. In a subsequent study, effects of 2-BP and 1, 2-dibromopropane (1, 2-DBP) on the antibody response were compared in mice. When mice were treated po with either one of these chemicals for 7 days, the antibody response was suppressed only by 1, 2-DBP. The present results suggest that 2-BP may have an immunotoxic potential in rats, and that 1, 2-DBP contained in the Solvent 5200 may contribute to the immunotoxicity, although 2-BP is a major component. (Supported by grant No. 2000-2-21800-001-3 from KOSEF).

706 ETHANOL ALTERS POLY I:C INDUCED NK CELL TRAFFICKING AND ACTIVATION.

P. Hébert, L. P. Myers, Q. Zheng and S. B. Pruett. *Cellular Biology & Anatomy, LSUHSC, Shreveport, LA.*

Natural killer (NK) cells are critical in resistance to lung tumor establishment in a B16F10 tumor model using female B6C3F1 mice. Polyinosinic:polycytidylic acid (poly I:C, 0.1 mg, i.p.) activation of NK cells increases elimination of tumor nodules. This effect is reduced following oral gavage of ethanol (EtOH, 6 g/kg). This study determined if decreased resistance is due to altered trafficking (flow cytometry) and/or NK cell activation (chromium release assay) in the spleen and lungs 4 and 12 h after EtOH and poly I:C administration. Initial studies using anti-NK1.1- (0.5 mg, i.p.) mediated NK cell depletion *in vivo* 48 h before and 0, 6, 12, and 24 h after B16F10 tumor injection ($4x10^5$, i.v.) demonstrated that the majority of tumor cells are cleared by NK cells in 12 h ($p<0.001$). Flow cytometry revealed that the percentage of NK cells in the lungs at 4 h (6±1%, mean±SEM) was equivalent after vehicle, poly I:C and EtOH/poly I:C treatment. At 12 h, however, an increase induced by poly I:C treatment (from 4±.1 to 6±1%, $p<0.001$) was abrogated by EtOH (4±1%, $p<0.01$). Corresponding normalized (poly I:C treatment as 100%) NK cell lytic function in the lungs was increased from 26±6 to 100±15% ($p<0.001$) and 11±1 to 100±7% ($p<0.05$) following poly I:C treatment at 4 and 12 h, respectively. EtOH reduced this function to 77±21% (ns) at 4 h and 60±8% ($p<0.001$) at 12 h. Similar analysis of splenocytes revealed no differences in percentage of NK cells at 4 (5±1) or 12 h (5±1). Lytic function, however, increased from 17±2 to 100±17% ($p<0.01$) at 4 h and 15±2 to 100±7% ($p<0.001$) at 12 h. EtOH/poly I:C treatment resulted in decreases to 57±16% ($p<0.05$) at 4 and 55±7% ($p<0.001$) at 12 h. These data indicate that EtOH decreases trafficking of NK cells into the lungs 12 h after poly I:C administration, accompanied by reduction in lytic function. Although EtOH did not alter numbers of NK cells in the spleen, it decreased lytic function by half at both 4 and 12 h. This suggests that while EtOH can alter trafficking, its affects NK cells primarily by limiting their activation.

707 IMMUNE STIMULATION FOLLOWING TREATMENT WITH THE HERBAL MEDICINE ECHINACEA PURPUREA IN FEMALE B6C3F1 MICE.

K. L. White, Jr.[1], T. L. Guo[1], R. D. Brown[1], C. S. Smith[2] and D. R. Germolec[2]. *[1]Virginia Commonwealth University, Richmond, VA and [2]NIEHS, Research Triangle Park, NC.*

Echinacea Purpurea (EP) is one of the few herbal medicinal plants indigenous to North America. For hundreds of years it has been used by American Indians to treat various aliments. As part of a comprehensive program of the National Toxicology Program, we have been evaluating the water/alcohol extract of EP for its ability to modulate the immune system. Female B6C3F1 mice were administered EP daily by oral gavage in a 0.5% methylcellulose vehicle at doses of 30, 100, 300, 600, or 1000 mg/kg for 28 days in range-finding studies and at 300, 600, or 1000 mg/kg in more comprehensive protocol studies. Overall, there were no remarkable effects on the toxicological parameters including, body weight, selected organ weights, or hematological parameters. Similarly, minimal immunological effects were observed. Parameters not affected included, splenocyte differential, mixed leukocyte response (MLR), and natural killer (NK) cell activity. Increases were observed in the spleen IgM antibody-forming cell (AFC) response to sheep erythrocytes at all dose levels; however, the response was not dose dependent and not always statistically significant. Enhanced T cell proliferation was observed following stimulation with anti-CD3 antibody in EP-treated animals. Furthermore, enhanced cytotoxic T lymphocyte (CTL) activity was observed at all effector-to-target ratios in the animals administered 300 mg/kg of EP, while the responses of animals treated with the higher doses of EP were not statistically different than the vehicle controls. Ongoing host resistance studies should help establish if the increases in the various components of the immune system stimulated by EP are sufficient to provide protection from various pathogens. (Supported by NIEHS Contract ES 55387).

708 COMPARISONS OF JP-8-INDUCED IMMUNE ALTERATIONS FOLLOWING TWO DIFFERENT ROUTES OF EXPOSURE IN FEMALE B6C3F1 MICE.

D. E. Keil, K. Scharstein, J. EuDaly and M. M. Peden-Adams. *Medical University of SC, Charleston, SC.*

JP-8 jet fuel is used widely in the military and commercial airline environments. Recent reports have implicated jet fuel as an acute immune and respiratory toxicant. Studies *via* inhalation and dermal exposures have reported similar results; however, oral exposure to jet fuel results in slightly different findings. Previously, no studies have assessed parallel exposures of JP-8 *via* different routes of administration. In this study female, B6C3F1 mice were exposed to JP-8 jet fuel either orally or dermally for 7 days. The oral dose used was 2000 mg/kg and was administered in a vehicle of olive oil. The dermal dose regime consisted of the application of 50 ul of neat JP-8, an exposure similar to previously published dermal studies. Two control groups were included for the dermal exposure; a group that was administered 50 ul of acetone and another with 50 ul of olive oil. Endpoints assessed included splenic and thymic weight and cellularity, liver weight, uterine wet weight, lymphocyte proliferation, natural killer cell activity, T-cell subpopulations, and the antibody plaque forming cell response. Decreases in thymus weight and cellularity were observed following oral exposure but not following dermal exposure. Liver weights

were increased following oral exposure but not following dermal exposure. Uterine wet weight was decreased by both exposure routes but this was not significantly different from the oil control. No effects were observed in NK-cell activity or mitogen-induced lymphocyte proliferation following the exposures. Splenic T-cell subpopulations were altered following dermal exposure. Suppression of the PFC response was observed in the oral JP-8 treatment as compared to its respective olive oil control. Additionally, the PFC cell response was suppressed following dermal exposure as compared to the oil control but not compared to the acetone control. Therefore, the varied findings regarding JP-8 immunotoxicity may be explained in part by the route of administration, as well as the types of controls used in reported studies.

709 SULFLURAMID-INDUCED ALTERATIONS IN IMMUNOTOXICOLOGICAL PARAMETERS.

M. M. Peden-Adams, J. G. EuDaly, S. Dabra, L. Heesemann, A. EuDaly and D. E. Keil. *Medical University of SC, Charleston, SC.*

Fluorinated organic compounds have been manufactured for over 50 years and are currently used throughout industry in semiconductors for computers and other electronic equipment, as stain and water repellents, in floor waxes, popcorn bags, firefighting foam, denture cleaners, carpet spot cleaners, pharmaceuticals, and as pesticides. Manufacture and use of these compounds has steadily increased since the 1970s. Studies show that this class of compounds cause peroxisomal proliferation, hepatomegaly, altered steroidogenesis, and body weight decreases that are associated with a wasting syndrome; however, effects on immune function have not been assessed. This study utilized sulfluramid, a perfluorinated pesticide, as a representative compound from this class of chemicals. Adult female B6C3F1 mice were exposed *via* gavage to either the oil control or sulfluramid (1, 3, 10, or 30mg/kg) for 14 days. Significant decreases in body weight at the high dose (30 mg/kg/day) and increased liver/body weight ratios at 10 and 30 mg/kg/day were noted. Additionally, spleen and thymus weights and cellularity were greatly reduced. Although no differences were observed in natural killer cell activity or mitogen-induced lymphocyte proliferation, suppression was noted in the plaque forming cell (PFC) response and decreases were observed in thymic T-cell subpopulations. These data indicate that sulfluramid may be a potent immunotoxicant. Further studies are needed to fully characterize the extent of immune parameters effected and the role of the parent compound versues the known metabolite PFOS.

710 DDT INHIBITS FUNCTIONAL ACTIVATION OF MURINE MACROPHAGES AND DECREASES RESISTANCE TO INFECTION BY MYCOBACTERIUM MICROTI.

E. S. Calderón-Aranda[1], M. A. Nuñez[1], I. Estrada[2], L. Acosta-Saavedra[1] and M. E. Cebrián[1]. *[1]Toxicología, Cinvestav-IPN, Mexico, D.F, Mexico and [2]Inmunología, Escuela Nacional de Ciencias Biológicas-IPN, Mexico, D.F, Mexico.*

DDT is still widely used in several parts of the world to control malaria, typhoid and dengue vectors. DDT has been shown to have immunotoxic effects in mice and to increase susceptibility to intracellular pathogens such as Mycobacterium leprae. However, little is known about the mechanisms underlying this effect. Activated macrophages play an important defensive role against intracellular pathogens, therefore our objective was to evaluate the effect of *in vitro* exposure to technical grade DDT, p, p'-DDT, p, p'-DDE and p, p'-DDD on the functional activation of J774A.1 macrophages and their capability to limit growth of intracellular pathogens, using Mycobacterium microti as a model. We evaluated cytotoxicity, cell proliferation, functional macrophage activity ($NO^{\bullet}$ and O_2^- production, and mRNA expression of TNF-*, IL-1* and iNO Synthase), and the ability of treated cells to limit infection by M. microti in IFN* activated macrophages exposed to 2.5, 5.0 and 10 µg/ml of DDT compounds. Doses of 5 and 10 µg/ml induced direct cytotoxic effects precluding meaningful analysis of the above parameters, whereas 2.5 µg/ml of all DDT compounds inhibited macrophage activity and reduced their ability to limit the intracellular growth of M.microti without inducing cytotoxicity. Technical grade DDT and p, p'-DDE were the more potent compounds. Therefore, exposure to DDT compounds could represent an important risk for infection development by those intracellular pathogens against which $NO^{\bullet}$ and/or O_2^- production represent the main immune protective mechanism.

711 ESTROGEN INDUCES THYMIC ATROPHY THROUGH INHIBITION OF CELL CYCLE.

Z. W. Lai, N. C. Fiore and A. E. Silverstone. *Microbiology & Immunology, SUNY Upstate Medical University, Syracuse, NY.*

Estrogen is a modulator of the immune response. One of the main targets for estrogen in immune system is the thymus. Although recent research suggests that estrogen may inhibit thymocytes at different development steps, the mechanism(s) by which estrogen induces thymic atrophy is still unclear. In the present study, we have determined that inhibition of cell proliferation is one such mechanism. Mice were injected at various times with estradiol (E2) and then BrdU was injected 2 hours before mice were sacrificed. Thymocytes were isolated and stained with fluorescence conjugated antibodies for cell surface markers and BrdU. Data was acquired using a FACSCalibur flow cytometer with two lasers for four-color analysis. Our results showed that E2 induced thymic atrophy and reduced the numbers of thymocytes in all CD4+, CD8+, CD4+CD8+ (DP) and CD4-CD8- (DN) subsets. In analysis for cell proliferation, we found that E2 could inhibit DNA synthesis with BrdU incorporation in thymocytes and this effect was mainly in CD3-CD4+CD8+ DP and CD3-CD4-CD8- triple negative (TN) thymocytes. Furthermore, within the CD3-CD4-CD8- TN subpopulation, E2 mainly inhibited cell proliferation at CD44-CD25+ and CD44-CD25- stages. A time course analysis showed that inhibition induced by E2 appeared as early as 1 day after exposure, whereas the number of total thymocytes was not affected at this time point. The proliferation activity in DP cells returned to normal level, but was still inhibited in TN cells at day 10 after exposure. We also determined the effects of E2 in SCID mice, whose thymuses only contain immature CD4-CD8- DN cells, allowing us to focus our study in the earliest development stages of thymocytes. Our results confirmed that inhibition of cell proliferation was in CD44-CD25+ stage in SCID mice. By using a DNA PI staining for cell cycle and flow cytometry analysis, our results indicated that E2 could inhibit cell cycle from G0/1 phase entry into S/G2M phase. Taken together, our results clearly suggest that estrogen induced thymic atrophy is mainly through inhibition of cell proliferation.

712 DIFFERENTIAL INDUCTION OF APOPTOSIS IN MURINE LYMPHOID SUBPOPULATIONS *IN VIVO* FOLLOWING CO-EXPOSURE TO LIPOPOLYSACCHARIDE AND VOMITOXIN.

Z. Islam[1], L. E. King[3], P. J. Fraker[3] and J. J. Pestka[1,2,4]. *[1]Food Science and Human Nutrition, Michigan State University, East Lansing, MI, [2]Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, [3]Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI and [4]Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Lipopolysaccharide (LPS) and vomitoxin (VT, deoxynivalenol) synergistically induce cell death at 12 hr in lymphoid tissue of the mouse, whereas the effects of these toxins alone were negligible. The purpose of this study was to assess the effects of LPS and VT co-exposure on apoptosis within specific T and B lymphocytes subsets in thymus, Peyer's patches, and bone marrow. Flow cytometry revealed that a single dose of LPS (0.1 mg/kg body, weight, po) together with VT (12.5 mg/kg body weight, po) resulted in apoptotic death of immature thymocytes ($CD4^-CD8^-$, $CD4^+CD8^+$) and mature thymocytes ($CD8^+$) in thymus with a concurrent loss of cell numbers. RU 486, a glucocorticoid receptor antagonist, significantly abrogated apoptosis in $CD4^-CD8^-$, $CD4^+CD8^+$ and $CD8^+$ subsets and also prevented loss in cell numbers. In Peyer's patches and bone marrow, $B220^+IgM^-IgD^+$ pro-B cells underwent apoptosis at 12 hr after toxin co-treatment. RU 486 blocked apoptosis in $B220^+IgM^-IgD^+$ subset, however, reduction of cell numbers was still observed at this time point. Taken together, these data suggest that LPS can interact with VT to induce the glucocorticoid-dependent apoptotic loss of immature thymocytes, cytotoxic T lymphocytes and pro-B cells in mouse lymphoid organs.

713 IMMUNOMODULATORY EFFECTS ASSOCIATED WITH ANTI TUMOR NECROSIS FACTOR (TNF) ANTIBODY TREATMENT IN THE FEMALE B6C3F1 MOUSE.

S. M. Furst[1], V. L. Peachee[2], K. L. White, Jr.[2] and W. J. Komocsar[1]. *[1]G.D. Searle & Co., Skokie, IL and [2]ImmunoTox, Inc., Richmond, VA.*

Tumor Necrosis Factor Alpha (TNF-α) is responsible for stimulating numerous biologic functions including the inflammatory response, as well as enhancing the production of other cytokines involved in both immune and non-immune processes. Inhibition of TNF-α has been shown to have therapeutic benefits for the treatment of rheumatoid arthritis by reducing the associated inflammation and tissue degradation. Recently clinical data from inhibitors of TNF activity (e.g., Enbrel and Remicade) suggest that these drugs may produce certain undesired immunomodulatory effects (e.g., increased incidence of infections). To understand the potential effect of TNF-αinhibition on innate and acquired immunity, a 4-week immunotoxicity study was conducted in female B6C3F1 mice administering anti-murine TNF-αantibody once a week at approximately 250 µg/dose by intraperitoneal (IP) injection. In addition to standard toxicity endpoints (including body weights, clinical observations, and spleen, thymus, liver, and kidney weights), spleen IgM antibody response to a T-dependent antigen, sheep erythrocytes, natural killer (NK) cell activity, and splenic and peripheral blood lymphocyte subsets were evaluated. Cyclophosphamide and Anti-Asialo GM1 (Rabbit) antibody were used as positive controls. No treatment-related effects on body or organ weights were observed.

Anti-TNF Ab treatment resulted in an approximate 35% decrease in IgM AFC response/10^6 splenocytes and an approximate 30% decrease in the absolute numbers of peripheral blood suppressor-cytotoxic T-cells (CD3+CD8+). No treatment-related effects in peripheral blood or splenic total B and T cells, splenic macrophages, or splenic T-cell subsets were noted. Although not statistically significant, NK cell activity was increased when compared with the vehicle control. These results suggest that inhibition of TNF-αactivity may affect the acquired immune response and therefore may contribute to the immunomodulatory effects seen with the inhibitors of TNF-αactivity.

714 DIESEL EXHAUST PARTICLES INCREASE LUNG INJURY AND INFLAMMATION DURING EARLY SENSITIZATION IN BROWN NORWAY RATS.

P. Singh[1], M. J. Daniels[2], D. Winsett[2], J. Richards[2], L. Bishop[2], C. A. Dick[3], M. Madden[2], K. B. Adler[1] and M. I. Gilmour[2]. *[1]CVM, NCSU, Raleigh, NC, [2]NHEERL, USEPA, Research Triangle Park, NC and [3]UNC, Chapel Hill, NC.*

Diesel exhaust particles (Department) possess demonstrated adjuvant activity in both human and experimental respiratory allergy, yet the mechanisms of adjuvancy remain poorly described. We have previously reported that intratracheal (IT) instillation of Department prior to allergic sensitization enhances pulmonary allergic responses to house dust mite (HDM) in Brown Norway (BN) rats. The purpose of the present study was to track the adjuvant effects of Department during early sensitization to HDM. BN rats were instilled IT on day 0 with either 100 or 500 μg Department (SRM 2975) or saline only and immunized IT 24 hr later with 10 μg HDM or saline (sham-immunized) on days 1 and 3. Lung injury and inflammatory status were assessed 6 and 24 hr after the final immunization. Department (500 μg) significantly increased total protein, lactate dehydrogenase (LDH) and total inflammatory cell numbers in bronchoalveolar lavage (BAL) fluid in both HDM and saline-treated rats. Specifically, Department (500 μg) induced a sharp increase in the total number of neutrophils in the BAL fluid, peaking at 6 hr and remaining significantly elevated at 24 hr after the final immunization. Department (500 μg) also increased total numbers of eosinophils in the BAL fluid at 24 hr. In order to account for Department-enhanced inflammatory cell influx during early sensitization, we quantitated chemokine levels in BAL fluid and lung homogenate at these time points. The kinetics of chemokine production in response to Department exposure indicated an early increase in MIP-2 and RANTES at 6 hr, followed by a decrease at 24 hr after the final immunization in both HDM-and sham-immunized rats. These results show that Department causes an early increase in lung injury and inflammatory cell influx and a coincident shift in local chemokine production, which may contribute to activation of specific immune responses. 715 TIME DEPENDENT INCREASE IN ALVEOLAR MACROPHAGE PHAGOCYTOSIS FOLLOWING INCUBATION WITH CARBON BASED PARTICLES.

C. A. Dick[1], M. Daniels[2], S. Becker[2], P. Singh[3], M. J. Selgrade[2] and M. I. Gilmour[2]. *[1]Center For Environmental Medicine and Lung Biology, UNC, Chapel Hill, NC, [2]Experimental Toxicology, HHEERL, USEPA, Durham, NC and [3]NCSU, Raleigh, NC.*

Epidemiological studies have shown that a rise in PM10 is associated with exacerbations of respiratory disease, increases in respiratory infection and increased morbidity. The mechanism of these effects are not well understood, but the ability of the lung to protect and remove inhaled particles will determine the outcome in terms of adverse health effects. We investigated whether exposure to carbon based particles could alter subsequent phagocytic ability. AM, isolated from rats, were exposed *in vitro* for 2, 4 or 24 hours to varying doses of fine carbon black (CB), ultrafine carbon black (UFCB), carbon black coated with 5% copper sulphate (CBCu), carbon black coated with a mixture of 1% iron, copper, vanadium and nickel sulphates (CBMix) and diesel exhaust particles (Department) (1, 10, 25 and 50ug/100, 000 cells). Secondary phagocytosis was assessed over a 3 hour period by monitoring ingestion of FITC labeled E.coli. After 2 hour incubation, all of the particle types increased secondary AM phagocytosis regardless of dose. This increase was sustained following 4 and 24 hours of particle incubation with the CBMix particles, but not with the other particle types which decreased to control levels. Biochemical analysis of supernatants revealed no change in LDH and marginal increases in total protein only after 2 hours incubation. Lysosyme levels were elevated after the 4 hour treatment period with all particles, compared to control levels. TNF alpha protein levels were also elevated 15-20% after 24hr incubation regardless of concentration or type of particle used. The data show that short term incubation with carbon based particles increases secondary AM phagocytosis with subsequent release of bactericidal enzymes and pro-inflammatory cytokines. The results suggest that host defenses may be activated in response to environmental insult. This abstract does not reflect EPA policy.

716 *IN OVO* MODULATION OF T CELL-DEPENDENT IMMUNE FUNCTIONS: POSSIBLE ROUTES OF Pb-INDUCED IMMUNOTOXICITY IN CHICKENS.

J. Lee and R. R. Dietert. *Microbiology & Immunology, Cornell University, Ithaca, NY.*

We studied potential thymus-based routes leading to Pb-induced T cell-dependent immunotoxicity after early developmental Pb exposure in the chicken. Using Cornell K strain White Leghorn chickens, the capacity of Pb to directly alter thymocyte function was evaluated with both an in vivo/*ex vivo* system and direct *in vitro* exposure. When the embryo was exposed to Pb (400 μg/egg) at 12 days of embryonic development (E12), the *ex vivo* production of interferon-γ (IFN-γ) by thymocytes collected from four-week old chickens decreased significantly compared to the control. Decreased IFN-γ production was also observed among thymocytes directly exposed to Pb *in vitro* and stimulated with thymic stromal supernatant but not ConA. These results suggest that Pb could directly influence thymocyte function in the absence of the thymic microenvironment. In the reverse experiment, when thymic stromal cells were exposed to Pb *in vitro*, Pb caused no change in the stimulating capacity of thymic stromal cells for thymocyte IFN-γ production. To examine the possible indirect effect of Pb on thymocyte function, thymulin was introduced along with a sublethal dose of Pb into fertilized chicken eggs through the air sac at E12. After hatching, female chickens were immunized with BSA, and then a delayed-type hypersensitivity (DTH) reaction and IFN-γ production were measured. Supplementation of thymulin partially reversed Pb-induced DTH depression without any change in IFN-γ production. Embryonic exposure to thymulin alone did result in a decreased DTH response. These results suggest that thymulin can influence Pb-induced immunotoxicity and raise the question whether endocrine status during Pb exposure might be important. Therefore, it is likely that Pb exposure could alter thymocyte populations directly; but indirect effects, those partially involving endocrine considerations, cannot be excluded.

717 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) DOES NOT DIRECTLY ALTER THE PHENOTYPE OF MATURING B CELLS IN A MURINE CO-CULTURE SYSTEM.

A. Wyman[1], A. L. Lavin[3,1], G. Wilding[2] and T. A. Gasiewicz[1]. *[1]Environmental Medicine, University of Rochester, Rochester, NY, [2]Biostatistics, University of Rochester, Rochester, NY and [3]Mitretek Systems, McLean, VA.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD), acting through the aromatic hydrocarbon receptor (AhR), elicits numerous toxicological effects, including immunosuppression. Previous work from our laboratory has suggested that TCDD exposure in mice is associated with altered lymphopoietic development, in particular altered B cell phenotype in the bone marrow. It remains to be determined which specific hematopoietic populations or sub-populations within the marrow cavity are directly targeted by TCDD. To examine the effects of TCDD on developing B cells *in vitro*, a stromal co-culture model was used. Primary bone marrow cells from 6-7 week old C57Bl/6 mice were co-cultured separately on two AhR-containing stromal cell lines (M2-10B4 and S17) that support B cell development in the presence of IL-7. The co-cultures were treated with 0 to 10 nM TCDD. Shifts in phenotype were quantified by cell surface marker staining and flow cytometry. Four populations in the maturing B cell (very early pre-pro-B, B220-/CD24-/CD43+; pre-pro-B, B220+/CD24-/CD43+; pro-B, B220+/CD24+/CD43-; and pre-B, B220+/CD24+/CD43-) were defined for quantification. The only statistically significant effect of TCDD was within the pre-pro-B population in cultures with the S17 stromal cell line. The increase in number of cells with this phenotype was seen in cultures with both wild type cells and AhR -/- primary bone marrow cells. These results suggest that the maturing B220+ B cell is not the direct target for TCDD-induced bone marrow B cell alterations. Supported in part by National Institutes of Health Grant ES02515, Center Grant ES01247, and Training Grant ES07026.

718 INDUCTION OF INTERLEUKIN-1, TUMOR NECROSIS FACTOR-ALPHA AND TRANSFORMING GROWTH FACTOR-BETA 1 IN ANILINE-INDUCED SPLENIC TOXICITY.

J. Wang, X. Wu and M. F. Khan. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Exposure to aniline causes selective toxicity to the spleen, leading to a variety of sarcomas, most commonly fibrosarcomas, in rats. Fibrosis appears to be an important preneoplastic event in the aniline-induced splenic toxicity. We have shown that aniline exposure causes oxidative stress in the spleen, which may cause induction of fibrogenic cytokines leading to splenic fibrosis. The present study was undertaken to determine the possible role of cytokines in the fibrogenic response of aniline. Male SD rats were given 0.5 mmol/kg/day aniline hydrochloride through drinking water for 30 days, while control rats received drinking water only. Aniline treatment

caused increases in spleen weight and splenocyte population. The splenocytes from aniline-treated rats showed greater mitogenic responses to concanavalin A and pokeweed mitogen, as detrmined by MTT assay. Interleukin-1 (IL-1), tumor necrosis factor-alpha (TNF-alpha) and transforming growth factor-beta 1 (TGF-beta 1) in the culture supernatants of splenocytes (cultured for 24 hr) from control and aniline-treated rats were quantitated using specific ELISA kits. All three cytokines, i.e., IL-1, TNF-alpha and TGF-beta 1 showed increased secretion in the culture supernatants from aniline-treated rats as compared to the controls. Greater induction of IL-1, TNF-alpha and TGF-beta 1 in the splenocytes from aniline-treated rats, alongwith morphological evidence of fibrosis, suggest a role for these cytokines in the aniline-induced splenic fibrosis.

719 PERINATAL EXPOSURE TO ATRAZINE ALTERS JUVENILE IMMUNE FUNCTION IN SPRAGUE-DAWLEY RATS.

A. A. Rooney[1] and R. W. Luebke[2]. [1]*Anatomy, Physiolgical Sciences, and Radiology, NCSU/USEPA, Research Triangle Park, NC and* [2]*NHEERL, USEPA, Research Triangle Park, NC.*

High doses (50-300mg/kg) of the chloro-triazine herbicide atrazine (ATR) alter endocrine function (e.g., luteinizing hormone and triidothyronine secretion) in juvenile or adult rats; however, ATR appears to have no effect on adult immune function. Exposure of nursing dams to ATR produces persistent changes in the immunomodulatory hormone prolactin in their offspring, reflecting the familiar trend of greater neonatal susceptibility. Furthermore, the immunoregulatory properties of prolactin and thyroid hormones suggest that ATR may have perinatal immunomodulatory potential either directly or through transitory hypoprolactinemia or hypothyroidism. Therefore, to evaluate ATR as a developmental immunotoxicant, pregnant Sprague-Dawley rats were subjected to 4 separate treatment regimes from gestational day 10 through post-natal day (PND) 23: 1) ATR (35mg/kg/day) in methylcellulose *via* gavage, 2) bromocryptine (0.2mg/kg/2x/day) *s.c.* to induce hypoprolactinemia, 3) propylthiouracil (2mg/kg/day) *s.c.* to induce hypothyroidism, or 4) methylcellulose via gavage for control dams. Offspring were then tested after PND 50 for: 1) natural killer (NK) cell function, 2) delayed-type hypersensitivity (DTH) response to bovine-serum albumin (BSA), and 3) phagocytosis of latex beads by peritoneal macrophages. Exposure of pregnant dams to ATR decreased NK cell function and DTH responses in male offspring but increased NK function in female offspring. These results demonstrate that perinatal exposure to ATR produced gender specific changes in immune function that persist into adulthood. Although transitory hypothyroidism increased phagocytic response in offspring, neither hypothyroidism or hypoprolactinemia altered NK or DTH responses, suggesting that immune changes associated with ATR are not mediated through suppression of these systems. (This abstract does not reflect EPA policy and was supported in part by the NCSU/EPA Cooperative Training Program in Environmental Sciences Research, Training Agreement CT826512010 with North Carolina State University).

720 ESSENTIAL ROLE OF DOUBLE-STRANDED RNA-ACTIVATED PROTEIN KINASE PKR IN VOMITOXIN-INDUCED MAPK PHOSPHORYLATION, TNF-ALPHA PRODUCTION AND APOPTOSIS IN HUMAN U-937 CELLS.

H. R. Zhou[1] and J. J. Pestka[1,2]. [1]*Food Science and Human Nutrition, Michigan State University, East Lansing, MI and* [2]*Institute of Environmental Toxicology, Michigan State University, East Lansing, MI.*

Vomitoxin (VT, deoxynivalenol) and other trichothecene mycotoxins inhibit translation and trigger a ribotoxic stress response that results in phosphorylation of mitogen-activated protein kinases (MAPKs) as well as induction of TNF-alpha expression and apoptosis in cloned murine macrophages. Previous studies with the chemical inhibitors 2-aminopurine and adenine have suggested that activation of double-stranded RNA-activated protein kinase (PKR) are involved in these events. The purpose of this study was to employ a stable transformant of human promonocytic U-937 cells containing an antisense PKR expression vector (CUA cells) to evaluate the roles of PKR in mediating VT-induced MAPK activation, translational arrest, TNF-alpha expression, and apoptosis. Significant reduction and delay of VT-induced phosphorylation of MAPKs was observed to occur in a dose-dependent fashion in CUA cells as compared to control cells transfected with vector only (CUC2 cells). Specifically, JNK 1 and JNK 2 phosphorylation was inhibited completely in CUA cells. ERK2 (p42) but not ERK1 phosphorylation was reduced whereas p38 was only partially suppressed. The ID50s for leucine incorporation in cells treated with VT or the translational inhibitors anisiomycin (AN) and emetine (EM) were increased by 25 to 50% in CUA as compared to CUC2. Stimulation index for VT-induced TNF-alpha expression was markedly decreased in CUA as compared to CUC. Both caspase activation and DNA fragmentation following VT, AN and EM exposure were markedly suppressed in CUA as compared to CUC2. The results suggest the PKR may be essential for VT-induction of MAPK phosphorylation and for resultant elevations in cytokine production and apoptosis in leukocytes (Supported by NIEHS Grants ES-09521 and ES-03358)

721 EVIDENCE FOR THE INVOLVEMENT OF THE CB2 RECEPTOR IN THE MODULATION OF INTRACELLULAR CALCIUM ($[Ca^{2+}]_i$) BY Δ^9-TETRAHYDROCANNABINOL (Δ^9-THC) IN HUMAN T CELLS.

G. K. Rao[1], E. L. Sawyer[2] and N. E. Kaminski[1]. [1]*Pharmacology & Toxicology, Michigan State University, East Lansing, MI and* [2]*Ohio Northern University, Ada, OH.*

Cannabinoids are a class of over 60 structurally-related plant-derived compounds present in the marijuana plant, *Cannabis sativa.* Cannabinoids are potent inhibitors of IL-2 production in T cells. In the present studies, HPB-ALL and Jurkat E6-1 human T cell lines were employed to elucidate the mechanism of IL-2 inhibition by Δ^9-THC, the primary psychotropic cannabinoid in marijuana. Previous work from this laboratory has demonstrated by Northern analysis that both cell lines lack transcripts for the central cannabinoid receptor, CB1; and that the transcript for peripheral cannabinoid receptor, CB2, was normal sized (2.4Kb) in HPB-ALL cells, but aberrant in Jurkat E6-1 cells (2.3, 4.5 and 5.7Kb). The objective of the present studies was to examine the effect of Δ^9-THC on $[Ca^{2+}]_i$ and inhibition of phorbol ester (PMA) and ionomycin (Io) induced IL-2 production in HPB-ALL and Jurkat E6-1 cells. Δ^9-THC (10μM) induced a rapid and transient rise (500-700nM) in $[Ca^{2+}]_i$ in HPB-ALL cells as compared to a slow and modest rise (80-100nM) in Jurkat E6-1 cells. This rise in $[Ca^{2+}]_i$ was attenuated in presence of the CB2 receptor antagonist, SR144528 (1μM), in HPB-ALL cells, but not in Jurkat E6-1 cells. In addition, Δ^9-THC inhibited IL-2 secretion in HPB-ALL cells in a concentration dependent manner, but not in Jurkat E6-1 cells. These data suggest that Δ^9-THC acts to disrupt $[Ca^{2+}]_i$ regulation in a CB2 receptor-dependent manner which may contribute to the inhibition of IL-2 secretion. (Supported in part by NIH grant DA07908).

722 PARADOXICAL MODULATION OF T CELL GROWTH BY THE ENDOGENOUS CANNABINOID, 2-ARACHIDONYL GLYCEROL, CAUSES AN INHIBITION OF THE T CELL GROWTH FACTOR, IL-2, AND A CONCURRENT ENHANCEMENT OF T CELL PROLIFERATION.

C. E. Rockwell and N. E. Kaminski. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

The putative endogenous cannabinoid, 2-arachidonyl glycerol (2-AG), is an arachidonic acid derivative that has been shown through radioligand binding studies, to bind with affinity to the cannabinoid receptors, CB1 and CB2. 2-AG mimics some of the immunomodulatory effects of the plant-derived cannabinoids, Δ^9-THC and cannabinol, including inhibition of cytokine production. The first objective of the present studies was to determine the role of the CB1 and CB2 receptors in 2-AG-mediated inhibition of IL-2. In activated murine splenic and thymic T cells, 2-AG causes a marked and concentration-responsive inhibition of IL-2 that is more potent than anandamide, another putative endogenous cannabinoid. The CB1 and CB2 antagonists, SR141716A and SR144528 respectively, did not antagonize the inhibition of IL-2 mediated by 2-AG or anandamide. The second objective of the present studies was to determine the effect of 2-AG upon T cell proliferation. Interestingly, 2-AG causes a concurrent concentration-responsive enhancement of T cell proliferation at the same concentrations at which it inhibits the production of IL-2. 2-AG caused a significant enhancement of T cell proliferation at 1 μM and an approximate 50% increase in proliferation at 10 μM. Neither anandamide nor arachidonic acid caused an enhancement of T cell proliferation. These data suggest that 2-AG enhances T cell proliferation while paradoxically and concurrently inhibiting the production of the T cell growth factor, IL-2, in activated murine splenic and thymic T cells. These data also suggest that the 2-AG-mediated enhancement of T cell proliferation is unique to 2-AG and not common to arachidonic acid and its derivatives. (Supported in part by NIH Grant DA 12740)

723 CONCENTRATION-DEPENDENT BIFUNCTIONAL EFFECTS OF TGF-β_1 on Immunoglobulin Production: Role for Smad3 in IgA Production *in vitro.*

S. C. McKarns[1], J. J. Letterio[1] and N. E. Kaminski[2]. [1]*Lab of Cell Regulation and Carcinogenesis, The NCI, NIH, Bethesda, MD and* [2]*Pharmacology and Toxicology, Michigan State University, East Lansing, MI.*

TGF-β_1 is a critical regulator of humoral and cell-mediated immune homeostasis. The molecular mechanisms responsible for the regulation of immune cell effector function by TGF-β_1 are not well defined. We demonstrate bifunctional augmenta-

tion and inhibition of *in vitro* T cell-dependent anti-SRBC- and T cell-independent DNP-Ficoll-induced AFC responses by femtomolar and picomolar concentrations of TGF-β_1, respectively. To investigate the molecular mechanisms responsible for the inhibitory effects of TGF-β_1 on T cell-dependent and -independent AFC responses, splenocytes were obtained from mice homologous for a null mutation in the gene encoding the TGF-β receptor-activated Smad3 ($Smad3^{Exon8-/-}$) and sensitized *in vitro* to either anti-SRBC or LPS. Inhibition by TGF-β_1 was markedly reduced in the $Smad3^{Exon8-/-}$ B cells compared with age-matched wild type littermates ($Smad3^{+/+}$). Moreover, LPS-sensitized $Smad3^{Exon8-/-}$ B cells were less sensitive to TGF-β_1-induced inhibition of IgM secretion as determined by ELISA. A role for Smad3 in IgA production *in vitro* was also investigated. TGF-β_1 did not induce IgA production in LPS-sensitized $Smad3^{Exon8-/-}$ B cells under conditions that yielded significantly increased IgA production $Smad3^{+/+}$ B cells. In conclusion, our results demonstrate a bifunctional, concentration-dependent effect of TGF-β_1 on Ig production. These results are also provide evidence for a role by Smad3 in IgA production by TGF-β_1 *in vitro*.

724 ENHANCEMENT OF TNF-α mRNA STABILITY BY DEOXYNIVALENOL THROUGH ACTIVATION OF P38 KINASE.

Y. Chung[1,2] and J. J. Pestka[1,2,3]. [1]*Food Science and Human Nutrition, Michigan State University, East Lansing, MI,* [2]*Institute for Environmental Toxicology, Michigan State University, East Lansing, MI and* [3]*Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.*

Deoxynivalenol (vomitoxin, VT), a common fungal metabolite in grains, up-regulates proinflammatory cytokine gene expression. This up-regulation is controlled by both transcriptional and post-transcriptional mechanisms. We have recently shown that VT up-regulates TNF-α gene expression post-transcriptionally *via* enhanced mRNA stability. Since stabilization of cytokine mRNA is often related to activation of mitogen activated protein kinases (MAPKs), we investigated the role of these kinases in enhanced TNF-α mRNA stability in RAW 264.7 macrophage cells. p38 kinase, ERK1, and ERK2 were found to be activated by VT. The effects of VT on increased mRNA stability in the presence of MAPK inhibitors were studied in lipopolysaccharide (LPS)-stimulated cells. After 4 hr stimulation by LPS, a transcription inhibitor, 5, 6-dichloro-1-beta-D-ribofuranosyl benzimidazole (DRB), with or without MAPK inhibitor (SB203580 or PD98059) was added to culture and VT-mediated changes in TNF-α mRNA stability were measured using a ribonuclease protection assay (RPA). Increased TNF-α mRNA stability by VT was abrogated in the presence of p38 kinase inhibitor (SB203580). Treatment of ERK inhibitor (PD98059) did not affect stabilization of TNF-α mRNA by VT. These results suggest that VT up-regulates TNF-α gene expression by increasing mRNA stability *via* activation of p38 kinase.

725 EXTRACELLULAR METALLOTHIONEIN ALTERS THE T_H RESPONSE TO COGNATE ANTIGEN PRESENTED BY ANTIGEN PRESENTING CELL.

K. C. Crowthers and M. A. Lynes. *Department of Molecular and Cell Biology, University of Connecticut, Storrs-Mansfield, CT.*

Metallothionein(MT) is a stress-induced protein that can modulate several key immune mechanisms. In previous work, MT has been demonstrated to decrease *in vivo* and *in vitro* measures of humoral and cell-mediated immunity. MT has also been shown to bind to leukocyte plasma membranes both *in vivo* and *in vitro*. These observations suggest that MT may alter cell function through interaction with surface proteins preventing effective cell:cell interaction. We have used antigen presenting and cell proliferation assays to address this possibility. Our results show that MT can significantly interfere with *in vitro* antigen recognition by T cells co-cultured with antigen presenting cells (APCs). In these experiments, MT decreased OVA-stimulated DO-11.10 T cell cytokine secretion by 20-30% when compared to vehicle control. This MT-mediated suppression of T cell responses to antigen also occurred in MT-null T cells when exogenous MT was added to cultures, indicating that the induction of intracellular MT is not required for the mechanism of suppression. Furthermore, using an array of H-2s restricted T cell lines that are each specific for different OVA epitopes, we observed MT-mediated suppression of IL-2 and IL-4 cytokine secretion in a majority of clonal T cell responses to antigen presented by APCs. Intriguingly, there was one OVA-specific T cell clonal response that was enhanced by the presence of MT. DO-11.10 T cell responses were also suppressed in the presence of MT when stimulated by fixed APCs, suggesting that MT need not be present during antigen uptake and processing to suppress subsequent T cell responses. T cell proliferation that is experimentally induced with anti-CD3 antibodies is also suppressed by the presence of MT, suggesting that MT may interfere with effective T cell responses through the T cell receptor:MHC immune synapse. These observations further extend the idea that metallothionein synthesized as a consequence of cellular stress may play an important role in the onset of stress-induced immune dysfunction.

726 SODIUM METHYLDITHIOCARBAMATE SUPPRESSES INTERLEUKIN-2, INTERLEUKIN-4, AND INTERFERON-γ PRODUCTION AFTER STIMULATION IN B6C3F1 MICE.

L. P. Myers and S. B. Pruett. *Department of Cellular Biology and Anatomy, Louisiana State University Health Sciences Center, Shreveport, LA.*

Sodium methyldithiocarbamate (SMD) is a commonly used fungicide, nematocide, and herbicide in agricultural soils, which is immunotoxic in mice. Since other dithiocarbamates (pyrrolidine dithiocarbamate, e.g.) have been implicated in cytokine alterations in mice, we investigated the effect of SMD on cytokine production. When pretreated with SMD (300 mg/kg) and then stimulated with anti-CD3 (3 μg/mouse), B6C3F1 mice showed marked suppression of serum cytokine production at 90 minutes post-stimulation. SMD suppressed Interleukin-2 (IL-2) (1323.2 pg/ml) compared to anti-CD3 alone (4653.2 pg/ml). Similar SMD-induced suppressions were seen with IL-4 (433.2 compared to 1091 pg/ml), and Interferon-γ (IFN-γ) (1398.0 compared to 5361.8 pg/ml). Expression of IL-2, IL-4, IL-13, and IFN-γ mRNA was significantly suppressed by SMD at 45 minutes, but the cytokines were not significantly different at 90 minutes post-stimulation when evaluated by RNAse protection assays. Since SMD increases serum corticosterone by inducing a stress response, aminoglutethimide was administered to evaluate the role of glucocorticoids in cytokine suppression. Although the overall levels of cytokines were increased (possibly due to the lack of corticosterone to regulate the cytokine expression), a similar pattern of cytokine suppression was noted when SMD was administered in the absence of corticosterone. Therefore, it is unlikely that corticosterone plays a role in SMD-induced cytokine suppression. Since other dithiocarbamates suppress cytokines by blocking NF-κB signaling, we evaluated the effect of a single dose of SMD (300 mg/kg) over a time course. SMD depleted basal levels of NF-κB in the nucleus of splenic T-cells by 50% at 60 minutes post-administration. NF-κB levels then increased to normal by 80-120 minutes after administration of SMD. Therefore it is possible that SMD suppresses cytokine expression by blocking NF-κB signaling in the cell. This work was supported by NIH grant #ES09158.

727 LOW CONCENTRATIONS OF INORGANIC MERCURY INHIBIT RAS ACTIVATION DURING T CELL RECEPTOR MEDIATED SIGNAL TRANSDUCTION.

A. J. Rosenspire[1], A. Felczak[1], C. C. Chen[1], M. J. McCabe Jr[2] and R. R. Mattingly[1]. [1]*Biological Sciences, Wayne State University, Detroit, MI and* [2]*Environmental Medicine, University of Rochester, Rochester, NY.*

Mercury is widespread in the environment, and consequently there are large populations who are currently exposed to low levels of mercury as a result of ubiquitous environmental factors. Whether these environmental levels of mercury are harmful is a matter of current debate, with epidemiological and animal studies suggesting detrimental effects on the immune and nervous systems. However specific cellular effects of low concentrations of mercury have been difficult to characterize. We now demonstrate that sub-toxic concentrations of $HgCl_2$ can potently (maximal at 1 μM) increase Ras.GTP levels in Jurkat, a human T cell line. Remarkably, this activation of Ras occurs without a concomitant increase in MAP kinase activation, suggesting that mercury may direct Ras into a non-productive state. In addition to its direct effect on Ras, concentrations of $HgCl_2$ as low as 0.6 μM inhibited the ability of the T Cell Receptor to activate Ras and MAP kinase. The inhibitory effect of mercury is selective, as activation of MAP kinase by phorbol diesters remain intact. Since the Ras/MAP kinase pathway is both highly conserved, and central to signal transduction processes mediated by a myriad of diverse membrane receptor systems in a variety of cell types, these results suggest a mechanism for adverse health effects resulting from exposure to low levels of mercury. They also support a model for regulation of the Ras/MAP kinase pathway, whereby partial but unproductive activation of Ras can diminish signaling from cell surface receptors.

728 MECHANISMS OF PPARγ-MEDIATED PRE-B CELL APOPTOSIS.

J. J. Schlezinger, B. Jensen, H. Y. Ryu and D. H. Sherr. *Environmental Health, Boston University School of Public Health, Boston, MA.*

The role of PPARγ in adipocyte differentiation and function is well recognized. In addition, PPARγ is expressed strongly in the immune system and also may influence immune cell function. As shown by propidium iodide staining, DNA ladder formation, and PARP cleavage, PPARγ agonists (15-deoxy-$\Delta^{12,14}$-prostaglandin J2, ciglitazone, troglitazone and rosiglitazone) rapidly (6 hours) induced apoptosis in pro/preB cells (BU-11), immature B cells (WEHI-231) and plasma cells (HS Sultan, U266, IM9). We hypothesize that activation of PPARγ and its dimerization partner retinoid X receptor (RXR) induces B cell apoptosis. Untreated B cells express PPARγ only in the cytoplasm. Following treatment with ciglitazone, the receptor translocates to the nucleus, binds a consensus PPARγ -binding nucleotide

sequence derived from the acetyl CoA oxidase promoter, and initiates transcription, as indicated by western blot, EMSA, and increased PPARE-driven reporter activity. The role of PPARγ in apoptosis is supported further by the fact that co-treatment with 9-cis retinoic acid (a specific agonist for RXR) synergistically increased the incidence of apoptotic B cells. Given previous studies indicating that PAH-induced pre-B cell apoptosis is triggered by NF-κB down-regulation, we also hypothesized that alteration of NF-κB-DNA binding is involved in PPARγ agonist-induced apoptosis. Ciglitazone caused a 3.6-fold increase in NF-κB binding to the κB site in the upstream regulatory element of c-myc. NF-κB-DNA binding increased as early as 1 hour post-treatment and was maximal 6-7 hours post-treatment; the p50, p65 and c-rel subunits of NF-κ B all contributed to this increase. In parallel with the apoptosis dose-response curves, co-treatment with 9-cis retinoic acid and ciglitazone decreased the ciglitazone dose required to activate NF-κB, suggesting that PPARγ-RXR heterodimer activation results in NF-κB activation. In summary, activation of PPARγ appears to initiate apoptotic signaling in B cells of multiple maturation stages, potentially through the activation of NF-κB.

729 CUMULATIVE IRRITATION (21 DAY) STUDY OF POLYVINYLIDENE FLUORIDE COATINGS ON HUMAN SUBJECTS.

K. C. Norbury, G. Siegel, B. Bhatt, H. R. Rawls and N. J. Girard. *Biomedical Development Corp., San Antonio, TX.*

Introduction: Our laboratory has developed a unique formulation, EpikieaTM coatings, for direct application to skin. This blend of polyvinylidene fluoride (PVDF) and acrylic polymers, is safe and remains intact on human skin for extended periods of time, making it beneficial in the prevention of irritation due to incontinence. Methods: PVDF coatings were applied in a randomized, cross-over design to the backs of 26 human subjects over a 21 day period and scored for irritation. Subjects were 21 to 75 years of age, had no clinically significant history of skin, kidney, lung disease, or diabetes and no evidence of any skin lesions. Subjects served as their own controls. Each subject had 10 sites of 4x4 cm2 areas on their mid-back, beneath the angles of the scapulae, demarcated with an indelible skin marker. Subjects reported for treatment and evaluation daily during weekdays. No treatment or evaluation took place over weekends. During daily treatment, coatings were removed, skin was scored for irritation, and the coatings were re-applied. Daily irritation scoring was made 24 hours after each application of the PVDF coating test material (except weekends). After scoring, the treatment area was cleaned with soap and water and air dried, and coatings were reapplied to the same sites. Visual scoring was made for erythema/eschar (0 - no erythema to 4 - severe erythema/ slight eschar formation) and edema (0 - no edema to 4 - severe edema/ raised more than 1 mm). In addition, non- invasive testing at each test site was performed using three instruments: a colorimeter which measures the color of the skin and erythema; an evaporimeter which measures the moisture content of the skin; and a laser-Doppler, which measures the microcirculatory blood flow. Results: No evidence of any erythema or edema was found on any subject at any time. There was never a score greater than 0 on any site during the 21 day study. Finally, none of the instruments showed any adverse effects. Conclusion: PVDF coatings are non-irritating to humans.

730 IMMUNOMODULATION FOLLOWING ORAL ADMINISTRATION OF THE ANTIFUNGAL AGENT SCH 56592.

R. V. House[1], G. L. Leatherberry[1], T. E. Davis[2] and J. M. Petruska[2]. *[1]Covance Laboratories Inc., Madision, WI and [2]Schering Plough Research Institute, Lafayette, NJ.*

SCH 56592 is a broad-spectrum azole antifungal drug in development for treatment of mucosal and systemic fungal infections. Immunocompetence of CD-1 mice following daily dietary dosing of 10, 30 and 90 mg/kg SCH 56592 for 1 and 3 months was assessed. A 1-month recovery period following 3 months of dosing was also included. Immunotoxicity assessment included lymphoid organ weights and cellularities, hematology, leukocyte phenotype analysis of blood and spleen, induction of antibody-forming cells (AFC), and natural killer (NK) cell activity. Animals dosed with SCH 56592 had an increased incidence of a common background ear lesion in CD-1 mice, but no changes in body weight or food consumption. Dose-related increases in spleen, liver and adrenal weights, and in spleen cellularity occurred; thymus weight and cellularity were unaffected. There were mild to moderate increases in leukocytes due to increases in monocytes, neutrophils and/or lymphocytes at 30 and 90 mg/kg after 1 and 3 months of dosing; these increases were still apparent 1 month postdose at 90 mg/kg. There was a dose-related trend toward increased NK cell number and monocyte number and percentage; these changes resolved following recovery. Splenic lymphocytes were also increased. SCH 56592 had no effect on AFC production in males; females were unaffected at 1 month, but at 3 months they exhibited a statistically significant increase in AFC at 10 mg/kg, and a statistically significant decrease in AFC at 90 mg/kg. Changes were minimal, and resolved following recovery. NK activity was increased in both sexes at both 30 and 90 mg/kg following a 1-month administration, and in males only following 3 months of dosing. Following recovery, NK activity returned to control levels in all mice. These data suggest that administration of SCH 56592 is associated with a modest immunostimulation in CD-1 mice. The resolution of most changes following cessation of dosing suggests that SCH 56592 has no permanent effect on the functional integrity of the immune system.

731 ASSESSMENT OF IMMUNOMODULATORY POTENTIAL OF FTY720 IN A MURINE CONTACT ALLERGY MODEL.

P. Ulrich, J. Streich, N. Runser, P. Heining and W. Suter. *Tox/Path, Novartis Pharma AG, Basel, Switzerland.* Sponsor: A. Wolf.

FTY720 is a chemically modified fungal product, which is in development for the use in organ transplantation to prevent allograft rejection. Contact allergy (CA) was induced by a 3 day topical treatment with dinitrochlorobenzene (DNCB) on the shaved back of BALB/c mice. 12 days later, elicitation of CA was provoked by a 3 day topical application of DNCB on the dorsum of both ears. FTY720 was administered orally during the elicitation phase in sensitised mice and the concurrent non-sensitised control animals. Necropsy was performed one day after the last treatment. In a preceding experiment FTY720 caused a marked reduction of peripheral lymphocyte counts and a marked decrease of ear-draining lymph node (LN) weights at 0.1 and 1mg/kg, when applied for 3 days together with topical application of DNCB. Oral application of 0.1 and 1 mg/kg FTY720 during elicitation of CA led to a decrement in the DNCB-caused hyperplasia of ear-draining LN and a reduction in the allergy-relevant increase in ear weight. However, evaluation of IL-2 receptor expression on the surface of CD4 T cells and the generation of CD4 T cell blasts by flow cytometry of cells from the ear-draining LN did not reveal significant changes in comparison to the respective control. In contrast, the immunosuppressant FK506 caused a marked reduction in this study not only of the LN hyperplasia and allergy-relevant ear swelling, but also of IL-2R expression and CD4 T cell blastocytosis. In addition, the cytokines IL-2, IL-4 and IFN gamma were determined in supernatants of restimulated LN cells derived from FTY720 and DNCB-treated mice. No substantial changes caused by FTY720 in the DNCB-induced pattern of these cytokines were observed. The presented findings correspond with the mechanism of action of FTY720, which prevents immune-mediated rejection of allotransplants by distracting lymphocytes from the periphery rather then by suppressing their activation. This study shows that a contact allergy-based murine model can be applied to investigate the influence of test articles on the immune systems function.

732 GENISTEIN MODULATES NK CELL ACTIVITY, ANTI-CD3-MEDIATED T CELL PROLIFERATION AND PHENOTYPIC MARKER EXPRESSION BY THYMOCYTES AND SPLENOCYTES IN F_0 AND F_1 GENERATIONS OF C57BL/6 MICE.

T. L. Guo[1], X. L. Zhang[1], D. L. Musgrove[1], C. Weis[2], D. R. Germolec[3] and K. L. White, Jr.[1]. *[1]Virginia Commonwealth University, Richmond, VA, [2]NCTR, Jefferson, AR and [3]NIEHS, Research Triangle Park, NC.*

Although the phytoestrogen genistein (GEN) has been hypothesized to have beneficial health effects in adults, concern exists about the long-term adverse effects of this compound. The objective of the present study was to evaluate the effect of GEN on the immune system in adult and developing mice. Pregnant C57BL/6 mice were exposed to GEN at low (L: 25 ppm), middle (M: 250 ppm) and high (H: 1250 ppm) concentrations in feed starting on day 14 of gestation. The offspring were exposed to GEN gestationally and lactationally, and to GEN-containing feed after weaning on postnatal day 21. Immunological evaluation was performed on postnatal day 42. In dams, exposure to GEN increased terminal body weight (M and H), splenic T cell and NK cell numbers (M), and the activity of NK cells (M). In F1 males, GEN increased terminal body and spleen weights (L and M), the number of $CD4^+CD8^+$ and $CD4^-CD8^-$ thymocytes (L), and the number of splenic T-cell subsets and NK cells (L and M). Moreover, splenic NK cell activity and anti-CD3-mediated splenocyte proliferation were increased in all dose groups. In F1 females, the percentages of $CD4^-CD8^+$ and $CD4^-CD8^-$ thymocytes (L and M), and the splenic $CD4^+CD8^-$ and $CD4^+CD8^+$ T cells (L and M) were increased. In contrast, the percentage and number of $CD4^+CD8^+$ thymocytes were decreased in the middle dose group. Exposure to GEN decreased the percentages of splenic NK cells in all dose groups, while decreased the activity of splenic NK cells in the low dose group. Overall, the results demonstrate that GEN can modulate the immune system with greater effects occurring in developing mice. The sexual dimorphic effects of GEN on the immune responses of F_1 male and female mice suggest that GEN may function as an endocrine disrupter. (Supported in part by the Jeffress Memorial Trust and NIEHS Contract ES 55387).

733 STRAIN-DEPENDENT PRIMARY AND SECONDARY DICLOFENAC-INDUCED POPLITEAL LYMPH NODE REACTIONS.

B. W. Gutting, F. Bouzahzah, P. Kong and J. E. Craft. *Yale University School of Medicine, New Haven, CT.*

Diclofenac (DF) is associated with immune-mediated drug hypersensitivity reactions (IDHRs). Although the mechanisms causing DF-induced IDHRs remain to be defined, it is thought that IDHRs are controlled by genetic factors. The aim of this study was to examine the immunomodulating potential of DF in two genetically diverse and MHC-mismatched mouse strains (BALB/c, H2d and B6, H2b). This study used a popliteal lymph node assay (PLNA) that was conducted in naïve and orally pretreated mice (3 weeks after a single dose of DF). In naïve mice, DF induced a PLN reaction in both strains that resulted in the accumulation of activated T cells in the PLN. Despite these similarities, strain-dependent effects were observed. For example, there was an increase in the % of CD3+CD4+, and CD3+CD8+ lymphocytes in B6 mice, whereas no increase was observed in BALB/c mice. Oral pretreatment with DF also had a strain-dependent effect. For example, BALB/c mice orally pretreated with DF were rendered hyper-responsive to footpad injection with DF; a significant increase in footpad swelling 24 hours post-injection and significant increases in PLN size, weight and cellularity on day 5 post-injection. By contrast, oral pretreatment with DF had no observable effect on PLN reactions in B6 mice or in congenic BALB/c mice where H2d MHC was replaced with H2b. Furthermore, the hyper-responsiveness in wild-type BALB/c mice was associated with a significant increase in the % of CD8+IL-2+ cells in the PLN. Finally, in *ex vivo* studies, PLN cells isolated from BALB/c mice injected with DF induced proliferation of splenocytes isolated from BALB/c mice orally treated with DF. Collectively, these results suggest that DF has strain-dependent immunomodulating properties in mice. Specifically, BALB/c mice, but not B6, orally pretreated with DF are hyper-responsive to the immunostimulating effects of DF when challenged in the footpad, which is a response that may be mediated, in part, by sensitized CD8+ T cells reacting to DF-modified antigens in the footpad presented by H2d molecules.

734 EVALUATION OF A SURROGATE ANTIBODY FOR SAFETY TESTING. PHARMACOLOGY OF A MURINE ANTI-CD11A ANTIBODY IN MICE.

J. Clarke[1], R. House[2], W. Leach[1], S. Pippig[1], E. Stefanich[1], S. Ortega[1] and J. Beyer[1]. *[1]Genentech Inc., S San Francisco, CA and [2]Covance, Madison, WI.*

Surrogate antibodies are a potential solution to the limited safety testing possible with humanized monoclonal antibodies of restricted species cross reactivity. Prior to use, potential surrogates should undergo rigorous evaluation to assess pharmacological activities in comparison to the clinical agent. The current studies evaluated the pharmacology of an anti-mouse CD11a monoclonal antibody (muM17) as a potential surrogate for efalizumab, a humanized anti-CD11a antibody in development for treatment of psoriasis. CD11a is a subunit of lymphocyte function associated antigen-1, an integrin involved in cell-cell interactions important to leukocyte adhesion and activation. *in vitro* studies examined the binding of muM17 to whole mouse blood and the inhibitory activity of muM17 in a mixed lymphocyte response (MLR) assay. As anticipated muM17 bound to mouse blood cells, with a binding affinity of 2.7 nM. In addition, muM17 had a dose dependent inhibitory effect on the MLR assay with an IC_{50} of 0.1-0.3 ug/ml. In an *in vivo* delayed-type hypersensitivity study in female CD-1 mice, muM17 (3 - 30 mg/kg) was administered subcutaneously on Days 1 and 7. Mice were sensitized and challenged with oxazolone by application to the abdomen and subsequently the ear on Days 3 and 9, respectively. In some animals muM17 was administered only prior to challenge. Ear thickness was measured up to 72 hours after challenge and compared to the unchallenged ear on the same animal. muM17 caused a dose dependent reduction in the delayed type hypersensitivity response up to a maximum inhibition of 100% (≥10 mg/kg). Administration of 30 mg/kg only prior to challenge was still active, but reduced the inhibition to 70% suggesting that the full effect of muM17 involves both inhibition of T cell activation during sensitization as well as trafficking into the tissues upon rechallenge. These studies demonstrate that muM17 has similar pharmacological activities to efalizumab and is active at doses intended for toxicology studies.

735 EVALUATION OF A SURROGATE ANTIBODY FOR SAFETY TESTING. TOXICOLOGY OF A MURINE ANTI-CD11A ANTIBODY IN MICE.

W. Leach, J. Beyer, D. Shih, C. Washington, K. Howell, L. Zuckerman and J. Clarke. *Genentech Inc., South San Francisco, CA.*

The development of surrogate antibodies is a potential solution to the limited safety testing possible with humanized monoclonal antibodies with restricted species crossreactivity. Prior to use, potential surrogates should undergo rigorous evaluation to assess pharmacological and toxicological activities in comparison to the clinical agent, as well as to provide dose selection information for subsequent GLP toxicology studies. The current studies evaluated the toxicity of a chimeric mouse/rat IgG anti-mouse CD11a monoclonal antibody (muM17) as a potential surrogate for efalizumab, a humanized anti-CD11a antibody in development for treatment of psoriasis. CD11a is a subunit of lymphocyte function associated antigen-1, a surface molecule involved in cell-cell interactions important to leukocyte adhesion and activation. Female CD1 mice were administered muM17 (0.1 to 30 mg/kg) *via* subcutaneous (SC) injections once a week for four weeks. Clinical observations, body weight, clinical pathology, T cell CD11a expression, immunogenicity and lymphoid organ histopathology were evaluated. Doses of ≥ 3 mg/kg muM17 caused a maximal downmodulation of CD11a on T cells (approximately 90% of baseline values) which was reversible, time to recovery of CD11a expression was dose dependent. muM17 caused a transient increase in peripheral white blood cell counts (2 -3 fold *versus* vehicle treated mice) as a result of increases in lymphocytes and neutrophils. muM17 was immunogenic, but to a greatly reduced extent than the parent antibody M17 (rat anti-mouse CD11a), with an incidence of anti-muM17 antibody positive mice of 1 in 181. There was no histologic evidence of muM17 adverse effects on the spleen or thymus including no lymphocyte depletion. In conclusion, there were no significant toxicities associated with muM17 treatment, downmodulation of CD11a expression and white blood cell changes represented pharmacological activities of the drug consistent with efalizumab.

736 APPLICATION OF A SURROGATE ANTIBODY FOR SAFETY TESTING. DEVELOPMENTAL TOXICITY STUDY OF A MURINE ANTI-CD11A ANTIBODY IN MICE.

S. Ortega[1], A. Hoberman[2], J. Beyer[1], C. Washington[1], S. Collins[1] and J. Clarke[1]. *[1]Genentech Inc., South San Francisco, CA and [2]Argus Research Laboratories, Horsham, PA.*

Surrogate antibodies are a potential solution to the limited safety testing possible with humanized monoclonal antibodies with restricted species crossreactivity. The purpose of this study was to detect potential adverse effects of a chimeric mouse/rat IgG anti-mouse CD11a monoclonal antibody (muM17) on CD-1 pregnant female mice and development of the embryo and fetus consequent to exposure of the dam through organogenesis. CD11a is a subunit of lymphocyte function associated antigen-1, a leukocyte surface molecule involved in cell-cell interactions important to leukocyte adhesion and activation. MuM17 is a surrogate antibody for efalizumab, a humanized anti-CD11a antibody in development for the treatment of psoriasis. Previous studies designed to evaluate the surrogate established pharmacological activity of muM17 at doses ≥ 3mg/kg. Further, pharmacodynamic comparisons to efalizumab in terms of downmodulation of CD11a expression on T cells indicated that 3 mg/kg muM17 was an appropriate clinically equivalent dose level and was the lowest dose level selected in this developmental study. Female CD1 mice were administered muM17 (3, 10 or 30 mg/kg) *via* subcutaneous (SC) injections once a week beginning on Day 2 of presumed gestation until Day 16. Exposure to muM17 and the development of anti-muM17 antibodies were determined. Upon caesarian-sectioning on day 18 of presumed gestation the number and distribution of corpora lutea, live and dead fetuses and resorptions and fetal observations were evaluated. Toxicokinetics confirmed exposure to muM17 and there were no detectable antibodies to muM17. There were no muM17 treatment-related effects on the examined parameters including no soft tissue or skeletal malformations. In conclusion, administration of muM17 to pregnant mice was not associated with any adverse developmental effects.

737 IMMUNOGENICITY OF INHALED MURINE CPG OLIGONUCLEOTIDES AS A MUCOSAL ADJUVANT IN COMBINATION WITH RECOMBINANT SEB VACCINE.

C. J. Roy[1], D. S. Reed[1], S. Duniho[2], A. M. Krieg[3] and L. DaSilva[1]. *[1]Toxicology and Aerobiology, USAMRIID, Frederick, MD, [2]Pathology, USAMRIID, Frederick, MD and [3]Coley Pharmaceutical Group, Wellesley, MA.*

Staphylococcal enterotoxin B (SEB) is an exotoxin derived from the bacterium *Staphylococcus aureus*. SEB, classified as a superantigen and a biological threat agent, is a known inducer of T-cells and can cause illness and death in humans. A USAMRIID-developed recombinant SEB vaccine (rSEBv) protected mice and primates against aerosolized SEB when the vaccine was administered with alhydrogel as an intramuscular (IM) injection. We tested whether administering rSEBv by inhalation would induce mucosal immunity, thus protecting against lethality while also blocking the enteric effects of SEB intoxication. A murine CpG-containing oligonucleotide (CpG) was used as a mucosal adjuvant in conjunction with rSEBv. Mice were dosed with either rSEBv + CpG (5 µg each), CpG alone (5 µg), or saline (sham) by inhalation or 20 µg rSEBv adsorbed onto alhydrogel IM in a prime/three boost vaccination schedule. The use of CpG either alone or with rSEBv induced a transient neutrophilic influx three hours post vaccination with no resulting notable

pathologic sequelae. Immune response was evident in the rSEBv + CpG group characterized by increased serum anti-SEB IgG and IgA in lavage. Pulmonary gene expression profile of mRNA species determined by cDNA array analysis indicated 67 upregulated and six downregulated genes in CpG-treated groups. Analysis of splenic lymphocytes had six times the CD4+ T-cells in the rSEBv + CpG group compared to the rSEBv or sham groups. All groups were then challenged with SEB by aerosol. Survival rates in mice vaccinated by inhalation (92%) were comparable to the mice who were injected (90%) whereas all sham-vaccinated animals died (0%). The results of this study suggest that CpG has the potential to be used as a safe and immunostimulatory mucosal adjuvant when delivered by inhalation.

738 CHARACTERIZATION OF A POTENTIAL ANIMAL MODEL OF AN IDIOSYNCRATIC DRUG REACTION: NEVIRAPINE-INDUCED SKIN RASH IN THE RAT.

J. M. Shenton and J. P. Uetrecht. *Pharmaceutical Sciences, University of Toronto, Toronto, ON, Canada.*

RATIONALE: Idiosyncratic drug reactions are difficult to study in humans due to their unpredictability. Unfortunately, this characteristic also hinders the development of animal models needed for mechanistic studies. Nevirapine (NVP), used to treat AIDS, results in a severe idiosyncratic skin rash in some HIV patients. We found that NVP can also cause a significant rash in some strains of rats. METHODS: Female rats, Lewis (n=6), Brown Norway (BN; n=12), Sprague-Dawley (SD; n=26) and male rats, BN (n=2), were administered NVP, 100-150 mg/kg/day, in their diet. Animals were monitored for development of skin rash, food intake and body weight. At either week 8 of treatment or after development of rash, animals were sacrificed and blood and skin samples acquired. Some animals presenting with skin rash were removed from drug, allowed to recuperate and then rechallenged. To determine the effects of lower doses of NVP female BN rats were treated with 50-75 mg/kg/day (n=4) or 25-40 mg/kg/day (n=4). RESULTS: NVP treatment induced skin rash in 7/26 female SD rats after 4-6 weeks of dosing and in all female BN rats after 3 weeks of dosing; however, male BN rats, female Lewis rats, and female BN rats treated with lower doses of NVP, were not affected. The skin rash consisted of scab-like lesions primarily on the back. Light microscopy revealed a mixed inflammatory infiltrate. Hematology and chemistry tests showed no consistent changes in treated animals. Animals rechallenged with NVP developed skin symptoms faster on reexposure, but the syndrome was different. Instead of presenting primarily with skin lesions, the animals exhibited excessive hair loss commencing at approximately 48 hours post reexposure, occasional skin lesions and general malaise that necessitated sacrifice after less than 2 weeks of treatment. By light microscopy the hair loss was characterized by a perifollicular inflammatory infiltrate. CONCLUSIONS: NVP-induced skin rash in rats may represent a new animal model for the study of drug-induced idiosyncratic skin reactions.

739 ENVIRONMENTAL FACTORS ASSOCIATED WITH INFANT MORTALITY IN SELECTED VIRGINIA REGIONS.

R. A. Bailey, A. T. Charity and P. W. Archer. *Natural Science, Virginia Union University, Richmond, VA.* Sponsor: M. Iszard.

Socio-economic status has been generally accepted as a primary predictor of susceptibility to Sudden Infant Death Syndrome (SIDS). However; recent evidence suggests that other more influential factors may be associated with SIDS, in particular and infant mortality (IM), in general. A computerized data file of matched birth and death tapes, to one year of age (1995-1998) for District 19 Virginia was obtained from the Division of Vital Records, Virginia Department of Health. The fetal deaths were matched for address and zip code at death in addition to birth weight, race and underlying causes of death. The International Classification of Diseases 9th Revision Clinical Modification (ICD 9 CM) was used to numerically code causes of death. The deaths of eighty-seven (87) infants between 1995 and 1998 in District 19 (a given geographical area of Virginia) were examined to determine if any relationship existed for infant death and selected environmental conditions. Fifty-six (56) of these infants were black and twenty-nine (29) were white (64.4% and 33.3% respectively). The majority of these deaths (40.2%) occurred in one geographic area in Petersburg area code 23803 followed by the area Hopewell City, Emporia and Petersburg 23805 (16.1%, 12.6% and 9.2% respectively). The majority of the Petersburg deaths (76%) were black infants. The suspected leading causes of death in this study were due to congenital anomalies (49%) followed by cardio-respiratory conditions including SIDS (26%) and low birth-weight (14%). All other conditions, as coded by ICD 9 categories, accounted for less than 3% of the deaths. Geographical imaging analysis of District 19 revealed that several neurotoxins were prevalent in areas where IM were highest. Other Districts in Virginia, where IM is relatively high, show similar results. As such, there may be a need to re-examine the risk factors associated with IM particularly among African American women and others disproportionately exposed to select environmental conditions. Supported by UNCF/EPA/PEJER VUU 2001

740 PRIORITIZATION OF TOXIC AIR CONTAMINANTS UNDER THE CALIFORNIA CHILDREN'S ENVIRONMENTAL HEALTH PROTECTION ACT.

M. A. Marty, A. G. Salmon, D. Morry, M. Miller, J. Brown, J. Budroe, J. Collins, S. Dawson, D. Lewis, T. McDonald, J. Polakoff, P. Raymond and B. Winder. *Office of Environmental Health Hazard Assessment, California EPA, Oakland, CA.*

California's legislature enacted the Children's Environmental Health Protection Act requiring Cal/EPA to specifically consider infants and children in setting criteria for toxic air contaminants (TAC) including cancer potency factors and reference exposure levels. The law required the Agency to consider exposure patterns of infants and children, special susceptibility, effects of exposure to more than one TAC with a common mechanism of action, and interactions of TAC and criteria air pollutants in assessing risks to children. The law also requires re-evaluation of the criteria for toxic air contaminants over the next several years to ensure adequate protection of infants and children, and establishment of an initial list of up to 5 TAC that may disproportionately impact children by July 1, 2001. Cal/EPA prioritized the TAC based on known toxicity and exposure. We conducted a focused literature review on 37 TAC looking for specific information pertinent to infants and children's exposure and potential differential response relative to adults. We focused on chemicals associated with developmental, neuro-, respiratory, endocrine, or immune toxicity, and endocrine disruptors. We considered asthma induction and exacerbation as disproportionately impacting children. We considered whether existing criteria were adequate to protect infants and children. After public and peer review by a UC Panel, five TAC were chosen to constitute the initial list: acrolein, polychlorinated dibenzo-*p*-dioxins and dibenzofurans, lead, polycyclic organic matter, and particulate matter from diesel-fueled engines. This paper describes the results of our deliberations on decision-making criteria and reasons for listing these five chemicals. In addition, we describe efforts to evaluate the adequacy of our risk assessment methods to protect infants and children.

741 POTENTIAL IMPACT OF ENVIRONMENTAL EXPOSURES TO POLYCYCLIC ORGANIC MATERIAL (POM) ON CHILDREN'S HEALTH.

A. G. Salmon[1] and T. Meehan[2]. [1]*Office of Environmental Health Hazard Assessment, California EPA, Oakland, CA and* [2]*Biotechnology and SBIR Consulting, Tiburon, CA.* Sponsor: L. Zeise.

POM, a class of compounds including polycyclic aromatic hydrocarbons (PAHs) and derivatives, e.g. quinones and nitro-PAHs, is listed as a California Toxic Air Contaminant. Sources include various industrial, domestic, and mobile combustion processes. In support of the Children's Environmental Health Protection Act (California SB25), we reviewed POM and PAH toxicity to identify hazards to which infants and children might be especially sensitive. Health standards for POM are typically based on carcinogenicity. Many PAHs are animal carcinogens by various routes. PAH-containing mixtures, such as tobacco smoke, coke-oven fumes, and diesel exhaust, are known human carcinogens. Theoretically, (from both Armitage-Doll and Moolgavkar models) carcinogen exposures early in life lead to greater lifetime cancer risk than later exposures. Experiments have also shown that fetal and neonatal rodents are more sensitive to carcinogenesis by PAHs and PAH derivatives than adults. Studies on pregnant rodents have revealed less widely recognized effects of PAHs, including intrauterine growth retardation (IUGR), fetal mortality, and teratogenesis. Recent studies of populations exposed to industrial air pollution have confirmed the sensitivity of the human fetus to PAH-induced IUGR and dysmorphogenesis. PAHs are toxic to the immune, hematopoietic, and reproductive systems. The toxicity to adult rodents is often reversible and at high doses, but the fetus or neonate may show severe and lasting effects at lower doses. Both cancer and non-cancer toxicity of PAHs generally correlate with the formation of protein and (especially) DNA adducts by reaction with metabolically generated reactive intermediates. Adducts and metabolites have been used as biomarkers of PAH exposure and adverse effect in humans exposed to air pollution and environmental tobacco smoke. Apparently, children may be both more heavily exposed and also more sensitive to the toxic effects of POM.

742 COMPARATIVE STUDY OF THE TOXICITY OF 4-NITROPHENOL AND 2, 4-DINITROPHENOL IN NEWBORN AND YOUNG RATS.

M. Koizumi[1], Y. Yamamoto[2], Y. Ito[2], M. Takano[3], T. Enami[3], E. Kamata[1] and R. Hasegawa[1]. [1]*Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan,* [2]*Research Institute for Animal Science in Biochemistry and Toxicology, Kanagawa, Japan and* [3]*Bozo Research Center Inc., Gotemba Laboratory, Shizuoka, Japan.* Sponsor: M. Ema.

As infants developing so quickly might be very strongly affected by various environmental circumstances, it is very important to examine the toxicological profiles and levels of chemicals in newborn to lactating animals and compare them with test results using young animals. For the comparative study, we selected 14 phenolic derivatives, of which 4-nitrophenol and 2, 4-dinitrophenol were chosen for evaluation

as the first trial. In the 18-day repeated dose newborn rat study, 4-nitrophenol was orally given from day 4 to day 21 after birth but did not induce any toxicity up to 160 mg/kg, although it induced death in one of six males at 160 mg/kg, and three of six males and one of six females at 230 mg/kg in the dose-finding study. In the 28-day repeated dose oral toxicity study starting at 6 weeks of age, 4-nitrophenol caused death of most males and females at 1, 000 mg/kg but was not toxic at 400 mg/kg except for male rat specific renal toxicity. Unequivocally toxic levels of 4-nitrophenol were considered to be 230 mg/kg/day in newborn rats and 600 to 800 mg/kg/day in young rats, and the NOAELs were 110 mg/kg/day in newborn rats and 400 mg/kg/day in young rats. In the newborn rat study of 2, 4-dinitrophenol, significant lowering of body and organ weights was observed at 20 mg/kg and animals died at 30 mg/kg in the dose-finding study. In the 28-day young rat study, clear toxic signs followed by death occurred at 80 mg/kg but there was no definitive toxicity at 20 mg/kg. Unequivocally toxic levels and NOAELs of 2, 4-dinitrophenol were considered to be 30 and 10 mg/kg/day in newborn rats, and 80 and 20 mg/kg/day in young rats, respectively. Based on these results, it can be concluded that the toxic response of these chemicals in newborn rats is at most 4 times higher than that in young rats.

743 EFFECTS OF PENTYL ETHER, 1, 4-DIETHOXYBUTANE AND 1, 6-DIMETHOXYHEXANE ON MALE RATS FOLLOWING 4-WEEK ORAL ADMINISTRATION.

R. Poon, A. Yagminas and I. Chu. *Environmental Health Science Bureau, Health Canada, Ottawa, ON, Canada.*

Monoethers such as pentyl ether (PE), and diethers such as 1, 4-diethoxybutane (DEB) and 1, 6-dimethoxyhexane (DMH) have been proposed as cetane boosters for diesel fuels. The present study was conducted to assess the short-term oral toxicity of these compounds. Male Sprague-Dawley rats (286 +/- 84 g) were divided into 10 groups of seven animals each. The ethers were dissolved in corn oil and administered by gavage to the animals at dose levels of 2, 20 and 200 mg/kg body weight/day, 5 days per week for 4 weeks. Control animals received corn oil only. No clinical signs of toxicity were observed throughout the treatment period. No significant treatment effects were detected in food consumption and body weight gain. At termination, animals receiving 200 mg/kg of DMH showed marked reduction in the weights of the testis (30%) and thymus (46%) when compared to the control group ($p<0.05$). Significant changes in serum chemistry and hematology were also observed in the 200 mg/kg DMH group only, and consisted of decreased serum uric acid level and lactate dehydrogenase activity, and a 40% reduction in platelet count. No treatment-related changes were detected in N-acetylglucosaminidase activity and protein level in the urine and in the cell-free bronchoalveolar lavage fluids. These results suggest that DMH is more toxic than DEB and PE. Its toxicity in male rats is characterized by testicular and thymic atrophy, and thrombocytopenia.

744 EVALUATION OF INFANT AND CHILD RISK FOR PEROXISOME PROLIFERATORS.

R. A. Roberts and M. J. Clapp. *HAES Research, Syngenta CTL, Macclesfield, United Kingdom.*

The evaluation of infant and child risk for the peroxisome proliferator (PP) class of rodent nongenotoxic hepatocarcinogens provides an interesting paradox. Normally, risk is determined from evaluation of the susceptibility of young rodents. However, there are marked species differences in response to PPs and human hepatocytes are resistant to key precursor events such as rodent hepatic peroxisome proliferation and cell proliferation. Here, we present an alternative approach based on human hepatocyte responsiveness to PPs correlated with the donor age. Data on maximal fold change in response to PPs for peroxisome proliferation (measured by cyanide insensitive palmitoyl CoA oxidation) and cell proliferation (measured by 3H thymidine or bromodeoxyuridine incorporation during DNA synthesis) were collated. For peroxisome proliferation, there were 14 donors with an age range from 2 to 54. As expected, the peroxisome proliferation response was weak ranging from 0.1 to 1.4 fold over control. For DNA synthesis, there were 19 donors with an age range from 2 to 26 and, as expected, the induction of DNA synthesis was very weak, ranging from 0.2 to 1.2 fold over control. For both of these key events in PP-induced rodent liver cancer, the correlation of human hepatocyte response with donor age was not statistically significantly different from zero (correlation coefficients of -0.28; p=0.25 and -0.15; p=0.62 for peroxisome proliferation and DNA synthesis, respectively). The power in the calculation gave a high (95%) chance of detecting a correlation of ±0.72 and ±0.80 for cell proliferation and peroxisome proliferation, respectively. These data confirm the resistance to PPs of human hepatocytes isolated from a range of ages of donor, providing evidence for a lack of age-dependent variation in human hepatic response to PPs.

745 MECHANISM BASED APPROACHES TO EVALUATE THE IMPACTS OF LIFE STAGE SPECIFIC EXPOSURES DURING NEURODEVELOPMENT.

J. M. Gohlke, S. M. Bartell, E. Y. Wong, T. A. Lewandowski, W. C. Griffith and E. M. Faustman. *Environmental Health, University of Washington, Seattle, WA.*

Biologically based Dose-Response (BBDR) models that incorporate mode of action information can improve risk assessment by increasing scientific robustness and applicability across various toxicants and life stages. Towards that goal we are developing and evaluating BBDR models for developmental toxicity based on an underlying hypothesis that rapidly dividing, proliferating and subsequently differentiating cells represent populations potentially sensitive to environmental impacts. Human and rat behavioral, morphological, and cellular studies on ethanol-induced neurodevelopmental toxicity provide a rich data set for application, development, and subsequent assessment of the model. Numerous studies suggest the neocortex is sensitive to ethanol exposure. Previous work modeling ethanol-induced inhibition of rodent neocortical neuronogenesis (G13-G19) has been extended in this current model to include the synaptogenesis period of neurodevelopment (P4-P10). During neocortical synaptogenesis, normal rates of apoptosis range from 30-50% of total neuronal cells affected. With ethanol exposure, dose-dependent increases in these rates are seen (Ikonomidou 2000). At human blood alcohol concentrations that occur after 4-6 drinks (~200 mg/dl), our expanded model predicts an additional 15-20% cellular deficit due to exacerbation of apoptosis during synaptogenesis. Although deficits occurring during the synaptogenesis period are great when the doses are high (> 200 mg/dl), our model suggests the importance of evaluating neuronogenesis at lower, chronic ethanol doses. The extension of our model provides additional mechanistic based approaches to evaluate the impacts of life stage specific exposures during neurodevelopment. Supported by the Center for Child Environmental Health Risks Research through EPA grant R826886 and NIEHS 1PO1ES09601 and the NIEHS Center for Ecogenetics and Environmental Health

746 EVALUATION OF HUMAN DEVELOPMENTAL TOXICITY FOLLOWING PESTICIDE EXPOSURE.

S. A. Laessig[1], S. A. Tabacova[1] and C. A. Kimmel[2]. [1]*NCTR, USFDA, Rockville, MD and* [2]*National Center for Environmental Assessment, USEPA, Washington, DC.*

Federal regulations require that pesticides be tested for reproductive and developmental toxicity in animals prior to registration to establish limits of exposure. Animal data are qualitatively believed to be predictive of human developmental toxicity, but direct comparisons are limited by the availability of adequate human data for specific chemicals. In this study, we identified pesticides with published human reproductive and developmental toxicity data and selected pentachlorophenol (PCP), a chlorophenate pesticide, for evaluation based on the number and type of human studies. A total of 7 epidemiological studies or reports of PCP exposure were identified, including 1 cross-sectional study, 3 case-control studies, 2 cohort studies, and a report of 2 cases. The data were extracted into a database and evaluated for reliability using uniform criteria. Overall, studies were of reliable design, excepting the case reports. Four studies included measurements of PCP in tissues or in environmental samples (indoor air). There was a strong effort in most studies to control for confounders of exposure-outcome relationships. Potential reproductive and developmental outcomes of PCP exposure included reduced birth weight and length, and increased risk of spontaneous abortion, pregnancy complications, altered female hormone levels, congenital anomalies (cataracts), and childhood brain cancer. There appears to be reasonable human evidence that elevated PCP levels are associated with adverse reproductive and developmental outcomes. Existing animal data from standard testing studies will be used to evaluate the predictability for the observed human effects. *Supported in part by an appointment (SAL) to the Postgraduate Research Participation Program at the NCTR administered by the Oak Ridge Institute for Science and Education through an interagency agreement between the USDE and the USFDA. 747 PHYSIOLOGICALLY BASED PHARMACOKINETIC ANALYSIS OF PERCHLORATE (ClO_4^-) DOSIMETRICS.

J. M. Gearhart[1], R. A. Clewell[2] and E. A. Merrill[3]. [1]*ManTech Environmental, AFRL/HEST Wright Patterson AFB, Dayton, OH,* [2]*Geo-Centers, Inc., Dayton, OH and* [3]*OpTech Corp., Beavercreek, OH.*

Perchlorate (ClO_4^-) has been found as a contaminant in surface and ground waters of various environmental sites, especially in the western United States. Due to the proven effectiveness of ClO_4^- to cause inhibition of iodide uptake by the thyroid gland of mammals, concern has arisen over the potential health consequences to humans consuming contaminated waters. In order to help quantitate the potential risk to humans, physiologically based pharmacokinetic (PBPK) models have been developed to calculate the absorption, distribution, metabolism and excretion of

ClO_4^- in rats and humans, thereby providing a means of examining the dose-response relationship of ClO_4^- induced iodide inhibition. A PBPK model for ClO_4^- was used to calculate the dosimetrics for ClO_4^- dosed humans, and pregnant and lactating rats, correlated with the inhibition of thyroidal uptake of iodide. Dosimetrics calculated were area under the ClO_4^- time-concentration curve (AUC) in the serum and thyroid, total urinary excreted ClO_4^- in a 24 hr period, peak serum and thyroid ClO_4^- concentrations, and percent inhibition of iodide uptake by the thyroid. A model parameter sensitivity analysis found the AUC of ClO_4^- in serum was most sensitive to the urinary clearance parameter, while the AUC of ClO_4^- in thyroid was most affected by the model parameters controlling uptake of ClO_4^- into the thyroid, plasma binding and transport rates of ClO_4^-. The upregulation (increased symporter Vmax) of ClO_4^- absorption in the thyroid of male rats during chronic ClO_4^- drinking water, hypothesized to be due to increased numbers of NA^+/I^- symporters, had the greatest impact on the interspecies comparison of ClO_4^- dosimetrics.Validated animal and human PBPK models of ClO_4^- kinetics and inhibition of thyroid iodide resulted in the ability to compare ClO_4^- effects in rats *versus* humans, after different exposure routes, both for acute *versus* repeated dosing.

748 STATISTICAL APPROACH TO BRAIN MORPHOMETRY DATA FROM DEVELOPMENTAL NEUROTOXICITY (DNT) TESTING GUIDELINES: PROFILE ANALYSIS.

A. M. Geller[1] and A. M. Jarabek[2]. *[1]ORD/NHEERL/NTD, USEPA, Research Triangle Park, NC and [2]ORD/NCEA, USEPA, Research Triangle Park, NC.*

Brain morphometry measurements are required in test guidelines proposed by the USEPA to screen chemicals for developmental neurotoxicity. Because the DNT is a screening battery, the analysis of this data should be sensitive to dose-related changes in the pattern of brain growth without requiring prior expectations about specific regions or the magnitude and direction of these changes. In addition, analysis should take into account the lack of independence between multiple brain region measurements taken within the same animal, since the sizes of different regions are likely related. Analysis with t-tests or univariate analyses of variance is inappropriate because it assumes independence and runs the risk of Type 1 error due to repeated sampling using the same error term. A multivariate analysis of variance, profile analysis, was adopted to examine brain morphometry data submitted for the risk assessment of perchlorate (ClO4-), an endocrine-disrupting compound shown to reduce thyroid hormone levels and alter brain development. Profile analysis reduces the number of main effects tested by making between-groups (dose group) comparisons using vectors that comprise all of the within-subject morphometric data from each animal, then comparing these vectors. It also allows gender to be nested within litter, which is necessary to address DNT study designs. The primary test of profile analysis examines whether the pattern made by the various measurements is similar for all treatment groups. This is a test of the interaction between the treatment factor and the within-subjects scores. If the profiles are not parallel, an interaction exists, and further analyses of the interaction factors may be made to elucidate the effects. Results of this analysis showed that ClO4- affected the pattern of brain growth in developing pups at all doses tested. We conclude that this analysis and approach are readily applicable to future DNT data. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

749 QUANTIFYING UNCERTAINTY IN HUMAN REPRODUCTIVE RISK PROJECTED FROM RAT INHALATION STUDIES ON ETHYLENE OXIDE: A FRAMEWORK BASED ON DATA-BASED STATISTICAL DISTRIBUTIONS OF EXTRAPOLATION FACTORS.

L. R. Rhomberg[1,3], S. J. Baird[2], J. S. Evans[3], P. L. Williams[3] and A. M. Wilson[3]. *[1]Gradient Corporation, Cambridge, MA, [2]Menzie-Cura Assoc., Chelmsford, MA and [3]Harvard School of Public Health, Boston, MA.* Sponsor: B. Beck.

Current noncancer risk assessment does not estimate risk as such but instead computes "safe" doses for the general human population, despite its variation in susceptibility. To account for this variation, and for uncertainty in the extrapolation from animals, "Uncertainty Factors" are applied to animal no-effect levels. Resulting "safe dose" estimates are conservative, but their statistical reliability and the protection actually afforded are poorly characterized. Risks (if any) at exposures above the conservative "safe" levels cannot be addressed, hampering rational risk management analyses. We propose an alternative analytical framework in which the specific sources of extrapolation uncertainty and inter-human variability are characterized as statistical distributions based not on policy choices but on actual data for the observed patterns of variation among cases in instances where they have been characterized. We separately propagate the distributions of extrapolation uncertainties and of human variability to estimate a dose-response curve for humans with empirically supported characterization of the uncertainty in dose levels leading to various levels of human population risk (e.g., 1/100, 1/1000). This allows characterization of the reliability of regulatory levels as "safe" doses and permits estimates of the likelihood of impacts (and lack of impacts) on individuals exposed above such regulatory levels. Using a rich database on the reproductive and developmental toxicity of ethylene oxide in rats, a probabilistic characterization of possible regulatory inhalation thresholds is presented as an example of this dose-response based distributional framework. Our method can be applied to comparative risk analysis and benefit-cost analysis, and it furthers harmonization assessment of carcinogens.

750 GENETIC POLYMORPHISMS IN ASSESSING INTER-INDIVIDUAL VARIABILITY IN DELIVERED DOSE.

L. T. Haber[1], A. Maier[1], P. R. Gentry[2], H. J. Clewell[3] and M. L. Dourson[1]. *[1]TERA, Cincinnati, OH, [2]ICF Consulting, Ruston, LA and [3]Environ, Ruston, LA.*

Genetic polymorphisms have been suggested as an important contributor to overall human variability. Recently, these data have been integrated with physiologically-based pharmacokinetic modeling as an approach for determining overall variability. We present an analysis of the potential contribution of polymorphisms in enzymes modulating the disposition of four diverse compounds: warfarin, parathion, methylene chloride, and dichloroacetic acid. Through these case studies, we identify key uncertainties likely to be encountered in the use of polymorphism data, and highlight potential simplifying assumptions that might be required to test the hypothesis that genetic factors are a substantive source of human variability in susceptibility to environmental toxicants. These uncertainties include (1) the relative contribution of multiple enzyme systems, (2) the extent of induction/inhibition through co-exposure, (3) allelic frequencies of major ethnic groups, (4) the absence of chemical-specific phenotype data, (5) large numbers of low-frequency alleles, and (6) uncertainty regarding differences between *in vitro* and *in vivo* kinetic data. Our effort sets the stage for further integration of polymorphism data with PBPK modeling as a means to quantitate population variability

751 RELATIONSHIP BETWEEN TOXICITY VALUES FOR THE HEALTHY SUBPOPULATION AND THE GENERAL POPULATION.

D. R. Sommerville and R. B. Crosier. *US Army ECBC, Aberdeen Proving Ground, MD.* Sponsor: S. Thomson.

The application of transport and dispersion models for risk assessment and management requires accurate estimates of human toxicity. For chemical warfare agents (CWA), most of the available toxicological data and estimates were generated in support of their offensive battlefield deployment. The available human toxicity data come from a limited segment of the general population (GP): relatively young, fit, 70 kg, male soldiers. The present military CWA toxicity estimates are not suitable for use with the GP because they are framed for male soldiers and do not consider potentially sensitive members of the GP. A method was created to convert a median effect dosage and probit slope from a military (or healthy subpopulation (HSP)) to a GP. Up until now, the conversion of a military probit slope to a GP probit slope has not been rigorously explored. It was assumed that individual susceptibilities can be modeled as a log-normal distribution. Modifications for gender differences were addressed. Two models were developed to mathematically describe subpopulations (SP) within the GP. The Tail Model assumes that the SP consists of all individuals having susceptibilities within a tail of the GP distribution. The Bell Model assumes that the SP has a log-normal distribution within the larger GP distribution. Historical military demographics were used to evaluated the probable size of the HSP: 20 to 30% of the GP. The ratio of the medians and the ratio of the probit slopes between the SP and GP are easily determined as a function of the SP size. The two models displayed similar trends in ratio values. Uncertainty factors (UF) were calculated based upon the medians of the SP and the GP, and the probit slope of the GP. UF values from this method were consistent with the results of two previous studies that quantified differences between SPs. Qualitative UF estimates used in establishing proposed AEGLs for CWAs require revision in some cases based upon the results of the present study.

752 INCORPORATION OF HUMAN INTERINDIVIDUAL ENZYME EXPRESSION AND BIOTRANSFORMATION VARIANCE INTO HUMAN HEALTH RISK ASSESSMENTS.

J. C. Lipscomb[1], L. K. Teuschler[1], J. C. Swartout[1] and G. L. Kedderis[2]. *[1]ORD / NCEA, USEPA, Cincinnati, OH and [2]CIIT Centers for Health Research, Research Triangle Park, NC.*

Risk assessments include assumptions about sensitive subpopulations, such as the fraction of the general population that is sensitive and the extent that biochemical or physiological attributes influence sensitivity. Uncertainty factors (UF) account

for both pharmacokinetic (PK) and pharmacodynamic (PD) components, allowing the inclusion of risk-relevant information to replace default assumptions about PK and PD variance (uncertainty). Large numbers of human organ donor samples and recent advances in methods to extrapolate *in vitro* enzyme expression and activity data to the intact human enable the investigation of the impact of PK variance on human susceptibility. The hepatotoxicity of trichloroethylene (TCE) is mediated by acid metabolites whose formation is limited by cytochrome P450 2E1 (CYP2E1) oxidation, and differences in the CYP2E1 expression are hypothesized to affect susceptibility to TCE's liver injury. We combined data sets describing 1) the microsomal protein content of human liver, 2) the CYP2E1 content of human liver microsomal protein, and 3) the *in vitro* Vmax for TCE oxidation by humans. The 5th and 95th percentiles of the resulting distribution differed by 7.6-fold, were converted to mg TCE oxidized/hr/kg body mass and incorporated in a human PBPK model. Simulations of 8 hr inhalation exposure to 50 ppm and oral exposure to 5 g TCE/L in 2L drinking water showed that the amount of TCE oxidized in the liver differs by 2% or less under extreme conditions of CYP2E1 expression and activity. This indicates that differences in CYP2E1 expression among the central 90% of the adult human population account for approximately 2% of the variance of the risk-relevant PK outcome for TCE-mediated liver injury. Integration of *in vitro* metabolism information into physiological models may reduce the uncertainties associated with risk contributions of variance in enzyme expression and the UF that represent PK variance.

753 PBPK MODELING OF BTEX AND N-HEXANE WITHIN A COMPLEX HYDROCARBON MIXTURE: GASOLINE.

J. E. Dennison[1], I. D. Dobrev[1], B. K. Cranmer[1], M. M. Mumtaz[2], M. E. Andersen[1] and R. S. Yang[1]. [1]*Quantitative and Computational Toxicology, Center for Environmental Toxicology, Colorado State University, Fort Collins, CO and* [2]*ATSDR, Atlanta, GA.*

We report an approach for developing PBPK models for gasoline using principal components of toxicological significance. The aim of the study was to determine the pharmacokinetics (PKs) of benzene, toluene, ethyl benzene, and xylene (BTEX) and n-hexane in gasoline, taking enzyme inhibition into account. Due to the mixture's complexity, existing bottom-up modeling approaches were impractical. Instead, we specifically evaluated BTEX and hexane and lumped the remaining components together during both analytical work and PBPK modeling. We conducted closed chamber gas uptake PK studies with F344 rats and monitored the chemical's disappearance from the chamber after treatment with BTEX and n-hexane, or to the whole gasoline, at initial exposure values between 100 and 2500 ppm. Samples of the chamber air were analyzed by gas chromatography/FID using a DB1 capillary column at 35°C and subsequent ramp rate of 25°C/min to 210°C. BTEX and hexane were identified and quantified and the remaining peaks were integrated against a common calibration curve. BTEX and hexane were adequately resolved under these conditions. Each chemical followed a typical gas uptake kinetic decay curve. These data were used to develop a PBPK model for gasoline, including BTEX and hexane as five separate chemicals and all remaining components as a lumped psuedo-chemical. After including previously determined model parameters for BTEX and hexane, kinetic rate estimates for the pseudo chemical were determined through optimization. The model adequately simulated the data for BTEX, hexane, and the lumped gasoline component. This approach appears to be a viable alternative to currently used approaches when complex mixtures are studied. [Supported in part by a Cooperative Agreement from ATSDR (U61/ATU 881475) and the NIEHS Quantitative Toxicology Training Grant T32 ES07321].

754 USING MONTE CARLO SENSITIVITY ANALYSES TO PRIORITIZE DATA NEEDS IN DEVELOPING A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR ACRYLAMIDE.

C. R. Kirman[1], M. L. Gargas[2], R. Deskin[3], L. E. Tonner-Navarro[3] and M. E. Andersen[4]. [1]*The Sapphire Group, Beachwood, OH,* [2]*The Sapphire Group, Dayton, OH,* [3]*Cytec Industries, West Patterson, NJ and* [4]*Colorado State University, Fort Collins, CO.*

Acrylamide is a multi-site carcinogen in rats following chronic, high-dose exposures. Currently, allometric scaling practices used in cancer risk assessment (i.e., interspecies differences in dose according to bodyweight raised to the 3/4 power)do not capture many of the complexities associated with the kinetics of acrylamide. For example, differences between rats and humans have been reported for the formation of hemoglobin adducts following exposure to acrylamide. In an effort to improve risk-based decisions for acrylamide, a PBPK model was developed for acrylamide in the rat using existing data from six published studies. The model provides a good description of the kinetics for acrylamide and its oxidative metabolite, glycidamide. Like many chemicals, uncertainty remains regarding the mode of action by which acrylamide produces its carcinogenic effects. For this reason, Monte Carlo methods were used to perform sensitivity analyses in model predictions for four dose measures, each corresponding to a different assumption for the potential carcinogenic mode of action of acrylamide: (1) genotoxicity; (2) sulfhydryl reactivity; (3) dopamine agonist; and (4) glutathione depletion. The results of the sensitivity analyses indicate that the model parameters for characterizing metabolism *via* cytochrome P450 and glutathione-S-transferase (4-57% of variance), and tissue binding (6-44% of variance) were the most important contributors to variation in dose measures predicted by the model. Although limited human data are available with respect to acrylamide kinetics, the PBPK model presented for acrylamide is useful with respect to (1) organizing existing information on acrylamide kinetics; (2) identifying critical data gaps for risk assessments; and (3) prioritizing the collection of additional data.

755 STATISTICAL ANALYSIS OF PHOTOCOCARCINOGENESIS STUDIES.

D. F. Molefe[1], J. J. Chen[1], P. C. Howard[1], P. D. Forbes[2], C. P. Sambuco[2] and R. L. Kodell[1]. [1]*NCTR, USFDA, Jefferson, AR and* [2]*Argus Research, Charles Rivers Laboratories, Horsham, PA.*

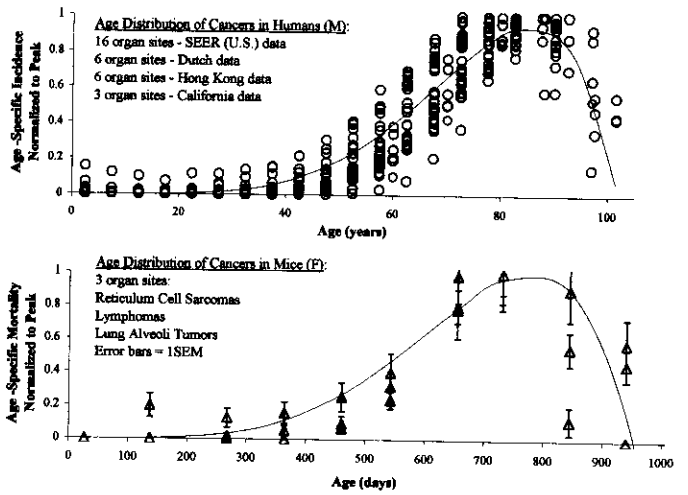
The induction of skin cancer in HRA:SKH-1(hr/hr) hairless mice has been studied for several decades using xenon-arc generated simulated solar light (SSL). This model is currently the most accepted surrogate for sunlight induced skin cancer in humans. Photococarcinogenesis experiments have been used to study the influence of chemicals on SSL induced skin cancer, where a chemical may decrease or increase tumor latency, or alter the number of tumors on the mice. We have compared several statistical methods for analyzing the tumor latency and multiplicity in a study where male and female SKH-1 mice were either untreated or treated with cosmetic vehicle, and exposed to either 600 or 1200 RBU/week of SSL for up to 40 weeks followed by up to 12 weeks of observation. The data were analyzed using a logrank test, negative binomial test, tumor multiplicity test of Dunson, or an adaptation of the single-induction likelihood ratio test of Kodell and Chen. The likelihood ratio, logrank, and negative binomial tests gave similar results with the data. A conclusion from the likelihood ratio test is that the difference between the groups (600 and 1200 RBU/week, no vehicle) was due to a difference in tumor latency (time to observation) and not tumor multiplicity (number of induced tumors/mouse), although the number of tumors per mouse actually observed at any given time was much higher in the 1200 RBU/week group than in the 600 RBU/week group for both sexes. Monte Carlo simulation was used to determine the accuracy of parameter estimates and to evaluate the Type I error rates of the tests. These results demonstrate the utility of these tests in analyzing skin tumor data from similarly designed studies.

756 FROM MICE TO MEN, CANCERS ARE NOT CERTAIN AT OLD AGE.

F. Pompei[1] and R. Wilson[2]. [1]*DEAS and Physics, Harvard University, Cambridge, MA and* [2]*Physics, Harvard University, Cambridge, MA.*

We have studied age-specific incidence data in humans from SEER (US), Holland, Hong Kong, and California and found that organ site incidences do not continue to increase with age, but tend to peak at about age 80, and reduce thereafter toward zero at age about 100. We have also studied cancer incidence (age-specific mortality for lethal cancers) in mice as a function of age in the ED01 undosed controls study cohort ("megamouse" 2-AAF study), where they have been allowed to live very close to their full natural lifetime, and found that similar turnover in incidence occurs at about age 800 days, or 80% of lifetime. A Beta function model [$I(t) = (at)^k e^{(1-bt)}$; a, b, k are constants] fits both the mouse data and the human data well. The model suggests that increasing replicative senescence with age might be the cause of the turnover at old age. Limited data from National Toxicology Program mice studies suggest that the cancer age distribution, including the turnover, may be time-shifted by dietary restriction. Results of a large rat cohort study ("two tons of rats"

nitrosomine study) were inconclusive since the rats did not live long enough for cancer incidence to either turn over, or to reach certainty.



Incidences are normalized to the peak value for each organ site. Organ site incidence data varied over two orders of magnitude for humans, and a factor of three for mice.

757 DNA STRAND BREAKS AND BREAST CANCER RISK.

T. R. Smith[1], M. S. Miller[1], K. Lohman[2] and J. J. Hu[1,2]. *[1]Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC and [2]Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, NC.*

Results from human genetic studies suggest that elevated DNA damage and suboptimal DNA repair activity may be associated with an increased breast cancer risk. DNA lesions caused by exogenous and endogenous agents, such as ionizing radiation (IR) and oxygen free radicals, may result in genetic alterations, leading to breast carcinogenesis. Accurate and effective DNA repair mechanisms are essential to maintain genomic integrity. We used the alkaline single-cell gel electrophoresis assay (Comet assay) to evaluate three types of DNA damages (baseline, IR-induced, and damage remaining after a 10-minute repair period) in peripheral lymphocytes of breast cancer cases (n=70) and controls (n=70). The results are presented as the mean comet tail moment of 50 cells using an image analysis system. Breast cancer cases consistently had significantly higher DNA damages compared to controls. Comet tail moments (mean±SD) for cases and controls were: 10.78±3.63 and 6.86±2.76 for baseline, 21.24±4.88 and 14.97±4.18 for IR-induced, and 14.76±5.35 and 9.75±3.35 for damage remaining after repair, respectively. Comet tail moments were independent of established breast cancer risk factors, such as age and family history. Above median baseline, IR-induced DNA damage, and damage remaining after repair were significantly associated with breast cancer risk; age-adjusted odds ratios (ORs) and 95% confidence intervals (CI) were 13.44 (95%CI= 5.97-30.24), 13.65 (95%CI= 6.07-30.71), and 6.54 (95%CI= 3.11-13.79), respectively. Our study suggests that susceptibility to DNA-damaging agents and/or deficient DNA repair may predispose women to breast cancer. A larger study is warranted to further assess the roles of DNA damage/repair in breast cancer susceptibility. Supported by PHS grants CA-73629 and CA-91221.

758 CANCER SLOPE FACTORS FOR IRIS CHEMICALS: COMPARISON OF THE NEW EPA GUIDELINES *VS.* THE TRADITIONAL Q1* METHOD.

R. P. Subramaniam and P. White. *NCEA, USEPA, Washington, DC.* Sponsor: J. Holder.

This work compares cancer slope factors for a large number of chemicals calculated by two different methodologies and softwares. In the past, the cancer slope factor has been calculated as the upper 95% confidence limit on the coefficient of the linear term of the multistage model (i.e. q1*) for the extra cancer risk over background. The USEPA's draft cancer guidelines, released in 1999, however, prescribe the cancer slope factor as the slope (s*) of the linear extrapolation between a point of departure (POD) from observed data and the origin of the dose-response curve. This POD is usually the lower 95% confidence limit on dose associated with 10% extra risk adjusted for background. This default in the EPA draft guidelines is thought to provide an upper bound estimate on cancer risk and to incorporate experimental variability. However, the extent of overestimation of risk inherent in this approach has often been raised as an issue. In this work, we examined to what extent the two approaches differed in practice by calculating s* and q1* for 102 carcinogenic chemicals from the IRIS database. In all cases, the constrained multistage model was used to fit the dose-response data using the commercial software Global86 and the EPA Benchmark Dose Software released in 2001. Both softwares obtained identical values of s*. Our results indicate that for 81.4% of the cases, s* is within 0.9 to 1.1 of q1*, and with one exception, the ratio s*:q1* is less than 3.0 for the remaining chemicals. The results validate the argument posed by other authors earlier (Crump and Howe, 1985; Gaylor et al., 1994) that the two approaches are likely to give nearly similar results when the multistage model is used. Our results suggest that for the vast majority of chemicals, the new EPA draft cancer guidelines for the cancer slope factor appears to be neither over nor under protective of public health in comparison with the traditionally estimated q1*. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the USEPA

759 THEORETICAL MODELS FOR DNA ADDUCT FORMATION AND *HPRT* MUTATION INDUCTION BY LOW-DOSE ETHYLENE OXIDE EXPOSURE OF MICE AND RATS.

D. M. Walker, V. E. Walker and B. R. Scott. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

In order to evaluate the effects of low-dose ethylene oxide (EO) exposures upon the induction of N7-(2-hydroxyethyl)guanine (7-HEG) and *Hprt* mutations, we characterized previously published data using theoretical models. These adduct and mutant frequency (MF) data were from male B6C3F1 mice and F344 rats exposed by inhalation for 4 weeks (6 h/day, 5 days/week) to 0, 3, 10, or 33 ppm EO (Wu et al., Carcinogenesis 20:1787-1792, 1999) or to 40, 1000, or 3000 ppm ethylene (Walker et al., Carcinogenesis 21:1661-1669, 2000). The Dose-Response curves for 7-HEG formation in liver, lung, brain, and spleen were adequately characterized using a power function (PF) model expressed as $y = \alpha C^{\beta}$, where C represents the concentration of EO and α and β are positive parameters which reflect the relative sensitivity of the tissue to EO-induced DNA damage. A value of $\beta = 1$ corresponds to the linear-no-threshold (LNT) model. Application of the PF model showed that, for the 7-HEG Dose-Response curves for EO-exposed mice, $\beta > 1$; while, for the corresponding curves for EO-exposed rats, $\beta < 1$. Thus, use of the LNT model to estimate adduct formation will overestimate the risk for EO-induced DNA damage in mouse tissues, but will underestimate the risk for DNA damage in rat tissues. The Dose-Response curve for EO-induced *Hprt* MFs in T-lymphocytes from exposed mice has been previously shown to be sub-linear (i.e., to have a lesser effect per unit dose of EO as the exposure concentration was lowered) (Walker et al., Mutat. Res. 392:211-222, 1997). We applied a mechanistic based model called NEOTRANS2-EO to induced MFs in ethylene/EO-exposed mice, and this model predicted that the threshold for the induction of excess mutations (i.e., over background) to be approximately 10 ppm EO. These analyses indicate that, at low doses of EO, the Dose-Response curves for 7-HEG and *Hprt* MFs in rat and mouse do not follow the LNT model. (Supported in part by the Department of Energy Office of Science and Environmental Management).

760 VINYL ACETATE-INDUCED INTRACELLULAR ACIDIFICATION: PROOF OF CONCEPT FOR MODE OF ACTION.

M. S. Bogdanffy. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

Inhaled vinyl acetate (VA) causes epithelial degeneration, cell proliferation and tumors in the nasal cavity of rats, but not mice. Carboxylesterase (CE) catalyzes hydrolysis of VA to acetaldehyde and acetic acid. Acetaldehyde is further oxidized to acetic acid with a stoichiometric yield of 3 protons. Intracellular acidification is hypothesized to be the critical first step preceding cytotoxicity. The purpose of these experiments was to demonstrate that exposure of CE-containing cells to VA causes reduction in intracellular pH (pHi). Primary rat hepatocytes were chosen as a model cell system because they contain CE activity comparable to rat nasal epithelium. Freshly isolated rat hepatocytes were attached to polylysine-coated glass coverslips and loaded with the intracellular dye BCECF-AM. Quantitative fluorescence imaging microscopy was used to monitor pHi in response to various concentrations of vinyl acetate. Concentrations of 10 µM - 800 µM VA produced rapid (≈ 70 sec.) decrements in pHi (Δ=-0.03 —0.53) that were rapidly reversible (≈ 70 sec.) upon removal of VA. Pretreatment of hepatocytes with bis(p-nitrophenyl)phosphate, a specific CE inhibitor attenuated the VA-induced intracellular acidification. These results support a mechanism of VA carcinogenesis involving intracellular acidification, cytotoxicity and cell proliferation and, together with other quantitative toxicity and dosimetry information, suggest a margin of exposure-based approach to risk assessment. Supported in part by the Vinyl Acetate Toxicology Group, Inc..

761 STRAIN-SPECIFIC DIFFERENCES IN SUPEROXIDE DISMUTASE AND 8-OXOGUANOSINE DNA-GLYCOSYLASE CAPACITY OF MALE C57BL/J, BALB/C, AND ICR MICE.

T. Stedeford[1], F. Cardozo-Pelaez[2], G. E. Luzardo[2], D. Mosquera[2], M. Banasik[1,3] and R. D. Harbison[4]. *[1]Institute for Chemical Research, Kyoto University, Uji, Kyoto, Japan, [2]Dept. of Neurology, University of South Florida, Tampa, FL, [3]Institute of Environmental Engineering, Polish Academy of Sciences, Zabrze, Poland and [4]Dept. of Environmental and Occupational Health, University of South Florida, Tampa, FL.*

Regulatory agencies use a variety of methods to estimate the risks to humans from exposures to toxic agents. Many of these methods are based on toxicological data derived from animal models, particularly rodents, and have limitations in their ability to predict human risk. The purpose of this study was to characterize the differences that exist in the enzymatic capacity of key enzymes responsible for the clearance of superoxide anion and the oxidized DNA base 8-hydroxy-2'-deoxyguanosine (oxo8dG), superoxide dismutase (SOD) and 8-oxoguanosine DNA-glycosylase (Ogg1), respectively. Brain regions, cerebellum and caudate putamen, from male C57BL/J, Balb/c, and ICR mice were analyzed. There was no significant difference between strains in the activity or protein level of Ogg1 in the cerebellum; however, the activity of Ogg1 in the caudate putamen of ICR mice was 34% and 31% lower than in C57BL/J and Balb/c, respectively. SOD activity in the cerebellum was twice as high in C57BL/J mice *versus* Balb/c or ICR. SOD activity in the caudate putamen of C57BL/J mice was four fold higher than in Balb/c and ICR. The functional relevance of these differences was determined by measuring levels of oxo8dG, an oxidized 2-deoxyguanosine formed by reactive oxygen species, such as superoxide anion. The levels of oxo8dG in the cerebellum and caudate putamen of C57BL/J mice were nearly twice as high as the respective regions in Balb/c and ICR mice. Based on these results, it is argued that risk estimations based on animal bioassay data may be unnecessarily high in some cases and, in others, there may be greater uncertainty. (Supported in part by a VAMR Grant, the Japan Society for the Promotion of Science, and a US Department. of Defense Grant)

762 TRANSGENIC DATA AS PREDICTORS OF CARCINOGENICITY.

O. Conerly[1], J. M. Donohue[1], J. Kim[2] and D. Gray[2]. *[1]Office of Science and Technology, USEPA, Washington, DC and [2]Sciences International, Alexandria, VA.*
Sponsor: C. Abernathy.

Studies of the tumorigenic potential of chemicals conducted in transgenic species offer several advantages. The transgenic strains carry genetic weaknesses that increase and shorten the time to tumor response thereby lessening cost and time for carcinogenicity assays. At the same time, observations of responses in transgenic animals increase our knowledge of the integrated impact of their genetic defects on the cancer mode of action. However, the limited data from transgenic studies makes it difficult to determine how transgenic results should be applied in weight of evidence determinations for carcinogenicity. EPA examined the concordance between the results from studies of several transgenic strains (p53+/-, Tg.AC, Tg rasH2, E -pim-1, and XPA-/- transgenic mouse strains) and the results from standard bioassays. The findings demonstrate the promise that transgenic data may offer an efficient option for identifying potential carcinogens without the necessity of conducting a bioassay in rodent species. However, it will be important to continue to build a database of transgenic data in order to refine its usefulness as a predictive tool. [The opinions expressed in this abstract are those of the authors and not necessarily those of USEPA.]

763 AREA-UNDER-THE-CURVE (AUC) AS A DOSE METRIC FOR PROMOTIONAL RESPONSES FOLLOWING 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) EXPOSURE.

A. H. Kim[1,2], M. C. Kohn[2] and N. J. Walker[2]. *[1]Curriculum in Toxicology, UNC-CH, Chapel Hill, NC and [2]Laboratory of Computational Biology and Risk Analysis, NIEHS, Research Triangle Park, NC.*

An underlying basis of risk assessment is that an equivalent risk for a certain dose metric exists that allows for extrapolation between species. To better understand the use of AUC as a dose metric for promotional responses following TCDD exposure, a novel study was designed using a newly revised physiologically-based pharmacokinetic model in the female Sprague-Dawley rat to obtain similar liver AUCs of TCDD by different patterns of exposure. In the first TCDD-treated group, rats received an administered average daily dose of 100 ng/kg/day TCDD in corn oil for the study duration of 15 weeks. In the second TCDD group, rats received a high peak dose averaging 1000 ng/kg/day for the first week followed by a lower TCDD administered dose of 23 ng/kg/day for the remainder of the study. Age-matched control rats received corn oil as a vehicle control. Altered hepatic foci (AHF) positive for the placental form of glutatione-*S*-transferase (PGST) enzyme were measured from representative lobes of the liver stained immunohistochemically for PGST expression. Volume fraction, expressed as a percentage, is considered to be the most stable measure of AHF. The median volume fraction was 0.045% in control rats and was significantly elevated in both TCDD treatment groups. However, the volume fraction of PGST-positive foci was significantly higher in the TCDD group given the high peak dose during the first week of TCDD treatment compared with the group receiving the same average daily dose over the study duration: 0.74% *vs.* 0.17%, respectively. This study also confirmed previous analyses that tissue burden of TCDD is not an appropriate dose metric for the promotional responses induced by TCDD following exposure. These findings suggest that the peak magnitude of TCDD in liver may play a significant role in additional to AUC in the induction of promotional responses by TCDD.

764 DOSE DEPENDENT LIVER REGENERATION FOLLOWING CO-ADMINISTRATION OF CHLOROFORM AND TRICHLOROETHYLENE-INDUCED HEPATOTOXICITY IN MALE SPRAGUE-DAWLEY RATS.

S. S. Anand, S. S. Devi, S. N. Murthy, M. M. Mumtaz and H. M. Mehendale. *Department of Toxicology, College of Pharmacy, The University of Louisiana at Monroe, Monroe, LA.*

Chloroform ($CHCl_3$) and trichloroethylene (TCE) are common contaminants present in drinking water and regarded as hepatotoxicants. The aim of this study was to develop a dose-response relationship for $CHCl_3$ + TCE binary mixture (BM) by measuring liver injury and tissue repair and to compare the previous results with CHCl3 and TCE alone. Male Sprague-Dawley rats (250-300g) were administered with 5-fold dose range of both $CHCl_3$ (74 to 370mg/kg, ip) and TCE (250 to 1250mg/kg, ip) in corn oil (maximum of 0.5ml/kg). Liver injury was assessed by plasma ALT and AST activities and tissue repair was measured by ^{3}H-thymidine incorporation into hepatonuclear DNA. Since both these compounds are known to cause nephrotoxicity, blood urea nitrogen (BUN) levels were assayed to evaluate kidney damage. Levels of both the parent compounds and two major metabolites of TCE [trichloroacetic acid (TCA) and trichloroethanol (TCOH)] were quantified by gas chromatography. The levels of $CHCl_3$ peaked in the liver and blood at 60 min and declined thereafter. $CHCl_3$levels were higher after injection of BM compared to injection of $CHCl_3$ alone. Liver injury, as assessed by ALT and AST, was higher at early time points and subsequently regressed. However, dose-response was not evident, possibly due to the inhibition of these plasma transaminases by TCA and TCOH, metabolites of TCE. Tissue repair response followed a dose-dependent increase at all time points, and was evident at 24 h and peaked at 48 h. At 24 h, only the highest combination caused kidney damage. The $CHCl_3$ + TCE BM caused either subadditive or no more than additive hepatotoxicity. Thus, the present results support the concept that tissue repair response is critical in restraining the progression of injury (supported by ATSDR U61/ATD 681482).

765 CHRONIC RISK ASSESSMENT FOR TRIBUTYL PHOSPHATE (CAS NO. 126-73-8).

A. R. McDonald[1], M. Odin[1] and H. Choudhury[2]. *[1]Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY, and [2]NCEA, ORD, USEPA, Cincinnati, OH.*

Tributyl phosphate (TBP) is a non-flammable, non-explosive liquid that is used as a solvent or an anti-foaming agent. Dietary exposure to tributyl phosphate at high doses produces a reversible hyperplasia of the urinary bladder epithelium which is not due to the presence of crystalluria, urinary precipitates or calculi, but may possibly be attributed to the presence of a toxic metabolite(s), tertiary butyl alcohol and or dibutyl hydrogen phosphate. A 2-year study of rats and mice identified both a NOAEL and LOAEL for bladder hyperplasia in rats, and was selected as the key study for the derivation of the provisional RfD. Mice did not show significant dose-response in any of the target organs examined in this 2-year chronic study. The 2-year rat study reported a significant increase of urinary bladder papillomas and carcinomas in males and urinary bladder papillomas in females, but only in animals exposed to the highest level of TBP in their diet. There is no clear evidence for the mode(s) of action for tributyl phosphate-induced urinary bladder tumors in rats. The vast majority of *in vitro* and *in vivo* tests indicate that tributyl phosphate is negative for genotoxicity. The apparent lack of genotoxic effects, coupled with low-dose hyperplasia and high-dose tumor formation, is suggestive of a non-genotoxic mechanism of carcinogenesis. Therefore, several different approaches were used when calculating a quantitative estimate of carcinogenic risk. Provisional oral slope factors were derived using both a linearized multistage model and a margin of exposure analysis, and the results produced by the different methods were compared. (This abstract does not necessarily reflect EPA policy).

766 PROPOSED ORAL SLOPE FACTOR FOR P-CHLOROANILINE UTILIZING LINEAR AND NON-LINEAR APPROACHES.

M. E. Fransen and M. Odin. *Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY.* Sponsor: G. Diamond.

A review of the available carcinogenicity data for p-chloroaniline identified the chemical as a candidate for analysis of carcinogenic risk by both the traditional linear method as well as the proposed nonlinear (margin of exposure) method. Although no human carcinogenicity data are available, published chronic oral studies in rats and mice provide evidence of multi-organ carcinogenicity. The cancer risk assessment for p-chloroaniline is complicated by species differences in target organ susceptibility and uncertainty as to which of the compound's possible carcinogenic mechanisms is most relevant to humans. There is evidence for genotoxic and non-genotoxic modes of action, both of which apparently require bioactivation of p-chloroaniline. The primary tumor types observed in the oral studies are rare splenic tumors (fibrosarcoma, osteosarcoma, or hemangiosarcoma) and adrenal medullary pheochromocytomas in male rats, and hepatocellular carcinomas in male mice. Data on tissue-specific distributions of reductase activities, which protect against the reactive intermediates of p-chloroaniline, suggest that the mouse hepatocellular tumors may not be relevant to humans. However, either of the rat tumors could be relevant to humans: the adrenal tumors induced by a genotoxic mechanism, and the splenic tumors induced by a non-genotoxic mechanism secondary to erythrocyte toxicity. Dose-response modeling of the incidence data for rat tumors was performed using both linear and non-linear methods. In deriving oral slope factors based on rat adrenal and splenic tumors, the default approach assuming linearity was compared with the margin of exposure approach, which assumes nonlinearity. The margin of exposure approach for splenic sarcomas was based on the assumption that an oral dose of p-chloroaniline that was protective for splenic fibrosis (a non-neoplastic lesion) would also be protective for carcinogenicity in the spleen.

767 ORAL SLOPE FACTOR FOR BUTYL BENZYL PHTHALATE (BBP): COMPARISON OF A LINEAR AND A NONLINEAR APPROACH.

M. H. Follansbee and M. Odin. *Environmental Science Center, Syracuse Research Corporation, North Syracuse, NY.* Sponsor: P. McGinnis.

A review of the available carcinogenicity data for BBP (CASRN 85-68-7) identified the chemical as a candidate for analysis of carcinogenic risk by both the traditional linear method as well as the proposed nonlinear (margin of exposure) method. Currently, BBP is classified as Group C (Possible Human Carcinogen) based on no human data and limited animal data. The basis for this classification is a 1982 NTP study wherein a statistically significant increase in mononuclear cell leukemia was reported in female rats following two years of exposure to 12, 000 ppm of BBP in the feed. A quantitative estimate of carcinogenic risk from oral exposure is not currently included on IRIS due to the qualitative weakness of the response, including similar pathologies in the control and treated groups and lack of reduction in time to first tumor. More recently, NTP conducted additional long-term feeding studies with BBP in F344 rats. The results of these studies provided some evidence of an increase in the incidence of pancreatic cancer in male F344 rats, though a significant increase was only seen at the highest exposure level (12, 000 ppm). Concurrent with these neoplastic lesions, the study reported a dose-dependent increase in preneoplastic lesions (acinar hyperplasia) in the pancreas. The mode(s) of action of BBP-induced carcinogenesis are not clear. There is limited evidence supporting both genotoxic and non-genotoxic mechanisms. The majority of data from genotoxicity testing have indicated that BBP is not strongly genotoxic. Moreover, BBP, like other phthalate diesters, induces peroxisome proliferation, which is the putative mechanism of action for the observed changes in the pancreas. A comparison of the results using the default linear approach and a nonlinear (margin of exposure) approach provides insight into the effect of linearity assumptions in deriving of quantitative estimates of oral carcinogenic risk for BBP.

768 QUANTITATIVE RISK ASSESSMENT OF INHALED REFRACTORY CERAMIC FIBERS (RCF).

D. Y. Lai[1], G. Oberdorster[3], C. P. Yu[4] and V. T. Vu[2]. *[1]Office of Pollution Prevention and Toxics, USEPA, Washington, DC, [2]OSCP, USEPA, Washington, DC, [3]University of Rochester, Rochester, NY and [4]State University of New York at Buffalo, Amherst, NY.*

Refractory ceramic fibers(RCF) are man-made vitreous fibers primarily used in industrial settings as a lining in high-temperature furnaces, heaters, and kilns. Occupational studies have noted, among workers in the RCF industry, decreases in lung function and an increased rate of pleural plaques. A multi-dose chronic inhalation study of RCF in rats has shown a dose-related response with respect to the development of chronic inflammation, fibrosis and cancer of the respiratory system. Using mathematical models that were developed for dosimetric extrapolation of the observed animal exposure-dose-response data to humans, quantitative risk assessments for cancer and non-cancer effects of the respiratory system in humans were conducted. For cancer risk assessment, a linearized multi-stage model was used which appears to be compatible with the rat lung tumor response data. The dose metric used was the number of retained WHO (World Health Organization) fibers (>5μm in length)in the lung. For non-cancer effects, a benchmark dose approach was used for deriving a reference concentration (RfC) for environmental RCF exposure. The dose metric used was the surface area of retained total fibers in the lung. Additional uncertainty factors of 3 and 10 for rat to human extrapolation and for more sensitive members of the population, respectively, were applied for estimating the RfC. The 95% upper-bound estimates of human cancer risk were 4.76 x 10^{-3} per airborne WHO fiber/cm^3 for continuous environmental exposure and 2.36 x 10^{-3} for intermittent occupational exposures. The RfC for interstitial fibrosis was 0.2 total fibers/cm^3 for continuous environmental RCF exposure. (The views and opinions expressed by the authors do not necessarily reflect the official position or policy of the USEPA.)

769 CARBON BLACK SHOULD NOT BE CLASSIFIED AS A HUMAN CARCINOGEN.

L. J. Rausch, E. Bisinger Jr and A. Sharma. *Shera, Akzo Nobel Chemicals Inc., Chicago, IL.*

In the 1996 monograph on carbon black (CB), IARC classified CB as a group 2B carcinogen, possibly carcinogenic to humans. In 1990, the State of California EPA listed CB extracts as a chemical known to the State to cause cancer. There is intent to list CB as well. We have reviewed the 1996 IARC monograph as well as data published subsequent to its release and conclude that CB should not be classified as a human carcinogen. CB has been shown to be carcinogenic to rats but not to mice, hamsters, guinea pigs or primates even when lung burdens are several times higher then the lowest tumor-inducing particle lung loads in rats. Studies conducted by inhalation and intratracheal administration to rats have shown significant increases in benign and malignant lung tumors and lesions described as benign cystic keratinizing squamous-cell (KSC) tumors. Most mutagenicity studies have been negative and therefore it appears that CB is not carcinogenic to rats *via* a genetic mechanism. Studies carried out to demonstrate a possible epigenetic mechanism have shown that in the presence of significant inflammation a significant increase in DNA adducts in alveolar type II cells and hprt (hypoxanthine-phosphoribosyltransferase) mutations occurs. It is postulated that the severe inflammation causes oxidant release which in turn causes DNA damage with resulting tumor formation. Because of the unique response by the rat to CB exposure, the rat bioassay should not be used to conduct a risk assessment. Lung tumor formation, including KSC lesions, occur only in rats. An expert panel reviewing KSC lesions induced by TiO_2 or p-aramid agreed that similar lesions are not seen in humans either. The location of lung tumors in rats and humans differs as well. When lung tumors occur in humans they are primarily located in the bronchial airways, whereas in the rat they occur in the parenchyma and are alveolar in origin. Epidemiology studies have failed to adequately demonstrate an increase risk of lung cancer due to occupational exposure to CB. Therefore, CB should not be classified as carcinogenic to humans.

770 ASSESSMENT OF "ALL CANCERS" IN DIOXIN EPIDEMIOLOGY STUDIES.

L. A. Beyer, B. D. Beck and K. W. Chan. *Gradient Corporation, Cambridge, MA.*

The carcinogenicity of dioxin in humans is a source of vigorous scientific debate. As a result, different organizations classify its carcinogenicity differently. For example, USEPA recently recommended that dioxin be classified as a human carcinogen. In contrast, the majority of members on USEPA's Science Advisory Board's Dioxin Reassessment Review Subcommittee did not support the classification of TCDD as a human carcinogen. It is therefore useful to compare results of the various epidemiology studies, which evaluated the cancer incidence/mortality in populations exposed to relatively large concentrations of dioxin. We selected the epidemiology studies, based on size of population, length of followup, and characterization of exposure, and summarized their findings for the category "all cancers." These studies involved nine occupational cohorts from a number of countries including the US, the Netherlands, and Germany; and one residential cohort in Italy (Seveso). We restricted our analysis to "all cancers, " the cancer increase relied on by USEPA as the basis for designating dioxin as a carcinogen. The results show that the relative risks are small or nonexistent even after accidents associated with high exposure levels. For example, in Bertazzi et al. (2001), a study of residents exposed to dioxin in Seveso, Italy, "all cancers" are not increased in the zone A (highest exposed) population in either men and women combined, or in women or men separately (overall or for any time interval since first exposure). In occupational studies, the relative risks are relatively small and mixed: Becher et al. (1996), in a study of four occupational cohorts, found a significant increase in only one of the four cohorts. The increase was relatively small (standardized mortality ratio (SMR) = 134), and was

found in the cohort with the shortest mean duration of employment. Therefore we conclude that, based on epidemiology studies, the evidence for an association between dioxin and excess total cancer in humans is mixed, at best.

771 ASSESSMENT OF BENZENE CARCINOGENIC POTENTIAL IN HUMANS.

K. W. Chan, L. A. Beyer and B. D. Beck. *Gradient Corporation, Cambridge, MA.*

Benzene is currently classified as a human carcinogen based primarily on increased risks of leukemia, with acute myeloid leukemia as the predominant form. Recently, some researchers have suggested that benzene also causes other types of cancer such as, lymphoma, non-Hodgkin's lymphoma, multiple myeloma, brain, lung, and kidney cancers. It is therefore of interest to assess the evidence for the carcinogenicity of benzene with respect to these other tumor sites. We selected seven epidemiological studies determined to be of sufficient quality, based on analysis of specific cancer outcomes, assessment of benzene exposure, and cohort size of more than 300 workers. These studies involved cohort studies of workers in painting, printing, painting and shoe-manufacturing, chemical production, oil refinery, and workers as car and mobile equipment mechanics, and filling station managers in China, Italy, Sweden, United Kingdom, and United States. While excess lymphoma, non-Hodgkin's lymphoma, and lung cancer were observed in a group of benzene-exposed Chinese workers, five other studies did not demonstrate any significant increase in risks among other workers exposed to benzene or benzene-containing petroleum products. Findings in multiple myeloma, brain and kidney cancers in workers were also inconclusive, for example, there was significant increased risk of brain cancer in small service filling stations, but not in large service filling stations, and two other studies did not demonstrate any significant increased risk of brain cancer in workers exposed to benzene. Therefore, we conclude that there is no convincing evidence for an association between benzene and the tumor types noted above.

772 AN ASSESSMENT OF THE HUMAN RISKS ASSOCIATED WITH RADIOFREQUENCY EXPOSURE.

A. L. Lavin and J. M. DeSesso. *Mitretek Systems, McLean, VA.*

Many emerging technologies depend on radiofrequency (RF) electromagnetic (EM) energy; consequently, public concern regarding potential hazards associated with RF exposure is high. To assess the human health effects of low-level RF exposure, 80 epidemiology studies published since 1965 related to EM radiation exposure were identified; these were categorized according to EM frequency ranges (0-300 kHz, 0.3-30 MHz, and 0.03-300 GHz). The majority of studies identified dealt with cancer endpoints. Within each EM frequency category, studies were further classified according to study design (cohort, ecological, case-control, etc). Studies of exposures in the 0.03-300 GHz range (the RF range) were given greatest weight in assessing potential health risks; these included eight cohort studies, four ecological analyses, twelve case-control studies, and one cross-sectional report. Overall, the individual epidemiology studies related to EM frequency exposures are deficient for risk assessment purposes; they suffer from methodological flaws, design biases, and inadequate exposure measurements. Analyzed as a whole using the Hill criteria for causation, these studies do not provide evidence of adverse health outcomes related to low-level RF exposure. Those studies that reported potentially increased health risks associated with RF exposure (primarily brain and hematopoietic cancers) failed to demonstrate consistent exposure-response relationships and showed disparate findings that were not confirmed in other studies. The studies related to the 0-300 kHz and 0.3-30 MHz frequency ranges also reported discordant findings with no consistent exposure-response data. The lack of epidemiological evidence for potentially adverse human health outcomes related to RF exposure is supported by animal data and mechanistic studies which demonstrate that temperature increases in exposed tissues (which do not occur at exposure levels below current US regulatory limits) are required to cause biological effects. In summary, the available epidemiology data suggest that exposure to low-level RF is not associated with adverse human health effects.

773 LUNG CANCER MORTALITY AMONG WORKERS EXPOSED TO AIRBORNE HEXAVALENT CHROMIUM.

R. S. Luippold[1], K. A. Mundt[1], J. M. Panko[2], E. W. Liebig[2], C. Crump[3], K. S. Crump[4], D. J. Paustenbach[5] and D. M. Proctor[5]. *[1]Applied Epidemiology, Amherst, MA, [2]AMEC Earth and Environmental, Pittsburgh, PA, [3]ICF Consulting, Ruston, LA, [4]Environ, Ruston, LA and [5]Exponent, Irvine, CA.*

This study assesses mortality through 1997 for 492 persons who worked at a chromate production plant for at least one year between 1940 and 1972. Cumulative airborne Cr(VI) exposures were quantified for each worker and, together with this mortality assessment, provide new data for use in cancer risk assessment. Cohort members were followed for mortality through 1997, and standardized mortality ratios (SMRs) were estimated. Lung cancer mortality was investigated further by calculating SMRs stratified by duration of employment, time since hire, year of hire, and categories of cumulative exposure to Cr(VI). Including 51 deaths due to lung cancer, 303 deaths occurred. SMRs were significantly elevated for all causes (SMR=129, 95% CI 115–144), all cancers (SMR=155, 95% CI 125–191), and lung cancer (SMR=241, 95% CI 180–317). Lung cancer mortality was significantly elevated for the highest two cumulative exposure groups—>1.05 to <2.70 mg/m^3-years, SMR=365, 95% CI 208—592; and >2.71 to <29.0 mg/m^3-years, SMR=463, 95% CI 283–716—but not for the lowest three exposure groups. Significantly elevated SMRs were also found for those hired before 1960, with 20 or more years of employment, and with latency of 20 or more years. No excess lung cancer was found among workers first employed after 1960, which may reflect the conversion to a lower-lime process and lower exposures due to improved industrial hygiene. The stratified analysis of lung cancer mortality by cumulative exposure suggests a threshold effect, because risk is statistically significantly elevated only at exposure levels over 1.05 mg/m^3-years. Although a threshold is consistent with recently published toxicological studies, this finding must be interpreted cautiously, because the data are also consistent with a linear Dose-Response, perhaps due to the small numbers of lung cancer deaths in the lowest exposure groups.

774 DOSE-RESPONSE ASSESSMENT FOR LUNG CANCER MORTALITY OF AN OCCUPATIONAL COHORT EXPOSED TO AIRBORNE HEXAVALENT CHROMIUM.

C. Crump[1], E. Hack[1], K. S. Crump[2], J. M. Panko[3], E. W. Liebig[3], D. J. Paustenbach[4] and D. M. Proctor[4]. *[1]ICF Consulting, Ruston, LA, [2]Environ, Ruston, LA, [3]AMEC Earth and Environmental, Pittsburgh, PA and [4]Exponent, Irvine, CA.*

The dose-response relationship for inhalation exposure to hexavalent chromium [Cr(VI)] and lung cancer mortality is assessed for persons who worked at a chromate production facility from 1940 through 1972. Dose metrics of maximum 8-hour time-weighted-average (TWA) exposure, defined as the highest TWA exposure estimated for each worker, and lifetime cumulative exposure (e.g., mg/m^3-years) were evaluated. Poisson and Cox regression models were used to estimate a benchmark dose for 10% additional lifetime risk and unit risks (risk from exposure to 1 µg/m^3) for occupational and continuous (e.g., environmental) exposure scenarios. Trend analyses were performed to identify the highest exposure level for which there is statistical evidence of an increased risk of lung cancer. Cumulative exposure to Cr(VI) ranged from 0 to 29 mg/m^3-years, and the maximum TWA exposures ranged from 3 µg/m^3 to 5, 518 µg/m^3. A linear dose-response was observed in both of these exposure ranges. The benchmark dose for continuous exposures was 10 µg/m^3, and the maximum likelihood estimate of unit risk was 0.011 µg/m^3. However, the dose-response was also consistent with a threshold for both dose metrics. There was no statistical evidence of an increased cancer risk at maximum occupational TWA exposures of 116 µg/m^3, or cumulative exposures of 0.8 mg/m^3-years, corresponding to a 40-year occupational exposure level of 20 µg/m^3. The estimated unit risks are approximately equal to those developed by the USEPA in 1984, and are two to six times lower than those proposed by OSHA in 1995. The absence of a linear trend below certain doses suggests a threshold effect although a non-threshold dose-response cannot be ruled out. The lack of an increased cancer risk at low exposure levels is consistent with mechanistic data suggesting that at low exposure levels, Cr(VI) is reduced to and detoxified by extra- and inter-cellular components of the lung.

775 USING QSAR IN THE SELECTION OF SURROGATE TOXICITY VALUE.

C. J. Moudgal, R. M. Bruce and H. Choudhury. *NCEA/ORD, USEPA, Cincinnati, OH.*

The National Center for Environmental Assessment, Cincinnati (NCEA-Cin), through it's Superfund Technical Support Center (STSC), provides rapid-turnaround technical support to Regional staff and others for time-critical decision making under the Superfund program. A key element of this support is the development of provisional toxicity values, such as oral Reference Doses (RfDs), inhalation Reference Concentrations (RfCs), oral cancer slope factors (SFOs), or inhalation cancer unit risks (URIs). When the published data are inadequate for the development of toxicity values, the Center makes an attempt to identify an appropriate surrogate using a quantitative structure activity relationship (QSAR) approach. A commercial QSAR model, TOPKAT®, is utilized to establish a degree of structural similarity between the query chemical (chemical under examination) and the compounds in the models database. The two models utilized in the selection process are the Oral Rat Chronic LOAEL and the Rat Oral LD_{50} models. The

query chemical is initially queried using the LOAEL model. Once a valid prediction is obtained (i. e., if all model requirements are satisfactorily met) a "similarity search" is conducted which determines the database compounds most similar to the query compound in terms of common descriptors. All database chemicals that satisfy the similarity distance of 0.200 (distance judged by TOPKAT® modelers to represent most similar compounds) are considered to be potential surrogates and are then evaluated for toxicity values on IRIS, HEAST or Provisional Toxicity Value databases. If the query chemical does not satisfy all model considerations for the LOAEL model a valid prediction is not obtained and the chemical is queried utilizing the LD_{50} model to determine a possible surrogate. An example of this selection process will be presented using dichlorobenzophenone (DCBP) a metabolite of chlorobenzilate (CB). This abstract does not necessarily reflect EPA policy or endorsement

776 A COMPARISON OF SIX DOSE-RESPONSE MODELS FOR USE IN QUANTITATIVE RISK ASSESSMENT OF WATERBORNE PATHOGENS.

N. A. Niemuth[1], Z. J. Ma[1], B. Boutin[2] and J. C. Lipscomb[2]. *[1]Battelle, Columbus, OH and [2]NCEA, USEPA, Cincinnati, OH.*

Assessment of risk from waterborne pathogens requires the development of a dose-response model to characterize the relationship between the level of microbial exposure and the probability of a particular adverse consequence (i.e., infection/illness). A properly chosen dose-response model enables us to estimate the individual infectious dose (ID) necessary to cause infection or illness in a percentage of the population. Several models have been used in the literature to describe microbial dose-response data. These include exponential and beta-Poisson models, which are considered biologically plausible models; log-logistic, log-probit and Weibull models, which are considered empirical models; and the Weibull-gamma model. There is no consensus on which model is most applicable to microbial dose-response assessment, although the biologically plausible models are favored by many authors. In selecting a dose-response model for microbial risk assessment, we recommend considering the following: (1) goodness-of-fit, (2) simplicity in model formulation, without sacrificing goodness of fit, and (3) conservative prediction of infectious dose at low levels. Each dose-response model was fitted to data collected by Schiff et al (1984) for echovirus 12 administered to healthy human volunteers in nonchlorinated water. The beta-Poisson, log-logistic, log-probit, and Weibull models all provided good fits to the data, with the estimated 1% IDs ranging from 1.7 to 17.0 PFU for these models. The most conservative estimate of 1.7 PFU from the Weibull model was at least four-fold less than doses predicted by the other models, although a bootstrap 95% confidence interval for the 1% ID from this model (0.06, 18.6) included all of the estimated values from the other models. Although not a formal test, this suggests that the model predictions were not substantially different.

777 DEVELOPMENT OF A TOXICOLOGY DATABASE FOR THE PREDICTION OF TOXICITY: AN ILSI/HESI STRUCTURE ACTIVITY RELATIONSHIP PROJECT.

P. N. Judson[1], P. A. Cook[1], K. A. Stitzel[2], K. V. Thomas[3] and W. J. Brock[4]. *[1]LHASA, Ltd., Leeds, United Kingdom, [2]Procter & Gamble, Cincinnati, OH, [3]Health and Environmental Sciences Institute, International Life Sciences Institute, Washington, DC and [4]Unilever, Edgewater, NJ.* Sponsor: W. Brock.

Scientists need to rapidly predict the toxicity of new compounds using computerized models based on quantitative structure activity relationship (QSAR) or other techniques. The predictive ability of these models will largely depend on the availability of reliable data for sufficient compounds covering a broad array of chemical categories. An international collaboration of the ILSI Health and Environmental Sciences Institute and LHASA, at the University of Leeds (UK), has developed a pilot database of toxicity testing data. The collaboration also includes global industrial manufacturing organizations in the consumer products, chemicals, and pharmaceutical sectors, as well as representatives from international regulatory agencies. The pilot database has been populated with toxicology data for four endpoints - carcinogenicity, mutagenicity, dermal sensitization and hepatic toxicity compiled from publicly available sources. The pilot database was derived from the European Chemical Bureau's (ECB) International Uniform Chemical Database (IUCLID) system, and the database can be used for structure or substructure searches and biological data. The database will be further populated with data from additional toxicological and environmental endpoints. The database will be made publicly available for development and improvement of predictive toxicological models, and as a screening tool for early chemical hazard identification. The benefits of this project include increased reliability and speed of prediction of toxicity for new chemical moieties, e.g., pharmaceuticals, cosmetic ingredients, etc., and a potential reduction in animal testing.

778 STATISTICAL METHODS FOR ANALYZING COMMUNITY INTERVENTION STUDIES: APPROACHES FOR EVALUATING SAMPLES BELOW DETECTION LIMITS.

W. C. Griffith, E. M. Faustman, C. L. Curl and R. A. Fenske. *Environmental Health, University of Washington, Seattle, WA.*

Interpretation of data below detection limits is always problematic because most methods of statistical analysis assume that all values are observed. When the fraction of samples below a detection limit is 10% or less, the common recommendations to substitute half of the detection limit or 0 for non-detects which allows reasonable use of many statistical methods. When a large fraction of the measurements are below a detection limit a more robust procedure is needed. A number of statistical methods have been developed to analyze this type of data, but often are not easily applied by investigators. We have developed simplified methods for simulating the data below detection limits such that standard methods of statistical analysis can be applied. These methods assume that the shape of the distribution of values above the detection limit provides information about the shape of the distribution below a detection limit through the use of quantile-quantile plots. We applied these methods to analyze data on organophosphorus pesticide metabolites in urine from children in a community intervention study. The pesticide metabolite data had multiple detection limits and groups of metabolites were summed for estimates of exposures. The results illustrate that in complex situations the proposed method has many advantages in reducing bias compared to the usual recommendations for dealing with measurements below a detection level, and provides better estimates of confidence intervals. Validation of the new methods through simulation studies showed that the reduction of bias by the proposed method compared to usual methods can be over 90% when non-detects are 95% of the samples, and that adjusted 95% confidence levels contain the true value 90% to 96% of the time. (Supported by Center for Child Environmental Health Risk Research through grants EPA R82688601, and NIEHS 5PO1ES09601-05, and by National Research Center for Statistics and the Environment through grant EPA CR825173.)

779 HIERARCHICAL CLUSTER ANALYSIS OF NEUROLOGICALLY RELATED ADVERSE EVENTS ASSOCIATED WITH THERAPEUTIC USE OF DRUGS.

P. S. Pine, E. J. Matthews, J. L. Weaver, J. F. Contrera and J. P. Hanig. *Center for Drug Evaluation and Research, USFDA, Laurel, MD.*

We extracted neurologically related data from the FDA adverse drug reports (ADR) database for up to the first five years of actual sales for ~335 drugs approved for marketing between 1978 and 1997. The dataset was then limited to drugs that had at least 5 reports for any one of the adverse events and adverse events that had at least 5 reports for any one drug (i.e., an average of one report per year). The result was a matrix of 262 drugs *versus* 114 neurologically related adverse events. Hierarchical cluster analysis of the dataset placed ~20% of the drugs into clusters with correlation coefficients of greater than 0.9. Half of those drugs were found in clusters containing other drugs with similar clinical indications, demonstrating the ability of this approach to detect relationships between drugs. Clusters containing drugs with dissimilar indications may be related by other activities dependent on common structural components. Next we looked at how the adverse event categories related. Cluster analysis placed ~25% of the adverse events into clusters with correlation coefficients of greater than 0.9. The National Library of Medicine's MeSH (medical subject heading) system was used to evaluate the relationships of the adverse event clusters. Half of the highly correlative events were found in clusters with similar MeSH headings. Combining data for adverse events with similar profiles creates composite event categories that may increase their utility in developing structural alerts. This database combined with structural data for this set of drugs has been used to develop neurotoxicity modules for a quantitative structure-activity relationship expert system.

780 CONTRIBUTION OF INTERLEUKIN-10 (IL-10) TO LANGERHANS CELLS MIGRATION IN MICE PROVOKED BY CHEMICAL CONTACT AND RESPIRATORY ALLERGENS.

M. Cumberbatch, R. J. Dearman and I. Kimber. *Immunology, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Following prolonged topical exposure of BALB/c strain mice to chemical contact and respiratory allergens divergent immune responses indicative of preferential T helper (Th)1- and Th2-cell activation are elicited, respectively. Thus, under conditions of exposure that induce equivalent levels of immunogenicity with respect to lymph node cell (LNC) proliferation and IgG antibody production, only respiratory allergens provoke IgE antibody and a Th2 cytokine secretion profile by LNC.

We have now investigated the contribution of dendritic cells (DC) to the development of these polarised immune responses. We report that topical exposure of mice to contact allergens such as 2, 4-dinitrochlorobenzene (DNCB; 1%) and oxazolone (Ox; 0.5%) results in a significant reduction in epidermal Langerhans cells (LC) frequency (20-30%) within 4 hours. In contrast, similar treatment with the respiratory allergen trimellitic anhydride (TMA; 25%) failed to provoke such changes in LC densities after 4 hours, although, LC values were significantly reduced by 17 hours. Enumeration of DC accumulating in draining lymph nodes (DLN) 18 hours following treatment with these chemicals revealed that increases in DC numbers induced by DNCB and Ox were 2-fold greater than those associated with exposure to TMA. Similar DC frequencies to those recorded for TMA were provoked by topical treatment with fluorescein isothiocyanate (FITC; 1%), a sensitizing chemical which also induces a Th2-type immune response. Furthermore, following local administration of a neutralizing anti-IL-10 antibody prior to exposure at the same site to chemical, TMA- and FITC- induced DLN DC accumulation was increased significantly, whereas responses to Ox and DNCB were unaffected. These data suggest that chemical contact and respiratory allergens display differential kinetics of LC migration and DC accumulation and that the delayed response observed to those chemicals that induce Th2-type responses may be due to an early inhibitory signal provided by IL-10.

781 MURINE cDNA ARRAY EXPRESSION PROFILING OF CUTANEOUS SULFUR MUSTARD INJURY.

C. L. Sabourin[1], Y. W. Choi[1], M. K. Stonerock[1], S. L. Casbohm[1], R. A. Gillespie[1], J. D. Waugh[1], R. C. Kiser[1], R. P. Casillas[1], M. C. Babin[2] and J. J. Schlager[3]. [1]*Medical Research & Evaluation Facility, Battelle, Columbus, OH,* [2]*Drug Assessment Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD and* [3]*Pharmacology Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

The chemical warfare agent, sulfur mustard (SM) produces skin blister formation with a severe inflammatory reaction in exposed individuals. The mechanism of SM induced tissue injury is not well understood and there is no established medical treatment to counter its toxicity. Our previous studies identified increases in inflammatory gene expression in both *in vivo* and *in vitro* models of vesicant injury. This study examined SM-induced alterations in gene expression in mouse skin using cDNA arrays to identify transcriptional events associated with SM toxicity. Ear skin from 5 mice, paired as SM-exposed (right ear) and unexposed (left ear) from the same animal, at seven exposure doses (5, 10, 20, 40, 60, 80, and 160 µg) was harvested at 24 hours post-exposure. The highest SM dose (160 µg) produced severe injury characterized by edema, dermal infiltration of inflammatory cells, premature death of basal layer epidermal cells, and epidermal-dermal separation. The lowest concentration (5 µg) produced no apparent tissue damage. Screening of 1176 cDNAs that were normalized as exposed/unexposed skin samples from the same mouse identified numerous genes activated or repressed ≧2-fold, with the number of altered genes increasing with SM dose. The mean level of expression (5 animals) for 54 genes increased and 78 genes decreased ≧2-fold at one or more exposure doses when compared to the 5 µg dose. Real-time RT-PCR confirmed the up-regulation of IL-1β and IL-6. The transcriptional activation or repression of a number of genes not previously known to be associated with SM toxicity was identified. (Supported by the US Army Medical Research and Materiel Command under Contract No. DAMD17-99-D-0010).

782 DERMAL PENETRATION OF TESTOSTERONE *IN VIVO*: PREDICTION FROM SKIN *IN VITRO*.

F. M. Williams and F. W. Lee. *Environmental Medicine, University of Newcastle, Newcastle upon Tyne, United Kingdom.* Sponsor: J. Timbrell.

Testosterone, the steroid hormone, has been used in topical applications to achieve a systemic effect. Due to its lipophilicity (Pow 3.32) it is efficiently absorbed and it has recently been proposed as a marker chemical for predictions of percutaneous penetration using skin *in vitro*. However there is limited data on direct comparisons of equivalent applications *in vivo* and *in vitro*. Whole or dermatomed (230 µm) fresh skin from 28 day old male Wistar rats was mounted in Scott-Dick flow-through diffusion cells at 32°C for 24 hrs. Receptor medium (Eagle's Minimal Essential Medium [MEM] supplemented with 2% (w/v) BSA, pH 7.4) was pumped below the skin at 1.5 $ml h^{-1}$. [4-^{14}C] Testosterone (10 µl [17 kBq]) was applied to the skin surface (0.64 cm^2) as 200 $\mu g ml^{-1}$ in ethanol and receptor fluid samples were collected hourly for 24 hrs. In a parallel *in vivo* study in four rats 100 µl testosterone was applied to a shaved dorsal area (6.25 cm^2) at 200 $\mu g ml^{-1}$. Lomir dermal jackets protected the backs of the animals for a 24 hr period. Animals were individually housed in metabolism cages from which the excreta are collected. Material in the carcass, urine and faeces was determined. *in vivo* 12% of the dose was recovered from the skin surface, 2% within the stratum corneum, 5% within the skin at the application site, 18% in urine, 2% in faeces and 40% in carcass. Therefore 65% of the dose was absorbed beyond the stratum corneum. By comparison, *in vitro* data indicated that 35% of the applied dose remained unabsorbed on the skin surface, 3% within the stratum corneum, 7% (1% if dermatomed skin) within the skin and 30% (40% if dermatomed skin) was recovered in the receptor medium. In conclusion *in vivo* absorption of testosterone in the rat can be reasonably predicted by an *in vitro* model however the underestimation may arise due to limited perfusion of the skin which cannot be modeled adequately . (Supported by SEAC Toxicology Unit, Unilever Research.)

783 NOVEL PEPTIDES PROTECT AGAINST SULFUR MUSTARD-INDUCED SKIN TOXICITY.

U. Wormser[1], B. Brodsky[1] and A. Nyska[2]. [1]*Faculty of Sciences, The Hebrew University, Jerusalem, Israel and* [2]*Laboratory of Experimental Pathology, NIEHS, Research Triangle Park, NC.*

Our previous studies demonstrated the protective effect of topical iodine treatment against sulfur mustard (SM)-induced skin lesions. It was proposed that the mechanism involves iodine-induced production of skin protective factors. To test this hypothesis guinea pig skin was exposed to heat followed by treatment with iodine and skin extraction. Intradermal injection of the tissue extract resulted in statistically significant reduction of 69% in SM-induced ulceration area. Two pharmacologically active peptides were identified, partial sequence of histone H2A and fibrinopeptide A; administration of each of these peptides resulted in statistically significant reduction of 67% and 62% respectively, in SM-induced ulceration area. The peptides were coadministered with a cocktail of proteinase inhibitors to prevent degradation. In order to stabilize the peptides we prepared a series of N-methylated analogs in which the hydrogen atom of the nitrogen of the peptide bond was substituted by a methyl group. The most active N-methylated analog of the partial sequence of histone H2A caused statistically significant reduction of 81% in SM-induced ulceration area in the absence of proteinase inhibitors. The present study proposes a new pharmacological approach for whole skin surface protection, and maybe for whole body protection, against vesicants and other noxious stimuli (supported by USAMRMC Cooperative Agreement No. DAMD17-98-2-8009).

784 UPTAKE AND ACTIVITY OF CAPSAICIN AND NONIVAMIDE IN HUMAN SKIN AS A FUNCTION OF VEHICLE.

L. K. Pershing, C. A. Reilly and D. J. Crouch. *Dermatology, University of Utah, Salt Lake City, UT.* Sponsor: M. Franklin.

Capsaicin and its analog, nonivamide, are commonly used in the preparation of commercial "pepper sprays" for use as less-than-lethal deterrents. These natural products produce a skin erythema response that can be quantified using the a* scale of the L*a*b* uniform color space of a reflectance colorimeter. This study compared erythema with the uptake of capsaicinoids and nonivamide in ventral forearm stratum corneum in seven subjects (47.3 ± 15.7 yrs) as a function of the vehicle: 95/5 (v/v) ethanol/methanol (EtOH), 70/30 (v/v) isopropyl alcohol/water (IPA), 80/20 (v/v) mineral oil/isopropyl alcohol (MO) and 80/20 (v/v) propylene glycol/isopropyl alcohol (PG). Solutions were prepared using 30 mcg/mL of capsaicin or nonivamide in the above vehicles and applied as a single, unoccluded 5 mcL dose to both ventral forearms of each subject for 10 minutes in a randomized manner. Capsaicinoid concentration was quantified by harvesting stratum corneum from treated sites using twenty 1.3 cm diameter adhesive discs that were subsequently weighed, extracted and analyzed for capsaicinoids using LC-MS. Erythema was quantified over 90 minutes after residual product removal on the other arm with a Minolta CR200 colorimeter. The amount of stratum corneum weight harvested from the various sites was independent of the vehicle applied (~ 264 mcg). The first ten adhesive discs contained the majority of capsaicinoids and nonivamide in the skin: EtOH and IPA delivered 3-5X greater amount of capsaicinoids to the stratum corneum than MO or PG ($p < 0.001$), while EtOH delivered 2-5X greater amount of nonivamide than IPA, MO or PG ($p < 0.05$). EtOH delivered 2X more nonivamide than capsaicinoids into stratum corneum, yet area-under-the a* scale-time curve (AUEC a*) demonstrated similar erythema independent of vehicle. Relative potency (AUEC a*/concentration) of capsaicinoids was 2X greater than nonivamide in EtOH and IPA vehicles, but similar in PG and MO. Thus, vehicle influences both delivery and potency of capsaicin and nonivamide in human skin *in vivo*.

785 TRANSCRIPTOMIC PROFILES IN RAT SKIN FOLLOWING DERMAL EXPOSURE TO SODIUM LAURYL SULFATE.

C. M. Garrett[1], J. V. Rogers[1], C. Wang[2] and J. N. McDougal[1]. [1]*Biomedical Sciences, Geo-Centers, Inc, Wright Patterson AFB, OH and* [2]*ManTech Environmental Sciences, Inc, Wright Patterson AFB, OH.*

Dermal irritation continues to be an important yet poorly understood occupational health issue. Irritant contact dermatitis (ICD), the most common occupational skin disease, costs government and industry millions of dollars each year. Gene array

technology can serve as a tool for assessing chemical irritancy potential. To determine the transcriptional response to dermal irritants, male Fisher 344 rat skins were exposed to 10% sodium lauryl sulfate (SLS, a model skin irritant) for 1 h *in vivo*. Skin total RNA was isolated at 0 h (control), and 1 and 4 hrs following the beginning of the exposure to monitor transciptomic profiles using the Affymetrix RatTox U34 array. Our results indicated that dermal exposure to SLS resulted in a significant change of gene expressions: more than 20 genes (ie., inflammatory, Bcl-2-related, oncogenes) were increased >2-fold, whereas more than 24 genes (ie., cytochrome P450-related, tumor suppressor) showed a >2-fold decrease (1h vs 0 h controls). By 4 hr, more than 60 genes (ie., inflammatory, oxidative and cellular stress, cell cycle, transcription factors, Bcl-2-related) were up-regulated and more than 10 genes (transcription factors, junctional proteins) were down-regulated by a factor >2-fold when compared to the 0 h controls. A strong temporal change of gene expression was observed in the skin following exposure to SLS. Characterization and analysis of the transcriptomic response of skin to SLS can enhance the risk assessment of dermal irritants.

786 *IN VITRO* ASSESSMENT OF OXIDATIVE STRESS AND CYTOTOXICITY IN LIVING DERMAL EQUIVALENTS EXPOSED TO M-XYLENE.

J. V. Rogers[1], C. A. Coleman[2], B. E. Hull[2] and J. N. McDougal[1]. [1]*Geo-Centers, Inc., Wright-Patterson AFB, OH and* [2]*Wright State University, Dayton, OH.*

Dermal exposure to volatile organic chemicals (VOCs) can lead to irritation, inflammation, and cytotoxicity *in vivo*. Using an improved *in vitro* exposure method for VOCs, we wanted to assess oxidative stress and cytotoxicity in dermal fibroblasts exposed to m-xylene. Dermal equivalents containing $2.5x10^5$ cells were incubated for 1 or 4 hr in a m-xylene/culture medium mixture (range=0.5 to 11.5 µg/ml m-xylene). Following exposure, cell viability (MTT assay and cellular LDH activity), cellular thiol levels, and endogenous catalase activity were measured. At 1 and 4 hr, cell viability decreased with increasing m-xylene concentration. The EC_{50} calculated using the MTT assay were 8.33 ± 0.26 and 6.85 ± 0.33 µg m-xylene/g tissue at 1 and 4 hr, respectively. The EC_{50} at 4 hr was significantly lower ($P<0.05$) compared to the EC_{50} calculated from the 1 hr exposures. At 1 hr, the EC_{50} determined from measuring cellular LDH activity was 23.7 ± 0.88 µg m-xylene/g tissue. By 4 hr, the EC_{50} had decreased significantly ($P<0.05$) to 9.24 ± 0.05 µg m-xylene/g tissue. A temporal decrease in the levels of endogenous antioxidants (catalase and thiols) was also observed with increasing m-xylene concentration. Pretreatment of dermal equivalents with the antioxidant N-acetylcysteine significantly increased ($P<0.05$) cell viability. These results suggest oxidative stress may promote m-xylene-induced cytotoxicity in living dermal equivalents. Moreover, these VOC-induced cellular responses could ultimately be related to actual dermal exposure scenarios. (Supported by NIOSH/CDC and AFOSR/NL)

787 PREDICTION OF MOLECULAR MECHANISM OF SKIN IRRITATION AFTER ACUTE EXPOSURE TO SODIUM LAURYL SULFATE.

P. G. Gunasekar[1], J. V. Rogers[2], M. B. Kabbur[3], W. W. Brinkley[3], C. M. Garrett[2] and J. N. McDougal[1,2]. [1]*Pharmacology and Toxicology, Wright State University, Dayton, OH,* [2]*Geo-Centers, Inc., Wright-Patterson AFB, OH and* [3]*Operational Toxicology Branch, Air Force Research Laboratory, Wright-Patterson AFB, OH.*

Sodium lauryl sulfate (SLS) is an anionic surfactant, causing irritant contact dermatitis. Skin irritation by this detergent is not well understood due to the complex molecular interactions. Knowledge of molecular mechanisms and the relationship between duration of surfactant exposures on the skin and the degree of irritation is limited. Here we measured an early inflammatory mediators, interleukin 1-alpha (IL-1α), inducible nitric oxide synthase (iNOS), nitric oxide (NO) and ROS in response to two different concentrations of SLS (1% and 10%)-induced irritation.The dorsal thoracic aspects of male F-344 rats were exposed to SLS for 1 hr using Hill Top Chambers. At 0, 1, 2, 4 and 6 hours after exposure, skin samples were processed for analysis. Western blot of 1% SLS exposed skin samples showed an increase in IL-1α protein levels from 13-37% over controls at various time points, while IL-1α in 10% SLS samples only increased by 10%. This protein induction reached a maximum at 2 hr. The change in iNOS levels in 1% SLS skin over the respective controls was comparable to change in 10% SLS exposed skin samples but occurred at 4 hours. However, NO levels showed a different response. Like NOS protein level in 1% SLS exposed samples, NO level increases peaked at 4 hr after beginning of exposure. In 10% exposed samples NO level peaked at 1 hr after exposure and gradually decreased. There was a significant generation of ROS seen in 1% SLS exposed skin, which reflects the damaging effects on the skin. The reduced level of thiol further strengthens the potential association of oxidative stress and skin damage during SLS exposures. These results suggest that the change in the levels of skin's molecular and biological response to SLS exposure explained the biochemical mechanisms associated with SLS-induced irritation (Supported by CDC/NIOSH RO1 OH03654-03).

788 HISTOPATHOLOGIC ASSESSMENT OF ACUTE DERMAL EXPOSURE TO *M*-XYLENE, *D*-LIMONENE AND SODIUM LAURYL SULFATE IN RATS.

W. W. Brinkley[1], J. V. Rogers[2], M. B. Kabbur[1], C. M. Garrett[2], J. N. Gunasekar[3] and J. N. McDougal[2,3]. [1]*AFRL/HEST, Wright-Patterson, AFB, OH,* [2]*GEO-CENTERS, Inc., Wright-Patterson, AFB, OH and* [3]*Wright State University, Dayton, OH.*

Skin exposure to organic chemicals and solvents may cause skin irritation and generate proinflammatory mediators that initiate an irritant response. Histopathology can serve as a fixed reference point in a changing microenvironment for explanation of concurrent cellular responses. Changes in the levels of selected proteins in the irritant cascade were quantified after an exposure and compared to visible tissue changes. Here we describe the dermal pathology of male F-344 rats exposed to meta-xylene, *d*-limonene and sodium lauryl sulfate for one hour using Hill Top Chambers®. Skin samples were collected at zero, one, two, four and six hours after the end of the exposure. Light microscopic evaluation was performed on formalin-fixed and paraffin embedded skin sections. Hematoxylin and eosin stained sections were assessed and scored. A single topical exposure to meta-xylene, *d*-limonene, and sodium lauryl sulfate resulted in granulocyte infiltration in rats as early as 2 hours. Segmental detachment of the epidermis from the dermal interface occurred in prolonged exposures of meta-xylene and *d*-limonene compared to the control groups. These findings were interpreted to be the consequences of potential up-regulation of inflammatory mediators that result in skin damage. (Supported by CDC/NIOSH RO1 OH03654-03)

789 PYRIDOSTIGMINE BROMIDE SUPPRESSES IL-8 IN HUMAN EPIDERMAL KERATINOCYTES AND IN ISOLATED PERFUSED PORCINE SKIN EXPOSED TO DEET AND PERMETHRIN.

N. A. Monteiro-Riviere, A. O. Inman, R. E. Baynes and J. E. Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Gulf War personnel were given pyridostigmine bromide (PB) as a prophylactic treatment against possible organophosphate exposure and then exposed to the insecticide permethrin (Pe) and the insect repellent DEET. Simultaneous exposure and the interaction of these compounds could contribute to the ill health effects in the Gulf War veterans. The purpose of this study was to assess the effects of DEET and /or systemic PB on permethrin absorption. A large combination of topical mixtures of permethrin and/or DEET in various vehicles were applied to isolated perfused porcine skin flaps (IPPSFs). The absorption data has been reported elsewhere. Concentrations of interleukin-8 (IL-8) and TNF-α were assayed in the absorption studies to probe for a potential inflammatory effects after complex mixture application. IPPSF's (n=4/treatment) were topically dosed with mixtures of Pe, DEET, Pe/DEET, and ethanol (EtOH). Each treatment was repeated with perfusate spiked with 50 ng/ml of PB. Timed IPPSF venous effluent samples (0, 0.5, 1, 2, 4, and 8 hrs) were assayed by ELISA for IL-8 and TNF-α and by EIA for PGE_2. Surprisingly, across most topical mixture combinations, release of IL-8 and TNF-α were significantly suppressed when PB was infused into the IPPSFs. To probe the potential mechanism of this PB effect, human epidermal keratinocyte (HEK) cell cultures were exposed to Pe, DEET, Pe/DEET, with and without PB in DMSO vehicle. IL-8 was assayed at 1, 2, 4, 8, 12, and 24hrs. PB suppressed IL-8 in permethrin treatments from 4 to 24 hrs supporting the IPPSF results. In conclusion, these studies clearly demonstrate that systemic exposure to PB suppressed the cytokine IL-8 release from keratinocytes. The relation of this finding to PB-induced changes in permethrin absorption and/or other factors in the pathogenesis of Gulf War illness deserves further attention. (Supported by USAMRMC Grant DAMD-17-99C-9047)

790 LACK OF EFFECTS OF SULFUR MUSTARD AND JP-8 JET FUEL ON PERCUTANEOUS ABSORPTION OF SIMULTANEOUSLY ADMINISTERED TOPICAL PERMETHRIN AND DEET.

J. E. Riviere, J. D. Brooks, R. E. Baynes and N. A. Monteiro-Riviere. *Center for Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Systemic absorption of topically-applied permethrin and/or DEET have often been cited as potential toxicants involved in the etiology of the Gulf War illness. Previous studies in our laboratory have implicated pyridostigmine bromide (PB) as a potential modulating factor on permethrin dermal absorption. Others have postulated a toxicodynamic interaction with systemically absorbed permethrin and DEET. The purpose of the present study was to assess the effects of simultaneously administered JP-8 jet fuel or low-level (sub-blistering) sulfur mustard (HD) on permethrin

and DEET percutaneous absorption using the isolated perfused porcine skin flap (IPPSF) model. IPPSFs were topically dosed with 40 μg/cm^2 ^{14}C permethrin and/or 75% DEET in various ethanolic vehicles with or without HD (40 μg/cm^2) or 75% JP-8. A total of 40 IPPSFs were studied (n=4 per treatment combination). Permethrin absorption was assessed by measuring radioactivity in perfusate and skin after completion of 8 hour experiments. DEET absorption was assessed by HPLC. Consistent with previous data, PB tended to enhance permethrin absorption, detected as ^{14}C radioactivity. Co-administration of JP-8 slightly enhanced permethrin absorption, however not to the extent that was seen with PB. DEET absorption was not effected. HD had no consistent effect on either permethrin nor DEET absorption or skin penetration. These results suggest that neither exposure to JP-8 nor low level HD significantly increases percutaneous absorption of either topically applied permethrin or DEET, and thus cannot be viewed as an additional risk factor for any role that these topically applied chemicals might play in Gulf War illness. (Supported by USAMRMC Grant DAMD-17-99C-9047).

791 ASSESSMENT OF CYTOTOXICITY TO HUMAN EPIDERMAL KERATINOCYTES AFTER EXPOSURE TO ALIPHATIC AND AROMATIC HYDROCARBONS.

C. C. Chou, N. A. Monteiro-Riviere, R. E. Baynes and J. E. Riviere. *Center of Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Our laboratory has shown that jet fuels cause dermal toxicity and the release of the proinflammatory cytokine IL-8 from human epidermal keratinocytes (HEK). More than 220 aliphatic and aromatic hydrocarbons are commonly formulated in jet fuels but the cytotoxic effects of the individual hydrocarbon are unclear. One major problem being that vehicle effects often confound chemical toxicity studies. The purpose of this study was to assess the dermal toxicity induced by each jet fuel hydrocarbon using a single vehicle. Eight aliphatic (dodecane, undecane, tridecane and hexadecane) and aromatic (benzene, toluene, xylene and napthalene) hydrocarbons at various concentrations in mineral oil were dosed directly on HEK. Cell viability at 24 hrs and IL-8 release from HEK at 4, 8, 12 and 24 hrs were assayed. There was no significant decrease in cell viability by all hydrocarbons. However, there appears to be significant differences among each aliphatic and aromatic hydrocarbon with respect to their effects on IL-8 release. Not all HEK exposed to hydrocarbons at normal jet fuel concentrations of 0.5% to 5% increased IL-8 production. Exposure to mineral oil alone for 30 min did not affect cell viability or IL-8 release. In conclusion, we have demonstrated that mineral oil is a suitable vehicle for studies in HEK culture systems especially for high-dose, short-term exposures of compounds with a wide range of lipophilicity. Utilizing 96-well plates also allows for the evaluation of cytotoxic effects of individual and clusters of hydrocarbons to be screened in a relatively short period of time. (US Air Force Office of Scientific Research F49620-01-1-0080)

792 DERMAL ABSORPTION OF AVERMECTIN: FORMULATION AND SPECIES DIFFERENCES.

B. Barlow and R. E. Baynes. *Center of Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Avermectins are approved for topical application in cattle only. There is however some concern that topical application in other domestic animals, may result in significant dermal absorption and possible violative residues in animal-derived food products. The primary aim of this study was to assess dermal disposition of [^{3}H]-avermectin in skin from food-producing species *in vitro* using commercial alcohol-based and oil-based formulations. Skin sections from cattle, sheep, goats, and pigs, were perfused in a flow-through diffusion cell system for 8 hours. Skin sections were dosed with 150 μg/cm^2 of ^{3}H-avermectin in 20 μl of 75% isopropanol+25% crodemol, 100% mineral oil, or 100% isopropyl alcohol. Perfusate samples were collected at various time points and surface swabs and dose skin samples were obtained at 8 hours. ^{3}H-avermectin absorption ranged from 0.09 - 0.20 % dose and there were no significant differences between formulations for ^{3}H-avermectin absorption in each species. The presence of isopropyl alcohol significantly increased skin deposition in all species when compared the oil formulation. Absorption was significantly greater in cattle skin than in pig skin for the isopropyl alcohol formulations, but there were no significant species differences for the oil formulation. While 11.69 - 50.23 % dose remained on the skin across species, the highest skin concentrations were in goat skin (28.09% dose) and the lowest skin concentrations were in pig skin (1.50% dose). In summary, these 8-hour preliminary experiments demonstrated that the alcohol-based formulations compared to oil-based formulations enhanced ^{3}H-avermectin absorption and skin deposition in several animal species, and that this effect is more likely to be observed in ruminant species than in porcine species. (Supported by North Carolina State University Grant FR&PD)

793 CUTTING FLUID FORMULATIONS INFLUENCE THE DERMAL DISPOSITION OF LINEAR ALKYLBENZENE SULFONATE (LAS).

R. E. Baynes, J. D. Brooks, B. Barlow and J. E. Riviere. *Center of Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC.*

Linear alkylbenzene sulfonate (LAS) is often added as a surfactant to cutting fluid formulations to enhance the performance of metal machining operations. Unfortunately, LAS and other cutting fluid additives can cause contact dermatitis in workers in the metalworking industry. The purpose of this study was to assess membrane absorption and deposition of ^{14}C-LAS when topically applied to inert membranes (silastic membranes) and porcine skin in *in vitro* flow-through diffusion cell system as mineral oil or polyethylene glycol (PEG) mixtures. ^{14}C-LAS mixtures were formulated with 3 other additives; namely, 0 or 2% triazine (TRI), 0 or 5% triethanolamine (TRE), and 0 or 5% sulfurized ricinoleic acid (SRA) as follows: TRI, TEA, SRA, TRI+TEA, TRI+SRA, TEA+SRA, TRI+TEA+SRA. In silastic membranes, LAS absorption ranged from 0.09 - 0.19% dose, and there were no differences between corresponding mineral oil and PEG mixtures. Membrane levels were greatest with TRI only in mineral oil and PEG mixtures. In porcine skin, ^{14}C-LAS absorption ranged from 0.06 - 0.32% dose, and there were significant differences between several mineral oil and PEG mixtures. LAS penetration into stratum coneum (SC) was often greater in mineral oil than in PEG mixtures. Surprisingly, LAS absorption was significantly greater in pig skin than in silastic membranes for PEG mixtures containing TRI+TEA. These observations suggest that although very little LAS is absorbed, cutting fluid components can alter LAS deposition into the SC and skin. Furthermore, chemical-biological interactions in viable skin with synergism with a biocide (TRI) and an amine (TEA) may be important determinants for LAS disposition in skin. (Supported by NIOSH Grant R01-OH-03669)

794 BIOMECHANICAL MONITORING TECHNIQUES TO ASSESS SULFUR MUSTARD LESIONS IN WEANLING PIGS.

F. M. Reid[1], J. D. Waugh[1], N. A. Niemuth[1] and J. S. Graham[2]. [1]*Medical Research & Evaluation Facility, Battelle Memorial Institute, Columbus, OH and* [2]*U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*
Sponsor: C. Olson.

The chemical warfare agent, sulfur mustard (SM) produces severe skin injury and there is no established medical treatment. In the present study, we investigated the use of biomechanical measurements as objective, quantitative, and non-invasive means for conducting SM burn assessments to evaluate medical treatments. Additionally, assessments were confirmed by histopathological evaluation. Six animals per group were exposed to SM (2- or 30-min exposure to 400 μL SM applied to each of 6 abdominal sites) and six animals received sham (control; 400 μL deionized water for 30-min) exposures. Each site was evaluated on days 0 and 2. Two-min and 30-min groups were significantly different from control and significantly different from each other, as characterized by histopathological endpoints of burn depth, basal cell necrosis, depth of necrosis, and vascular necrosis. Two-min and 30-min dermal burns were significantly different from control using redness (Chroma Meter) and transepidermal water loss (Evaporimeter), but not significantly different from each other. The 2-min burns and control were significantly different from 30-min burns for skin thickness (Ultrasound). Compared to control, the 2-min burns were significantly increased and the 30-min burns were somewhat decreased for microcirculation blood flux (Laser Doppler). We demonstrate that both biomechanical and histopathological evaluations are useful methods for characterizing SM burns in a weanling pig model. (Supported by the US Army Medical Research and Materiel Command under Contract No. DAMD17-89-C-9050.)

795 α-AMYLCINNAMALDEHYDE (α-ACA) AND α-HEXYLCINNAMALDEHYDE (α-HCA) DO NOT PRODUCE DERMAL SENSITIZATION OR CROSS-SENSITIZATION IN HUMANS.

C. S. Letizia and A. M. Api. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.*

Both α-ACA (heptanal, 2-(phenylmethylene)-) and α-HCA (octanal, 2-(phenylmethylene)-) are important fragrance ingredients. Studies were conducted to evaluate the potential of these two materials to induce sensitization and cross-sensitization in a normal human population. Sensitization was evaluated using either a modified Draize human repeated insult patch test (HRIPT) procedure consisting of nine 24 hour occluded induction applications followed two weeks later by a 24 hour occluded challenge application; or by a human maximization test procedure consisting of occluded induction applications to the same site for five alternate-day 48 hour periods followed ten to fourteen days later with a 48 hour occluded challenge application. Cross-sensitization between these two materials was also evaluated using a HRIPT procedure. α-ACA produced no sensitization in 71 human

volunteers when tested at 6% in human maximization tests or in 95 human volunteers when tested at 20% in a HRIPT. α-HCA produced no sensitization in 81 human volunteers when tested at 12% in human maximization tests or in 324 human volunteers when tested in HRIPTs at dose levels ranging from 5% to 20%. Cross-sensitization was not observed in 95 subjects tested with 20% α-ACA and then cross-challenged with 20% α-HCA or in 95 subjects tested with 20% α-HCA and then cross-challenged with 20% α-ACA. Although sensitization has been reported in animal tests, the results of these human studies indicate no evidence of dermal sensitization with α-ACA or α-HCA after repeated application. Additionally, no evidence of cross-sensitization was produced with either substance.

796 A NOVEL TECHNIQUE TO STUDY PERCUTANEOUS ABSORPTION BY USING A SILASTIC MEMBRANE COATED FIBER.

X. R. Xia[1], R. E. Baynes[1], N. A. Monteiro-Riviere[1], R. B. Leidy[2] and J. E. Riviere[1]. *[1]Center of Cutaneous Toxicology and Residue Pharmacology, North Carolina State University, Raleigh, NC and [2]Pesticide Residue Research Laboratory, Department of Toxicology, North Carolina State University, Raleigh, NC.*

Silastic membrane coated on a section of fused silica fiber has been used successfully as an analytical tool to extract analytes from aqueous solution. In this study, the silastic membrane coated fiber was used as a permeation membrane to study the percutaneous absorption of model pesticides. It represents a half compartment of the conventional Franz diffusion cell, which allows for more detailed permeation kinetics to be investigated. The membrane coated fiber was immersed in the magnetic stirred donor phase to adsorb the permeants from the solution, the fiber was then transferred directly into the injection port of a Gas Chromatograph/Mass Spectrometer for quantitative analysis. This technique can assess the permeation amounts at various permeation times, stirring speeds and donor compositions. A theoretical model was proposed to describe the permeation processes of the silastic membrane coated fiber in terms of diffusion parameters. This model allows for the boundary layer between the donor phase and the silastic membrane to be considered, it's thickness is assumed to be constant under steady-state diffusion. The permeation kinetics of 30 different compounds having a wide range of partition coefficients were examined utilizing a silastic membrane coated fiber. The experimental permeation flux and time profiles were well described by the proposed mathematical model. The thickness of the boundary layer, the diffusion coefficients in the donor phase and in the silastic membrane, and the partition coefficients can be measured simultaneously with this novel technique. This approach would foster development of high-throughput determination of skin diffusion parameters. (Supported by NIOSH R01-OH 03669 and 07555)

797 A GENOMICS APPROACH FOR THE DEVELOPMENT OF AN *IN VITRO* METHOD FOR SKIN SENSITIZATION.

C. A. Ryan[1], B. C. Hulette[1], R. J. Dearman[2], I. Kimber[2] and G. F. Gerberick[1]. *[1]The Procter & Gamble Company, Cincinnati, OH and [2]Syngenta CTL, Macclesfield, United Kingdom.*

For the development of an *in vitro* method for predictive skin sensitization testing, a genomics approach is being used to elucidate pathways that are involved in the immune recognition of chemical allergens by dendritic cells (DC) and T-cells, the key cells involved in the induction and elicitation of allergic contact dermatitis. The overall aims are to identify and characterize those genes in both DC and T cells which provide sensitive, selective and robust markers of skin sensitization and which allow discrimination between contact allergens and skin irritants. To date, there are no published reports describing genomic-scale analysis of the early changes induced in either T cells or DC resulting from antigen-specific interactions between the two cell types. There are a limited number of reports regarding microarray analysis of T cell activation following heat shock or exposure to activating agents such as staphylococcal enterotoxin B or PHA and phorbol ester. While changes in the expression of some genes were found to be similar in all activated T cells, there were some changes that were dependent upon the nature of the activating signal. Therefore, to gain an understanding of the changes in gene expression that are induced by antigen-specific T-cell/DC interactions in humans, we examined T cell activation *via* the T cell receptor, using anti-CD3, with co-stimulation provided by DC. An *in vitro* co-culture system comprised of peripheral blood derived DC as antigen presenting cells and responding T cells was used. Total RNA was isolated from co-cultures after 2 and 6 hrs of culture with and without anti-CD3. Genomics analysis was conducted using the Affymetrix GeneChip® human U95Av2 array. Changes in gene expression of 2-fold or more were observed in 108 genes, ranging from an up-regulation of 42-fold to down-regulation of 10-fold. Information gained in this study will be used as a benchmark in the examination of primary responses in non-sensitised T cells co-cultured with hapten-treated DC.

798 INHIBITION OF PHOTOCARCINOGENESIS BY TOPICAL ADMINISTRATION OF DAPSONE.

D. B. Learn[1], C. P. Sambuco[1], P. D. Forbes[1], K. M. Holland[2], D. Osborne[2] and A. M. Hoberman[1]. *[1]The Center for Photobiology, Argus Research, Horsham, PA and [2]Atrix Laboratories, Fort Collins, CO.*

Dapsone (DAP) is a potent anti-inflammatory and anti-bacterial approved as an oral therapy for leprosy and dermatitis herpetiformis. While effective for these diseases and acne, the relatively high oral doses of DAP can cause adverse events. Topical administration would deliver high local DAP concentrations to skin but greatly reduce the systemic dose and side effects. Because of the high absorbance of DAP in the ultraviolet portion of the solar spectrum and it's anticipated chronic topical administration to facial skin exposed to sunlight, a photocarcinogenesis test assessed the potential of topical DAP to modify the development of solar-simulated radiation (SSR)-induced skin tumors in Crl:SKH1-hrBR hairless mice. Dapsone was formulated in a diethyl glycol monoether (DGME)-based vehicle at DAP/DGME ratios of 1%/10%, 3%/17.5% or 5/25%. The study design included a group of mice administered vehicle (25% DGME) and low and high UVR calibration groups. Mice were administered formulations and exposed to SSR five days per week for 40 weeks then observed for an additional 12 weeks. Clinical observations and tumor mapping were performed weekly. Cutaneous responses indicated DAP administration reduced the incidence of erythema, edema and thickening in the groups of mice administered the DAP/DGME formulations as compared with mice exposed to SSR alone. Dapsone concentration-dependent hyperactivity occurred throughout the 40 week dosing period. The unbiased median latent weeks to tumor, sexes combined, were 41.50, 47.50, 48.00 and 49.00 weeks for the vehicle, low, middle and high dose DAP/DGME formulations, respectively, compared to 41.50 weeks for the low UVR calibration group, indicating a delay in tumor development in the DAP/DGME formulation-treated groups and no vehicle effect. In conclusion, topical DAP administration does not enhance photocarcinogenesis in the hairless mouse model and indeed affords protection against SSR-induced skin tumor development and cutaneous responses to SSR exposure.

799 ABSORPTION OF ^{14}C-CYLOTRIMETHLYENETRINITRAMINE (RDX) THROUGH HUMAN SKIN *IN VITRO*.

G. Reddy, N. A. Allen and M. A. Major. *Health Effects Research Program, U.S.Army Center for Health Promotion and Preventative Medicine, Aberdeen Proving Ground, MD.*

Dermal exposure of the explosive chemical RDX can occur to humans during the manufacturing process and occupational (load, assembly and package) operations. There is no information on dermal absorption of RDX in humans for risk assessment. We studied dermal absorption of RDX in human skin *in vitro* in flow-through diffusion cells. RDX (38.46μg / 0.5 μCi) in acetone (10 μl) was applied to the skin and collected as diffused receptor fluid for every 6 hr up to 24 hrs. At the end of the experiment, the unabsorbed RDX was washed with soap water and water with cotton swabs, and radioactivity present in washings was determined. The RDX absorbed or penetrated in the skin was also determined by separating stratum corneum, epidermis and dermis at the end of the experiments. Our results show that the total of approximately 6 % of applied dose was absorbed in the skin (receptor fluid and skin) in 24 hr. The absorption of RDX in the receptor fluid was relatively slow with about 1.28 % of applied dose in 24 hrs. Preliminary results of analysis of stratum corneum (tape strips), epidermis and dermis revealed that a majority of radioactivity localized in the upper stratum corneum and epidermis and it was very low in the dermis of the skin after 24 hrs. The total recovery of applied dose (receptor fluid, skin and washings) was about 80 %. These results show that RDX is absorbed in the skin but diffusion through skin was relatively slow. This may be due to liposolubility of RDX in the skin. The estimated levels of RDX in the skin can be used to evaluate health risks associated with dermal exposure (Abstract does not reflect US Army policy).

800 *IN VITRO* HUMAN SKIN PENETRATION OF THE RADIOLABELLED FRAGRANCE MATERIALS, AHTN AND HHCB.

A. M. Api and D. A. Isola. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.*

in vitro human skin permeation rate and distribution of two radiolabelled polycyclic musks, AHTN and HHCB, following application under non-occlusive conditions was determined. The studies followed the European Scientific Committee on Cosmetic Products and Non-Food Products (SCCNFP) guidelines and used human cosmetic reduction skin from surgery. Screening studies were conducted to identify the most appropriate receptor fluid, which for these studies was 6% of the surfactant VolpoN20 in physiologically balanced saline. The skin samples were heat separated and the epidermal membranes comprising both the stratum corneum and the epidermis were used. Because the system was static, the dermis was stripped

away. The integrity of the membranes was determined prior to dosing using tritiated water. A 1% solution of radiolabelled (^{14}C) test material in ethanol was applied to the membrane (20 µliters/cm^2). After 24 hours, the amount of material in the receptor fluid was determined using a scintillation counter. Mass balance was determined and included test material collected from the surface wipes, 10 skin strippings, remaining epidermis, receptor phase, donor chamber, and filter paper supports. After 24 hours, 0.38% of the applied AHTN dose permeated the epidermal membranes into the receptor phase. The total absorbed dose for AHTN, determined by adding the amounts of test material in the remaining epidermis, the receptor phase and the filter paper was 4.1% of the applied dose. The evaporative loss was 2.9%. Overall recovery of applied AHTN was high at 92.5% or 95.4% when loss due to evaporation is included. For HHCB, the penetration through the epidermal membranes was 0.40% after 24 hrs. The total absorbed dose for HHCB was 5.2% of the applied dose. The evaporative loss was 2.4%. Overall recovery of applied HHCB was good at 92.1% or 94.5% with evaporative loss included. The results of these studies show that the percutaneous absorption of both of these fragrance materials was low - 4.1% for AHTN and 5.2% for HHCB.

801 *IN VITRO* HUMAN SKIN PENETRATION OF SEVEN RADIOLABELLED FRAGRANCE MATERIALS.

D. A. Isola and A. M. Api. *Research Institute for Fragrance Materials, Inc., Hackensack, NJ.*

in vitro human skin penetration studies on 7 fragrance materials were conducted according to the FDA guidelines. The materials studied were acetyl cedrene, estragole, methyl atrarate, methyl dihydrojasmonate, methyl eugenol, α-methyl-3, 4-methylenedioxy hydrocinnamic aldehyde (MMDHCA) and 1, 2, 3, 4, 5, 6, 7, 8-octahydro-2, 3, 8, 8-tetramethyl-2-acetonaphthone (OTNE). Each of the test materials was radiolabelled with ^{14}C. The full thickness human skin samples were either from the breast or abdomen of cosmetic surgery patients. The skin samples were heat separated and the epidermal membranes were used in the studies. The epidermal membranes were mounted on filter paper supports. The supports, with the membranes, were then placed onto diffusion cells and trimmed to size. The integrities of the membranes were determined using tritiated water. Twenty µl of a 1% solution of each material in ethanol was applied to the surface of the membranes. At 2, 8, 24, 36, and 48 hours 200 µl samples of the receptor fluid (50% ethanol/water solution) were taken from the receptor chamber and analyzed by liquid scintillation chromatography. Evaporative loss of each fragrance material was also determined. At 24 and 48 hours the following percentages of the applied dose permeated into the receptor phase: 6 and 11% of acetyl cedrene, 17 and 16% of estragole, 14 and 20% of methyl atrarate, 31 and 46% of methyl dihydrojasmonate, 36 and 34% of methyl eugenol, 42 and 50% of MMDHCA, and 9 and 15% of OTNE. These results suggest varying percutaneous absorption of these materials. However, it should be noted that the donor phase became somewhat depleted through evaporation and could affect the amount of test material available for absorption.

802 INVESTIGATION OF THE SENSITIZATION POTENTIAL OF MUSK KETONE USING THE GUINEA PIG MAXIMIZATION TEST (GPMT).

J. Cocchiara, D. A. Isola and A. M. Api. *Research Institute for Fragrance Materials, Hackensack, NJ.*

As part of a risk assessment on musk ketone, a widely used synthetic musk fragrance ingredient, a Guinea Pig Maximization Test (GPMT) was used to investigate the sensitization potential of this material. The GPMT was conducted according to OECD Guideline 406, and Good Laboratory Practices were followed. Preliminary testing determined dose levels for the main study. Exposure during the induction phase of the GPMT consisted of a pair of intradermal injections with 3% musk ketone followed by a 48-hour occlusive dermal application with 75% musk ketone seven days later. After a 2-week rest period, the challenge phase consisted of 24-hour occluded dermal applications with three concentrations: 75, 25 and 7.5% musk ketone. The vehicle used for all phases was 9:1 olive oil/acetone. Skin sites were examined at 24 and 48 hours following patch removal, erythematous reactions were quantified and scored. No irritation responses were observed, and the test was maximized. At 75% 5/20 test animals and 1/10 control animals responded; and at both 25 and 7.5% 3/20 test animals and 0/10 control animals responded. According to OECD guidelines, this material is not considered a sensitizer requiring a label, since there was less than a 30% response rate.

803 INHIBITION OF FLK-1/KDR, PDGFR AND FGFR DOES NOT ALTER HEALING OF INCISIONAL SUTURED SKIN WOUNDS IN MICE.

E. Blomme[1], W. R. Duan[1], S. L. Li[2], S. Patyna[2] and I. Ivens[2]. [1]*Pharmacia Corporation, Skokie, IL and* [2]*SUGEN, Inc., South San Francisco, CA.*

The control of angiogenesis during tissue repair events is of crucial importance and disturbances of this process have been suggested to play a role in impaired skin wound healing. Vascular endothelial growth factor (VEGF), platelet-derived growth factor (PDGF) and fibroblast growth factor (FGF) are the major angiogenesis factors, although other growth factors can also modulate angiogenesis during wound repair. Using an incisional wound model in SKH1 hairless mice, we evaluated the effects of therapeutic and supratherapeutic doses of SU006668, an inhibitor of PDGFR (Ki=0.008 µM), Flk-1/KDR (Ki=2.1 µM) and FGFR (Ki=1.2 µM), on the healing of skin wounds. Mice were administered vehicle, SU006668 (100 mg/kg/day and 400 mg/kg/day, b.i.d.), or dexamethasone (1 mg/kg/day; positive control) continuously for 6 days prior to wounding and for 28 days post wounding. A full-thickness incision was made on the dorsum of mice and closed with three equidistant sutures. Wound healing was monitored histologically and using a tensiometer up to 4 weeks post-wounding. SU006668 at therapeutic doses (100 mg/kg) had no significant effect on the tensile strength and macroscopic and microscopic morphology of the wounds, whereas dexamethasone treatment resulted in skin atrophy, decreased tensile strength, and delayed epidermal and dermal restoration. At supratherapeutic doses (400 mg/kg), where SU006668 may non-specifically inhibit other receptor tyrosine kinases, there were subtle transient histologic changes and slight decreases in tensile strength of minimal biological significance, suggesting a slight delay in the wound healing process up to 14 days post-wounding with complete return to control levels thereafter. In conclusion, these data indicate that PDGFR, Flk-1/KDR and FGFR inhibition at levels necessary to inhibit tumor growth in mouse xenograft models, does not affect the healing of incisional wounds and that redundant pathways likely compensate for inhibition of PDGF, VEGF and FGF function in normal cellular processes.

804 EFFICACY OF DIPHOTERINE HCL DECONTAMINATION IN RATS: A COMPARATIVE STUDY.

A. H. Hall, M. Cavallini, M. M. Corsi, L. Mathieu and J. Blomet. *Department of Emergency Medicine, Division of Toxicology, El Paso, TX.*

Efficacy of Diphoterine(R) HCl Decontamination in Rats. A comparative study. Cavallini M, Corsi MM, Mathieu L, Blomet J, Hall AH. Twenty-five male rats had dermal exposure to 25% HCl for 15 seconds. Five control rats had no decontamination. All applicable animal use guidelines were followed. The other groups of 5 rats each were decontaminated as follows: saline solution; calcium gluconate; Diphoterine. Assays of IL-6, TNF-alpha, NO, and substance P indicated that Diphoterine was more efficacious than the other decontamination solutions.

805 CALIBRATION OF *IN VITRO* DERMAL ABSORPTION TEST SYSTEMS: INTER-SYSTEM VARIATION IN TRITIATED-WATER KP VALUES?

R. P. Moody, M. Akram and S. A. Qureshi. *Health Canada, Safe Environments Program, Banting Research Centre, Ottawa, ON, Canada.*

The skin permeability coefficient (Kp) is used to predict dermal systemic exposure to environmental contaminants. Since many different *in vitro* dermal absorption test systems have been reported in the literature for measuring Kp values, our laboratory conducted inter-system tests for calibration purposes. Tritiated water (^3H_2O) was selected as the test chemical since the Kp of ^3H_2O is often used to test human skin barrier integrity. Our tests were conducted following standard OECD guidelines. Three different flow-through type *in vitro* test systems were used; the Bronaugh, Amie and AIDA systems. The Bronaugh and Amie systems were obtained commercially, the Automated *In-vitro* Dermal Absorption (AIDA) system was developed in-house. All three systems used flow-through donor and receivor solutions except for the Bronaugh system which used a non-flowing static donor. The Bronaugh, Amie and AIDA systems demonstrated average ^3H_2O Kp values (units of cm X 10^3/hr) of 2.3 ± 1.38 (n = 6), 1.0 ± 0.40 (n = 6), and 0.5 ± 0.11 (n = 4), respectively. Normalized for the Bronaugh Kp data, the average Kp was 2.4 and 4.5 fold lower for the Amie and AIDA systems, respectively. As tests were conducted with fresh/unfrozen human breast skin from the same donor and all experimental conditions (e.g. temperature, donor and receivor solution concentrations/compositions) were kept the same, the reason for an intra-system difference in Kp values was not apparent. The higher Kp obtained for the Bronaugh system was not considered to be due to its use of a static donor supply since a flowing donor should act to stir the donor solution, and if anything increase the absorption rate. Given the range in standard deviation in the average Kp data reported here, further corroboratory tests are required with ^3H_2O and other chemicals to examine the need for developing inter-system calibration factors.

806 DIETHANOLAMINE (DEA) *IN VITRO* DERMAL ABSORPTION IN FUZZY RAT SKIN.

J. J. Yourick[1], A. Marks[1], R. Y. Lochhead[2] and R. L. Bronaugh[1]. [1]*Office of Cosmetics and Colors, USFDA, Laurel, MD and* [2]*Department of Polymer Science, University of Southern Mississippi, Hattiesburg, MS.*

Diethanolamine (DEA) is used in cosmetic formulations as an emulsifier, thickener, wetting agent, detergent, and foam booster. DEA is reported to be used in mainly wash-off cosmetic formulations. DEA is also used in the preparation of

DEA conjugates (DEA condensates and DEA salts). DEA conjugates are used almost entirely in wash-off products, but there are uses reported in leave-on products. Unreacted DEA concentrations in DEA condensate cosmetic raw materials may be as high as 20%. Concerns about DEA's safety have been raised by National Toxicology Program carcinogenicity testing in rodents. Therefore, we initiated *in vitro* studies to measure DEA fuzzy rat dermal absorption. [^{14}C]DEA (approx. 0.1 μCi/cell) skin absorption was measured by using one dosing vehicle which was a spiked consumer lotion product applied at 3.0 mg/cm^2. The dosing vehicle containing DEA was applied to skin in the diffusion cells for 24 hr, then the skin was washed. Absorption was measured over a period of 72 hr by using flow-through diffusion cells (0.64 cm^2) with a receptor fluid consisting of HHBSS (pH 7.4). In rat skin(n=3), the percentage of applied dose absorbed over 24 hr was 1.4 ± 0.5 (mean ± SEM) with approximately 4% remaining in skin. At 72 hr after DEA application, the percentage of applied dose absorbed was 1.6 ± 0.5 with approximately 4% remaining in skin. At 24 hr, there was 1.9 ± 0.8 and 1.9 ± 0.5 of the applied dose remaining in the stratum corneum and viable epidermis/dermis, respectively. Skin levels of DEA did not change even when followed for 72 hr. These studies indicate that little of the DEA that was found in the skin at 24 hr diffused through the skin to be absorbed into the receptor fluid. Therefore, skin levels of DEA should not be included in the estimate of systemic absorption used in an exposure assessment.

807 *IN VITRO* PERCUTANEOUS ABSORPTION OF DIETHANOLAMINE (DEA) IN HUMAN SKIN.

M. E. Kraeling, C. T. Jung, J. J. Yourick and R. L. Bronaugh. *Office of Cosmetics and Colors, USFDA, Laurel, MD.*

Diethanolamine (DEA) is an alkanolamine contained in pharmaceuticals and various cosmetic and personal care products either as a conjugate (DEA condensates and DEA salts) or as a constituent of triethanolamine (TEA). Concerns about the safety of DEA have been raised by the National Toxicology Program (NTP). Therefore, we initiated studies to measure the extent of DEA absorption in human skin relevant to exposures from consumer products. DEA penetration was determined from three different product classes: shampoos, hair dyes and body lotions. Two commercial products from each class were spiked with [14C]DEA and applied to excised viable and non-viable human skin mounted in flow-through diffusion cells maintained with a physiological buffer (HHBSS, pH 7.4) as receptor fluid. Products remained on the skin for 5 min, 30 min and 24 hours for shampoos, hair dyes and body lotions, respectively. At the end of 24 hours, the amount of DEA absorbed in skin layers and the receptor fluid was determined and expressed as the percent of the applied dose absorbed for each product type. Most of the absorbed dose was found in skin: 2.8%, 2.9% and 10.0% for shampoos, hair dyes and body lotions respectively. Only small amounts penetrated into the receptor fluid: 0.08%, 0.09% and 0.9% for shampoos, hair dyes and body lotions respectively. In skin absorption studies extended to 72 hours only small amounts of additional DEA were absorbed into the receptor fluid. Therefore, skin levels of DEA should not be included in estimates of systemic absorption used in exposure assessments. Substantially more systemic absorption of DEA would be expected when applied in a leave-on product. In daily repeat dose studies with a lotion, DEA penetration into receptor fluid increased slightly but not significantly from 0.47% (day 1) to 0.76% and 0.88%, on the second and third days respectively. A [3H]water test indicated that the barrier of the skin remained intact throughout the study. DEA appeared to accumulate in the skin (29.2%) with very little diffusing out into the receptor fluid.

808 RISK ASSESSMENT OF ORGANOPHOSPHORUS CHEMICALS INCLUDING CHEMICAL WARFARE AGENTS.

R. C. Wester[1], H. Tanojo[1], X. Hui[1], H. I. Maibach[1], E. Olajos[2] and H. Salem[2]. *[1]Dermatology, University of California, San Francisco, CA and [2]Edgewood CB Center, Aberdeen Proving Grounds, MD.*

The objective was to perform analysis on existent dermal absorption data on selected organophosphorus compounds including chemical warfare agents – sarin (GB), soman (GD) and VX – and develop a postulate of critical factors in observed regional differences in toxicant uptake/absorption by human skin. Body contours for skin absorption and lethality were developed. Parathion and malathion exposed head and neck region (x4), trunk (x3) and genital area (x12) absorb more chemical than arms and hands, and legs and feet. In field use, parathion has caused human death while malathion is considered safe. Permeability constants (Kp) (potential chemical absorbed through human skin per unit area and time) indexed to regional variation gives the mass of chemical absorbed through all regions of the human body. Human skin is more permeable to parathion than malathion. Further overlap of toxicity data to the construct showed lethality with parathion but not for malathion. VX has a high Kp and is also the most toxic; 50% lethality is reached not only for total systemic exposure but also for just trunk exposure in the first hour. In later hours, 50% lethality is reached when exposure is to any single region of the body. Sarin and soman are less toxic percutaneously than VX, and they have the same toxicity level. However, soman has greater skin absorption than sarin. Estimates of 50% lethality are only reached for sarin at the 24-hour exposure level, whereas the 50% lethality estimate for soman is reached in the first hour. Chemical warfare agents are a serious threat to human life. In order to minimize or prevent the hazard of these agents, we need to understand the way that these chemicals get onto and into the human body, both for military function and protection of life.

809 EVALUATION OF AN *IN VIVO* MODEL: HUMAN SKIN GRAFTED ON "NUDE" MICE TO PREDICT DERMAL ABSORPTION IN HUMAN.

A. P. Luzy[1], S. Diot[1], J. P. Marty[2] and N. Carmichael[1]. *[1]Experimental Toxicology, Aventis CropScience, Sophia-Antipolis, France and [2]Laboratoire de Dermopharmacologie, Faculte de Pharmacie, Chatenay-Malabry, France.*

Dermal absorption data from an *in vivo* model based on human skin grafted on "nude" mice were compared with data from human volunteer studies and two other models currently used (rat *in vivo* model and *in vitro* human skin model using diffusion cell) for three lipophilic chemicals. Results indicate that for lindane and cypermethrin dermal penetration and diffusion were similar for the human skin grafted on "nude" mice and diffusion cell models. For malathion, although similar diffusion was found in *in vitro* and grafted human skin, the amount remaining in *stratum corneum* (SC) was three times higher with diffusion cell model. Rat skin is more permeable than human skin independently of the human skin model used. Absorption through human skin in diffusion cell and human skin grafted on mice were two times higher than absorption in human volunteers. Inclusion of SC content in total absorbed dose would markedly overestimate absorption in human volunteers for malathion and cypermethrin. So, the fate of the high amount of cypermethrin in SC has been evaluated both with human skin grafted on mice and the rat *in vivo*. Four days after decontamination, 15.4% of cypermethrin was still present in SC of rat skin compared to only 2.5% in human skin grafted on "nude" mice. Further, results with human skin grafted on "nude" mice indicate that only one-third of the quantity of cypermethrin remaining in SC at the end of exposure period was absorbed while the remainder was presumably lost through desquamation. This work indicates that the diffusion cell using human skin is a good model for assessing absorption of chemicals. However for a lipophilic compound stored in *stratum corneum*, an *in vivo* model like the human skin grafted on "nude" mice may predict more accurately the level of absorption in human.

810 ALLERGEN-INDUCED CHANGES IN INTRACELLULAR EPIDERMAL TUMOR NECROSIS FACTOR α EXPRESSION.

S. Camus, M. Cumberbatch, R. J. Dearman and I. Kimber. *Immunology, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

Following topical exposure of mice to skin sensitizing chemicals, mRNA expression for a number of epidermal cytokines is upregulated, including that for tumor necrosis factor α (TNF-α). To measure directly intracellular TNF-α protein at the single cell level, a two-colour flow cytometric method for the detection of cytokine-producing keratinocytes and Langerhans cells (LC) prepared *ex vivo* from BALB/c strain mice has been developed. We report that the process of trypsinization of dorsal ear halves to prepare epidermal cell suspensions results in the production of TNF-α by the majority of keratinocytes, with the subsequent induction of other epidermal cytokines. However, the inclusion of monensin during epidermal cell preparation and fixation early in the isolation procedure with formaldehyde reduced significantly non-specific upregulation of TNF-α expression. Using this approach, permeabilization of epidermal cell suspensions with saponin and two-colour staining for a number of cytokines together with MHC class II revealed approximately 3-5% of keratinocytes derived from naive mouse skin to be positive for TNF-α. Under these conditions it was also found that a proportion of keratinocytes (approximately 20%) was associated with interleukin (IL)-6 and IL-12 expression, with approximately 40% exhibiting IL-10. At least 70% of LC were positive for intracellular IL-6 and IL-10, with only a minority population of LC displaying intracellular IL-12. Following topical application on the dorsum of both ears with the contact allergen oxazolone (Ox; 0.5%), enhanced intracellular TNF-α expression by a small proportion of keratinocytes, relative to vehicle treated mice, was observed within 30 minutes of exposure. Further increases of up to 10% in the frequency of keratinocytes positive for TNF-α were detected 1-4 hours following exposure to allergen. Taken together these data suggest that this technique provides a useful approach to the investigation of changes induced in epidermal cytokine expression as a result of skin sensitization.

811 EVALUATION OF THE DERMAL ABSORPTION OF METHYL ETHYL KETONE IN F344 RATS USING REAL-TIME BREATH ANALYSIS AND PBPK MODELING.

A. D. Woodstock and K. D. Thrall. *Molecular Biosciences, Battelle, Pacific Northwest Division, Richland, WA.*

Methyl ethyl ketone (MEK) is an industrial solvent found as a component of a variety of paints and coatings. Dermal exposure to MEK can result from the occupational or household use of paints and other commercial products. To understand the significance of these exposures, the dermal bioavailability of MEK was assessed in F344 male rats using a combination of real-time exhaled breath analysis and physiologically based pharmacokinetic (PBPK) modeling. Animals were exposed to MEK at a 5 mg/ml aqueous concentration using a 2.5-cm diameter occluded glass patch system attached to a clipper-shaved area on the back of the rat. Immediately following exposure the animal was placed in a glass off-gassing chamber and exhaled breath was monitored as chamber concentration in real time using an ion trap mass spectrometer (MS/MS). This real-time methodology was able to discern the uptake, peak concentration and clearance phases associated with the dermal exposure. For example, the exhaled breath profile clearly demonstrated the rapid absorption of MEK, with peak chamber concentrations ranging from 20 to 25 ppm observed within 30-60 minutes from the start of exposure. The PBPK model describing the exposure and off-gassing system was used to estimate a single dermal permeability coefficient to describe all the sets of exhaled breath data from n=6 animals. These rat studies using aqueous MEK will form the basis for comparing the dermal bioavailability of MEK in various paint products and may ultimately aid in understanding human health risk under a variety of exposure scenarios. (Supported by NIOSH 1-RO1-OH03658-01A2).

812 ASSESSMENT OF DERMAL IRRITATION OF THREE BENZENE SULFONATE COMPOUNDS.

B. H. Magee[1], C. H. Tay[2] and S. Craig[3]. [1]*AMEC Earth & Environmental, Westford, MA,* [2]*Toxikon, Corp., Bedford, MA and* [3]*Beazer East, Inc., Pittsburgh, PA.*

Three benzene sulfonate compounds are present in groundwater near a former disposal site at concentrations ranging from <1 mg/L to <500 mg/L. Dermal irritation studies were performed for each of the three sulfonate compounds to determine if they would cause irritation to the skin of persons using water containing the compounds for bathing, showering, or other uses where skin would be exposed. The three compounds are: (1) benzene sulfonate; (2) benzene meta-disulfonate; and (3) para-hydroxybenzene sulfonate. The studies were performed in accordance with USEPA's Health Effects Test Guidelines: OPPTS 870.2500, Acute Dermal Irritation, 1998. At the highest dose tested (5, 000 mg/L), all three sulfonate compounds were considered to be slight irritants, producing very slight to mild erythema. In all cases, the reactions were reversible. At the second highest dose tested (2, 000 mg/L), benzene meta-disulfonate and para-hydroxybenzene sulfonate caused no irritation and were considered not to be irritants. At the second highest dose only benzene sulfonate is considered a slight irritant, producing a mild erythema that was completely reversible within 24 hours. Benzene sulfonate is not considered an irritant at 1, 000 mg/L or at 500 mg/L. It is important to note that all three sulfonate compounds produced only a slight irritation at the highest dose tested. No compound produced edema or a severe irritation (i.e., severe erythema). Furthermore, all irritation responses at the highest dose tested were reversible within 72 hours, and the only irritation response observed at the second highest dose (2000 mg/l of benzene sulfonate) was reversible in less than 24 hours.

813 ASSESSMENT OF DERMAL PENETRATION OF THREE BENZENE SULFONATE COMPOUNDS.

T. A. Roy[1], B. H. Magee[2] and S. Craig[3]. [1]*Petrotec, Inc., Paulsboro, NJ,* [2]*AMEC Earth & Environmental, Westford, MA and* [3]*Beazer East, Inc., Pittsburgh, PA.*

Three benzene sulfonate compounds are present in groundwater near a former disposal site at concentrations ranging from <1 mg/L to <500 mg/L. Dermal penetration studies were performed for each of the three sulfonate compounds to determine if they would be systemically absorbed by persons using water containing the compounds for bathing, showering, or other uses where skin would be exposed. The three compounds are: (1) benzene sulfonate (BSA); (2) benzene meta-disulfonate (BDSA); and (3) para-hydroxybenzene sulfonate (HBSA). The dermal penetration studies with infinite doses of 2, 000 mg/L aqueous solutions were performed *in vitro* for 24 hours with human abdominal skin using Franz diffusion cells with 0.9% saline solution as receptor fluid. Each compound was tested with six skin samples from a minimum of three donors. The integrity of human skin was tested with 3H-water before use. Aliquots of receptor fluid were analyzed for the presence of the test compounds using ion-pairing reverse phase high performance liquid chromatography (HPLC) and ultraviolet absorption. HPLC conditions were 53:47, 25 mM tetrabutylammonium bromide:methanol (isocratic). Analytical wavelengths were 263, 267 and 271 nanometers for BSA, BDSA and HBSA, respectively. No sulfonate compounds were detected in the receptor fluid at 24 hours in any of the test cells. The Estimated Quantitation Limit (EQL) for all compounds was determined to be 0.5 ng/ul. Assuming that the compounds were present at one-half the EQL, the permeability constants, Kp, were 2E-05 cm/hour. The results of this study confirm the results of a pilot study performed using the same methods but different chromatographic conditions.

814 MECHANISMS OF UVB LIGHT-INDUCED SUPPRESSION OF NITRIC OXIDE PRODUCTION IN MURINE KERATINOCYTES.

R. Sur[1], T. M. Mariano[1], D. E. Heck[2] and J. D. Laskin[1]. [1]*Environmental and Community Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and* [2]*Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.*

Ultraviolet light of high energy and shorter wavelengths (UVB, 290-320 nm) is utilized therapeutically to reduce irritation in inflammatory dermatosis. The mechanisms underlying the actions of UVB are unknown. We hypothesize that the UVB light suppresses oxidant generation in the skin. Nitric oxide is a highly reactive oxidant generated by keratinocytes by an inducible form of nitric oxide synthase (NOS2) in response to the inflammatory cytokine, gamma interferon. In the present studies we examined the effects of UVB light on NOS2 activity in keratinocytes. We found that UVB light suppresses gamma-interferon-induced nitric oxide production in these cells. This effect was dose-dependent in the range of 2.5-25 mJ/cm^2. This was found to be due to inhibition of NOS2 mRNA and protein expression in the cells, as determined by RT-PCR and western blotting, respectively. Two transcription factors known to be important in regulating expression of NOS2 are signal transducer and activator of transcription-1 (STAT-1) and nuclear factor κB (NF-κB). Using electrophoretic mobility shift assays, we found that gamma interferon readily induced STAT-1 activity while NF-κB was constitutively expressed in the cells. UVB light (25 mJ/cm^2) was found to cause a 30-40% reduction in the activation of these transcription factors. Nuclear translocation of the p50 and p65 subunits of NF-κB was also marked reduced by UVB light. Taken together, our data suggest that UVB light functions to suppress expression of NOS2 by inhibiting activation of key transcription factors important in regulating expression of the NOS2 gene. Decreased expression of NOS2 and subsequent nitric oxide production in keratinocytes may be an important mechanism for the anti-inflammatory and therapeutic actions of UVB light. Supported by NIH grant ES 06897.

815 THE EFFECTS OF CHRONIC ALCOHOL CONSUMPTION ON DERMAL PENETRATION OF PESTICIDES.

R. M. Brand, A. Charron, L. Dutton, C. Mueller and T. L. Hannah. *Biological Systems Engineering, University of Nebraska, Lincoln, NE.* Sponsor: P. Iversen.

The skin is the major source of xenobiotic exposure in occupational settings. Topically applied ethanol is commonly used as a dermal penetration enhancer. The hypothesis of this work is that ethanol, consumed orally, will also behave as a dermal penetration enhancer. A series of four pesticides, paraquat (MW = 257, log K_{ow} = -4.5), 2, 4 D (MW = 221, log K_{ow} = 2.8), atrazine (MW = 216, log K_{ow} = 2.3) and trifluralin (MW = 335, log K_{ow} = 5.1) were selected as model compounds to test this hypothesis. These compounds were chosen for their diverse octanol water partition coefficients (K_{ow}), a factor known to influence percutaneous penetration. Male Wistar rats were fed a diet of 36% ETOH (25 mM in blood) or control in a liquid diet for 4-8 weeks. The animals were then sacrificed, their skin shaved, removed and placed in an *in vitro* Bronaugh Style flow through diffusion chamber. The test compound was spiked with ^{14}C labeled pesticide and placed on the epidermis for 24 hours. Buffer flowing past the dermal side of the skin was collected in 90-minute fractions and counted *via* liquid scintillation. Chronic ethanol consumption significantly enhanced dermal penetration for the three most hydrophilic compounds tested ($p<0.05$). The penetration of trifluralin, the most hydrophobic pesticide, was inhibited by chronic ethanol consumption ($p<0.05$). A regression analysis demonstrates a correlation between hydropholicity and enhancement of transdermal penetration by chronic ethanol consumption. Chronic ethanol consumption, therefore, leads to compromised dermal barrier in rats resulting in increased penetration of pesticides. These studies imply that alcoholic workers have greater dermal exposure of chemicals than previously estimated.

816 TRANSCRIPT PROFILING OF MURINE LYMPH NODE CELLS : ALLERGEN-INDUCED EARLY GENE CHANGES.

C. J. Betts[1], J. G. Moggs[1], H. Caddick[1], M. Cumberbatch[1], G. Orphanides[1], R. J. Dearman[1], G. F. Gerberick[2], C. A. Ryan[2] and I. Kimber[1]. [1]*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom and* [2]*The Procter & Gamble Company, Cincinnati, OH.*

In order to identify early events induced in lymphoid tissue following topical treatment of mice with contact allergen, gene expression changes in draining lymph node cells (LNC) have been profiled using DNA microarrays. BALB/c strain mice

were exposed topically to the potent skin sensitizer 2, 4-dinitrofluorobenzene (DNFB; 0.5%) on the dorsum of both ears. Control mice were exposed to vehicle (4:1 acetone:olive oil) alone. At 18 or 48 hours post-exposure, draining LNC were isolated and the mRNA prepared. Radiolabelled cDNA probes were generated from mRNA samples and hybridized to in-house nylon microarray filters comprising of 8734 murine gene sequences arrayed in duplicate (3336 assigned to known genes, 5398 expressed sequence tags [ESTs]). Changes in gene expression were calculated as the ratio of values for LNC isolated from DNFB-treated animals compared with LNC from concurrent controls (changes of 1.5 fold or greater were considered significant). At 18 hours post-exposure, the expression of more than 95% of represented genes was unchanged by DNFB treatment. However, a number of consistently down-regulated genes was identified, including several ESTs and glycosylation-dependent cell adhesion molecule 1 (GlyCAM-1). Further analysis of tissue sampled 48 hours after exposure to DNFB provided examples of both up- and down-regulated genes including onzin and guanylate binding protein-2, and GlyCAM-1 respectively. Induced changes in these three genes were confirmed over a more extensive time course (18 to 120hr) using Northern blotting and/or RT-PCR analyses, indicating that changes in gene expression of GlyCAM-1, onzin and possibly GBP-2 are robust markers of early changes in the lymph node provoked by contact allergen. In subsequent experiments the selectivity of these markers for contact allergens will be investigated.

817 SUBCHRONIC TOXICITY OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) OBEYS HABER'S C X T RULE AFTER ORAL ADMINISTRATION.

M. Lebofsky[1], C. R. Croutch[1] and K. K. Rozman[1,2]. [1]*Pharmacology, Toxicology and Therapeutics, KU Medical Center, Kansas City, KS and* [2]*Section of Environmental Toxicology, GSF-Institut fur Toxikologie, Neuherberg, Germany.*

Groups of 8 to 11 A/J mice were administered a loading dose of 100, 150 or 200 microg/kg of TCDD followed by weekly maintenance doses of 15.0, 22.5, or 30 microg/kg by gavage in corn oil. A positive control group (n=10) received a single dose of urethane (1 mg/g). All positive control mice developed by 4 months after dosing adenocarcinomas of the lung. None of the TCDD-treated animals developed adenocarcinomas of the lung by 6 months after initial dosing. On day 76 the first mouse died in the highest dose group and on day 226 the last mouse died in the lowest dose group of nonspecific subchronic toxicity. Mean time to deaths were 178 ± 7.9 (S.E.), 137 ± 7.6 and 116 ± 7.3 days for the 100, 150 and 200 microg/kg initial dose groups, respectively. The c x t products for the respective dose groups were 83.3 ± 7.1, 78.1 ± 6.9 and 77.7 ± 8.2 microg•day. The hypothesis that TCDD will cause adenocarcinomas in A/J mice without initiation has been refuted. However, under conditions of kinetic steady state once again the fundamental law of toxicity emerged with a mere 1.8% variability in still another species. This experiment provides further support for the notion that Haber's rule is not limited to inhalation but is generalizable for all studies conducted under conditions of kinetic steady state.

818 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) EXPOSURE OF MALE MOUSE UROGENITAL SINUS IN EXPLANT CULTURE IMPAIRS PROSTATIC BUD FORMATION.

D. C. Upton, T. M. Lin, N. T. Rasmussen and R. E. Peterson. *School of Pharmacy, Univ. of Wisconsin, Madison, WI.*

in utero TCDD exposure on Gestation Day (GD) 13 impairs prostatic bud formation from the urogenital sinus (UGS) of the C57Bl/6J mouse fetus on GD 18. Our objectives were to determine: (1) if the inhibitory effect of TCDD on prostatic bud formation following *in vivo* exposure also could be produced by *in vitro* exposure of GD 14 UGS explants in organ culture for 5 days to TCDD, and (2) whether the inhibition of budding, if observed, was AhR-dependent. Prostatic bud formation from the fetal mouse UGS is androgen-dependent. On GD 14 the UGS from wild-type and AhR knock-out (AhRKO) C57Bl/6J male fetuses were removed and cultured in 5% charcoal-dextran stripped FBS supplemented with either vehicle (Control), 10^{-8} M testosterone (T), or 10^{-8} M testosterone and 10^{-9} M TCDD (T+TCDD). Media were changed every 48 hr. UGS explants were harvested after 5 days in culture and examined for prostatic bud formation by scanning electron microscopy. In Control UGS explants derived from both wild type and AhRKO fetuses only 2 dorsolateral buds and no ventral buds were observed. This lack of prostatic bud formation was expected and is consistent with previous studies showing that this is an androgen-dependent process. Thus, in the absence of androgen stimulation virtually no buds were observed in either of the two Control groups (wild type and AhRKO). Supplementation of the culture medium with T caused formation of DLBs and VBs in explants of both genotypes, wild type and AhRKO. In UGS explants exposed to T+TCDD the effect on budding was genotype-dependent. In wild type UGS explants exposed to T+TCDD prostatic bud formation resembled that of Control wild type UGS explants that received no androgen stimulation. On the other hand, UGS explants obtained from AhRKO fetuses and exposed to T+TCDD were similar to UGS explants obtained from AhRKO fetuses exposed to T only. Collectively these results demonstrate that TCDD can act directly on the UGS to disrupt prostatic bud formation by a mechanism that is AhR-dependent. (NIH grant ES01332)

819 ALTERED SENSITIVITY OF THE MOUSE FETUS TO IMPAIRED PROSTATIC BUD FORMATION BY DIOXIN: INFLUENCE OF GENETIC BACKGROUND AND NULL EXPRESSION OF TGFα AND EGF.

N. T. Rasmussen[1], T. M. Lin[1], S. E. Fenton[2], B. D. Abbott[2] and R. E. Peterson[1]. [1]*School of Pharmacy, Univ. of Wisconsin, Madison, WI and* [2]*USEPA, Reproductive Toxicology Division, NHEERL, Research Triangle Park, NC.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) inhibits prostatic bud formation from the urogenital sinus in the C57Bl/6J mouse fetus. Knock-out EGF (EGFKO), TGFα (TGFαKO), and EGF+TGFα (EGFKO/TGFαKO) mice were used to investigate the roles of EGF and TGFα in the impairment of prostatic budding by TCDD. The EGFKO and EGFKO/TGFαKO mice share a "mixed" genetic background of the 129 and C57Bl/6J strains; whereas genetic background of TGFαKO mice resembles the C57Bl/6J strain. Compared to the wild-type C57Bl/6J strain (WT), wild-type mice of the "mixed" genetic background (WT-m) required about 100 times more TCDD to produce an equivalent inhibitory effect on prostatic budding following *in utero* TCDD exposure. On gestation day (GD) 12, timed pregnant WT and TGFαKO dams were dosed with 0, 0.2, and 1 μg TCDD/kg and dams producing WT-m, EGFKO, and EGFKO/TGFαKO offspring were dosed with 0, 1, 10, 50, 100, or 150 μg TCDD/kg. Essentially complete agenesis of ventral buds (VBs) and a reduction in dorsolateral bud (DLB) numbers were observed in 1 μg/kg TCDD-exposed WT and TGFαKO fetuses on GD 17.5, suggesting that the absence of TGFα does not affect responsiveness to TCDD. WT-m fetuses showed no inhibition of budding at 1 μg TCDD/kg, but at 50 μg/kg and higher doses of TCDD there were dose-related reductions in VB and DLB number. The 10 μg TCDD/kg EGFKO group showed an inhibition of VB and DLB formation similar to the 150 μg TCDD/kg WT-m group. EGFKO and EGFKO/TGFαKO groups treated with 150 μg TCDD/kg showed agenesis of VBs and nearly complete agenesis of DLBs. Sensitivity to TCDD-induced impairment of prostatic budding is enhanced in EGFKO and EGFKO/TGFαKO fetuses. Thus, null expression of EGF appears to increase sensitivity of TCDD-inhibited prostatic bud formation. (Supported by USEPA and NIH grant ES01332)

820 PROTECTION BY VITAMIN E SUCCINATE OF TCDD-INDUCED OXIDATIVE STRESS IN RATS.

E. Hassoun and A. Abu Mahfouz. *Pharmacology, The University of Toledo, Toledo, OH.*

TCDD is known to induce oxidative stress in hepatic, as well as brain tissues of rats after acute, subchronic and chronic exposures. In this study we demonstrate that subacute treatment of rats with TCDD can also induce oxidative stress in the same tissues, and that vitamin E succinate can provide protection against this effect. Animals were randomly assigned to four different groups, including a control (C), TCDD-treated (T-treated), vitamin E succinate-treated (E-treated) and TCDD plus vitamin E-treated (T + E-treated) group. All treatments were given by gavage, daily for 30 days. The T- treated group received 100 ng TCDD/kg/day, while the E-treated group received Vitamin E-succinate at doses of 150 mg/kg/day for the first three days, followed by doses of 40 mg/kg/day for 27 days. However, The T + E-treated group received combined dose regimens of the forementioned T- and E-treated groups, and control group received corn oil vehicle used to dissolve TCDD and vitamin E succinate . Animals were sacrificed at the end of the treatment period and brain and hepatic tissues were assayed for various biomarkers of oxidative stress including production of superoxide anion (SA), lipid peroxidation (LP) and DNA damage. While subacute treatment with TCDD produced significant production of SA and LP, with significantly more effects produced in hepatic as compared with brain tissues, it didn't produce significant DNA damage in either tissues. The results also indicate that vitamin E-succinate provided significant protection against TCDD-induced SA and LP production in hepatic and brain tissues, with significantly more protection provided in brain as compared with hepatic tissues.

821 LOW DOSE PRENATAL DIOXIN EXPOSURE IN RATS INDUCES SEXUALLY DIMORPHIC CHANGES IN OPERANT BEHAVIOR AND BRAIN MORPHOLOGY.

R. Hojo[1], S. Stern[1], G. Zareba[1], R. Baggs[1], C. Cox[2], J. Kost[2], V. Markowski[3], J. W. Kai[1] and B. Weiss[1]. [1]*Department of Environmental Medicine, U of Rochester, Rochester, NY,* [2]*Department of Biostatistics, U of Rochester, Rochester, NY and* [3]*Department of Psychology, U of Southern Maine, Portland, ME.*

Prenatal exposure to high doses of dioxin(TCDD;2, 3, 7, 8-tetrachloro- dibenzo-*p*-dioxin) induces changes in motor activity and cognitive and sexual behavior. In an earlier study, prenatal exposure in rats to a single low dose of TCDD on gestational

day 18 (GD18) produced a significant dose-related reduction in wheel running operant behavior. In addition, a quantitative study of brain morphology showed that TCDD also altered normal patterns of sexually dimorphic asymmetries in cortical thickness. The current study examined exposure to low, environmentally relevant levels of TCDD at an earlier stage of gestation. It employed two endpoints: schedule-controlled operant behavior based on lever-pressing for food reinforcement, and cell counts in selected areas of cerebral cortex. Pregnant Spraque-Dawley rats were given a single p.o. dose of 0, 20, 60 or 180 ng TCDD/kg on GD 8. Male-female pairs of offspring 90 days old from all dose groups were trained on two operant procedures: (1) an incremental fixed ratio (FR) schedule, and (2) a multiple FR/differential reinforcement of low rate schedule (mult FR/DRL). TCDD evoked sexually dimorphic response patterns in both procedures. Exposed males responded at lower rates than male controls, while exposed females responded at higher rates than their controls. Cortical cell counts from areas 17, 18a and 39 in bregma -3.9 from offspring exposed to 180 ng/kg, the only dose examined so far, exhibited significant reversal of hemispheric dominance in both males and females. These data demonstrate that prenatal exposure to low environmental doses of TCDD evokes sexually dimorphic patterns of operant behavior and cortical asymmetry in a manner consistent with previous reports. (Funded by ES08958 and ES01247 from NIEHS.)

822 EFFECTS OF TCDD, 2, 3, 4, 7, 8-PCDF AND PCB 126 ON ESTROGEN HYDROXYLATION IN MALIGNANT (MCF-7) AND BENIGN (MCF-10A) HUMAN MAMMARY TUMOR CELLS.

M. B. van Duursen, J. T. Sanderson and M. van den Berg. *Institute for Risk Assessment Sciences (IRAS), Universiteit Utrecht, Utrecht, Netherlands.*

Mounting evidence suggests a role for estrogen metabolites in the etiology of breast cancer. In human breast tissue, estrogens are mainly hydroxylated by cytochrome P450 1A1 (CYP1A1, estrogen 2-hydroxylase) and P450 1B1 (CYP1B1, estrogen 4-hydroxylase). In several studies, the 4-hydroxylated but not the 2-hydroxylated metabolites of estrogens were found to be carcinogenic. This study investigated the effects of several dioxin-like compounds on estrogen hydroxylase activity in human mammary tumor cell lines MCF-7 (adenocarcinoma) and MCF-10A (fibrocystic disease). Cell cultures were exposed to various concentrations of 2, 3, 7, 8-TCDD, 2, 3, 4, 7, 8-PCDF or PCB 126. After 72 hours the media were replaced with media containing 1 µM estradiol. Estrogen 2- and 4-hydroxylase activities were determined by measuring 2- and 4-methoxylated estrogen levels by GC/MS. Both the constitutive and induced estrogen hydroxylase activities were lower in MCF-10A than in MCF-7 cultures. This was also true for ethoxyresorufin O-deethylase (EROD) activity in both cell lines. In MCF-7 cells, estrogen metabolism was induced in a dose-dependent manner with relative potencies in the order TCDD ≡ PCDF > PCB 126, conform the WHO TEF values. Induction of estrogen metabolism was mainly attributed to induction of 2-hydroxylation of estradiol. In MCF-10A cells, only TCDD induced estrogen metabolism markedly, while PCDF and PCB 126 appeared to have only a moderate inductive effect. Induction of estrogen metabolism by TCDD mainly resulted in elevated levels of both 4- and 2-hydroxylated metabolites of estrone. These data suggest a difference in response to dioxin-like compounds between malignant and benign mammary tumor cell lines. Studies on the effects of several other dioxin-like compounds on estrogen metabolism and mRNA levels of CYP1A1 and CYP1B1 in MCF-7 and MCF-10A cells are in progress.

823 TCDD-INDUCED ABNORMAL DEVELOPMENT OF PAWS IN TCDD-RESPONSIVE LACZ TRANSGENIC MICE.

N. F. Alejandro, D. A. Nazarenko and T. A. Gasiewicz. *Environmental Medicine, University of Rochester, Rochester, NY.*

The aryl-hydrocarbon Receptor (AhR) is a ligand-dependent transcription factor that mediates the toxicity of halogenated aromatic hydrocarbons including 2, 3, 7, 8-tetra-chlorodibenzo-*p*-dioxin (TCDD). These compounds are potent reproductive and developmental toxicants due to their ability to modulate gene expression and cellular differentiation/proliferation. Determination of tissue-specific AhR transcriptional activity *in vivo* will allow the identification of tissues/cells where the AhR may have some functional role susceptible to disruption by TCDD exposure. We have developed a transgenic mouse model containing an AhR-responsive reporter that can delineate the temporal and spatial context of active AhR in a cell-/region-specific manner. This model has identified several targets tissues during gestational days (GD) 13 to 16 including the lung, liver, genital tubercle, and paws after 24h TCDD exposure. Most transgene induction is in tissue that have been previously identified as target tissues, with the exception of the paw, a novel target. We hypothesize that TCDD-induced AhR activity in developing paws of mice is associated with alterations in gene expression and aberrant development. Pregnant females were exposed to TCDD (30 µg/kg) on GD 14. Twenty-four hours later and on post-natal day (PND) 2 pups were evaluated at a morphological and gene expression level. Significant differences were identified upon morphometric analysis of the paw at PND 2 in both epithelial cell layer and digit thickness, with TCDD exposed tissues being increased in both cases. Preliminary microarray analysis identified novel genes as well as known dioxin-responsive genes (e.g. CYP1B1) in the paws of day 15 embryos that were affected by TCDD exposure. The results indicate that the model is capable of detecting AhR activation, thus allowing the identification of developmental cell and gene targets of TCDD. (Funded by NIH grant ES0943, Training grant 07026, and Center grant 01247).

824 EFFECT OF TCDD ON THE SURVIVAL OF BONE MARROW-DERIVED DENDRITIC CELLS *IN VITRO.*

C. J. Funatake[1], C. E. Ruby[1] and N. I. Kerkvliet[1,2]. [1]*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and* [2]*Environmental Health Science Center, Oregon State University, Corvallis, OR.*

Previous studies in our laboratory have shown that an immunosuppressive dose of TCDD, in the absence of antigen, activates splenic dendritic cells (DC) *in vivo*. However, recovery of DC was subsequently reduced approximately 40%. We hypothesized that TCDD sensitizes DC to Fas-mediated apoptosis. To demonstrate a TCDD effect on DC survival, we used an *in vitro* bone marrow-derived dendritic cell (BMDC) model. On day 0, cells from the bone marrow of femurs from C57Bl/6 mice were cultured in media containing 20% FBS and GM-CSF for 6 days. TNF-α was added on day 6 to generate a mature DC phenotype. On day 7, media and cytokines were removed and replaced with media containing 5% FBS and vehicle or TCDD. On day 8, agonistic anti-Fas (Jo-2) or control IgG antibodies were added to the cultures. On day 9, the cells were assayed for apoptosis using Annexin V and 7-AAD and analyzed using flow cytometry. In separate experiments, TCDD alone increased apoptosis or enhanced the degree of apoptosis induced by Fas ligation. In all experiments, the highest degree of apoptosis was seen when TCDD (10^{-8} M) and anti-Fas were combined. In order to determine if the increase in apoptosis was due to increased levels of Fas on the cell surface, we looked at the level of Fas expression on BMDC by flow cytometry. We found no difference in Fas expression between vehicle- and TCDD-treated cells, suggesting that TCDD may alter intracellular signaling pathways leading to apoptosis. Further studies are necessary to determine if the relationship between TCDD and Fas signaling is additive or synergistic. Supported by NIH Grants P01 ES00040 and P01 ES07060.

825 TIME-DEPENDENCE OF TCDD- AND HXCDD-INDUCED CYP 1A1 EXPRESSION AS MEASURED BY EROD ACTIVITY, WESTERN AND NORTHERN BLOTS.

C. R. Croutch[1], M. Lebofsky[1], A. DeZoysa[1,3], D. S. Son[1], K. W. Fried[1] and K. K. Rozman[1,2]. [1]*Pharmacology, Toxicology and Therapeutics, KU Medical Center, Kansas City, KS,* [2]*Section of Environmental Toxicology, GSF-Institut fur Toxikologie, Neuherberg, Germany and* [3]*Moravian College, Bethlehem, PA.*

Female Sprague-Dawley rats (~250 g - Harlan) were housed in large polycarbonate cages with hardwood bedding. Feed and water were provided ad libitum to all animals. Rats were given a loading dose of either 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) or 1, 2, 3, 4, 7, 8-hexachlorodibenzo-*p*-dioxin (HxCDD) in corn oil *via* oral gavage (five animals per treatment group); controls were dosed with vehicle alone. In addition, animals were administered maintenance doses of TCDD or HxCDD every third or ninth day, respectively, to maintain pharmacokinetic steady state. Three iso-effective doses of TCDD/HxCDD (0.0125/0.3125, 0.05/1.25, or 0.2/5 microg/kg) were selected based on their toxic equivalence. Rats were terminated 2, 8, 32, or 64 days after receiving the loading dose. Livers were removed, weighed and snap frozen in liquid nitrogen. TCDD caused a dose- and time-dependent induction of EROD activity. There was about a 100-fold increase in EROD activity at constant time (day 2) and about an additional 5-fold increase at constant dose (day 64). The same samples that were used to measure EROD activity were also analyzed for CYP 1A1 mRNA and protein by Northern and Western blotting, respectively. For Western blots, a rabbit anti-rat CYP1A1 polyclonal antibody from XenoTech (Kansas City, KS) was used. Murine CYP1A1 cDNA was obtained from ATCC for use in Northern blots. Semi-quantitation of Western and Northern blot results were obtained using Gel Pro image analysis. Both CYP 1A1 mRNA and protein increased in a time-dependent manner in both the TCDD- and HxCDD-treated rat livers, in agreement with the induction of EROD activity. The CYP1A1 protein induction was approximately 2-fold between 32 and 64 days at constant dose; there was a greater (approximately 8 fold) increase in EROD activity in the same samples.

826 DIOXIN IMPAIRS OSMOREGULATION IN THE ZEBRAFISH LARVA.

S. M. Bello, W. Heideman and R. E. Peterson. *School of Pharmacy, University of Wisconsin, Madison, WI.*

The most prominent sign of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) developmental toxicity in the zebrafish larva is edema. However, the cause of the edema and its relation to the other signs of TCDD toxicity in zebrafish is unknown. One

possibility is that the edema results from impaired osmoregulation, which allows water to move into the larva. To test this hypothesis, the osmolality of the water in which TCDD-exposed embryos underwent development was increased with the addition of 250 mM mannitol. Accordingly, embryos were exposed for 1 hr to vehicle or 10 ng TCDD/ml (LC100 dose) within 4 hours post fertilization (hpf). Embryos from the vehicle and TCDD groups, respectively, were then maintained throughout development in water either with or without osmotic support. Larvae from the 4 groups were examined for signs of toxicity at later stages of development. Increasing external osmolality had no significant effect on the incidence or severity of pericardial edema at 100 hpf, suggesting that this early stage of pericardial edema is not secondary to impaired osmoregulation. In contrast, osmotic support significantly reduced the incidence of pericardial edema in TCDD-exposed embryos at 130 hpf when compared to larvae without osmotic support and this protective effect was maintained through 150 hpf. Increasing external osmolality had an even greater protective effect against yolk sac edema than pericardial edema at 130 and 150 hpf when compared to that of larvae exposed to TCDD without osmotic support. In addition, there was a striking reduction in the severity of yolk sac edema and a less dramatic decrease in the severity of late stage pericardial edema in TCDD-exposed larvae with osmotic support. Osmotic support had no effect on either the incidence or severity of other endpoints of TCDD toxicity (reduced lower jaw length and decreased blood flow). Taken together, these results demonstrate that TCDD-induced yolk sac edema and late stage pericardial edema in the zebrafish larva are associated with impaired osmoregulation. (UW Sea Grant)

827 EFFECTS OF *IN UTERO* / LACTATIONAL EXPOSURE TO TCDD ON BONE IN RATS.

M. Viluksela[1], T. Jämsä[2], H. M. Kattainen[1], U. Simanainen[1], J. T. Tuomisto[1], J. Tuomisto[1] and J. Tuukkanen[3]. *[1]Department of Environmental Health, National Public Health Institute, Kuopio, Finland, [2]Department of Medical Technology, University of Oulu, Oulu, Finland and [3]Department of Anatomy and Cell Biology, University of Oulu, Oulu, Finland.*

We have previously shown that TCDD treatment alters bone geometry and decreases mechanical strength in adult rats. In this study bone geometry, mineral density and mechanical strength were examined in rats exposed to TCDD *in utero* / lactationally. Pregnant female rats of TCDD sensitive line C were given a single oral dose of TCDD (0, 0.03, 0.1, 0.3 or 1 μg/kg) on gestational day 15, and female offspring examined on postnatal day 35. Tibial and femoral diaphysis was scanned using a peripheral quantitative computed tomography (pQCT) system. Mechanical properties of tibial and femoral shaft and femoral neck was assessed using three-point bending test and axial loading, respectively. Body weights of offspring were slightly decreased at the highest dose-level only. Tibial and femoral length, as well as diaphyseal cortical and medullary cross-sectional areas were significantly decreased. In addition, cortical mineral density and polar moment of inertia were decreased. Some of these changes were dose-dependent, but reached statistical significance only at 1 μg/kg TCDD. Biomechanical testing revealed significantly decreased bending breaking force and bending stiffness of tibial and femoral shaft, and femoral neck. These changes were only seen at the highest dose level. The results indicate that bone is a sensitive target of dioxin toxicity, and that pre- and neonatal rats are clearly more sensitive to the bone effects than adult rats. (Supported by the Academy of Finland, the Finnish Research Programme on Environmental Health, Project 42551, and the European Commission, Contract QLK4-CT-1999-01446)

828 ADULT TCDD EXPOSURE AND EFFECTS ON MALE REPRODUCTIVE ORGANS IN THREE DIFFERENTIALLY TCDD SENSITIVE RAT LINES.

U. Simanainen[1,2], H. Kattainen[1,2], A. Adamsson[3], J. Tuomisto[1,2], J. Toppari[3] and M. Viluksela[1]. *[1]Laboratory of Toxicology, National Public Health Institute, Kuopio, Finland, [2]University of Kuopio, Kuopio, Finland and [3]Dept of Physiology, University of Turku, Turku, Finland.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) exposure during adulthood is known to cause adverse reproductive effects. The exceptional resistance of Han/Wistar (Kuopio; H/W) rats to acute lethality of TCDD is dependent on two different genes: the H/W-type mutated Ahr^{hw} and the other unknown B^{hw}. The resistance genes are separately expressed in three rat lines; line A (Ahr^{hw} alleles), line B (B^{hw} alleles) and line C (no resistance alleles). Some AHR-mediated effects (e.g. EROD) are insensitive (type 1 effects) to the alterations in resistance genes, while some (e.g. lethality) are sensitive (type 2 effects). To better understand the role of the resistance genes in TCDD toxicity, the significance of these genes in TCDD-caused reproductive defects were analyzed. Adult male rats were given a single oral dose of TCDD at 0-1000 μg/kg (line A), 0-300 μg/kg (line B), and 0-30 μg/kg (line C). Rats were killed and testes, epididymis, ventral prostate (VP) and seminal vesicles (SV) were collected and weighed. Cauda epididymis was weighed separately and frozen for sperm counts. Serum testosterone levels were analyzed using RIA / FIA. TCDD doses were high enough to decrease the body weights in each line. Relative organ weights were not affected in line C rats, but VP and SV weights were decreased in line A and line B rats at the highest doses. Cauda epididymal sperm reserves were significantly decreased at 100-1000 μg/kg TCDD in line A and B rats, and at 10-30 μg/kg in line C rats. Serum testosterone levels were decreased in line A (100-1000 μg/kg) and line C (30 μg/kg) rats. As line C rats were most sensitive to many of the studied reproductive endpoints, the resistance alleles Ahr^{hw} and B^{hw} seem to increase the resistance of adult males to these TCDD-induced reproductive defects. (Academy of Finland, Project 42551 and European Comission Contract QLK4-CT-1999-01446)

829 RELATIONSHIP OF TISSUE DOSE OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) TO REVERSIBLE BIOLOGICAL RESPONSES.

J. J. Diliberto, M. DeVito and L. S. Birnbaum. *ORD/NHEERL, USEPA, Research Triangle Park, NC.*

Exposure to TCDD and dioxin-like chemicals causes a wide range of adverse effects that can be produced regardless of exposure route and time, but may vary with administered (admin) dose. Dose is uncertain in humans; therefore, appropriate dosemetrics and effects derived from animal data are important for risk assessment. To test the hypothesis: tissue concentration (conc) is a useful dosemetric for reversible biochemical changes, female B6C3F1 mice were acute (ac) or subchronic (sub) dosed with [3H]TCDD at graded doses and times. Livers were removed; TCDD conc, EROD & ACOH (markers for CYP1A1 & 1A2, respectively) were determined. The Hill model was fit to enzymatic data using admin dose, daily dose or tissue conc as dosemetric. When ac or sub EROD or ACOH data were analyzed separately, using total admin or daily dose showed adequate fits to the data ($R>0.75$). When ac and sub EROD or ACOH data were analyzed together, using total admin or daily dose as dosemetric did not provide an adequate description of a Dose-Response (DR) relationship for either endpoint examined. Using TCDD tissue conc as dosemetric resulted in similar DR relationships when ac or sub EROD and ACOH data were analyzed separately or combined. When tissue conc was used as dosemetric, fits resulted in $R>0.88$ and $p<0.0001$ for all data sets analzyed. When the Hill model was fit to: EROD data, ED50s were estimated at 60±10, 20±2.58 and 37±4.5 ng TCDD/g tissue for sub, ac and combined, respectively; to ACOH data, ED50s were estimated at 7.6±0.44, 1.7±0.28 and 4.4±0.78 for sub, ac and combined, respectively. The Hill shape parameter indicates that when tissue dose is used as dosemetric, DR curves are supralinear. While estimates of ED50s were similar, ED50 was slightly higher (2-3 fold) in sub studies compared to ac studies. These studies demonstrate tissue conc is a useful dosemetric for describing DR relationships for reversible biochemical responses to dioxins. (This abstract does not reflect USEPA policy.)

830 17 β-ESTRADIOL METABOLISM AND EROD ACTIVITY IN RAT LIVER AND LUNG AS BIOMARKERS OF CHRONIC EXPOSURE TO TCDD AND RELATED COMPOUNDS.

D. E. Shubert, L. H. Chi, D. C. Manns and J. R. Olson. *Pharmacology/Toxicology, University at Buffalo, Buffalo, NY.*

The expression of cytochrome P450 1A1 (CYP1A1) and cytochrome P450 1B1 (CYP1B1) represents sensitive biomarkers of exposure to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) and related halogenated aromatic hydrocarbons (HAHs). CYP1A1 mediated ethoxyresorufin O-deethylase (EROD) and estradiol metabolism were assessed in liver and lung microsomes from female Sprague-Dawley rats following 13 weeks of daily oral (gavage) exposure to TCDD, 2, 3, 4, 7, 8-PeCDF, PCB 126, or PCB 153. Estradiol 4-hydroxylase (4-OHE2) activity, a marker of human CYP1B1 expression, is currently being evaluated as a marker of rat CYP1B1 expression. In addition, estradiol 2-hydroxylase (2-OHE2) activity was measured because of its significant role in estradiol metabolism. TCDD exposure produced a dose related increase in these three activities which, with the exception of 2-OHE2 in liver, were significantly increased at an exposure of 3 ng/kg/d. Tissue-specific differences were noted with lung showing a greater fold induction in 4-OHE2 and 2-OHE2 activities, while liver displayed a greater increase in EROD activity. With the exception of PCB153 (TEF=0), each of the HAHs increased EROD, 4-OHE2, and 2-OHE2 activities in a dose-related manner, which generally supports the current Toxic Equivalency Factors (TEFs) for these compounds. Dose-response relationships following tertiary (TCDD, PeCDF, PCB 126) and binary (PCB 126, PCB 153) exposures at 13 weeks also support the additive activity of these agents, based on the current TEFs for these HAHs. These studies were carried out using tissues provided to us by the National Toxicology Program as part of a series of chronic 2-year rat bioassays examining the relative carcinogenic potencies of dioxin-like compounds. Following completion of the cancer studies, it will be

possible to establish whether tissue-specific biomarker responses are related to the tissue-specific carcinogenic potency of these agents. (Supported in part by NIEHS ES09440, USEPA R825808)

831 ZEBRAFISH FIN REGENERATION AS A MODEL FOR DEVELOPMENTAL TOXICITY OF 2, 3, 7, 8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD).

J. M. Zodrow and R. L. Tanguay. *School of Pharmacy, University of Colorado Health Sciences Center, Denver, CO.*

Adult zebrafish completely regenerate their caudal fins following amputation. Fin regrowth can easily be followed *in vivo* and the new tissue can be used to study developmental processes. 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is known to cause toxicity through the AhR pathway, binding to AhR allowing it to translocate to the nucleus and bind with ARNT, activating gene transcription of xenobiotic responsive genes. Hif-1α, a protein of the hypoxia responsive pathway, also requires ARNT dimerization for activation of the hypoxia responsive element and transcription of hypoxia genes. The expression of hypoxia regulated genes are essential for wound repair and neovasularization. Our laboratory has been using caudal fin regeneration in zebrafish to investigate molecular mechanisms of TCDD toxicity during development. When adult zebrafish were treated with 70 ppb TCDD (i.p.) and their fins were amputated, there was consistent inhibition of caudal fin regeneration. To determine the regeneration stage blocked by TCDD toxicity, zebrafish caudal fins were amputated and fish were injected at various time points during regeneration. We found that TCDD impaired fin regeneration at multiple stages of regeneration. Effects of TCDD on vasculature regrowth of the fin were studied using transgenic zebrafish that express green fluorescent protein driven by the blood cell specific GATA-1 promoter, allowing us to visualize the functional vasculature. TCDD significantly affects caudal fin vascular structure and function. We propose that TCDD activation of the AhR pathway squelches the Hif-1α pathway, resulting in decreased expression of hypoxia regulated genes, thereby decreasing neovascularization and fin regeneration.

832 INHIBITION OF HUMAN AND RAT CYP1A2 BY TCDD AND DIOXIN-LIKE CHEMICALS.

D. F. Staskal[1], L. S. Birnbaum[2] and M. J. DeVito[2]. *[1]Curriculum in Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and [2]ETD, NHEERL, ORD, USEPA, Research Triangle Park, NC.*

The tissue distribution of dioxins is dose-dependent due to hepatic sequestration by CYP1A2, which is an inducible binding protein. Thus the disposition of dioxins is dependent upon the ability to bind and induce CYP1A2. Current risk assessments assume that humans and rats sequester dioxins in a similar manner. The present study examines this assumption by comparing the ability of dioxins to inhibit human and rat CYP1A2 activity. Rat and human CYP1A2 + P450 reductase SUPERSOMES were obtained from GenTest Corporation (Woburn, MA). Methoxyresorufin-O-deethylase (MROD) activity, a prototype substrate, was monitored in human and rat CYP1A2 SUPERSOMES in the presence of varying concentrations of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), 1, 2, 3, 7, 8-pentachloro-*p*-dioxin (PCDD), 2, 3, 4, 7, 8-pentachlorodibenzofuran (4-PeCDF), 2, 3, 7, 8-tetrachlorodibenzofuran (TCDF), 3, 3', 4, 4', 5, 5'-hexachlorobiphenyl (PCB 169), 3, 3', 4, 4', 5-pentachlorobiphenyl (PCB 126), 2, 3, 3', 4, 4', 5-hexachlorobiphenyl (PCB 156), 2, 3', 4, 4', 5-pentachlorobiphenyl (PCB 118), and 2, 3, 3', 4, 4'-pentachlorobiphenyl (PCB 105). Both human and rat CYP1A2 metabolized methoxyresorufin, evidenced by similar K_M values between species (0.10nM human, 0.09nM rat). Rat SUPERSOMES had a slightly higher V_{max} than human SUPERSOMES, 3.5 and 2.4 pmol/min/mg CYP1A2 respectively. Our results demonstrate similar dose-dependent inhibition of human and rat CYP1A2 activity for all chemicals tested. TCDD, TCDF and 4-PeCDF were the most potent inhibitors. These chemicals appear to be mixed type inhibitors, with K_i values of approximately 1-100 μM. Inhibition of CYP1A2 activity by this series of chemicals *in vitro* may explain the lack of correlation between CYP1A2 activity and dioxin exposure in human epidemiology studies (This abstract does not reflect EPA policy.)

833 SUBCHRONIC TOXICITY OF 3, 3', 4, 4'-TETRACHLOROAZOBENZENE(TCAB) ADMINISTERED BY GAVAGE TO HARLAN SPRAGUE-DAWLEY RATS.

D. F. Gerken[1], M. J. Ryan[1], A. F. Fuciarelli[2], D. E. Hartter[3], M. R. Hejtmancik[1], S. W. Graves[1], M. J. Hooth[3], N. J. Walker[3], A. P. van Birgelen[4,3] and M. Vallant[3]. *[1]Battelle Columbus, Columbus, OH, [2]Battelle Toxicology Northwest, Richland, WA, [3]NIEHS, Research Triangle Park, NC and [4]Hoffmann-La Roche, Inc., Nutley, NJ.*

Tetrachloroazobenzene is a by-product formed during the manufacture or environmental degradation of 3, 4-dichloroaniline or its herbicidal derivatives. Because of the structural resemblance of TCAB to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD), this study was performed to obtain data for the determination of the potency of TCAB relative to TCDD for a variety of endpoints. Male and female Sprague-Dawley rats (10/sex/group) were administered TCAB (100% pure) in corn oil containing 1% acetone by gavage at dosages of 0(control), 0.1, 0.3, 1, 3, 10, 30 and 100 mg/kg, 5 days/week, for approximately 13 weeks. No treatment-related clinical signs were observed or early deaths occurred during the study. There was a statistically significant treatment-related decrease of less than 8% in mean body weight in all female treatment groups above 0.3 mg/kg at termination. Serum total and free T4 were decreased in all dosage groups with generally undetectable concentrations in the groups above 3 mg/kg; no effects were noted on serum T3 or TSH concentrations. TCAB-related decrease in hemoglobin and increases in alkaline phosphatase and cholesterol were noted in both sexes. Liver CYP1A1, CYP1A2, CYP2B and pulmonary CPY1A1 activities were increased at 0.1 mg/kg and higher in a dose-related manner. Significant effects on P450 activity and thyroid hormones were reported in the lowest dosage (0.1 mg/kg); therefore, a NOEL could not be determined. Dose-dependent induction by TCAB of the expression of cytochromes P450, CYP1A1 and CYP1A2 was compared to the induction by TCDD after 13 weeks of daily dosing under similar study conditions. The daily doses needed for similar levels of induction of these genes was 6 orders of magnitude higher than for TCDD indicating that TCAB is only a weak Ah receptor agonist *in vivo*. (Supported by N01-ES-65406.)

834 COMPARING MIXTURES OF DIOXIN-LIKE AND NON-DIOXIN-LIKE PCBs TO TCDD.

D. E. Burgin[1], J. J. Diliberto[2] and L. S. Birnbaum[3]. *[1]Toxicology, UNC, Research Triangle Park, NC, [2]ETD/PKB, USEPA/ORD/NHEERL, Research Triangle Park, NC and [3]HSD, USEPA/ORD/NHEERL, Chapel Hill, NC.*

Environmental exposures to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) always occur as part of a complex mixture. In order to assess the potential risk associated with these exposures, the Toxic Equivalency Factor (TEF) method was developed, and uses toxic equivalents (TEQ) to relate a chemical to TCDD. While this method adequately accounts for the effects of mixtures of TCDD or dioxin-like (DL) chemicals, there are almost always non-dioxin-like (NDL) chemicals present, in particular, the NDL polychlorinated biphenyls (PCBs). To further examine the interactions of dioxin with NDL PCBs, the present study compared the effects on multiple responses of different laboratory-defined mixtures, based on mass ratios found in food, of dioxin and NDL PCBs in both wild type C57BL/6J and CYP1A2 null male and female mice. These chemical groups are: 1) TCDD alone; 2) DL Mix A containing TCDD, 1, 2, 3, 7, 8 Pentachlorodibenzo-*p*-dioxin, 2, 3, 4, 7, 8 Pentachloro-dibenzofuran, PCB 126; 3) NDL Mix B containing PCB 118, PCB 138, PCB 153, PCB 180; and 4) Mix C - a combination of Mixes A and B. The dose levels used were 0.0, 0.001, 0.01, 0.1, 1.0, and 10.0 μg TEQ/kg body weight for Mix A, B and C, and the same plus 100.0 μg /kg for TCDD. No effects were seen in body weight or other tissues, in male or female wildtype or knockout mice. Although we expected an increase in liver weights in Mix B and Mix C, liver weight was increased only in Mix C in both male and female, wildtype and knockout. The effect appears to be synergistic, not additive. No effects were observed in levels of glutathione, a marker of oxidative stress, in either wildtype or knockout, although this is not surprising due to the large pools of glutathione in the body. Based on these findings, it appears that these mixtures have a synergistic effect greater than the sum of the individual congeners, or TCDD alone. (This abstract does not reflect EPA policy. This research was supported by EPA CT902908)

835 EFFECT OF CHLORINATED PHENOTHIAZINES ON OVULATION IN RATS.

K. W. Fried[1,2], X. Gao[4,5], B. K. Petroff[4,5], K. W. Schramm[2], P. F. Terranova[4,5,6] and K. K. Rozman[1,3]. *[1]Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS, [2]Section of Ecotoxicology, GSF-Institut für Ökologische Chemie, Neuherberg, Germany, [3]Section of Environmental Toxicology, GSF-Institut für Toxikologie, Neuherberg, Germany, [4]Center for Reproductive Science, University of Kansas Medical Center, Kansas City, KS, [5]Molecular & Integrative Physiology, University of Kansas Medical Center, Kansas City, KS and [6]Obstetrics & Gynecology, University of Kansas Medical Center, Kansas City, KS.* Sponsor: K. Rozman.

Adult female Sprague-Dawley rats were administered 1mg/kg/day of tetrachlorophenothiazine (TCPT) or its sulfoxide (TCPT-O) in xylene (4ml/kg). Estrous cyclicity of the rats was determined by obtaining vaginal smears for three weeks prior to the beginning of dosing and for two weeks during daily dosing. Similar to 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) both phenothianzines had a profound effect on cycling with prolonged periods of diestrous and the loss of proestrous and estrous. The sulfoxide was more potent than the parent compound.

Immature female rats were administered 1 and 2mg/kg/day of TCPT or TCPT-O in xylene (4ml/kg) for 4 days. Equine chronic gonadotropin (eCG; 5IU) was administered 24h after the first dose rate to induce follicular development. The animals were terminated at 72h after eCG injection, ovaries harvested and the number of ova shed counted. There was an insignificant decrease (about 50%) in the number of ova ovulated among the TCPT-treated rats. However, TCPT-O dose-dependently and at the higher dose completely inhibited ovulation. In addition, ethoxyresorufin-O-deethylase (EROD) was determined in the livers of all rats. There was a very slight induction of EROD with both compounds at the higher dose. The structure of TCPT was elucidated by UV-VIS spectroscopy, HPLC, NMR spectroscopy and by GC/MS. Single crystal X-ray spectroscopy provided the final proof for the structure of 1, 3, 7, 9-TCPT.

836 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN INHIBITS TRANSCRIPTIONAL ACTIVITY OF THE 3'α ENHANCER IN LIPOPOLYSACCHARIDE-STIMULATED CH12.LX B-CELLS.

C. E. Sulentic[1], Y. J. Na[2], J. H. Oestreich[1], M. P. Holsapple[3] and N. E. Kaminski[1]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI, [2]Korea Advanced Institute of Science and Technology, Daejon, South Korea and [3]Dow Chemical Company, Midland, MI.*

The B-cell is a sensitive cellular target of 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) with the inhibition of the antibody forming cell response being a hallmark endpoint of TCDD toxicity. The actual molecular mechanism responsible for altered B-cell function by TCDD is unclear. Our previous results describing the CH12.LX (AhR-expressing) and BCL-1 (AhR-deficient) B-cell lines have supported an AhR/dioxin-responsive enhancer (DRE)-mediated mechanism for TCDD-induced inhibition of μ heavy chain expression and thus of immunoglobulin (Ig) M secretion. Transcriptional regulation of the Ig heavy chain genes involves several regulatory elements including the 3'α enhancer, which is composed of four regulatory domains. One of these domains, 3'α-hs4, contains a DRE overlapping a κB motif. We have previously demonstrated binding of the AhR nuclear complex and NF-κB proteins to these motifs. In the present studies, a luciferase reporter gene containing only the 3'α-hs4 domain or the full-length 3'α enhancer was transiently transfected into the CH12.LX cells to determine the effect of TCDD and LPS on the activity of these enhancers. The co-treatment of TCDD and LPS had the greatest effect on these enhancers compared to either treatment alone. Interestingly, the co-treatment of TCDD and LPS markedly induced the activity of the 3'α-hs4 domain; whereas, LPS alone induced the full-length 3'α enhancer but this induction was markedly inhibited with the addition of TCDD. Induction of the 3'α-hs4 domain by the co-treatment of TCDD and LPS may negatively regulate the full-length 3'α enhancer leading to inhibition of μ heavy chain expression. (These studies were supported by NIH ES02520 and NIEHS 5F32ES05914-01)

837 NON-COPLANAR POLYCHLORINATED BIPHENYL (PCB) CONGENERS INHIBIT PCB 126-INDUCED ACTIVATION OF THE 3'α-HS4 ENHANCER IN LIPOPOLYSACCHARIDE-STIMULATED CH12.LX B-CELLS.

Y. J. Na[1], C. E. Sulentic[1], K. Yang[2] and N. E. Kaminski[1]. *[1]Pharmacology & Toxicology, Michigan State University, East Lansing, MI and [2]Korea Advanced Institute of Science and Technology, Daejon, South Korea.*

Polychlorinated biphenyls (PCB) are ubiquitous contaminants in the environment and many of their toxic effects including inhibition of B-cell differentiation are elicited by binding to the aryl hydrocarbon receptor (AhR). However, non-coplanar, di-ortho-chlorinated PCB congeners have been shown to inhibit AhR agonist-mediated responses, such as inhibition of μ heavy chain expression and immunoglobulin (Ig) M secretion. Transcriptional regulation of the Ig heavy chain gene involves several regulatory elements including the 3'α enhancer, which is composed of four regulatory domains. One of these domains, 3'α-hs4, contains a DRE overlapping a κB motif. In transient transfection experiments, 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) enhanced the activity of a luciferase reporter gene containing the 3'α-hs4 enhancer domain in lipopolysaccharide (LPS)-activated CH12.LX B-cells. The purpose of the present studies was to determine the effect of PCB 126 (3, 3', 4, 4', 5), an AhR agonist, alone or in combination with the non-coplanar PCB 153 (2, 2', 4, 4', 5, 5') or PCB 52 (2, 2', 5, 5') on the activity of the 3'α-hs4 enhancer domain in LPS-activated CH12.LX cells. Similar to TCDD, PCB 126 enhanced the LPS-induced activation of the 3'α-hs4 domain. In addition, PCB 153 and PCB 52 reversed the effect of PCB 126 on 3'α-hs4 activity. Activation of the 3'α-hs4 domain by PCB 126 may alter the normal activation pattern of the 3'α enhancer leading to inhibition of μ heavy chain expression. In addition, PCB 153 and PCB 52 may antagonize the effects of PCB 126 by interfering with the AhR signaling pathway. (These studies were supported by NIEHS ES04911-13 and NIEHS 5F32ES05914-01)

837A INDUCTION OF TELOMERASE BY 2,3,7,8-TETRACHLORODIBENZO-*P*-DIOXIN (TCDD) AND ESTROGEN IN BEWO CELLS.

P. Sarkar[1], H. Sone[1,3], C. Tohyama[1,2,3] and J. Yonemoto[1,3]. *[1]Endocrine Disruptors and Dioxin Research Project, NIES, Tsukuba, Japan, [2]Environmental Health Sciences Division, NIES, Japan and [3]CREST, JST, Kawaguchi, Japan.*

In an attempt to clarify the underlying mechanism of tumor progression by TCDD, we studied its effect on telomerase activity. Since telomerase is associated with tumor progression and also controlled by sex steriods, effects of TCDD on this enzyme might be one of the pathways towards its tumorogenic action. We used BeWo cells derived from human placental choriocarcinoma as a model system. Stretch PCR analysis showed that TCDD and estrogen induced telomerase activity in BeWo cells. However, an increase in activity was high with TCDD as compared to an equimolar concentration of estrogen. Co-treatment of TCDD and estrogen resulted in a partial decrease in telomerase activity as compared to TCDD alone. The expression of hTERT, a regulatory subunit of telomerase as determined by RT-PCR, was affected by TCDD alone, E2 alone and TCDD+E2 in a similar manner that to telomerase. Furthermore, the expression of *c-myc*, a positive regulator of hTERT, was also increased by TCDD, suggesting the up-regulation of telomerase was *c-myc* dependent. Co-treatment with E2 and TCDD decreased expression of *c-myc* and was comparable to estrogen alone. Since telomerase activity is often associated with proliferating cells, we performed FACS analysis which revealed that both estrogen and TCDD increased cells from G1 to S phase. In contrast, co-treatment of estrogen and TCDD resulted in a decrease in S phase. Our findings do provide evidence that a low concentration of TCDD(1 and 10 nM) activated telomerase as an estrogen agonist while there is the possibility that TCDD(1 and 10 nM) acts as a partial antagonist in the presence of E2 or that the suppression may be due to a yet unknown mechanism.

838 ALTERED GENE EXPRESSION AND CUTANEOUS TOXICITY.

F. Gerberick[1] and I. Kimber[2]. *[1]Procter & Gamble, Cincinnati, OH and [2]Syngenta, Cheshire, United Kingdom.*

Adverse skin reactions can take a variety of forms and be induced by many biologically independent mechanisms. Recently, important progress has been made in defining the molecular bases for skin sensitization, skin irritation and other forms of cutaneous toxicity. In particular the application of transcript profiling and related technologies has allowed the characterization of altered patterns of gene expression that collectively provide important new insights into the relevant toxic mechanisms. Moreover, it is anticipated that the association of novel genes with particular forms of dermal toxicity will yield exciting new opportunities for hazard identification. This proposed Symposium brings together for the first time experts in skin biology and cutaneous toxicity to review how characterization of changes in gene expression are providing new insights into mechanisms of toxicity and opportunities for new approaches to hazard assessment. This Symposium is particularly timely because speakers will be describing the application of transcript profiling and proteomic analysis to monitor changes in gene expression and protein production.

839 INDUCTION OF SKIN SENSITIZATION : GENE EXPRESSION PROFILES.

R. J. Dearman and I. Kimber. *Research, Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.*

An increasingly sophisticated appreciation of the cellular and molecular events associated with skin sensitization, linked with the availability of methods for transcript profiling, provides an opportunity to design alternative approaches to toxicological evaluation based on induced changes in gene expression. A central event in the acquisition of contact allergy is the induction of lymph node cell (LNC) proliferation, a response that forms the basis of the local lymph node assay (LLNA), a method used for the identification and characterization of skin sensitization hazard. We have now examined whether changes in gene expression patterns induced selectively by allergen exposure can be identified using DNA microarray technology. Gene expression changes have been assessed following topical exposure of BALB/c strain mice to the contact allergen 2, 4-dinitrofluorobenzene (DNFB). In parallel investigations, transcript profiling has been performed on human blood derived dendritic cells (DC) cultured in the presence of non-toxic concentrations of

DNFB. Custom DNA microarrays comprising 8734 murine genes (3336 of which are assigned to known genes) or approximately 12500 human genes, each arrayed in duplicate, were utilized. In both cases, the majority of genes was unaffected by treatment with DNFB. Modest DNFB-induced changes in gene expression patterns of human DC were recorded, however, using the current culture conditions, these appear to be largely donor-dependent. Robust changes (up- and down-regulations) in the expression of mRNA for a small number of genes were observed following topical treatment of BALB/c strain mice with DNFB, with onzin and glycosylation-dependent cell adhesion molecule- 1 (GlyCAM-1) being the strongest up- and down-regulated genes, respectively. These genes may provide for robust and relatively sensitive markers of early changes induced by contact allergens.

840 ALTERED KERATINOCYTE GENE EXPRESSION FOLLOWING TREATMENT WITH IRRITANTS.

E. Corsini and C. L. Galli. *Pharmacological Sciences, University of Milan, Milan, Italy.*

In the screening of topic drugs, cosmetics and other chemicals for human use, it should be very important, both from safety and economic point of view, to have biological markers to discriminate irritant and allergic contact dermatitis that have different impact on human health. Due to their anatomical location, keratinocytes are among the first cells to be exposed to various toxicants and, the use of these cells as simplified *in vitro* model to evaluate the potential toxicity of chemicals destined for cutaneous application is amply justified. The identification of new target genes selectively modulated by skin toxicants offers the possibility to develop mechanism-based *in vitro* assay. We have data indicating the possibility to use the mRNA differential display technology (DD-PCR) and DNA macroarray to identify differentially expressed genes following allergen or irritant treatment in commercially available reconstituted human epidermis (EpiDermTM). Results identified adipose differentiation-related (ADRP) protein as up-regulated by both irritant and allergen, and KIAA0368 as selectively up-regulated by contact allergen. ADRP is a 53kDa membrane-associated protein and it is a marker of lipid accumulation, being an ubiquitously expressed lipid storage droplet-associated protein. The induction of ADRP is indicative of increased intracellular lipid deposits, which may herald cell degeneration and maybe also indicative of abnormal keratinization. On the contrary, KIAA0368 is probably an elongation factor involved in protein neosynthesis. It codes for a protein of apparent molecular mass >100kDa, located on chromosome 9 and ubiquitously expressed. Its role in skin irritation or allergy is at present unknown. These data indicate the enormous potential of functional genomic techniques, which allow the identification of genes not immediately connected with the immune response, or even novel genes with unknown functions.

841 MOLECULAR CHANGES IN SKIN FOLLOWING ACUTE DERMAL EXPOSURES WITH JP-8 JET FUEL AND SOLVENTS.

J. N. McDougal. *Geo-Centers Inc. (AFRL/HEST), Air Force Research Laboratory, Wright-Patterson AFB, OH.*

Many products and chemicals cause irritation when they contact the skin. Whole animal primary irritation testing (Draize test) has been around since 1944 with many modifications and variations. With acute tests, the barrier function of the skin is often disrupted and then the substance is placed in occluded contact with the skin for 24 hours and the responses are graded. Irritancy testing was designed to provide relative irritancy of substances, but these tests don't provide useful information for risk assessments or industrial hygiene. In a real exposure situation, a substance would have to diffuse past the stratum corneum barrier down into the viable tissue to produce irritation. Since chemicals diffuse through the skin at different rates and have different irritant potencies, there is an exposure duration for most substances that would not cause irritation. Only minutes of contact could be safe for some substances but it might take hours or days for other substances to cause irritation. The purpose of these studies, using substances with different irritant properties, is to characterize the biological cascade in the skin that results from an acute irritating event. Ultimately our goal is to develop a biologically based model of irritation that can be used to predict safe exposure durations for a wide variety of compounds. We exposed the backs of rats to jet fuel, m-xylene, d-limonene and sodium lauryl sulfate for one hour and investigated the temporal changes in interlukin-1 alpha levels, inducible nitric oxide synthase levels and nitric oxide production. We also measured the time course of lipid peroxidation, oxidative stress and low molecular weight DNA levels in response to these substances. Traditional histopathology and immunohistochemistry were also used to compare response of the skin to the fuel and solvents. We found that the parameters in the irritant cascade that we investigated responded differently depending on the degree of irritancy of each chemical. Further work will refine our preliminary understanding of this acute irritant cascade.

842 ALTERED GENE EXPRESSION IN KERATINOCYTES FOLLOWING ARSENIC EXPOSURE.

D. R. Germolec. *Environmental Immunology, NIEHS, Research Triangle Park, NC.*

Previous studies in our laboratory have suggested that arsenic modulates neoplastic disease in the skin by inducing overexpression of genes encoding specific cytokines and growth factors. We have completed *in vitro* studies which compare altered cytokine gene expression following exposure to either ArsenicIII and ArsenicV or their monomethyl and dimethyl metabolites in normal human epidermal keratinocyte (NHEK) cultures and have found that methylated arsenicals may be as potent as their inorganic counterparts. Microarray studies using NHEK indicate that short-term, non-toxic arsenic-exposure results in the modulation of multiple genes from several classes (e.g., oxidative stress, glutathione metabolism, heat shock/stress response, cell proliferation and DNA damage). Gene expression changes have been validated *via* RPA and northern blotting. Additional microarray studies have examined similar/dissimilar gene expression profiles in NHEK and HaCaT keratinocytes (an immortalized cell line commonly used in arsenic, oxidative stress, and epidermal research) following arsenic exposure. Pathway mapping, FACs analysis and viability studies also have been performed and the correlation between altered gene expression and physiological effects (e.g., cell cycle arrest, DNA damage, elevated cell proliferatory responses, etc.) will be presented.

843 OVEREXPRESSION OF MOUSE HOMOLOGUE OF HOS UBIQUITIN LIGASE RECEPTOR IN SKIN TUMORS IMPLICATION IN CONSTITUTIVE ACTIVATION OF NF-κB.

T. J. Slaga[1], V. S. Spiegelman[1], N. Bhatia[1] and S. Y. Fuchs[2]. *[1]AMC Cancer Research Center, Lakewood, CO and [2]Department of Animal Biology, University of Pennsylvania, Philadelphia, PA.* Sponsor: G. Gerberick.

The mouse skin model of multistage carcinogenesis is an excellent model to study the critical role of specific gene expression in the induction of squamous cell carcinomas. We have found that the function of NF-κB is altered during the induction of skin cancer. NF-κB transcription factor is activated upon ubiquitination and subsequent proteolysis of its inhibitor IκB. The phosphorylation-dependent ubiquitination is mediated by SCF E3 ubiquitin ligase. We identified a novel murine F-box/WD40 repeat-containing protein, mHOS (a homologue of HOS/βTrCP2). mHOS efficiently binds Skp1 protein (a "core" component of SCF ubiquitin ligase), and phosphorylated Iκβa. We found that mHOS associates with SCF-ROC1 E3 ubiquitin ligase activity. We have also observed that mHOS is overexpressed in chemically-induced mouse skin tumors, and its overexpression (but not accelerated IκB phosphorylation) coincides with the accelerated degradation of IκB *in vivo*. The role of mHOS in the constitutive activation of NF-κB in skin carcinogenesis will be discussed.

844 DEFINING THE CELLULAR AND MOLECULAR MECHANISMS OF TOXICANT ACTION IN THE TESTIS.

J. H. Richburg[1] and K. Boekelheide[2]. *[1]College of Pharmacy, The University of Texas at Austin, Austin, TX and [2]Pathology and Laboratory Medicine, Brown University, Providence, RI.*

Despite the association of environmental toxicant exposure and testicular injury, there is little mechanistic data of the molecular and cellular pathways involved. This symposium is focused on the identification of novel molecular and cellular pathways that modulate the response to testicular toxicants. The recently discovered G-protein coupled receptor family member, flamingo, mediates cell-cell adhesion and has been identified in the testis. A specific subset of flamingo homologs exhibits a reduced cell-specific expression at early time points after phthalate exposure suggesting that they may be proximal phthalate targets. Observations of the newly identified death receptors (DR4, 5 & 6) in the testis and differential cellular changes in their expression after phthalate exposure suggest that they may act as surrogates or in concert with the widely described Fas-signaling pathway in the initiation of germ cell apoptosis. A variety of exposures in rodents (radiation, chemotherapeutics, toxicants) results in a persistent post-exposure testicular atrophy. Hormonal manipulations that lower testosterone and serum FSH levels allow for a re-initiation of spermatogonial development. Recent investigation of additional models of persistent atrophy such as knockout mice, the aged Brown Norway rat, EDS-induced Leydig cell deficient rat, and primates, have broadened insight into the mechanisms responsible for persistent atrophy. cDNA arrays are a useful technique for examining changes in mRNA expression. A custom mouse testis

cDNA array has been developed that contains 950 genes. cDNA array analysis of testis mRNA from mice exposed to bromochloroacetic acid (BCA), a drinking water disinfectant, shows an alteration in 42 of 950 genes. Of these, a specific set of 10 genes was identified that represents proteins involved in cell adhesion complexes. This strengthens the findings that BCA acts by disrupting spermiogenesis and provides new insights into the cellular and molecular mechanisms by which BCA acts.

845 PURSUIT OF THE TESTIS PHTHALATE TARGET: A NOVEL CADHERIN IS AN EARLY RESPONDER.

K. Johnson, S. Thompson and K. Boekelheide. *Pathology and Lab. Medicine, Brown University Medical School, Providence, RI.*

Phthalates are environmental pollutants found in soft plastics, and human exposure levels are significant. Phthalates target the testis, with toxicity features including early alterations in Sertoli cell morphology and biochemistry, disruption of Sertoli-germ cell adhesive contact, and altered Sertoli cell G protein-stimulated cAMP generation. These endpoints indicate that a Sertoli-germ cell adhesion complex and a G protein coupled receptor (GPCR) signaling pathway are early phthalate targets. Recently, GPCR family members termed flamingos were discovered which mediate cell-cell adhesion, likely *via* extracellular cadherin domains. Thus, flamingos appear to couple cell-cell adhesion to the stimulation of G protein-based signaling, making them attractive early phthalate targets. Using a degenerate RT-PCR cloning strategy, we discovered that all three flamingo homologs (1, 2, and 3) are expressed in rat testis with unique, cell-specific expression patterns. By analyzing flamingo mRNA expression in postnatal testis, flamingo1 and 3 are likely Sertoli cell products while flamingo2 a germ cell product. To determine if flamingo biology is affected by phthalate exposure, the testis mRNA expression of these flamingos was examined by semi-quantitative RT-PCR following exposure of 28 day old rats by gavage to 1 gm/kg mono-(2-ethylhexyl) phthalate. Significantly, the mRNA expression of flamingo1 and 2was reduced to 70% of control within 3 hrs with additional declines at later time points (35-50% of control at 6 hrs). However, the effect of phthalate was specific to flamingo 1 and 2 GPCRs; the mRNA level of another Sertoli cell GPCR (the FSH receptor) was reduced somewhat at 3 hrs but recovered at 6 hrs post-exposure, while flamingo3 mRNA levels were elevated at 6 hours. These data indicate that flamingo1 and 2 respond early after phthalate exposure and lead to a model of testicular phthalate toxicity in which a flamingo-based Sertoli-germ cell adhesion/signaling complex is a proximal phthalate target, leading to germ cell detachment and apoptosis.

846 NOT SO FAS: EVIDENCE FOR THE DIFFERENTIAL INVOLVEMENT OF FAS-INDEPENDENT SIGNALING PATHWAYS IN THE TESTIS.

J. H. Richburg. *College of Pharmacy, The University of Texas at Austin, Austin, TX.*

The Fas-FasL signaling system is proposed to be critical in the regulation of testicular germ cell apoptosis and maintenance of spermatogenesis. The Fas-signaling system has been implicated in the initiation of germ cell apoptosis after exposure to the Sertoli cell toxicant mono-(2-ethylhexyl) phthalate (MEHP). Interestingly, *gld* mice, which express a mutant form of FasL, are fertile and display normal spermatogenesis. In addition, a limited protection against MEHP-induced germ cell apoptosis was observed in *gld* mice. To evaluate the participation of non-Fas death receptor signaling systems in the testis, we examined the expression of the newly described death receptors (DR 4, 5 and 6) in both C57BL6 (B6) and *gld* mice after MEHP exposure (1 g/kg). By western blot analysis, each of the DR's was present in B6 and *gld* mouse testis. A comparison of the pattern of protein expression of Fas to that of the DR's in B6 mice after MEHP exposure revealed that Fas, DR4 and DR5 show similar patterns of expression whereas DR6 has a unique expression pattern. DR6 expression in *gld* mice was also strikingly different from that in B6 mice with an early increase in protein expression (3 h) that remained for the duration of MEHP exposure. The delayed induction of DR6 after MEHP exposure in the B6 testis suggests that this receptor may be activated as a secondary response in B6 germ cells to decreased hormonal, nutritive or physical support that results from MEHP-induced Sertoli cell injury. The early induction of DR6 in *gld* mice implies that the mechanism that leads to the induction of DR6 is already primed. The evaluation of NF-κB in the *gld* testis shows an early increase in NF-κB DNA binding similar to the changes in DR6 expression seen in these mice. Taken together, these findings indicate that the DR4, 5 or 6 systems in mice may be functioning in parallel with the Fas system to regulate germ cell apoptosis and/or that one or more of these DR's may act as a surrogate for the Fas system when it is either overwhelmed or dysfunctional.(Supported by NIEHS ES09145 & ES07784)

847 REVERSAL OF TOXICANT-INDUCED TESTICULAR ATROPHY: MODELS AND MECHANISMS.

H. A. Schoenfeld[1], K. Boekelheide[1], G. Shetty[2] and M. L. Meistrich[2]. *[1]Pathology and Laboratory Medicine, Brown University, Providence, RI and [2]University of Texas M.D. Anderson Cancer Center, Houston, TX.*

In rodents, severe toxicant-induced testicular injury results in a persistent post-exposure atrophy with ongoing proliferation of stem germ cells and apoptosis of their progeny. The block to further spermatogonial development is relieved by hormonal manipulations that lower testicular testosterone and serum FSH levels. In the rat it appears that both the testicular testosterone and FSH levels are responsible for inhibiting spermatogonial development, whereas in a similar model of spontaneous spermatogenic failure, jsd mutant mice, it appears to be only testosterone. Any androgen appears to be inhibitory and acts through the androgen receptor. In some cases, even a transient suppression of testosterone can result in maintenance or reinitiation of spermatogonial development for a prolonged period to restore complete spermatogenesis and fertility. However, therapy with the toxicant ethane dimethane sulphonate, which selectively ablates testosterone-producing Leydig cells, suppresses both serum testosterone and testicular testosterone yet fails to stimulate a reversal of 2, 5-hexanedione-induced injury, regardless of whether it is administered alone or in combination with GnRH agonist therapy. These studies suggest that paracrine-acting factors produced by Leydig cells may also be required for the reversal of testis injury. This paradigm of induction of otherwise "irreversible" injury, followed by hormonal manipulations to maintain spermatogenesis, is currently being tested in a non-human primate model. The results of this primate study will be discussed along with insights into the mechanism of atrophy reversal derived from ongoing investigations of rodent models.

848 GENOMIC ANALYSIS OF THE TESTICULAR TOXICITY OF HALOACETIC ACIDS.

D. J. Dix and J. C. Rockett. *Reproductive Toxicology Division, USEPA, Research Triangle Park, NC.*

Gene expression profiles from testes of mice exposed to effective doses of reproductive toxicants can be used to identify genes and gene networks critical to male fertility, infer toxicant mode of action, and understand gene-environment interactions. A custom mouse cDNA microarray interrogating 950 genes was used to analyze gene expression in the testes of mice exposed to a haloactetic acid (HA). HAs are unintended byproducts of drinking water disinfection. Bromochloroacetic acid (BCA) is a commonly occurring HA that acts as a reproductive toxicant in male rodents, targeting sperm and spermatids. Adult C57BL/6N male mice were dosed *via* gavage with 0, 8, 24, 72 or 216 mg/kg of BCA once daily for 14 days. The mice were then used in a 40-day sequential breeding assay to determine if BCA negatively affects reproductive performance by targeting a particular phase of spermatogenesis. Decreased fecundity and infertility was observed during the first 10 days of the breeding assay, indicating that BCA was affecting post-meiotic spermatogenesis. Histological analysis of testes harvested at the end of dosing revealed spermatid retention and abnormal residual bodies, consistent with disruption of spermiation (the process of spermatid separation from Sertoli cells). DNA array analysis of these testes indicated that expression of 42 of the 950 genes interrogated was significantly altered by the higher doses of BCA. Of the 42 altered genes, 10 were cell adhesion genes, 7 stress response genes, and 4 steroid metabolism genes. These 10 cell adhesion-signaling genes included vinculin, a catenin, an integrin and tubulin. These families of proteins are components of or associated with the ectoplasmic specializations (ES) which form cell-cell junctions between Sertoli cells and between Sertolis and spermatids. Thus the gene expression results suggest that BCA exposure disrupts normal ES function and signaling cascades regulating sperm release. Further studies to examine the dose-responsiveness of these effects on gene expression are underway. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy)

849 DRUG-INDUCED HUMAN HEPATOTOXICITY: PREDICTIVE STRATEGIES.

S. K. Durham[1] and J. E. Sanders[2]. *[1]Discovery Safety Optimization, Bristol-Myers Squibb, Princeton, NJ and [2]Safety Intelligence Evaluation, Aventis, Bridgewater, NJ.*

Clinical studies have been the pivotal step of drug development in modern medicine. Despite extensive and thorough evaluation in preclinical species, hepatotoxicity is the most common cause for drug failures during clinical trials. Our inability to adequately predict adverse events in patients following the administration of therapeutic compounds is an industry-wide enigma. The enhancement of our knowledge-based understanding of the adverse responses arising from the peculiarities of genetic diversity will greatly improve the robustness of our prediction. The goal of this symposium is to present new developments in our understanding of human

liver toxicity following the administration of pharmaceuticals. A broad range of fruitful avenues worthy of pursuit includes advances in pharmacogenomics, virtual space, and predictive systems utilizing emerging technology platforms.

850 DRUG-INDUCED LIVER INJURY IN MAN: PHARMACOGENOMICS AND PREDICTIVE SYSTEMS.

P. B. Watkins. *University of North Carolina, Chapel Hill, NC.*

Most drugs that are recognized as capable of causing severe liver injury in man cause no liver injury at all in most treated patients. That is, only a small subset of treated patients are susceptible to the injury. The basis for this idiosyncrasy is widely believed to largely be genetic. As genomic DNA is now routinely collected in drug trials, it is possible to test hypotheses concerning specific gene mutations by searching for these mutations in patients with and without signs of liver toxicity, usually serum alanine aminotransferase [ALT] elevations. A problem with this mutation specific approach is that target genes are rarely known, and it is likely that toxicity reflects mutations in multiple genes simultaneously present in the susceptible individual. An alternate approach is to simultaneously screen the genomic DNA pools for many single nucleotide polymorphisms (SNPs) simultaneously to identify regions of the genome that may contain susceptibility genes. When associations are found, the specific genes and mutations can theoretically be identified. A problem with this approach includes the large number of samples that must be analyzed and the current costs of this analysis. It should also be noted that with many drugs, most patients with ALT elevations in clinical trials will have reversal of the elevations, and hence resolution of the liver injury, even if continued on drug. The "adaptation" may involve multiple mechanisms, including immune tolerance. The subset of patients who develop clinically important liver injury may be those with genetic mutations that prevent them from adapting to the initial injury. Since most patients in clinical trials have treatment discontinued when serum ALT rises significantly, it is not possible to identify the poor adapters. This issue may only be addressable after creation of a nation-wide bank of DNA obtained from patients with severe liver injury due to specific drugs.

851 HEPATOTOXICITY: VIEWS FROM VIRTUAL SPACE.

G. M. Pearl. *Discovery Safety Optimization, Bristol-Myers Squibb, Hopewell, NJ.* Sponsor: S. Durham.

Currently, hepatotoxicity is the most common safety liability responsible for the attrition of drug candidates in the discovery and development process, including black box warnings issued on marketed pharmaceuticals. Despite the importance of this liability, there are no commercially-available predictive computational models for hepatotoxicity. We have established computational modeling algorithms for other safety liabilities that have had a favorable impact on the drug discovery process, especially when these models are used as a sentinel filter for predicting common drug safety liabilities. We are currently developing a predictive hepatotoxicity model that concentrates on the subset of chemical space related to pharmaceuticals. This model is based upon the various statistical algorithms that utilize a central structure activity relationship (SAR/QSAR) scaffold. The standard statistical toolkit, including recursive partitioning, principle component analysis, and neural networks, are especially useful in the development of these models. This presentation will focus on the global strategies, tactical approaches, and infrastructure requirements necessary to establish a robust virtual model of hepatotoxicity.

852 APPLICATION OF EMERGING TECHNOLOGIES FOR THE IDENTIFICATION OF "FINGERPRINTS" OF HUMAN HEPATOTOXICITY.

D. M. Dambach. *Discovery Safety Optimization, Bristol-Myers Squibb, Princeton, NJ.*

Hepatotoxicity remains the most common cause for drug failures during clinical trials. This is due, in part, to inherent physiological differences between humans and pre-clinical rodent species leading to inadequate prediction of adverse responses in humans. To address this issue, there is a need to develop robust assays and identify biomarkers which are predictive of human hepatotoxicity. The ideal biomarker should be utilized throughout the discovery and development periods to select the safest drugs. Predictive assays, suitable biomarkers, and the determination of the mechanisms of toxicity for compound classes are the new focus areas within drug safety evaluation. An ever-expanding armamentarium of new technologies is being utilized to help identify macromolecular endpoints as potential surrogates of toxicity. The profiles very useful for evaluation include the transcriptome, the proteome, and the metabonome. We applied transcriptional and proteomic analyses in parallel to compare platform technologies and identify potential biomarkers of PPAR-gamma agonist-induced hepatotoxicity. Comparative analysis of oligo- *versus* cDNA-based arrays, and surface enhanced laser desorption ionization (SELDI) *versus* LC-LC/MS protein identification methods proved that the benefits of these platforms were additive. The application of both transcriptional and proteomic analyses expanded the potentially useful endpoints for toxicity biomarker identification.

853 COMPARATIVE DRUG-INDUCED HEPATOTOXICITY EXPRESSION PROFILES IN RODENTS AND HUMANS.

J. A. Rininger. *CuraGen Corporation, New Haven, CT.*

The ultimate goal of gene expression and toxicogenomics analyses is to improve the efficiency of drug development by prioritization of lead compounds. Unfortunately, a continuing limitation is the relevance of gene expression profiles derived from animal model systems to human toxicity and efficacy. The commercial availability of primary human hepatocytes represents a promising means of bridging this gap. However, the use of human hepatocytes in toxicogenomic studies is challenged by variables associated with human donors such as age, gender, ethnic background, and medical history. To evaluate the reproducibility of gene expression studies with primary human hepatocytes, our laboratories have employed GeneCalling® and RTQ-PCR to generate and compare gene expression profiles from different human donor cells treated with PPAR-gamma agonists. This presentation will also compare the gene expression profiles of PPAR-gamma agonists in primary human hepatocytes to those observed primary rat hepatocytes and rat liver *in vivo*. Primary human hepatocytes were non-responsive to prototypical peroxisome proliferator-modulated genes observed in the rodent models. In addition, human hepatocytes showed reproducibility of response in target genes that suggest a different mechanism of action for the fibrate drug class.

854 FACTORS THAT AFFECT THE IMPACT OF DELIVERED DOSE OF INHALED MEDICINES: AN UPDATE OF THE ISSUES.

P. A. Weideman[1] and B. O. Stuart[2]. [1]*Schering-Plough Corporation, Union, NJ and* [2]*Schering-Plough Research Institute, Lafayette, NJ.*

There have been rapid advances in the use of the respiratory tract as a route of administration for aerosolized medicines to combat systemic disease *via* the pulmonary vasculature, or to treat lung specific disorders such as asthma, chronic obstructive pulmonary disease or cystic fibrosis. Inhaled pharmaceuticals offer a painless and reasonably convenient technology for the treatment of several life-threatening diseases, but the consistent daily delivery of the prescribed dose of medication is critically dependent upon physical and physiological factors. Exacting aerosol engineering is needed for metered dose inhalers and dry powder inhalers to generate regulated amounts of medicines of defined particle size distributions to reach targeted sites within the respiratory tract. Physiological factors that greatly influence the quantity of drug reaching these sites are breathing patterns, volumes and flows which vary among individuals with age (pediatric vs adult) and extent of pre-existing disease, which may also significantly alter absorption. Following deposition of the inhaled aerosol at the desired site within the respiratory tract, subsequent retention (for pulmonary disease) and bioavailability (for treatment of systemic disease) of the drug are critical factors in minimizing adverse reactions and obtaining maximum efficacy. This workshop should provide the audience with an understanding of new developments in the technology for the delivery of drugs by the respiratory tract administration, and reviews of updated modeling approaches for deposition of pharmaceuticals and current physiological factors that may affect the deposition and bioavailability of these intentionally biologically active, potent compounds. Finally, clinical aspects of inhaled therapeutic aerosols, including current treatments for various disease states, the side effects (or lack of) of inhaled steroids, receptors and targets for maximum therapeutic effect, and innovative therapies using the respiratory system as the portal of entry, will be discussed.

855 INNOVATIONS IN DEVICES AND ENGINEERED POWDERS FOR THE DELIVERY OF INHALEABLE MEDICATIONS.

A. R. Clark. *Inhale Therapeutic Systems Inc., San Carlos, CA.* Sponsor: B. Stuart.

The first pressurized metered dose inhalers (pMDIs) and single dose dry powder inhalers were introduced nearly 50 years ago. Their introduction marked a new era in the treatment of respiratory diseases. However, these early devices suffer from relatively poor efficiency and reproducibility, typically delivering only 5 to 20% of the

nominal dose to the lungs. While adequate for an inexpensive molecule with a wide therapeutic index, improvements were needed if the lung was going to fulfill its full potential as both a topical and systemic delivery site. Over the last two decades improvements in efficiency and compliance have been sought in both device design and particle/formulation engineering. Initially "add-on" devices for pMDIs and multidose versions of dry powder inhalers were developed. Recently, however, fundamentally new device and formulation technologies have emerged. Active devices, which use an internal energy source to supply the energy for aerosol generation, have been developed by a number of companies. Powder technologies, using novel excipients and/or particle morphology to improve powder properties, have also been developed for use with conventional device technologies. While none of these new technologies have reached the market yet they promise improved delivery efficiency, 60-70% of the nominal dose reaching the lungs, and improved reproducibility and compliance.

856 USING MODELS THAT PREDICT INHALED AEROSOL DEPOSITION.

O. R. Moss[1], B. Asgharian[1] and R. F. Phalen[2]. [1]*CIIT Centers for Research, Research Triangle Park, NC and* [2]*University of California, Irvine, CA.*

Physical properties of the aerosol and physiological factors of individual subjects affect the amount of inhaled medicine to reach targeted sites within the respiratory tract. Some, but not all, of these factors are included in existing models that predict deposition of inhaled material. These models broadly fall into four basic categories: empirical models, deterministic-(single or typical)-path models, deterministic-multiple-path models, and stochastic models. All of the models incorporate to some extent physiological states in the population. Deterministic and stochastic models incorporate physical properties of the aerosols and mechanisms of airflow and deposition, while empirical models for the most part do not. All models predict total deposition in the respiratory tract, but only a few multiple-path models predict lobar deposition or depositions relevant to respiratory tract tomography. Stochastic models provide the greatest flexibility in representing the impact of intersubject variability on the deposition of inhaled medicinal aerosols. Software programs for some empirical and deterministic deposition models are available for user calculations on a personal computer. Sufficient information on other empirical and deterministic models is available for user programming, while several deterministic and stochastic models are available only at the sites where they were first created. Since most models are compared against a common inhalation exposure database, the predictions of aerosol deposition are similar for standard subject size and breathing rate but begin to differ significantly for other physiological states. Because of their availability and continued refinement in the incorporation of computational fluid dynamics, deposition models will play a key role in setting design criteria for the next generation of inhalers.

857 PHYSIOLOGICAL FACTORS AFFECTING INHALED AEROSOL DEPOSITION.

R. F. Phalen[1], M. J. Oldham[1] and O. R. Moss[2]. [1]*University of California, Irvine, CA and* [2]*CIITCenters for Health Research, Research Triangle Park, NC.*

The deposition patterns of inhaled particles show enormous variability both among individuals and for a given individual at different times. Theoretical and empirical models indicate that variations in respiratory tract anatomy and breathing patterns are major contributors to this variability. The primary purpose of this presentation is to discuss how age and gender influence airway anatomy and ventilation, and thus affect the deposition of inhaled particles. Postnatally, the respiratory tract undergoes significant remodeling and enlargement for about 15 years. During this period, airway sizes correlate with body size, and changes in oxygen demand produce changes in respiratory frequency and tidal volume. Such anatomical and ventilatory changes after early development appear to be more closely correlated to body size than age per se. Respiratory tract growth appears to cease when general body growth stops. During normal senescence, the changes in anatomy and ventilation are not very well understood, but include an increase in anatomical dead space. Gender-related differences in airway anatomy are largely related to body size effects, but gender-specific characteristics of the upper airways are known to exist. Clinical measurements of aerosol deposition in children and women are consistent with predictions made by using the existing information on anatomy and ventilation. Information on particle deposition in old age is difficult to find. Even when age, gender, body size and ventilation are known, aerosol deposition patterns are variable. It is apparent that additional details relating to respiratory tract anatomy and ventilation must be explored in order to predict the aerosol deposition pattern for any specific individual.

858 THE EFFECT OF PARTICLE SIZE ON THE RETENTION AND DISPOSITION OF INHALED MEDICATIONS.

B. O. Stuart. *Schering-Plough Research Institute, Lafayette, NJ.*

The aerodynamic behavior of solid dry particle or liquid droplet aerosols of inhaled medicines produced from nebulizers, metered dose inhalers (MDI's) or dry powder inhalers (DPI's) determines their deposition site within the respiratory tract of the patient. However, the deposition site environment, including airway or alveolar lining fluids, and availability and viability of pulmonary macrophages, as well as the particle's size and surface area, determine the subsequent retention, disposition and efficacy of the inhaled aerosolized drug. The effectiveness of the inhaled medication in the control of asthma and chronic obstructive pulmonary disease will depend upon its retention time at the target site, with limited systemic absorption. Here the role of drug carrier materials can be important. Conversely, the rapidly expanding use of the respiratory tract as a route for treatment of systemic diseases such as osteoporosis, diabetes or hepatitis C is based upon the rapid dissolution of small aerodynamic size inhaled drug particles deposited in the alveolar lung, comprising 100 square meters of surface in healthy adults, plus intimate contact with the extensive pulmonary vasculature. Recently available data and approaches in predictive modeling of pulmonary retention, dissolution and cell mediated clearance will be examined as they apply to the efficacy of inhaled medications.

859 AEROSOL THERAPY FOR PULMONARY AND SYSTEMIC DISEASE: FROM ASTHMA TO DIABETES AND BEYOND.

M. T. Newhouse[1,2]. [1]*Inhale Therapeutic Systems Inc., San Carlos, CA and* [2]*McMaster University, Hamilton, ON, Canada.* Sponsor: B. Stuart.

The past 20 years has seen important advances in treating pulmonary and systemic disease with aerosols. Aerosols provide needleless administration, IV-like onset of action, absent first-pass metabolism and a greatly improved therapeutic index. Asthma and chronic obstructive pulmonary disease (COPD) are syndromes that afflict about 30, 000, 000 Americans for which inhaled bronchodilators (beta-agonists; anticholinergics) and corticosteroids (mainly for asthma control) are safe, efficacious, and cost effective in adults and children. Administered by metered dose inhalers (MDIs), dry powder inhalers (DPIs) and small volume nebulizers (SVNs) they are likely to remain the mainstay of therapy for many years. Chronic Pseudomonas aeruginosa infections in cystic fibrosis (CF) and non-CF bronchiectasis are treated with high dose inhaled aminoglycosides (also ceftazidime or peptide antibiotics) to improve the therapeutic ratio, increase bacterial killing and minimize bacterial resistance. Antibiotics and inhaled rhDN-ase, mannitol or hypertonic saline mobilize secretions and improve pulmonary function. In immuno-suppressed patients, pulmonary fungal infections, particularly with Pneumocystis carinii and Aspergillus fumigatus, are frequently lethal. For chronic prophylaxis, nebulized pentamidine and amphotericin B, respectively, are safe and effective. Aerosol therapy may also be used for systemic disease. Instilled/aerosolized small molecules (e.g., morphine for pain in pulmonary edema) achieve rapid IV-like therapy. Macromolecular (proteins/peptides) absorption using aerodynamically small particles (< 3um) deposited in the alveoli has enabled commercial development of inhaleable insulin. Additional inhaleable macromolecules under active development include growth hormone, parathormone, antiproteases, leuprolide, interferons, and many others. Future inhaleables will probably include viral and bacterial vaccines, lung cancer prophylaxis/therapy with modified adenovirus "scavengers" and/or chemotherapy as well as IL-2 and GM-CSF. In the coming decade, dozens of important medications will be administered by inhalation and provide needleless "therapy without tears".

860 MODELING OF POPULATION VARIABILITY.

M. L. Dourson[1] and G. Johanson[2]. [1]*Toxicology Excellence for Risk Assessment, Cincinnati, OH and* [2]*National Institute for Working Life, Stockholm, Sweden.*

One key aspect in toxicological risk assessment is the variability in the population in response to a toxicant. In essence, this variability determines the shape of the dose-response curve (at the population level). Knowledge of the shape of the curve, especially in the lower dose range, is helpful in defining assessment (uncertainty/safety) factors. Such knowledge may reduce the need for such factors, and is helpful to successful risk assessment. Variabilty may be predicted in pharmacokinetic, pharmacodynamic, and other biomathematic models e.g., by Monte Carlo techniques, where the output is generated from repeated simulations using parameter distributions, rather than from single simulation with single parameter values. On the other hand, variabilty of population parameters within a specific model may be estimated by mixed effects modeling or hierarchical population modeling, e.g., in a Bayesian statistical framework using Markov chain Monte

Carlo simulations. The objective of this workshop is to provide the state-of-the art of different approaches to estimate the population variability in model parameters and to predict population variability in toxicity.

861 DATA-DERIVED REPLACEMENT OF DEFAULT UNCERTAINTY FACTOR.

M. L. Dourson. *TERA, Cincinnati, OH.*

Uncertainty (or safety) factors in noncancer Dose-Response assessment have been used as a rough indication of the variability in the population Dose-Response curve of a toxicant. In essence, these factors divide a NOAEL (a point on the Dose-Response curve of low but generally unknown response) to estimate a subthreshold dose (i.e., zero response). Different shapes of Dose-Response curves could be used to adjust the value of these uncertainty factors, but generally are not. This presentation will focus on the history and scientific basis of uncertainty factors, newer methods to estimate uncertainty factors based on compound specific pharmacokinetic and pharmacodynamic data, and Monte Carlo analyses in estimating the probability of uncertainty factors. Each of these methods will be related to population variability to the toxicity of a chemical as exemplified by the Dose-Response curves of different chemicals.

862 MIXED EFFECTS MODELING OF TOXICOKINETIC DATA.

L. Aarons. *School of Pharmacy, University of Manchester, Manchester, United Kingdom.* Sponsor: G. Johanson.

The analysis of sparse pharmacokinetic data in clinical studies has become known as the population approach and is now widely used in drug development. The population approach has not been applied as extensively to pre-clinical pharmacokinetic data, often gathered in toxicokinetic studies. Toxicokinetics is the assessment of systemic exposure in toxicity studies, in which pharmacokinetic data are generated, either as an integral component in the conduct of the nonclinical toxicity studies or in specially designed supportive studies, in order to assess systemic exposure. The data may be used in the interpretation of toxicity findings and contribute to the assessment of the relevance of these findings to clinical safety. Data may be obtained from all animals in a toxicity study, in representative subgroups, in satellite groups or in separate studies. Applying a mixed effects modelling approach in toxicokinetics offers many advantages over the current approach of having satellite groups. Sparse samples for measuring drug/metabolite concentration are collected in all main animals in the majority of studies where toxicological findings are obtained. Such sampling is unlikely to distress the animals, disturb the conduct of a toxicological study or affect the outcome of the study. Many of the outcome measures in toxicological studies are categorical in nature. For example, lesions may be scored on a one to four scale, from none to severe. The analysis of such data is usually carried out using a general mixed modelling approach. In this presentation data arising from a toxicokinetic experiment and a clinical study with pharmacokinetic data will be used to illustrate the principles of general mixed effects modelling, particularly the analysis of sparse pharmacokinetic and pharmacodynamic data.

863 BAYESIAN APPROACHES IN RISK CHARACTERIZATION.

F. Y. Bois and S. Micallef. *Experimental Toxicology Lab., INERIS, Verneuil en Halatte, France.* Sponsor: G. Johanson.

Complex physiological models are increasingly used for exploring hypotheses about mechanisms of toxicity and for risk assessment. Such models cannot and should not be simply fitted to data, but they still deserve an appropriate statistical treatment (e.g., to help decide about the model validity, choose between competing models, or dissociate uncertainty from variability in model parameters and predictions). Recent developments in computational statistics, particularly in a Bayesian framework, offer new scientific tools to tackle the problem. We first present an overview of the basic concepts needed to implement these tools in toxicology: prior *vs.* posterior distributions, data likelihood, information flow, hierarchical population modeling, and Markov chain Monte Carlo simulations. Examples of recent applications are given to illustrate the power of these methods for model calibration, model checking and validation, uncertainty analysis, study of variability, and optimization of experimental design. It is argued that these tools will clear the way for further progress on model development, and for an improved treatment of sparse biomarker data in occupationally or environmentally exposed human populations.

864 ESTIMATION OF INDIVIDUAL VARIABILITY BY POPULATION PBPK MARKOV-CHAIN MONTE CARLO ANALYSIS.

G. Johanson[1]. [1]*Toxicology and Risk Assessment, National Institute for Working Life, Stockholm, Sweden and* [2]*Medical Sciences - Occupational and Environmental Medicine, University Hospital, Uppsala, Sweden.*

The health hazard of a pollutant is in general more closely related to internal exposure to chemical, i.e. target dose, than to external exposure. Thus, population variability in target dose is of great importance in risk assessment. We have used a three-step approach to assess inter-individual variability in target dose and health hazard. In a first step, we retrieve raw data from controlled inhalation exposure of human volunteers to some volatiles (methyl chloride, dichloromethane, toluene, and styrene). We then subject these data to a Bayesian analysis by Markov-chain Monte Carlo (MCMC) simulations within a population Physiologically-Based Pharmacokinetic (PBPK) model. The Bayesian analysis makes it possible to merge prior knowledge on model parameters with the toxicokinetic information embedded in the experimental data and yields posterior estimates of the mean and distribution of the model parameters at the individual (representing measurement error and intra-individual variability) as well as the population level (representing inter-individual variability). In a second step, we calculate the population variability in target dose by regular Monte Carlo simulations, combining the results from the first step with population data on age, gender, body build, metabolic genotype, etc, in a population PBPK model. This step has been carried out for methyl chloride (using total amount metabolized as target dose surrogate) and dichloromethane (amount metabolized *via* the GST pathway). In a third step we calculate the variability in health effect or risk as a function of target dose. So far, we have done this for dichloromethane, by applying the linearized multistage model on the target dose calculated as above. Obviously, this step requires more quantitative knowledge about the relationship between target dose and effect (toxicodynamics) than is presently available for most chemicals. The project was funded by the Swedish council for working life and social research.

865 IMMUNE SUPPRESSION BY TCDD REQUIRES AH RECEPTOR EXPRESSION IN T LYMPHOCYTES.

N. I. Kerkvliet, L. B. Steppan and D. M. Shepherd. *Environ. & Molec. Toxicology, Oregon State University, Corvallis, OR.*

The cellular basis for the potent suppression of T cell-mediated immune responses in mice following exposure to TCDD is not understood. Although activation of the AhR is required, the specific AhR+ cells that transduce the suppression have been difficult to identify *in vivo*. The recent availability of AhR-/- mutant mice provides novel ways to investigate the direct targets of TCDD. We used an *in vivo* graft *versus* host (GVH) model of T cell immunity to address the direct AhR-dependent effects of TCDD in T cells. In this model, T cells from C57Bl/6 (B6) mice are injected into B6xDBA/2(D2) F1 host mice. The B6 T cells recognize the MHC disparity of the B6D2 host cells, leading to the generation of a CD4+ T cell-dependent CD8+ CTL response that results in loss of body weight by the host. By comparing the ability of TCDD to suppress the GVH response of T cells derived from AhR+/+ and AhR-/- mice, the importance of the AhR in T cells could be determined. We found that the CTL response of T cells from AhR+/+ mice was suppressed when host mice were treated with 15 µg/kg TCDD, and the host mice did not lose body weight. However, when grafted T cells came from AhR-/- mice, there was no suppression of the CTL response by TCDD, and the host animals lost significant body weight. T cells derived from AhR+/+ and AhR-/- mice generated comparable CTL responses in the absence of TCDD, indicating that the absence of the AhR did not alter the innate responsiveness of the T cells. To determine if AhR-mediated effects of TCDD were selective for CD4+ or CD8+ cells, T cells from AhR+/+ and AhR-/- mice were separated into CD4+ and CD8+ subsets, intermixed in various combinations, and injected into host mice. Results showed that the AhR must be expressed in both T cell subsets to have full suppression of the GVH response by TCDD. Future studies will exploit the GVH model using a variety of mutant T cells to directly assess the role of various signaling pathways involved in AhR-mediated T cell dysfunction. (Supported by P01 ES00040 and OSU Unsponsored Research Fund)

866 EXPOSURE TO TCDD SUPPRESSES THE EXPANSION OF ANTIGEN-SPECIFIC T CELLS DURING INFECTION WITH INFLUENZA VIRUS.

K. A. Mitchell, M. C. Nguyen and B. P. Lawrence. *Pharmacology/Toxicology Graduate Program and Department of Pharmaceutical Sciences, Washington State University, Pullman, WA.*

One of the most sensitive effects of exposure to the environmental contaminant 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is suppression of the immune system during influenza virus infection. To determine mechanisms by which exposure to

TCDD impairs cell-mediated immunity, we are using a murine model of infection with human influenza A virus. Cell-mediated immunity to influenza virus depends on the activation, proliferation and differentiation of T cells in the mediastinal lymph nodes (MLN). Specifically, activated CD8+ T cells differentiate into cytotoxic T lymphocytes (CTL), which migrate to the lung and kill virus-infected cells. We have previously shown that exposure to TCDD suppresses the generation of CTL in influenza virus-infected mice and attribute this to impaired activation of influenza virus-specific T cells. Thus, we tested the hypothesis that exposure to TCDD impairs the generation of CTL by suppressing proliferation and increasing apoptosis of influenza virus-specific T cells. To follow influenza virus-specific T cells, we used either MHC class I-restricted tetramers or clonotypic antibodies specific for the T cell receptor of influenza virus-specific T cells. For these studies, mice were gavaged with TCDD (10μg/kg) or vehicle one day prior to i.n. infection with influenza virus. Bromodeoxyuridine was added to the drinking water (0.8 mg/ml) to examine proliferation. Mice were killed 3 to 9 days post infection and MLN cells were stained and analyzed using flow cytometry. Exposure to TCDD caused a three-fold reduction in influenza virus-specific CD8+ T cells that were BrdU+. Contrary to our hypothesis, TCDD had no effect on apoptosis of influenza virus-specific CD8+ T cells, based on staining with 7-AAD and annexin V. These findings suggest that decreased cellularity is due to impaired T cell activation, not enhanced cell death. Future experiments will determine whether decreased proliferation is due to the induction of anergy in influenza virus-specific T cells.

867 EXPOSURE OF MICE TO TCDD DECREASES MUCOSAL IMMUNITY AND INCREASES SUSCEPTIBILITY TO ORAL INFECTIONS BY *SALMONELLA TYPHIMURIUM*.

T. R. Ierrells and D. Hoerman. *Pathology and Microbiology, University of Nebraska Medical Center and Omaha VA Med. Center, Omaha, NE.*

Study results from several laboratories have shown that 2, 3, 7, 8-tetrachlorodibenzo-*p*-dioxin (TCDD) is a potent immunosuppressive compound. Although antibody production is affected, the cellular immune system is the most sensitive to the immunotoxic effects of TCDD. It is clear that the systemic immune organs are affected by TCDD; however, the effects of TCDD on the mucosal immune system have not been well studied. The studies described in this abstract were designed to define the effects of TCDD on mucosal immune responses to the pathogenic enteric bacterium *Salmonella typhimurium*, and to relate these changes to changes in susceptibility of mice to an oral infection with this organism. It was found that treatment of C57Bl/6 mice with an oral TCDD dose of 15 ug/kg resulted in a significant increase in susceptibility to an oral infection as measured by bacterial numbers in the liver, as well as liver damage determined with histologic procedures and serum levels of ALT. TCDD treatment also was found to inhibit the proliferation of mesenteric lymph node lymphocytes to bacterial antigen. To further define the effects of TCDD, mice treated as above were infected with an attenuated strain of *S. typhimurium*that expresses tetanus toxoid (strain BRD 847). The TCDD-treated mice showed a more severe liver infection and pathologic effects by the attenuated bacteria, as well as suppression of lymphocyte proliferative responses to the bacterial antigen or tetanus toxoid. Serum levels of antibody to tetanus toxoid of all IgG isotypes were less in the TCDD-treated mice, but the mucosal IgA response was not affected by TCDD treatment. These data show that TCDD suppresses mucosal cellular-immune responses and T-cell-dependent antibody production to pathogenic and attenuated *S. typhimurium*.

868 SUPPRESSIVE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) ON TH2-DERIVED CYTOKINE PRODUCTION IN PRIMARY IMMUNE REACTION OF MICE.

K. Nohara[1,2], T. Ito[1,2], K. Inouye[1,3], H. Fujimaki[1,2] and C. Tohyama[1,2]. *[1]National Institute for Environmental Studies, Tsukuba, Japan, [2]CREST, JST, Kawaguchi, Japan and [3]JST, Kawaguchi, Japan.*

TCDD has been reported to suppress antigen-specific antibody production, but the precise mechanism remains to be clarified. The type 2 helper T (Th2) cell-derived cytokines are known to be involved in the humoral immune response. We have previously demonstrated that TCDD affects Th2-derived cytokine production by splenocytes in the secondary immune response. In the present study, we investigated whether TCDD affects the Th2-derived cytokine production in the primary immune reaction, where these cytokines play a pivotal role in the proliferation of antigen-specific B cells and their differentiation into antibody-producing plasma cells. Female C57BL/6 mice (6 week-old) were orally administrated TCDD (20 μg/kg) or vehicle alone (corn oil-4% nonane), and simultaneously immunized with ovalbumin (OVA, 100 μg/mouse)/alum intraperitoneally. Four days after the treatment, TCDD significantly suppressed the IL-4, IL-5 and IL-6 production by splenocytes re-stimulated *ex vivo* with OVA, while it did not alter the cell numbers and populations of T and B cells. The production of IL-5 and IL-6, but not of IL-4, was suppressed by TCDD from the day 4 through day 14. Among them, IL-5 was particularly sensitive to TCDD and significantly suppressed at a low dose of TCDD-exposure (1 μg/kg). To clarify whether T cells or antigen-presenting cells (APCs) are attributable to the suppression of cytokine production by TCDD, T cells and APCs were separated from TCDD- and vehicle-treated mice, and subjected to splenocyte-reconstitution cultures. We found that TCDD-treated T cells were essential for the suppression of IL-5 production. In conclusion, these results showed that TCDD exposure suppresses the Th2-derived cytokine production in the primary immune response by mainly affecting T cells, and suggested that these effects of TCDD are involved in the impairment of antigen-specific antibody production.

869 THE EFFECTS OF TCDD ON GERMINAL CENTER FORMATION IN THE SPLEEN OF C57BL/6 MICE.

K. Inouye[1,2], T. Ito[1,3], H. Fujimaki[1,3], C. Tohyama[1,3] and K. Nohara[1,3]. *[1]National Institute for Environmental Studies, Tsukuba, Japan, [2]JST, Kawaguchi, Japan and [3]CREST, JST, Kawaguchi, Japan.*

2, 3, 7, 8-Tetrachlorodibenzo-*p*-dioxin (TCDD) is known to suppress the antibody production in humoral immune response. However, the mechanisms by which TCDD causes immunosuppressive effects remain to be defined. After thymus-dependent antigen (Ag) immunization, Ag-activated B cells migrate into lymphoid follicles to form germinal centers (GCs). In GCs, B cells undergo proliferation and selection to differentiate into plasma cells that produce high-affinity antibodies. The aim of this study was to elucidate at which stage TCDD affects B cell development. We therefore investigated the effects of TCDD on GC formation. Female C57Bl/6 mice were orally administered 0 (vehicle) or 20 μg/kg of TCDD and immunized intraperitoneally with 100 μg of alum-precipitated ovalbumin (OVA) (day 0). *in ova*lalum system, OVA-specific IgG1 in plasma was detected from day 10 by ELISA and the increased proportion of GC B cells in spleen was detected from day 7 by flow cytometry, so that mice were sacrificed on days 7, 10 and 14 to determine the time course effects of TCDD. Suppression of antibody production by TCDD treatment was observed on days 10 and 14. TCDD significantly reduced cell number of GC B cells, as defined by B220$^+$Peanut agglutinin (PNA)$^+$, from day 7 through day 14, indicating that TCDD inhibited GC formation from its early stage. Besides, the suppression of GC formation by TCDD was also histochemically detected by PNA staining. TCDD did not affect immunohistochemical staining pattern of follicular dendritic cells, which are involved in GC formation. These results suggest that TCDD suppresses antibody production through preventing B cell proliferation or differentiation in GCs.

870 EARLY T CELL CYCLE BLOCK BY HYDROQUINONE AND CATECHOL.

J. McCue, S. Lazis and B. Freed. *School of Medicine, University of Colorado Health Sciences Center, Denver, CO.*

Cigarette smoke induces profound suppression of T cell responses in the lungs. We have reported that the two major phenolic components of cigarette tar, hydroquinone (HQ) and catechol, block DNA synthesis in proliferating lymphocytes by reversibly inhibiting ribonucleotide reductase. However, inhibition of DNA synthesis following HQ- and catechol-exposure of resting lymphocytes was not reversible, implicating additional mechanisms of inhibition. The purpose of these experiments was to investigate the molecular basis of HQ- and catechol-induced cell cycle arrest. Peripheral blood mononuclear cells (PBMC) were activated with anti-CD3 and PMA in the presence or absence of 50 μM HQ or 50 μM catechol, and a set of key events that mediate progression through G_0- and G_1-phases were analyzed. HQ and catechol blocked cells in the G_0/G_1-phase and also inhibited blast transformation. However, induction of CD25 and CD69 on the cell surface was unaffected, and the production of IL-2 was reduced by only 35-40%, suggesting that HQ- and catechol-treated T cells initiate the activation process, but inhibition of one or more pathways halts further progress. RNA synthesis, which is characteristic of G_1-phase entry and progression, was inhibited by greater than 75% in HQ- and catechol-treated cells. Additionally, HQ and catechol diminished the number of transferrin receptors (TfR) per cell, and western blot analyses revealed that E2F-dependent gene expression, including genes encoding Cdk1 and Mcm2, was reduced by 60-80%. Finally, HQ or catechol exposure prevented dissociation of E2F4 from p130, which may explain reduced E2F activity. The relationship between inhibition of E2F activity and TfR expression is not yet known, but the combined effects clearly contribute to the failure of activated T cells to progress through G_1-phase of the cell cycle. To our knowledge, these studies provide the first explanation of how these benzene derivatives affect the first stage of proliferation in any cell type. *Supported by the Cancer League of Colorado and NIEHS grant ES05673.*

871 EVIDENCE FOR THE INDUCTION OF APOPTOSIS IN IMMUNE CELLS BY DELTA-9-TETRAHYDROCANNABINOL.

R. J. McKallip, C. Lombard, B. R. Martin, M. Nagarkatti and P. S. Nagarkatti. *Microbiology and Immunology and Pharmacology and Toxicology, MCV/VCU, Richmond, VA.*

Delta 9-tetrahydrocannabinol (THC), the main psychoactive component of marijuana has been shown to suppress the immune response. However the exact mechanism of THC-induced immunosuppression remains unclear. In the current study we tested the hypothesis that exposure to THC leads to the induction of apoptosis in lymphocyte populations. Splenocytes cultured in the presence of 10 μM or greater concentrations of THC showed significantly reduced proliferative responses to mitogens, including anti-CD3 mAbs, Con A, and LPS *in vitro*. Thymocytes as well as naïve and activated splenocytes exposed to 10 μM or 20μM THC showed significantly increased levels of apoptosis. *in vivo* studies revealed that 10 mg/kg of THC injected i.p. led to thymic and splenic atrophy as early as 6 hours after treatment. THC exposure led to reductions in all subpopulation of splenocytes and thymocytes examined. Functional studies revealed that splenocytes from THC-treated mice had significantly reduced proliferative responses to anti-CD3 mAbs, Con A, and LPS *in vitro*. Finally, examination of apoptosis in the thymus and spleen revealed that exposure to THC resulted in increased levels of apoptotic cells in both thymic and splenic cultures. Together these results suggest that exposure to THC can lead to significant suppression of the immune response by induction of apoptosis. (Supported in part by NIH grants: RO1ES09098 and RO1HL58641).

872 EFFECTS OF ETHANOL ON CYTOKINE INDUCTION BY POLYINOSINIC POLYCYTIDYLIC ACID (POLY I:C).

S. B. Pruett, R. Fan and Q. Zheng. *Cellular Biology & Anatomy, LSU Health Sci. Center, Shreveport, LA.*

Ethanol suppresses Natural Killer (NK) cell activation by poly I:C in a binge drinking model in mice. This leads to diminished resistance to B16F10 tumor cells. Possible mechanisms for this effect are under investigation. In the present study, the effect of ethanol (EtOH) on the induction of cytokines that are important in activation of NK cells was investigated. Mice were treated with poly I:C (0.1 mg/mouse, ip) and EtOH (6 g/kg as a 32% solution in water, by gavage) or corticosterone (18 mg/kg in 2% beta-cyclodextrin, sc) at the same time. Mice were then bled and the spleen was obtained for analysis. RNAse protection assays were used to examine expression of cytokine mRNAs in the spleen 2 hr after dosing (using a custom probe kit from Pharmingen). Ethanol suppressed expression of IFN-alpha, IFN-beta, IFN-gamma, IL-12, and IL-15. Expression of IL-6 was not affected and expression of IL-10 was increased. Because EtOH induces a stress response, corticosterone was evaluated using a dosing scheme that produces the same area under the corticosterone concentration *vs.* time curve as measured in EtOH-treated mice. Corticosterone decreased expression of IFN-alpha, IL-6, and IL-12 but had no effect on the other cytokines. To confirm that changes in mRNA changed the concentration of cytokine proteins, IFN-alpha, IL-12, and IL-10 were evaluated by ELISA (using kits from PBL Biomedical and Pharmingen). All three of these cytokines reached peak levels 4-8 hr after poly I:C. EtOH and corticosterone decreased serum IFN-alpha from ~300 pg/ml to less than 50 pg/ml at 2 and 4 hr. In contrast, EtOH increased IL-10 concentration, whereas corticosterone had no effect. The levels of IL-12 were significantly decreased from ~38, 000 pg/ml to less than 5000 pg/ml at 2 hr. These results indicate suppression of NK cell activating cytokines and enhancement of immunosuppressive IL-10 may contribute to the deleterious effect of EtOH on resistance to tumor cells and that corticosterone is not the major mediator of most of these changes. This work was supported by NIAAA grant AA09505.

873 GALLIUM ARSENIDE INDUCES MACROPHAGE ACTIVATION.

K. L. McCoy, M. T. Harrison, S. M. Becker and C. B. Hartmann. *Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA.*

Gallium arsenide (GaAs), a semiconductor utilized in the electronics and computer industries, has the paradoxical effects of causing systemic immunosuppression and local inflammatory reaction at the exposure site. Macrophages at the exposures site appear activated. To distinguish between GaAs' primary mode of action and secondary consequences, macrophages isolated from unexposed mice and macrophage cell lines were exposed to GaAs *in vitro*. In culture, GaAs upregulated expression of invariant chain, and the proteases, cathepsins B and L, regardless of the cell source. Invariant chain cleavage was also enhanced. Hence, GaAs directly influences macrophages. However, not all phenotypic changes exhibited by macrophages chemically exposed *in vivo* were observed after *in vitro* exposure, such as increased major histocompatibility complex class II expression. These findings raise the possibility that the complete impact of GaAs on macrophages may require cytokine secretion. To study the role of cytokines in GaAs' immunomodulation, DNA microarray analysis and mice having disrupted cytokine genes are being used. The ability of GaAs to activate macrophages may contribute to the chemical-induced inflammation at the exposure site. This work was supported by NIEHS grant ES07199, and M. T. Harrison was supported, in part, by training grant T32 ES07087.

874 CISPLATIN INDUCED GENE EXPRESSION AND ALTERED MORPHOLOGY IN RAT AND HUMAN KIDNEY SLICES.

A. E. Vickers, M. J. Saulnier, K. Rose, J. Markovits, P. Sahota and P. Bentley. *Toxicology/Pathology, Novartis, E. Hanover, NJ.*

To improve the prediction for man, gene expression technology in combination with measurements of cell function and morphology has been applied to rat and human kidney slices and to a rat *in vivo* study, exposed to the broadly used anticancer agent cisplatin. Kidney of rats administered 1 mg/kg for 5 days or a single dose of 8 mg/kg exhibited tubular degenerative and regenerative changes, granular and proteinaceous casts and tubular/intratubular mineralisation at 96 hours. Kidney slices of rat (10-80 μM) and human (40-500 μM) revealed changes consistent with acute nephrosis of the tubular epithelium. In the rat the cellular injury was localised preferentially in the medulla and at the cortico-medullary junction, whereas in the human kidney slices there was no preferred location. Convoluted regions of the tubules were more susceptible to injury followed by the straight and collecting ductules. Immunohistochemistry staining for apoptosis correlated with the location of damage. In both species, the glomerulus appeared resistant even at high concentrations of cisplatin. The gene categories induced by cisplatin were time and dose dependent and preceded a change in morphology in both species. Gene categories included: apoptosis, DNA damage, cell stress, protein damage, cell cycle/proliferation, metabolism and transport-related genes. In summary, cisplatin-induced nephrotoxicity was demonstrated in rat and human kidney slices by changes in gene expression profiles followed by morphological features. Refinement of the understanding of the gene pathways to better define the mechanisms of toxicity and relate them to interspecies differences in morphology is ongoing.

875 CISPLATIN-INDUCED RENAL CELL APOPTOSIS IS p53 AND CASPASE-DEPENDENT AND INDEPENDENT.

B. S. Cummings and R. G. Schnellmann. *Pharmaceutical Sciences, Med. University of South Carolina, Charleston, SC.*

The chemotherapeutic cisplatin causes renal dysfunction and renal proximal tubular cell (RPTC) apoptosis by mechanisms known to involve the activation of caspase 3. The goal of these studies was to determine the mechanism of cisplatin-induced caspase 3 activation and apoptosis. Cisplatin (50 μM) produced time-dependent apoptosis over 24 hr in primary cultures of RPTC, causing cell shrinkage, a 50-fold increase in caspase 3 activity, a 4-fold increase in phosphatidylserine externalization, and 5- and 15- fold increases in chromatin condensation and DNA hypoploidy, respectively. Caspase 8 and 9 activities did not increase at any time during the 24 hr cisplatin exposure, suggesting these enzymes did not mediate cisplatin-induced caspase 3 activation. Immnocytochemistry and immunoblot analysis revealed that cisplatin treatment of RPTC increased nuclear p53 expression as early as 4 hr after treatment. This increase preceded caspase 3 activation and chromatin condensation by 4 hr. Pretreatment with the p53 inhibitor α (2-(2-imino-4, 5, 6, 7-tetrahydrobenzothiazol-3-yl)-1-*p*-tolylethanone) (PFTα, 10 μM) prior to cisplatin treatment inhibited p53 nuclear expression at 4, 8 and 12 hr and totally inhibited phosphatidylserine externalization and caspase 3 activation at 12 hr. In contrast, PFTα only partially inhibited caspase 3 activation, chromatin condensation and DNA hypoploidy after 24 hrs of exposure. Neither the caspase 3 inhibitor DEVD-fmk nor the general pan caspase inhibitor ZVAD-fmk (50 μM) inhibited cisplatin-induced p53 nuclear expression. Both DEVD-fmk and ZVAD-fmk completely inhibited caspase-3 activity but, like PFTα, only partially inhibited cisplatin-induced chromatin condensation, annexin V labeling and DNA hypoploidy after 24 hr. These data demonstrate that approximately 50% of cisplatin-induced apoptosis is dependent on p53 and caspase 3 while another 50% occurs independently of both proteins.

876 DISRUPTION OF N- AND KSP-CADHERIN LOCALIZATION AND EXPRESSION IS ASSOCIATED WITH MERCURY-INDUCED ACUTE RENAL FAILURE.

J. Jiang[1], R. C. Burghardt[2] and A. R. Parrish[1]. [1]*Medical Pharmacology & Toxicology, College of Medicine, Texas A&M University System Health Science Center, College Station, TX and* [2]*Veterinary Anatomy and Public Health, College of Veterinary Medicine, Texas A&M University, College Station, TX.*

Adhesion molecules play a critical role in maintaining the integrity and polarity of proximal tubular epithelial cells. Although a disruption of cell-cell interactions is suggested in acute renal failure (ARF), little information is known about the expression or integrity of both zonula occludens (tight junctions) and zonula adherens (cadherin) during ARF. The purpose of this study was to investigate the expression and localization of adhesion molecules during mercury chloride-induced

ARF. Male C3H mice were challenged with 25 μM/kg mercury i.p. Plasma creatinine and blood urea nitrogen were significantly elevated at 12, 24, and 48 hr, indicating a reduction of renal function. Western blot analysis revealed no major changes in the expression of tight junction components, ZO-1, ZO-2, or claudin-1 at 48 hr. In addition, no change in the expression of E- or K-cadherin, or β-catenin was seen. However, large decreases in N- and Ksp-cadherin, and α- and p120 catenin were observed. These decreases were not observed at 6 and 12 hr, but were seen following 24 hr of mercury challenge. Immunohistochemistry demonstrated that the Ksp-cadherin was localized along the lumen of renal proximal and distal tubule. At 48 hr, there was a distinct loss of immunoreactivity, and a loss of luminal localization. Similar findings were seen with N-cadherin. Our results indicated that Hg-induced nephrotoxicity is associated with distinct changes in the distribution and expression of zonula adherens proteins, most notably Ksp- and N-cadherin, in the absence of alterations in the expression of zonula occludens consituents. These results further our understanding of toxicant-induced renal failure, and the potential role of adhesion molecules as molecular targets of xenobiotics.

877 SELECTIVE LOSS OF N-CADHERIN EXPRESSION IN THE KIDNEYS OF AGED FISHER 344 RATS, BUT NOT SHR RATS.

S. Gaylor[1], J. Jiang[1], R. C. Burghardt[2], W. H. Griffith[1] and A. R. Parrish[1].
[1]Medical Pharmacology & Toxicology, College of Medicine, Texas A&M University System Health Science Center, College Station, TX and [2]Veterinary Anatomy and Public Health, College of Veterinary Medicine, Texas A&M University, College Station, TX.

Aging is associated with a loss of renal reserve, and increased sensitivity to either xenobiotic or physiologic insult. Given the critical role of adhesion molecules in maintaining the integrity and polarity of proximal tubular epithelial cells, it was hypothesized that loss of zonula occludens (tight junctions), zonula adherens (cadherin), or desmosomal proteins may be associated with aging. The purpose of this study was to investigate the expression and localization of adhesion molecules in young (3-4 month) and old (24-26 month) male Fisher 344 rats. Western blot analysis revealed no difference in the expression of several components of tight junctions, including occludin, claudin-1, ZO-1 or ZO-2. Similarly, no differences in the expression of desmocollin, desmoglein, or desmoplakin, constituents of desmosomal junctions, were observed. However, a pronounced loss of N-cadherin was observed, in the absence of major changes in the expression of E- or Ksp-cadherin. The decreased protein expression of N-cadherin cannot be accounted for by solely by the loss of proximal tubular cells since Ksp-cadherin is expressed in an overlapping population of cells. As N-cadherin is also present in neurons projecting to the kidney, immunohistochemical analysis was used to demonstrate that the loss of N-cadherin was localized to proximal tubular epithelium. Decreased protein expression of two catenins, α- and β- was also observed in the aged kidneys with only slight changes seen with γ- or p120 catenin expression. Taken together, these data suggest that aging is associated with decreased expression of N-cadherin and α- or β-catenin, in the absence of significant changes in other adhesion molecules.

878 ADVANCING AGE AND GLOMERULAR LOCATION PLAY SIGNIFICANT ROLES IN THE DEVELOPMENT OF RENAL DISEASE IN LABORATORY DOGS.

M. J. Pomeroy and J. L. Robertson. *Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA.* Sponsor: B. Jortner.

It is well documented that the incidence of renal disease, and therefore renal dysfunction, increases with age in many species of mammals. Such alterations in renal structure and function may significantly affect long-term toxicology studies. The purpose of this study was to assess the temporal evolution of glomerulosclerosis, an important renal lesion, in laboratory housed dogs, an important model system in chronic toxicology studies. We histopathologically examined representative sections of dog kidneys, quantified glomerular lesions (using the 0-5 scale of the World Health Organization classification system) and performed of statistical analysis of extent and distribution of such changes. The kidney samples were obtained by necropsy, and occasionally biopsy, procedures from a collection of 159 purebred Beagle dogs maintained for their entire lifespan in well-controlled conditions. The lesions were correlated with sex, age, and intra-renal location of affected glomeruli to determine the relationship of each in the development of glomerulosclerosis. All dogs examined had some degree of glomerulosclerosis. In the youngest (up to 2 years of age), this was minimal, but was more advanced by middle age (3-7 years). The condition progressed with further aging and was associated with progressive fibrosis and tubular loss. Location and advancing age were significantly related to the development of glomerulosclerosis such that as age increases, the incidence of glomerulosclerosis increases, with the inner ray and inner cortex demonstrating the highest occurrence ($p<0.0001$ for both). This study indicates that glomerulosclerosis is progressive over the lifetime in a genetically similar population of laboratory Beagle dogs maintained under optimal standard environmental conditions. This information needs to be taken into consideration when conducting chronic toxicological experiments using such animals.

879 MERCURY DECREASES TRANSEPITHELIAL RESISTANCE IN MDCK I CELLS: ASSOCIATION WITH ALTERATIONS IN CADHERIN/CATENIN COMPLEXES.

A. R. Parrish and J. Jiang. *Medical Pharmacology & Toxicology, College of Medicine, Texas A&M University System Health Science Center, College Station, TX.*

The loss of transepithelial resistance (TER) in confluent MDCK I monolayers has been used extensively as an *in vitro* model to investigate mechanisms associated with disruption of cell-cell adhesion. The current studies were designed to determine if mercuric chloride is associated with a reduction of TER in MDCK I cells. Cells were seeded on insert 12-well Transwell® insert chambers and following 8 days in culture the cells were challenged with mercuric chloride (0-25 μM) in HBSS. A dramatic reduction in TER was seen with 25 μM mercury at all timepoints examined (15-120 min). A loss of TER was also seen with 12.5 μM mercury at 60 and 120 min, with no effect seen at 6.25 μM. The finding that a more dramatic reduction in TER was seen at 15 min when 25 μM mercury was added to the basolateral compartment *versus* the apical chamber (29 & 52.5% control, respectively) suggests that the adherens junction (cadherin/catenin complex) may be disrupted prior to changes in the zonula occludens (tight junction). This finding is supported by Western blot data that demonstrate a small, but significant, increase in the amount of β- and p120 catenin in the Triton X-100 soluble fraction of MDCK cells at 15 and 60 min following mercury challenge. These data suggest that *in vitro* mercury challenge is associated with a disruption of cell-cell adhesion, as evidenced by the loss of TER, and suggest that alterations in cadherin/catenin complexes may precede changes in the tight junction following mercury challenge.

880 TISSUE REPAIR: A KEY TO SURVIVAL FOLLOWING NEPHROTOXIC CHALLENGE.

V. S. Vaidya[1], K. Shankar[1], E. A. Lock[2], T. J. Bucci[3] and H. M. Mehendale[1].
[1]Toxicology, The University of Louisiana at Monroe, Monroe, LA, [2]Central Toxicology Laboratory, Syngenta, Macclesfield, Cheshire, United Kingdom and [3]Pathology Associates International, NCTR, Jefferson, AR.

Trichloroethylene (TCE), a common industrial degreasing solvent, is produced in the United States at about 130, 000 metric tons per year. One of the primary mechanisms hypothesized for TCE-induced renal damage and tumors in humans and rodents is *via* the glutathione-dependent β-lyase-mediated formation of S-(1, 2-dichlorovinyl)-L-cysteine (DCVC) metabolite *in vivo*. Our preliminary studies suggested that a timely and adequate renal tissue repair response results in survival of the animals from a low or medium toxic dose of DCVC. However, inhibition of tissue repair, known to occur after a high dose of DCVC, leads to animal death by renal failure. The objective of this study was to investigate the effects of modulation of tissue repair on the ultimate outcome of renal toxicity. When cell division and timely tissue repair were blocked with colchicine, an ordinarily non-lethal dose of DCVC (30 mg/kg, ip) resulted in 90 % mortality suggesting that patency of cell division is very critical for recovery from renal injury of DCVC. The next strategy was to "preplace" renal tissue repair by two different approaches. First approach was to administer a low dose (15 mg/DCVC/kg, ip) 72 h prior to administering a normally lethal dose (75 mg/kg, ip). Second approach was to administer mercuric chloride (6 mg/kg, ip), a well-known nephrotoxicant, 96 h prior to a lethal dose of DCVC. In both the cases augmented and sustained cell division and tissue repair (^{3}H-thymidine pulse labeling and PCNA immunohistochemistry) induced by the priming low dose resulted in 100 % survival inspite of initial massive renal injury. These findings clearly suggest that tissue repair is the key mechanism for survival following an ordinarily lethal nephrotoxic challenge. These results point to novel post-exposure pharmacotherapeutic avenues for treatment of acute renal failure to change the clinical course from hopeless to one of a positive prognosis.

881 CALPAINS MEDIATE PROTEOLYSIS OF PAXILLIN, VINCULIN, AND TALIN DURING ACUTE RENAL CELL DEATH.

X. Liu and R. G. Schnellmann. *Pharmaceutical Sciences, Med. University of South Carolina, Charleston, SC.*

Calpains, Ca^{2+}-activated neutral cysteine proteases, play a critical role in acute renal cell injury/death. However, their cellular substrates in this process remain poorly defined. Paxillin, vinculin, talin, and α-actinin are cytoskeleton-associated proteins that have been reported to be calpain substrates. The goals of the present study were to determine 1) if paxillin, vinculin, talin and α-actinin are calpain substrates during acute renal cell death, and 2) the effects of the calpain inhibitors PD150606 (a

Ca^{2+}-binding site inhibitor) or SJA7029 (a catalytic site inhibitor) on these proteins during cell death. Rabbit renal proximal tubules (RPT) were exposed to antimycin A (10 μM) or subjected to hypoxia for 30 min. LDH release was used as a marker of cell death. Using immunoblot analysis, rabbit RPT expressed 68-kDa paxillin, 117-kDa vinculin, 210-kDa talin, and 100-kDa α-actinin. Treatment of control RPT lysate with purified μ-calpain resulted in decreased parental forms of paxillin, vinculin, talin, but not α-actinin. These results suggest that paxillin, vinculin, and talin, but not α-actinin, are *in vitro* calpain substrates. Antimycin A exposure and hypoxia decreased cytoskeleton-associated paxillin, vinculin, and talin levels, altered RPT morphology, and increased LDH release. α-Actinin levels were not altered during antimycin A- or hypoxia exposure. PD150606 (100 μM) or SJA7029 (100 μM) preserved cytoskeleton-associated paxillin, vinculin, and talin levels, preserved RPT morphology, and blocked LDH release. The results demonstrate that calpains cleave paxillin, vinculin, and talin during acute renal cell death, and suggest that calpain proteolysis of these substrates may lead to the cell death morphology.

882 QUANTITATION OF THE DOSE-RESPONSE FOR FORMATION OF DNA ADDUCTS IN RAT LIVER BY 2-ACETYLAMINOFLUORENE.

G. M. Williams, M. J. Iatropoulos, J. D. Duan and A. M. Jeffrey. *Dept. of Pathology, New York Medical College, Valhalla, NY.*

We have developed an initiation/promotion model of rat liver carcinogenesis to quantify initiation effects of genotoxic carcinogens at low exposures for 12 weeks followed by phenobarbital promotion for 24 weeks to elicit tumor development. In previous studies, we demonstrated non-linearities and no effect levels for some of the critical early events of initiation, including DNA adduct formation, inhibition of bioactivation, liver cell toxicity and compensatory hepatocellular proliferation and induction of preneoplastic lesions, as well as no-effect levels for promotable neoplasia, for 2-acetylaminofluorene (AAF) (*Toxicol. Sciences.*, **45**, 152, 1998) and diethylnitrosamine (*Arch. Toxicol.*, **73**, 394, 1999). With AAF at the lowest cumulative exposure (126 μmol/kg bw over 12 weeks), DNA adducts were formed, but no promotable liver neoplasia was found. At the next highest exposure (420 μmol/kg bw), DNA adducts were about 4-fold higher and weak promotable neoplasia (1 adenoma) was observed. The purpose of the present study was to assess DNA adduct formation and initiation at similar and lower exposures than those used in the previous study. As before, AAF was administered over 12 weeks for cumulative exposures of 4.2, 42, 420 (the mid dose from the previous study), or 840 μmol/kg/bw followed by 4 weeks recovery. Increases occurred in relative liver weights, but no increase in plasma alkaline phosphatase or transaminases was evident. DNA adducts, expressed as % of the highest dose (100%) were 0.8, 2.9 and 21.8% for the other exposures, respectively, and 1.1% for the controls. The controls showed 1 spots, one of which was co-chromatographic with the AAF-DNA adducts thus limiting detection of the latter at the lowest dose. Further efforts are underway to resolve this analysis. We conclude that AAF forms DNA adducts at exposures below those producing even early biological markers of initiation.

883 ACCELERATOR MASS SPECTROMETRY: A TOOL FOR TRACING ENVIRONMENTALLY-RELEVANT DOSES OF ^{3}H AND ^{14}C-LABELED CARCINOGENS.

K. Dingley, E. Sanchez, M. Chiarappa-Zucca and K. Turteltaub. *Biology and Biotechnology Research Program, Lawrence Livermore National Laboratory, Livermore, CA.*

Accelerator mass spectrometry (AMS) is a nuclear physics technique for quantifying rare, long-lived isotopes with high sensitivity and precision. Consequently, AMS has facilitated *in vivo* studies at environmentally relevant exposure levels of carbon-14 and tritium labeled carcinogens. We have performed low-level dosimetry studies in laboratory animals, hence establishing the dose-responses for covalent binding of compounds to DNA and protein at ng/kg body-weight doses, with DNA adduct level detection limits as low as 1 adduct/10^{11}nucleotides. More recently, human studies have been conducted in which volunteers have been administered dietary relevant doses of heterocyclic amine food mutagens. Adduct levels were 10-fold higher in humans than in rats administered the equivalent dose. Through these studies we are able to more accurately determine the risk associated with environmental exposure to carcinogens. The work was conducted under the auspices of the US DOE by LLNL (W-7405-ENG-48) and partially supported by NIH (NCRR) and DOD.

884 DNA ADDUCT CONFORMATION DEPENDS ON DNA CONFORMATION.

G. H. Jiang[1], M. Skorvaga[2], B. Van Houten[2] and J. C. States[1]. *[1]Pharmacology & Toxicology, University of Louisville, Louisville, KY and [2]NIEHS, Research Triangle Park, NC.*

Benzo[*a*]pyrene is metabolically activated to the highly mutagenic derivative (+)-7*R*, 8*S*-dihydroxy-9*S*, 10*R*-epoxy-7, 8, 9, 10-tetrahydrobenzo[*a*]pyrene (BPDE). BPDE-adducts can be one of two stereoisomers and each can adopt several conformations. BPDE-adducts along the DNA are repaired at different rates suggesting that sequence context influences repair rate. How sequence context alters repair efficiency is unknown. Our hypothesis is that adduct conformation plays a key role in the recognition and incision of adducts by the NER system and that DNA conformation influences stereo-specific structure and conformation of BPDE-adducts. We examined the role of DNA conformation in the formation of BPDE-adducts and in the recognition and excision of BPDE-adducts by *B. caldotenax* UvrABC. Both supercoiled and linear plasmid DNAs were reacted with BPDE and subjected to uvrABC incision. Incision efficiency on adducts formed in supercoiled DNAs were 2-5 fold greater than of adducts formed in linear DNAs. Linearizing supercoiled plasmid DNAs after BPDE adduct formation did not diminish incision efficiency. Heat denaturation and reannealing of supercoiled plasmids decreased incision efficiency suggesting that the conformation of the adducts changed. Others have shown that *E. coli* UvrABC more efficiently incises (+)-*cis*-BPDE isomers than (+)-*trans*-BPDE isomers which were both site-specifically constructed into 50-mer substrates. If *B. caldotenax* UvrABC works similarly to *E. coli* UvrABC, our results suggest that on supercoiled DNA (+)-*cis*-BPDE isomer adducts are predominantly formed, whereas on linear DNA the (+)-*trans*-BPDE isomer adducts predominate. These results support our hypothesis, and these stereoisomeric lesions can serve as a conformational structural tool not only for exploring the mechanism of DNA damage processing by NER but also to provide insights into the potential impact of lesions on mutagenesis. (Supported by NIH Grant 1R01-ES06460 and the Commonwealth of Kentucky Research Challenge Trust Fund.)

885 IDENTIFICATION AND CHARACTERIZATION OF THREE NOVEL N^2-DEOXYGUANOSINE ADDUCTS OF DIEPOXYBUTANE.

X. Zhang and A. A. Elfarra. *Comparative Biosciences, University of Wisconsin-Madison, Madison, WI.*

1, 3-Butadiene (BD) is a known rodent and human carcinogen, but the molecular mechanisms of its carcinogenicity are not well understood. Diepoxybutane (DEB), a potent mutagenic metabolite of BD, has been suggested to play a significant role in BD-induced carcinogenicity, and has been reported to react with 2'-deoxyguanosine (dG) to yield *N*-7-(trihydroxybutyl)guanine adducts. In the present study, three novel dG adducts of DEB were characterized from the reaction of DEB and dG at physiological conditions (pH 7.4, 37°C). The adducts were purified from the reaction mixture using Sephadex-LH-20 chromatography and semi-preparative C-18 HPLC. The structures of the adducts, as determined by ESI MS and NMR (including ^{1}H, ^{1}H-COSY, ^{13}C, ^{13}C DEPT135 and HMQC spectra), were N^2-(2-hydroxy-3, 4-epoxy-1-yl) deoxyguanosine and a diastereomeric pair of N^2-(1-hydroxy-3, 4-epoxy-2-yl) deoxyguanosine. Time-course experiments under different pH conditions indicated that the three adducts were formed readily under both neutral and alkaline conditions (pH 10.0) and that the isolated products were stable for several days under purification and storage conditions. A degradation product of N^2-(2-hydroxy-3, 4-epoxy-1-yl)deoxyguanosine was obtained under certain lyophilization conditions and characterized as N^2-(2-hydroxy-3, 4-epoxy-1-yl)guanine by MS and NMR. These results, which shed new light on the reactivity of DEB, may aid in the development of useful biomarkers for DEB. The results may also contribute to a better understanding of the molecular mechanisms of BD- and DEB-induced mutagenicity and carcinogenicity (This research was supported by NIH Grant ES06841 from the National Institute of Environmental Health Sciences).

886 SYNTHESIS, CHARACTERIZATION AND *IN VITRO* IDENTIFICATION OF N^7-GUANINE ADDUCT OF 2-BROMOPROPANE.

E. S. Lee[1], L. X. Zhao[2], E. K. Kim[1], Y. S. Moon[1], H. T. Lim[1], N. H. Kim[1], T. H. Kim[2], S. H. Ahn[2], T. C. Jeong[1] and W. Chae[3]. *[1]College of Pharmacy, Yeungnam University, Kyongsan, South Korea, [2]Institute for Drug Research, Yeungnam University, Kyongsan, South Korea and [3]College of Medicine, Catholic University of Daegu, Daegu, South Korea.*

Recently, we have reported that 2-bromopropane might have an immunotoxic potential in rats when exposed for 28 days. In the present studies, the possibility of 2_i^--deoxyguanosine adduct formation by 2-bromopropane was investigated *in vitro* to elucidate molecular mechanism of 2-bromopropane-induced immunosuppression. N^7-Guanine adduct of 2-bromopropane (i.e., N^7-isopropyl guanine) and its derivatives were chemically synthesized and structurally characterized by analysis of UV, ^{1}H NMR, ^{13}C NMR, COSY and fast atom bombardment mass spectrometry to use as a reference material. Incubation of 2_i^--deoxyguanosine with an excess amount of 2-bromopropane in PBS buffer solution, pH 7.4, at 37°C for 16 hr, followed by a thermal hydrolysis, produced a detectable amount of N^7-isopropyl guanine by an HPLC analysis. In addition, calf thymus DNA was incubated with an excess amount of 2-bromopropane in PBS buffer solution, pH 7.4, at 37°C for 16

hr. After a thermal hydrolysis, followed by removal of DNA by a microfiltration, N^7-isopropyl guanine was detedcted by an HPLC analysis. The present results suggest that 2-bromopropane might form a DNA adduct in N^7 position of 2_i^--deoxyguanosine at a physiological condition.

887 *IN VIVO* AND *IN VITRO* ADDUCT FORMATION AND MUTATIONAL SPECTRA OF S-(2-CHLOROETHYL)-GLUTATHIONE AND N-ETHYL-N-NITROSOUREA IN THE P53 GENE.

J. G. Valadez[1,2] and F. P. Guengerich[1]. [1]*Biochemistry and Center in Molecular Toxicology, Vanderbilt University, Nashville, TN and* [2]*Biotecnologia y Bioingenieria, CINVESTAV-IPN, Mexico City, Mexico.*

Mutations on p53 tumor suppressor are common in diverse types of human cancers. It is known that p53 binds to DNA in a sequence-specific manner and activates several genes that induce cell cycle arrest or apoptosis following DNA damage. Most of the mutated p53 genes found in human tumors are deficient in sequence-specific trans-activation. The central domain of p53 (encoded by the exons 5 to 8) includes the residues responsible for binding to specific DNA sequences. We employed a yeast functional assay consisting of a double-selection method (Environment Mol. Mutagenesis 35:31-8, 2000) to characterize the nature of N-ethyl-N-nitrosourea (ENU) and S-(2-chloroethyl)-glutathione (CLEGS)-induced mutations of p53 trans-activating activity, in a physiological environment. Both mutagens produced transitions, mostly on G-rich regions. However, the sequence analysis revealed different patterns of hotspots depending on the mutagen used. With ENU high frequency of mutation was observed at codons 141, 177, 194, 199, and 278; with CLEGS high frequency was observed at codons 152, 177, 244, and 279. On the other hand, a ligation mediated polymerase chain reaction (LM-PCR) assay, using fluorescent-labeled primers, was developed to establish if those hotspots corresponded to the sites where adducts are produced *in vivo* and *in vitro* by CLEGS. We observed a complex pattern of adduced nucleotides, preferentially on G-rich sequences along both strands in exons 5 to 8 of p53. This profile of adducts did not correspond to the pattern of hotspots observed, indicating that different factors are responsible for mutation fixation inside the cell than those revealed by the LM-PCR analysis.

888 THE SCREENING OF TARGET CANDIDATE REGIONS SUSCEPTIBLE TO MUTATIONS IN THE GENOME OF HAMSTER KIDNEY TUMORS INDUCED BY STILBENE ESTROGEN.

K. P. Singh and D. Roy. *Environmental Health Sciences, University of Alabama at Birmingham, Birmingham, AL.*

Diethylstilbestrol (DES) is a renal carcinogen in Syrian hamsters. However, the mechanism of DES-induced carcinogenesis is not clear. In order to understand the sequential molecular events involved in the DES-induced tumorigenesis, it is important to identify the genomic target candidate regions susceptible to mutations. In this study, we used the Random Amplified Polymorphic DNA (RAPD), a polymerase chain reaction based fingerprinting assay, to screen the entire genome for mutations in DES induced hamster kidney tumors. Tweleve out of hundred primers used for RAPD amplification revealed 22 amplification products harboring mutation(s) in DES induced hamster kidney tumor genome as compared to the age matched untreated control kidney genome. Further characterization revealed that some of these regions harboring mutations are from the coding regions of the kidney tumor genome. Gene expression analysis by RT-PCR revealed that one of the uncharacterized mutated genes is downregulated by several folds in the kidney tumors as compared to the age-matched controls. Findings of this study indicates that RAPD is an efficient method to identify the target candidate regions in the genome that are susceptible to mutations induced by exposure to synthetic estrogen, DES.

889 MECHANISTIC STUDIES OF ACRYLAMIDE INDUCED CARCINOGENICITY IN THE F344 RAT.

J. S. Lafferty, L. M. Kamendulis, M. A. Friedman and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Chronic treatment with acrylamide in drinking water increased the incidences of adrenal pheochromocytomas, mesotheliomas of the tunica of the testes, and follicular adenomas of the thyroid in male F344 rats. The mechanism(s) for these chronic effects of acrylamide is unresolved. The present studies were conducted to determine whether acrylamide or an acrylamide metabolite altered cell growth in the target tissues in the rat. Specifically, DNA synthesis, mitosis and apoptosis were examined in F344 rats treated with acrylamide (0, 2, or 15mg/kg/day) for 7, 14, or 28 days. Acrylamide treatment produced an increase in DNA synthesis in the target tissues (thyroid, testicular mesothelium, adrenal medulla) at all doses and time points examined. In contrast, in a non-target tissue (liver), no increase in DNA synthesis was seen. No changes in apoptosis or mitosis were observed in any of the tissues examined. Blockage of oxidative metabolism of acrylamide using 1-aminobenzotriazole reduced acrylamide-induced DNA synthesis only in the adrenal medulla. Examination of DNA damage using the Comet assay (single cell gel electrophoresis) showed an increase in DNA damage in the target tissues, but not in non-target tissue (liver). In summary acrylamide causes both an increase in DNA synthesis and DNA damage in the previously reported tumor target sites suggesting that these events in concert may contribute to the observed acrylamide-induced carcinogenicity in the rat.

890 INDUCTION OF MICRONUCLEI IN RAT HEPATOCYTES FOLLOWING DNA DOUBLE-STRAND BREAKS CAUSED BY FURAN TOXICITY *IN VITRO*.

Y. Zhang, V. A. Wong, D. J. Abernethy, L. Recio and G. L. Kedderis. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Furan is hepatotoxic and hepatocarcinogenic in rodents but is not mutagenic. Our laboratory has shown that furan metabolites deplete hepatocyte ATP and activate endonucleases that produce DNA double-strand breaks (dsb). We hypothesize that misrepair of DNA dsb results in mutations involved in furan carcinogenesis. Our objective was to determine whether misrepair of furan-induced DNA dsb leads to cytogenetic events such as micronuclei formation. F-344 rat hepatocytes were incubated in suspension with furan (0 to 100 μM) for up to 3 hr and then placed in monolayer culture with EGF (50 ng/ml) for 72 hr. The number of hepatocytes with micronuclei stained with DAPI and the mitotic index were determined by fluorescence microscopy. Flow cytometry analysis of BrdU incorporation was used to evaluate cell cycle effects. The spontaneous micronuclei frequency was 6.0 ± 0.7%. Furan treatment significantly increased the frequency of micronuclei in a concentration- and time-dependent manner but did not affect mitotic indices. The micronuclei frequencies for the 3-hr exposure to furan at concentrations of 2, 10, 30, and 100 μM were 7.0 ± 0.4%, 10.3 ± 2.1%, 13.1 ± 1.7%, and 17.8 ± 1.2%, respectively. Both inhibition of furan biotransformation by the cytochrome P450 inhibitor 1-phenylimidazole (200 μM) and inhibition of the endonuclease activity by aurintricaboxylic acid (100 μM) prevented micronuclei induction, indicating a requirement for metabolic activation and the need for endonuclease-mediated DNA damage. The labeling index of hepatocytes treated with furan at 30 μM for 3 hr (61.0 ± 6.2%) was significantly greater than that of control cultures (17.8 ± 3.6%), indicating the induction of DNA synthesis. The results of these studies show that hepatocyte DNA dsb formed by furan-induced activation of endonucleases lead to cytogenetic events such as micronuclei formation. The cytogenetic events coupled with furan-induced cell proliferation in the livers of treated rodents are likely to be involved in the development of hepatocellular carcinomas.

891 TOXICITY AND CARCINOGENICITY OF BENZO(A)PYRENE IN SKIN OF DNA REPAIR-DEFICIENT MICE.

S. V. Vulimiri, M. Gallegos and J. DiGiovanni. *Carcinogenesis, UT M.D.Anderson Cancer Center, Smithville, TX.* Sponsor: J. DiGiovanni.

In the present study, we hypothesized that transcription coupled repair (TCR) and global genomic repair (GGR) might modulate BENZO(A)PYRENE (B[a]P)-induced toxicity and carcinogenicity, respectively, in the skin of XP knockout (KO) mice belonging to subgroups C (XPC) and A (XPA). For this purpose, we treated wild type (WT), and XPC and XPA KO mice topically with B[a]P as a single (20, 50 or 200 nmol [group#1]) or multiple doses (20, 50, 100 or 200 nmol once-weekly for 3 weeks [group#2] or 200 nmol once-weekly for 6 weeks [group#3]). Levels of B[a]P diol epoxide-deoxyguanosine (BPDE-dGuo) adducts, hyperplasia and bromodeoxyuridine labeling index (LI) were examined in the epidermis at different time points. Preliminary results showed that Group#1 mice did not differ in the level and disappearance of DNA adducts from epidermal DNA after a single dose of B[a]P, except in XPA KO mice, adducts disappeared more rapidly at the highest dose (200 nmol) tested, which paralleled increased epidermal hyperplasia and LI. In group#2 mice, levels of BPDE-dGuo adducts were similar between all backgrounds of mice at 20 nmol dose of B[a]P. However, at and above 50 nmol of B[a]P XPC KO mice had higher adduct levels than both WT and XPA KO mice. Also in group#3 mice, BPDE-dGuo adduct levels in XPA KO mice were lower than WT and XPC KO mice after multiple doses (200 nmol) of B[a]P. Notably, the decrease in adduct levels in XPA KO mice (Groups#2 & #3) again paralleled increased epidermal hyperplasia and LI suggesting that the lower levels of BPDE-dGuo adducts were due to dilution with newly synthesized DNA. Results from a complete carcinogenesis experiment with several doses of B[a]P suggest that the hyperplasia and cell proliferation induced by higher doses of B[a]P in XPA KO mice leads to a promoting stimulus. XPC KO mice appeared to be more sensitive to

B[a]P complete carcinogenesis at low doses compared to WT or XPA KO mice suggesting that GGR may play an important role in modulating carcinogenesis by PAH in mouse skin.(Supported by grants CA16672 & ES07784)

892 ARSENIC COCARCINOGENESIS: A NEW PARADIGM.

T. G. Rossman, A. N. Uddin, F. J. Burns and M. C. Bosland. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Epidemiological evidence strongly associates arsenic exposure with increased cancer risk, yet attempts to induce carcinomas in animals have generally failed. This has hindered mechanistic studies of arsenic carcinogenesis. Low concentrations of arsenite are not mutagenic but act as comutagens, most likely due to inhibition of DNA repair. There is evidence that both base and nucleotide excision repair are compromised. However, in biochemical assays, no specific repair enzyme has been found to be sensitive to low concentrations of arsenite, leading to the hypothesis that the effects of arsenite on DNA repair may result from faulty DNA damage-inducible signaling which controls DNA repair. In a test of this hypothesis, Vogt & Rossman (2001) recently showed that in cells treated with submicromolar arsenite and ionizing radiation, the p53-dependent increase in p21 expression, normally a block to cell cycle progression after DNA damage, is deficient. In addition, arsenite upregulated cyclin D1. These results suggest that the failure to find an animal model for arsenic carcinogenesis is because arsenite is not a carcinogen per se, but rather acts as an enhancing agent (cocarcinogen) with a genotoxic partner. We tested this hypothesis with solar UVR as partner in hairless Skh1 mice. Mice given 10 mg/l sodium arsenite in drinking water for 26 weeks had a 2.4-fold increase in tumors yield after 1.7 KJ/m2 UVR 3 times weekly compared with mice given UVR alone. The tumors were mostly squamous cell carcinomas, and those occurring in mice given UVR plus arsenite appeared earlier and were much larger and more invasive than in mice given UVR alone. Mice exposed to arsenite showed increased skin proliferation. These results are consistent with the hypothesis that arsenic acts as a cocarcinogen with a second (genotoxic) agent by inhibiting DNA repair and/or enhancing positive growth signaling. Since arsenic exposure is also associated with lung cancer in humans, it is likely that similar effects will be found in lung cancer as well. This work was supported by NIEHS grant ES09252.

893 SPONTANEOUS AND DNA DAMAGE INDUCED HOMOLOGOUS RECOMBINATION IN MICE DEFICIENT FOR Atm OR p53

A. J. Bishop[1] and R. H. Schiestl[2]. [1]*Genetics, Harvard Medical School, Boston, MA and* [2]*Pathology and Environmental Health, UCLA Medical School, Los Angeles, CA.*

DNA damage is a consequence of both environmental exposure and normal metabolism. A cell is therefore constantly reacting to and repairing DNA damage, the p53 damage response pathway being central to this response. For example, following ionizing radiation, ATM is activated, which then activates p53, which transcriptionally upregulates p21/CIP1/WAF1 and GADD45 to coordinate cell cycle and DNA repair. We have demonstrated that all types of DNA damage induce homologous recombination (HR), leading us to ask whether a relationship exists between the p53 damage response pathway and HR repair. The pink-eyed unstable (pun) murine mutation, a 70 kb tandem duplication within the p locus, results in a dilute coat color and a transparent retinal pigment epithelium (RPE). Reversion by HR deletion of the duplication occurs spontaneously in premelanocytes of the embryo, to produce, after clonal expansion, pigmented cells visible in both the fur and RPE. Such deletion events can be induced by DNA damage. This system allows the examination of both timing of spontaneous HR events, the relative frequency of HR and its inducibility by carcinogens. We have examined the pattern of spontaneous HR in mice with mutations in Atm, p53, p21 and Gadd45. Atm deficient mice display an increasing frequency of HR events during embryogenesis. In contrast, p53 and Gadd45 deficient mice display an increased level of HR only early during embryogenesis, but not later. p21 deficient mice do not display an increased frequency of HR events but do demonstrate a developmental defect in RPE patterning. We have gone on to examine the inducibility of HR in the absence of either Atm or p53 using the differently acting genotoxins X-ray, cisplatin and benzo(a)pyrene. Atm appears to be necessary for X-ray induction of HR, whereas p53 appears to be necessary for both X-ray and cisplatin induction of HR. Neither Atm nor p53 appear to be necessary for benzo(a)pyrene induction of HR. Supported by the NIH (RO1 ES 09519-01, RCDA ES00299 and F32-GM-19147)

894 IDENTIFICATION AND FUNCTIONAL STUDY OF POLYMORPHIC HUMAN XPA GENES.

P. C. Porter[1], T. Hock[2], B. D. Beauerle[1], I. Mellon[2] and J. C. States[1]. [1]*Pharmacology & Toxicology, University of Louisville, Louisville, KY and* [2]*Pathology, University of Kentucky, Lexington, KY.*

XPA initiates excision complex formation in nucleotide excision repair (NER). XPA mutations cause NER deficiency and severe xeroderma pigmentosum (XP) disease. XP patients have a 2, 000-fold higher incidence of skin cancer resulting from impaired repair of UV induced photoproducts. We hypothesize that there are polymorphic XPA alleles that do not eliminate UV-photoproduct repair and thus do not cause XP disease. These polymorphic XPA alleles may reduce repair of chemically induced DNA damage and may be associated with increased incidence of chemically induced cancers. The XPA DNA binding domain is encoded by exons 4 and 5. Exon 6 encodes the transcription factor IIH (TFIIH) binding domain. To identify XPA polymorphisms, PCR amplified fragments containing exons 4, 5 or 6 from 180 random pathology specimens were sequenced. High quality sequence was obtained from fragments containing exon 4 from 129 samples, exon 5 from 146 samples, and exon 6 from 103 samples. Four SNPs and one single nucleotide deletion were found in intron 4. No polymorphisms were found in exons 4 and 5. Only one intron 4 SNP (T to G at -154 bp 5'of exon 5) creates an alternative splice site. Three single nucleotide polymorphisms (SNPs) were found in exon 6 all 3 of which cause missense changes (Arg228Leu, Val234Leu, Leu251Val). The Arg228Leu and Val234Leu alleles are being tested for functional effects on nucleotide excision repair capacity. Survival assays suggest that Arg228Leu and Val234Leu have equivalent survival to the wild type allele for both UV survival and benzo[*a*]pyrene-7, 8-dihydrodiol-9, 10-epoxide (BPDE) survival. Gene specific repair in the DHFR gene shows that the polymorphic XPAs have repair capacity for UV photoproducts equivalent to wild type XPA. Gene specific repair of BPDE-induced DNA damage is currently being performed. Supported by NIH grants ES06460 and RR11803 and funds from the University of Louisville, Kentucky EPSCoR, Markey Cancer Center and Commonwealth of Kentucky Research Challenge Fund.

895 CARCINOGENIC STUDIES WITH ARSENICAL SPECIES IN FEMALE TG.AC (ζ-GLOBULIN-PROMOTED V-HA-RAS) TRANSGENIC MICE.

G. J. Moser[1], R. Goodwin[1] and D. Germolec[2]. [1]*Health Science Division, ILS, Inc., Research Triangle Park, NC and* [2]*NIEHS, Research Triangle Park, NC.*

Studies have shown that arsenic potentiates 12-O-tetradecanoyl-phorbol-13-acetate (TPA)-induced skin papillomas in the TgAC (ζ-globin promoted v-Ha-ras) transgenic mouse model. To characterize the carcinogenicity of arsenic, female homozygous TgAC mice were administered 4 treatments of 2.5 μg TPA followed by one of the following arsenicals administered in water: an inorganic arsenical, sodium arsenite (NaAs) or sodium arsenate, or a pentavalent methylated arsenical, monomethylarsinic acid (MMA) or dimethylarsinic acid (DMA). NaAs (20, 50, and 100 mg arsenic/L) enhanced the papilloma response in TPA-treated mice as compared to mice treated only with TPA. Sodium arsenate increased the incidence of papillomas at doses of 50 and 200 mg arsenic/L, but not at the 100 mg arsenic/L level. The latency and peak number of papillomas were not increased at any dose of sodium arsenate. MMA (500 and 1500 mg arsenic/L) and DMA (200 and 1000 mg arsenic/L) did not increase papilloma induction. These data indicate that only NaAs enhanced papilloma induction in TPA-treated TgAC mice. To discern the role of oxidative damage in NaAs-potentiated skin papillomas, TPA-treated female homozygous TgAC mice were also treated with Vitamin E acetate (Vit E) or Natural Anti-Oxidant (NAO). NaAs (0.015%) was administered beginning at week 3. Vit E or NAO treatment alone had little effect on papilloma induction. The papilloma response of animals treated with Vit E or NAO in conjunction with NaAs was not significantly altered from the response of animals treated with NaAs alone. These data demonstrate the usefulness of the TgAC model system to evaluate tumor induction in the skin and demonstrate that there are different skin carcinogenic responses among arsenical species. The lack of response to antioxidant treatment suggests that arsenic potentiates skin tumors through a mechanism other than the generation of oxygen radicals. (This work was sponsored by NIEHS [contract no. NO1-ES-95442]).

896 DICHLOROACETIC ACID (DCA) TOXICITY STUDY USING Tg.AC AND p53 TRANSGENIC MICE.

G. Boorman[2], J. D. Johnson[1], S. W. Graves[1], M. R. Ryan[1], J. D. Toft, II[1], M. Hejtmancik[1], R. Chhabra[2] and M. Vallant[2]. [1]*Toxicology, Battelle, Columbus, OH and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

DCA, a disinfection by-product (DBP) of drinking water chlorination/ozonization, was administered to Tg.AC and p53 transgenic mice to determine whether these transgenic strains could serve as models to identify the carcinogenic potential of DBP chemicals. In addition, the models may serve to rank families of DBP chemicals for toxicity. Tg.AC and/or p53 mice were exposed to DCA in drinking water (0, 500, 1000 or 2000 mg/L) or by topical application (0, 31.25, 125, or 256 mg/Kg/day) for 26 (Core) or *gE* 39 (Special) weeks. In the drinking-water study, Tg.AC and p53 mice exhibited decreased body weight (>10%) and water consumption, increased liver weight (>10%), lung neoplastic changes (alveolar-bronchiolar adenoma; male Tg.AC mice only), and liver non-neoplastic changes. In the dermal study, Tg.AC mice exhibited an increased incidence of papillomas at the

site of application, increased liver weight (>10%), and non-neoplastic changes at the site of application and in the liver and testes. (Supported by Contract No. N01-ES-65406.)

897 SODIUM BROMATE TOXICITY STUDY USING Tg.AC AND p53 TRANSGENIC MICE.

M. Vallant[2], J. D. Johnson[1], S. W. Graves[1], M. R. Ryan[1], J. D. Toft, II[1], M. Hejtmancik[1], G. Boorman[2] and R. Chhabra[2]. [1]*Toxicology, Battelle, Columbus, OH and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

Sodium Bromate, a disinfection by-product (DBP) of drinking water chlorination/ozonization, was administered to Tg.AC and p53 transgenic mice to determine whether these transgenic strains could serve as models to identify the carcinogenic potential of DBP chemicals. In addition, the models may serve to rank families of DBP chemicals for toxicity. Tg.AC and/or p53 mice were exposed to sodium bromate in drinking water (0, 80, 400 or 800 mg/L) or by topical application (0, 64, 128, or 256 mg/Kg/day) for 26 (Core) or *gE* 39 (Special) weeks. No sodium bromate-related neoplastic lesions were observed in any of the groups. In the drinking-water study, Tg.AC and p53 mice exhibited decreased body weight (>10%) and changes in clinical pathology endpoints. Tg.AC mice also exhibited decreased survival and non-neoplastic changes in the thyroid gland, kidneys, pituitary gland, and testes/epididymides. In the dermal study, Tg.AC mice exhibited decreased body weight (>10%), clinical pathology endpoint changes, and non-neoplastic changes at the site of application, as well as in the thyroid gland, kidneys, spleen, liver, and testes. (Supported by Contract No. N01-ES-65406.)

898 BROMODICHLOROMETHANE (BDCM) TOXICITY STUDY USING Tg.AC AND p53 TRANSGENIC MICE.

J. D. Johnson[1], S. W. Graves[1], G. V. Marit[1], M. R. Ryan[1], M. Hejtmancik[1], G. Boorman[2], R. Chhabra[2] and M. Vallant[2]. [1]*Toxicology, Battelle, Columbus, OH and* [2]*National Toxicology Program, NIEHS, Research Triangle Park, NC.*

BDCM, a disinfection by-product (DBP) of drinking water chlorination/ozonization, was administered to Tg.AC and p53 transgenic mice to determine whether these transgenic strains could serve as models to identify the carcinogenic potential of DBP chemicals. In addition, the models may serve to rank families of DBP chemicals for toxicity. Tg.AC and/or p53 mice were exposed to BDCM in drinking water (0, 175, 350 or 700 mg/L), by gavage (0, 25, 50, or 100 mg/Kg/day) or by topical application (0, 64, 128, or 256 mg/Kg/day) for 26 (Core) or *gE* 39 (Special) weeks. No BDCM-related neoplastic lesions were observed in any of the groups. In the drinking water and gavage studies, mice exhibited increased liver weight and hepatocellular vacuolization (Tg.AC/p53 females); decreased liver weight and hepatocellular vacuolar changes (p53 males); and decreased kidney weight, nephropathy, and tubular dilatation (Tg.AC/p53 males). No site of application or systemic effects was observed for the Tg.AC or p53 mice in the dermal study. (Supported by Contract No. N01-ES-65406.)

899 USE OF C57BL/6 MICE IN CARCINOGENICITY BIOASSAYS.

M. Attia[1], J. Richard[1], R. Forster[1], V. Payraudeau[2] and N. Carmichael[2]. [1]*CIT, Evreux, France and* [2]*Aventis CropScience, Sophia Antipolis, France.*

We present data from control groups of dietary carcinogenicity studies performed with C57BL/6 mice, for a total of 150 male and 150 female animals. The studies had a duration of 78 weeks. On termination of the studies the average survival was 92% for males and 90% for females. The most frequent causes of death were malignant lymphomas and generalised amyloidosis. During the study period average body weight gain for males was 12.2 g., and for females was 12.0 g. Average daily food consumption was 5.2 g (males) and 6.2 g (females); estimation was complicated by spillage of the diet, which was greater for females than males. Plasma levels of hepatic enzymes (ALAT, ASAT and ALP) were evaluated after 52 weeks and did not indicate any abnormalities. No palpable masses were observed at routine evaluation of the animals during the course of the studies. At histopathological examination of all organs, masses and macroscopic abnormalities, common non-neoplastic pathology findings included subcapsular spindle cell proliferation and ceroid degeneration in adrenals, vacuolation of brain white matter, necrotising inflammation of the Harderian gland, mononuclear cell aggregation in the renal pelvis, liver and pancreas, hepatic steatosis, histiocytosis of lymph nodes, atrophic changes in the ovaries, uterus and testes and generalised amyloidosis (adrenals, GI tract, heart, thyroids etc). Commonly observed tumours included malignant lymphomas (13% of males, 15% of females), hepatocellular adenomas (7% of males, 1% of females), and pituitary adenomas (8% of females). Remarkably few neoplastic lesions were found in the other organs and tissues, especially the lungs and the male and female reproductive organs. On the basis of the low and well-defined incidence of non-neoplastic and neoplastic lesions, it is concluded that the C57BL/6 mouse is a suitable model for carcinogenicity testing and that the present data will provide a useful basis for the future use of this strain in our laboratory.

900 COMPARISON OF THE INCIDENCE AND NATURE OF TUMORS IN AD LIBITUM AND RESTRICTED FEEDING REGIMENS FOR CHRONIC STUDIES USING THE SPRAGUE-DAWLEY RAT.

S. McPherson, M. Boyer, P. Batham and C. Banks. *Toxicology, CTBR, Senneville, PQ, Canada.* Sponsor: G. Lulham.

Over the past years investigators working on life span calorie restriction aging and/or carcinogenicity studies have provided unequivocal evidence that the caloric restriction (about 25 to 40% of maximal caloric intake) supplemented with essential nutrients, retards the onset of aging and disease in rodents. Following these and similar findings there has been a move away from ad libitum feeding to restricted feeding in an attempt to increase animal survival by improving the overall health status of the animals. Previous analysis of the data collected at CTBR has shown that animals on these studies had improved survivability and had a lower body weight at the end of the dosing period. Lesion data from control animals from carcinogenicity studies using Sprague-Dawley rats from Charles River Canada were compared between restricted and ad libitum feeding regimens. The percentage incidences (total number of masses/total number of rats) of the major types of tumors/lesions were compared for evidence of any significant differences between the two feeding regimens and to determine any populations of tumors/lesions that were unique or predominately expressed in one of the two feeding regimens. Analysis of the data showed an increased incidence of spontaneous and endocrine tumors for ad libitum feeding when compared to restricted feeding (eg. pituitary adenoma); some significant differences in the incidences between the sexes of certain lesions within the same feeding regimen (eg. mammary gland ectasia); and that it was possible to identify tumors that were either unique or predominate to one of the two types of feeding regimens (eg. pituitary adenoma). In conclusion, restricted feeding results in a decreased incidence of spontaneous and endocrine tumors when compared to ad libitum feeding. Thus providing a more sensitive model for determining carcinogenic potential of a test compound.

901 THE EFFECT OF DIET AND ESTRADIOL ON ACI RAT MAMMARY CARCINOGENESIS.

V. K. Turan[1], A. H. Conney[1,2], J. J. Li[3], S. A. Li[3], H. L. Newmark[2], K. R. Reuhl[1,4] and P. E. Thomas[1,2]. [1]*Joint Grad Prog Toxicol, Rutgers Univ/UMDNJ RWJMS, Piscataway, NJ,* [2]*Lab for Cancer Res, Rutgers College of Pharm, Piscataway, NJ,* [3]*Kansas Cancer Inst, U Kansas Med. Center, Kansas City, KS and* [4]*Pharmacol and Toxicol, Rutgers College of Pharm, Piscataway, NJ.*

The ACI rat, an inbred cross of Copenhagen Irish and August strains, is a valuable model in the study of factors modulating susceptibility to mammary carcinogenesis. ACI rats are highly susceptible to mammary carcinogenesis when estrogen levels are chronically elevated. This study investigates the effect of a Western-style diet (high in fat and low in vitamin D and calcium) on estradiol-induced mammary oncogenesis. Adult female, ovary-intact ACI rats were implanted sc with a control 20 mg cholesterol pellet or a cholesterol pellet that also contained 1 or 3 mg of estradiol. Rats from each group were fed either the test Western-style diet or the control semipurified AIN-76A diet. After 10 weeks of study, one group of rats was sacrificed. There was a significant ($p < 0.05$) increase in liver wet weight for the estradiol-treated rats compared with the cholesterol-treated control rats, though not between either the two doses of estradiol or between the two diets alone. Estradiol caused a significant dose-dependent increase in pituitary wet weight that was not influenced by the diet. A second group was maintained until there was an appreciable mammary tumor burden or the rat became moribund. Rats implanted with the 3 mg estradiol pellet developed palpable mammary tumors at a median of 22 weeks. The diet did not influence estradiol-induced onset of palpable mammary tumors. Histological evaluation of tumors is being evaluated. Rats implanted with 1 mg estradiol and cholesterol are still under study. At this point in the study (32 weeks), it appears that the Western-style diet has little or no effect on the development of estradiol-induced mammary oncogenesis in this model. (Supported by ES05022, ES07148, GM44982)

902 EVALUATION OF THE CARCINOGENICITY OF BISPHENOL A TO RODENTS AND RELEVANCE OF FINDINGS TO HUMANS.

L. A. Haighton[1], J. J. Hlywka[1], J. Doull[2], R. Kroes[3], B. S. Lynch[1] and I. C. Munro[1]. [1]*Cantox Health Sciences International, Mississauga, ON, Canada,* [2]*University of Kansas Medical Center, Kansas City, KS and* [3]*Utrecht University, Utrecht, Netherlands.*

Bisphenol A (BPA) is a monomer component of polycarbonate plastics and epoxy resins, which are used in numerous consumer products, including food-contact plastics. There has been considerable attention and scientific debate regarding the

relevance to humans of reported estrogenic actions of BPA. Conversely, there has been limited consideration of the carcinogenic potential of BPA. The issue of carcinogenicity is important in the regulation of chemicals for which there is potential for widespread exposure. An evaluation of the carcinogenic potential of BPA to humans was completed using metabolic data, genetic toxicity studies, long-term toxicity/carcinogenicity studies, and estimated consumer exposures. Two-year feeding studies in rats and mice administered diets containing up to 2, 000 and 10, 000 ppm BPA, respectively, provided no substantive evidence to indicate that BPA is carcinogenic to rodents. In addition, a battery of standard *in vitro* genetic toxicity assays and a GLP-compliant *in vivo* mouse micronucleus assay demonstrated a lack of genotoxic and mutagenic activity of BPA. Metabolism studies show that ingested BPA is rapidly glucuronidated and excreted. Furthermore, it is estimated that current uses of BPA, including those of food-contact materials, would result in very low human exposure. The toxicology data, taken together with the trivial exposure, support the conclusion that BPA is not a carcinogenic risk to humans.

903 ATRAZINE EXPOSURE *IN UTERO* INCREASES DIMETHYLBENZ[A]ANTHRACENE-INDUCED MAMMARY TUMOR INCIDENCE IN LONG EVANS OFFSPRING.

S. E. Fenton and C. C. Davis. *Reproductive Toxicology Division, USEPA, ORD, NHEERL, Research Triangle Park, NC.*

Recently, we found that ATR exposure during mammary bud outgrowth (late gestation) delays normal postnatal epithelial progression in Long Evans (LE) to a greater extent than in Sprague-Dawley (SD) rats. To determine if ATR-induced developmental delays alter susceptibility of LE females to mammary carcinogen, we gavaged time-pregnant LE (10/treatment) and SD (11-15/treatment) dams with 0, 12.5, 25, or 50 mg ATR/kg body weight (2X/day) on gestation days 15-19. The female offspring were gavaged with dimethylbenz[a]anthracene (30 mg/kg) on postnatal day 45, a time when mammary glands have largely matured in controls. Animals were evaluated for palpable tumors weekly and killed 18 and 24 weeks later. SD offspring exposed to 0, 12.5, 25, and 50 mg ATR/kg (respectively) had overall mammary tumor incidences of 40, 25, 52, and 52% (X^2, p=0.15). Their tumor latency (20, 22, 21, and 22 weeks), multiplicity (2.25, 2.4, 2.9, and 1.5 tumors/tumor-bearing animal), and tumor volumes (3.05, 5.63, 1.81, and 1.08 cm3) were unchanged by gestational ATR. In contrast, LE offspring exposed to 0, 12.5, 25, and 50 mg ATR/kg had overall mammary tumor incidences of 41, 45, 62, and 60% (X^2, p=0.04). Although LE displayed no decrease in tumor latency (20.0, 21.6, 18.3, and 21.7 weeks), they had increased multiplicity (1.1, 1.5, 1.7, and 2.0) and larger tumor volumes (0.8, 0.2, 1.3, and 13.4 cm^3, P=0.04) following ATR *in utero*. Further, LE (but not SD) rats had significant increases in the percentage of animals with abnormalities in additional organs compared to controls (i.e, adrenal nodules, pituitary foci, ovarian cysts>2mm, and lymph node and spleen enlargement) at all ATR doses tested (p<0.05). Our data demonstrate that by delaying mammary gland development, gestational ATR exposure increases the susceptibility of the LE female to carcinogen, perhaps by extending the period of vulnerability. *(This abstract does not necessarily reflect EPA policy).*

904 CHLOROETHANE TOXICITY COMPARED TO STRUCTURALLY-RELATED CHLOROHYDROCARBONS.

J. W. Holder. *NCEA/ORD, USEPA, Haymarket, VA.*

Chloroethane (CE) exposures at 15K ppm causes 86% uterine cancer incidence in B6C3F1 female mice(FM). CE's the most potent carcinogen in the NTP database by incidence. These cancers are (1) an uncommon tumor type, (2) highly metastatic, & (3) the cause of early FM deaths due to tumor load. Contrastingly, F344 rats similarly exposed were almost tumor free. This analysis examines uptake data into mice, rats, cats, guinea pigs, and human volunteers and is based on a peer reviewed a IRIS document and the open literature. Uptakes are similar among species. CE uptake relates to boiling point, Henry's constant, blood:air coefficient, and oil dissolution. SAR chlorohydrocarbons (CHCs)are compared with CE. Based on the physicochemical factors, CE shows the least tendency to get in and stay in the body of any CHC examined. Only high CE levels demonstrate any pharmacologic activity, analgesic (13K ppm) & anesthetic (35K ppm). The lowest recorded chronic pathologic level (5K ppm)is where oxidation is saturated and GSH is depleted especially in the adrenals, ovary, uterus, and liver. CE exposures > 5K ppm may be less detoxified and more available for toxicity. Hyperkinetic activity was observed only in the female mice (FM), but not in MM, MR or FR. Recursive running was observed only during CE exposure which likely produces a state of constant stress in FM. It's known human endometrial cancers can be caused by hyperadrenal activity. Thus, the unusual FM cancers may also be based on overt adrenal stimulation. While murine cancers are known only at the high CE above, low CE has never been tested. It's not likely that lower[CE]-which do not induce stress in FM-will cause uterine carcinogenesis. Re-doing the bioassay to include lower CE exposures, especially < 5K ppm, may indicate whether CE is a threshold carcinogen, or not. As it is, the present data set indicates CE has to considered possibly carcinogenic to humans. Nevertheless, long human use of CE as an surgery anesthetic, with few adverse reports, indicates the expectation of possible carcinogenicity may not hold upon further testing and analysis of CE.

905 ACRYLONITRILE IS A CARCINOGEN IN MALE AND FEMALE B6C3F1 MICE.

B. I. Ghanayem, A. Nyska and J. R. Bucher. *Environmental Toxicology Program, NIEHS/NIH, Research Triangle Park, NC.*

Acrylonitrile is a heavily produced unsaturated nitrile, which is used in the production of synthetic fibers, plastics, resins, and rubber. Once considered a probable human carcinogen, IARC recently changed the classification for acrylonitrile to a possible human carcinogen. Acrylonitrile is a multi-site carcinogen in rats after exposure *via* gavage, drinking water, or inhalation. No carcinogenicity studies of acrylonitrile in a second animal species were available. The current studies were designed to assess the carcinogenicity of acrylonitrile in B6C3F1 mice of both sexes. Acrylonitrile was administered by gavage at 0, 2.5, 10 or 20 mg/kg/day, 5 days per week, for 2 years. A dose-related increase in the incidence of forestomach papillomas and carcinomas was detected in mice of both sexes with the incidences in the high dose reaching approximately 60% in both males and females. Higher incidences of focal or multifocal epithelial hyperplasia of the forestomach were observed in dosed mice. The incidence of harderian gland adenomas and carcinomas was also markedly increased in the acrylonitrile-dosed groups. In female mice, the incidence of benign or malignant granulosa cell tumors (combined) in the ovary in the 10 mg/kg dose group was greater than that in the vehicle control group, but because of a lack of dose-response, this was considered an equivocal finding. In addition, the incidences of atrophy and cysts in the ovary of the 10 and 20 mg/kg dose groups were significantly increased. The incidences of alveolar/bronchiolar adenoma or carcinoma (combined) were significantly increased in female mice treated with acrylonitrile at 10 mg/kg/day for 2 years. This was also considered an equivocal result. In conclusion, these studies demonstrated that acrylonitrile causes multiple carcinogenic effects after gavage administration to male and female B6C3F1 mice for 2-years.

906 TERMINAL OBSERVATIONS IN SPRAGUE-DAWLEY RATS AFTER LIFETIME DIETARY EXPOSURE TO POTASSIUM PERFLUOROOCTANESULFONATE.

A. M. Seacat[1], P. J. Thomford[2] and J. L. Butenhoff[1]. *[1]Medical, 3M, Saint Paul, MN and [2]Toxicology, Covance, Madison, WI.*

Sprague-Dawley rats were given potassium perfluorooctanesulfonate (PFOS, 86.7 %) in the diet at 0, 0.5, 2, 5, & 20 ppm for up to 104 weeks. A recovery group received compound for 52 weeks. Results from interim sacrifices at weeks 4 and 14 were previously described. An interim sacrifice occurred at week 53 for histopathology, cell proliferation and PFOS determination. This report describes observations at 53 weeks through term. At 53 weeks, hepatic histomorphologic changes (without cell proliferation) and body weight effects were observed in 20-ppm animals. Through term, survival was significantly increased for males and body weights were significantly decreased for females at 5 and 20 ppm. Absolute and relative liver weights in males and relative liver weights in females were increased at 20 ppm. Liver toxicity was present at minimal doses of 2 ppm in males and 5 ppm in females. Hepatotoxicity was not present in 20-ppm recovery animals. For males, hepatocellular adenoma was increased for trend (p = 0.028) and pair-wise at 20 ppm (p = 0.046). Hepatocellular adenoma was not observed in the 20-ppm recovery group. Thyroid follicular cell adenoma was increased pair-wise for the 20-ppm recovery group (p = 0.028) which was outside the range of historical control values, yet there were no other indications of thyroid abnormality. For females, hepatocellular adenoma was increased for trend (p = 0.015) and pair-wise at 20 ppm (p = 0.039), hepatocellular adenoma/carcinoma was increased for trend (p = 0.006) and pair-wise at 20 ppm (p = 0.020), and mammary fibroadenoma was decreased for trend (p = 0.015) and pair-wise at 20 ppm (p = 0.024). The only hepatocellular carcinoma observed in the study was in a 20-ppm female.

907 TERMINAL OBSERVATIONS IN SPRAGUE-DAWLEY RATS AFTER LIFETIME DIETARY EXPOSURE TO N-ETHYL PERFLUOROOCTANESULFONAMIDO ETHANOL.

P. J. Thomford[1], A. M. Seacat[2] and J. L. Butenhoff[2]. *[1]Toxicology, Covance, Madison, WI and [2]Medical, 3M, St. Paul, MN.*

Sprague-Dawley rats were given N-ethyl perfluorooctanesulfonamido ethanol (N-EtFOSE, 98.1 %) in the diet at 0, 1, 3, 30, 100 & 300 ppm for up to 104 weeks. A recovery group at 100 ppm received compound for 52 weeks. The 300-ppm groups

were terminated after seven weeks of treatment. Results from interim sacrifices at weeks 4 and 14 were previously described. An interim sacrifice occurred at week 53. This report describes observations at 53 weeks through term. At 53 weeks, decreased body weight, increased liver weight and hepatic histomorphologic changes (without cell proliferation), including a hepatocellular adenoma in a female, occurred at 100 ppm. Through term, survival was unaffected by treatment. Bodyweights were lower at 100 ppm. All liver effects occurred at 100 ppm, with the exception of cystic degeneration in 30-ppm males. Hepatotoxicity was not present in 100-ppm recovery animals. In males, thyroid follicular cell adenoma and combined thyroid follicular cell adenoma/carcinoma were increased for trend ($p = 0.017$ and 0.016, respectively) and pair-wise at 100 ppm ($p = 0.011$ for both); however, thyroid follicular cell carcinoma alone was not increased. For females, hepatocellular adenoma was increased for trend ($p=0.005$) and pair-wise for 100-ppm ($p = 0.012$) and 100-ppm-recovery ($p = 0.050$) groups, and combined hepatocellular adenoma/carcinoma was increased for trend ($p = 0.002$) and pair-wise for 100-ppm ($p = 0.007$) and 100-ppm-recovery ($p = 0.050$) groups. There was no increase for trend or pair-wise for hepatocellular carcinoma alone. The only hepatocellular carcinoma observed in the study was in a 100-ppm, terminal-sacrifice female. Significant negative trends and pair-wise decreases at 100 ppm occurred among females for mammary tumors (fibroadenoma, combined fibroadenoma/adenoma and combined fibroadenoma/adenoma/carcinoma). Trends for pituitary adenoma and combined adenoma/carcinoma were also negative in females.

908 CARCINOGENICITY OF DEPLETED URANIUM FRAGMENTS IN WISTAR RATS.

F. F. Hahn[1] and R. A. Guilmette[2]. *[1]Lovelace Respiratory Research Institute, Albuquerque, NM and [2]Los Alamos National Laboratory, Los Alamos, NM.*

The carcinogenicity of depleted uranium (DU) fragments embedded in muscle was determined in Wistar rats. Tissue reactions to DU fragments were compared to those of foreign-body fragments of tantalum (Ta) and to a radioactive compound, Thorotrast® (Th®). Flat squares or pellets of the metals were surgically implanted. Three sizes of DU fragments were used, 5x5x1.5 mm, 2.5x2.5x1.5 mm or 2.0x1.0 mm diam. Four fragments were embedded in each rat, 2 in each thigh muscle. Additional groups of rats received Th®injections *im.* as controls for radioactive materials, Ta implants (5x5x1.5 mm) as controls for foreign-body materials, or sham surgery as negative controls. Fifty rats per group were observed for life span for the onset, incidence, and types of reactions at the site. At death, all major organ systems were microscopically examined for lesions. Neither type nor amount of implant affected life span. Connective tissue capsules formed around the metal implants, but were much thicker around the DU fragments. Soft tissue tumors arose from some capsules 16 to 20 mo after implantation. Over 90% were malignant. Tumor incidence was significantly increased around the 5x5 mm squares of DU (18%) and the radioactive control, Th® (50%), when compared with the sham controls (0%). Incidence was slightly increased in rats with 2.5x2.5 mm DU squares (6%) and with 5x5 mm squares of Ta (4%). No tumors were seen in rats with the small DU pellets or in the sham controls. No increase in tumors was found in any other tissues. DU fragments of sufficient size cause local tissue reactions in the muscles of rats that can lead to localized soft tissue sarcomas. Implanting materials into the muscles of rats is sensitive for detecting potentially carcinogenic materials in humans. These findings do not indicate, however, that DU fragments are necessarily carcinogenic in humans. Funding:US Army Medical Research Development Command:MIPR# KVFM5529 with US DOE, Coop.Agreement #DE-FC04-96AL76406. Research conducted using SOT criteria and in AAALAC-accredited facilities.

909 INDUCTION OF LUNG TUMORS BY 7H-BENZO[c]FLUORENE.

E. H. Weyand[1], L. S. Goldstein[2], K. R. Reuhl[1], J. Q. Wang[3] and R. G. Harvey[3]. *[1]Pharmaceutical Chemistry, Rutgers University, Piscataway, NJ, [2]Environment Sector, Electric Power Research Institute, Palo Alto, CA and [3]Ben May Institute for Cancer Research, University of Chicago, Chicago, IL.*

7H-BENZO(C)FLUORENE (B[c]F) is a major lung DNA adductor in mice treated with coal tar suggesting that B[c]F may be capable of inducing lung tumors. This study evaluates the tumorigenic potential of B[c]F using the A/J mouse model. Female A/J mice 7 weeks of age were administered BENZO(A)PYRENE (B[a]P) or B[c]F (100 mg/kg) by ip injection. These mice were fed 5001 rodent LabDiet for the remainder of the study. Groups of mice were also fed diets containing B[a]P (397 umol/kg diet), or B[c]F, (397 or 27 umol/kg diet). In addition, a mixture of twenty synthetic PAH known to be present in coal tar was also fed to mice in the presence or absence of B[c]F. A basal gel diet system was used to administer hydrocarbons within the diet. Mice were maintained on control or adulterated diets for 260 days. B[c]F administered ip (1.8 mg) induced multiple lung tumors in 92% of the treated mice, with an average of 4.0 tumors per mouse. 90% of the mice treated with 1.8 mg of B[a]P by ip administration also had lung tumors with an average of 6.7 tumors per mouse. However, the highest level of lung tumor induction was observed in mice fed 397 umol/kg diet B[c]F. A 100% tumor incidence and an average of 46 lung tumors per mouse was observed. In contrast, mice fed a diet containing 397 umol of B[a]P, had a 77% tumor incidence with an average of 1.4 tumors per mouse. Mice fed a 27 umol B[c]F per kg diet, or the mixture of synthetic hydrocarbons with or without B[c]F resulted in tumor incidences and multiplicity not different from controls. These results demonstrate that B[c]F is tumorigenic in lung of mice when administered by ip injection and in particular when fed to mice in the diet. These data, strongly suggest that B[c]F contributes to the potent mouse lung tumorigenicity previously demonstrated with coal tar when fed to mice . (This research was supported by funds from EPRI.)

910 COMBINATION EFFECTS OF HARMAN, NORHARMAN AND AMITROLE WITH NANO2 IN RAT HEPATOCARCINOGENESIS.

T. Ichihara[1,2], K. Miyashita[1,2], M. Kawabe[1], K. Imaida[2], M. Asamoto[2], T. Ogiso[2], S. Tamano[1], M. Hirose[3] and T. Shirai[2]. *[1]Daiyu-kai Institute of Medical Science, Ichinomiya, Japan, [2]1st Dept.Pathol, Nagoya City Univ.Med.Sch., Nagoya, Japan and [3]Div.Pathol., Natl.Inst.Health.Sci., Tokyo, Japan.*

N-Nitroso compounds, which induce cancers in various organs, may be formed endogenously after intake of amino compounds such as secondary amines and NaNO2 in combination. Harman and norharman, ÉÀ-carboline derivatives, which are found in some vegetables and in pyrolysis products. Amitrole had been used in pesticide. Therefore, the present study was performed to determine whether typical amino compounds (harman, norharman or amitorole) with NaNO2 might have modifying potential on liver carcinogenesis using a medium-term bioassay system. A total of 90 rats were divided into 6 groups, all given a single i.p. injection of DEN(200 mg/kg) at the commencement. After 2 weeks, the rats in group 1 and 6 received basal diet and diet containing amitorol(0.01%), respectively. Animals in groups 2, 3, 4 or 5 received diet containing basal diet, harman(0.05%), norharman(0.05%) or amitorole(0.01%) combination with 0.1% NaNO2 (given in the drinking water) for the remaining experimental duration. All rats were subjected to two-thirds partial hepatectomy at week 3 and survivors were sacrificed under ether anesthesia at week 8 for examination of livers immunohistochemically for glutathione S-transferase placental form (GST-P)-positive foci. Significant retardation of body weight gain and increment of thyroid weights were observed in rats treated with amitorole. Increase of kidney and/or liver weights were observed in the groups receiving harman or norharman. No modifying potential was evident in terms of numbers or areas of GST-P-positive foci in any groups. These results demonstrate that combinations of harman, norharman and amitrole with NaNO2 lack initiating or modifying potential for liver carcinogenesis in our medium-term bioassay system.

911 COMBINED INHALATION AND ORAL EXPOSURES OF MALE RATS TO CHLOROFORM ENHANCE CARCINOGENICITY IN THE KIDNEY AND THYROID.

S. Yamamoto, K. Nagano, H. Kano, M. Matsumoto, T. Nishizawa, K. Yamazaki, H. Arito and T. Matsushima. *Japan Bioassay Research Center, Hadano, Japan.*

Community residents are usually exposed to hazardous chemicals such as chloroform through multiple routes of exposure in the living environment. For the purpose of assessing health effects of the exposed people, effects of combined inhalation and oral exposures to $CHCl_3$ on carcinogenicity/chronic toxicity were examined in male F344 rats. A group of 50 rats each was exposed through inhalation to 0 (clean air), 25, 50 or 100 ppm (v/v) of $CHCl_3$-vapor containing air for 6 hrs/day x 5 days/wk x 104 wks, and each inhalation group was given *ad libitum* either $CHCl_3$-containing drinking water of 1, 000 ppm (g/g) or the vehicle drinking water during the 104-wk period. Incidences of both the renal tumors (renal cell adenomas and carcinomas) and the pre-neoplastic lesion of atypical tubule hyperplasia in the kidney as well as incidence of the thyroid tumors (follicular adenoma and adenocarcinoma) increase in the combined exposure groups compared to the groups of the single exposure route. The incidences and/or severities of the non-neoplastic kidney lesions including karyomegaly of the proximal tubule, basophilic change and dilatation of tubular lumen and urinary glucose were also remarkably enhanced in the combined exposure groups, as compared to the groups of the single exposure route. The liver tumors were not observed, but the cases of both liver fatty change and inflammatory cell nest were increased primarily in the groups of oral administration. The non-neoplastic lesions of the nasal cavity were observed in the olfactory region, and affected primarily by the inhalation exposure. It can be concluded that the combined inhalation and oral exposures to $CHCl_3$ significantly

enhance the cacinogenicity of the kidney and thyroid in male rats. The non-neoplastic lesions of the liver and the nasal cavity seem to be affected, depending on the oral administration and the inhalation exposure, respectively. This study was contracted and supported by Japanese Ministry of the Environment.

912 PROMOTION OF THYROID FOLLICULAR CELL TUMORS IN RATS BY PREGNENOLONE-16α-CARBONITRILE (PCN).

N. R. Vansell, J. R. Muppidi, S. M. Habeebu and C. D. Klaassen. *Univ Kansas Med. Ctr, Kansas City, KS.*

Pregnenolone-16α-carbonitrile (PCN) and Aroclor 1254 (PCB) both reduce serum thyroid hormone levels, but only PCN produces an increase in serum thyrotropin (TSH). PCN-mediated increases in TSH result in increased thyroid follicular cell proliferation and hyperplasia, which may represent early events on a morphological continuum leading to neoplasia. The purpose of this study was to assess whether PCN, which increases serum TSH, and PCB, which does not increase TSH, promote thyroid tumors in a 2-stage carcinogenesis model. Male SD rats were administered the thyroid tumor initiator diisopropanolnitrosamine (2.5 g/kg, sc), and after 7 days were fed control diet, diet containing 1000 ppm PCN, or diet containing 100 ppm PCB for 19 weeks. Body weight was unaffected by PCN treatment, however after 19 weeks of PCB treatment, body weights were reduced 21%. PCN treatment significantly reduced serum T4 through week 3 before recovery, whereas T4 levels following PCB treatment fell below detection limits by week 3 and remained drastically reduced through week 19. TSH concentrations in PCN-treated rats increased 3 fold at week 2, then declined to near control values at week 19. Unexpectedly, TSH concentrations reached nearly 2 times control after 1 week of PCB treatment, and were sustained until week 6. The incidence of thyroid follicular cell proliferative lesions, including cystic and follicular hyperplasia, cystic and follicular adenoma, and follicular carcinoma, was significantly increased following PCN treatment but not PCB treatment. PCB treatment caused an increase in thyroid carcinomas (4 of 22 rats) not associated with the proliferative-type lesions produced by PCN, despite an increase in TSH serum concentrations. In conclusion, PCN appears to promote thyroid tumors in a manner consistent with known effects of excessive TSH stimulation. However, thyroid carcinomas stemming from PCB treatment indicate that separate mechanisms exist for the production of thyroid cancer in rodents by chemicals classically considered microsomal enzyme inducers. (NIH grants ES-08156 and ES-07079)

913 PROMOTION OF TRIHALOMETHANE-INDUCED COLON ABERRANT CRYPT FOCI (ACF) BY A HIGH-FAT DIET.

M. George, S. Kilburn, T. Moore and T. DeAngelo. *National Health and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC.*

Bromodichloromethane (BDCM) and tribromomethane (TBM) enhanced neoplasia in the large intestine of rats when given by corn oil gavage; BDCM in the drinking water to male rats did not induce colon tumors, but did increase liver tumors. However, TBM and a mixture of THMs high in brominated trihalomethanes (THMs) induced colon neoplasia after 52 weeks. We found that brominated THMs induced ACF, putative preneoplastic lesions, in the colon when included in the drinking water of male rats. This study was undertaken to determine if the ACF can be promoted by a diet high in fat. Male F344/N rats were exposed to isomolar concentrations of the THMs: 0.5, 0.7, 0.9 and 1.1 g/l. of chloroform (TCM), BDCM, dibromochloromethane (DBCM) and TBM in the drinking water. Emulphor (0.25%) and 15 mg azoxymethane/kg ip (AOM) were the vehicle and positive control groups. Animals from each treatment group were fed the HF diet (Purina 5001; 19% fat). Groups from the emulphor, AOM, and BDCM treatments were given corn oil (0.5 ml/kg, po) 5 days/week. After 26 weeks the colons were examined for ACF. There was a statistically significant positive association between the ACF/colon (± SD) and the number of bromine atoms on the THM molecule: 0.25% emulphor (0), TCM (0.67 ± 0.75), BDCM (1.33 ± 1.11), DBCM (2.67 ± 2.36) and TBM (2.83 ± 2.34). AOM treated animals had 23.17 ± 7.75 ACF/colon. Corn oil did not increase the ACF/colon in the vehicle control or BDCM treatment groups, but did in the AOM group (32.5 ± 9.0). The HF fat diet was effective in promoting only the ACF induced by TBM (5.33 ± 2.26). The same result was found for the total number of crypts/colon. The data suggest a fundamental difference between TBM-induced ACF and those induced by the other THMs, a difference that might help to explain the ability of TBM, and not BDCM to induce colon neoplasia when administered chronically in the drinking water (This abstract of a proposed presentation does not necessarily reflect the views of the EPA)

914 THE INDUCTION OF COLORECTAL NEOPLASIA BY A MIXTURE HIGH IN BROMINATED TRIHALOMETHANES (THMS) ADMINISTERED IN THE DRINKING WATER TO MALE F344/N RATS.

C. Sistrunk[1], M. George[2] and T. DeAngelo[2]. *[1]USEPA/UNC Cooperative Trainee, NC Central University, Durham, NC and [2]NationalHealth and Environmental Effects Research Laboratory, USEPA, Research Triangle Park, NC.*

The THMs are the most widely distributed and concentrated of the chlorine disinfection by-products (DBPs). Bromodichloromethane (BDCM) and bromoform (TBM) administered in corn oil were found to increase the incidence of colon neoplasia in the rat. BDCM administered in the drinking water to male rats did not induce colon neoplasia. Since THMs occur together in finished drinking water, we initiated a study to evaluate the ability of a mixture high in brominated THMs (Krasner et al., J. Amer. Water Works Assoc., 81: 41-53, 1989) to induce colon neoplasia in male F344/N rats. The animals were exposed to mixtures of THMs at 10x, 100x, 1, 000x, and 10, 000x ambient concentrations. Water containing 0.25% emulphor (vehicle control), 15 mg azoxymethane/kg ip (positive control) and 477 mg TBM/L (= to the 10, 000X mixture) were included. Colon aberrant crypt foci (ACF; putative preneoplastic lesions) or neoplasia were scored at 13, 26 and 52 weeks. At 13 weeks the incidence (% of animals with ACF) was 100% (AOM), 63 % (TBM) and 88% (10, 000X THM). The 26 week incidence of ACF was 12% (0.25% emulphor), 100% (AOM and TBM), and 63%, 88%, and 88% in the 100X, 1000X, and 10, 000X THM groups respectively. At 52 weeks the incidence of ACF declined in all groups from the earlier time points. Pathologic analysis demonstrated an adenomatous polyp and hyperplasia (1/7 rats)in the 477 mg TBM/L and adenocarcinoma (1/7 rats)in the 10, 000X mixture treatment group. There are data to support the conclusion that ACF are preneoplastic and colorectal neoplasia is rare in F344/N rats; we consider this finding to be biologically significant. This is the first report of DBPs administered in drinking water to test animals inducing neoplasia in animals at a site concordant with the findings of epidemiological studies. (This is an abstract of a proposed presentation and does not necessarily reflect the view of the EPA.)

915 HISTOPATHOLOGICAL EFFECTS OF PROSTAGLANDINS AND ANALOGUES ON THE LIMITING RIDGE OF THE STOMACH IN RODENTS.

J. M. Daniels[1], B. L. Lynch[1], G. Goodfellow[1] and I. C. Munro[1,2]. *[1]Cantox Health Sciences International, Mississauga, ON, Canada and [2]CanTox US Inc., Bridgewater, NJ.*

The effect of oral exposure of rodents, notably rats, to certain prostaglandins of the E and F series was evaluated, particularly with respect to neoplastic potential. Exposures to misoprostol, 16, 16-dimethyl-PGE_2, and CL115 574, an older experimental PGE_1 analogue, in the range of 0.01 to 1 mg/kg bw/d are associated with proliferation of basal epithelial cells of the limiting ridge that separates the gastric stomach from the forestomach. Daily treatment for 10 days to several weeks, depending upon the prostanoid involved, results in gross observation of enlargement of the limiting ridge. Histological alterations include hyperplasia, acanthosis, and hyperkeratosis. Edema may also be present. In addition to specific effects on the limiting ridge, misoprostol, rioprostil, natural PGE_2, 16, 16-dimethyl-PGE_2, and methyl-PGE_2 also show trophic effects on the mucosa of the gastric stomach. Prostaglandin-associated pathology of the limiting ridge is non-neoplastic in nature as evidenced by the lack of progression in rat and mouse 2-year studies with misoprostol. Treatment of Sprague-Dawley rats with misoprostol at doses of 0.016 to 9.0 mg/kg bw/d for 52 weeks produced hyperkeratosis of the forestomach and limiting ridge that resolved following a 13-week recovery period. Reversibility was also shown for 16, 16-dimethyl-PGE_2 and CL115 574. In addition, there is no evidence that prostaglandins, natural or synthetic, possess genotoxic activity. The mechanism(s) by which prostaglandins exert a proliferative effect on the limiting ridge is not clear, but may involve an irritant and a direct trophic effect. Increased cell survival, retarded exfoliation, and the resultant accumulation of cells, may be postulated to potentially contribute to the effects observed. The role of the demonstrated cytoprotective effects of many PGE analogues is not known. Further elucidation of the mechanism(s)involved may shed light on the relevance to humans of the effects of prostaglandins on the forestomach in rodents.

916 EVIDENCE FOR THE CARCINOGENCITY OF DIAZOAMINOBENZENE BASED ON SHORT-TERM STUDIES.

N. B. Ress[1], K. L. Witt[2], L. T. Burka[1], J. Xu[3], J. R. Bucher[1] and R. S. Chhabra[1]. *[1]NIEHS, Research Triangle Park, NC, [2]ILS, Research Triangle Park, NC and [3]SITEK Research Labs, Rockville, MD.*

A series of short-term toxicity and metabolism studies on diazoaminobenzene (DAAB) provide clear evidence that DAAB can be designated as a carcinogen without performing a two-year bioassay. DAAB was nominated to the National

Toxicology Program (NTP) because of the potential for worker exposure from its use in laboratories, positive *Salmonella* mutagenicity data, its presence as an impurity in foods and cosmetics, and lack of adequate toxicological data. Structurally similar compounds to DAAB are carcinogenic, and it was speculated that DAAB would be metabolized to benzene (BZ) and aniline (AN). Recently reported metabolism studies confirmed that DAAB is rapidly metabolized to BZ and AN in mice and rats, with the predominant circulating metabolites being common to those of BZ and AN (Mathews and De Costa, 1999). In a later study, phenyl radicals were shown to be produced both *in vitro* and *in vivo* during the reductive metabolism of DAAB to BZ and AN (Kadiiska *et al.*, 2000). Based on these studies, it was expected that a combination of adverse effects consistent with BZ and AN would be observed *in vivo*. 16-Day dermal exposure studies in mice and rats indicated that DAAB induced a methemoglobinemia and Heinz body anemia similar to that induced by AN. Some observed toxicological effects possibly related to BZ included splenic lymphoid follicle atrophy and hematopoietic cell proliferation. To further explore similar toxicological effects of DAAB and BZ, mice were gavaged with BZ or DAAB once a day for two days and assessed for the frequency of micronuclei in bone marrow erythrocytes. DAAB induced a similar number of micronuclei as BZ, but at a 10-fold lower dose suggesting that AN, and possibly the phenyl radicals formed during the reductive metabolism of DAAB, induce micronuclei and may act in a synergistic manner with BZ. In conclusion, because DAAB is metabolized to the carcinogens, BZ and AN, and has similar toxic effects to these compounds *in vivo*, it should be regarded as a carcinogen.

917 THE NORWEGIAN NATIONAL REGISTRY OF SEVERE ALLERGIC REACTIONS TO FOOD.

M. Lovik[1], R. Kjelkevik[2], H. G. Wiker[1], A. K. Sommer[2], B. Mangschou[2], A. V. Mork[3] and B. Gondrosen[2]. [1]*Dept. Environmental Medicine, NIPH-Folkehelsa, Oslo, Norway,* [2]*Norwegian Food Control Authority (SNT), Oslo, Norway and* [3]*Municipal Food Control Authority (KNT), Oslo, Norway.* Sponsor: E. Dybing.

There is a public perception that food allergy is very common. However, in some studies, it has been possible to diagnostically verify only 1 out of 5 to 10 self-claimed cases. The prevalence of food allergy in Norway is unknown, and little is known about risk groups, foods, and the circumstances under which the reactions occur. Diagnostic follow-up and patient care appear to vary greatly. Patients often feel that their problems are neglected. As part of the Government Action Plan against asthma, allergy, and indoor air-related diseases, funding has from year 2000 on been provided for a national reporting system for severe allergic reactions to food. The purpose is to obtain data for the incidence and other information about severe allergic reactions to food in Norway, in the first instance as experienced in the health care system-patient interface before more extensive diagnostic work has been performed. Further, free food allergen analysis in relation to reported cases is offered, and also standard diagnostic and advanced serum analysis including a food allergen macroarray with more than 100 food allergens. The reporting system also has a surveillance function in relation to food labelling and allergen occurrence in presumably "safe" foods. The reporting system was launched July 1, 2000. Information material, single-page reporting forms and informed consent forms were mailed to all doctors (6500) with relevant practices, clinics and emergency wards. By December 31, 2000, after 6 months, 42 cases had been reported. Peanuts were found to be the most common food allergen causing specific IgE sensitization. There were about equal numbers of males and females among the cases. The age distribution of the reported severe food allergy reaction cases showed a very marked peak for cases with age 20-30 years, and to a lesser extent small children and teenagers. Data including year 2001 results will be presented.

918 EVALUATION OF THE HEALTH ASPECTS OF METHYL PARABEN IN SUPPORT OF AN ACCEPTABLE DAILY INTAKE IN HUMNAS.

M. G. Soni[1], S. L. Taylor[2], N. A. Greenberg[3] and G. A. Burdock[1]. [1]*Burdock Group, Vero Beach, FL,* [2]*Dept. of Food Science & Technology, Univ. of Nebraska, Lincoln, NE and* [3]*Novartis Nutrition Corporation, St. Louis Park, MN.*

Methyl paraben (CAS No. 99-76-3) is a methyl ester of p-hydroxybenzoic acid. It is a stable, nonvolatile compound used as an antimicrobial preservative in foods, drugs, and cosmetics for over 50 years. Methyl paraben is readily and completely absorbed through the skin and from the gastrointestinal tract. It is hydrolyzed to p-hydroxybenzoic acid, conjugated and the conjugates are rapidly excreted in the urine. There is no evidence of accumulation. Acute toxicity studies in animals indicate that methyl paraben is practically non-toxic by both oral and parenteral routes. In a population with normal skin, methyl paraben is practically nonirritating and nonsensitizing. In chronic administration studies, no observed effect levels (NOEL) as high as 1050 mg/kg have been reported and a no observed adverse effect level (NOAEL) in the rat of 5700 mg/kg is posited. Methyl paraben is not carcinogenic or mutagenic. It is not teratogenic or embryotoxic and is negative in the uterotrophic assay. The mechanism of cytotoxic action of parabens may be linked to mitochondrial failure dependent upon induction of membrane permeability transition accompanied by the mitochondrial depolarization and depletion of cellular ATP through uncoupling of oxidative phosphorylation. Parabens are reported to cause contact dermatitis reactions in some individuals exposed cutaneously. Parabens have been implicated in numerous cases of contact sensitivity associated with cutaneous exposure, however the mechanism of this sensitivity is unknown. Sensitization has occurred when medications containing parabens have been applied to damaged or broken skin. Allergic reactions to ingested parabens have been reported, although rigorous evidence of the allergenicity of ingested paraben is lacking. Based on the history of the safe use of methyl paraben and literature reviewed, an increase in average daily intake (ADI) to 55 mg/kg/day for methyl paraben is justified.

919 UP-REGULATION OF GASTRIC ALDEHYDE DEHYDROGENASE (ADH) IN RATS BY SHORT TERM FEEDING OF 2, 4-HEXADIENAL (HX).

P. C. Lee and C. Picchiottino. *Pediatrics, Pharmacology & Toxicology, Medical College of Wisconsin, Milwaukee, WI.*

Many foods and food products contain HX (an aldehyde) either naturally or as additives. Low level of exposure to HX is widespread. Long term feeding of HX led to high incidence of forestomach cancers in young rodents. ADH, being a key enzyme for metabolizing aldehydes, would play a role in modulating the biological activity of ingested HX. We studied gastric ADH in young rats to see whether this enzyme acts on HX and whether short term feeding of HX affects the gastric ADH activity. Both the rat fore- and glandular stomach contained ADH activity and preferred using HX > acetylaldehyde > formaldehyde as the substrate. In postweaned rats, the forestomach has a higher level of ADH compared to the glandular stomach. Feeding of HX to ~26 day old rats for 5 days led to minimal changes in stomach weight, but increased ADH activity in the forestomach (3X of control). ADH activity did not change significantly in the glandular stomach, esophagus, liver or small intestine of the treated rats. The increase in ADH activity was dependent on the duration of feeding. Moderate increase was found after 2 days feeding of HX (100 mg/Kg body wt. daily). The activity increased to 3-3.5X of controls after 4 to 5 days of feeding. Thus, HX selectively up-regulated ADH activity in the forestomach but not in any other tissues of the GI tract. This suggests HX specifically targets the forestomach. The present observation also indicates the occurrence of underlying cellular changes that eventually might manifest as carcinogenesis in the forestomach. The exact changes are unknown and currently under study.

920 EXTRACTS OF GRAPES AND BERRIES INHIBIT OXIDATION AND MUTATION BY PEROXYNITRITE IN THREE MODEL SYSTEMS.

K. Van Dyke[1], P. McConnell[3], M. Sacks[3], C. Ogle[1] and M. Reasor[2]. [1]*Biochemistry and Molecular Pharmacology, West Virginia University, Morgantown, WV,* [2]*Physiology and Pharmacology, West Virginia University, Morgantown, WV and* [3]*Genetics and Developmental Biology, West Virginia University, Morgantown, WV.*

Oxidative and nitrosative damage plays a major role in the etiology and progression of a number of diseases involving inflammation. Experimental evidence exists that dietary sources of antioxidants can retard or prevent this type of damage. The objective of this study was to develop simple model systems to study the effects of dietary sources of antioxidants toward the actions of the powerful oxidative and nitrosative substance, peroxynitrite. With these systems, we tested the ability of grape-derived beverages, extracts of white, red and black grapes as well as raspberries, blueberries, and cranberries, to inhibit oxidative/nitrosative processes including chemiluminescence, DNA nicking and plasmid infectivity of E. coli. The results demonstrate that grape-derived beverages (wines and grape juice), and grape and berry extracts inhibited luminol-dependent chemiluminescence induced by SIN-1 (which breaks down into peroxynitrite) over a wide range of dilutions. Generally, the darker the test material, the more potent the action. Peroxynitrite was incubated with the G-Wiz luciferase high expression plasmid which contains a kanamycin resistance marker and the luciferase gene. Extracts of grapes and berries were effective inhibitors of plasmid DNA nicking. In another set of experiments, incubation of the plasmid with peroxynitrite caused mutation so that it could not infect E. coli strain DH1alpha. Extracts of blueberries, black grapes, dried cranberries and golden raisins were the only preparations effective in reversing the inhibition. In conclusion, antioxidant potencies of the preparations were not equivalent across the three systems; in general the darker the extract the greater the potency.

921 MECHANISM OF APPETITE SUPRESSION BY A NOVEL, NATURAL HYDROXYCITRIC ACID.

S. E. Ohia, C. A. Opere, A. M. LeDay, M. Bagchi and D. Bagchi. *Pharmacy Sciences, Creighton University School of Pharmacy & Allied Health Professions, Omaha, NE.*

A growing body of evidence demonstrates the efficacy of *Garcinia cambogia*-derived natural (-)-hydroxycitric acid (HCA, CitriMax®) in weight management by curbing appetite and inhibiting fat synthesis. In a previous study, we showed that HCA

can increase the release/availability of radiolabeled 5-HT ([^{3}H]-5-HT from rat brain cortex (FASEB J. 15: Abs. 207.13, 2001), and this could explain HCA's reported role in appetite suppression. Although HCA has been reported to suppress appetite and reduce food intake in experimental animals and humans, its mechanism of action is not fully understood. In the present study, we investigated the possibility that the observed effect of HCA on [^{3}H]-5-HT release from isolated rat brain cortex could be due to an action on 5-HT uptake. Isolated rat brain cortex slices were initially incubated in oxygenated Krebs solution for 20 minutes and then transferred to buffer solutions containing [^{3}H]-5-HT for different time intervals. In test experiments, tissues were exposed to HCA (10 μM – 1 mM), fluoxetine (100 μM) and cloimipramine (10 μM). Uptake of [^{3}H]-5-HT was expressed as d.p.m./mg wet weight. A time-dependent uptake of [^{3}H]-5-HT occurred in cortical slices reaching a maximum at 60 mins. HCA, fluoxetine and/or clomipramine inhibited the time-dependent uptake of [^{3}H]-5-HT. At 90 mins, HCA (300 μM) caused a 20% decrease whereas fluoxetine plus cloimipramine inhibited [^{3}H]-5-HT uptake by 30%. Thus, HCA can inhibit [^{3}H]-5-HT uptake (and increase 5-HT availability) in isolated rat brain cortical slices in a manner similar to those of selective serotonin reuptake inhibitors (SSRI) and may have the antidepressant properties of fluoxetine. In addition, safety studies including acute oral toxicity, dermal toxicity, dermal irritation and eye irritation, were conducted to determine HCA's safety profile. The LD_{50} of HCA was found to be greater than 5000 mg/kg when administered orally, and other results were encouraging. Taken together, these results demonstrate that HCA is safe and helps suppress appetite.

922 BUTYLATED HYDROXYTOLUENE INHIBITS AFLATOXIN B_1 ACTIVATION AND RELATED METABOLIZING ENZYMES IN TURKEY LIVER MICROSOMES.

J. A. Guarisco, P. J. Klein and R. A. Coulombe. *Toxicology Graduate Program, Department of Veterinary Science, Utah State University, Logan, UT.*

The mycotoxin aflatoxin B_1 (AFB_1) is a potent hepatotoxin, and a common contaminant of foods and feeds. Turkeys are extremely susceptible to the toxic effects of even small amounts of this mycotoxin, a condition we have shown to be due to a combination of efficient hepatic cytochrome P450 (CYP)-mediated activation and deficient glutathione S-transferase (GST)-mediated detoxification of AFB_1. We recently demonstrated that butylated hydroxytoluene (BHT) protects against nearly all of clinical signs of aflatoxicosis in turkeys, an effect that is not apparently mediated by induction of GSTs. The purpose of this study was to determine the possible mechanism of BHT-mediated protection of aflatoxicosis in turkeys. Here we show that BHT is a competitive inhibitor (Ki = 5.38 mM) of AFB_1 activation to the AFB_1-8, -9-epoxide (AFBO) in liver microsomes prepared from male white turkeys. Furthermore, BHT inhibited microsomal ethoxyresorufin O-deethylase (EROD), methoxyresorufin O-demethylase (MROD), and pentoxyresorufin O-depentylase (PROD), indicator activities of CYPs 1A1, 1A2 and 2B1, respectively, in a dose-related manner. That 1A activities were the most sensitive to BHT inhibition supports an earlier observation that AFB_1 activation in turkey liver is largely mediated by a CYP 1A homolog. It is therefore possible that the observed chemoprotective properties of BHT in turkeys may be due, at least in part, to its ability to inhibit hepatic AFB_1 activation to reactive toxic intermediate(s). (Supported by USDA-NRI grants 97-3081 and 98-3754).

923 CHEMICAL CHARACTERIZATION OF CHROMIUM PICOLINATE MONOHYDRATE.

L. L. Reed[1], J. A. Dill[1], D. E. McCready[2], S. W. Graves[3], V. B. Godfrey[4], C. S. Smith[4] and A. F. Fuciarelli[1]. *[1]Battelle Toxicology Northwest, Richland, WA, [2]Pacific Northwest National Laboratory, Richland, WA, [3]Battelle Memorial Institute, Columbus, OH and [4]NIEHS, Research Triangle Park, NC.*

NTP is conducting rodent 90-day toxicity and 2-year carcinogenicity studies of chromium picolinate which is a nutritional supplement that is being marketed for weight loss. The present work describes the methods and results of studies to confirm the identity of the bulk chemical and to estimate its purity and stability. IR, ^{1}H-NMR, and XRD spectroscopy were consistent with the structure and identity of the bulk chemical as chromium picolinate monohydrate $Cr(Pic)_3 \bullet H_2O$. LC-ESI/MS revealed the presence of an intense ion at *m/z* 436 consistent with the $[M + H]^+$ ion of $Cr(Pic)_3 \bullet H_2O$. The presence of one mole of water in the complex was also revealed by Karl Fischer titrimetry. Elemental analysis for carbon, hydrogen, and nitrogen (98.5%, 94.9%, and 97.3%, respectively, of theoretical values), and ICP-AES analysis for total chromium(103 ± 2% of the theoretical value) supported the identity of the bulk chemical as $Cr(Pic)_3 \bullet H_2O$. Total impurities detected by PIXE were <0.5%. Using LC-ICP/MS, the maximum concentrations of either free Cr(III) or Cr(VI) in the bulk chemical were <0.025%. Purity evaluation using HPLC with UV detection at 265 nm revealed a major component at ~96%, one impurity present at 2.1%, and an additional five impurities each present at levels below ~0.7%. The presence of impurities was not unexpected since several chromium:picolinate complexes can arise from the aqueous phase equilibria of this compound. LC-ESI/MS revealed that many of the components present in synthetic mixtures of chromium:picolinate complexes were also present as impurities in the bulk chemical, but unequivocal identification of the components was not possible due to the lack of pure authentic reference standards. Stability studies revealed that the bulk chemical was stable for at least two weeks at temperatures up to 60°C, demonstrating that storage at room temperature is acceptable for long-term studies.

924 THE EFFECT OF TRIBUTYLTIN ON MICROBIAL INFECTIONS OF MICE.

Y. Konishi[1], F. Amano[2] and Y. Sugiura[3]. *[1]Biomedical Food Research, NIIH, Tokyo, Japan, [2]Phamacplogy, Osaka Phamacology College, Osaka, Japan and [3]Parasitic agents, Kobe Institute of Health, Kobe, Japan.*

Tributyltin compounds (TBTs) are immuno-toxic chemicals, having been artificially introduced to marine environments. Recently, the contamination of more than 1ppb TBTs has been found in most of fishes yielded in Japanese Fish Market. This suggests continuous exposure of TBTs to the Japanese people through direct ingestion of fish or other sea foods. In the present study, the effect of tributyltin chloride (TBTCl) by oral exposure was examined on host resistance of ICR off-spring mice against challenge of microbial infection. Off-spring mice received TBTCl from lactation of mother mice that had taken drinking water with 0, 5, 15 or 50 ppm TBTCl. On werning time (day 21), they were infected with *Listeria monocytogenes* or *Candida albicans* . The host resistance to these microbial infections were estimated by the numbers of recovered microbes in spleen at the day 2, 4 and 6 for *L. monocytogenes* infection, and by those in kidney and brain at the day 43 for *C. albicans* infection, respectively. The Listeria was detected in spleen throughout the experiment obtained from off-spring groups that were lactated by mother given TBTCl at the concentration of 50 ppm. Besides, Candida was also found in the brain of off-spring groups given 50 ppm TBTCl, while no Candida was detected in the control group without TBTCl. In addition, FACS analysis at the weaning point showed that TBTCl induced the slight decrease of CD8+ T cell population in spleen. These results suggest that the exposure of the extremely low levels as 50 ppm TBT through lactation by mother leads to decline of host resistance against microbial infection in off-spring.

925 YEAST ESTROGEN SCREEN TO TEST FOR ESTROGENIC ACTIVITY OF VARIOUS INFANT FOODS.

A. M. Tritscher and C. Verguet. *Food Safety, Nestlé Research Center, Lausanne 26, Switzerland.* Sponsor: M. Younes.

High intake of estrogenic compounds has raised concern about potential adverse effects on reproduction and development, especially in infants as susceptible subgroup of the population. Intake estimates are usually based on analytical chemistry and take not into account actual biological activity. Yeast stabely transfected with the estrogen receptor and a reporter construct is a commonly used assay to screen for estrogenic activity of chemical compounds. The purpose of our study was to use this screening tool, expressing the human ERα, to test for estrogenic activity in various infant foods. Soy infant formula, containing isoflavones, are compared to milk-based formula, human and cow's milk, which may contain phytoestrogens as well as steroidal estrogens. We screened the extracts of the various foods as well as directly the diluted or reconstituted foods in comparison to the main conjugated and free isoflavones as well as steroidal estrogens. Overall activity of soy formula was low compared to steroidal estrogens and isoflavones. No activity was detectable in any of the other foods under the conditions of our test system. Extracts of the foods are easier to analyze, reconstituted milks tested directly influence the cell growth and interfere with OD measurements. Since the compounds tested in this estrogen screen have different chemical structures with different physico-chemical properties, we tested the penetration of test compounds into the yeast cell, using C14-labelled estradiol and C14-labelled genistein. In both cases the rate of penetration was below 1% of the total amount added after over night incubation. Although a fairly easy and simple to use system, the yeast estrogen screen allows only for relative comparison of overall estrogenic activity of food extracts and for screening purposes of pure compounds. Conclusions on potential health effects of high intake of dietary estrogens cannot be drawn based on results from such an assay. More information on *in vivo* uptake, metabolism, distribution and internal exposure in target organs is necessary.

926 ASSESSMENT OF THE ALLERGENICITY OF KNOWN HUMAN ALLERGENIC AND NON-ALLERGENIC FOOD PROTEINS IN MICE.

D. A. Delker, C. Smith, J. P. Sloskey, R. S. Scott, G. S. Ladics and C. S. VanPelt. *Discovery Toxicology, DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

No validated animal model exists which can predict protein allergenicity. A model has been proposed by Dearman et al. that has exhibited divergent antibody isotype responses (IgE vs IgG2a) in female BALB/c mice exposed IP to a known human allergen, ovalbumin (OVA) vs a non-allergen, BSA. To examine the reproducibility

and predictability of the proposed model, two additional proteins, potato acid phosphatase (PAP) and β-lactoglobulin (β-lac), and two additional strains of mice, C3H/HeJ and A/J, were evaluated for allergic responses. Ten female mice of each strain were IP injected once a week for two weeks with 1, 2 or 5% BSA, OVA, β-lac, or PAP in PBS buffer. One week after the last injection, animals were euthanized and blood was collected from the vena cava. Serum antigen-specific IgG, IgG1, and IgG2a were determined by ELISA and bioactive IgE to each protein was determined by PCA in naïve rats. Serum antigen-specific IgG was observed in a dose dependent manner for all four proteins tested. Overall, BSA demonstrated the highest titer of IgG followed by OVA, β-lac, and PAP. Unlike the results of the Dearman study, bioactive IgE was not observed in BALB/c mice treated with OVA, or with β-lac or PAP, a human food allergen and non-allergen, respectively. A/J mice treated with 2 and 5% OVA demonstrated clinical signs of anaphylaxis. Bioactive IgE was observed in A/J mice treated with OVA at all dose levels. Bioactive IgE was also observed in A/J and C3H/HeJ mice treated with PAP and β-lac. The strongest IgE responses in terms of the number of responder mice and antibody titer were observed in A/J mice treated with 2% OVA or 1% PAP. Bioactive IgE was not observed in any strain treated with BSA. These results suggest that the production of bioactive IgE is dependent on the genetic background of the mice exposed and the dose of protein that is administered. The IgG response to each protein is more uniform and may be a useful means of determining exposure to a test protein.

927 CHLORINATED HYDROCARBON AND CHLORINATED ORGANOPHOSPHATE RESIDUES IN HORSEMEAT FROM THE FSIS NATIONAL RESIDUE MONITORING PROGRAM, 1990–1999.

A. M. Kadry, R. Kishore, A. Yoffe, P. Zervos and W. James. *RB/FASD, USDA/FSIS, Washington, DC.*

The National Residue Program (NRP) conducted by the USDA Food Safety and Inspection Service (FSIS) includes a comprehensive testing program for residues of pesticides, drugs, and other chemical contaminants in meat, poultry, and egg products. Samples are taken statistically so that inferences can be made on the overall national incidence of residues. Since 1990, there has been a large decline in the number of horses slaughtered for food in the US The number of horses slaughtered in federally inspected establishments in 1999 is only 20% of the number slaughtered in 1990 (60, 138 in 1999 *vs.* 306, 771 in 1990). Using a methodology that simultaneously detects and quantitates 36 different CHC's/COP's, FSIS conducted 3, 490 analyses in horses between 1990 and 1999. During this period only 13 violative residues were found, resulting in a violation rate of 0.4%. The violative findings consisted of the following; five coumaphos violations; three dieldrin violations; two heptachlor violations; and three PCB violations. In addition, FSIS detected 339 non-violative positive residues (i.e., residues present at levels less than or equal to the tolerance or action level). The compounds found at non-violative levels were: dieldrin, DDT, heptachlor, lindane, methoxychlor, hexachlorobenzene, mirex, endosulfan, PCB's, chlorpyrifos, coumaphos and endrin. Since 1972, the United States Environmental Protection Agency has banned all uses of DDT, except for public health emergencies. Nevertheless, non-violative residues of DDT were found every year except 1990, with the highest numbers in 1993 and 1998 (40 and 25, respectively). This can be explained by the environmental persistence of DDT residues that were introduced by usage prior to the 1972 ban. These findings indicate the value of the FSIS NRP in assessing and communicating human exposure to chemical residues, and in maintaining consumer confidence in the safety of the US food supply by demonstrating that the incidence of violative levels of these contaminants is very low.

928 RELATIONSHIP OF TRICHOTHECENE STRUCTURE TO COX-2 INDUCTION IN THE MACROPHAGE MODEL.

Y. Moon and J. J. Pestka. *Food Science and Human Nutrition, Institute for Environmental Toxicology, Michigan State University, East Lansing, MI.*

Cyclooxygenase-2 (COX-2) is a crucial rate-limiting enzyme in the production of proinflammatory eicosanoids. Previous studies have shown that deoxynivalenol (DON) induced COX-2 expression by promoting transcriptional activity and mRNA stability *via* mitogen activated protein kinase (MAPK) signaling pathway. Based on this model, representative members of the three major trichothecene families (A, B, and D) were screened for the inducibility of COX-2 expression using murine macrophage, RAW264.7 cells. When treated with the 20% inhibitory doses (ID_{20}) based on MTT assay, Type B trichothecenes including DON, 15-acetylDON, 3-acetylDON and fusarenon-X (FX) were potent inducers of COX-2 expression whereas Type A and D had little effect on COX-2 expression. To assess the effect of the trichothecenes on transcriptional and post-transcriptional activity, luciferase reporter vectors containing 5' promoter or 3'-untranslated region (UTR) of COX-2 gene were transfected into RAW 264.7 cells and the reporter activities were compared following the trichothecene treatment. Typically, type B trichothecenes enhanced the COX-2 promoter activity and UTR-linked mRNA stability whereas Type A and D did not affect the reporter activities. The COX-2-inducing trichothecenes also activated MAPK signaling pathways, and ERK or p38 inhibitor significantly reduced the COX-2 induction. In contrast, the dominant negative JNK expression did not diminish the trichothecene-induced COX-2 expression although JNK was activated by the four toxins. Additionally, pyrrolidine dithiocarbamate, an inhibitor of nuclear factor-kB (NF-kB) activation, suppressed the trichothecene-induced COX-2 expression. Taken together, type B trichothecenes including DON, its derivatives and FX are direct strong inducers of COX-2 gene and the induction is due to both enhanced transcription and mRNA stabilization. Furthermore, MAPK and NF-kB signaling pathways mediate the trichothecene-induced COX-2 expression, which may contribute to the type B trichothecene immunotoxicity.

929 SAFETY EVALUATION OF EPHEDRA DIETARY SUPPLEMENTS.

E. R. Nestmann[1], V. M. Tai[2] and J. M. Daniels[1]. [1]*Cantox Health Sciences International, Mississauga, ON, Canada and* [2]*Cantox Health Sciences International, Vancouver, BC, Canada.*

The safety of ephedra/ephedrine alkaloids has been studied in animals and humans. A series of clinical investigations have been done with obese but otherwise healthy volunteers receiving oral ephedra or ephedrine over periods of 10 d to 26 m. The range of total doses within these studies was from 50 to 150 mg/d (the LOAEL) in 1 to 3 doses. Monitoring data for adverse effects identified the NOAEL of 90 mg/d; reported symptoms, such as chest pain, palpitation, irritability, nausea and constipation were similar among supplement and placebo groups. Carcinogenicity studies in mice and rats demonstrated a lifetime NOAEL of 9 mg ephedrine/kg bw/d. The only finding at this dose was decreased body weight gain, which increased, or had no effect on, survival. These lifetime rodent studies showed that there were no long-term, cumulative effects that may not be detected in clinical studies. Using the results obtained from these investigations, application of the National Academy of Sciences Upper Level (UL) Model derived a UL of 90 mg/d of ephedrine alkaloids in ephedra for a generally healthy population. This assessment included the use of an Uncertainty Factor of 1, applied to the human NOAEL. This UF is based on consideration of the pharmacokinetics of ephedrine, use patterns, duration of expected use, animal and clinical studies, without consideration of the voluntary database of adverse event reports that we found to be generally unreliable and insufficient to draw any conclusion about the safety of ephedra dietary supplements.

930 13-WEEK FEEDING STUDY IN RATS FED GRAIN FROM YIELDGARD ® EVENT MON 810 CORN.

B. R. Dudek, B. G. Hammond, J.K. Lemen, M. A. Nemeth and J. D. Astwood. *Monsanto Company, St. Louis, MO.*

As part of the safety assessment of food/feed derived from genetically modified crops, it is important to evaluate unintended consequences owing to the insertion of the transgene into the genome or expression of the resulting trait. In combination with other approaches such as compositional evaluations and nutritional assessments in farm animal feeding studies, a subchronic feeding study in rats may address such unintended effects. This study compared the responses of rats fed diets containing grain from YieldGard (YG) corn to rats fed (1)diets containing grain from near-isogenic control (C) (non-transgenic) corn and (2)a population of diets containing grain from commercial reference corn (RC) hybrids. Male and female CD IGS rats (20/sex/group) were fed one of the following diets for 13 weeks: 11 or 33% (wt/wt) (YG) or (C) grain; 33% (RC) grain (6 commercial lines were tested). There were a total of 10 groups/400 rats in the study. Diets containing 11% YG or C grain were supplemented with 22% grain (non-transgenic commercial corn) to bring the total corn grain to 33%, consistent with other diets. Laboratory rat feed contains corn grain at 33%. Diets were balanced to be nutritionally equivalent. Animals were observed daily; body weights and food consumption were recorded at least weekly. At 5 and 13 weeks, blood and urine were collected from 10 rats/sex/group for clinical evaluations. After 13 weeks, all animals were sacrificed, necropsied and selected tissues weighed and examined microscopically. Body weights and food consumption were comparable for all groups. Clinical parameters were comparable across groups with few exceptions. The few differences were not considered biologically meaningful as they were either not dose related, or were not consistently different from both control groups. In conclusion, rats fed grain from YieldGard corn responded similarly to rats fed control grain. This conclusion was consistent with previous studies showing that YG corn grain is compositionally and nutritionally equivalent to traditional corn.

931 ONE YEAR TOLERANCE STUDY WITH LUTEIN AND ZEAXANTHIN IN CYNOMOLGUS MONKEYS.

E. Wolz[1], O. Froescheis[1], C. P. Aebischer[1], R. Goralczyk[1], B. Niggemann[2], J. Bausch[1] and E. Pfannkuch[1]. [1]*Nutrition Safety, Roche Vitamins Ltd., Basel, Switzerland and* [2]*Exp. Toxicology, Covance Laboratories, Muenster, Germany.*

A one year tolerance study was performed in Cynomolgus monkeys to evaluate the toxicity of lutein and zeaxanthin administered as 10% beadlet formulations by gavage at 0, 0.2 and 20 mg/ kg/ day (pure Carotenoid) to groups of 2 male and 2 female Cynomolgus monkeys. Additionally, 1 male and 1 female animal at 20 mg/kg/day were sacrificed after 6 months of treatment. All animals survived the treatment period. All animals in the 20 mg/kg/day group of lutein and zeaxanthin showed orange/yellow discolored feces from day 2 of the study onwards. There was no effect on overall mean body weight gain and on overall group mean food intake in animals of all treated groups. There were no changes in electrocardiography and blood pressure data, which could be regarded as being related to treatment. There were no treatment related changes in hematological and serum clinical chemistry parameters, nor changes in urine parameters. There were no organ weight changes, which could be associated with treatment. Most of the animals showed dark-yellow colored mesenteric fat at interim sacrifice and gold-yellow mesenteric fat at the terminal sacrifice. This finding is considered to be related to the color of the compounds. At histopathological examinations no treatment-related findings were reported. Ophthalmoscopic examinations, electroretinography and eye pathology examinations were performed. There was no clinical and no morphological evidence for treatment-related adverse changes in the eyes of Cynomolgus monkeys during or after 52 weeks treatment with lutein or zeaxanthin. Specifically, there was no evidence for crystal formation in the eyes of treated monkeys. Administration of the test article resulted in dose-dependent increase of lutein or zeaxanthin (HPLC determinations) in plasma, liver, macula lutea and peripheral retina. Extrapolation of results in Cynomolgus monkeys to man is reliable, especially regarding eye findings, and it was concluded that lutein and zeaxanthin are safe products.

932 AN ASSESSMENT OF THE GENOTOXICITY AND SUB-CHRONIC TOXICITY OF PHYTOSTEROL OXIDES.

L. J. Lea, A. M. Wolfreys and P. A. Hepburn. *Approval and Support, Unilever SEAC, Bedford, United Kingdom.*

Phytosterols are structurally very similar to cholesterol and their cholesterol-lowering ability has been well documented since the 1950's. Added to vegetable oils spreads as the fatty acid esters they have been marketed as a cholesterol lowering functional food. The safety of phytosterol-esters has been well established and has led to regulatory approval of vegetable oil spreads enriched with phytosterol-esters in over 20 countries world wide. Phytosterol-esters also have GRAS status in the US. Phytosterols are very stable molecules and oxidation only occurs at low (ppm) levels even under extreme heating conditions. As such conditions could occur during shallow frying with phytosterol-ester enriched spreads safety data has been generated on the breakdown products, phytosterol oxides. The genotoxicity and subchronic toxicity of a mixture of phytosterol oxides was assessed in a series of *in vitro* mutagenicity assays and a 90-day feeding study in rats. There was no evidence of mutagenicity in either a bacterial or mammalian cell assay and an additional assay designed to detect aneuploidy was also negative. In the 90 day feeding study in rats the same phytosterol oxide mix was added to the diet of Wistar rats at levels of 0.2, 0.6 and 1.6% w/w. A number of minor toxicological findings were observed in the high dose group particularly in female animals. These consisted of reduced body weight gains, small changes in a number of clinical chemistry and haematology parameters and increased liver weights. However, no histopathological changes were observed. Based on these findings the NOAEL (no observed adverse effect level) was set at the mid dose level of 0.6%w/w phytosterol oxides. This was equivalent to an intake of the phytosterol oxide mix of 425mg/kg/bw/day for males and 481mg/kg/bw/day for females.

933 RESPONSIVENESS OF HEAT SHOCK PROTEIN GENES TO A RANGE OF HERBAL SUPPLEMENTS.

M. Xie and B. Yan. *Biomedical Sciences, University of Rhode Island, Kingston, RI.*

The genes that encode heat shock proteins (HSP) are coordinately regulated in response to acute exposure of cells to a range of physiological and environmental factors such as heat shock, oxidative stress, and anti-inflammatory drugs. Many herbal supplements are marketed as anti-oxidants and anti-inflammatory agents. The present study was undertaken to test activation activity of 14 commonly used herbal supplements on reporters HSP27, 70 and 90b. Co-transfection experiments in 293T cells were conducted with an HSP reporter and the pRL-TK plasmid (transfection efficiency control). After a 12-hr incubation, the transfected cells were treated with an herbal supplement or vehicle for 24 hr. Luciferase activity was determined and used as an indicator for supplement-mediated regulation on the HSP reporters. Majority of the supplements exhibited activity toward the HSP90b reporter. In contrast, only one third of them exerted activity toward the HSP27 reporter. The magnitude of activation of the HSP27 reporter was less that that of the HSP90b. In addition, both green tea and Kava-kava caused activation of all three reporters to a similar extent. It is known that HSPs mediate antiapoptotic activity by interacting directly with caspases. The data presented suggest that induction of HSPs plays roles in cell protection exerted by many herbal supplements.

934 TEA TREE OIL ADMINISTERED ORALLY INDUCES SPECIFIC NEUROTOXICITY IN RATS.

D. H. Kim, D. R. Cerven, S. D. Craig and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

Tea Tree Oil (from Melaleuca alternifolia) is frequently used as a topical anti-irritant, and has been formulated in numerous consumer products, such as shampoos and toothpastes. Although toxicology data on Tea Tree Oil is limited, a number of studies have reported muscle weakness, ataxia and tremors in humans and other mammals following oral and topical administration. In this study, we examined neurotoxic effects of orally administered Tea Tree Oil. Specifically, we used a modified functional observational battery (FOB) to assess the development of specific neurotoxicity following Tea Tree Oil treatment. Groups of nulliparous female rats were administered increasing doses of Tea Tree Oil or sham control by oral gavage, and were observed at 1, 2, and 4 hours and then daily post-dose for signs of toxicity and specific neurotoxicity. At 72 hours post dose, all treated animals appeared to be lethargic, and exhibited markedly decreased overall activity patterns. Forelimbs and hindlimbs exhibited severe weakness and animals were unable to locomote normally; rats were dragging both forelimbs and hindlimbs and very few weight supporting steps were taken both in the home cage and testing arena. By day 4, all but one animal treated with ≤1.5g/kg appeared to have regained locomotor functions. In that one animal, the hindlimb functions were shown to be normal although forelimbs appeared to be completely paralyzed. The forelimbs remained immobile for the duration of the testing period. In groups administered with ≥1.6g/kg, the majority of animals displayed general ataxia, and forelimbs were affected to a much greater degree compared to the hindlimbs, remaining paralyzed for the duration of the testing period. These results suggest that Tea Tree Oil administered orally at doses greater than 1.5g/kg appears to induce neurotoxic lesions in pathways controlling limb movements.

935 13-WEEK FEEDING STUDY IN RATS FED GRAIN FROM ROUNDUP READY® EVENT NK603 CORN.

B. G. Hammond, B. R. Dudek, M. A. Nemeth and J. D. Astwood. *Monsanto Company, St. Louis, MO.*

As part of the safety assessment of food/feed derived from genetically modified crops, it is important to evaluate unintended consequences owing to the insertion of the transgene into the genome or expression of the resulting trait. In combination with other approaches such as compositional evaluations and nutritional assessments in farm animal feeding studies, a subchronic feeding study in rats may address such unintended effects. This study compared the responses of rats fed diets containing grain from Roundup Ready (RR) corn to rats fed (1)diets containing grain from near-isogenic control(C)(non-transgenic)corn and(2)a population of diets containing grain from commercial reference corn(RC)hybrids. Male and female CD IGS rats (20/sex/group) were fed one of the following diets for 13 weeks: 11 or 33 % (wt/wt)(RR)or(C)grain; 33% (RC) grain (6 commercial lines were used). There were a total of 10 groups/400 rats in the study. The diets that contained 11% RR or C grain were supplemented with 22% grain (non-transgenic commercial corn) to bring the total corn grain up to 33%, consistent with other diets. Laboratory rat feed contains corn grain at approximately 33%. Diets were balanced to be nutritionally equivalent. Animals were observed daily; body weights and food consumption were recorded at least weekly. After 5 and 13 weeks, blood and urine were collected from 10 animals/sex/group for clinical evaluations. After 13 weeks, all animals were sacrificed, necropsied and selected tissues weighed and examined microscopically. Body weights and food consumption were comparable for all groups. Clinical parameters were comparable across groups with few exceptions. The few differences were not considered biologically meaningful as they were either not dose related, or were not consistently different from both control groups. In conclusion, rats fed grain from Roundup Ready corn responded similarly to rats fed control grain. This conclusion was consistent with previous studies showing that RR corn grain is compositionally and nutritionally equivalent to traditional corn.

936 COMPARATIVE ACUTE AND COMBINATIVE TOXICITY OF AFLATOXIN B1 AND T-2 TOXIN IN RATS AND FISH.

L. S. Wang[1,2], Y. Liu[1,2], C. W. Theodorakis[1,2], L. A. Chiodo[1,2] and R. J. Kendall[1,2]. [1]*Dept. of Environmental Toxicology, Texas Tech University, Lubbock, TX and* [2]*The Inst. of Environment & Human Health, Texas Tech University System, Lubbock, TX.*

Aflatoxin B1 (AFB1) and T-2 toxin (T-2) are important food-borne biotoxins that have been implicated in human health and potential biological and chemical threats. In this study, acute and combinative toxicities of AFB1 and T-2 were tested

in F-344 rats and Mosquitofish (*Gambusia affinis*). Young male rats were randomly divided into five groups and were orally treated with 10.0, 4.64, 2.15, 1.0, and 0 mg/kg AFB1 or T-2 according to the Horn's method. The rats were observed for 7-days and lethality and toxic symptoms were recorded. Death of AFB1 treated rats appeared after 48 hrs, and death of T-2 treated rats, within 24 hrs. The LD50 for AFB1 was calculated as 2.71 mg/kg with the 95% of confident limit (CI) at 2.00-3.69 mg/kg and 3.71 mg/kg with 95% CI at 2.69-5.01mg/kg for T-2. Healthy fish (half male and female) were randomly assigned to 6 groups and treated with 4, 640, 2, 150, 1, 000, 464, 215, and 0 ppb of AFB1 or 2, 150, 1, 000, 464, 215, 100, and 0 ppb of T-2. The treated fish were observed for 5-days and death and toxic signs of fish were recorded. The LC50 for AFB1 was calculated to be 681 ppb with 95% CI at 420-800 ppb and LC50 for T-2 was 147.0 ppb with 95% CI at 95.1-227.0 ppb. Fish seem more sensitive to the acute toxicity than rats. Combinative studies used both biotoxins at doses of 1.0, 3/4, 1/2, 3/8, 1/4 LD50 or LC50 in both species. Synergistic and additive toxic effects were observed in rats and fish, respectively. These results will form the basis for our future study on combinative toxic and health effect of these biotoxins and their mixtures. This work was financially supported by the research contract DAAD13-00-C-0056 from Soldier and Biological Chemical Command (SBCCOM), US Army.

937 A NEW AETIOLOGY FOR RHABDOMYOLYSIS: *TRICHOLOMA* SPECIES INTOXICATION.

I. Baudrimont[1], R. Bedry[2], G. Deffieux[3] and E. E. Creppy[1]. [1]*Toxicology, Université de Bordeaux 2, Bordeaux, France,* [2]*Resuscitation and medical toxicology, Université de Bordeaux 2, Pessac, France and* [3]*Mycology and vegetal biotechnology, Université de Bordeaux 2, Bordeaux, France.*

Tricholoma equestre is a well-known mushroom considered to be edible and occurring worldwide. In France since 1992 it has been incriminated in 12 intoxications in humans. The intoxication has been seen after repetitive ingestion of these mushroom harvested in South West of France and is associated with 25% lethality. All subjects exhibited pure rhabdomyolysis without noticeable liver and kidney damage. The clinical pathology findings included large increases of circulating creatine kinase activity (CK) of up to 600 000 IU /L. Electromyography (EMG) and skeletal muscles histology confirmed the presence of rhabdomyolysis, without any neurological involvement. Using doses corresponding to mushroom quantities eaten by intoxicated patients, we have reproduced this intoxication in the mouse by gavage with *T. equestre*, the commercial mushroom *Pleurotus ostreatus* and p-phenylenediamine were taken as controls. Only in mice fed *T. equestre*, was circulating CK increased dose-dependently from 140 IU/L to 1600 IU/L. This was confirmed by histological images of mild disorganisation of muscle fibres in surviving mice. Some mice died (about 30%) following the highest dose. ASAT, ALAT, LDH and creatininemia were determined and did not show significant increase. Since all other aetiologies have been discarded in human cases of *T. equestre* intoxication and since this mushroom produces the similar tissue changes and death in animals we concluded that the consumption of large quantities of *T. equestre* may indeed be harmful and or lethal in humans.

938 *IN VITRO* SCREENING OF CRUDE AQUEOUS PREPARATIONS OF WHOLE FOODS FOR POTENTIAL TOXICANTS.

G. D. Charles[1], V. A. Linscombe[1], B. Tornesi[1], J. L. Mattsson[2] and B. B. Gollapudi[1]. [1]*TERC, The Dow Chemical Company, Midland, MI and* [2]*Global Toxicology, DowAgrosciences, Indianapolis, IN.*

The application of organic, conventional and molecular techniques may have the potential to alter the intrinsic levels of natural toxicants in crop plants. To maximize nutritional benefits and minimize the detoxification burden (metabolic cost) of ingesting crop foods, methods are needed to efficiently screen whole foods for unexpected changes in potential toxicity. We evaluated four *in vitro* mammalian toxicity screens utilizing crude, aqueous preparations of whole foods purchased from a local market. Thirty-seven whole foods were evaluated (0.05-10% vol. extract/vol. culture medium) in one or more of the following tests: (1) general toxicity (cytotoxicity, all 37 foods) and (2) genetic toxicity (chromosomal aberration test, 9 foods) both performed in Chinese hamster ovary cells; (3) developmental toxicity (limb bud micromass assay, 9 foods) using 11-day old CD-1 mouse embryos and (4) estrogenicity (MCF-7 cells transfected with a chimeric Gal4-estrogen receptor construct and a Gal4-regulated lucerifase reporter gene, 12 foods). Cytotoxicity levels ranged from <0.1% v/v (garlic) to non-cytotoxic (18 foods) at the maximal concentration tested (10% v/v). Five of the nine whole food preparations (soybeans, broccoli, garlic, snowpeas and corn) were clastogenic and two (soybeans and snowpeas) exhibited an ability to inhibit chrondrogenesis in the limb bud micromass assay. Four of nine preparations (soybeans, cumin, asparagus and bean-sprouts) produced positive estrogenic responses comparable to 17 beta-estradiol. Therefore, each of the tests showed some degree of response to these crude, whole foods extracts, and overall the 12 foods evaluated in two or more of the tests showed different patterns of response. These preliminary data indicate that screening for differences in potential toxicant profiles is possible with fast, relatively inexpensive *in vitro* tests.

Funded by The Dow Chemical Company.

940 FOUR WEEK INHALATION STUDY WITH A MIXTURE OF DICHLOROETHYLENE AND PERFLUOROBUTYLENE IN RATS.

L. A. Malley, J. F. Hansen, N. E. Everds and D. B. Warheit. *DuPont Haskell Laboratory for Health and Environmental Sciences, Newark, DE.*

A study was conducted to determine the subchronic toxicity of a mixture of trans-1, 2-dichloroethylene (trans-DCE, 70%), cis-1, 2-dichloroethylene (cis-DCE, 5%), and perfluorobutylethylene (PFBE, 25%). Groups of 20 male and 20 female rats were exposed by inhalation to 0, 400, 2000, or 8000 ppm of the mixture vapor for 6 hr/d, 5 d/wk for 20 exposures. Subgroups of 10 rats/sex/group were observed during a 1-month recovery period. Functional observational battery (FOB) and motor activity (MA) evaluations were conducted prior to initiation of exposures, during week 4, and at the end of recovery. Clinical pathology evaluations were conducted during week 4 and recovery. At the end of exposure, and at the end of recovery, tissues were collected for microscopic evaluation. Decreased body weights and weight gains occurred in 8000 ppm males and females. Decreased food consumption and/or efficiency occurred in 8000 ppm males. During exposure to 8000 ppm, rats exhibited tremors and ataxia. Tremors were also observed during exposure to 2000 ppm. Rats exposed to 2000 or 8000 ppm also had a diminished or no alerting response to a sharp sound stimulus during the daily exposures. No evidence of compromised neurological function were detected when the rats were evaluated upon return to their cages following exposure. There were no test substance-related effects on FOB parameters or MA conducted the day following the last exposure or during recovery. In addition, there were no compound-related changes in clinical chemistry parameters. There were no compound-related gross or microscopic morphological changes. The mixture produced neurological effects during the exposure period which where not observed previously with either trans-DCE or PFBE alone. Although cis-DCE has been previously reported to cause neurological effects during exposure, the effects were observed at concentrations of 13, 500 -15, 700 ppm. Therefore, the mixture appears to have an additive or synergistic effect in producing transient neurological effects during exposure.

941 FOUR-WEEK INHALATION TOXICITY OF METHYLGLUTARONITRILE IN RATS.

G. L. Kennedy, D. P. Kelly, G. T. Makovec, S. R. Frame, L. A. Malley and N. E. Everds. *Haskell Laboratory, DuPont Co., Newark, DE.*

Methylglutaronitrile (MGN) is a high-boiling (263 °C) solvent/intermediate used in the fiber industry. Twenty male rats per group were exposed nose-only to approximately 5, 25, or 200 mg/m3 of MGN for 6 hours/day, 5 days/week over a 4 week period. Only a small amount of aerosol (<0.2 mg/m3) was present at the two lowest concentrations, the rest was vapor; however, 160 mg/m3 of aerosol was present at the highest concentration (MMAD 3.8 µm) along with 40 mg/m3 of vapor. Ten rats/group were sacrificed one day after the final exposure and the remaining rats after a four-week recovery period. Rats were given clinical, neurobehavioral, and pathologic examinations. No effects were observed in clinical observations during the exposure period, but body-weight gains were depressed in the 200 mg/m3 group. The 200 mg/m3 group showed minimal decreases in RBC, HGB, and HCT values accompanied by increases in reticulocytes followed by decreased reticulocytes at the end of the recovery period. There were no other effects observed in clinical, neurobehavioral, or pathologic evaluations in the study. During the 4-week recovery, weights in the high level group returned to normal and there were no other clinical or pathological effects observed in any groups. Based on these results, MGN was considered to have low toxicity in rats in repeated inhalation exposures.

942 FOUR-WEEK INHALATION TOXICITY OF N-VINYL CARBAZOLE IN RATS.

D. P. Kelly, G. T. Makovec and G. S. Ladics. *Haskell Laboratory, DuPont Co., Newark, DE.*

n-Vinyl carbazole (nVC) is a component in photo film. Fifteen male and 15 female rats per group were exposed nose-only to condensation aerosol/vapor concentrations of approximately 0, 2, 9.5, or 44 mg/m3 of n-vinylcarbazole (nVC) for 6 hours/day, 5 days/week over a 4 week period. Rats were exposed to mainly aerosol along with 0.4, 0.6 and 0.4 mg/m3 of vapor, respectively. Ten rats/group were sacrificed one day after the final exposure and the remaining rats after a four-week recovery period. No effects were observed in clinical observations or body weight de-

terminations during the exposure phase or recovery phase of the study. However, pathological effects were observed at all concentrations in nVC exposed rats of both sexes. The effects were confined to the upper respiratory tract and consisted of degeneration/necrosis of olfactory epithelium, mucoid depletion of goblet cells, and squamous metaplasia and hyperplasia of respiratory epithelium in the anterior nasal passages and squamous metaplasia of the larynx. At the end of the four-week recovery period, the depletion of goblet cells in noses of female rats was no longer present, and was of decreased severity in the male rats, however, the olfactory epithelial degeneration/necrosis was still present in both sexes. Further work is underway to determine a no-effect level for nVC exposure in rats.

943 DIMETHYL GLUTARATE (DMG), DIMETHYL SUCCINATE (DMS), AND DIMETHYL ADIPATE (DMA): 90-DAY INHALATION TOXICITY STUDY IN RATS.

J. R. Bamberger, L. A. Malley, E. Mylchreest, J. C. O'Connor and G. L. Kennedy. *Toxicology, The DuPont Company, Newark, DE.*

Groups of male and female rats were exposed *via* inhalation to 0, 10, 50, or 400 mg/m^3 DMG, 400 mg/m^3 DMS, or 400 mg/m^3 DMA for 6 hrs/day, 5 days/wk over a 90-day period. The exposure period was followed by a 1-month recovery period. Rats were evaluated for clinical signs and growth throughout the study. Samples for hepatic, lung, and nasal cell proliferation (CP) were collected from rats approximately 2 weeks and 90 days after study initiation. Clinical pathology, anatomical pathology, male reproductive endpoints, neurobehavioral assessments, neuropathological evaluation, estrous cycle, and hormonal analyses were conducted during the study. No compound-related effects were observed on mortality, clinical signs, clinical pathology, neurobehavioral endpoints, neuropathology, sperm motility or morphology, or estrous cycle. Male rats exposed to 400 mg/m^3 DMG had lower mean body weights and mean body weight gains during the study. Compound-related focal and minimal effects were observed in the noses of rats exposed to 400 mg/m^3 of DMG, DMS, or DMA for 90 days. CP in the noses of rats exposed to 400 mg/m^3 of DMG, DMS, or DMA was increased compared to controls during the study. In male rats exposed to DMG, serum testosterone concentrations were statistically significantly decreased at concentrations of 50 and 400 mg/m^3. Serum luteinizing hormone concentrations were decreased in a dose-dependent manner and were statistically significantly decreased at 400 mg/m^3. In female rats, DMS caused a statistically significant decrease in serum estradiol concentrations. There was an increase in epididymal sperm counts following exposure to DMG and the number of sperm per cauda and per gram cauda epididymis was significantly increased at 50 and 400 mg/m^3. In male rats exposed to DMS, epididymal sperm counts were significantly increased. In this study, the no-observed-effect level (NOEL) for repeated exposure to DMG was 10 mg/m3. NOELs for DMS and DMA were not established. Sponsored by the Dibasic Esters Group, Washington DC.

944 ROLE OF SENSORY NERVES IN THE AIRWAY AND CARDIAC RESPONSES TO SULFUR DIOXIDE (SO_2) IN A GUINEA PIG MODEL.

J. Stanek[1,3], Q. Krantz[3], L. Wichers[2,3], J. Nolan[3], D. Winsett[3], W. Watkinson[3] and D. Costa[3]. [1]*College of Veterinary Medicine, NCSU, Raleigh, NC,* [2]*School of Public Health, UNC, Chapel Hill, NC and* [3]*Pulmonary Toxicology Branch, ETD, NHEERL, USEPA, Research Triangle Park, NC.*

Sulfur Dioxide (SO_2) is a common component of polluted urban air. Exposure to SO_2 has been shown to significantly alter airway compliance and resistance. Recently, high concentrations of SO_2 during air pollution episodes have been associated with heart rate elevation. Using non-invasive methodology, our laboratory has previously shown that exposure to SO_2 produces a concentration dependent increase in airway resistance and a significant decrease in breathing frequency. The purpose of our current study is to: 1) determine if exposure to SO_2 produces simultaneous changes in airway and cardiac function and, 2) ascertain the role of sensory nerves in these responses. To this end, guinea pigs were surgically implanted with radiotelemeters capable of transmitting ECG, heart rate and core body temperature data in 1-minute intervals. Animals were then exposed to either 0 or 100 ppm SO_2 in the head-space of a double-chamber plethysmograph. Airway and cardiac function were monitored continuously for a 10-minute baseline period and the 60-minute exposure period. Exposure to SO_2 produced a significant decrease in heart rate during the second half of the exposure period ($p<0.05$). To determine the role of sensory nerves in these responses, animals were pretreated with the neurotoxin, capsaicin (total dose 125 mg/kg sc). Pretreatment with capsaicin significantly diminished the SO_2-induced increase in SRAW and decrease in breathing frequency ($p<0.05$). In addition, capsaicin pretreatment attenuated the SO_2-induced decrease in heart during the second half of the exposure period ($p<0.05$). In summary, these results suggest that exposure to SO_2 produces simultaneous changes in both airway and cardiac function and that stimulation of sensory nerves play a role in both of these responses. (Funded by the NCSU/EPA Cooperative Training Program CT826512010.) (This abstract does not reflect EPA policy.)

945 EFFECTS OF WELDING FUMES ON LUNG INJURY AND INFLAMMATION: THE POSSIBLE ROLE OF FREE RADICAL PRODUCTION.

M. D. Taylor, A. B. Lewis, J. R. Roberts, S. S. Leonard, X. Shi and J. M. Antonini. *HELD, NIOSH, Morgantown, WV.*

The goals of this study were to examine lung damage and inflammation as well as free radical production caused by welding fumes of different composition. Fume was collected during flux-covered manual metal arc welding using a stainless steel consumable electrode (MMA-SS) and gas metal arc welding using a mild steel electrode (GMA-MS) or a stainless steel electrode (GMA-SS). Metal composition analysis by energy dispersive spectroscopy revealed that only MMA-SS was highly soluble, containing both soluble Cr and Mn, while GMA-MS and GMA-SS were relatively insoluble. Using electron spin resonance, hydroxyl radicals were observed in a suspension of MMA-SS fume containing hydrogen peroxide. Both GMA fumes showed no evidence of free radical production. To examine the effects of the fumes on lung damage and inflammation, male Sprague-Dawley rats were intratracheally instilled with either a welding fume suspension at 2 mg/rat or the saline vehicle. On day 3, the right lung was assayed for lipid peroxidation (LPO) products while the left lobes were subjected to bronchoalveolar lavage (BAL). LPO products were elevated in the lungs following MMA-SS treatment only, implicating possible oxidative damage. All fumes caused increases in BAL cell number, including elevated macrophage and neutrophil recovery. However, only MMA-SS led to an increased recovery of eosinophils, indicating a possible immune reaction. MMA-SS treatment caused an elevation of albumin in the first BAL fraction, indicating damage to the alveolar-capillary barrier, while all fumes produced an increase in lactate dehydrogenase activity in that fraction. Total protein in the first BAL fraction was most elevated following MMA-SS treatment. These findings indicate that different welding fumes caused varied responses in the lungs of rats, and that these responses may be correlated to the soluble metal composition of the fume and the ability of the fume to produce free radicals.

946 TEMPORAL CHANGES IN BAL ELECTROLYTE LEVELS IN MICE AFTER EXPOSURE TO AN EDEMAGENIC GAS.

A. M. Sciuto, L. B. Carpin, T. Moran and J. Forster. *Pharmacology/Neurotoxicology, US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.*

Detection of acute lung injury is important if therapeutic medical countermeasures are to be used to reduce toxicity in a timely manner. Indicators of injury may aid in the eventual treatment course and enhance the odds of a positive outcome following a toxic exposure. This study was designed to investigate the effects of a toxic exposure to the industrial irritant gas phosgene on the electrolyte levels in bronchoalveolar lavage (BAL) fluid. Phosgene (CG) is a well- known chemical intermediate capable of producing life-threatening pulmonary edema within hours after exposure. Four groups of 40 each CD-1 male mice were exposed whole-body to either air (A) or a concentration x time (c x t) amount of 32 mg/m3 (8 ppm) CG for 20 min (640 mgxmin/m3). BAL from A- or CG-exposed mice was taken at 1, 4, 8, 12, 24, 48, and 72 h postexposure. After euthanasia, the trachea was excised, and 800 ul of saline was instilled into the lungs. The lungs were washed 5x. Eighty ul of BAL was placed in a cartridge and inserted into a clinical I-STAT analyzer. Na+, K+, Cl-, and ionized Ca++ were analyzed within 2 minutes of insertion. The left lung was removed to determine wet weight (WW), an indicator of pulmonary edema. Temporal changes in BAL Na+ and Cl- in CG mice were not statistically different from those in the A mice. Both Ca++ and K+ were significantly higher than in the A mice over 72 h, $p<.03$ and $p<.001$, respectively. Significant changes in BAL Ca++ and K+ occurred as early as 4 h postexposure in CG, $p<.05$, *versus* A mice. CG caused a time dependent significant increase in WW from 4-12 h, $p<.05$, compared with A mice. BAL Ca++ at 1 hr in CG-exposed was 60% higher than in the time-point matched A mice. These data indicate that measuring BAL electrolyte levels may serve as an alternate indicator of lung injury since both Ca++ and K+ follow temporal increases in tissue damage. In addition, knowledge of these levels may indicate how rational therapeutic intervention could be most beneficial.

947 OZONE EXPOSURE ENHANCES ANTIGEN-PRESENTING ACTIVITY ON BRONCHOALVEOLAR LAVAGE CELLS CONCENTRATION DEPENDENTLY IN RATS.

H. Watanabe[1,3], E. Koike[2,3] and T. Kobayashi[3]. [1]*Department of Medical Sciences, University of Tsukuba, Tsukuba, Japan,* [2]*Department of Medicine, University of Tsukuba, Tsukuba, Japan and* [3]*Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan.* Sponsor: S. Hirano.

Previous studies have shown that O_3 exposure aggravates allergy like diseases such as asthma and rhinitis. Our previous studies have shown that expression of cell-surface molecules associated with antigen presentation on bronchoalveolar lavage cells

(BAL cells) is increased by exposure to O_3 in rats. The present study designed to investigate concentration dependencies of the effect of O_3 on the expression of cell-surface molecules associated with antigen presentation and on accessory activity of BAL cells. Male Wistar rats were exposed to 0.3, 0.56, 1 ppm O_3 or filtered air for 3 days. Expression of cell-surface molecules (Ia, B7.1, B7.2, and CD11b/c) was measured by flow cytometry. Accessory activity of BAL cells was assessed by the allogeneic mixed lymphocyte reaction (MLR) and ovalbumin (OVA)- specific antigen-presenting activity. The numbers of Ia^+, $B7.2^+$, $CD11b/c^+$, $Ia^+/B7.2^+$, and $Ia^+/CD11b/c^+$ BAL cells were increased by O_3 exposure concentration dependently. The accessory activity of BAL cells measured by MLR and OVA-specific antigen-presenting activity was also enhanced by O_3 exposure concentration dependent manner. These results suggest that the enhancement of antigen-presenting activity of BAL cells is caused by the increasing of expression of cell-surface molecules associated with antigen presentation by O_3 exposure. This enhancement may trigger the subsequent immune response that could make worse allergic asthma and rhinitis.

948 ULTRASTRUCTURAL CHANGES IN THE AIRWAYS OF RATS INHALING BUTTER FLAVORING VAPORS.

A. F. Hubbs[1], R. R. Mercer[1], L. Battelli[1], S. Friend[1], D. Schwegler-Berry[1], V. Castranova[1], K. Kreiss[2], G. Kullman[2], D. Frazer[1], W. T. Goldsmith[1] and W. G. Jones[2]. *[1]Health Effects Laboratory Division, NIOSH, CDC, Morgantown, WV and [2]Division of Respiratory Disease Studies, NIOSH, CDC, Morgantown, WV.*

A cluster of eight cases of fixed airway obstruction occurred in former workers in a microwave popcorn plant. As part of a request to NIOSH to find the cause, extensive medical and environmental measurements were made at the plant. High levels of organic gases and decreased pulmonary function among workers were associated with butter flavoring in use at the plant but other exposures existed. To assess the biological effects of the flavoring, we exposed rats by inhalation for 6 hours to butter flavoring vapors. Qualitative GC-MS analysis yielded a variety of organic gases including diacetyl and acetoin. Average diacetyl concentration in the exposure chamber was about 350 ppm. By transmission electron microscopy (TEM), the principal finding in the mainstem bronchus of exposed rats was airway epithelial necrosis. Unusual features of the epithelial alterations included rarefaction of basilar cytoplasm and relative preservation of cilia. Denuded basement membrane was frequently observed although a thin fragment of basilar cytoplasm of respiratory epithelium remained attached in some foci. Damage in the mainstem bronchus extended beneath the basement membrane into the lamina propria where edematous changes were characterized by disorganization and separation of collagen fibers and fibrils. Necrotizing changes were less frequent in smaller airways. By scanning electron microscopy (SEM), ulceration of bronchiolar epithelium tended to be localized at bronchiolar bifurcations. No evidence of alveolar injury was evident in TEM or SEM sections. These findings document that artificial butter flavoring, while considered safe to consume at concentrations present in food, produces vapors capable of inducing severe airway injury in laboratory animals when inhaled at high concentrations similar to peak exposures in the workplace.

949 SPECIES DIFFERENCE IN ACUTE RESPIRATORY RESPONSES TO VAPOR AND AEROSOL IRRITANTS BETWEEN RATS AND MICE.

J. T. Pierce, J. R. Decker, Jr., L. A. Wisse, D. L. Redetzke and K. M. Lee. *Toxicology NW, Battelle, Richland, WA.*

This study was to compare acute respiratory responses upon exposure to a vapor (cumene) or an aerosol (vanadium pentoxide, V_2O_5) irritant between young male F344 rats and SW mice. Animals (4/species/chemical/dose/timepoint) were exposed to either chemical and their tidal volume (TV), respiratory rate (RR), and minute volume (MV) were measured. For cumene exposure, respiratory function was measured for 10-min preexposure and during 30-min nose-only inhalation exposure to 100 or 300 ppm cumene. For V_2O_5 exposure, animals were exposed *via* intratracheal instillation (0, 0.63, or 6.3 mg V/kg in saline) and respiratory function was measured 1 and 3 days post dosing. For V_2O_5-instilled mice, bronchoalveolar lavage (BAL) was performed, and data were compared with those from V_2O_5-instilled rats under the same study design (Lee et al., 2000). Cumene exposure at both concentrations significantly depressed TV and RR of mice, resulting in 39-41% reduction in MV compared to preexposure baseline. In rats, reduced respiratory function was observed only at 300 ppm (38% reduction in MV). For V_2O_5-instilled mice, respiration became rapid (RR ↑–) and shallow (TV ↓), which was most severe with the high-dose group on day 1 (MV reduced by 37% compared to saline-instilled controls). Signs of pulmonary inflammation (increases in LDH, NAG, protein, and neutrophil count in BAL fluid) were also observed in V_2O_5-instilled mice. For V_2O_5-instilled rats, rapid and shallow breathing was most severe in high-dose group on day 3 (MV reduced by 43%). Therefore, although acute respiratory responses between rats and mice varied depending on the exposure concentration and time, mice appeared to be more sensitive in terms of modifying respiratory functions or inducing inflammatory responses upon single exposure to these respiratory irritants.

950 INITIAL CONCENTRATIONS AND DISAPPEARANCE OF SELECTED MALODOROUS COMPOUNDS FROM FRESH AND AGED DAIRY MANURES.

L. B. Willett[1], D. C. Borger[1], D. L. Elwell[2] and H. M. Keener[2]. *[1]Animal Sci., Ohio State Univ., Wooster, OH and [2]Food, Agricultural & Biol. Eng., Ohio State Univ., Wooster, OH.*

Malodorous compounds from livestock manures are offensive and can cause health hazards to humans and cattle. Changes of manure storage and handling methods may prevent the formation and/or enhance the degradation of odors. This study was to quantify volatile fatty acids (VFAs), phenol, cresols, indoles and NH_3 in and emitted from fresh and 12-day-aged manure. Loss of these compounds was monitored during pilot-scale composting in 205 L vessels either aerated continuously (AC) with high (2.3 kg/hr)/low (0.8 kg/hr) air flow controlled by thermostats or intermittently (AI) on a 5 min high air flow 55 min off cycle. Manures were mixed with sawdust (3:1, w/w). Six replicates were conducted on each treatment combination, with 16 day trials. Emissions from the composting masses were measured. FID/GC was used to analyze VFAs in condensates and pH 2 water extracts of solids. Ether extracts of phenolics and indolics were quantified by GC/MS. Mean NH_3 emissions from fresh and aged manure AI were 50 and 60 g. Fresh and aged manure AC emitted 121 and 110 g NH_3. NH_3 peaked early and decreased to undetectable by day 17. Aged, compared to fresh manure, contained greater varieties and amounts of VFAs, phenols and indoles with the most offensive odors. Fresh manure contained acetate, propionate, isobutyrate, isovalerate, phenol, p-cresol, and indole (5000, 500, 40, 70, 35, 200 and 5 μg/g). Aged manure contained acetate, propionate, isobutyrate, butyrate, isovalerate, valerate, phenol, p-cresol, indole and skatole (9000, 2700, 200, 2500, 2800, 350, 50, 350, 10 and 30 μg/g). By day 8, trace quantities of acetate remained in fresh manure, while acetate, propionate and butyrate (900, 120 and 130 μg/g) were in aged manure. Acetate, propionate and butyrate co-distilled with water being highest from aged manure. Bioprocesses associated with AC and AI influenced the loss of certain chemicals. Avoiding anaerobic aging of dairy manure was important in reducing concentrations of the chemicals studied.

951 WHOLE BODY EXPOSURE SYSTEM FOR ADMINISTERING NITRIC OXIDE (KINOX®) BY INHALATION TO NEONATE RATS.

T. J. Kenny[1], I. S. Gilkison[1] and M. Lemaire[2]. *[1]Toxicology, Huntingdon Life Sciences, Huntingdon, United Kingdom and [2]Air Liquide Santé International, Paris, France.* Sponsor: C. Atterwill.

A whole body exposure system has been designed in order to expose neonate rats to controlled concentrations of nitric oxide for inhalation toxicity studies and to prevent levels of the oxidation product NO_2 rising above 1 ppm for an atmosphere containing 100 ppm NO. The exposure chambers comprise a polycarbonate nesting box with a perforated floor and a pyramidal lid incorporating a gas mixing chamber. Each exposure chamber accommodates a dam plus litter. A nitric oxide/nitrogen mixture of known concentration, oxygen and clean air are mixed and pass into the chamber *via* a duct in the chamber lid. The atmosphere is exhausted through the perforated floor. Gas flow rates are set to ensure a minimum residence time in the chamber to prevent NO_2 build up while maintaining temperature and relative humidity in the chamber conducive for exposure of animals. The NO/N_2 mixture, oxygen and airflow rates are controlled, monitored and recorded throughout exposure. An automated sampling and data capture system monitors the chamber concentrations of NO and NO_2 in real time. An inhalation toxicity study was conducted where neonate rats were exposed for 6 hours a day with dams from Days 2–10 *post-partum* and litters alone from Days 11-29 *post-partum*, target levels of NO were 10, 30 and 100 ppm. Mean achieved concentrations of NO were 10.2, 30.3 and 100.2 ppm. Concentrations of NO_2 were 0.0, 0.2 and 1.1 ppm. In conclusion, the study results demonstrate that the system is capable of excellent control of NO concentration and can maintain the required low levels of NO_2.

952 ALDEHYDE DEHYDROGENASE (ALDH2) POLYMORPHISM AND THE PULMONARY EFFECTS ASSOCIATED WITH EXPOSURE TO ETHANOL VAPORS IN THE RAT.

G. Del Zoppo[1], R. Tardif[2] and M. Charbonneau[1]. *[1]Human Health Research Center, INRS-Institut Armand-Frappier, Université du Québec, Montreal, PQ, Canada and [2]Environmental and Occupational Health, Université de Montréal, Montreal, PQ, Canada.*

Addition of ethanol to gasoline aiming at reducing the greenhouse effect is likely to increase atmospheric emissions of ethanol and acetaldehyde. By converting acetaldehyde to acetate ALDH2 plays a major role in the metabolism and toxicity of EtOH. A significant polymorphism exists in both humans and rats. In the latter, a

point mutation gives rise to a slow metabolizing enzyme. This mutation is present on the ALDH2R allele but is absent on the ALDH2Q allele, with the ALDH2R allele expressing an incomplete dominance. Our hypothesis is that atmospheric ethanol may cause pulmonary toxicity and that individuals expressing the ALDH2R allele could be at greater risk. ALDH2 polymorphism was determined by PCR amplification of the polymorphic site followed by a digestion with DdeI enzyme. Characterization of the various genotypes in a group of Sprague-Dawley rats (Charles River Canada) (N=115) gave the following distribution: 2R/2R (17%), 2Q/2R (53%), 2Q/2Q (30%). Pulmonary ALDH2Q/2Q isozyme showed greater *in vitro* metabolic activity, assessed by NADH formation, than ALDH2R/2R isozymes. Inhalation exposure experiments (500 ppm, 6h) showed that EtOH is rapidly excreted from blood., i.e. around 94 % of the dose is excreted in 60 min for female rats. Blood levels of acetaldehyde could not be detected in these rats suggesting its binding to proteins. Intratracheal instillation of ^{14}C-EtOH in female rats showed that after a 3 h period, ethanol-derived radiolabeled material binds to pulmonary proteins. Ongoing studies are aimed at determining if differences in amounts bound exist between ALDH2Q/2Q and ALDH2R/2R genotypes. Similarities between acetaldehyde and formaldehyde binding to proteins suggest that EtOH vapors may lead to pulmonary toxicity. Overall, this work may improve the health risk assessment associated with the addition of ethanol to gasoline. (Supported by the Toxic Substances Research Initiative)

953 THE EFFECT OF COMBUSTION OF MOSQUITO COILS ON CHILDREN'S RESPIRATORY HEALTH.

J. Juliana[1], W. Liu[3], A. A. Dayang[1], H. H. Jamal[1], H. Zailina[2], J. Zhang[3], S. Mazumdar[4] and B. D. Goldstein[4]. *[1]Univ Kabangsaan Malaysia, Kuala Lumpur, Malaysia, [2]Univ Putra Malaysia, Kuala Lumpur, Malaysia, [3]Environmental and Occupational Health Sciences Institute, Piscataway, NJ and [4]Univ of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

We report a significant impact on the respiratory health of children due to combustion of mosquito coils. Two groups of healthy Malaysian schoolchildren, ages 7-11, from 3 rural schools were chosen based on exposure to indoor air pollution. One group of 125 children came from homes in which there was cigarette smoking, home cooking twice or more daily, and the burning of insecticide-impregnated mosquito coils at night to protect children from mosquitos. The control group of 156 children was negative for all of these characteristics. Pulmonary function studies showed that the FVC and FEV1 in girls and boys were each more than 10% lower in the exposed groups ($p<.001$ for each). Respiratory symptoms were much higher in the exposed group; e.g., chronic cough was observed in 25/125 children in the exposed group vs 2/156 in the exposed group ($p<.001$). Further analysis showed that the pulmonary function and symptom effects for the most part could be attributed to the mosquito coils. Studies of combustion products from mosquito coils from Malaysia and China revealed high levels of fine particulates and aldehydes. Coupling the observed emission rates with the range of expected room sizes and air exchange rates suggest that night time exposures to PM2.5 would range from 129 to 4, 340 ug/m3 (US annual std 15 ug/m3); to formaldehyde 3.3 to 131.3 ug/m3; and to acrolein 0.10 to 5.8 ug/m3 (EPA chronic exposure effect level for formaldehyde 3 ug/m3 and for acrolein 0.06 ug/m3). It is conceivable that at least 100 million children in Asia, Africa and Latin America are exposed indoors to burning mosquito coils.

954 RAT SUBCHRONIC INHALATION STUDY OF SMOKE FROM CIGARETTES CONTAINING FLUE-CURED TOBACCO CURED EITHER BY DIRECT-FIRED OR HEAT EXCHANGER CURING PROCESSES.
