

The Toxicologist

Supplement to *Toxicological Sciences*

Society of
Toxicology

46th Annual Meeting and ToxExpo™
Charlotte, North Carolina

*An Official Journal of the
Society of Toxicology*

www.toxsci.oxfordjournals.org

OXFORD
UNIVERSITY PRESS

ISSN 1096-6080
Volume 96, Number 1, March 2007

Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the symposium, platform, poster discussion, workshop, and poster sessions of the 46th Annual Meeting of the Society of Toxicology, held at the Charlotte Convention Center, Charlotte, March 25–29, 2007.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 449.

The issue also contains a Keyword Index (by subject or chemical) of all the presentations, beginning on page 480.

The abstracts are reproduced as accepted by the Program Committee of the Society of Toxicology and appear in numerical sequence.

Copies of *The Toxicologist* are available at \$45 each plus \$5 postage and handling (U.S. funds) from:

Society of Toxicology
1821 Michael Faraday Drive, Suite 300
Reston, VA 20190

This abstract book has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each article appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.

1

REACH – A NEW FRAMEWORK FOR THE REGULATION OF CHEMICALS.

J. Galvin², E. S. Williams¹ and M. J. Dastin von Rijn³. ¹Houston, *ChemRisk*, Houston, TX, ²Conoco-Phillips, Bartlesville, OK and ³U.S. Mission to the EU, Department of State, Brussels, Belgium.

The European Commission (EC) is increasing its regulation of chemicals through a comprehensive new program known as REACH (Registration, Evaluation, and Authorization of Chemicals). The legislation, which is based on the precautionary principle, shifts the burden from government to industry to prove that chemicals can be used safely before they are marketed. As a part of this new system, manufacturers and importers of chemicals will be required to submit hazard, use, and risk data for many substances manufactured in or imported into the EU. Chemicals which exist in preparations or as part of articles sold in the marketplace will also be subject to these regulations. Thus, while REACH is a European regulation, it will impact manufacturers worldwide. A key aspect of the program is the requirement to submit data concerning the physicochemical properties, toxicity, and environmental effects of those chemicals. Registration will be mandatory before a new chemical can be marketed, as well as to keep an existing chemical on the market, and chemicals of greatest concern will be subject to formal authorization procedures much like pharmaceuticals. The amount of information required for registration will be proportional to the chemical's health risks and production volumes. Chemicals that are classified as carcinogenic, mutagenic, toxic to reproduction, persistent, or bioaccumulative may be banned entirely if the manufacturer cannot demonstrate that risks associated with the chemical can be controlled. REACH will impact the global chemicals industry and their downstream users. The estimated costs to industry for complying with REACH have been reported to be as high as \$64 billion ([1] 150 billion). Chemicals produced in quantities greater than 1000 tons, as well as the most toxic chemicals, will have to be registered within 3 years of the regulation entering into force, and all chemicals over 1 ton must be registered within 11 years. Compliance with this regulation will require significant toxicology and laboratory resources.

2

CONCEPTS, METHODS AND APPLICATIONS OF DISCOVERY AND INVESTIGATIVE TOXICOLOGY.

J. Davis¹, D. Badger², J. McKim³, J. Steidl-Nicholls⁴, B. Car⁵ and K. Kolaja⁶. ¹DSRD, PGRD, Chesterfield, MO, ²Drug Safety Evaluation, Allergan, Irvine, CA, ³Cee-Toxicology, Kalamazoo, MI, ⁴DSRD, PGRD, La Jolla, CA, ⁵Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ and ⁶Investigative Toxicology, Roche, Palo Alto, CA.

Drug development is a long, complex and expensive process. Typical development timelines are between 10 and 15 years with attrition rates that are often too high for companies to sustain productive pipelines. Investigational and discovery toxicology are extensions of the field of general toxicology, created to fulfill the growing need for generating higher throughput, integrative, and predictive toxicological information, in an effort to reduce attrition at later stages of drug development. These novel ideas have begun to be employed more frequently and its widely anticipated that this will pave the way for future drug testing paradigms. This course will provide first an overview on the role of toxicology in discovery units including a description of how the discovery toxicologist can support non-clinical drug development. The next lecture will cover in vitro methods and interpretation of cytotoxicity. Following this, an iterative approach to de-risking strategies of QT prolongation will be discussed. The forth speaker will discuss strategies to partner with pharmacology colleagues to probe and understand toxicology. The course will conclude with a lecture discussing emerging technologies that hold near-term potential for improving drug safety evaluation. By the conclusion of this course it is anticipated that the attendees will be able to better assess which approaches would be most appropriate for their organization.

3

GENOMICS: FROM NOVICE TO EXPERT, FROM CHALLENGES TO PROMISES.

B. Sen¹, J. Tucker², S. Hester¹, H. Auer³ and H. Hamadeh⁴. ¹U.S. Environmental Protection Agency, Research Triangle Park, NC, ²National Institute of Environmental Health Sciences, Research Triangle Park, NC, ³Columbus Children's Research Institute, Columbus, OH and ⁴Amgen, Inc., Thousand Oaks, CA.

Microarrays, when used properly, can be a powerful tool for genomics research. The complexity of the technology provides numerous challenges and potential pitfalls to the uninitiated. The FDA has developed guidelines for submission of genomics data and the EPA has guidelines for submission under development. It is becoming increasingly necessary for toxicologists in many fields, including regulatory review, to have some level of understanding of the design and interpretation of microarray based studies. The ability to utilize this technology and generate reproducible re-

sults requires a detailed understanding of the process. The first presentation will focus on the design considerations of a successful microarray experiment. In a typical microarray experiment, lists of significant differentially expressed genes are created. The common task faced by any researcher is to translate these gene lists into a better understanding of the biological phenomenon involved. The second presentation will discuss the use of various bioinformatic tools for data mining. From drug discovery, to a better understanding of the disease process, to unraveling the toxicity profile of unknown chemicals, genomics offers many promises. The second half of the course will highlight the applications and limitations of this emerging technology in disease and toxicity profiling. The third presentation will focus on the use of microarray in disease outcome prediction. The final presentation will examine the potential of genomics in evaluating toxicity and identifying biomarkers. This course is aimed at providing investigators contemplating or pursuing studies in differential gene expression, and practicing toxicologists involved in data interpretation for safety assessment and regulation, valuable knowledge of experimental design, sample processing, data analysis, and an understanding of the scope and limitations of this powerful tool.

4

ALLERGY AND ALLERGIC DISEASE: A PRIMER FOR TOXICOLOGISTS.

I. Kimber¹ and G. Gerberick². ¹Central Toxicology Laboratory, Syngenta, Cheshire, United Kingdom and ²Miami Valley Innovation Center, Procter & Gamble, Cincinnati, OH.

Allergy to chemicals and proteins is an important health issue, and some forms of allergy are increasingly prevalent diseases. Moreover, there is no doubt that skin sensitization represents the most common manifestation of immunotoxicity in humans. Allergy may take a variety of forms, those of greatest relevance to toxicology being allergic contact dermatitis resulting from skin sensitization, respiratory allergy and occupational asthma associated with both proteins and chemicals, gastrointestinal and systemic allergic responses caused by food proteins, and a variety of local and systemic adverse reactions to drugs where allergic reactions are frequently implicated. The purpose of this Continuing Education Course is to explore, in the context of toxicological sciences, and following a general introduction to the principles of allergy, each of the four main types of allergic disease mentioned above. In each case clinical manifestations of disease, biological mechanisms, and approaches available for toxicological evaluation will be described. This Basic Level course will be of value to immunotoxicologists, and also to those with interests in respiratory, skin and gastrointestinal toxicology, occupational medicine, the development of approaches to hazard characterization, and risk assessment.

5

FUNDAMENTALS OF HUMAN HEALTH RISK ASSESSMENT WITH A CASE STUDY APPROACH.

T. Leavens¹, J. Orme-Zavaleta², G. Foureman², E. Cohen-Hubal², H. Clewell¹ and M. Gargas³. ¹CIIT Centers for Health Research, Research Triangle Park, NC, ²U.S. EPA, Research Triangle Park, NC and ³The Sapphire Group, Inc., Beaver Creek, OH.

This course will provide a general overview of the process of human health risk assessment to educate students and post doctorates interested in careers in risk assessment and researchers interested in how their work can impact and strengthen the science upon which the assessments are based. Risk assessment is used by toxicologists to estimate the likelihood of an adverse event from exposure to a hazardous agent. In 1983 the National Academy of Sciences-National Research Council published "Risk Assessment in the Federal Government: Managing the Process" in which the process of risk assessment was clearly outlined into 4 components including hazard identification, dose-response assessment, exposure assessment, and risk characterization. This course will focus on each of these 4 components and will use vinyl chloride, especially the U.S. EPA IRIS assessment, as a case study to illustrate the development and application of the 4 components. The presentations will cover historical studies incorporated into hazard identification including acute, subchronic, and chronic animal assays as well as epidemiology studies, in vitro assays, predictive models, and genomics research. Information will also be presented on determination of the mode-of-action from non tumor data, and how it may guide and direct the assessment process to reduce uncertainty in extrapolating effects. Various methods of dose-response assessment will be presented including statistical and mechanistic models used to extrapolate effects among doses and species. Available exposure factor data, exposure modeling tools, biomonitoring data, and potential sources of variability and uncertainty in exposure assessment will be highlighted. The final component, risk characterization, will address statistical and biological issues, such as appropriate models and target populations, as well as connect the process of risk assessment with risk management.

6

TOXICOLOGY AND MOLECULAR BIOLOGY OF TISSUE REPAIR.

H. M. Mehendele² and C. Corton¹. ¹NHEERL, U.S.-EPA, Research Triangle Park, NC and ²Department of Toxicology, University of Louisiana, Monroe, LA.

After chemical exposure, injury may progress unabated leading to tissue and organ dysfunction and failure, or regress leading to recovery. When recovery occurs, tissue injury resolves as a result of cell division, restored tissue architecture, structure and function. The molecular biology of these events, and their dynamic relationships to progression or regression of tissue injury are of significant mechanistic interest, because risk of adverse effects from chemical exposure should consider not only the level of tissue damage but the dynamics of recovery from that damage. In addition, interventional therapeutic opportunities may be developed through this understanding. These dynamic events apply to acute injuries such as ischemia-reperfusion, drug or toxicant-induced necrosis, or chronic tissue injuries. The first lecture will cover the sequential events that occur during tissue regeneration using recent genomic analyses of the partial hepatectomy model and other models of tissue regeneration. The second lecture will describe various models of liver injury, dose-response relationships and modulations of injury and progression leading to hepatic failure, and regression of injury leading to recovery from injury. The third lecture will cover the cellular and biochemical changes associated with renal injuries, and how injury initiated by drugs, toxicants, and ischemia-reperfusion may progress leading to renal failure. Both renal as well as hepatic injury and tissue repair models will be discussed in the context of modulation by disease, dose, duration of ischemia before reperfusion, and nutritional factors. The last lecture will cover the role of the dynamic events of tissue destruction and restoration focusing on hydrolysis of extracellular matrix components by activated matrix metalloproteinases in preparation for restoration of tissue architecture. The role of angiogenesis in restoring extracellular matrix, cell mobility and placement are dynamic and critical events needed in re-establishing tissue homeostasis.

7

THE BIOLOGY AND TOXICOLOGY OF THE PERI- AND POST-NATAL DEVELOPMENT.

D. J. Auyeung-Kim¹, R. Chapin², R. Tyl³, L. W. Jackson⁴, G. Cappon² and S. Makris⁵. ¹Toxicology, Charles River Laboratories, Preclinical Services, Sparks, NV, ²Pfizer Global Research & Development, Groton, CT, ³Center for Life Sciences & Toxicology, RTI International, Research Triangle Park, NC, ⁴Epidemiology & Biostatistics, Case Western Reserve University School of Medicine, Cleveland, OH and ⁵ORD NCEA, U.S. Environmental Protection Agency, Washington, DC.

The period of post-natal development has always been of societal, scientific, and regulatory concern. This concern is heightened by the growing literature which shows that exposures and health status in early (prenatal and post-natal) life can have significant health consequences much later in life; in humans, this may mean 50-60 years later. This basic course will begin with a review of the recent data showing the connection between early-life events and later-life health, and move on to a discussion of the comparative developmental biology of rodents and humans. The third talk will describe regulatory and tailored study designs which address perinatal exposures and adult outcomes and discuss endpoint selection. The last speaker will address the issues and challenges of data interpretation and regulatory action. Attendees will take home an appreciation of the complex biology, the length of the health trajectory that is set up by very early exposures, and the challenges of dealing with these issues from a regulatory perspective.

8

TOXICOLOGICAL EVALUATION OF CHEMICAL AND DRUG MIXTURES.

C. Borgert¹, J. Simmons², A. Constan³, M. Mumtaz⁴ and K. Krishnan⁵. ¹Applied Pharmacology and Toxicology Inc., Gainesville, FL, ²U.S. EPA, Research Triangle Park, NC, ³Infinity Pharmaceuticals, Cambridge, MA, ⁴ATSDR, Atlanta, GA and ⁵SEST, University of Montréal, Montréal, QC, Canada.

Drugs, consumer and personal care products, pesticides, environmental chemicals, and foods are often assessed for safety and risk without extensive consideration of numerous potential pharmacological and toxicological interactions that might occur as these agents are encountered as mixtures by patients, consumers, and through environmental exposures (e.g. mixtures present in air, water, soil). Such assessments are complex due to the potential pharmacokinetic and pharmacodynamic mechanisms that underlie interactions in mixtures, necessitating study designs, methods of analysis, and limits on interpretation not required for single chemicals. This course will cover the fundamentals of study design and data analysis for mixtures that apply to all uses of chemicals, regardless of market application. The first presentation will cover the basic principles underlying component-based and whole mixture techniques as well as study designs available for evaluating the toxicity of mixtures. The second presentation will review the concepts for evaluat-

ing data on mixtures, including data on binary and higher order interactions, and will apply those concepts to various examples from the published scientific literature. The third talk will focus on the pharmacokinetic and pharmacodynamic mechanisms of interactions among drugs and chemicals. The final talk will present the current approaches and guidance for conducting risk assessment of chemical mixtures and safety assessment of drug combinations. The course will be of interest to experimentalists who wish to conduct studies on mixtures that are more probative and relevant for safety and risk assessment, as well as for safety and risk assessors who must evaluate and apply data on mixtures and interactions in assessments.

9

PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELING FOR RISK ASSESSMENT APPLICATIONS.

H. A. Barton¹ and J. G. Teeguarden². ¹ORD National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC and ²Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WV.

Pharmacokinetics is a key step in mechanistically based risk assessments, linking chemicals exposures with the mode of action leading to toxicity. Physiologically based pharmacokinetic (PBPK) modeling is one approach for incorporating pharmacokinetics into risk assessment, particularly quantitative dose-response analyses. This course will guide the student through the PBPK modeling process, from model development through the use of the modeling results in risk assessment. The basic principals of PBPK model development will be described, focusing on the range of different model structures that have been developed to address compounds with a variety of physicochemical characteristics, toxicological properties, and exposure pathways. Models for endocrine active compounds will be described to illustrate issues of serum protein and receptor binding and modeling in vitro and in vivo systems. Characterizing variability of the human population can be incorporated in PBPK models using distributions of physiological and chemical-specific parameters (e.g., metabolism) and Monte Carlo methods. Bayesian statistical approaches implemented with Markov Chain Monte Carlo analyses and maximum likelihood methods will be described as these have been the major approaches to characterizing uncertainty in model estimated dose metrics. Qualitative and quantitative evaluations of PBPK models are a critical step in their application in risk assessments. A variety of risk assessment applications (e.g., route-to-route extrapolation) and examples of using PBPK models to develop reference concentrations/doses and cancer unit risks will be presented.

10

PROTEIN THERAPEUTICS: ASSESSMENT AND IMPACT OF IMMUNOGENICITY ON STUDY DESIGN AND INTERPRETATION.

Y. Ouyang¹, L. LeSauteur², D. Wierda³, D. Finco-Kent⁴, R. House⁵ and S. Kirshner⁶. ¹CDER/OND/OODP/DMIHP, U.S. FDA, Silver Spring, MD, ²Laboratory Sciences, Preclinical Services, Charles River Laboratories, Senneville, QC, Canada, ³Biopharmaceutical Immunotoxicology, Eli Lilly & Company, Greenfield, IN, ⁴World Wide Safety Sciences, Pfizer Inc., Groton, CT, ⁵DynPort Vaccine Company LLC, Frederick, MD and ⁶CDER/OPS/OBP/DTP, U.S. FDA, Bethesda, MD.

Immunogenicity is a unique and significant safety and efficacy concern in developing protein therapeutics and could have significant impact on safety, pharmacokinetics, and efficacy. Anti-erythropoietin (EPO) antibodies-elicited pure red cell aplasia has highlighted the significant impact of immunogenicity on human safety of protein therapeutics. Immunogenicity is also a critical issue in designing and interpreting animal toxicity studies. The purpose of this basic CE course is to highlight important aspects of immunogenicity including an overview of current FDA regulation with regards to nonclinical and clinical immunogenicity assessment. Specifically, the course will address what makes protein therapeutics potentially immunogenic, and how an antibody response is produced. The development and validation of common methods used to detect an antibody response will be presented by describing development/optimization parameters and validation criteria for immunogenicity assays, followed by case studies describing antibody screening approaches, and total and neutralizing antibodies determination. This course will also review the current practice in immunogenicity evaluation in animal models and recent development of new animal models. The consequences of immunogenicity will be discussed using specific case studies highlighting safety evaluation, risk assessment, potential clinical consequence and the impact of immunogenicity on designing and interpreting toxicity studies. With the current drug development approach on targeted therapeutics, protein therapeutics are becoming increasingly important. Immunogenicity is a challenge for anyone involved in immunotoxicity research and in the research and development of protein therapeutics.

**11** RODENT IMAGING OVERVIEW FOR THE TOXICOLOGIST.

K. Gabrielson¹, R. Maronpot², B. Tsui³ and P. Contag⁴. ¹Molecular and Comparative Pathobiology, Johns Hopkins University, Baltimore, MD, ²Laboratory of Experimental Pathology, National Institute of Environmental Health Sciences, Research Triangle Park, NC, ³Radiology, Johns Hopkins University, Baltimore, MD and ⁴Imaging, Xenogen Corporation, Alameda, CA.

In the last decade, in vivo imaging methods have become established tools in basic science research. This course is designed to provide a general overview of imaging modalities utilized in basic science with applications to drug discovery and toxicological research. This review will focus on five imaging modalities including: MR, PET, SPECT, optical and ultrasound. Each speaker will give a basic overview of the modality and present specific examples relevant to drug discovery and toxicological research. In this review, several applications of MRI, Magnetic Resonance Spectroscopy and Electron Paramagnetic Resonance in oncology, cardiovascular disease and morphological phenotyping during toxicological studies will be described. PET and SPECT imaging of radioactively labeled compounds will be reviewed in the setting of drug discovery and toxicological research. The application of the multi-modality imaging scanners will also be discussed. These multi-modalities studies provide comprehensive evaluation that enables the toxicologist to study structure, function, in tandem with distribution and metabolism of radioactively labeled drugs. PET imaging of gene expression during pharmacology studies will be reviewed. Optical imaging will be reviewed in the context of imaging gene expression in transgenic mice engineered with gene promoters from enzymes (CYP1A2 or CYP3A4) driving luciferase expression. Signal transduction pathway discovery in toxicological research will be discussed using optical imaging in transgenic mice with a Smad-responsive luciferase reporter. Ultrasound imaging will be overviewed using applications of toxicity and drug discovery in cardiovascular and cancer mouse models. Following completion of this workshop, attendees should have basic understanding of the various imaging modalities and applications to drug discovery and toxicological research.

**12** APPLICATION OF HUMANIZED MOUSE LINES TO TOXICOLOGICAL AND PHARMACOLOGICAL STUDIES.

R. S. Pollenz. *Biology, University of South Florida, Tampa, FL.*

A major challenge to human risk assessment is the translation of toxicological and pharmacological results produced in rodents to human populations. This is further complicated by the fact that many toxicologically relevant enzymes and receptors exhibit differences in response to activating compounds that are species specific. In addition, for any chemicals that have carcinogenic properties, it is often impossible to obtain results in human populations for comparisons to rodents. In an effort to address some of these issues, "humanized" mouse lines are being generated in which human genes have been used to replace orthologous mouse genes. Such models are termed "knock-in" mouse lines. Alternatively, mouse lines can be generated in which human hepatocytes have been transplanted into mice. In these studies it often possible to obtain mice that show 70-98% replacement ratios of the mouse hepatocytes. The advantage to such humanized mouse lines is that they are likely to show phenotypes closer to that of humans and be applicable to a wide variety of in vivo studies. Such lines make it feasible to carry out risk assessment studies in rodents that may be directly applicable to human populations. This symposium session is aimed at exploring the generation and analysis of mouse models harboring hCYP1A1, hCYP1A2, pregnane X receptor (hPXR), and the peroxisome proliferator-activated receptor (hPPAR). These studies will be contrasted to those in mice harboring human hepatocytes. These novel animal models have relevance to pharmacology, toxicology, drug development and human risk assessment.

**13** MOUSE METABOLOMICS IN THE SEARCH FOR ENDOGENOUS P450 METABOLITES AND METABOLIC PROFILING.

F. Gonzalez¹, C. Chen¹, K. Krausz¹ and J. Idle². ¹NCI, Bethesda, MD and ²Charles Univeristy, Prague, Czech Republic. Sponsor: D. Nebert.

Metabolomics is the study of changes in small molecules in cells, tissues and biological fluids such as serum and urine. Metabolomics, using 1H-NMR, has gained prominence and been embraced by the pharmaceutical industry as a means to determine the potential toxic effects of drugs. For example, a chemical is administered to rodents and urine examined for the presence of metabolites that reflect organ-specific toxicity. In an attempt to find biomarkers for cytochromes P450 expression, P450-null and humanized mice were compared. By use of metabolic cages, urine was collected and subjected to ultra performance liquid chromatography coupled time-of-flight mass spectrometry (UPLC-TOFMS). The UPLC-TOFMS data

were deconvoluted by principle component analysis software in order to find compounds that correlate with the presence or absence of a specific P450 form. To study drug metabolism, drugs were administered to mice and serum and urine examined for the production of metabolites that were not found in untreated mice. In this manner, metabolites derived from the drug and endogenous metabolites that reflect the drugs biological activity or toxicity can be resolved. This high resolution of MS-based metabolomics offers great promise in the fields of drug metabolism and toxicology.

**14** PREGNANE X RECEPTOR (PXR) HUMANIZED MICE IN TOXICOLOGY STUDIES.

W. Xie. *University of Pittsburgh, Pittsburgh, PA.* Sponsor: D. Nebert.

The regulation of hepatic CYP enzymes is important in drug metabolism and toxicological studies. The CYP genes are up-regulated by numerous foreign chemicals (xenobiotics), yet the inducibility shows distinct species specificity. The orphan nuclear receptor PXR (NR1I2) in the mouse and its human ortholog, have been established as species-specific xeno-sensors that regulate CYP3A enzymes. By knocking-out the mouse Nr1i2 gene (encoding mPXR) and replacing it with the human NR1I2 gene (encoding hPXR), a "humanized" mouse model has been established. In addition to the original liver-specific hPXR mouse line, we have recently also created a mouse line with hPXR expressed in both the liver and intestine. We have found that the humanized mice readily responded to human P450 inducer drug rifampicin in the equivalent range of the standard oral dosing regimen in humans (300-600 mg per 70-kg man). These humanized mouse lines, which display human drug response profiles, represent unique tools for dissecting responses to drugs and foreign chemicals and should aid in the development of safer drugs. —Supported in part by NIH grants ES012479 and CA107011.

**15** REPOPULATION OF MOUSE LIVER WITH HUMAN HEPATOCYTES: CHARACTERIZATION OF THIS MOUSE LINE AND USE IN DRUG METABOLISM STUDIES.

K. Yoshizato. *Biological Science, Hiroshima University, Higashihiroshima, Hiroshima, Japan.* Sponsor: D. Nebert.

Chimeric mice were produced by transplantation of human hepatocytes into immuno-deficient and liver-diseased mice (urokinase-type plasminogen activator-transgenic severe combined immune deficiency mice). These animals were normal and survived for more 100 days post-transplantation. Some animals were given bromodeoxy uridine (BrdU). Liver sections were stained with antibodies against human cytokeratin 8/18 (hCK8/18) and BrdU. The hCK8/18-positive-hepatocyte colonies gradually increased their size. Some chimeric mice showed an almost-complete replacement with human hepatocytes after 9 weeks post-transplantation. Approximately a half of the chimeric mice had a replacement index (RI, the number of hCK8/18-positive human hepatocytes divided by total number of hepatocytes) of more than 70%. BrdU-labeling index was about 9% at 1 week and gradually decreased to a background level at 11 weeks post-transplantation. The chimeric mice showed normal liver lobules and sinusoid structures: the sinusoids were lined up with mouse endothelial cells; the space of Disse was occupied with mouse stellate cells; mouse Kupffer cells were distributed on the luminal aspect of the endothelium. The human hepatocytes in the chimeric liver expressed major human cytochrome P450 (hCYP) subtypes in a manner nearly equivalent to those of the original donor hepatocytes. hCYP3A4 and hCYP1A1/1A2 were specifically induced in the liver by rifampicin and 3-methylcholanthrene, respectively. The profile of bile acid composition of taurocholic and glycocholic acids was closer to human than to mouse. Efficient infection and propagation of both hepatitis B and C viruses were observed in the chimeric mice: known anti-hepatitis virus agents dramatically decreased the level of viremia in the infected mice. This animal model will have wide usefulness for human liver-related studies, especially for predicting the metabolism of drugs in the human liver and to screen an anti-human hepatitis virus drug. —Supported in part by CLUSTER Project.

**16** REPLACEMENT OF THE MOUSE *CYP1A1* AND *CYP1A2* GENES WITH THE HUMAN *HCYP1A1-CYP1A2* LOCUS.

D. W. Nebert, S. Derkenne, T. Doetschman and T. P. Dalton. *Department of Environmental Health, University Cincinnati Medical Center, Cincinnati, OH.*

The human *CYP1A1* and *CYP1A2* genes are oriented head-to-head, sharing a common 5'-flanking region of 23.3 kb. The mouse *Cyp1a1* and *Cyp1a2* genes are also oriented head-to-head and share a common 5'-flanking region of only 13.3 kb; this region is so small that one would need to generate thousands of offspring from a

Cyp1a1(-/-) x Cyp1a2(-/-) cross to obtain a double-knockout. Using Cre-mediated interchromosomal recombination between *loxP* sites inserted at the 3' ends of both the *Cyp1a1* and *Cyp1a2* genes, we have succeeded in generating a *Cyp1a1/1a2(-/-)* double-knockout mouse line. This lab has also created a bacterial artificial chromosome (BAC)-transgenic mouse line, carrying both human *CYP1A1* and *CYP1A2* genes, the 23.3-kb spacer region, >55 kb of *CYP1A1* 3' flank, and >85 kb of *CYP1A2* 3' flank. Both lines have been backcrossed into C57BL/6J (B6) so that their genomes comprise >99.8% B6 genes. The humanized *hCYP1A1_1A2* line—in the absence of the mouse *Cyp1a1* and *Cyp1a2* orthologous genes—expresses human *CYP1A1* and *CYP1A2* mRNA, protein and enzyme activities in all tissues in a pattern very similar to that of the mouse: basal *CYP1A1* is nil, whereas TCDD-inducible *CYP1A1* is robust and occurs in all tissues examined; basal *CYP1A2* is prominent in liver, whereas TCDD-inducible *CYP1A2* occurs in liver, duodenum, stomach and lung. Theophylline was chosen to prove human P450 participation in metabolism; the drug is predominantly metabolized by *CYP1A2* in humans and rodents. Replacement of mouse *Cyp1a2* with the functional human *CYP1A2* gene restored the capacity to metabolize theophylline, and the metabolism changed from the mouse to the human profile (*i.e.* 3-methylxanthine formation was now seen, which does not occur in wild-type mice). This humanized *hCYP1A1_1A2* BAC-transgenic line will be helpful in estimates of human risk assessment, following exposure to a variety of drugs, carcinogens, and other environmental pollutants that are *CYP1A1* and/or *CYP1A2* substrates or inducers. —Supported in part by NIH grants R01 ES08147 and P30 ES06096.

17 GENOMICS AND DOSE-RESPONSE MODELING.

M. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

In recent years, with the completion of the Human Genome project and evolving capabilities and technologies in the area of genomic research, there has been a significant increase in information about consequences of chemical exposure on gene expression. While these types of information are currently being used qualitatively to make decisions, the challenge remains to be able to incorporate genomic information quantitatively into the risk/safety assessment process. The main challenge facing scientists in the regulatory arena is not only attempting to identify a genomic signature or threshold associated with chemical exposures, but to also correlate this information with a phenotypic threshold, whether that is at the level of a protein, cell, tissue or behavior. The purpose of this symposium is to present examples of the gathering of dose-dependent genomic information on toxic compounds and to discuss how this information might be considered in dose-response modeling for risk assessment application. Several case studies will be presented, as well as reviews of the types of information or studies needed to facilitate the consideration of genomic data in dose-response modeling.

18 THE CURRENT STATE OF THE USE OF GENOMIC INFORMATION IN RISK ASSESSMENT.

R. J. Preston. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*
Sponsor: R. Gentry.

The recently released U.S. EPA Guidelines for Carcinogen Risk Assessment provide a framework for the consideration of mechanistic data in the cancer risk assessment process. A tumor is induced by a set of key events that are required for the conversion of a normal cell into a transformed one and ultimately to produce a malignant phenotype. The key events for a particular chemical are described by the mode-of-action (MoA) for that chemical; for example, DNA-reactivity, cytotoxicity and regenerative cell proliferation, and receptor interactions. It is likely that multiple modes of actions are operating for any particular chemical. Given the complexity of tumor formation and that multiple key events are involved, it is of considerable value, if not essential, to assess effects of potential or known carcinogens at the whole-genome level, and at the tissue/organ level. It is this systems (cell or tissue) approach that is likely to be the most fruitful for assessing cancer risks at low, environmental exposure levels. In this way, it is feasible to enhance the ability to conduct the various extrapolations that have to be a part of the risk assessment process. These extrapolations include high to low dose, animal to human and tumor site to site. Genomics data at the DNA, mRNA and protein levels have already been informative in the identification of specific genetic and phenotypic alterations associated with tumor formation. This approach can lead to the development of informative biomarkers of tumor response and their use as surrogates for tumors for the types of extrapolation noted above. The use of genomics approaches is just entering the realm of risk assessments; there remains considerable groundwork before a clearly defined use can be established. (This abstract does not necessarily reflect U.S. EPA policy).

19 GENOMIC CONSIDERATIONS IN THE DOSE-RESPONSE MODELING FOR FORMALDEHYDE.

M. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

This presentation will provide a discussion of the development of a mechanistic dose-response model with genomic data for formaldehyde. Inhalation exposures in rats were conducted at concentrations ranging from 0.7 to 15 ppm, 6 hours per day, 5 days per week, for three weeks. These concentrations were previously examined in long term inhalation studies in rats. Instillation exposure to 400 mM formaldehyde served as a positive control. Gene expression was evaluated with a whole genome rat array. Dose-response analyses of genomic responses at several time-points showed dose-dependent transition for the mode of action of formaldehyde nasal carcinogenicity, in which increasing exposure concentration activates different gene pathways. Qualitatively large scale changes in gene expression occurred with increasing concentration from 6 to 15 ppm. The 15 ppm more resembled the instillation results. The differential activation of these pathways correlates with different cellular responses noted by histological observations and measurements of cell proliferation rates.

20 USING GENOMIC DOSE-RESPONSE INFORMATION TO INFORM A POTENTIAL MODE OF ACTION FOR ARSENIC.

R. Gentry¹, T. McDonald¹, J. Yager³ and H. Clewell². ¹ENVIRON, Ruston, LA, ²CIIT, Research Triangle Park, NC and ³EPRI, Palo Alto, CA.

A comprehensive literature search was conducted that identified more than 400 studies containing information on gene expression changes following exposures to inorganic arsenic compounds. This information was organized by compound, exposure, dose/concentration, species, tissue, and cell type. Initial dose-response analysis focused on in vitro data obtained with primary human cells exposed to arsenite. A concentration-related hierarchy of responses was observed, beginning with changes gene expression associated with adaptive responses (e.g., pre-inflammatory responses, delay of apoptosis). Between 0.1 and 10 μ M, additional gene expression changes related to oxidative stress, proteotoxicity, inflammation, and proliferative signaling occur along with those related to DNA repair, cell cycle G2/M checkpoint control, and induction of apoptosis. At higher concentrations (10 - 100 μ M), changes in apoptotic genes dominate. Comparisons of primary cell results with those obtained from immortalized or tumor-derived cell lines were also evaluated to determine the extent to which cell lines predict the responses of primary cells. While immortalized cells appear to respond similarly to primary cells, caution must be exercised in using gene expression data from tumor-derived cell lines, where inactivation or overexpression of key genes (e.g., p53, Bcl-2) may lead to altered genomic responses. Data from acute in vivo exposures is of limited value for evaluating the dose-response for gene expression, due to the transient, variable, and uncertain nature of tissue exposure in these studies. The available in vitro gene expression data, together with information on the metabolism and protein binding of arsenic compounds, supports a mode of action for inorganic arsenic carcinogenicity involving the superposition of highly-specific direct interactions with critical proteins such as those involved in DNA repair, overlaid against a background of chemical stress, including proteotoxicity and depletion of non-protein sulfhydryls, resulting in increased oxidative damage to DNA.

21 GENE EXPRESSION DOSE-RESPONSE IN THE MOUSE BLADDER FOLLOWING EXPOSURE TO ARSENATE IN DRINKING WATER.

H. Clewell¹, R. Thomas¹, E. Kenyon², M. Hughes² and J. Yager³. ¹CIIT Centers for Health Research, Research Triangle Park, NC, ²EPA/NHEERL, Research Triangle Park, NC and ³EPRI, Palo Alto, CA.

The association between drinking water exposures to inorganic arsenic and life-threatening tumors in the human is strongest for bladder cancer. Moreover, a working model for the pathogenesis of human bladder cancer has been developed. To investigate the mode of action for inorganic arsenic carcinogenicity in the bladder, a study was conducted to explore the dose-response for genomic expression in bladder epithelial cells resulting from exposure of C53Bl/6J mice to arsenate in drinking water for up to 12 weeks at concentrations ranging from 0.05 to 50 mg As/L. Bladder and urine concentrations of all arsenic species, including arsenite and the methylated metabolites, were also determined in order to support the design of in vitro analyses on primary bladder epithelial cells at concentrations of arsenite equivalent to those achieved in the in vivo study. Animals exposed at 0.05 mg/L arsenate showed no significant differences from controls in urinary arsenic species, tissue concentrations, or bladder gene expression. However, tissue concentrations were significantly increased at the higher exposures, with MMA as the dominant species in kidney tissue and DMA in bladder and urine. In addition, a dose-dependent up-

regulation in a variety of genes related to DNA repair, cell cycle control, proteotoxicity, and apoptosis was observed. This presentation will discuss the implications of these genomic data for understanding the mode of action of arsenic bladder carcinogenicity and will also describe how similar data obtained in primary human bladder epithelial cells will be used to inform the quantitative dose-response assessment for the bladder carcinogenicity of inorganic arsenic.

22 THE FUTURE OF GENOMICS IN DOSE RESPONSE MODELING: USEFUL LESSONS FROM SYSTEMS BASED APPROACHES.

E. Faustman, X. Yu and B. Griffith. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

The increasing availability of "Omic" information requires a reassessment of quantitative risk assessment interpretative tools. Although microarray technology has emerged as a powerful tool to explore expression levels of thousands of genes or even complete genomes after exposure to toxicants, the functional and quantitative interpretation of microarray datasets still represents a time-consuming and challenging task. Gene ontology (GO) and cell signaling pathway mapping have both been shown to be powerful approaches to generate an overall global view of biological processes and cellular responses impacted by toxicants. However, current methods do not allow for adequate comparisons across dose and time points and have limited capabilities for translation across levels of biological complexity. Frequently results are presented in extensive gene lists with minimal or limited quantitative information, data that is crucial in the application of toxicogenomic data for risk assessment. To facilitate quantitative interpretation of dose or time dependent genomic data, we propose several approaches. First, we have developed an extended program (GO-Quant) to extract quantitative gene expression values and to calculate the average intensity or ratio for those significantly altered by functional gene category based on MAPPFinder results. An application of this approach will be given. Secondly, computational approaches will be discussed that allow for integration of GO-Quant across cellular, organ, and organism level responses. To evaluate these responses across biological systems necessitates the use of toxicokinetic and dynamic models that can incorporate biological information. These studies were supported by USEPA and NIEHS ES08601, ES07033, ES 11387, ES 10613 and R 826882.

23 ENVIRONMENTAL RISKS FACTORS FOR AUTISM.

E. Silbergeld. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Autism spectrum disorders (ASD) are a prevalent and severe health issue for children and their families, with estimated prevalence rates between 1:200 and 1:600 live births. It has been generally recognized that ASD involves gene:environment interactions, but very little information has been developed on environmental risk factors that may contribute to these serious diseases. There are many new initiatives in research on ASD with both private and public support. The opportunity to discuss current research on the cellular and molecular biology of brain development, new information on the molecular events in ASD as well as on candidate susceptibility genes makes a workshop on environmental risks timely and appropriate. This workshop will bring together experts on ASD, neuroscientists, and neurotoxicologists to discuss the state of knowledge, promising experimental models, and methods for translating research into clinical practice and public health policy.

24 TRENDS IN THE INCIDENCE AND PREVALENCE OF AUTISM SPECTRUM DISORDERS: CLUES FOR GENERATING HYPOTHESES ON ENVIRONMENTAL RISK FACTORS.

C. J. Newschaffer. *Epidemiology, Johns Hopkins University, Baltimore, MD.*
Sponsor: E. Silbergeld.

Data on secular trends in autism prevalence have fueled the current debate over the potential role of environmental risk factors in autism etiology. This presentation will summarize existing data on secular and cross-national trends in autism prevalence. Challenges to the meaningful etiologic interpretation of these ecologic data will be highlighted. Results from a simulation analysis will also be presented that will underscore the complexities of interpreting incidence, prevalence, and cumulative incidence trend data for a developmental condition, like autism, whose diagnosis is behaviorally based.

25 CELL AND MOLECULAR MECHANISMS OF NEURODEVELOPMENT: CLUES FOR IDENTIFYING ENVIRONMENTAL RISK FACTORS FOR AUTISM?

P. Lein. *Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR.*

Autism spectrum disorder (ASD) is a behaviorally defined syndrome with diverse clinical presentations. Although altered neurodevelopment is widely recognized as the underlying neuropathological cause of ASD, the etiology and pathogenesis of ASD is poorly defined at the cellular and molecular levels. Genetic factors exert a strong influence in aggregate; however, it is clear that ASD susceptibility is determined by not only complex interactions between genes but also gene-environment interactions. There is, therefore, significant interest in identifying and characterizing epigenetic and environmental risk factors for ASD. One approach towards realizing this goal is to identify and characterize the cell and molecular mechanisms that control normal neurodevelopment in order to identify molecular targets whose disruption contributes to ASD-related traits. This presentation will provide an overview of recent advances in our understanding of the cellular and molecular mechanisms of neurodevelopment in the context of the neurobiology of autism. The major goals are to familiarize attendees with developmental mechanisms that control (1) cell migration; (2) the patterning of the balance between excitatory and inhibitory signaling pathways; and (3) synaptogenesis and synaptic plasticity. In addition, recent research delineating the influence of immune mediators on neurodevelopment will be discussed in light of the emerging theme that immunological challenge represents a point of convergence between genetic and environmental causal factors in ASD.

26 IDENTIFYING ENVIRONMENTAL CONTRIBUTORS TO AUTISM RISK: INSIGHTS FROM NEUROBIOLOGY AND IMMUNOLOGY.

I. N. Pessah^{1,2}. ¹VM: *Molecular Biosciences, University of California, Davis, Davis, CA* and ²*Center for Children's Environmental Health, Davis, CA.*

Autism is among the most complex neurodevelopmental disorders with potential susceptibility genes (current estimates range from 3 up to 100 genes) spread across the entire genome. Concordance between monozygotic twins for autism is significantly less than unity and phenotypic presentation can vary broadly between sibs. Autism therefore presents unique opportunities and challenges to study interactions among multiple susceptibility genes, and how epigenetic factors and exposure to environmental modifiers may contribute to variable expression of autism, and autism-related traits. The major goals of this presentation are to familiarize attendees with (1) genetic and epigenetic mechanisms implicated in altering the ratio of excitation/inhibition within central processing circuits of the autistic brain; including nicotinic, glutamatergic, gabaergic, and calcium signaling systems; (2) early immunologic differences in humoral and cellular immunity identified in autistic children that may impact brain development and behavior; and (3) approaches that toxicologist can develop in mouse models to better understanding how specific genetic or epigenetic defects alter sensitivity to chemical exposure(s) of current concern to children's health and autism. The development of mouse models to study gene-environment interaction relevant to autism present special challenges because the impact of altered immunity on the development of complex behaviors, key brain structures and neurotransmitter receptors relevant to autism must be studied in concert. How these challenges can be met will be discussed by presenting specific approaches used by the UC Davis Center for Children's Environmental Health and Disease Prevention. A better understanding of the mechanisms by which environmental, immunologic, and molecular factors interact to influence the risk and severity of autism is essential for developing relevant strategies for intervening and/or mitigating autism's devastating impact.

27 TERATOGENS AND AUTISM.

P. M. Rodier. *Departments of Obstetrics and Gynecology and Environmental Health Sciences, University of Rochester School of Medicine, Rochester, NY.*

Five teratogens are known to increase the risk of autism: rubella, thalidomide, valproic acid, ethanol and misoprostol. The critical period of exposure is early in the first trimester for each of these. The discovery of autism cases among the thalidomide-exposed population in Sweden has led to greater understanding of autism's origins by pinpointing the time of neural tube closure as important in the development of the disorder. In these cases, dysfunctions of the cranial motor nerves indicated brain stem injury and hearing impairments occurred with ear malformations. A newly discovered genetic syndrome (BSA) includes similar anomalies of the motor innervation of the eye muscles and facial muscles, deafness, and autism. It is

caused by homozygous inheritance of a large mutation of the gene, HOXA1. An animal model based on valproic acid exposure during neural tube closure has been studied anatomically and behaviorally. It resembles the histology of human cases of autism in having a reduction of the volume of the cerebellar cortex, reduced numbers of Purkinje cells, reduced volume and neuron number in the inferior olive and reduced volume and neuron number in the deep nuclei, especially the nucleus interpositus. Because these injuries involve several parts of the neural circuits responsible for eyeblink conditioning, one might expect that behavior to be disturbed in both human cases of autism and the animal model. The result is the opposite: eyeblink conditioning is enhanced in both. Further, the animal and human data exhibit identical abnormalities in the timing of the blink response. These results are noteworthy because many neurological and psychiatric disorders have been tested for eyeblink conditioning and autism is the only one in which enhancement has been observed. Human cases exposed to valproate in utero are now being studied for eyeblink conditioning. We are comparing exposed children who developed autism to exposed children who did not, and comparing both to typically-developing children.

28 AUTISM: WHAT DOES MERCURY HAVE TO DO WITH IT?

E. Silbergeld. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Research on complex neurological disorders has utilized animal models exposed to agents that do not contribute to the burden of human disease, such as the use of 6-hydroxydopamine to emulate pathophysiological mechanisms in Parkinsonism or specific gene knockouts in mice to study dementias. In this sense, research on mechanisms of mercury-induced developmental neurotoxicity may be valuable in understanding pathophysiological mechanisms involved in some aspects of autism spectrum disorders. Exposures to inorganic and organic mercury (Hg) compounds induces developmental neurotoxicity, involving glial activation and altered neuronal migration. The neuroimmunological effects of Hg are highly dependent upon genotype in rodent models. In addition to developmental neurotoxicity, early exposure to Hg also affects the development of the immune system, and increases the likelihood and severity of autoimmunity consequent to infection. Because these events are also reported in many cases of ASD, these similarities suggest that further mechanistic research on Hg, the role of genotype, and interactions with infection may be valuable in increasing understanding of early and potentially reversible or compensable events in ASD. Research supported by Cure Autism Now Foundation.

29 THE FUTURE OF RISK ASSESSMENT IN ENVIRONMENTAL HEALTH – CAN CURRENT APPROACHES FULFIL PUBLIC HEALTH NEEDS? INTRODUCTORY THOUGHTS.

A. Tritscher¹ and C. Portier². ¹World Health Organization, Geneva, Switzerland and ²National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Risk assessment needs to use all available information to address the relevance of environmental exposures to human health. In practice, current risk assessment approaches tend to consider single hazards, most sensitive toxic endpoints, and often simple exposure scenarios. Most available data are from basic toxicological tests, which have been standardized and accepted for regulatory purposes. Also, most risk assessments are based on deterministic approaches and variability in the population and during life-stages may not be taken sufficiently into account. Real life situations are much more complex and human exposures occur to mixtures of agents and also never in isolation from other factors such as life-style and environmental issues. New scientific developments may provide tools to address more complex questions in the evaluation of environmental hazards, quantification of exposure, calculation of risks and quantification of associated uncertainties. However, they are often not sufficiently integrated into the regulatory process. Application of new scientific knowledge and tools to medicine and public health could change the nature of risk assessments in the future. Questions to be addressed are e.g.: can new 'omics' technologies be used to quantify interindividual variation in susceptibility? Can these tools be used to identify and quantify consequences of exposures to multiple environmental agents? Can dose-response assessment methods address exposures to mixtures of compounds? How can new scientific developments and new mechanistic knowledge be integrated in the regulatory risk assessment process? This session tries to address if currently applied risk assessment procedures, following the defined steps of hazard identification, hazard characterization with dose-response assessment, exposure assessment and ultimately risk characterization, are appropriate to address complex real life situations, and how new scientific knowledge and tools can be integrated to improve risk assessment.

30 THE FUTURE OF HAZARD IDENTIFICATION.

S. M. Roberts. *Center for Environmental & Human Toxicology, University of Florida, Gainesville, FL.*

Currently, hazard identification is based primarily on the results of toxicity studies conducted in laboratory animals. Hazard identification that is well conducted using the current approach is both costly and time consuming. New tools made available by advances in biotechnology, such as the "omics" and high-throughput screening, have the potential to provide a more comprehensive assessment of hazard, more rapidly, and perhaps at reduced cost. "Omics" tests can provide a much more complete picture of the biological responses to an agent than traditional studies, offering alerts for possible adverse effects as well as aiding in the identification of modes of action. With high throughput screening, information on specific effects at the cellular and sub-cellular level can be obtained for tens of thousands of chemicals in a short period of time. There is general agreement regarding the value of new technologies such as these as aids in hazard identification and as screening tools to help prioritize chemicals for conventional toxicity studies. What it would take for these technologies to supplant conventional in vivo studies in hazard identification is more controversial, especially for use in risk assessments to support regulatory action. If hazard identification is to move from a foundation in observational studies to one in predictive studies (i.e., from in vivo to in vitro and in silico), several obstacles must be overcome. Perhaps one of the more difficult challenges will be to resist the temptation to oversimplify toxic responses, trying to reduce them to one or a few key biological events. Lessons learned from decades of trying to predict carcinogenesis, for example, indicate that the complexity of pathophysiology needs to be acknowledged and embraced. Nevertheless, a future can be imagined in which hazard identification is shaped primarily by predictive modelling of biological responses, with in vivo studies reserved for validation and confirmation.

31 EXPOSURE ASSESSMENT.

L. W. Reiter and C. Trent. *National Exposure Research Laboratory, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Environmental exposures are a known etiology of preventable disease. The quantitative assessment of these exposures is a critical component of the risk assessment paradigm. Yet, despite its obvious importance in the risk assessment continuum, exposure assessment often is the weak link, resulting in large uncertainties that can perpetuate throughout the risk assessment process. Major sources of these uncertainties arise from either a lack of adequate data to characterize exposure or a poor understanding of the relationships between environmental concentrations, exposure and health outcomes. This presentation will discuss how recent scientific/technical advances will likely improve our ability to collect data needed to reduce these uncertainties. Advances in sensor technology for example, will provide more sensitive, real time and affordable methods to measure both ambient concentrations and human exposures. The availability of biosensors when applied in tandem will allow us to better define and understand the relationships between external exposure and internal dose. Novel applications of emerging electronics and information technologies (e.g. GIS) provide new possibilities to accurately record human activities and describe their relationship to exposure. Improvements in computational methods are providing new opportunities to link exposure models with pharmacokinetic and dose-response models and hence our ability to conduct more integrated quantitative risk assessments. In the specific case of air pollution, data fusion techniques are also being developed to add air quality models to these linkages. Finally, the rapid advances in genomics are providing new and better biomarkers of exposure which are mechanistically linked to health outcomes. Consequently, they serve to closely link exposure assessments to health outcome including how gene environment interactions affect sensitivity/susceptibility. Potential applications as well as challenges for using these biomarkers as part of the exposure assessment process will be discussed.

32 DOSE-RESPONSE ANALYSIS – THE QUANTITATIVE CHALLENGE.

C. J. Portier. *Office of Risk Assessment Research, NIEHS, Research Triangle Park, NC.*

Dose-response analysis is that part of risk assessment tasked with developing a quantitative description of the relationship between a given level of exposure and the risk of disease morbidity or mortality in human populations. The major challenges in quantifying these risks are presenting an accurate picture of the variability of the estimated risks for known components that contribute to variation in response and providing a clear discussion of the uncertainty in the risk estimates due to untestable assumptions that were needed for the analysis. This talk will focus on the future of dose-response analysis in its broadest context (modelling at all levels, sensitivity to assumptions, statistical objectivity, uncertainty analysis, etc.) in light

of our emerging understanding of interactions between organisms/organs/tissues/cells/biomolecules with exposures that alter these systems. The talk will be from the perspective of the analyst attempting to use the broadest array of current and emerging tools and approaches to evaluate dose-response relationships with a focus on the “the good, the bad and the ugly” regarding the strengths of new tools and approaches for risk assessments, their weaknesses and the really difficult aspects of using tools that are at the cutting edge of risk assessment research. Additionally, there will be discussion of the linkage between the usage of these data for risk assessment and feedback into the laboratory setting to develop appropriate designs to improve their utility. Finally, the discussion will switch to emerging data sources and some of the advantages and challenges seen for their use in the next 5 years. Examples of dose-response evaluations that have used emerging tools historically and currently will be included in the talk to illustrate the points being made.

33 RISK CHARACTERIZATION - THE BOTTOM LINE.

S. Olin. *Research Foundation, ILSI, Washington, DC.*

The true product of a risk assessment is not simply a number (e.g., a tolerable daily intake or a cancer slope factor). Rather, it is an integrative analysis and discussion of the risk assessment findings, including their scope and applicability, assumptions and uncertainties, and interpretation(s) for human health or the environment. This integrative analysis and discussion has been called the risk characterization. It is the foundation, the basis for communication between the risk assessor and those who need to understand and use the risk assessment findings. Because a risk characterization reflects the identified hazard(s), whatever is known about the relationship between dose and effect(s), the available information on exposure, and the approach(es) chosen to describe and sometimes quantify the risks, it must adapt to developments in all of these areas as they are incorporated into the risk assessment. Some specific examples include the focus on problem formulation as a first step in a risk assessment and its impact on the risk characterization; the availability of new tools and approaches for characterizing the human relevance of modes of action occurring in test species; the increasing use of Margin of Exposure in risk characterization; the incorporation of life-stage-related differences; and the call for improved characterization of uncertainties. The complex problem of characterizing combined risks from multiple stressors or at multiple endpoints has received some attention, and sophisticated models for estimating cumulative risks (from exposure to multiple chemicals operating by the same mode of action) have been developed and applied in a few cases; issues and prospects for further progress will be noted. Overlaying all of these is the challenge of finding better ways to reach consensus on the adoption of this new science in risk assessments at national and international levels. Strengths and weaknesses of current approaches will be discussed, and opportunities to improve “the bottom line” will be considered.

34 RISK ASSESSMENT AND REGULATION.

L. L. Smith. *CTL, Syngenta, Cheshire, United Kingdom.*

Risk assessment should be a scientific process with the outcome based on a holistic evaluation of good quality data on hazard characterisation and exposure. Regulation of risk requires an appreciation of the process of risk assessment and the incorporation of precautionary safety factors. Also, regulation must necessarily take account of societal mores, often resulting from non-scientific drivers particular to individual countries. However, it is vital for the good governance of regulation that the process is transparent, and the rationale for the decision clearly stated. This is important so that the scientific community, NGO's and other regulatory authorities can critique the outcome.

Originally hazard characterisation was essentially an observational science that relied on an understanding of the physiology and biochemical function of individual organs and of various cell types. Progressively, hazard characterisation has improved with the advent of mechanistic toxicology which increases the reliability of the extrapolation of animal data to humans. However, this extrapolation requires expert interpretation and greater openness on the limitations of the utility of animal data. The availability of new technology platforms provides insights into the individual genes and biochemical pathways that are altered as a consequence of exposure to particular chemicals. While our ability to improve hazard characterisation continues, the competence and speed of some regulatory authorities to incorporate these new concepts is mixed. However, perhaps the real challenge to better risk assessment, and hence regulation, is our ability to determine realistic exposure measurements.

Hence, scientifically robust models of exposure need to be developed.

The future of risk assessment should be driven by a more mechanistic approach to hazard characterisation combined with improved measures of exposure. Only by the thoughtful application of these capabilities will the predictability of human

health hazards improve now. This approach, together with the exquisite balance of judgement, by regulators should lead to a more certain protection of humans without the damaging consequences of exaggerated concerns.

35 HEALTH RISKS OF OF CARBON NANOTUBES: WHAT CAN WE LEARN FROM MINERAL FIBERS OR ULTRAFINE PARTICULATES?

J. S. Tsuji¹ and F. S. Mowat². ¹*Exponent, Bellevue, WA* and ²*Exponent, Menlo Park, CA.*

As major building blocks in nanotechnology, carbon nanotubes (CNTs) are among the most studied nanomaterials, although understanding of their health risk is far from complete. Factors affecting toxicity include chemistry, shape and structure, persistence, and surface characteristics. Exposure characterization is also critical given the complexity of particle size and shape distributions. Similar issues have been extensively investigated for mineral fibers and ultrafine particulates (UFPs). For example, increasing toxicity with aspect ratio has been established for asbestos fibers, and biopersistence of synthetic vitreous fibers (SVFs) influences disease potential. Although CNTs may have similar properties, they differ in their chemistry and in some other aspects (e.g., electrical conductivity, photochemistry, tensile strength). In addition, differences among types of CNTs are apparent. Single-walled CNTs (SWCNTs) agglomerate and have different morphology from SVFs, as they are typically very flexible. By contrast, multi-walled CNTs (MWCNTs) do not agglomerate, are more rigid, and will therefore react differently than SWCNTs. Besides producing lung lesions, CNTs may potentially cause cardiovascular toxicity by either translocation of CNTs from the lung or by cytokine release (as seen with UFPs). Recent identification of MWCNTs in fine particulate matter ($\leq \text{PM}_{2.5}$) from natural gas combustion indicates that environmental exposures to MWCNTs may be common and could play a role in air pollutant-induced diseases, although a direct link has yet to be established. Information from other well-studied aerosols may help guide research and assessments of the health effects of CNTs, although the complexity of these structures may also inform understanding of exposure and health effects of different types of aerosols in general.

36 CHALLENGES OF MONITORING EXPOSURE TO AIRBORNE CARBON NANOTUBES.

A. Maynard. *Project on Emerging Nanotechnologies, Woodrow Wilson International Center for Scholars, Washington, DC.* Sponsor: J. Tsuji.

Single and multi-walled carbon nanotubes form complex aerosol particles that are not easily characterized using conventional exposure monitoring methods. For instance, recent research on single walled carbon nanotubes has demonstrated that the chemistry and morphology of aggregates released from as-produced material may differ over different size ranges. At the same time, research is indicating that physical and chemical structure is critical to determining the behavior of these particles in the lungs.

The characteristics of carbon nanotube aerosols will depend on the source material—whether it is as-produced or processed in some manner—and the mechanisms of aerosolization. Likewise, the characteristics of carbon nanotube aggregates used in toxicity studies will depend on how they are prepared and introduced to the test system. Sophisticated methods are needed to characterize and monitor the material appropriately if potential impact is to be evaluated. Advanced aerosol analysis techniques such as differential mobility analysis, aerosol particle mass analysis, and high resolution electron microscopy can be used to provide insight into the nature of airborne carbon nanotube aggregates.

Simpler approaches are needed for routine exposure monitoring. However, representing such a complex material with a single index of exposure presents many challenges. The diverse morphologies of carbon nanotube aggregates makes analogy with other airborne materials difficult. Nevertheless, there may be sufficient similarities to inform future approaches. For instance, some aggregates of carbon nanotubes will be typified by high surface-to-area ratios, as are many aerosols of aggregated nanometer-diameter particles. Others may share similar morphologies to mineral fibers—both natural and synthetic—that would suggest microscopy-based monitoring would be applicable. But while we will be able to learn from previous experience when monitoring exposure to carbon nanotubes, future methods must be responsive to biologically relevant characteristics and unique carbon nanotube attributes.

37 BIO-PERSISTENCE OF SYNTHETIC VITREOUS FIBERS AND TUMORIGENIC POTENTIAL.

T. W. Hesterberg. *International Truck and Engine Corp., Warrenville, IL.*

Because inhalation of asbestos, a naturally occurring, inorganic fibrous material, is associated with lung fibrosis and thoracic cancers, concerns have been raised about the possible health effects of synthetic vitreous fibers (SVFs). SVFs include a very

broad variety of inorganic fibrous materials: fiber glass, mineral wool, and refractory ceramic fiber. Ongoing epidemiology studies of SVF manufacturing workers have provided very little evidence of harmful effects in humans. Research using rodents exposed by inhalation have confirmed that SVF pulmonary effects are determined by fiber dose (to the lung), dimension, and durability. Fiber dose over time is determined by fiber deposition and biopersistence in the lung. Deposition is inversely related to fiber diameter. Biopersistence is directly related to fiber length and inversely related to fiber dissolution and fragmentation rates. Inhaled short fibers ($< 5 \mu\text{m}$) are cleared from the lung relatively quickly by mobile phagocytic cells, but long fibers ($> 20 \mu\text{m}$) persist until they dissolve or fragment. In contrast to asbestos, most of the SVFs tested in rodent inhalation studies are cleared rapidly from the lung and were innocuous. However, several biopersistent SVFs induced chronic inflammation, lung scarring (fibrosis), and thoracic neoplasms. Thus, biopersistence of fibers is now generally recognized as a key determinant of the toxicologic potential of SVFs. In vitro dissolution of fibers in simulated extracellular fluid correlates fairly well with fiber biopersistence in the lung and pulmonary toxicity, but several exceptions suggest that biopersistence involves more than dissolution rate. In vitro cell culture studies indicate that the biological effects of fibers are coordinated by a complex system of inter-cellular messengers and cytotoxic cell products; phagocytic lung cells appear to be central players. Research demonstrating the relationship between biopersistence and SVF toxicity has provided a scientific basis for hazard classification and regulation of SVFs. It is unclear whether the mechanisms of SVF lung clearance and toxicity apply to carbon nanotubes.

38 HOW THE PROGRESSION OF PULMONARY TOXICITY RESEARCH IS INFORMING COMPARISONS OF CNT WITH MINERAL FIBERS.

D. B. Warheit, DuPont Haskell Laboratory, Newark, DE.

Previously we reported that intratracheal instillation exposures to laser ablation-type single wall carbon nanotubes (SWCNT) in rats produced a non-dose-dependent series of multifocal granulomas; evidence of a foreign tissue body reaction. In addition, instillation of high-dose SWCNT produced some mortality, resulting from mechanical blockage of the upper airways by the agglomerated instillate. Other investigators have demonstrated similar granulomatous lesions in mice exposed to a variety of SWCNT-types. In our study in rats, we have noted that the development of these granulomatous lesions is not consistent with a normal dust-related paradigm, including adverse pulmonary reactions caused by cytotoxic dusts such as quartz particles or asbestos fibers. These lesions generally develop following lung inflammatory responses at the anatomical sites of bronchoalveolar junctions. In contrast, we observed the presence of SWCNT-nanorope-induced multifocal granulomas located primarily in the distal airways. As a consequence, we have questioned the physiological relevance of our findings following instillation exposures. Moreover, it is conceivable that due to the electrostatic nature and tendency of SWCNT to agglomerate into nanorope structures, instillation of SWCNT may produce very different pathological results when compared to exposures via the inhalation route. In contrast to SWCNT, chrysotile asbestos fibers are highly respirable, tend to fibrillate, and produce similar lung pathological responses following either inhalation or instillation exposures. The main criteria for the pathogenicity of chrysotile asbestos fibers is biopersistence concomitant with the length dimension, with chrysotile fibrils greater than 10 microns producing lung inflammation, fibrosis and tumors in rats. Indeed, the pathological sequelae of these pulmonary lesions are very different from those reported thusfar with exposures to SWCNT. This issue of similarities or differences in responses to SWCNT vs. asbestos can be reconciled following the implementation of inhalation toxicity studies in rats with aerosolized SWCNT samples.

39 COMPARISON OF PULMONARY RESPONSES TO SINGLE-WALLED VS. MULTI-WALLED CARBON NANOTUBES.

V. Castranova, PPRB, NIOSH, Morgantown, WV.

Exposure of mice to purified single-walled carbon nanotubes ($< 0.25\%$ iron) by pharyngeal aspiration resulted in a rapid but transient inflammatory response as well as an early onset and progressive fibrotic reaction. Labeling of single-walled carbon nanotubes with gold nanoparticles indicated that granulomas occurred at deposition sites of large agglomerates, while interstitial fibrosis was associated with deposition of more dispersed nanotube structures. Techniques were developed to improve the dispersion of single-walled nanotubes. Aspiration of this dispersed single-walled carbon nanotube sample resulted in greater interstitial fibrosis in the absence of granulomas. Aspiration of a dispersed preparation of gold-labeled single-walled carbon nanotubes resulted in rapid movement of nanotube structures into the alveolar interstitium and measurable translocation to systemic organs. Mice are currently being exposed by pharyngeal aspiration to a dispersed preparation of pu-

rified multi-walled carbon nanotubes. Results of these studies will be compared to those of single-walled carbon nanotubes to evaluate the effect of nanotube dimension (diameter) on pulmonary response. Single-walled carbon nanotubes were also evaluated in vitro to determine their ability to generate reactive species and stimulate oxidant production from macrophages. In vitro assays were not very good predictors of the in vivo fibrogenic potential of single-walled carbon nanotubes. In conclusion, results indicate that it would be prudent to implement strategies to limit exposure to carbon nanotubes in the workplace.

40 TOXICITY OF CARBON NANOTUBES AND ITS IMPLICATIONS FOR OCCUPATIONAL AND ENVIRONMENTAL HEALTH.

C. Lam^{1,2} and J. James¹. ¹Johnson Space Center Toxicology Group, NASA Johnson Space Center, Houston, TX and ²Wyle Labs, Houston, TX.

Carbon nanotubes (CNTs), which possess desirable electrical and mechanical properties, potentially have wide industrial applications. CNTs exist in two forms, single-wall (SW) and multi-wall (MW). There has been great concern that if CNTs enter the work environment as suspended respirable particulate matter (PM), they could pose an inhalation hazard. The results of recent rodent studies have collectively shown that CNTs can produce inflammation, epithelioid granulomas, fibrosis, and biochemical changes in the lungs. Studies in mice given equal amounts of test dusts showed that CNTs were more toxic than quartz and produced lesions that became progressively more pronounced. These results have led us to recommend that respirable CNT dust be considered a serious occupational health hazard, and that exposure limits be established in the expectation of expanded industrial applications. CNTs, which are totally insoluble and fibrous, would be expected to be more biopersistent than mineral fibers. Biopersistence is the key factor determining the long-term toxicity of mineral fibers and certainly of CNTs too. We have postulated that the electrical and fibrous properties of CNTs also play important roles in the toxicity of CNTs in the lungs. Recently, MWCNTs have been found in ultra-fine PM aggregates in combustion streams of methane, propane, and natural-gas flames of typical stoves; indoor and outdoor fine (< 2.5 micron) PM samples were reported to contain significant fractions of MWCNTs. Environmental fine PM is mainly formed from combustion of fuels, and fine PM has been reported to be a major contributor to the induction of cardiopulmonary diseases by pollutants. Given that manufactured SWCNTs and/or MWCNTs have elicited pathological changes in the lungs and heart, we have postulated that exposure to combustion-generated MWCNTs in fine PM in the air may play a significant role in air pollution-related cardiopulmonary diseases. Therefore, CNTs from manufacturing and combustion sources in the environment could have adverse effects on human health.

41 HEALTH RISKS OF CARBON NANOTUBES (CNTS): WHERE DO WE GO FROM HERE?

F. S. Mowat¹ and J. S. Tsuiji². ¹Exponent, Menlo Park, CA and ²Exponent, Bellevue, WA.

Health concerns of CNTs are related to their 1) nano-size and hence high surface area and increased reactivity relative to mass, as has been shown for ultrafine particulates (UFPs); 2) fiber-like shape and potential for respiratory effects; 3) reported fibrosis, inflammation, granulomas, and other effects, 4) challenges for quantifying exposure; and 5) high biopersistence, like asbestos and synthetic vitreous fibers (SVFs). While research to date indicates similarities of CNTs with SVFs and UFPs, differences are also apparent and must be considered in drawing analogies between CNTs and more well-studied substances to assess health risks. Comparisons to UFPs, SVFs, and asbestos also raise interesting issues. For example, single-walled CNTs that agglomerate to larger bundles may have similar size and shape as SVFs that are retained in the lung. Mixtures of single and multi-walled CNTs may not agglomerate and could be cleared from the lung; however, although health risk is often discounted for SVFs that are not retained because of smaller size and aspect ratio, translocation to the heart (and other organs) or effects on cytokines affecting the heart is a concern for UFP with some similarities indicated for CNTs. Moving forward, testing and evaluation of CNT health effects should examine issues such as: particle size/number distribution; shape and surface area; type of administration/exposure; dose delivered to the target site; chemical composition, including metal content (intended and as impurities); structure, whether multi-walled or single-walled, and distribution of types; use of standard reference dusts (carbon black, quartz, and TiO₂) to benchmark CNT toxicity; CNT properties, including surface treatments/charges, agglomeration, and characteristics of larger structures; biopersistence; and translocation and fate within the body and in the environment. As has been shown for asbestos, SVFs, and UFPs, characterization of each type of CNT will be imperative, as not all nanotubes are similar, and differences in the above properties can greatly affect exposure, target organ effects, and resulting health risk.

**42 METHODS FOR INVESTIGATING SKIN IRRITATION.**

M. Sachdeva¹ and J. McDougal². ¹Pharmacy, Florida A&M, Tallahassee, FL and ²Pharmacology and Toxicology, Wright State University, Dayton, OH.

Occupational skin diseases are believed to be more prevalent than reported with annual costs (including lost workdays and loss of productivity) reaching over \$1 billion. Skin irritation can be defined as a non-specific inflammatory response of the skin to direct chemical damage which is characterized by erythema, mild edema and scaling (Irritant contact dermatitis). All the chemical agents (e.g. soaps, cleansers, solvents) damage the skin by causing structural change in lipids leading to a release of inflammatory mediators predominantly from cells in epidermis. Absorption of the chemical into skin reflects the potential for irritation. Differences in blood flow, vascular permeability, skin thickness and leukocyte infiltration may vary depending on the irritant. Understanding the signaling mechanisms involved in chemical induced irritation has been recognized to be a very important topic and this is being currently studied at several different levels. Most mechanistic studies have used cultured cells and also human stratified epidermis. Also, various publications do exist from whole animal studies but there are very few studies which have a) correlated in vitro and in vivo data and b) used a model capable of investigating the molecular effects of chemicals in the epidermis and dermis based on measured skin concentrations in an effort to demonstrate cause and effect. This workshop will discuss the basic issues with skin irritation (irritant and contact dermatitis), update the audience about the current status of in vivo methods to assess skin irritation, discuss some novel in vitro culture methods being employed in skin irritation (3-D cultures), enumerate the use of skin microdialysis in assessing skin irritation by monitoring various neuropeptides (Substance P, alpha-MSH etc.) and finally discuss the regulatory issues important in this process. This symposium is timely because of the international interest in protecting individuals from skin irritation from chemicals.

**43 OVERVIEW OF SKIN IRRITATION: INCIDENCE, MECHANISMS AND MANAGEMENT.**

E. Corsini. Department of Pharmacological Sciences, University of Milan, Milan, Italy.

A major task of the epidermis is to defend the organism against outside harm, which can be of biological, physical or chemical nature. Today's lifestyle involves frequent exposure to chemicals with irritating properties, making irritant contact dermatitis a common dermatologic problem, with a prevalence of up to 10% of the population. In addition, occupational contact dermatitis resulting from exposure to chemicals in the workplace, depending on the country, comprise from 20 to 70 per cent of all occupational diseases.

Skin irritation is a local inflammatory reaction induced by primary contact with chemicals, which is characterized by erythema, edema and scaling. Irritant contact dermatitis is a multifactorial disease, the onset of which depends on both intrinsic (i.e. age, genetic background, race, gender) and extrinsic factors (i.e. chemical properties of the molecule itself, concentration applied, duration of exposure, etc.). Substances that are keratin solvents, dehydrating agents, oxidizing or reducing agents, and others may be irritants.

Skin inflammatory reactions involve resident epidermal cells and fibroblasts of dermis, as well as invading leukocytes, each interacting under the control of a network of cytokines and lipid mediators. Generally, the inflammatory reaction is initiated by external damage to the stratum corneum, resulting in disruption of the epidermal barrier and release of inflammatory mediators by keratinocytes, which in turn rapidly puts the innate immune system on alert in order to prevent invasion of pathogens through the weakened barrier.

Considering the increasing number of occupational skin diseases, it is essential that the mechanism of protection and efficacy be assessed together with a proper therapeutic approach. The prevention of skin diseases is accepted as an important part of occupational dermatology. Correctly identifying the inciting irritants permits appropriate personal avoidance. Barrier creams, mild topical cortisones may represent valuable treatment options, while pramoxine, phenol, camphor, and menthol may be valuable in allaying symptoms of pruritus.

**44 UNDERSTANDING THE CASCADE OF EVENTS IN IRRITATION AT A MOLECULAR LEVEL - IN VIVO METHODS.**

J. N. McDougal. Pharmacology and Toxicology, Wright State University School of Medicine, Dayton, OH.

Tests for chemical-induced skin irritation have identified a variety of chemicals that have the potential to initiate inflammatory processes in the skin. The Draize rabbit skin test has been used for over 50 years to identify chemicals that may irritate the skin. Patch testing for chemical irritation in humans has been used as an alternative

and perhaps more reliable test. Once a chemical irritant is identified, rational therapeutic or prophylactic interventions require an understanding of the irritant cascade at the molecular level. The irritant response could be blocked or lessened with appropriate pharmacological intervention. *In vivo* experiments in laboratory animals have been used to aid in the understanding of the molecular events that occur during skin irritation. Many of the mediators of inflammation involved in the acute inflammatory response and vascular permeability have been identified, but the "triggers" or initiating events in chemical-induced irritation are not completely understood. These first responses in the skin would be expected to be the most likely points for intervention if they can be recognized. Several types of molecular studies have the potential to help in our understanding of the sequence of events in skin irritation. The sequence of changes in signaling protein levels, including cytokines and chemokines, can be used to understand the crosstalk between the epidermis and the dermis. Gene expression studies may be useful to identify activation of molecular pathways involved. Immunohistochemistry studies can be used to localize the molecular responses to specific skin layers or appendages. A systems biology approach may be useful to integrate a variety of responses and provide a coherent framework for the inflammatory response. The potential for understanding chemical-induced skin irritation is tremendously improving as molecular methods rapidly advance.

**45 IN VITRO MODELS FOR ASSESSING SKIN IRRITATION POTENTIAL.**

P. J. Hayden, J. Kubilus, S. Ayehunie, Y. Kaluzhny and M. Klausner. MatTek Corp., Ashland, MA.

In vitro models for assessing skin irritation include submerged monolayer cell cultures (e.g. mouse 3T3 cells or human keratinocytes), as well as differentiated 3-D human epidermal (partial-thickness) or epidermal/dermal (full-thickness) skin equivalents cultured at the air-liquid interface. Submerged monolayer cultures may be useful for irritation screening in some instances, and have been validated for applications such as phototoxicity. However, submerged cultures do not adequately model the physiologic and biochemical properties of differentiated epithelial tissues, and do not allow for topical application of water insoluble materials. Endpoints for submerged monolayer culture assays include cell viability (e.g. neutral red assay) or cytokine release (e.g. IL-1 α , IL-8, TNF α). 3-D human skin equivalents cultured at the air-liquid interface offer differentiated properties including barrier function (i.e. stratum corneum) and Phase I/II drug metabolizing enzyme activity, and allow for more realistic in vivo-like treatment options, including topical application of creams, lotions and other water insoluble treatments. Endpoints may be culture viability, cytokine release or histological evaluation as well as more recent genomic and proteomic technologies. Ongoing validation programs for skin irritation with 3-D skin equivalents have shown promising correlation with in vivo results.

**46 IN SITU METHODS FOR IRRITATION- SKIN MICRODIALYSIS.**

M. Sachdeva and S. Fulzele. Pharmacy, Florida A&M University, Tallahassee, FL.

Microdialysis is an in vivo sampling technique for measuring endogenous and exogenous solutes in the extracellular space of tissues. It is of great value in pharmacokinetic & pharmacodynamic investigations and in monitoring disease status and progression. Applications of Dermal microdialysis can be classified as (a) measurement of inflammatory mediators in the dermis (b) studies of skin metabolism (c) determination of the absorption of drugs or other agents in the skin and (d) utilization as an alternate route of drug administration. Skin irritation is an observable physiological reaction to a stimulus and is visualized as erythema and edema as a result of local inflammatory processes. Neurogenic inflammation refers to the ability of the neurological system to evoke local inflammatory responses through the release of neuropeptides such as Substance P (SP), calcitonin gene-related peptide (CGRP) and alpha-melanocyte stimulating hormone (alpha-MSH). There is accumulating evidence to suggest that these mediators contribute to inflammation and skin irritation. Conventional methods to assess irritation include measurements of skin condition [transepidermal water loss (TEWL), skin capacitance & erythema], release of inflammatory cytokines (IL-1 α & TNF α) and chemokines. We hypothesize that the relationship between skin irritation and exposure period can be quantified well enough by measurement of neuropeptides in the skin by dermal microdialysis in response to topical exposures with irritant chemicals. Jet fuel (JP-8) and its component chemicals were used as model skin irritants. In order to validate dermal microdialysis, release of neurochemicals after topical exposure with irritant chemicals was correlated with TEWL and cytokine (IL-1 α & TNF α) expression in skin & blood from experimental animals exposed under similar conditions. The results from these studies will be discussed.

47 REGULATORY ISSUES WITH SKIN IRRITATION: AN FDA PERSPECTIVE.

A. Jacobs. CDER, U.S. FDA, Silver Spring, MD.

Guidelines for evaluation of pharmaceuticals have been developed by the International Conference on Harmonization (ICH). However, these guidelines do not address skin irritation, other than under the umbrella of local effects. The Organization for Economic Cooperation and Development (OECD), which the United States is a party to, develops guidelines that describe protocols, including those for skin irritation and skin corrosion. Recently, laws in the EU have been enacted that either ban the use of animals in testing for certain products or mandate the development and validation of alternative methods to animal testing. Research has resulted in much activity in the development of in vitro methods intended for use as screens, adjuncts, and replacements for current in vivo standards. In the United States, the Interagency Committee for the Validation of Alternatives Methods coordinates validation of alternative methods and the FDA is a very active participant. Because it is desirable to use fewer animals for evaluation of toxicity and to cause less pain and suffering and because of the impetus of legislation in the EU regarding cosmetics evaluation, several in vitro skin corrosion assays have been developed and validated and several in vitro skin irritation methods are being worked on. Although knowledge of dermal irritation of clinical formulations rather than of neat materials is desirable and despite limitations of the various in vitro assays, such assays may be useful in evaluation of a number of pharmaceutical products in a number of contexts.

48 ROLE OF RELB IN AH-RECEPTOR (AHR) SIGNALING.

C. F. Vogel¹, E. M. Sciuillo¹, W. Li¹, P. Wong¹, G. Lazennec² and E. Matsumura¹. ¹ETOX, UC Davis, Davis, CA and ²Molecular and Cellular Endocrinology of Cancers, INSERM, Montpellier, France.

The AhR is a member of basic helix-loop-helix (bHLH-PAS) transcription factors including Period (Per), ARNT, and single minded (SIM) regulating hypoxia, circadian rhythm, and cellular processes like differentiation and apoptosis. We show that the NF- κ B subunit RelB is functionally associated with the AhR and mediates the transcriptional regulation of e.g. IL-8 via AhR and protein kinase A (PKA) activation. Thus, RelB/AhR complexes bind to an unrecognized response element (RelBAhRE) linking two signaling pathways to activate IL-8. Furthermore, RelB/AhR complexes are found to bind on NF- κ B consensus elements and xenobiotic regulatory elements (XRE) without addition of any stimuli implicating the true endogenous function of the AhR. The interaction of RelB with AhR-regulated genes and AhR with NF- κ B signaling represents a new mechanism of cross talk between the two receptor paradigms.

49 LACK OF A ROLE OF CALPAIN PROTEASES IN THE LIGAND-INDUCED DEGRADATION OF THE AHR RECEPTOR.

R. S. Pollenz. Cell Biology, Microbiology and Molecular Biology, University of South Florida, Tampa, FL.

The Ah receptor (AHR) is rapidly degraded both in vivo and in vitro following binding to ligands. The exact enzymes involved in the ligand-induced degradation have not been identified, but there is compelling evidence that the degradation is mediated via the ubiquitin proteasome pathway (UPP). To firmly establish the role of the UPP in AHR degradation, mouse Hepa-1, rat retinal epithelial and human retinal epithelial cell lines were exposed to several novel inhibitors specific to the UPP, calpain proteases or both pathways and then exposed to TCDD. The level of AHR as well as CYP1A1 protein was then measured by quantitative Western blotting. Exposure of cells to MG-132 (an inhibitor of both UPP and calpains) blocked TCDD-induced degradation in all lines at 5-10 μ M and did not impact the induction of CYP1A1. In contrast, treatment of cells with the calpain inhibitors: calpeptin, calpain inhibitor III, or PD150606 either individually or in combinations up to 75 μ M did not affect TCDD-induced degradation of the AHR or the induction of endogenous CYP1A1. Since the results with the calpain inhibitors were negative, a reduction in calpain activity was verified in Hepa-1 and RPE cells using an in vivo calpain assay. Importantly, exposure of cells to the specific proteasome inhibitors: epoxomicin (5 μ M), proteasome inhibitor I (10 μ M) or lacitactine (15 μ M) completely blocked the TCDD-induced degradation of the AHR. Inhibition of AHR degradation with these compounds did not reduce the induction of endogenous CYP1A1, and in some treatments actually enhanced the level of CYP1A1 protein or mRNA that was detected. Finally, Western blot analysis of the DNA bound AHR showed that the molecular mass was unchanged in comparison to unliganded AHR. Thus, these studies conclusively implicate the UPP and not calpain proteases in the ligand-induced degradation of the mouse, rat and human AHR and suggest that the pharmacological use of UPP inhibitors may impact the time course and magnitude of gene regulatory events mediated through the AHR. Supported by ES10991.

ROLE OF CYCLIN-DEPENDENT KINASE INHIBITORS P21CIP1 AND P27KIP1 IN AH RECEPTOR-MEDIATED SUPPRESSION OF LIVER REGENERATION.

K. A. Mitchell and C. J. Elferink. Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX.

Numerous studies indicate that aryl hydrocarbon receptor (AhR) activity regulates cell cycle progression. Exposure to the persistent agonist 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) elicits a G1 arrest in hepatocyte-derived cell lines as well as the regenerating liver following 70% partial hepatectomy (PH). Several cell culture studies link this G1 arrest with the AhR-mediated upregulation of p27Kip1 or p21Cip1, which are G1 phase cyclin-dependent kinase inhibitors that negatively regulate cell cycle progression. However, little is known regarding the role of these regulatory proteins in the AhR-mediated suppression of in vivo cell cycle progression. In the present study, p21Cip1^{-/-} mice were used to evaluate how the Cip/Kip inhibitors regulate the AhR-mediated G1 arrest observed during liver regeneration. Mice were gavaged with TCDD (20 μ g/kg) or peanut oil, immediately subjected to 70% PH, and sacrificed 12-96 hours later. Liver tissue was fixed for histological analysis, homogenized for western blotting, or used to prepare RNA for quantitative real-time PCR. In contrast to results obtained in wild-type mice, treatment of p21Cip1^{-/-} mice with TCDD failed to suppress liver regeneration as measured by BrdU incorporation. Accordingly, cyclin-dependent kinase-2 (CDK2) activity was largely unaffected by TCDD treatment. Lack of TCDD-induced G1 arrest in these mice was not due to impaired AhR function, based on increased transcript levels of several AhR-regulated target genes including CYP1A1, PAI-1, and p27Kip1. However, despite increased levels of p27Kip1 transcript, there was no evidence of a compensatory role of p27Kip1 in the absence of p21Cip1. These findings suggest that p21Cip1 protein expression is critical for the AhR-mediated G1 arrest observed in cycling hepatocytes during liver regeneration.

51

ANALYSIS OF ARNT2 FUNCTION IN AH RECEPTOR-MEDIATED SIGNAL TRANSDUCTION.

E. J. Dougherty and R. S. Pollenz. Cell Biology, Microbiology and Molecular Biology, University of South Florida, Tampa, FL.

The aryl hydrocarbon nuclear translocator (ARNT) is a member of the basic-helix-loop-helix PER/ARNT/SIM (bHLH-PAS) family of proteins and functions as a dimerization partner for a variety of bHLH-PAS proteins such as the aryl hydrocarbon nuclear receptor (AHR), hypoxia-inducible factor 1 and the SIM protein. Importantly, there are several ARNT isoforms and ARNT and ARNT2 exhibit high levels of amino acid identity and appear to dimerize with the same partners. Although knock-out of ARNT or ARNT2 is lethal, the mice show different phenotypes. This could be due to differential tissue expression or the specificity of each ARNT to a given pathway. Analysis of ARNT and ARNT2 protein levels in total tissue lysates shows that both ARNT and ARNT2 are detected in the brain, eye, and kidney and to a lesser extent in the heart, spleen, and thymus. Thus, it was of interest to determine how ARNT and ARNT2 functioned in various signaling pathways when the proteins were expressed individually or in combination. Studies show that stable or transient expression of ARNT in the ARNT defective LA-I cell line can restore TCDD-mediated induction of CYP1A1. In contrast, LA-I cell lines stably expressing ARNT2 by means of retroviral transfection exhibit some complementation of TCDD-mediated induction of CYP1A1 but to a much lower magnitude than cells expressing ARNT. To validate these findings under endogenous conditions, the human retinal pigmented epithelial cell line (hRPE) was evaluated. hRPE cells co-express both ARNT and ARNT2 protein. siRNA reduction of ARNT results in complete ablation of TCDD-mediated induction of CYP1A1 even though ARNT2 levels are unaffected. However, while siRNA reduction of ARNT2 does not ablate TCDD-mediated induction of CYP1A1, reduction of ARNT2 does result in a decrease in the time course and magnitude of TCDD-mediated induction of CYP1A1. Thus, under endogenous stoichiometry, both ARNT and ARNT2 may participate in the AHR-mediated induction CYP1A1 to produce a maximal response. Supported by ES10991 (RSP).

52

CHARACTERIZATION OF LIGAND-INDUCED CONFORMATIONAL CHANGES IN THE ARYL HYDROCARBON RECEPTOR BY PROTEOLYSIS.

A. Soshilov, D. DeGroot and M. S. Denison. Environmental Toxicology, University of California, Davis, CA.

The Ah receptor (AhR) is a ligand-dependent transcription factor, which regulates the biochemical and toxic effects of structurally diverse chemicals. Ligand binding to the AhR is thought to result in a conformational change leading to its activation. The activated AhR dimerizes with a homologous protein Arnt to form a transcriptional factor capable of stimulating transcription from promoters with adjacent dioxin responsive elements (DRE). Utilizing limited proteolysis to detect AhR con-

formational changes, we detected formation of the AhR/Arnt dimer, and the results were equivalent to those obtained with the DRE-based gel-retardation assay. The ability of a representative group of structurally diverse AhR ligands was subsequently analyzed by gel retardation analysis and limited proteolysis. Strong agonists of the Ah receptor such as beta-naphthoflavone were found to proportionally induce AhR:Arnt dimerization and DRE-binding, and to stimulate the formation of an approximately 40 kDa protected fragment by limited proteolysis. Common antagonists of AhR function neither stimulated AhR transformation or DNA binding, nor induced the proteolysis resistant pattern. Modifications of the limited proteolysis assay are necessary to allow detection of ligand-specific differences in AhR protein conformation. (NIH ES07685, ES012498)

53 ARYL HYDROCARBON RECEPTOR GENOTYPE IN BIRDS: A POTENTIAL BIOMARKER FOR SPECIES SENSITIVITY TO DIOXIN-LIKE COMPOUNDS.

J. A. Head¹, A. S. Kehoe¹, S. I. Karchner², M. E. Hahn² and S. W. Kennedy¹.
¹National Wildlife Research Centre, Environment Canada, Ottawa, ON, Canada and ²Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.

Risk assessment for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and dioxin-like compounds in avian wildlife is challenged by a scarcity of species sensitivity data and dramatic differences in sensitivity among species. Because standard toxicity tests are difficult to carry out in wildlife, we are interested in determining if the aryl hydrocarbon receptor (AHR) might be useful for predicting sensitivity. Using chimeric AHR proteins and site-directed mutagenesis we discovered that amino acid substitutions in the ligand binding domain (LBD) of chicken and common tern AHR (Ile324 and Ser380 in chicken) contribute to important differences in TCDD binding affinity and TCDD-dependent transactivation in these species. We then determined the sequences of the AHR LBD in over twenty species from diverse avian orders and compared previously published LD50 data to AHR LBD genotypes. Chickens, the only species classified as very sensitive to dioxins (LD50: < 1 ppb TCDD equivalents (TEQ)), were unique in having a Ser residue at position 380. Two species of galliforms classified as moderately sensitive (LD50: 1 – 10 ppb TEQ) had a chicken-like Ile-324, and a tern-like Ala-380. Common terns, as well as other fish-eating birds from several different orders were classified as insensitive to dioxin-like compounds (LD50: > 10 ppb TEQ) and all had Val-324 and Ala-380 substitutions. Interestingly, Japanese quail, the only galliform with tern-like residues at both positions, was also classified as insensitive from LD50 data, suggesting that AHR LBD genotype is predictive of dioxin sensitivity both within and between avian orders. These findings further our understanding of species differences in sensitivity to dioxin-like compounds in avian wildlife and suggest the possibility of a simple assay that would use either RNA or DNA sequence of the AHR to classify avian species as sensitive, moderately sensitive or relatively insensitive to dioxin-like compounds.

54 EPIGALLOCATECHIN-3-GALLATE, A MAJOR COMPONENT IN GREEN TEA, ACTS AS AN ARYL HYDROCARBON RECEPTOR INHIBITOR BY INTERACTING WITH HSP90.

Z. Yin and T. A. Gasiewicz. *Env Med., University of Rochester, Rochester, NY.*

Numerous animal studies have shown that epigallocatechin-3-gallate (EGCG), a major component of green tea, protects against certain types of cancers, although the mechanism has not yet been determined. Our laboratory demonstrated that EGCG blocks the Aryl hydrocarbon Receptor (AhR) -mediated transcriptional ability induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Unlike other AhR antagonists that directly bind to the AhR, EGCG blocks AhR-mediated transcription by binding to hsp90. Since hsp90 inhibitors, such as 17-allylaminogel-danamycin (17-AAG), are being intensively studied for cancer therapy in clinical trials, it is attractive to hypothesize that EGCG exerts anti-AhR AND anti-cancer effects by acting as an hsp90 inhibitor. The use of a proteolytic footprint assay implicates that EGCG directly modulates the conformation of hsp90 and binds to the C-terminus of hsp90. Hsp90 dimerization, which occurs at the C-terminal end of hsp90, is also inhibited by EGCG treatment. These data suggest that EGCG acts as an hsp90 inhibitor. Coimmunoprecipitation studies show that EGCG decreases the association of aryl hydrocarbon nuclear translocator (Arnt) to ligand-activated AhR. This is consistent with electrophoretic mobility shift assays showing that EGCG inhibits TCDD-induced dioxin response elements (DRE) binding. Thus, EGCG through its ability to bind to AhR-associated hsp90, alters the AhR conformation, resulting in decreased association with Arnt and loss in DRE recognition. These studies indicate a novel mechanism whereby EGCG blocks ligand-induced DRE binding and inhibits the AhR-mediated transcription activity. Future studies will investigate how EGCG binds to hsp90 and affects its functions such as the ability to interact with other client proteins in addition to the AhR. These studies will provide directions for future research to investigate the possibility that the anti-cancer effects of green tea could be attributed to EGCG's interference with hsp90 functions. Supported by NIH grants ES014364 and ES01247.

55 ANTI-TUMOUR BENZOTHAZOLE DRUGS: POTENT ARYL HYDROCARBON RECEPTOR LIGANDS.

R. Bazzi¹, E. L. Stone², T. D. Bradshaw² and D. R. Bell¹. ¹School of Biology, University of Nottingham, Nottingham, United Kingdom and ²Pharmacy, University of Nottingham, Nottingham, United Kingdom.

The Aryl Hydrocarbon Receptor (AhR) is a ligand-dependent transcription factor that mediates the toxicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). It has been suggested that the AhR may mediate the action of anticancer test agents; the 2-(4-aminophenyl)benzothiazole analogues (series 1) (Trapani et al 2003) and the dimethoxyphenylbenzothiazoles derivatives (series 2). This study quantifies the interactions of these agents with the AhR and investigates the structure activity relationships for binding to the AhR and biological activities.

Interactions of chemicals with AhR were studied in rat hepatic cytosols, using a competitive binding assay. The apparent kd and Bmax for [3H]-TCDD were 0.37 nM and 40fmole/mg, respectively. Among the 24 agents tested, 18 competitively inhibited TCDD binding to the Ah receptor with subnanomolar IC50 values. These molecules are co-planar, and less hydrophobic than typical Ah receptor ligands. AhR binding was enhanced by hydrophobic substituents and weakened by polar groups. The 4-amino group in the phenyl moiety is required for binding in series 1 and the 3,4-dimethoxy group in series 2. The most potent inhibitors were the halogenated-derivatives 5F203 and GW610 with IC50 of 12nM and 25nM respectively. Fluorination at position 5 enhances potency in series 1 and is important for activity in series 2 (Hutchinson et al 2001) but not affinity in both series. A good correlation appears between AhR binding affinity and growth inhibitory potency in all the compounds in series 1 but this is not true in series 2. These data identify benzothiazoles as potent ligands for the AhR, and provide insight into the mechanism of action of these agents and the structure activity relationships for ligand-binding to the AhR.

56 ROLE OF PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR-ALPHA (PPAR α) IN MEDIATING THE DEVELOPMENTAL TOXICITY OF PERFLUOROOCTANOIC ACID (PFOA) IN THE MOUSE.

B. D. Abbott, C. J. Wolf, K. P. Das and C. S. Lau. *RTD (MD67), U.S. EPA, Research Triangle Park, NC.*

PFOA is a member of a family of fluorinated chemicals that have a variety of commercial/industrial applications. PFOA persists in the environment and is found in wildlife and humans. PFOA is developmentally toxic, reducing *in utero* and neonatal survival, development and growth. PFOA binds to PPAR α and activation of this receptor is considered causal for induction of hepatic tumors in rodents. This study used PPAR α knockout (KO) and 129S1 wild type (WT) mice (Jackson Laboratories, Bar Harbor, ME) to determine if the PPAR α pathway is required for induction of developmental toxicity by PFOA. After mating overnight, the next day was designated gestation day (GD) 0. Pregnant females were dosed orally from GD1-17 with water (vehicle), 0.1, 0.3, 0.6, 1, 3, 5, 10 or 20 mg PFOA/kg/day. PFOA did not affect the number of embryos implanted (not significant across all dams and groups) or the weight gain in pregnant females with surviving litters. However, PFOA significantly increased the rate of full litter resorption in both WT and KO mice at doses of 5 mg/kg or higher. These embryos died early in gestation (dams did not gain weight but had uterine embryonic implantation sites) and, of the 33 pregnant mice exposed to 5 mg PFOA/kg or higher, only 2 had litters that survived to term (1 KO litter each at 5 and 10 mg/kg). Neonatal survival of WT pups was significantly reduced by PFOA at 0.6 and 1 mg/kg, but was not adversely affected in KO litters at any dose. In WT pups, PFOA exposure at 1 mg/kg reduced weight gain compared to WT controls and eye opening was delayed as dose increased with significant delays in pups exposed to 1 mg vs 0.1 or 0.3 mg/kg. However, weight gain and eye opening in KO pups were not significantly affected at 1 or 3 mg/kg. It is concluded that PFOA-induced early gestational lethality is not mediated by PPAR α . However, neonatal lethality, developmental delay, and growth deficits are dependent on activation of PPAR α . This abstract does not necessarily reflect US EPA policy.

57 LONG TERM EFFECTS OF ADVERSE DEVELOPMENTAL ENVIRONMENTS: EFFECTS IN ADULT RATS EXPOSED TO TOXICANTS OR UNDERNUTRITION *IN UTERO*.

B. E. Grey, J. Norwood, K. Das, C. S. Lau and J. M. Rogers. *NHEERL, U.S. EPA, Research Triangle Park, NC.*

Studies have shown correlations between *in utero* and early life environments and adult diseases including hypertension, coronary heart disease, diabetes, obesity, schizophrenia, early onset chronic renal failure, cancer and compromised reproduction. Current study designs for developmental toxicity do not assess long-term

health in offspring. This study was undertaken to determine if toxicant exposure during pregnancy in rodents would have long-term health effects on offspring. Pregnant rats were exposed to perfluorooctane sulfonate, atrazine or dexamethasone in regimens designed to result in reduced birth weight. Another group was subjected to undernutrition (50% of control intake). At birth, offspring were cross-fostered to naive dams with each group subdivided into large (n = 12) or small (n = 6) litters. Body weight, blood pressure, fasting serum glucose, insulin response, and overall health of offspring were monitored through adulthood. At 18 months, these rats were killed for tissue analysis. Maternal exposure to toxicants or undernutrition resulted in lower birth weight. While body weight lagged in adulthood, initial recovery of body weight was observed, with those in small litters preceding the large. Male offspring in all groups had higher blood pressure than controls at seven weeks of age, while female offspring did not exhibit elevated blood pressure until 37 weeks. Rats reared in small litters had slightly higher blood pressure than those reared in large. Fasting serum glucose levels were not affected, but insulin response to glucose challenge was altered in experimental groups. These studies indicate that prenatal toxicant exposure may result in elevated blood pressure as well as other adverse adult health effects. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

58 LONG-TERM HEALTH EFFECTS OF PFOA AFTER PRENATAL AND LACTATIONAL EXPOSURE IN MICE.

S. E. Fenton¹, C. Lau¹, E. P. Hines¹, J. Thibodeaux² and S. S. White^{3,1}.

Perfluorooctanoic acid (PFOA), an environmentally persistent chemical detected in humans and wildlife, is a surfactant with wide consumer and industrial applications. It has been shown to induce tumors in lifetime fed adult rats and to delay mammary gland development in mouse pups exposed to the compound prenatally. To evaluate the long-term health effects of PFOA, pregnant CD-1 mice were given 1, 3, 5 or 10 mg/kg PFOA by oral gavage daily from gestation days (GD) 2-18 (n=15-20/dose group) and their female offspring were evaluated until 18 months of age. Exposure to PFOA at 10 mg/kg caused neonatal mortality shortly after birth. Postnatal survival of the offspring improved at lower doses and was not compromised at 1 or 3 mg/kg, but significant growth retardation was noted in the 3 mg/kg group. Body weights recovered to the control level by 6 weeks of age and, these mice continued to gain more weight compared to controls as they aged. This led to a dose-related increase in body weight by 16 months (p<0.05, 4-17%), at a time when little to no residual serum PFOA was detectable. At 18 months, gross evaluations revealed a significant dose-related increase in >1mm ovarian cysts visible in 25, 47, 60, and 80% of the animals in the 0, 1, 3, 5 mg/kg PFOA groups, respectively (p<0.05). In whole mount preparations of the mammary glands, macroscopic examination revealed abnormal nodules in the glands and the number of nodules per affected gland increased with dose. In addition, a marked reduction in spleen weight and an increase in brown adipose tissue were noted in the PFOA exposed mice. There was no significant change in liver:body weight ratio at 18 mo, but significant centrilobular hepatocellular hypertrophy was evident in all PFOA groups upon pathological examination. These results suggest that in utero and lactational exposure to PFOA may lead to obesity in adulthood as well as abnormalities in a number of tissues. (This abstract does not necessarily reflect EPA policy).

59 NADH BALANCE DURING ROTENONE TOXICITY: A NONGENOMIC, MITOCHONDRION-BASED EFFECT OF TUMOR SUPPRESSOR P53.

T. B. Knudsen, M. L. Green, A. V. Singh, J. Case, R. Singh and L. Ruest. *Mol Cell Cran Biol, University of Louisville, Louisville, KY.*

Tumor suppressor p53 is an environmental-responsive transcription factor that can influence NADH metabolism in mouse embryos. Rotenone, a general use pesticide, alters NADH metabolism by inhibiting respiratory complex I. To test for interaction between rotenone and p53 we exposed NIH 3T3 and p53-null mutant mouse embryonic fibroblast cell lines to rotenone (20 – 1000 nM) in DMSO for 3–48h. Mitochondria were labeled with mitotracker; p53 was visualized as recombinant protein fused to EGFP and transfected in forms competent for nuclear translocation (p53-EGFP) or sequestered in the mitochondrion (m53-EGFP); microtubules were visualized by anti-tubulin; and nuclear counterstain was visualized with Hoechst. Cell growth was monitored by MTT assay, flow cytometry, and anti-BrdU. Effects of exposure became evident at 500 nM rotenone with respect to cell rounding (3h), polyploidy (24h), and growth arrest (48h). These effects correlated with disruption of the microtubular network in 3T3 and p53-deficient cells and were insensitive to taxol. Recombinant p53-EGFP or m53-EGFP protein distribution was not altered by rotenone. On the other hand, HPLC revealed differential

effects on NADH content. Whereas NADH declined in 3T3 cells at 3h it markedly increased in p53-null cells. Transfection of p53-null cells with m53-EGFP (mitochondrial wild-type p53), m53DD (mitochondrial dominant negative mutant p53), or p53-EGFP (nucleo-cytosolic wild-type p53) suppressed rotenone-induced accumulation of NADH in the rank order m53 > m53DD > p53. We conclude that microtubule disruption and NADH imbalance are early effects in rotenone toxicity. Although rotenone toxicity does not appear to mobilize p53 the modulation of NADH metabolism may reflect a non-genomic effect of p53 on the inner mitochondrial membrane. (Supported by NIH grants RO1 ES09120 and T32 ES014559 and a pilot grant from the UoFL CGEMM).

60 THE EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ON MOLARS DIFFER AMONG NON-RESISTANT INBRED STRAINS OF MICE.

J. M. Keller, Y. M. Huet-Hudson and L. J. Leamy. *Biology, University of North Carolina at Charlotte, Charlotte, NC.* Sponsor: R. Di Giulio.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is an environmental toxicant and teratogen that causes tooth abnormalities and molar agenesis. Variations in susceptibility to TCDD's effects have been attributed primarily to differences at the Aryl hydrocarbon receptor (*Ahr*) locus. Differences in endpoint-specific sensitivity to TCDD, however, suggest that other genes influence TCDD's effects on a given character. We therefore hypothesized that the effect of TCDD on molar development would differ even among inbred mouse strains possessing similar *Ahr* alleles. To test this, we evaluated the effects of several different levels of TCDD (control, 0.01, 0.1, and 1.0 µg/kg) on molar development in mice of several different inbred strains bearing TCDD-sensitive *Ahr* alleles. We evaluated the amount of molar agenesis, the prevalence of an observed morphological variant, and differences in molar size, shape and asymmetry in the offspring of dosed females from five different inbred strains of mice possessing TCDD-sensitive *Ahr* alleles. We found that a maternal dose of 1 µg TCDD/kg body weight on gestation day 13 altered the shape (but not the size or asymmetry) of the first two molars and increased the amount of third molar agenesis in mice from the CBA/J and C3H/HeJ strains of mice. We concluded that the CBA/J and C3H/HeJ strains were most sensitive to disrupted molar development due to TCDD exposure and that the C57BL/6J strain was the least sensitive. Therefore, it would be appropriate to cross the C57BL/6J strain with either the CBA/J or the C3H/HeJ strain in order to conduct a QTL study designed to locate the genes responsible for this sensitivity. Support for this research was provided by grant # 1 R21 DE 015597-01A1 from the National Institute of Dental and Craniofacial Research to L.J. Leamy.

61 DEVELOPMENTAL METHYLMERCURY EXPOSURE IN ZEBRAFISH AND THE POTENTIAL INFLUENCES OF MATERNAL DIET ON EARLY LIFESTAGE TOXICITY.

M. J. Carvan¹, D. N. Weber¹, M. Dellinger¹, J. Dellinger¹ and M. L. Rise².
¹University of Wisconsin-Milwaukee, Milwaukee, WI and ²Memorial University, St. Johns, NF, Canada.

Methylmercury (MeHg) affects the developing nervous system, and the children of women that consume high quantities of wild-caught fish during pregnancy may be at risk for neurological impairment. Data suggest that diets containing significant amounts of selenium (Se) may reduce the toxic effects of MeHg. The goal of this project is to identify neural and molecular biomarkers as predictors of MeHg exposure and deficits in specific neurobehavioral endpoints, and to explore the effect of Se on toxicity. Specifically, we are investigating the effects of sublethal MeHg exposure on developing zebrafish by analyzing early life stage (ELS) toxicity and changes in global gene expression by microarray analysis. We exposed zebrafish embryos using direct water-borne exposure (as methylmercuric chloride) with or without the addition of selenium (as selenomethionine). Uptake of MeHg in direct exposures was nearly linear through all exposure concentrations (0.01-0.3 µM). Selenium uptake was non-linear but still concentration dependent in the range of 0.03-0.3 µM. Interestingly, selenium co-treatment reduced the uptake of methylmercury and ameliorated the resultant ELS toxicity. We also exposed zebrafish embryos to varying concentrations of MeHg via maternal diet using freeze-dried wild-caught wall-eye fillets grouped as low, medium and high Hg content representing 1.0, 2.0 and 3.5 ppm dry weight, respectively. Maternal walleye diet resulted in an increase in embryo Hg content and an increase in ELS toxicity. Gene expression analysis in exposed embryos was performed using an 8,000 element zebrafish cDNA microarray. Microarray analysis revealed changes in the expression of a number of genes primarily associated with neurological structure and function, mitochondrial function, and immune system function. This is consistent with our phenotypic analyses which revealed a number of learning and neurobehavioral deficits.

62 ETHANOL ATTENUATES ALDH mRNA EXPRESSION IN JAPANESE MEDAKA (ORYZIAS LATIPES) EMBRYOGENESIS.

A. K. Dasmahapatra^{1,2}, X. Wang², S. Zhu² and I. A. Khan¹. ¹National Center for Natural Product Research, University of Mississippi, University, MS and ²Department of Pharmacology, University of Mississippi, University, MS.

The mechanisms of teratogenic effects of ethanol in Japanese medaka embryogenesis were investigated by testing the hypothesis that ethanol or its metabolite ameliorates the expression of ethanol metabolizing enzymes. Like human, ethanol metabolism in medaka is catabolized by the enzyme alcohol dehydrogenase (ADH) and Aldehyde dehydrogenase (ALDH). We have previously demonstrated that medaka embryos express two subtypes of ADH mRNAs during development (Adh5 and Adh8), and ethanol is unable to alter the expression pattern of these two mRNAs. We, therefore, extend our investigations to ALDH system, the next enzyme of alcohol metabolic pathway. Initially, we have cloned two Aldh cDNAs from the liver tissue of adult Japanese medaka (*Oryzias latipes*). The coding region spanned 1557 and 1515 nucleotides, and the deduced amino acid sequence data and phylogenetic analysis identified them as an ortholog of human Aldh1A2 and Aldh9A genes, respectively. Reverse transcriptase polymerase chain reaction (RT-PCR) analysis further showed that both Aldh mRNAs are constitutively expressed in all organs tested (brain, eye, gill, GI, heart, liver, kidney, muscle, skin, testis and ovary). Using quantitative real time RT-PCR, we have measured Aldh1A2 and Aldh9A mRNA expression during development. We have observed that Aldh9A which encodes the enzyme betaine aldehyde dehydrogenase was expressed at all time points analyzed and was lowest between 1-8 h post fertilization (hpf), however, ALDH1A2, which encodes for retinaldehyde dehydrogenase 2, expressed low copies in early stages (1-48 hpf) and increased several folds at hatching. Treatment of the embryos with ethanol for 48 hpf attenuates the expression of both Aldh mRNAs. This modulation may cause abnormality in embryonic ethanol metabolism and induce teratogenesis in medaka embryo. [Support: National Center for Natural Product Research and the Department of Pharmacology, University of Mississippi].

63 URINE CORTICOSTERONE CORRELATES WITH IMMUNOLOGICAL CHANGES CAUSED BY EXOGENOUS CORTICOSTERONE AND CHEMICAL STRESSORS: IMPLICATIONS FOR SAFETY TESTING OF DRUGS.

B. Latimer¹, T. T. Kawabata², M. Lawton², S. Deng², J. Lapointe² and S. B. Pruett¹. ¹Department Cellular Biology & Anatomy, LSU Health Sciences Center, Shreveport, LA and ²Drug Safety R & D, Pfizer Global Research and Development, Groton, CT.

Drugs and chemicals at the high dosages used in safety testing often induce non-specific stress responses. The ICH S8 Guidance Document for Immunotoxicity testing indicates that changes in immunological end points typically affected by stress responses may not be sufficient to demonstrate that adverse immunological effects are mediated by stress. Therefore, the present study was performed to add a direct measure of stress to the usual immunological end points. Male Sprague-Dawley rats were treated for 5-10 days with chemical stressor or with exogenous corticosterone to produce a similar increase in serum corticosterone as noted in chemically treated rats. Urine samples were collected 0-6 and 6-24 hr after the last administration of chemical stressors and were analyzed for corticosterone metabolites using a commercial ELISA kit (Assay Designs), and immunological parameters were quantified 24 hr after the last dose. Urine samples collected over a period of time should provide a good representation of the cumulative increase in corticosterone expression in a similar manner as the area under the corticosterone concentration vs. time curve does for serum corticosterone data. Results were analyzed by linear and non-linear modeling, and r-squared values greater than 0.7 were obtained for the correlation between urine corticosterone (normalized to express the control group as 100%) and several immunological parameters including lymphocyte and neutrophil differential, thymus weight to body weight ratio, and NK cell percentage in the blood. The data collected thus far suggest a quantitative relationship between corticosterone and immunological parameters. This relationship may be used in the future to help determine if changes in immunological parameters are mediated by stress induced corticosterone release in rats. This work was funded by a grant from Pfizer Inc.

64 DELTA-9-TETRAHYDROCANNABINOL-INDUCED DRAMATIC INFILTRATION OF NEUTROPHILS IN MICE IS MAST-CELL DEPENDENT.

V. L. Hegde, S. Hegde, M. Nagarkatti and P. S. Nagarkatti. *Pathology, Microbiology & Immunology, University of South Carolina, School of Medicine, Columbia, SC.*

Delta-9-tetrahydrocannabinol (THC), the major psychoactive component of marijuana, possesses significant immunomodulatory properties. We observed that i.p. administration of THC in C57BL/6 (WT) mice resulted in dramatic dose-depen-

dant accumulation of cells (THC 9±3.5, vehicle 1.8±0.6 million) in the peritoneal cavity, which peaked at 12-24 hrs. FACS analysis for CD3, F4/80 (macrophage) and Gr-1 showed infiltrating cells were predominantly granulocytes. Also, >90% of these granulocytes were found to be neutrophils when stained with mouse neutrophil-specific mAb (NIMP-R14). A significant increase in Gr-1⁺ cells was also observed in liver, but not in blood. Similar results obtained in C3H mice ruled out any effects due to possible contaminating LPS. Chronic nasal challenge of WT mice also resulted in significant increase in granulocyte number in lungs. Cannabinoids mediate their effect through G-protein-coupled cannabinoid (CB) receptors. CB1 receptors are expressed in brain and immune cells, whereas, CB2 receptors are found primarily on immune cells. Both CB1 and CB2 receptor selective agonists (JWH 133 & ACEA, respectively) independently induced intraperitoneal granulocyte infiltration comparable to THC. Moreover, pretreatment of animals with CB1 or CB2 select antagonists resulted in partial blocking, whereas, a combination completely blocked THC-induced granulocyte infiltration. Mast cells release potent inflammatory mediators, including chemotactic factors upon activation. To test if THC-induced granulocyte infiltration is caused by degranulation of tissue mast cells, we used mast cell-deficient (W/W^v) mice. Unlike WT mice, W/W^v mice did not show significant granulocyte accumulation upon THC injection. We found murine bone marrow derived mast cells expressed both CB1 and CB2 mRNA. In conclusion, THC can activate tissue mast cells *in vivo* leading to dramatic neutrophil-specific chemotaxis. (Grant support: NIH R01AI053703, R01ES09098, R01 AI058300, R01DA016545, R01HL058641).

65 DOSE-RESPONSE OF PERFLUOROOCTANOIC ACID-INDUCED IMMUNOMODULATION IN ADULT C57BL/6 MICE.

J. DeWitt¹, C. B. Copeland² and R. W. Luebke². ¹Curriculum in Toxicology, UNC, Chapel Hill, NC and ²Immunotoxicology Branch, ETD/NHEERL/ORD, U.S. EPA, Research Triangle Park, NC.

Perfluorooctanoic acid (PFOA), used in fluoropolymer production, is environmentally persistent, present in human and wildlife populations worldwide, and associated with myriad health effects in laboratory animals. A preliminary risk assessment by the US EPA identified immunosuppression as an endpoint of concern, citing reports of splenic and thymic atrophy and reduced antibody synthesis in adult mice fed 30 mg PFOA/kg body weight (BW) for 15d (Yang et al., 2001, 2002). The level of Agency concern and lack of corroborating studies warranted a more thorough dose-response assessment. C57BL/6 female mice were given 0, 3.75, 7.5, 15, or 30 mg PFOA/kg BW in drinking water for 15d. Mice were immunized with SRBC on d11 of dosing and serum for evaluation of IgM titers was collected 1d post-dosing (PD). Booster immunizations with SRBC were given 10d PD and serum for evaluation of IgG titers was collected 15d PD. Mice were sensitized to BSA on d11 of dosing, challenged with BSA 3d PD, and footpad swelling measured 4d PD. IgM titers were suppressed at all PFOA doses; IgG titers were suppressed by 30 mg PFOA/kg but were elevated at lower doses, suggesting recovery and rebound. DTH responses were suppressed by 7.5 and 15 mg PFOA/kg. At 1d PD, 15 and 30 mg PFOA/kg decreased body, spleen and thymus weights; liver weights increased at all doses. By 15d PD, body, spleen and thymus weights were normalizing but liver weights remained elevated. These data indicate that 15d of PFOA exposure suppresses IgM titers but that humoral function recovers within 15d PD at doses below 30 mg PFOA/kg. Similar recovery was observed in spleen and thymus weights 15d PD. DTH responses were suppressed by PFOA exposure but appear less sensitive than humoral responses. Although we failed to identify a NOAEL for the immune functions evaluated, our LOAEL for IgM titers (3.75 mg PFOA/kg) was nearly 10-fold lower than the 30 mg PFOA/kg reported by Yang et al. (2002). [This abstract does not reflect EPA policy and was supported by UNC/EPA Cooperative Training Agreement CT829472.]

66 TISSUE DISTRIBUTION AND PRO-INFLAMMATORY CYTOKINE INDUCTION BY THE TRICHOHECENE DEOXYNIVALENOL IN THE MOUSE: COMPARISON OF NASAL VS. ORAL EXPOSURE.

C. J. Amuzie^{1,2}, J. R. Harkema^{1,2} and J. J. Pestka^{1,2}. ¹Comparative Medicine and Integrative Biology, Michigan State University, East Lansing, MI and ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Ingestion of the trichothecene mycotoxin deoxynivalenol (DON), a common contaminant of cereal grain, causes adverse effects on growth and immune function in experimental animals and thus poses a health risk to consumers. However, relatively little is known about the risks posed to farmers and grain handlers who are exposed to DON via inhalation of contaminated grain dust. The purpose of this research was to test the hypothesis that DON will distribute in tissues and induce proinflammatory cytokines to a greater extent following nasal exposure than by oral challenge. B6C3F1 mice were treated with a single dose of DON (5 mg/kg) either by

nasal instillation or oral gavage. After 0, 15, 30, 60, 120 minutes, mice were euthanized and serum, spleen, liver, lung and kidney samples were collected. An ELISA was devised for the sensitive measurement of DON burden in serum and tissue. In both oral and nasal treatment groups, DON serum and tissue concentrations peaked after 15 minutes and declined by 75 to 90% after 120 minutes. However, DON concentrations were 1.5 to 3.5 times higher in serum and other tissues of mice exposed by the nasal route at all time points assayed as compared to orally exposed mice. The functional significance of different DON tissue concentrations was assessed by measuring the expression of the pro-inflammatory cytokines IL-6, TNF α , and IL-1 β in spleen. As expected, oral exposure to DON induced cytokine mRNA expression after 60 and 120 minutes. However, mRNAs for these cytokines were 2 to 3 times higher in spleens of mice exposed to DON by the nasal route. Taken together, these toxicokinetic and functional data indicate that DON is potentially more toxic when inhaled than when ingested. Furthermore, they suggest that adverse human health effects could potentially result from inhalation of DON-contaminated grain dust. (This study was supported by USDA U.S. Wheat and Barley Scab Initiative)

67 LOW CONCENTRATIONS OF VANADIUM MODULATE EXPRESSION OF INNATE IMMUNE GENES IN AIRWAY EPITHELIUM.

A. M. Pavlosky², M. E. Klein-Patel², G. Diamond¹ and L. K. Ryan¹. ¹Oral Biology, UMDNJ, Newark, NJ and ²Interdisciplinary Program in Biomedical Sciences, Graduate School of Biomedical Sciences-UMDNJ, Newark, NJ.

Airway epithelial cells utilize the innate immune system to eliminate bacteria, yet the mechanisms of many of these processes are still being investigated. Vanadium, a transition element, is a major component of residual oil fly ash (ROFA), which can exacerbate respiratory infection and cardiovascular disease. These airway pollutants can inhibit innate immunity against microorganisms but the mechanism of how such pollutants do so is not well studied. We previously published that low doses of vanadium, either as V₂O₅ or as VOSO₄, inhibit lipopolysaccharide (LPS) induction of the antimicrobial peptide, β -defensin-2, in both human A549 alveolar type II and bovine tracheal epithelial cells (BTE). We hypothesized that other key mediators that participate in innate immune mechanisms to eliminate infection are inhibited as well. BTE were stimulated with 0, 0.145, 0.29, 0.59, 1.5, or 2.5 μ g/cm² VOSO₄ for 6 hours, washed with PBS, and then stimulated with 100ng/mL LPS in fresh medium for 18 hours. RNA was harvested, purified and gene expression of interleukin-8 (IL-8), matrilysin, and inducible nitric oxide synthetase (iNOS) was quantified using quantitative RT-PCR. Vanadium inhibited LPS-mediated IL-8 gene expression in a similar manner to β -defensin 2 gene expression. At concentrations of 0.145 to 2.5 μ g/cm², LPS-mediated induction of IL-8 mRNA was inhibited, which would lessen the ability of the airway to recruit neutrophils in the event of bacterial infection or an inhalation exposure to LPS. LPS did not induce iNOS in BTE in the absence of vanadium. However, when cells were pretreated with vanadium, LPS induced a 10-fold increase in iNOS mRNA levels. Matrilysin mRNA levels were not affected by vanadium, LPS or the combination of the two. These results suggest that lower concentrations of vanadium could impact innate immune responses in the airway independent of the inflammatory response observed with higher concentrations of particulate matter and their metal components.

68 PRE-TREATMENT WITH LOW DOSE INORGANIC MERCURY MODULATES THE INNATE IMMUNE RESPONSE TO COXSACKIE VIRUS-INDUCED MYOCARDITIS IN MICE.

J. F. Nyland¹, D. Fairweather¹, S. Frisnacho-Kiss^{1,3}, N. R. Rose^{2,3} and E. K. Silbergeld¹. ¹EHS, Johns Hopkins Medical Institutions, Baltimore, MD, ²MMI, Johns Hopkins Medical Institutions, Baltimore, MD and ³Pathology, Johns Hopkins Medical Institutions, Baltimore, MD.

Mercury is a widespread environmental contaminant with neurologic and immunotoxic impacts observed even at low dose exposures. Inorganic mercury (iHg) has a range of immunotoxic effects, including induction of autoimmunity in some rodent strains. Epidemiological studies have demonstrated an association between Hg exposure and risks of autoimmune disease or development of biomarkers of autoimmune disease. We have previously treated mice with low doses of iHg and induced autoimmune cardiac disease using coxsackievirus B3 (CVB3) in BALB/c mice. CVB3 induces a biphasic cardiac disease which is characterized by a primary acute phase, peaking at day 12 post-infection (pi), and a chronic phase, peaking at day 35 pi. The animals were pre-treated with iHg (200 μ g/kg, every other day for 15 days) before infection with CVB3. In these preliminary studies, animals were euthanized 6 hours pi and peritoneal lavage and spleen cells were harvested and analyzed for cell phenotype and markers of activation by flow cytometry (FACS). Additionally, cytokine levels were measured in spleen samples by ELISA. In the peritoneum, we found that expression of co-stimulatory molecules (CD80 and

CD86) was decreased on macrophages while the regulatory molecule, tim-3, was increased; however, the opposite was true of expression on mast cells. Further, we found that IL-4 and IL-10 levels were increased in the spleen of iHg-treated animals. These results suggest that Hg alters the innate immune response following CVB3 infection and sets the stage for exacerbated autoimmune disease later in the immune response to infection.

69 POTENTIAL ROLE OF CYCLOXYGENASE-2 (COX-2) IN NI-DEPENDENT ALTERATIONS IN RELEASE OF IMMUNE-MODULATORS FROM HUMAN LUNG FIBROBLASTS (HLF) BY TLR-2 AGONIST, MALP-2.

K. A. Brant, D. A. Pasino and J. P. Fabisiak. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

We have previously shown using HLF that NiSO₄ can synergistically enhance IL-6 release in response to Mycoplasma fermentans-derived lipopeptide (MALP-2). Here we evaluate the ability of Ni and MALP-2 to interact and modulate other cytokine and chemokine targets, as well as document changes in expression of various toll-like receptor signaling components that may account for Ni-dependent alterations in MALP-2 responsiveness. A RT2-PCR array that screens for 84 genes involved in TLR signaling pathways revealed that pre-exposure to Ni synergistically enhanced MALP-2-induced IL-8/CXCL-8, as well as IL-6, mRNA compared to cells treated with Ni or MALP-2 alone. The effect of Ni on MALP-2-induced monocyte-chemoattractant protein 1 (MCP-1) was minimal and Ni-pretreatment inhibited MALP-2-induced CXCL10 (interferon- γ -inducible protein, IP-10) expression. ELISA assay of cytokine proteins in media from Ni and MALP-2-exposed cells paralleled the changes in the level of mRNA. Ni or MALP-2 did not alter the mRNA level for any of the known toll-like receptors (1-10) or downstream signaling mediators (MyD88, TRAF6, TBK1, TICAM1 & 2, among other). Exposure to Ni alone, however, produced a 3.5-fold increase in COX-2 mRNA, which was synergistically enhanced by subsequent exposure to MALP-2 (19-fold increase). The specific COX-2 inhibitor, NS-398, attenuated the synergistic release of IL-6 and IL-8/CXCL8 following Ni + MALP-2 exposure. Basal MCP-1 release, as well as that following MALP-2 and Ni + MALP-2 was also attenuated by NS-398. In contrast, the COX-2 inhibitor reversed the Ni-dependent inhibition of MALP-2-induced CXCL10. These data indicate that Ni qualitatively alters the pattern of inflammatory mediator release from HLF in response TLR-2 dependent stimuli. Reversal of these changes via inhibition of COX-2 suggests that eicosanoid-like mediators may, in part, selectively amplify or retard cytokine production during mixed exposures to Ni and microbial stimuli.

70 DIESEL EXHAUST PARTICLE COMPOSITION AND THE METHOD OF SONICATION INFLUENCE THE ADJUVANCY EFFECT AND TARC PRODUCTION.

T. Stevens¹, M. Daniels², E. Boykin² and L. Gilmour². ¹Toxicology, UNC, Chapel Hill, NC and ²NHEERL, EPA, Research Triangle Park, NC.

Numerous reports have shown diesel exhaust particles (DEP) can act as an immunological adjuvant in asthma. Recent interest has focused on thymus and activation-regulated chemokine (TARC) as an important modulator of this effect. This study evaluated the adjuvancy effects of three chemically different DEP prepared by two different sonication methods and measured TARC production for all conditions. The samples were NIST SRM 2975 (NDEP) generated from a heavy forklift, an automobile generated DEP (ADEP), and DEP (CDEP) generated from a diesel engine used to power a compressor. These samples differed in the percentage of extractable organic material; NDEP, ADEP, and CDEP contained 1.5%, 67%, and 18.9%, respectively. Samples were sonicated in a waterbath for 40 min or with a point sonicator for 10 min. BALB/C mice were instilled intranasally with saline or 150 μ g of NDEP, ADEP, or CDEP with 20 μ g of ovalbumin on days 0 and 13, and then challenged with ovalbumin on days 23, 26, and 29. Immune and inflammatory endpoints in the lung were assessed 18 and 48 hrs after the last challenge. With the waterbath sonicated samples, mice exposed to NDEP had significantly higher neutrophil infiltration and IL4, IL5, and IL13 cytokine production in the BAL fluid after 18 hrs relative to ovalbumin alone. By 48 hrs, these mice had the highest levels of eosinophils and lung injury compared to all groups. However, exposure to point sonicated ADEP or CDEP caused greater adjuvancy than NDEP for these same indicators of allergic lung disease. In addition, airway hyperactivity was measured and found to be highest in the ADEP exposed mice. Analysis of TARC showed that this chemokine was associated with the strongest adjuvant effect depending on the preparation technique. These results show that source and composition as well as methods of sonication are important in regulating the extent of adjuvancy, and that these effects are associated with the presence of the Th2 chemokine, TARC. (This abstract does not reflect EPA policy)

71 CHRONIC ARSENIC EXPOSURE ALTERS GLUCOSE METABOLISM IN MICE.

M. D. Pysher¹, J. Sollome¹, S. Regan¹, T. R. Cardinal², J. B. Hoying², H. L. Brooks³ and R. R. Vaillancourt¹. ¹Pharmacology and Toxicology, University of Arizona, Tucson, AZ, ²Biomedical Engineering, University of Arizona, Tucson, AZ and ³Physiology, University of Arizona, Tucson, AZ.

Millions worldwide suffer from the effects of chronic arsenic exposure, which typically occurs via ingestion of contaminated drinking water or agricultural products. Epidemiological studies link arsenic exposure to increased risks of cancers of the skin, kidney, lung, bladder and liver, as well as a variety of non-cancerous conditions including diabetes mellitus. However, although many of these studies have demonstrated the diabetogenic effects of arsenic, the biological and molecular mechanisms by which it exerts its effects remain elusive. In our studies with adult male C57BLK/6 mice we have found alterations in glucose metabolism in response to chronic, low-level arsenic exposure. Mice were exposed to 10 ppb or 50 ppb arsenite in their drinking water for times varying between 3 and 21 days, after which the mice were euthanized and their tissues and fluids collected for analysis. Increased blood glucose levels were observed in the arsenic treated mice as early as 2 days after exposure began, and excreted glucose was observed in their urine within 5 days. Additionally, insulin levels in the blood of the exposed mice were significantly higher than in the control mice. Harvested tissues were also analyzed for enzymatic and transporter expression. Increased hexokinase II (HKII) expression was observed in the renal cortex of the arsenic exposed mice. The discovery of high levels of cortical HKII has significant biological implications. HKII is a key enzyme in cellular metabolism, growth and survival, with its primary function being the phosphorylation of glucose to yield glucose 6-phosphate. Overall, our data suggests that chronic, low-level exposure to arsenic induces diabetogenic effects in mouse model systems. In addition, the dysregulation of glucose metabolism and alteration of renal HKII expression may be involved in arsenic-induced pathological conditions involving the kidney.

72 CHRONIC LOW DOSE ARSENIC EXPOSURE IN MICE CAUSES GENE EXPRESSION CHANGES ASSOCIATED WITH CHOLESTEROL BIOSYNTHESIS.

A. P. Nomikos^{1,2}, T. H. Hampton^{1,2}, J. C. Davey^{1,2}, J. A. Gosse^{1,2}, C. D. Kozul¹, L. A. Warnke³, M. A. Ihnat³ and J. W. Hamilton^{1,2}. ¹Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH, ²Center for Environmental Health Sciences, Dartmouth Medical School, Hanover, NH and ³Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Chronic arsenic (As) ingestion has been associated with increased risks of cancer, cardiovascular disease, diabetes, developmental problems and other diseases. Gene arrays represent a powerful tool to examine patterns of gene expression changes that can reveal underlying mechanisms. However, previous studies of As effects on gene expression in mice have used high, often cytotoxic doses. In this study, we exposed C57Bl/6 mice (n=5 per group) for 5 weeks to purified drinking water or with As (10 or 100 ppb) and a purified AIN-76A mouse chow diet with minimal As (5 ppb total) or chow with added As (10 ppb). At 5 weeks, groups of control mice (As-free water and chow) were injected either with saline, dexamethasone (Dex, 1mg/kg), As (1mg/kg), or Dex+As 8 hr prior to sacrifice. Tissues were obtained and gene expression changes measured with Affymetrix Mouse Whole Genome 430 2.0 oligonucleotide arrays. We observed significant alterations in liver expression of cholesterol biosynthesis genes with Dex, and these genes were further altered in the Dex+As group. Cholesterol biosynthesis genes were also altered in the mice exposed for 5 weeks via both drinking water and chow, though not as extensively as with the acute injections. These results suggest that dysregulation of cholesterol homeostasis may be an early contributor to As-related diseases. Epidemiology studies have suggested cholesterol dysregulation as a contributing pathway in many As-related diseases including type 2 diabetes and vascular disease, though the precise mechanism is poorly understood. This current work provides new insight into early changes in gene expression associated with As exposure at doses typically encountered in contaminated water and food in the US and throughout the world. (NIH-NIEHS P42 ES07373)

73 TOXICOGENOMIC STUDIES WITH NORMAL HUMAN LUNG FIBROBLASTS REVEAL GLOBAL EFFECTS OF LOW-DOSE ARSENIC ON GLUCOCORTICOID RECEPTOR SIGNALING.

J. A. Gosse^{1,2}, T. H. Hampton^{1,2}, J. E. Bodwell^{2,3}, F. D. Barr³, C. D. Kozul¹ and J. W. Hamilton^{1,2}. ¹Department of Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, ²Center for Environmental Health Sciences, Dartmouth Medical School, Hanover, NH and ³Department of Physiology, Dartmouth Medical School, Lebanon, NH.

Chronic arsenic (As) intake has been associated with increased risk of various cancers, developmental and reproductive problems, cardiovascular disease, and other diseases. This disease burden may be caused in part by the potent endocrine disruption

activity of As. Low dose As has been shown to disrupt transcription mediated by all five steroid receptors as well as by other nuclear hormone receptors. Here we have examined the acute global gene expression changes in normal, non-transformed, telomerase-immortalized human lung fibroblasts (WHTBF-6) treated for 8 hr with As alone (25 ppb, ~0.3 uM, the 24hr-LC01) or in combination with dexamethasone (Dex) to stimulate glucocorticoid receptor (GR)-mediated gene expression. We determined that WHTBF-6 cells have ~20,000 GR per cell and exhibit a robust GR-mediated gene response due to 50 nM Dex. Background levels of total As in the complete cell media were determined to be < 0.6 ppb. We used Affymetrix GeneChip U133 Plus 2.0 human whole genome arrays (n=4 per treatment group) to analyze gene expression using robust statistical analyses. As alone altered many genes including those involved with chromatin modification/assembly/disassembly, immune response, and protein ubiquitination and phosphorylation. Exposure of cells to As+Dex resulted in a gene profile largely different from that of cells exposed to Dex alone. Effects caused by As+Dex vs. Dex exposure that were not caused by As alone include genes associated with nucleosomes, translation regulation, histone modification, and various signal transduction processes. These differences provide important clues for elucidating the basis for endocrine disruption by As, as well as other As effects on normal cells. (NIH-NIEHS: P42 ES07373, R01 ES011819)

74 ARSENIC DISRUPTS THYROID HORMONE-INDUCED GENE TRANSCRIPTION IN GH3 CELLS AND AMPHIBIAN TAIL METAMORPHOSIS.

J. C. Davey^{1,2}, A. P. Nomikos^{1,2}, M. Wungjiranirun², J. R. Sherman², L. Ingram^{1,2}, C. Batki^{1,2}, J. P. Lariviere^{1,2} and J. W. Hamilton^{1,2}. ¹Department of Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH and ²Center for Environmental Health Sciences, Dartmouth College, Hanover, NH.

Arsenic (As) is a significant human health threat and has been associated with increased risks of multiple cancers, diabetes, heart disease, and reproductive and developmental problems. We previously demonstrated that arsenic acts as a potent endocrine disruptor at very low levels, altering steroid signaling at the level of receptor-mediated gene regulation for all five steroid receptors plus the type II retinoic acid receptor (RAR). We investigated whether thyroid hormone signaling through the thyroid hormone receptor (TR), a type II receptor like RAR, is also disrupted by As. Rat GH3 cells were treated with 0.01-5 uM sodium arsenite for 6 or 24 hr, with or without thyroid hormone (T3). Arsenic significantly altered expression of a transiently transfected TRE-luciferase construct as well as the endogenous TR-regulated Type I Deiodinase (D1) gene, and in a manner very similar to that observed previously for the other nuclear receptors suggesting a common mechanism. We then used an amphibian tail metamorphosis assay to determine whether such disruption would have patho-physiological consequences. Tail metamorphosis is principally regulated by thyroid hormone via TR and is tightly controlled by the sequential activation of specific genes at specific stages and in specific tissues. Xenopus tails were removed, cultured ex vivo and treated with As with or without thyroid hormone. Ex vivo tail metamorphosis closely mimics natural tail metamorphosis. TR-dependent tail metamorphosis was inhibited in a dose-dependent manner by As from as low as 7.5 ppb up to 300 ppb. Thyroid hormone is also critical to human development as well as adult function. Disruption of amphibian development by arsenic is therefore not only direct evidence of a patho-physiological effect of As-induced endocrine disruption but is also directly relevant to human health. (NIH-NIEHS P42 ES07373)

75 TRANSPLACENTAL EXPOSURE TO INORGANIC ARSENIC AT A HEPATOCARCINOGENIC DOSE INDUCES FETAL GENE EXPRESSION CHANGES INDICATIVE OF ABERRANT ESTROGEN SIGNALING AND DISRUPTED STEROID METABOLISM.

J. Liu¹, Y. Xie¹, F. Cooper¹, D. Ducharme², R. Tennant², B. Diwan³ and M. Waalkes¹. ¹LCC, NCI at NIEHS, Research Triangle Park, NC, ²NIEHS, Research Triangle Park, NC and ³BRP, SAIC-Frederick, Frederick, MD.

Exposure to inorganic arsenic *in utero* produces hepatocellular carcinoma in male offspring when they reach adulthood. To help define the molecular events associated with the fetal onset of arsenic hepatocarcinogenesis, pregnant C3H mice received drinking water with 0 (control) or 85 ppm arsenic from day 8 to 18 of gestation. At the end of the arsenic exposure period, male fetal livers were removed and RNA isolated for microarray analysis using the Agilent mouse 22K oligo chips. Arsenic exposure *in utero* produced significant (p < 0.001) alterations in expression of 187 genes, and approximately 25% of aberrantly expressed genes were related to either estrogen signaling or steroid metabolism. Real-time RT-PCR confirmed these changes on selected genes. Various genes controlled by estrogen, including X-inactive-specific transcript, anterior gradient 2, trefoil factor 1, CRP-ductin, ghrelin, and small proline-rich protein 2A, were dramatically over-expressed. Estrogen-regulated genes including cytokeratin 1-19 and Cyp2a4 were over-expressed,

although Cyp3a25 was suppressed. Several genes involved with steroid metabolism also showed remarkable expression changes, including increased expression of 17 β -hydroxysteroid dehydrogenase 7 (HSD17 β 7; involved in production of estradiol) and decreased expression of HSD17 β 5 (involved in production of testosterone). The expression of key genes important in methionine metabolism, such as methionine adenosyltransferase 1a, betaine-homocysteine methyltransferase and thioether S-methyltransferase, were decreased. Thus, exposure of mouse fetus to inorganic arsenic during a critical period in development significantly alters the expression of various genes encoding estrogen signaling and steroid or methionine metabolism, which could disrupt genetic programming at very early life-stage leading to tumor formation much later in adulthood. Funded in part by DHHS #NO1-CO-12400.

76 ARSENIC EXPOSURE EXACERBATES ATHEROSCLEROSIS IN APOE-KNOCKOUT MICE.

S. Srivastava¹, S. E. D'Souza² and J. C. States³. ¹Medicine, University of Louisville, Louisville, KY, ²Physiology, University of Louisville, Louisville, KY and ³Pharmacology & Toxicology, University of Louisville, Louisville, KY.

Chronic arsenic (As) ingestion causes inflammation and peripheral vascular disease in humans. In the present study, we examined the effect of As-feeding on atherogenesis in apoE-knockout mice. Three week old mice were maintained either on tap water or water containing 49 ppm As. The mice were sacrificed at age 10 or 16 wk. Plasma lipoprotein profiles, indices of oxidative stress and inflammation, and atherosclerotic lesion formation were examined. Plasma cholesterol and phospholipids were unchanged in 10 or 16 wk old mice. Plasma triglycerides were decreased 15-20% in 10 wk old As-fed mice. Fatty streak formation in aortic roots and arch in 10 wk old As-fed mice (n=9) were increased 3-4 fold (P<0.01) relative to controls (n=12). Enhanced lipid accumulation (P<0.01) occurred at lesion prone sites in 16 wk old As-fed mice (n=14) relative to controls (n=20). Immunohistochemical analysis at 16 wk showed a >2-fold increase in macrophage content in aortic valves of As-fed mice, whereas very little if any T-cells or smooth muscle cells were detected in these lesions. As-fed mice also showed increased (P<0.01) staining for markers of inflammation (monocyte chemotactic protein-1, MCP-1) and oxidative stress [protein-4, hydroxynonenal (HNE) and protein-malondialdehyde (MDA)]. Significant increases (P<0.05) in levels of free HNE, MDA and inflammatory cytokines and chemokines (TNF- α , IL-1 β , MCP-1, VEGF) were observed in plasma of As-fed mice. Vasoreactivity studies, performed on the distal aorta from 10 wk old mice, indicated that the ability of phenylephrine (10-5M) pre-contracted aortic rings to relax in response to acetylcholine (10-6-10-5 M) was compromised by 15-20% in As-fed mice. Collectively, our data suggest that early life-exposure to As causes endothelial dysfunction, enhances oxidative stress and inflammation and accelerates atherosclerosis in apo E-knockout mice. (Supported in part by PHS grants R01HL65618, R01ES011314, and a grant from UofL Center for Genetics and Molecular Medicine)

77 IN UTERO ARSENIC EXPOSURE INDUCES EARLY ONSET OF ATHEROSCLEROSIS IN APOE-KNOCKOUT MICE.

J. States¹, S. Srivastava², U. Sen³ and S. E. D'Souza³. ¹Pharmacology & Toxicology, University of Louisville, Louisville, KY, ²Institute of Molecular Cardiology, University of Louisville, Louisville, KY and ³Physiology & Biophysics, University of Louisville, Louisville, KY.

Consumption of arsenic contaminated drinking water has been linked to higher rates of coronary disease, stroke and peripheral arterial disease. Exposures to toxicants during development may play a significant role in the onset of chronic adult diseases. The potential for *in utero* arsenic exposure to accelerate the onset of cardiovascular disease was investigated by exposing pregnant ApoE-knockout mice to 49 ppm arsenic as sodium arsenite in their drinking water and examining the aortic trees of their male offspring for evidence of early disease 10 weeks after birth. Offspring mice were maintained on normal chow after weaning. Mice exposed to arsenic in utero showed a >2-fold increase in lesion formation in the aortic roots as well as the aortic arch compared to control mice. Total plasma cholesterol, phospholipids and total abundance of VLDL or HDL particles were unchanged in arsenic exposed mice. However, arsenic exposed mice had a >40% decrease in total plasma triglycerides. A decrease in large VLDL particles was apparent upon sub-fractionation of VLDL particles. Disturbance of endothelial cell signaling was suggested by a vasorelaxation defect in response to acetylcholine in phenylephrine pre-contracted aortic rings from arsenic exposed mice. These results indicate that in utero arsenic exposure induces an early onset of atherosclerosis in ApoE-knockout mice without a hyperlipidemic diet and support the hypothesis that in utero arsenic exposure may be atherogenic in humans. (Supported in part by PHS grants R01HL65618, R01ES011314, and a grant from UofL Center for Genetics and Molecular Medicine)

78 CARCINOGENICITY OF AN ACTIVE METHYLATED ARSENIC (MMAIII) AND IT'S EFFECTS ON GENE REGULATION IN THE MOUSE.

M. Krishnamohan¹, A. A. Seawright¹, M. R. Moore¹, M. M. Ahmed² and J. C. Ng¹. ¹National Research Centre for Environmental Toxicology, The University of Queensland, Brisbane, QLD, Australia and ²Weis Center for Research, Geisinger Clinic, Danville, PA. Sponsor: M. Waalkes.

Although arsenic is a proven human carcinogen, lack of a proper animal model until recently makes it difficult to understand the mechanism of its carcinogenicity. MMAIII (monomethylarsonous acid) is formed as an intermediate metabolite during arsenic methylation. Arsenic metabolism was considered to be a detoxification mechanism. However, recent in-vitro studies have shown that MMAIII is more potent cytotoxic and genotoxic than inorganic arsenic. Our aim is to study whether MMAIII is carcinogenic to mice and the differences between spontaneous tumours and arsenic induced tumours at the molecular level. Groups of female C57Bl/6J mice were exposed to 0, 100, 250 or 500 μ g As/L as MMAIII in drinking water for up to 2 years. 24h pooled urine specimens were collected at time intervals of 0, 1, 2, 4, 8 weeks and then every 8 weeks over 2 years for arsenic speciation by HPLC-ICP MS. The major metabolite was found to be DMAV and neither MMAV nor MMAIII was detected. The apparent absence of these metabolites justifies future metabolic profile study in the available tissue bank. MMAIII treated mice showed statistically significant increases in the incidences of keratoacanthoma, lymphoma, plasmacytoma, histiocytic sarcoma and multiple tumors compared to the control group. Over 10,900 genes were significantly upregulated in tumors in mice from the treatment groups compared to those of the control group. Up regulated genes included those involved in cell cycle, cell proliferation, oncogenes, stat genes and DNA damage genes. The genes which are involved in NF κ B signaling pathway such as Traf, NF κ B, IKK β , Tank and Bcl2 are all present in the treated tumors but not in the control tumors. Our result shows MMAIII alone can cause tumors in vivo without any promoter, and supports the contention that arsenic metabolism is not only a detoxification pathway but rather it could also be a toxic process.

79 ALTERED GAIT IN RATS SUB-CHRONICALLY EXPOSED TO ARSENITE PROTECTION OF ALPHA TOCOPHEROL SUPPLEMENTATION.

E. Garcia-Chavez¹, I. Jimenez², B. Segura³, J. C. Guadarrama² and L. M. Del Razo¹. ¹Toxicology, Cinvestav-IPN, Mexico D.F, Mexico, ²Physiology & Biophysics, Cinvestav-IPN, Mexico D.F, Mexico and ³FES-Iztacala, UNAM, Mexico D.F, Mexico.

Exposure to inorganic arsenic (iAs) results impairment of superior neurological functions and demyelination and morphological alterations in axons of the peripheral nerve, evoking changes in the generation and propagation of action potentials. Recent studies have shown that iAs exposure causes oxidative damage in rat brain, spinal cord and peripheral nerves. Thus, the nervous injuries induced by iAs exposure can be defended by alpha tocopherol (α -TOC) administration, due to their antioxidant role. To better understand the functional consequences of iAs exposure, we compared the quantitative assessment of the two-dimensional angular kinematics based on flexion, extension and balance during walking in adult male Wistar rats according the follow experimental groups **A) Control**; **B) α -TOC**. Rats supplemented with α -TOC, 230 IU/kg bw/d, by gavage, daily for 20 days. **C) Arsenite**. Rats supplemented with a daily dose of sodium arsenite included in water (10 mg/kg of bw/d, by gavage, during 30 d). **D) Arsenite + α -TOC**. Rats arsenite-treated (10 mg/kg bw/d, by gavage, during 30 d) and supplemented with α -TOC (230 IU/kg bw/d, by gavage), initiated 10 d after administration of the first dose of arsenite and continued for 20 d.

The results no showed alterations in the phases of flexion, extension and balance of locomotion in all groups. Nevertheless, the rats showed an increment in the support phase (24%) and the duration of the elevation phase of the leg (25%), a decrease in the length of step (10%), in velocity of step (20%), with displacement slow and eventual only in the group exposed to arsenite. The group co-exposed with arsenite- α -TOC no showed altered locomotion. Our results suggest that the gait alteration is related with the oxidative damage induced by iAs exposure in several nervous regions, affecting the normal nervous transmission from periphery to the central nervous system.

80 CD EXPOSURE INCREASES CHOLINE TRANSPORT IN CHOROID PLEXUS OF IMMATURE RATS.

A. Villalobos, K. Bentley, L. Huang, T. Zarccone and J. Tay. University of Rochester School of Medicine & Dentistry, Rochester, NY.

The potential for heavy metal accumulation to alter choline transport in choroid plexus was examined in Sprague-Dawley rats administered 0, 0.25 or 0.50 mg Cd per kg by gavage from PND 8-28 (n=12 per dose). Among dose groups, there were

no differences in growth rate or development and no evidence of renal or hepatic dysfunction. In Cd-treated rats, final Cd concentrations in choroid plexus exceeded that in blood or brain by 30- and 40-fold. Discrete changes in the epithelium's ultrastructure were also observed. There was no detachment from the basement membrane or attenuation of the microvilli, and tight junctions remained intact. However, Cd increased the incidence of enlarged cytosolic vacuoles and dilation of intercellular spaces. Moreover, as compared to that in control tissues, 30-min uptake of 10 micromolar 3H-choline in choroid plexus isolated from rats treated with 0.25 and 0.5 mg Cd/kg increased by 30% and 45%, respectively. This suggested increased removal of choline from CSF. Central neural deficits associated with choline-deficiency in other studies were observed in Cd-treated rats. Specifically, in rats treated with 0.5 mg Cd/kg, brain weight (normalized to bod. wt.) was decreased, and operant learning was impaired. Thus, in the absence of pronounced toxicity, low dose exposure to Cd may stimulate choline transport in choroid plexus; this may limit availability of the nutrient in the developing brain. NIEHS-P30-ES01247

81 THE EFFECT OF MANGANESE ACCUMULATION ON NEUROTRANSMITTER UPTAKE.

J. G. Anderson, S. C. Fordahl, P. T. Cooney and K. M. Erikson. *Nutrition, UNC-Greensboro, Greensboro, NC.*

Manganese (Mn) is a trace element important in many cellular processes, but over-exposure is characterized by accumulation in dopamine-rich brain regions leading to Parkinson's like symptoms in extreme cases. Previous studies have shown Mn accumulation is exacerbated by dietary iron deficiency (ID) and disturbances in other neurotransmitters have been reported. Because behaviors associated with Mn neurotoxicity are complex, the goal of this study was to examine the effects of Mn-exposure on dopamine (DA), serotonin (5-HT) and norepinephrine (NE) uptake in synaptosomes derived from three rat brain regions. Sprague-Dawley rats were randomly assigned to four dietary groups (n=12 per group): control (CN), ID, CN with Mn supplementation (CNMn), and ID with Mn (IDMn). Synaptosomes from striatum (STR), locus ceruleus (LC), and cerebellum (CB) were isolated from treated rats at four, five, and six weeks and 3H-DA, 3H-5HT and 3H-NE uptake was measured. We found that 3H-NE uptake decreased significantly ($R=-0.753$, $p=0.001$) with increased Mn concentration in the LC at six weeks. ID was associated with decreased uptake of DA, 5-HT and NE in the STR at six weeks ($p<0.05$). A comprehensive look at the data collected indicates that after six weeks of dietary treatment, ID decreases uptake of DA, NE, and 5HT in the STR and exacerbates the effect of Mn supplementation in the LC. Supported by NIEHS #ES013791-01.

82 DOSE-DEPENDENT DEPOSITION OF MANGANESE IN OLFACTORY BULB AND DOPAMINERGIC STRUCTURES AFTER NOSE-ONLY INHALATION.

J. L. Lewis¹, J. Karlsson¹, G. Bench², B. Pacheco¹, M. Cajero³, M. Menache¹ and E. Barr³. ¹College of Pharmacy, University of New Mexico, Albuquerque, NM, ²Lawrence Livermore National Lab., Livermore, CA and ³Lovelace Respiratory Res Inst., Albuquerque, NM.

Parkinson's disease has been linked to environmental exposures. This research examines whether inhalation of environmental concentrations of Mn, which produces a Parkinson's-like syndrome occupationally, results in olfactory uptake and subsequent deposition to the substantia nigra. The role of Fe status on uptake and deposition is also examined. Adult mice were nose-only inhalation exposed to air, low (2 mg/m³) or high dose MnCl₂ aerosol (7-10 mg/m³) for 10 or 30 days (5 d/wk, 6h/d). Additional mice were fed Fe-deficient diets and exposed to air or low MnCl₂ for 29-30 days. Mn and Fe were measured in olfactory glomeruli (OG) and tuberculum, globus pallidus (GP), caudate putamen (CPu) and substantia nigra pars compacta (SN) at 7 DPE using proton-induced X-ray emission. A dose-dependent Mn uptake was seen in all brain regions except CPu where increased Mn was only seen after high-dose inhalation. Mn deposition was greatest in the OG. These results are in line with our previous Mn brain deposition time-course studies. Although Fe concentration in brain regions was not affected by Mn inhalation alone, Fe-deficient diet reduced Fe levels in all brain regions except GP. The effect was most pronounced in OG and SN. There was, however, no clear impact of iron-deficiency on inhaled Mn uptake. Dose-dependent deposition of Mn in the SN, the region vulnerable in Parkinson's disease, identifies a mechanism for direct toxicity to the dopaminergic system, and time course and localization patterns implicate neuronal pathways rather than systemic or bulk-flow mechanisms in deposition of inhaled Mn. Evaluations of neuronal degeneration, astrogliosis and inflammation in these brains at 7 or 180 DPE is in progress and will contribute to our understanding of the CNS toxicity of environmental concentrations of inhaled Mn.

83 IRON (FE) TRANSPORT ACROSS THE BLOOD-CSF BARRIER *IN VITRO* AS AFFECTED BY MANGANESE (MN) EXPOSURE.

X. Wang¹, G. J. Li¹ and W. Zheng¹. ¹Health Sciences, Purdue University, West Lafayette, IN and ²Pathology, University of Washington, Seattle, WA.

The blood-cerebrospinal fluid (CSF) barrier (BCB) resides within the choroid plexus, with the apical side facing the CSF and the basolateral side towards the blood. Previous studies from this laboratory demonstrate that Mn exposure in rats decreases Fe concentration in blood, but increases Fe in the CSF, indicating a compartmental shift of Fe possibly by crossing the BCB. In the present study, a primary culture of rat choroidal epithelial cells growing on the transwell chamber system was used to investigate the transepithelial transport of Fe. Mn treatment (100 μ M for 24 hr) significantly reduced the transepithelial electrical resistance, an indicator of the tightness of the barrier. Transferrin-bound 59Fe (Tf-59Fe) or free 59Fe was added to the outer chamber and the radioactivity in the inner chamber counted to determine the influx of Fe; the efflux was determined vice versa. Under the normal condition, the influx rate of Tf-59Fe was significantly higher than the efflux rate ($p<0.05$). Following Mn exposure, the efflux rate of Tf-59Fe was increased by 135% as compared to controls ($p<0.05$); this effect was blocked by a transferrin receptor inhibitor, bafilomycin A1. At 24 hrs, the storage of Tf-59Fe in primary choroidal epithelia was 60.6% higher in influx than efflux studies. Unlike Tf-59Fe transport, the influx rate of free 59Fe was much lower than that of the efflux ($p<0.01$). Mn exposure significantly increased the efflux rate of 59Fe ($p<0.01$). Pre-treatment of the *in vitro* BCB model with the antibody against divalent metal transporter-1 (DMT1) blocked 59Fe transport. Taken together, these data suggest that Tf-bound Fe appears to be favorably transported from the blood toward CSF, whereas free Fe is favored for the opposite direction from the CSF to blood. Mn exposure facilitates Fe transport across the BCB by increasing cell permeability and by facilitating the fluxes of Tf-59Fe and 59Fe in their natural directions. (Supported in part by NIEHS ES08146 and ES 013118)

84 MANGANESE DISTRIBUTION IN BRAINS OF CYNOMOLGUS MONKEYS SHOWING HIGH MRI T1 SIGNAL INTENSITIES AFTER 8 MONTHS OF WELDING-FUME EXPOSURE.

J. Park¹, Y. Chung², C. Kim⁴, C. Ha⁴, S. Yang³, H. Khnag³, H. Cheong⁵, J. Lee⁶, C. Song⁴, I. Kwon⁷, J. Han², J. Sung⁸, J. Heo⁴, B. Choi¹ and I. Yu⁸. ¹Chung-Ang University, Seoul, South Korea, ²Occupational Safety & Health Research Institute, Daejeon, South Korea, ³Eulji University, Daejeon, South Korea, ⁴Korea Institute of Toxicology, Daejeon, South Korea, ⁵Sungkyunkwan University, Suwon, South Korea, ⁶Center for Occupational Lung Diseases, WAMCO, Ansan, South Korea, ⁷National Institute of Scientific Investigation, Daejeon, South Korea and ⁸Biosafety Evaluation Headquarter, KEMTI, Incheon, South Korea.

Several pharmacokinetic studies on inhalation exposure to Mn have already demonstrated that Mn readily accumulates in the olfactory and brain regions. However, the absorption and transportation of Mn from welding fumes may be due to the influence of various other metals contained in the welding fumes. Furthermore, the idea of transporters competing for binding sites makes more complicated. Accordingly, to clarify the Mn distribution in the brain and blood concentration of Mn after welding-fume exposure, non-human primate cynomolgus monkeys were assigned to 3 dose groups: unexposed, low (31 mg/m³ TSP, 0.9 mg/m³ of Mn), and high (62 mg/m³ TSP, 1.95 mg/m³ of Mn). The primates were exposed to manual metal-arc stainless steel welding fumes for 2 hrs per day in an inhalation chamber system equipped with an automatic fume generator for 8 months, their blood concentrations of Mn monitored, and the Mn distribution examined using MRI technology. Subsequently, the tissue Mn were measured after reaching the maximum MRI T1 relaxation time. Dose-dependent increase in the Mn was found in the lungs, and significant increases in the Mn were found in the various tissues such as liver, kidneys, epididymus, testes and spleen. Slight increases in the Mn were found in the caudate, putamen, and substantia nigra, a dose-dependent significant increase was found only in the globus pallidus. Our results indicated that a high MRI T1 signal intensity is well correspond with Mn concentration and the presence of a certain amount of iron or other metals, such as Cr and Ni, in the inhaled welding fumes may not have a significant effect on the uptake of Mn into the brain.

85 RECOVERY OF WELDING-FUME EXPOSURE INDUCED MRI T1 SIGNAL INTENSITIES AFTER CESSATION OF WELDING-FUME EXPOSURE IN BRAINS OF CYNOMOLGUS MONKEYS.

Y. Chung¹, J. Park², C. Kim³, S. Yang⁴, H. Khang⁴, H. Cheong⁵, J. Lee⁶, C. Ha³, C. Song³, I. Kwon⁷, J. Han¹, J. Sung⁸, J. Heo³, B. Choi² and I. Yu⁸.
¹Center for Occupational Toxicology, KOSHA, Daejeon, South Korea, ²Chung-Ang University, Seoul, South Korea, ³Korea Institute of Toxicology, Daejeon, South Korea, ⁴Eulji University, Daejeon, South Korea, ⁵Sungkyunkwan University, Suwon, South Korea, ⁶Center for Occupational Lung Diseases, WAMCO, Ansan, South Korea, ⁷National Institute of Scientific Investigation, Daejeon, South Korea and ⁸Biosafety Evaluation Headquarter, KEMTI, Incheon, South Korea.

The shortening of the MRI T1 relaxation time has been known to be an effective biomarker for Mn exposure after short-term welding-fume exposure. Our previous study indicated that the T1 relaxation times decreased time-dependently after exposure, and a visually detectable high signal intensity appeared after 150 days of exposure. The plateau for the shortening of the T1 relaxation time corresponded well with the blood Mn, as previously shown in welders, suggesting a correlation between a prolonged high Mn concentration in the blood and a shortening of the T1 relaxation time. Accordingly, to clarify the Mn clearance in the brain concentration of Mn after cessation welding-fume exposure, non-human primate cynomolgus monkeys were acclimated for a month and assigned to 3 dose groups: unexposed, low (31 mg/m³ TSP, 0.9 mg/m³ of Mn), and high dose (62 mg/m³ TSP, 1.95 mg/m³ of Mn). The primates were exposed to manual metal-arc stainless steel welding fumes for 2 hrs per day in an inhalation chamber system equipped with an automatic fume generator for 8 months, their blood concentrations of Mn monitored, and the Mn distribution examined using MRI. After reaching the maximum T1 relaxation time, the primates were allowed to recover from the high MRI T1 signal intensities by ceasing the welding-fume exposure. The primates showed recovery of MRI T1 signal intensities nearly same level as the unexposed within 2 months. Our results indicated that a high MRI T1 signal intensity induced by welding fume exposure can be reversible even after prolong exposure but tissue concentrations of brains and recovery of other parameters remain to be studied further.

86 NEUROBEHAVIORAL CHANGES AFTER PROLONG WELDING-FUME EXPOSURE IN CYNOMOLGUS MONKEYS.

C. Kim¹, Y. Chung², C. Song¹, C. Ha¹, J. Park³, S. Yang⁴, H. Khang⁴, H. Cheong⁵, J. Lee⁶, I. Kwon⁷, J. Han², J. Sung⁸, J. Heo¹, B. Choi³ and I. Yu⁸.
¹Korea Institute of Toxicology, Daejeon, South Korea, ²Center for Occupational Toxicology, KOSHA, Daejeon, South Korea, ³Preventive Medicine, Chung-Ang University, Seoul, South Korea, ⁴College of Medicine, Eulji University, Daejeon, South Korea, ⁵School of Medicine, Sungkyunkwan University, Suwon, South Korea, ⁶Center for Occupational Lung Diseases, WAMCO, Ansan, South Korea, ⁷National Institute of Scientific Investigation, Daejeon, South Korea and ⁸Biosafety Evaluation Headquarter, KEMTI, Incheon, South Korea.

Chronic human exposure to high concentrations of metal fumes, as observed among welders, has been shown to induce adverse health effects. A neurological and neurophysiological study of workers occupationally exposed to Mn exhibited an increased emotional irritability, dysmnnesia, concentration difficulties, and sleepiness, and limb paresthesia. Our previous study indicated that a high MRI T1 signal intensity is well correspond with Mn concentration in the globus pallidus. Accordingly, to clarify the relationship between brain concentration of Mn and neurological signs after prolong welding-fume exposure, non-human primate cynomolgus monkeys were acclimated for a month and assigned to 3 dose groups: unexposed, low dose (31 mg/m³ TSP, 0.9 mg/m³ of Mn), and high dose (62 mg/m³ TSP, 1.95 mg/m³ of Mn). The primates were exposed to manual metal-arc stainless steel welding fumes for 2 hrs per day in an inhalation chamber system equipped with an automatic fume generator for 8 months. The profiles of home cage locomotor activity and its rhythmicity were investigated using a camera system for consecutive days in cynomolgus monkeys. Our results indicated that the home cage locomotor activity increased 5-6 times at 25 and 32 week in the high dose exposed comparing with the unexposed, and the increased locomotor activity was maintained 7 weeks after cessation of welding-fume exposure, but changed to 3 times at 13 weeks after the cessation. Taken together, our results indicated that prolong welding-fume exposure inducing MRI T1 high signal in globus pallidus and increased blood Mn concentration can cause neurobehavioral change in non-human primates.

87 MORPHOLOGICAL AND BEHAVIORAL EVIDENCES THAT INHALED MANGANESE INDUCES A PARKINSON'S DISEASE MODEL.

Manganese is known to produce irreversible damage to the central nervous system in humans and other primates. The mechanism by which this metal injures neurons of the basal ganglia remains unclear. Some reports assume that Mn induces alterations mainly in globus pallidus and substantia nigra pars reticulata, but no experimental information is available about its inhalation, for that reason our goal was to determine if the structures directly involve in Parkinson's disease are affected by Mn inhalation through immunocytochemical and ultrastructural analysis and to correlate those changes with motor performance. CD-1 male mice 35g inhaled 0.04 M MnCl₂ and 0.02 M AcMn₃, one hour twice a week for 38 weeks. Animals were trained on the reaching task and on the beam walking test before the inhalation and evaluated each week after the Mn exposure, then were sacrificed, perfused by intracardiac puncture with saline and fixed with glutaraldehyde and paraformaldehyde. Corpus striatum and substantia nigra pars compacta were processed for electron microscopy and for tyroxine hydroxylase (TH) immunocytochemistry. The animals showed poor performance in both motor tests after Mn inhalation, decreased number of TH-positive cells, necrosis and apoptosis in both substantia nigra and striatum and evident neuropile alterations. Our data provides evidence that Mn inhalation produces similar morphological and behavioral alterations to those observed in Parkinson disease providing a useful experimental model for the study of this neurodegenerative disease.

88 CERULOPLASMIN MEDIATES MANGANESE DISPOSITION AND ALTERS OXIDATIVE STRESS LEVELS IN MANGANESE-TREATED MICE.

T. Jursa and D. Smith. *Environmental Toxicology, UC Santa Cruz, Santa Cruz, CA.*

The protein ceruloplasmin (Cp) is a copper containing ferroxidase that is expressed as a soluble form circulating in plasma and as a GPI-anchored form on the outer surface of membranes in the CNS. Cp is thought to oxidize manganese (Mn) in humans and promote the loading of Mn onto plasma transferrin. Studies have suggested that GPI-anchored Cp in the brain may facilitate cellular iron efflux and modulate extracellular oxidative stress. Transgenic mice deficient in Cp have been shown to accumulate iron in the CNS and exhibit neurodegeneration, consistent with animal and human studies showing that elevated CNS accumulation of transition metals promotes cytotoxicity and neurodegeneration. Here we tested the hypotheses that the Cp mediates the distribution of Mn in peripheral and CNS tissues, alters the levels of oxidative stress associated with Mn toxicity, and mediates motor deficits of Mn toxicity. Wild type and Cp null (Cp -/-) mice were injected with a cumulative dose of 0, 90, or 180 mg/kg of Mn over 4 weeks. Total Mn content of blood and liver was not significantly different between Cp null and wild type mice at any treatment level, but Mn accumulation in brain tissue was greater in the Cp null mice compared to wild type. The 90 mg/kg Mn treatment produced higher levels of lipid oxidation than controls, based on cerebellum TBARS levels, and the Mn-treated Cp nulls had lower TBARS than treated wild type mice. Consistent with this, GSH levels in cerebellum were higher in Mn-treated Cp null versus treated wild type mice. Finally, while Mn treatment caused a reduction in motor activity, this effect was not significantly different between Cp null and wild type mice. The greater oxidative stress apparent in brain tissue of wild type mice than knockouts is consistent with Cp acting as a pro-oxidant, despite the greater Mn amounts present in the brains of Cp null mice. Collectively, these data suggest that Mn-induced oxidative stress in the brain is facilitated by Cp.

89 ANTIOXIDANTS SUPPRESS MANGANESE-INDUCED OXIDATIVE INJURY, ALTERATIONS IN MEMBRANE PERMEABILITY AND ENERGY METABOLISM.

M. Aschner¹, R. C. Gupta², Z. Yin¹, H. Jiang¹ and D. Milatovic¹. ¹Pediatrics, Vanderbilt University Medical Center, Nashville, TN and ²Breathitt Veterinary Center, Toxicology Department, Murray State University, Hopkinsville, KY.

Chronic exposure to manganese (Mn) leads to neurotoxicity (manganism) and is characterized by neuropsychiatric symptomatology that often resembles Parkinson's disease. It is well-established that astrocytes sequester Mn and therefore, protect neurons from Mn-induced neurotoxicity. Although the mechanisms by which Mn induces neuronal cell death are not well defined, its neurotoxicity is regulated by a number of factors, including mitochondrial dysfunction and oxidative injury. We

investigated the mechanisms underlying Mn neurotoxicity and showed that biomarkers of oxidative damage, F2-isoprostanes (F2-IsoPs) were significantly ($p < 0.001$) increased (140%) in rat primary astrocytes exposed to 500 μM MnCl_2 for 30 min. Additionally, primary astrocytes exposed to Mn showed significant ($p < 0.001$) decrease in high energy phosphate (ATP) and mitochondrial membrane potential to 37% and 85% of control, respectively. Finally, Mn-induced alterations in F2-IsoPs, ATP and mitochondrial membrane potential were suppressed when primary astrocytes were pretreated with spin trapping agent, PBN (alpha phenyl-N-tert butyl nitrene) and antioxidants tempol (4-hydroxy-2,2,6,6-tetramethylpiperidinyl-n-oxy) or a hydrophilic vitamin E analog, trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid). The present study established that Mn-induced oxidative stress in astrocytes may indirectly lead to neuronal death and that the effects of Mn toxicity in astrocytes are fully reversed by antioxidants (Supported by NIEHS 007331 and DoD W81XWH-05-0239).

90 GENE EXPRESSION CHANGES IN THE FRONTAL CORTEX OF MANGANESE EXPOSED NON-HUMAN PRIMATES.

N. C. Burton¹, V. Prabhut², K. G. Becker², J. S. Schneider³ and T. R. Guilarte¹. ¹Env Hlth Sciences, Johns Hopkins University Baltimore, MD, ²National Inst. on Aging, NIH, Baltimore, MD and ³Anatomy, Pathology, & Cell Bio, Thomas Jefferson University Philadelphia, PA.

Environmental exposure to high levels of manganese has been associated with a complex neurological syndrome including psychiatric, cognitive, and motor abnormalities. Research has focused on the characterization of manganese-induced deficits in the basal ganglia, which modulates motor activity, but less is known about the effects of manganese in other parts of the brain that could lead to the cognitive and psychiatric sequelae of manganese exposure. In the present study, we have examined gene expression in the frontal cortex in a non-human primate model of manganese exposure. These animals have been shown to express subtle deficits in cognitive and motor function (Schneider et al., Brain Res. 2006) as well as deficits of in vivo striatal dopamine release (Guilarte et al., Exp. Neurol. 2006) and cortical deficits in brain metabolites reflective of neuronal dysfunction (Guilarte et al., Tox. Sci. 2006). Cynomolgous macaques (5-6 years of age) were given i.v. injections of 10-15mg/kg MnSO_4 (n=4) once a week for approximately nine months. Microarray analysis revealed that 61 genes were consistently up-regulated and 4 genes were down-regulated in the frontal cortex of animals exposed to manganese compared to naive control (n=3). We identified clusters of up-regulated genes involved in apoptosis, cholesterol homeostasis, ubiquitin-proteasome function, cell cycle regulation, and inflammation. Interestingly, the most highly up-regulated gene was amyloid beta (A4) precursor-like protein 1, a member of the amyloid precursor protein family that has been associated with the neuropathology of Alzheimer's disease. Our analysis reveals that manganese exposure causes changes in the expression of a network of interconnected genes in the frontal cortex that are involved in neural injury. These results suggest that some of the early gene expression changes in the frontal cortex may be involved in the neurotoxicity of manganese. [supported by ES10975]

91 A POSSIBLE ROLE FOR MITOGEN ACTIVATED PROTEIN KINASE-3/6 IN THE PHOSPHORYLATION OF P38 KINASE IN MICROGLIAL CELLS EXPOSED TO MANGANESE AND LPS.

P. L. Crittenden and N. M. Filipov. CEHS, Basic Sciences, Mississippi State University, Mississippi State, MS.

Manganese (Mn) neurotoxicity resembles many of the features of Parkinson's disease (PD), and it has been suggested that activated microglia are involved in both pathologies. In previous work, we have demonstrated that Mn enhances the production of inflammogen (lipopolysaccharide; LPS)-induced proinflammatory cytokines such as IL-1 β , IL-6, and TNF- α by microglial cells and that the Mn-caused enhancement of LPS-induced cytokine production occurs via a p38-alpha mitogen activated protein kinase alpha (p38 α) and nuclear factor kappa B (NF- κ B)-dependent mechanism. Although exposure to Mn+LPS increased and prolonged p38 α activation, the mechanism of this activation is not understood. In our current study we are examining the mitogen activated protein kinases (MAPK) upstream of p38 α , including the MAPK kinase 3 and 6 (MKK-3/6). N9 microglial cells were exposed to 250 μM Mn, 100 ng/ml LPS, or Mn+LPS for various time periods. At the end of exposure, cell lysates were isolated and examined using western blot analysis with antibodies specific for MKK-3/6. Compared to controls, exposure to Mn, LPS, and Mn+LPS for 1h increased MKK-3/6 phosphorylation, with the greatest effect being observed in the cells exposed to Mn+LPS. Additionally, preliminary data suggest that exposure to Mn+LPS may increase MKK-3/6 phosphorylation as early as 15min. Besides examining the effect of Mn on MKK-3/6 activation in greater detail, future experiments will also focus on other kinases that may

be involved in the phosphorylation of p38 α . As enhanced production of proinflammatory cytokines by microglial cells may cause damage to surrounding cells (i.e. neurons), determining the mechanism of Mn-enhanced proinflammatory cytokine production will increase our understanding of Mn neurotoxicity and similar neuropathologies. (Supported by NIEHS ES11654).

92 MANGANESE-INDUCED ASTROCYTE APOPTOSIS VIA MITOCHONDRIAL-DEPENDENT PATHWAYS.

H. Jiang, Z. Yin and M. Aschner. Pediatric Toxicology, Vanderbilt University Medical Center, Nashville, TN.

Manganese (Mn) is essential for maintaining the proper function and regulation of multiple biological processes, including various antioxidant enzymes, such as superoxide dismutase (Mn-SOD) and glutamine synthetase (GS). Chronic exposure to excessive Mn results in a movement disorder termed manganism, which resembles Parkinson's disease. The pathogenic mechanisms underlying this disorder are not fully understood. Several lines of evidence implicate astrocytes as an early target of Mn neurotoxicity. In the present study, we investigated the hypothesis that cytotoxicity of Mn in astrocytes is mediated via mitochondrial control of apoptosis. Primary astrocyte cultures were prepared from cerebral cortices of one day old Sprague-Dawley rats. Cultures were grown to confluency in minimal essential media (MEM) with Earle's salts supplemented with 10% heat-inactivated horse serum. Cells were treated for 30 min and 1, 2, or 6h with Mn at 0, 100, 500, and 1000 μM . Astrocyte metabolic activity was assessed by lactate dehydrogenase (LDH) leakage into the culture medium. Mn cytotoxicity was determined by measuring the conversion of a tetrazolium salt (3-(4, 5-Dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide, MTT) to a formazan product. The potentiometric dye tetramethylrhodamine ethyl ester (TMRE) was used to assess the effect of Mn on astrocytic mitochondrial membrane potential ($\Delta\Psi\text{m}$). Our results show that Mn-induced a concentration-dependent ($p < 0.05$ by ANOVA) release of LDH into the culture media and MTT reduction. Mn treatment (1 and 6 hrs) significantly ($p < 0.01$) dissipated the $\Delta\Psi\text{m}$ in astrocytes as evidenced by a decrease in mitochondrial TMRE fluorescence. These results suggest that Mn plays a pivotal role in oxidative responses in astrocytes and that mitochondrial-dependent pathway is involved in this response to Mn neurotoxicity.

93 DOPAMINE NEURON DEGENERATION IN C. ELEGANS: IDENTIFICATION OF GENETIC AND CHEMICAL MODULATORS IN A NOVEL MODEL OF PARKINSON'S DISEASE AND MANGANISM.

C. Au^{1,2}, M. Fullard^{2,3,1}, M. Aschner^{2,3,1} and R. Nass^{2,3,1}. ¹Center of Molecular Neuroscience, Vanderbilt University, Nashville, TN, ²Department of Pediatrics, Vanderbilt University, Nashville, TN and ³Department of Pharmacology, Vanderbilt University, Nashville, TN.

Parkinson's disease (PD) and manganism are characterized by motor deficits and dopamine neuron dysfunction, and dopamine or its metabolites are believed to contribute to the disorders. Furthermore, expression of the pre-synaptic protein α -synuclein, and the oxidative stress-induced protein parkin have been proposed to contribute to the pathogenesis of both disorders, and occupational exposure to Mn^{2+} has been invoked to predispose individuals to PD. Despite the initial characterization of these disorders well over a century ago, and intensive research within the past several decades, the origin of the pathogenesis and the molecular determinants involved in PD and manganism have yet to be fully elucidated. A significant hindrance in dissecting the molecular components is the high complexity of the vertebrate brain and lack of facile *in vivo* genetic models to determine and explore the mechanisms involved in the cell death. We have developed a novel pharmacogenetic model using the genetically tractable nematode *C. elegans* to dissect and characterize the molecular components involved in DA neuron degeneration. We show that the DA neurons are sensitive to the PD-associated neurotoxin 6-OHDA and Mn, and cell death likely occurs through a novel pathway. We also show that a number of PD-associated genes contribute to the cell death. We have now instituted genetic and chemical screens for regulators of toxin-mediated cell death, and we have isolated several mutants and compounds that suppress the neurodegeneration. This system will allow us a facile test to examine the role xenobiotics and Mn^{2+} play in the degeneration of DA neurons.

94 BHT PROTECTION OF RAT HIPPOCAMPAL ASTROCYTES FROM MANCOZEB-INDUCED CYTOSKELETAL ALTERATIONS.

M. Tsang and L. D. Trombetta. Pharmaceutical Sciences, St. John's University, New York, NY.

Mancozeb belongs to the subclass of dithiocarbamate pesticides having a metal atom coordinated with ethylene-bis-dithiocarbamate (EBDC). Specifically, it is a polymeric complex of Mn-EBDC with zinc salts. The extreme reactivity of dithiocarbamates have been shown to involve their metal-chelating properties and high

affinity for -SH groups. The effects of manganism are associated with considerable neurological damage. Cecconi et al. (2006) demonstrated that Mancozeb can adversely affect reproduction by perturbing microtubular organization during meiotic maturation. In vitro studies have shown that Mancozeb is considered a prooxidant and has the ability to produce oxidative stress in cells by increasing reactive oxygen species and 8-hydroxy-2'-deoxyguanosine (8-OHdG). Astrocytes play an essential role in protecting neurons since they are equipped with a full range of antioxidant machinery. Previous studies from this lab examining the effects of antioxidants and chelators on Mancozeb-treated astrocytes revealed BHT as a sole protectant against Mancozeb induced cytotoxicity. This investigation further studied the protective role of BHT in Mancozeb-induced cytoskeleton destruction. Rat hippocampal astrocytes were exposed to 7.5 μ M of Mn-Zn dithiocarbamate for an hour at 37 degrees C. The cells were re-fed complete media or media containing 50 μ M BHT. Immunofluorescence and scanning electron microscopy were performed to study cytoskeletal structures. Results showed that BHT partially restored Mancozeb-induced destruction as evidence by immunofluorescent staining with α -tubulin antibody at 4, 8, 12 and 24 hr post-treatment. Scanning electron microscopy of cytoskeletal preparations at 8 hr post-treatment also revealed the protective effects of BHT on actin sheets, intermediate filaments and microtubules. Antioxidant data indicated that BHT significantly increased ($p < 0.05$) antioxidant activity within the cells.

95 **ROLE OF GLYCOLYSIS IN DIFFERENTIAL RESPONSE OF NON-DIFFERENTIATED (ND) AND DIFFERENTIATED (D) PC12 CELLS EXPOSURE TO MN, MPP+ AND ROTENONE.**

L. T. Russell IV, A. Elnabawi and K. Squibb. *Epidemiology and Preventative Medicine, University of Maryland School of Medicine, Baltimore, MD.*

Exposure to Mn, MPP+ and rotenone (Rot) cause Parkinson symptoms in humans and other primates by affecting dopaminergic neurons. The PC12 cell system is a neoplastic dopaminergic cell line with a high rate of glycolysis accompanied by a high lactate production and low use of glucose carbon through the Krebs cycle. MPP+ and Rot target complex I in mitochondrial respiration and elicit less cytotoxicity in cells using a high rate of glycolysis as their primary energy pathway. Previous studies have shown that MPP+ has greater toxicity in DPC12 cells compared to NDPC12, and that a high rate of glycolysis reduces the cytotoxicity of MPP+ on NDPC12 cells. This study examines the role of glycolysis on the toxicity of Mn, MPP+ and Rot in DPC12 and NDPC12 cells. Glycolysis was inhibited by using glucose free media and iodoacetic acid (IAA) exposure prior to treatment with neurotoxins. Cytotoxicity studies revealed Mn was toxic in both PC12 cell types following 24, 48 and 72 hrs exposure compared to MPP+ and Rot which were both toxic only in DPC12 cells and only at 48 and 72 hrs. The EC50s for Mn in NDPC12 cells were 6.1 mM, 1.8 mM and 1.2 mM at 24, 48 and 72 hrs, respectively, and in DPC12 cells 25.0 mM and 6.4 mM at 48 and 72 hours. The EC50 for MPP+ in DPC12 cells was 120 μ M at both 48 and 72 hrs and for Rot 500 nM at 24 hr and 30 nM at 48 and 72 hrs. Glycolysis inhibition by IAA revealed NDPC12 and DPC12 cells are equally sensitive, but NDPC12 cells show significantly greater ($p < 0.05$) sensitivity to glucose free media. In both NDPC12 and DPC12 cells, cytotoxicity of Mn, MPP+ and Rot was significantly increased ($p < 0.05$) during glycolysis inhibition. The results suggest that cell differentiation status and glycolysis use are involved in PC12 cell susceptibility to neurotoxins.

96 **CONTROL OF THE LATERAL CILIATED GILL EPITHELIUM OF *CRASSOSTREA VIRGINICA* AND *MYTILUS EDULIS* (BIVALVIA) AND THE NEUROTOXIC EFFECTS OF MANGANESE.**

K. Martin¹, J. Robinson², A. Crawford¹, T. Huggins¹, M. A. Carroll¹ and E. J. Catapano¹. ¹Biology, Medgar Evers College, Brooklyn, NY and ²Biology, Kingsborough Community College, Brooklyn, NY. Sponsor: A. Villalobos.

Lateral cilia of gill of *Mytilus edulis* is known to be controlled by a reciprocal serotonergic-dopaminergic innervation from their ganglia. Other bivalves have been studied to lesser degrees, and lateral cilia of most respond to serotonin and dopamine when applied directly to gill, indicating a possible neuro or endocrine mechanism. Lateral cilia in *Crassostrea virginica* are affected by serotonin and dopamine, but little work has been done with respect to ganglionic control of cilia. Presently we examined the role of the cerebral and visceral ganglia in innervating lateral gill cilia of *C. virginica* and *M. edulis*. Ciliary beating rates were measured by stroboscopic microscopy of gill preparations which had ipsilateral cerebral and visceral ganglia attached. Superfusion of gill with serotonin increased ciliary beating rates. This response was antagonized by pretreating with methysergide. Superfusion with dopamine decreased beating rates and this was antagonized by ergonovine. Furthermore, superfusion of the cerebral ganglion or visceral ganglion with serotonin increased ciliary beating rates which was antagonized by pretreating with

methysergide. Superfusion with dopamine decreased beating rates and this was antagonized by ergonovine. Acute treatment with 1 mM manganese, a neurotoxin known to induce Manganism, a Parkinson's-like Disease in humans, reduced the cilio-inhibition caused by dopamine, which is in agreement with the method of action of manganese in humans. This study demonstrates there is a reciprocal serotonergic-dopaminergic innervation of the lateral gill ciliated cells of *C. virginica* which originates in the cerebral ganglion of the animal, similar to that of *M. edulis*, and this preparation is useful as a model to study manganese neurotoxicity and the pharmacology of drugs affecting it and biogenic amines.

97 **NEUROTOXIC EFFECTS OF MANGANESE ON BIOGENIC AMINES OF THE NERVOUS SYSTEM AND INNERVATED ORGANS OF *CRASSOSTREA VIRGINICA*.**

S. Murray¹, D. Lecky², C. King², A. Lovell², M. A. Carroll² and E. J. Catapano². ¹Biology, Kingsborough Community College, Brooklyn, NY and ²Biology, Medgar Evers College, Brooklyn, NY. Sponsor: A. Villalobos.

Manganese is a neurotoxic substance which induces Manganism, in individuals exposed to high airborne levels or ingesting high concentrations. Manganism occurs because too much manganese injures dopaminergic neurons in the brain. *Crassostrea virginica* is identified by the EPA as a test animal for studying marine pollutants. It possesses a simple nervous system with monoaminergic neurons. We studied if acute exposure of *C. virginica* to manganese results in increases in tissue levels of manganese and decreases in biogenic amine levels. Oysters were exposed to 1 mM and 10 mM manganese by maintaining them in containers of artificial sea water at 18°C for 3 days, and metal levels were determined by Atomic Absorption Spectrophotometry using electrothermal vaporization with deuterium lamp background correction in a Perkin Elmer AA800 Atomic Absorption spectrophotometer with a THGA graphite furnace. Biogenic amines were measured by HPLC with fluorescence detection using a Beckman HPLC system with a Phenomenex Gemini 5 μ C18 column and a Jasco FP 2020 Spectrofluorometer. Manganese was distributed in the tissues of untreated animals in μ g/g dw amounts, with palps and gill having the highest. Treated animals accumulated about a 10 fold increase in manganese in the tissues. The 1mM manganese treatment caused statistically significant reductions in dopamine levels in both the cerebral and visceral ganglia (77% and 74% respectively) and both gill and palps (79% and 63% respectively), but no changes in the levels of norepinephrine, octopamine or serotonin. The results are consistent with reported mechanisms of action of manganese in human and mammalian systems and shows marine invertebrates can be damaged by high environmental levels of manganese and *C. virginica* is a suitable test animal to further study neurotoxic actions of manganese and related agents.

This work was supported by grants 0516061071 of the CSTEP Program of the NYS Dept. of Education, 678760036 of PSC/CUNY and 1R25GM62003 of NIGMS

98 **PROTECTIVE EFFECTS OF VERAPAMIL ON MERCURY TOXICITY IN *C. ELEGANS*.**

L. Koselke, C. Sam, R. Hajela and B. Atchison. *Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

The free living soil nematode *C. elegans* has become an important model as an indicator of environmental contamination in soil and water. Specific cells and their lineage can be traced in the whole animal throughout development and into adulthood permitting analysis of effects of toxicant on individual cells. We are attempting to optimize the *C. elegans* model for studies on neurotoxicity of mercurials in attempts to facilitate studies of chronic and developmental effects of these neurotoxins on specific neurons in the whole organism. Mercurials, especially methylmercury (MeHg) impair neurodevelopment. Some of their effects are thought to be due to Ca^{2+} channels and perturbation of $[Ca^{2+}]_i$. We established a lethality index for MeHg and $(HgCl_2)$ and tested for protection by the Ca^{2+} channel blocker verapamil on cytotoxicity. Worms feeding on saturating liquid cultures of *E. coli* were exposed to varying concentrations of MeHg and $HgCl_2$ for 48 hrs. At that time motile (live) vs immotile (dead) worms were counted using motility as an index of viability. Over the concentration range of 0.25 - 10 μ M and 10-70 μ M for MeHg and Hg^{2+} , respectively there was a concentration-dependent increase in lethality. Treatment with 20 μ M MeHg and 70 μ M $HgCl_2$ caused > 90% lethality in wildtype (N2) *C. elegans* and a strain KC136 expressing green fluorescent protein under control of a heat shock gene promoter. Worms were then exposed to 70 μ M $HgCl_2$ in the presence of varying concentrations of the L-type Ca^{2+} channel blocker verapamil for 48 hrs. Simultaneous treatment with 50 μ M verapamil resulted in reduction of lethality by $HgCl_2$, to 20%. This suggests that Hg^{2+} induced mortality in *C. elegans* is mediated by pathways associated with membrane Ca^{2+} channels. The work was supported in part by NIH grants R01ES116622 and R21ES01457. L. Koselke was supported by an ASPET Summer Research Fellowship.

99 DIFFERENTIAL EFFECTS OF Ca^{2+} CHANNEL α_1 SUBUNITS ON METHYLMERCURY-INDUCED CHANGES IN $[\text{Ca}^{2+}]_i$ IN HEK293 CELLS.

E. M. Sparkenbaugh, D. Atchison, R. Hajela and B. Atchison. *Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

Methylmercury (MeHg) disrupts Ca^{2+} homeostasis in a biphasic manner in rat cerebellar granule cells. The 1st phase is due to release of intracellular Ca^{2+} , and the 2nd to Ca^{2+} influx through nifedipine and ω -conotoxin-MV1IC-sensitive pathways, suggesting a role for the L-, N- and P/Q-type Ca^{2+} channels (VGCC). To investigate the role of these individual VGCC subtypes directly, HEK293 cells were cotransfected with a constant VGCC $\alpha_{2\delta}$ and β subunit, and either α_{1A} , α_{1B} , or α_{1C} subunits, corresponding to P/Q-, N-, and L-type VGCCs, respectively. The Ca^{2+} -sensitive fluorophore fura-2 and cell imaging was used to examine the effect of in vitro exposure to MeHg on Ca^{2+} homeostasis. In WT cells, which express no VGCCs, 1.0 μM MeHg caused a transient increase in $[\text{Ca}^{2+}]_i$ after 68 ± 17 sec (mean $\pm$ SEM). In cells transfected with VGCC, MeHg induced a biphasic increase in $[\text{Ca}^{2+}]_i$, consistent with data in rat cerebellar granule cells. At 1 μM MeHg, the 1st and 2nd phases occurred at 114 ± 22 and 686 ± 107 sec (α_{1B}) and 204 ± 42 and 863 ± 160 sec (α_{1C}). At 2.5 μM MeHg, 1st and 2nd phases occurred at 170 ± 30 and 689 ± 49 (α_{1A}), 28 ± 1.6 , and 270 ± 57 (α_{1B}) and 100 ± 30 and 560 ± 110 sec (α_{1C}), respectively. Thus cells with α_{1B} respond to MeHg more quickly, and MeHg may prefer to enter the cell through N-types VGCCs. When Ca^{2+} was removed, the 2nd increase in $[\text{Ca}^{2+}]_i$ was prevented. Additionally, cells expressing α_{1C} channels were exposed to 10 μM nifedipine for 5 min before and during exposure to 2.5 μM MeHg with 2 μM Ca^{2+} . Nifedipine did not affect the time-to-onset of the 1st phase but abolished the 2nd. These support further that the 2nd phase is due to Ca^{2+} influx through VGCC, and that MeHg disrupts Ca^{2+} homeostasis by inducing Ca^{2+} release from intracellular stores and extracellular influx. Ca^{2+} can reach cytotoxic levels within the cell and activate signal transduction cascades that lead to cell damage and death. Supported by NIH grant ES03299.

100 BOTH RYANODINE RECEPTOR-SENSITIVE AND INSENSITIVE INTRACELLULAR Ca^{2+} POOLS PLAY A ROLE IN METHYLMERCURY (MeHg)-INDUCED INITIAL STIMULATION OF SPONTANEOUS INHIBITORY SYNAPTIC CURRENTS.

W. D. Atchison and Y. Yuan. *Pharmacology/Toxicology, Neuroscience Program, Michigan State University, East Lansing, MI.*

We have previously shown that the time to onset of MeHg-induced change in $[\text{Ca}^{2+}]_i$ in the entire molecular layer and granule cells in cerebellar slices appears to be correlated to the time to onset of initial increases in frequency of spontaneous inhibitory synaptic currents (sIPSCs) recorded from Purkinje cells. In addition, pretreatment of slices with caffeine, a ryanodine receptor opener, or cyclopiazonic acid (CPA), an inhibitor of smooth endoplasmic reticulum (SER) Ca^{2+} -ATPase, markedly reduced MeHg-induced increases in $[\text{Ca}^{2+}]_i$ in both molecular and granule layers in cerebellar slices. To determine further if these treatments are also effective at reducing or preventing MeHg-induced initial stimulation of spontaneous release of inhibitory neurotransmitter, effects of caffeine and CPA on sIPSC frequency of Purkinje cells in cerebellar slices were examined using whole cell current recording techniques. Consistent with previous findings of confocal Ca^{2+} imaging, pretreatment of slices with 5 - 10 mM caffeine or 10 - 25 μM CPA apparently reduced MeHg-induced increase in sIPSC frequency in Purkinje cells. However, both treatments failed to alter the general pattern of effects of MeHg on sIPSC frequency i.e. MeHg initially stimulates and subsequently suppresses sIPSC frequency. Neither caffeine nor CPA pretreatment significantly changed the time courses of effects of MeHg on sIPSC frequency and amplitudes. These results suggest that Ca^{2+} release from both ryanodine receptor-sensitive and SER intracellular Ca^{2+} pools play a role in MeHg-induced increase in $[\text{Ca}^{2+}]_i$ and the frequency of sIPSCs, although other Ca^{2+} sources or mechanisms may also contribute to the early stimulatory effects of MeHg on spontaneous transmitter release. Supported by NIH grants R01ES03299 and R01ES11662.

101 DISRUPTION OF INTRACELLULAR CALCIUM REGULATION IN A MOTORNEURON CELL LINE-NSC34 BY METHYLMERCURY.

C. Dupré, K. Osterlund, R. Hajela and B. Atchison. *Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

Environmental effects have been postulated to contribute to the onset of the sporadic form of amyotrophic lateral sclerosis (ALS). Among the environmental factors proposed as potentially contributory, are neurotoxic metals such as Pb and Hg. The prospective role of these metals in ALS has never been tested directly. We are attempting to determine whether chronic exposure to Hg can enhance excitotoxicity

in spinal motoneurons. As a 1st step in this, we tested the effect of acute exposure of a neuroblastoma motoneuron cell line -NSC34- to methylmercury (MeHg), the most prominent environmental form of Hg exposure. The Ca^{2+} indicator fura-2 and single cell fluorescence imaging was used to examine the effect of *in vitro* exposure to MeHg on Ca^{2+} . Over the range of 0.5-2 μM , MeHg induced a biphasic increase in fura fluorescence. The two phases frequently were separated by a plateau phase. Times to onset of 1st and 2nd phases were MeHg-concentration-dependent - 80, 120 and 220 sec respectively at 0.5, 1 and 2 μM , for the 1st phase, and 590, 640 and 800 sec for 2nd phase. The total increase in fluorescence ratio and rate of rise of fluorescence during the initial phase of the increase were both also MeHg concentration-dependent. Concomitant treatment with the Na^+ channel activator veratridine (30 μM) and 1 μM MeHg was used to depolarize the cell and potentially increase the rate of entry of MeHg. Veratridine did not affect the time of onset of either phase of increased $[\text{Ca}^{2+}]_i$, but did speed up the rate of rise of fluorescence at 1 μM MeHg. Thus in a spinal motoneuron cell line, exposure to MeHg induces changes in $[\text{Ca}^{2+}]_i$ consistent with those seen in native neurons, so the NSC-34 cell line should be an acceptable model system for further studies of effects of chronic exposure to MeHg. Supported by NIH grant R21ES01457. C. Dupré was supported by a Summer Research Fellowship from ASPET.

102 METHYLMERCURY-INDUCED APOPTOSIS BY MITOCHONDRIA-DEPENDENT PATHWAY IN RAT PRIMARY ASTROCYTE CULTURES.

Z. Yin, D. Milatovic, R. Lu, H. Jiang and M. Aschner. *Pediatric Toxicology, Vanderbilt University Medical Center, Nashville, TN.*

Methylmercury (MeHg) preferentially accumulates in astrocytes. Mitochondrial dysfunction is a prominent feature of MeHg-induced cell death, leading us to test the hypothesis that MeHg affects critical pathways in these organelles. Primary astrocyte cultures were prepared from cerebral cortices of one day old Sprague-Dawley rats. Cultures were grown to confluency in minimal essential media (MEM) with Earle's salts supplemented with 10% heat-inactivated horse serum. Cells were treated for 0.5, 1, 2, 6, 12, or 24 h with MeHg at 0, 1, 5, and 10 μM . Cytotoxicity was evaluated by lactate dehydrogenase (LDH) leakage into the culture medium and proteins were collected for immuno-blotting analysis. The potentiometric dye tetramethylrhodamine ethyl ester (TMRE) was used to probe mitochondrial membrane potential ($\Delta\psi_m$). Our studies show that MeHg induced significant LDH release into the culture media in a concentration-dependent manner ($p < 0.05$ by ANOVA); MeHg treatment also resulted in significant activation of astrocyte phosphorylated extracellular signal-regulated kinase (p-ERK) ($p < 0.05$), peaking at 30 min and sustained through 6 hrs of exposure. MeHg also markedly increased apoptosis-inducing factor (AIF) expression ($p < 0.05$) and the effect was maintained for 24 hrs. MeHg treatment (1 and 6 hrs) significantly ($p < 0.01$) dissipated the $\Delta\psi_m$ in astrocytes as evidenced by a decrease in mitochondrial TMRE fluorescence. These studies are consistent with the hypothesis that MeHg exerts its effect via oxidative stress, and that its toxicity is associated, at least in part, with the dissipation of astrocytic mitochondrial membrane potential and activation of apoptotic cascades. These results suggest that early activation of ERK and AIF is involved in MeHg-induced neurotoxicity via mitochondrial-dependent pathways in astrocytes.

103 IN UTERO EXPOSURE TO METHYLMERCURY CAUSES DELAYED CHANGE IN MITOCHONDRIAL MEMBRANE POTENTIAL OF EARLY POSTNATAL MOUSE CEREBELLAR GRANULE CELLS.

K. A. Thuett, D. Ghandi, T. Kannadan and L. C. Abbott. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

Methylmercury (MeHg) is a neurotoxicant that affects both adult and developing brains. Our lab has previously shown that chronic low doses of MeHg cause a decrease in mitochondrial membrane potential (MMP) in adult mouse cerebellar granule cells (CGC). In addition, MMP was also decreased in human SH-SY5Y cells used as a neuronal developmental model system, when exposed to chronic low doses of MeHg. Therefore, in the current study, we exposed pregnant C57BL/6J mice to a total MeHg dose of 0.3 $\mu\text{g}/\text{kg}$ or 1.0 mg/kg body weight over a 10-day period from gestational day 8 to 18. CGC from newborn pups at postnatal (P) day 0 and P10 were analyzed for MMP using tetramethyl rhodamine methylester (TMRM) dye and fluorescence microscopy. No difference in MMP was observed in non-treated CGC between P0 and P10. MMP was different among treatments at P10; MMP at 0.3 μg was less than that for controls, and MMP at 1.0 mg was greater than that for controls. In addition, MMP at 0.3 μg was decreased at P10 compared to P0, and MMP at 1.0 mg was increased at P10 compared to P0. These data indicate that *in utero* MeHg exposure has a delayed affect on MMP of CGC,

that can be observed by P10. The increase in MMP in P10 cells at 1.0 mg may be a result of the need for increased cell activity to compensate for the effects of MeHg neurotoxicity. This research was funded in part by CERH NIEHS Grant #P30ES09106 to LCA.

104 METHYLMERCURY (MeHg) CAUSES A BIPHASIC EFFECT ON SPONTANEOUS SYNAPTIC CURRENTS IN LAYERS II/III AND IV NEURONS IN VISUAL CORTEX SLICES OF RAT.

Y. Yuan, *Pharmacology/Toxicology, Neuroscience Program, Michigan State University, East Lansing, MI.*

One of the most conspicuous and consistent findings in MeHg-induced neurological disorders in humans and animals following acute and chronic MeHg exposure is disturbance of visual function. Pathological evidence suggests that lesions in the visual cortex are primarily responsible for MeHg-induced visual functional deficits. To characterize the effects of MeHg on visual synaptic transmission, we examined *in vitro* acute effects of MeHg on spontaneous synaptic responses in layers II/III and IV neurons in visual cortex slices of rat using whole cell voltage-clamp recording technique. At 10 -100 μ M, MeHg initially stimulated and subsequent suppressed both the frequency and amplitudes of glutamate receptor-mediated spontaneous excitatory postsynaptic currents (sEPSCs) in layer II/III pyramidal neurons and layer IV nonpyramidal neurons. Times to onset of stimulation and suppression of sEPSCs were MeHg concentration-dependent. Similar pattern of effects of MeHg on GABAergic spontaneous inhibitory postsynaptic currents (sIPSCs) was also observed in these neurons. Thus, consistent with its effects on synaptic function in other brain slice preparations such as cerebellar slices, MeHg may also act at both pre- and postsynaptic sites to affect synaptic transmission in the visual cortex slices. These results again suggest that mechanisms underlying the effects of MeHg *in vitro* on spontaneous synaptic responses are generally similar. Supported by NIH grant 5R21ES013767-02 and MSU funding 06-HBRI-II-616.

105 TROLOX, A VITAMIN E DERIVATIVE, PROTECTS AGAINST PERSISTENT NEUROBEHAVIORAL DISRUPTION INDUCED BY NEONATAL METHYLMERCURY EXPOSURE.

M. A. Cheh¹, A. K. Halladay², K. Reuhl², M. Polunas², X. Ming⁴ and G. C. Wagner^{3,1}, ¹*Neuroscience, Rutgers University-UMDNJ, New Brunswick, NJ*, ²*Pharmacology & Toxicology, Rutgers University, New Brunswick, NJ*, ³*Psychology, Rutgers University, New Brunswick, NJ* and ⁴*Neuroscience, Rutgers University-UMDNJ, Newark, NJ.*

Methylmercury (MeHg) is a neurotoxicant that poses a potential health risk to humans, particularly when exposure occurs during neural development. Antioxidants protect against MeHg-induced toxicity *in vivo* and *in cell culture*. However, the protective effect of antioxidants on long-term behavioral function following early MeHg exposure has not been well studied. We examined whether Trolox (6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid), a water soluble vitamin E derivative, would ameliorate MeHg-induced disruptions of a number of behavioral measures in mice. Mice received 4 mg/kg MeHg or vehicle on alternate days from postnatal days 3-15. Some mice were pretreated with 2.5 mg/kg or 1 mg/kg Trolox sc 1 hr prior to each MeHg administration. Body weight, reflex development, spatial learning, and social interaction/aggression were examined beginning in early postnatal life through 3-4 months of age. MeHg treatment resulted in decreased weight gain and a defective mid-air righting reflex. Treated mice showed poorer spatial learning performance in the water maze as adolescents. Increased aggressive behavior and reduced social investigation were also observed in MeHg treated mice in the resident-intruder paradigm at 3-4 months of age. Trolox pretreatment attenuated the MeHg-induced reduction in weight gain and the mid-air righting deficit in a dose-related fashion. Trolox also reduced learning deficits observed in the water maze, with the higher dose showing superior protection. Finally, 2.5 mg/kg Trolox completely prevented the increase in aggressive behavior and decrease in social investigation in adult mice elicited by early MeHg exposure. These data indicate that Trolox offers significant protection against long-term MeHg-induced neurobehavioral deficits.

106 SELENIUM'S PROTECTION AGAINST METHYLMERCURY. CHRONIC EXPOSURE TO MEHG WHILE ON HIGH OR LOW SELENIUM DIET TO TEST HYPOTHESIS THAT SELENIUM BLOCKS MEHG NEUROTOXICITY.

J. C. Heath, E. Pesek and M. C. Newland, *Auburn University, Auburn, AL.*

Chronic exposure to at least 5 ppm of MeHg produces a constellation of neurological signs indicative of sensory and motor dysfunction. Selenium has been shown to protect against some of these signs in short-duration, high-dose experiments but lit-

tle is known about dose or time-related protection in long-term experiments. Female rats were exposed chronically to methylmercury via drinking water containing 0, 0.5 or 5 ppm of Hg as MeHg, producing an estimated 0, 40, or 400 μ g/kg/day of Hg, while consuming a purified diet containing 0.06 or 0.6 ppm of Se (as sodium selenite) for more than a year. The rats were tested every two to three months for sensitivity to tail pinch, the appearance of hind-limb cross (clasp reflex) and limb flexion, grip strength, and overnight activity in a running wheel. This formed a 2 (lifespan diet) X 3 (chronic MeHg) X N (repeated testing) factorial design. Grip strength and sensory function diminished with age, this loss was accelerated by MeHg exposure and the loss was attenuated by dietary selenium. Selenium delayed but did not prevent the appearance of hind-limb cross and flexion. Selenium did not prevent MeHg's effects on running but did ameliorate changes seen with aging. Selenium confers protection against some overt neurological signs of chronic, moderate-to-high dose MeHg exposure [Supported by NIH ES 10865]

107 "LOW-RATE CHALLENGES" IN RATS EXPOSED DEVELOPMENTALLY TO METHYLMERCURY AND SELENIUM.

M. Newland¹, J. Heath¹ and W. D. Donlin², ¹*Auburn University, Auburn University, AL*, ²*Auburn University, Auburn, AL* and ³*Johns Hopkins University, Baltimore, MD.*

Developmental exposure to methylmercury produces response perseveration and disrupted sensitivity to reinforcing consequences. High-rate behavior in adulthood may be especially sensitive to developmental MeHg exposure. We examined MeHg's effects on the acquisition and persistence of high-rate behavior. Female rats were exposed *in utero* to methylmercury via maternal exposure to drinking water containing 0, 0.5 or 5 ppm of Hg as MeHg, producing an estimated 0, 40, or 400 μ g/kg/day of Hg. The rats' mothers also consumed a purified diet containing 0.06 or 0.6 ppm of Se (as sodium selenite), and the offspring continued these diets throughout life. This formed a 2 (lifespan diet) X 3 (developmental MeHg) factorial design. As adults, the offspring acquired lever-pressing under two schedules of reinforcement designed to maintain high-rates of lever-pressing. A differential reinforcement of high-rate (DRH) schedule imposed a rigid, unchanging response requirement. A Percentile schedule also reinforced high-rate behavior but constantly adjusted the response requirement according to recent performance. Responding under each schedule could be described by bouts of high-rate (2-5 rs/sec) responses separated by 2-20 sec pauses. Acquisition of responding and the result of "low-rate challenges," in which low rates of lever pressing were reinforced, were examined. Developmental methylmercury exposure promoted the acquisition of high-rate responding and tended to produce higher response rates during steady-state performance. When rats were abruptly required to respond at low, rather than high, response rates, exposed rats showed considerable difficulty, compared to controls, in adjusting to the low-rate challenge. They required many sessions to achieve steady state and continued to respond at higher response rates than controls. Dietary selenium did not influence MeHg's effects. This extends to high-rate operant behavior the phenomenon of perseveration previously reported using choice procedures. [Supported by NIH ES 10865]

108 MODIFICATION OF BASAL AND DEXAMETHASONE-INDUCED SUPPRESSION OF CORTICOSTERONE LEVELS IN FEMALE OFFSPRING EXPOSED TO MATERNAL LEAD EXPOSURE, MATERNAL STRESS OR THE COMBINATION.

M. Virgolini, A. Rossi-George, R. Lisek, D. Weston and C. A. Deborah, *Environmental and Occupational Medicine, Environmental and Occupational Health Sciences Institute, University Med. Dent New Jersey, Piscataway, NJ.*

Prior experimental studies from our laboratory demonstrate that maternal Pb exposure permanently alters basal and stress-induced corticosterone levels in both male and female offspring. To evaluate the role of negative feedback inhibition of corticosterone as a mechanism of these effects, the ability of the synthetic glucocorticoid dexamethasone (DEX) to suppress corticosterone levels (DEX suppression test, 0, 10 or 15 mg/100g i.p.) over time was examined in adult female offspring subjected to either maternal Pb exposure (0, 50 or 150 ppm initiated 2 mos prior to breeding and continuing through lactation; corresponding mean blood Pb of <2, 12 and 30 μ g/dl, respectively), maternal restraint stress (45 min restraint, 3x per day on gestational days 16-17) or both. Maternal Pb alone notably delayed the post-injection reduction in corticosterone. Maternal stress interacted with maternal Pb exposure. Specifically, in controls, maternal stress delayed the post-injection reduction in corticosterone, but the blunting of the corticosterone response by DEX was equivalent in both normal and maternal stress offspring, with dose-related reductions peaking

4 hrs post DEX and returning to control levels at 8 hr. In contrast, DEX suppression showed a blunted pattern in response to combined maternal Pb and maternal stress at all 3 time points post-injection, particularly at 50 ppm. Thus, both maternal Pb and maternal stress alone reduce negative feedback inhibition in the HPA axis, and combined maternal Pb and maternal stress increases resistance to control of corticosterone feedback. Given that DEX appears to be mediated by its actions on the pituitary, these findings suggest a peripheral mode of action of Pb that can impact CNS functions. ES012712.

109 BEHAVIORAL CONSEQUENCES OF CONTINUOUS LEAD EXPOSURE COMBINED WITH MATERNAL AND OR OFFSPRING STRESS.

A. Rossi-George, M. Virgolini, R. Lisek, D. Weston and D. A. Cory-Slechta. *Environmental and Occupational Medicine, Environmental and Occupational Health Sciences Institute, University Med. Dent New Jersey, Piscataway, NJ.*

Pb exposures are highest in low socioeconomic status populations that are also thought to experience the highest levels of environmental stress. Our prior studies confirm permanent alterations in baseline fixed interval (FI) performance and its alteration following stress challenges in response to maternal Pb, maternal stress and their combination. The current study extended these observations to an experimental model that would most closely approximate human parameters of these risk factors. Dams were exposed to 0, 50 or 150 ppm Pb in drinking water, maternal restraint stress, or both. Offspring were continued on the same Pb exposure as the dam, and a subset were also subjected to offspring stress challenges. Mean blood Pb values of offspring ranged from <2, 11-12 and 27-29 $\mu\text{g/dl}$, respectively with slightly elevated levels for males and for those subjected to offspring stress. Performance on an FI schedule of food reinforcement, a baseline with known sensitivity to Pb exposure, was examined over time, including sessions preceded by one of three different stress challenges (restraint, cold, novelty). Behavioral consequences were more pronounced in females than males, with significant increases in FI response rates across behavioral session in the groups exposed to Pb alone or Pb combined with either maternal or maternal +offspring stress, whereas only marginal increases occurred in the 0 ppm maternal or 0 ppm maternal + offspring stress groups. These changes were largely attributable to increased run rates and decreased inter-response times, with postreinforcement pause times not systematically affected. Similar trends were evident in males, but restricted to the 50 and 150 ppm + maternal stress groups. These findings confirm that stress can enhance the behavioral toxicity of Pb even at very low blood Pb levels and highlight a preferential vulnerability of females to these effects. ES012712

110 DEFICITS IN EXTINCTION OF CONDITIONED FEAR IN LEAD-EXPOSED YOUNG ADULT RATS.

J. L. McGlothlin, M. Karcz-Kubicha and T. R. Guilarte. *Environmental Health Sciences, Johns Hopkins University School of Public Health, Baltimore, MD.*

Pavlovian fear conditioning is a model of emotional learning in which a neutral stimulus such as a tone is paired with an aversive stimulus such as foot shock. Presentation of a tone with a foot shock in a context (test box) elicits a freezing response representative of stereotypic fear behavior. Daily presentation of the context (test box) in the absence of the conditioned (tone) and unconditioned stimulus (shock) causes extinction of the fear response. Rats chronically exposed to environmentally relevant levels of lead (Pb^{2+}) and controls were tested in a contextual fear (CF) paradigm at 50 days of age (PN50). Littermates to CF rats received an immediate shock (IS) when placed in the test box with no tone or were placed in the test box with no tone or shock (naïve). Blood Pb^{2+} levels in control and Pb^{2+} -exposed animals were (mean $\pm$ sem): 0.76 ± 0.11 ($n=15$) and 25.8 ± 1.28 $\mu\text{g/dL}$. Freezing behavior was recorded during acquisition or during 4 consecutive extinction days. Control and Pb^{2+} -exposed CF rats exhibited the same level of freezing time in the acquisition day. No freezing behavior was measured in IS or naïve rats regardless of treatment. Presentation of context 24 hrs later produced an enhanced freezing response on both control and Pb^{2+} -exposed-CF rats but not in IS or naïve. When tested in the extinction phase, Pb^{2+} -exposed-CF rats exhibited deficits in extinction compared to control-CF rats. That is, when presented with context on 4 consecutive days after acquisition of the fear response, Pb^{2+} -exposed-CF rats exhibited a greater freezing response than control-CF rats. These findings indicate that chronic Pb^{2+} exposure produces a deficit in extinction learning and the animals remain more fearful than controls. Since long-term retention of extinction involves a transfer from NMDA receptor-independent to NMDA receptor-dependent memory (Santini et al., J. Neurosci. 21, 9009, 2001), our present findings add additional evidence that Pb^{2+} -exposed rats have deficits in NMDA receptor-dependent memory [supported by grant ES06189 to TRG].

111 EFFECTS OF LEAD EXPOSURE ON SYNAPTIC TARGETING OF NMDA RECEPTOR SUBUNITS AND SIGNALING PATHWAYS IN RAT HIPPOCAMPAL NEURONS.

A. P. Neal and T. R. Guilarte. *Env Hlth Sciences, Johns Hopkins University Baltimore, MD.*

Lead (Pb^{2+}) exposure in children and in animal models produces deficits in cognitive function and synaptic plasticity. In animals, Pb^{2+} -induced deficits in spatial learning and long-term potentiation in the hippocampus have been attributed to alterations in the expression of NMDA receptor subunits and NMDA receptor composition at the cellular level. However, information on the effects of Pb^{2+} exposure on the expression of NMDA receptor subunits at the synaptic level and their effects on downstream signaling pathways is lacking. In the present study, we used immunohistochemistry and integrated morphometric analysis to examine the effects of Pb^{2+} exposure on the number of dendritic spines expressing different NMDA receptor subunits and their synaptic targeting in primary cultures of rat hippocampal neurons. Neurons at 14 days *in vitro* were exposed for 5 days to 0.0, 0.01, 0.1 and 1.0 μM Pb^{2+} -acetate. The data indicates that the number of puncta per unit length of dendrite labeled with NR1 or NR2A subunits was significantly increased by the Pb^{2+} exposure with no change in NR2B labeled puncta. At the lowest concentration of Pb^{2+} tested, there was an increase in the co-localization of the NR2A subunit with the postsynaptic density protein PSD-95 but decreased co-localization of the NR2B subunit. No significant change was measured on the co-localization of NR1. We also examined the functional consequences of these changes by assessing the level of CREB and ERK phosphorylation (p). Under non-stimulated conditions, Pb^{2+} -exposure produced a significant decrease in both pCREB and pERK in hippocampal neurons. Further, using a protocol that increases synaptic activity, Pb^{2+} -exposure produced a dose-dependent decrease in pCREB and a general increase in pERK relative to the control condition. These data indicate that chronic exposure of hippocampal neurons to Pb^{2+} results in significant changes in NMDA receptor subunit composition and targeting to the synapse altering activity-dependent changes in nuclear pCREB and pERK [ES06189 to TRG]

112 LIFETIME EXPRESSION PROFILE OF THE AMYLOID PRECURSOR PROTEIN IN BOTH THE BRAIN AND BLOOD OF DEVELOPMENTALLY Pb-EXPOSED MICE.

R. S. Dosunmu, R. M. Basha and N. H. Zawia. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Alzheimer's disease is a neurodegenerative disease hallmarked by senile plaques composed of Amyloid-beta ($\text{A}\beta$) protein aggregates. Definitive diagnosis is achieved through post-mortem examination of brain tissue, therefore utilizing $\text{A}\beta$'s precursor, the Amyloid Precursor Protein (APP), as a potential biomarker allows one to follow disease progression and/or the effects of treatment. Our lab has previously shown that lead (Pb) exposure alters APP expression in the brain by inducing transcriptional up-regulation, initiating an increase in APP leading to a rise in $\text{A}\beta$. However, it is not known if changes in the brain are reflected in the blood. The objective of this study is to compare alterations in AD-related proteins in the brain with those in the blood so as to test the utility of blood screening as means to report on events occurring in the brain. Control and developmentally Pb-exposed animals were sacrificed at different time-points of their entire lifespan and their cortices were removed. Quantitative RT-PCR was performed to monitor the expression of APP over the mouse's lifetime (24 months). Data analysis showed that Pb-exposed mice unregulated their brain APP expression both early and late in life. APP expression was also altered in the blood following Pb exposure. These preliminary studies suggest that APP expression in blood cells may be used as an indicator for changes in APP expression in the brain.

113 INFANTILE EXPOSURE OF PRIMATES TO LEAD ELEVATES ALZHEIMER-RELATED PROTEINS LATE IN LIFE VIA ALTERATIONS IN EPIGENETIC PATHWAYS.

J. Wu¹, R. B. Mahammad¹, B. Brock¹, D. K. Lahiri², J. Harry³, D. C. Rice⁴ and N. H. Zawia¹. ¹Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI, ²Psychiatry, Indiana University School of Medicine, Indianapolis, IN, ³Neurotoxicology Group, National Institute of Environmental Health Sciences, Research Triangle Park, NC and ⁴Maine Department of Health and Human Services, Augusta, ME.

Alzheimer's disease (AD) is a progressive neurodegenerative disease clinically manifested by deterioration of memory and dementia. The intracellular accumulation of beta-amyloid ($\text{A}\beta$), which is a cleavage product of the amyloid precursor protein (APP), has been implicated in the development of AD. Greater than 90% of AD cases are sporadic and have no genetic predisposition; thus environmental factors

may play a key role in the development of AD. Our lab has previously demonstrated that early life exposure of rodents to lead (Pb) enhances cerebral APP and A β production late in life suggesting that epigenetic mechanisms are involved in mediating this early exposure/late onset of AD pathology. Recently, we acquired aged monkey brains which were exposed to lead as infants. Again APP and A β levels were elevated in the monkeys with a past history of infant exposure to Pb and the brains of these aged monkeys exhibited more intense AD plaque pathology. The activity of DNA methyltransferase was also found to be low and was accompanied by disturbances in DNA methylation. These data suggest that environmental exposure to Pb is a risk factor for AD and that exposure during brain development pre-determines late life pathogenesis through an epigenetic pathway.

114 NEUROPATHOLOGICAL LESIONS AND ALTERATIONS IN BRAIN MORPHOMETRY FOLLOWING TREATMENT OF MALE RATS WITH TRIETHYLtin BROMIDE.

D. P. Myers, I. Taylor, S. Cooper and A. Broadmeadow. *Huntingdon Life Sciences, Eye, Suffolk, United Kingdom.* Sponsor: D. Mitchell.

As part of a positive control validation study, triethyltin bromide was administered by oral gavage to groups of 70 day old male Crl:CD (SD) rats at doses of 1 or 2 mg/kg on Days 1, 4, 7, 10, 14 and 17 of study. A concurrent Control group was dosed daily with water for formulation. All animals were killed on Day 29 by an overdose of barbiturate and perfused with glutaraldehyde:paraformaldehyde fixative followed by immersion in this fixative. A range of nervous system tissues were processed and examined microscopically and the thickness of the neocortex, hippocampus, corpus callosum and folia of the cerebellum were estimated in standard sections of the brain. Treatment-related neuropathological lesions included widespread vacuolation of the white matter in the brain and spinal cord, myelin vacuolation in the optic nerves and degenerate fibres in the peripheral nervous system at both doses of triethyltin bromide. The incidence and severity of these changes showed a clear dose-response. In addition, morphometric analyses on standard sections of the brain indicated that treatment at 2 mg/kg was associated with statistically significant reductions in the mean thickness of the neocortex and hippocampus and an increase in the mean thickness of the folia of the cerebellum. Treatment at 1 mg/kg was associated with a reduction in the mean thickness of the hippocampus. The results from the study demonstrated that morphometric measurements of various regions of the brain were sensitive enough to detect changes in brain architecture following administration of a known neurotoxicant.

115 CHRONIC EXPOSURE TO DEPLETED URANIUM (DU) INCREASES HIPPOCAMPAL GLUTAMATE (GLU) RELEASE AND RECEPTOR DENSITY IN RATS.

S. M. Lasley, L. C. Wang and K. R. Vietti. *Cancer Biol. & Pharmacology, University of Illinois Coll. Med., Peoria, IL.*

Studies utilizing acute exposure to uranyl ion in vitro have demonstrated an inhibition of hippocampal GLU release with an IC₅₀ ~ 2 μ M. This study was performed to determine if chronic DU exposure in vivo disrupts K⁺-stimulated GLU release and activation of the NMDA receptor channel. Male rats received 0, 300, or 600 mg of DU implanted i.m. at 70-90 days of age. Animals were sacrificed after 15-17 months exposure, 400 μ m thick hippocampal slices prepared, and superfused with 10 mM HEPES-sucrose buffer, pH 7.4. Endogenous release was stimulated with 50 mM K⁺, and collected fractions quantified by liquid chromatography. For receptor studies a crude membrane fraction was prepared by homogenization of hippocampal tissue in 50 mM Tris acetate (pH 7.4) followed by multiple washing steps. Membrane aliquots were incubated with 25 nM tritiated MK-801 and 8 concentrations of unlabeled MK-801 in the range of 1-1000 nM. The incubation occurred in the presence of GLU and glycine at 20 μ M. Nonspecific binding was defined by 100 μ M MK-801. In contrast to the effects of acute uranyl ion exposure, chronic DU produced an increase in the response of GLU release compared to slices from control animals; the effect was most apparent at the 600 mg DU dose, but also could be seen in the 300 mg group. The response under Ca²⁺-free perfusion conditions exhibited a smaller increase in GLU after high K⁺ relative to controls at the high DU exposure level. In addition chronic DU exposure resulted in an up-regulation of high affinity hippocampal NMDA receptors by more than doubling receptor density in both the 300 and 600 mg dose groups compared to control values. The enhancement in stimulated GLU release may be due to uptake of DU into astrocytes, disruption of mitochondrial function, and consequent inhibition of GLU uptake, similar to actions reported for MeHg. Further studies are required to determine whether the NMDA up-regulation reflects a direct effect on the receptor or a compensatory response to presynaptic changes. (Supported by USAMRMC DAMD17-02-1-0212)

116 ENVIRONMENTAL ESTROGENIC COMPOUND BISPHENOL A INDUCED ROS SIGNALING MOLECULES AND THEIR ADVERSE ROLE IN BRAIN DEVELOPMENT.

N. Garba, Q. Felty and D. Roy. *Florida international University, Miami, FL.*

Bisphenol A (BPA) is an estrogenic chemical, and humans are usually exposed through food and beverage containers, dental composites and various work place and domestic products. Bisphenol A perturbs the development of the neocortex and possesses the capacity to alter important events during critical periods of brain development. However, the mechanism by which BPA alters brain development and function is thus far unclear.

In this study, we have used normal human brain cells (HCN-1A) as a cell model for studying the effects of environmental estrogen on the brain. Low doses (environmental exposure levels) of BPA and 17- β -Estradiol (E2) were used for this study. The level of ROS was measured using 2',7'-Dichlorodihydrofluorescein diacetate (DCFH) assay while DNA synthesis was measured by means of Bromodeoxyuridine (BrdU) assay. Environmental concentrations of bisphenol A (1 pg - 100 ng/ml) triggered a dose-dependent and rapid production of intracellular ROS ranging from a one- to several-fold increase in HCN-1A cells. The formation of ROS continued beyond 2hrs. E2 also increased ROS formation dose dependently. Low doses of BPA induced ROS formation while high doses inhibited it. BPA at 100pg/ml increased DNA synthesis by 40 percent. Recently, we showed that estrogen-induced ROS are signal transduction messengers. Our data therefore allude to the role of environmental estrogen mediated ROS signaling in the perturbation of brain development. The biological significance of our findings from this study provide the basis for the development of novel antioxidant-based drugs or gene therapy targeted for the prevention and treatment of defects in brain development.

117 THE PENALIZED OPTIMAL EXPERIMENTAL DESIGN: THE PRECISE ESTIMATION OF AN INTERACTION THRESHOLD IN A MIXTURE OF EIGHTEEN POLYHALOGENATED AROMATIC HYDROCARBONS.

S. D. Yeatts¹, C. Gennings² and K. M. Crofton³. ¹*Biostatistics, Bioinformatics and Epidemiology, Medical University of South Carolina, Charleston, SC,* ²*Biostatistics, Virginia Commonwealth University, Richmond, VA and* ³*Neurotoxicology Division, National Health and Environmental Effects Research Laboratory, ORD, U.S. EPA, Research Triangle Park, NC.*

Crofton et al. (EHP, 2005) conducted a study of 18 polyhalogenated aromatic hydrocarbons (PHAHs) on serum total thyroxine (T₄). Young female Long-Evans rats were dosed with the 18 single agents or a fixed-ratio mixture, and serum total T₄ was measured via radioimmunoassay. The initial analysis found significant interaction among the chemicals, with evidence of synergy at high doses (Crofton et al., 2005). To address the subsequent question of dose-dependency, Gennings et al. (JABES, 2006) fit an interaction threshold model to the data. The resulting estimate of the interaction threshold was positive and within the observed dose region, however, the corresponding confidence interval was wide and included zero. In order to more precisely estimate the location of the interaction threshold, a Ds-optimal second stage design was determined, with the objective of minimizing the variance of the hypothesized interaction threshold. Substantial concerns regarding the practicality of this design led to the use of the penalized optimality criterion (Parker and Gennings, JABES, under review), which uses desirability functions to penalize impractical experimental designs. Results demonstrate that, while the Ds-optimal second stage design can be used to more precisely define the interaction threshold, the penalized Ds-optimal second stage design has the characteristics deemed important in practice, while allowing only a minimal increase in the variance of the interaction threshold. (*This abstract does not necessarily represent EPA policies.*)

118 EFFECTS OF 2, 3, 7, 8-TETRACHLORDIBENZO-P-DIOXIN (TCDD) ON GENE EXPRESSION IN THE RAT PITUITARY GLAND AND PITUITARY-DERIVED GH3 CELLS.

J. Cao and S. L. Petersen. *Biology, University of Massachusetts, Amherst, MA.*

Exposure to the dioxin, TCDD, has been shown to cause reproductive dysfunctions. The effects of dioxin are mediated by the ligand-activate arylhydrocarbon receptor (AhR), a basic helix-loop-helix PAS transcription factor. The AhR regulates transcription of target genes and also exerts crosstalk with a number of other nuclear signaling pathways, particularly with estrogen receptor signaling. TCDD likely acts throughout the reproductive axis, but exposure to AhR ligands affects plasma levels gonadotropins and prolactin, suggesting that the anterior pituitary gland is a target. Previously we used cDNA microarray analysis of pituitary glands and found that the prolactin gene, as well as the glycoprotein hormone alpha subunit gene, are possible targets of both TCDD and estradiol (E2). In the present

study, we verified these findings with real-time PCR in vivo. We showed that TCDD had no effect on Prl gene expression, but it interfered with E2 upregulation of the gene. In contrast, TCDD upregulated expression of the alpha subunit gene, but E2 downregulated expression of this gene. Interestingly, E2 interfered with the ability of TCDD to upregulate the alpha subunit gene. We obtained similar findings when we examined the effects of E2 and TCDD on LH beta subunit gene expression. We also showed that E2 interfered with the ability of TCDD to induce the cyp1A1, but not cyp1B1. Subsequently, we used dual-luciferase assays and pituitary-derived GH3 cells to show that TCDD interfered with E2-induced upregulation of the prolactin promoter. Mutation of the putative DRE sequence did not affect the ability of TCDD to decrease E2-induced Prl promoter activity, except at low (0.1 nM) and high (100 nM) doses. These findings show that TCDD and E2 show crosstalk in the regulation of pituitary hormones important for reproductive functions, but the molecular mechanisms remain to be determined. Funded by NIH grants ES08774 and ES013885 to SLP

119 EFFECTS OF ATRAZINE (ATR) AND METABOLITE, DIAMINO-S-CHLOROTRIAZINE (DACT), ON THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS IN RATS.

S. C. Laws, J. Ferrell, M. Hotchkiss, A. Buckalew, A. Murr and R. Cooper. *NHEERL, ORD, U.S. EPA, Research Triangle Park, NC.*

Previously, we reported that a single dose of atrazine (ATR) caused an immediate release of adrenocorticotrophic hormone (ACTH) in male Wistar rats. These dose and time-dependant changes in ACTH were correlated with increased serum corticosterone (C) and progesterone (P), and indicated that ATR may have a direct effect on the brain and/or pituitary. Here, we continue to evaluate the effects of ATR and the primary metabolite, DACT, on the HPA axis. Sixty-day-old male rats were acclimated to dosing with vehicle (methylcellulose) for 7 days by gavage. On day 8, the rats were divided into groups of 10, given a single dose of DACT (0, 3.37, 33.7, 67.5, 135 mg/kg) by gavage at 0900 (12/12 light cycle, on @ 0700) and killed by decapitation 5, 15, 30, or 60 min later. Plasma ACTH and serum steroids were measured by radioimmunoassay. Doses of DACT were equimolar to those used in our previous study with ATR (0, 5, 50, 100, 200 mg/kg). Another group, dosed with ATR (200 mg/kg), served as a replicate of our previous study with ATR and enabled the direct comparison of ATR and DACT. ATR significantly increased plasma ACTH by 2.6, 3.9, 3.9-fold at 15, 30 and 60 min, respectively. Serum progesterone (P) and corticosterone (C) were also increased after ATR exposure. However, while DACT (33.7 and 135 mg/kg) increased ACTH at 30 and 60 min. by 1.3-fold, this increase was not entirely dose responsive and was moderate when compared with the response to an equimolar dose of ATR. Small increases in P and C were also observed for animals dosed with DACT (135 mg/kg) at 30 and 60 min. Thus, this study shows that while both ATR and DACT can elevate ACTH and adrenal steroids, the parent chlorotriazine herbicide, ATR, may be more active when compared to equimolar doses of DACT. Additional studies are ongoing to identify the primary target site for these effects, and to determine the role that adrenal steroids may play in mediating ATR-induced adverse effects on the reproductive system. This abstract does not necessarily reflect EPA policy.

120 ASSESSMENT OF THE GRAVIMETRIC, HISTOPATHOLOGICAL AND PROTEOMIC CHANGES INDUCED BY THE WEAK ANTI-ANDROGENS DDE AND LINURON, IN THE TESTOSTERONE-PROPIONATE STIMULATED WEANLING RAT.

H. Tinwell¹, C. Friry-Santini¹, L. Elies², S. Belluco², F. Schorsch² and R. Bars¹. ¹Research Toxicology, Bayer CropScience, Sophia Antipolis, France and ²Pathology, Bayer CropScience, Sophia Antipolis, France. Sponsor: N. Carmichael.

The rapid in vivo identification of anti-androgens generally relies on the conduct of the Hershberger assay, which monitors weight changes of androgen-sensitive tissues following compound exposure for 10 days. However, as the assay requires the use of castrated male rats, the OECD is currently investigating the testosterone-propionate (TP) stimulated weanling rat as a suitable alternative. As part of this validation programme, we investigated the activity of two weak anti-androgens, DDE and Linuron using a range of dose levels and included the potent anti-androgen, Flutamide (FLUT) as a positive control. In addition to gravimetric measurements, histopathological assessment of the testes, seminal vesicles and prostate of vehicle control animals, TP-stimulated animals and TP-stimulated animals co-exposed to 160 mg/kg/d DDE, 100mg/kg/d Linuron or 3mg/kg/d FLUT was conducted. The proteomic profile of the prostates of these same animals was also investigated. Our gravimetric data confirmed the weak anti-androgenic activity of DDE and Linuron previously recorded in the classic Hershberger assay. A strong correlation between the weight changes and the sexual maturity of the tissue, based on the histopatho-

logical findings, was recorded. Finally, a novel protein thought to be associated with apoptosis, L-amino acid oxidase (LAO), was up-regulated in the TP-stimulated weanling prostate by DDE and Linuron. As this protein was recently identified in adult rat prostate following exposure to the anti-androgens, FLUT and Finasteride, it is possible that LAO could be used as a biomarker for anti-androgenic effects. In conclusion, the TP-stimulated weanling rat appears to be a suitable animal model to use in the Hershberger assay. Our investigations also indicate that the assay has the potential to provide additional information on the MOA of a compound if required.

121 EFFECTS OF LOW CONCENTRATIONS OF ESTROGENS AND THEIR METABOLITES ON THE CACO-2 CELL LINE.

D. Scholten¹, M. van den Berg¹, A. A. Bergwerff² and M. B. van Duursen¹. ¹Toxicology, Institute for Risk Assessment Sciences, Utrecht, Utrecht, Netherlands and ²Veterinary Public Health, Institute for Risk Assessment Sciences, Utrecht, Utrecht, Netherlands.

Through our daily diet, humans are continuously exposed to low concentrations of estrogens, their metabolites and compounds that might act as estrogens. Exposure to these compounds has been associated with higher incidences of fertility problems and hormone-dependent cancers. A scientific controversy exists with respect to effects of estrogens on colonic cells in either stimulating cell proliferation or apoptosis. ER- β is predominant in human colon and mediates apoptosis, whereas ER- α , which mediates proliferation, is less present in colon cells. Based on ER- β occurrence in colonic cells, apoptosis would be expected upon exposure to estrogens. Cytochrome-P450-1A1/1B1 are present in colonic tissue and formation of estrogen metabolites is therefore likely. Presently, we study effects of estrogens and their metabolites on Caco-2 colon cells. The potent phytoestrogen 8-prenyl naringenin is also included in our experiments. Possible proliferating effects of 17 β -estradiol (E2) and its potentially genotoxic 4-OH metabolite were assessed with the MTT assay. E2 or 4-OH-E2 did not induce cell proliferation in the range of 0.01 nM-100nM.

Preliminary data from the Apo-ONE apoptosis assay (Promega) showed a minor induction of apoptosis by E2 and 4-OH-E2 at concentrations higher than 10 nM. Similar experiments are ongoing with other estrogenic compounds and estrogen hydroxy- and methoxy-metabolites. So far, these data suggest that low concentrations of dietary estrogens appear not to contribute to colon cancer risk.

122 EFFECTS OF MARINE ORGANISM-DERIVED INDIRUBINS ON PROSTATE-SPECIFIC ANTIGEN (PSA) EXPRESSION AND CELL PROLIFERATION IN LNCAP HUMAN PROSTATE CANCER CELLS.

M. Renaud¹, L. Meijer² and T. Sanderson¹. ¹INRS-Institut Armand-Frappier, Pointe-Claire, QC, Canada and ²Station Biologique, Roscoff, Bretagne, France.

Certain indirubins and related compounds are potent cyclin-dependent kinase (CDK) inhibitors and may be effective in the treatment of various cancers. We tested the effects of olomoucine, roscovitine, indirubin-3'-oxime (I-3'-M), 6-Br-I-3'-M, aminopurvalanol and aloisin A on cell proliferation and PSA expression in androgen-dependent LNCaP human prostate cancer cells. The overall goal was to identify structural derivatives with antiandrogenic properties that may be suitable candidates for the treatment of hormone-dependent prostate cancer. LNCaP cells were exposed to the test compounds (1.0 and 10 μ M in steroid-free serum containing 0.1% DMSO) for 5 days in the presence or absence of DHT (0.3 nM) after which cell proliferation was assessed by MTT reduction assay. PSA expression (mRNA) was determined by semi-quantitative RT-PCR after a 24 h exposure. Olomoucine did not affect DHT-induced cell proliferation but it increased basal cell proliferation at 1.0 μ M. At 1.0 and 10.0 μ M, basal PSA expression was statistically significantly increased; DHT-induced PSA expression, on the other hand, was decreased to basal levels. Roscovitine had no effects on DHT-induced cell proliferation, but had a biphasic effect on basal cell proliferation with an increase at 1.0 and decrease at 10 μ M. Roscovitine (10 μ M) significantly reduced basal and DHT-stimulated PSA expression. Indirubin-3'-monoxime concentration-dependently stimulated basal and DHT-induced LNCaP cell growth. Its 6-Br-analog stimulated basal and DHT-induced cell proliferation at 1.0, but strongly reduced it at 10 μ M. Aminopurvalanol produced a similar biphasic response. Aloisin A had no effect on basal or DHT-stimulated cell growth at 1.0 μ M, but reduced DHT-induced proliferation to basal levels at 10.0 μ M. Our results indicate that certain CDK inhibitors exhibit pro- and/or antiandrogenic effects in LNCaP cells and are interesting candidates for more detailed studies concerning their effectiveness against hormone-dependent prostate cancer.

123 MASPIN EXPRESSION IN LNCAP CELLS AS MARKER FOR CHEMOPREVENTIVE ACTIONS BY PHYTOCHEMICALS.

M. B. van Duursen, S. N. Nijmeijer and M. van den Berg. *Institute for Risk Assessment Sciences (IRAS), Utrecht University, Utrecht, Netherlands.*

Curcumin, the active ingredient of the Indian curry spice turmeric, is often studied as anticancer agent for example against prostate cancer. In this study, the effects of curcumin on maspin expression were determined in human prostate cancer cell line LNCaP. Maspin expression is negatively correlated with tumor suppression in breast and prostate cancers. Although the mechanism is not clear, maspin is suggested to inhibit tumor-induced angiogenesis and sensitize tumor cells to undergo apoptosis.

Incubation of LNCaP cells with curcumin (10 microM) increased maspin mRNA expression, while DHT (dihydrotestosterone, 10 nM) decreased maspin expression. Since curcumin actions appear to be mostly mediated by interactions with PPAR-gamma (peroxisome proliferator-activated receptor gamma), effects on PPAR-gamma mRNA levels were also determined. Incubation with curcumin resulted in a slight increase of PPAR-gamma mRNA, while DHT decreased PPAR-gamma expression. These results concur with the hypothesis that curcumin acts as anticancer agent in prostate cancer cells and the clinical findings that androgen withdrawal increases maspin expression, which results in better prognosis for prostate cancer. Effects of other suggested chemopreventive compounds sulforaphane and lycopene on maspin and PPAR-gamma in prostate cancer cells are currently under investigation in our laboratory.

124 CIMICIFUGA EXTRACT FROM BLACK COHOSH IS NO PHYTOESTROGEN.

J. B. Schulze¹, C. Siegers² and M. Schulze². ¹Office of the Dean, JWU University Frankfurt, Frankfurt/Main, Germany and ²Inst. Exp. Clin. Pharmacology Toxicol., University in Luebeck, Luebeck, Germany.

Aromatase catalyses the six electron transfer to form the estrogens estrone and estradiol from androstenedione, testosterone and other endogenous precursors. We have developed a product based assay for aromatase activity allowing to separate and quantify individual aromatase products i.e. estrone and estradiol, as well as other possible microsomal metabolites like estradiol sulfate. Placental microsomes formed only estradiol and estrone with a dose dependent ratio of 3 : 1 to 5 : 1 in favor of estradiol. Extracts from plants like Cimicifuga, also known as black cohosh, have long been used to treat menopausal symptoms like hot flashes and postmenopausal osteoporosis. Since these symptoms can also be treated by estrogen supplementation cimicifuga extracts have been assumed to act as phytoestrogens, possibly by modulating estrogen metabolism. In preliminary experiments we found a decrease in estradiol but not in estrone formation at high concentrations. However, dose dependent addition of cimicifuga extract showed no effect on aromatase activity in lower concentrations comparable to those that may be achieved by therapeutic doses. The shift in the product ratio at high concentrations may result from an interaction of cimicifuga extracts with 3-hydroxysteroid dehydrogenase catalysing the product equilibrium. We found no evidence to support a proestrogenic activity of cimicifuga extracts by modulation of estrogen formation; in cell culture experiments cimicifuga extracts possessed antiestrogenic activity which may be explained by the observed shift to the hormonally inactive estrone. Therefore we conclude that cimicifuga extracts cannot be considered phytoestrogenic; its therapeutic effects on perimenopausal symptoms appear to be due to central nervous effects.

125 USE OF THE H295R CELL TO EVALUATE THE EFFECT OF ENVIRONMENTAL COMPOUNDS ON STEROID HORMONE PRODUCTION.

A. R. Buckalew¹, J. W. Laskey², J. M. Goldman¹, E. B. Higley³, J. P. Giesy³, M. Hecker³ and R. L. Cooper¹. ¹Endocrinol. Br., RTD, NHEERL, ORD, U.S. EPA, Res. Triangle Pk., NC, ²Senior Environmental Employment Program, Res. Triangle Pk., NC and ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

H295R cells constitute a pluripotent cell line that has retained the enzymatic ability to produce steroids along the entire steroidogenic pathway, including C19 androgens and C18 estrogens. For this reason, they have been a valued research tool, and have been employed in an ever-increasing number of studies. The US EPA is interested in the utility of these cells as an *in vitro* screen for environmental compounds which may have direct effects on steroidogenesis. This study examined the effects of selected chemicals on the production of progesterone, androstenedione, testosterone, estradiol, estrone and corticosterone by these cells *in vitro*. After a 48h incubation period, the concentration of each hormone was readily detectable in the medium. Using a 24-well plate format with 200,000 cells per well, it was possible to measure by RIA concurrently up to 4 - 5 hormones per well in a single incubation.

Exposure of the cells to chemicals known to modify steroidogenesis affected concentrations of the appropriate hormones as expected. For example, forskolin (which increases cyclic AMP activity) induced a dose-dependent increase of each hormone examined. In contrast, incubation with aminoglutethimide (which inhibits multiple P450s) caused a dose-dependent decrease in the production of several hormones. As part of this work, cells were also examined for any potential effects of compound application on cell viability. These data support the usefulness of this approach as a screen for toxicant effects on steroid hormone production and can also provide valuable insight into sites of impact along the steroidogenic pathway. (This abstract does not necessarily reflect EPA policy.)

126 SOY ISOFLAVONE AND ORAL CONTRACEPTIVE EFFECTS ON ESTROGEN METABOLISM.

L. M. Scott¹, X. Xu², T. D. Veenstra², C. E. Wood¹, T. C. Register¹ and J. Cline¹. ¹Wake Forest University School of Medicine, Winston Salem, NC and ²SAIC-Frederick, Inc., National Cancer Institute at Frederick, Frederick, MD. Sponsor: A. Townsend.

Estrogen metabolism may play an important role in mammary carcinogenesis in postmenopausal women. We evaluated the long-term effects of prior oral contraceptive (OC) use and soy isoflavones (IF) on endogenous estrogen metabolism in a primate model. One hundred eighty-one female cynomolgus monkeys were randomized to receive OC or placebo for 28 months premenopausally, then ovariectomized and randomized to either an IF-depleted soy protein isolate (SPI-) diet or a diet containing soy protein isolate with a human equivalent of 129 mg IF/day (SPI+) for 36 months. At month 35 of the postmenopausal phase overnight urine samples were collected. Reversed-phase HPLC-ESI-MS/MS was used to measure the concentrations of 15 estrogens including estrone (E₁), estradiol (E₂), and 2-, 4-, and 16 α -OHE₁/E₂ catabolites. Overall prior OC treatment was associated with lower urinary 2-OHE₁, 16 α -OHE₁, 4-OHE₁, E₁, E₂, and total estrogens, although those differences were only statistically significant in the animals who were fed an IF free diet postmenopausally (p<0.05 for each). Over all animals isoflavone consumption resulted in no significant changes in the aforementioned metabolites. However, an IF+ diet in monkeys receiving premenopausal placebo was associated with a significant increase in the ratio of urinary 2-OH/4-OHE₁ (p<0.001), with 45% higher levels of 2-OHE₁ (p=0.2) and 48% lower 4-OHE₁ (p=0.1). IF consumption in OC-treated monkeys resulted in 121% higher 16 α -OHE₁ (p<0.001) compared to 22% higher levels in the placebo-treated IF fed group (p=0.4). Thus: (1) premenopausal OCs may have long term lowering effects on estrogen excretion postmenopausally; (2) a postmenopausal diet that is high in soy isoflavones may modulate the urinary estrogen metabolite profile towards a less carcinogenic profile; (3) prior OC use may alter postmenopausal estrogen metabolism pathways challenged by phytoestrogens. These findings suggest that OC use may modulate a woman's response to postmenopausal therapies.

127 THE COMPARATIVE SENSITIVITY OF THE CD-1 MOUSE, FISHER 344 RAT, AND THE CD SPRAGUE DAWLEY RAT TO THE PHYTOESTROGEN GENISTEIN.

G. Caviness, J. E. Thigpen, A. Helmich, S. Little, T. Whiteside, J. Locklear, E. Padilla-Banks, M. Grant and D. Forsythe. *NIEHS, Research Triangle Park, NC.* Sponsor: W. Jefferson.

Dietary phytoestrogens can significantly alter the results of uterotrophic assays and vaginal opening (VO) endpoints in animals used to evaluate the estrogenic activity of endocrine disruptor compounds (EDC). Species and strains differ in their sensitivity to the phytoestrogen genistein (G). The objective of the study was to compare the sensitivity of the CD-1 mouse, Fisher 344 (F344) rat, and the CD Sprague Dawley (SD) rat to genistein. Dams with standardized litters of 10 female pups were housed in a polycarbonate microisolator cage containing autoclaved hardwood bedding. The dams were fed the Zeigler 5412-01 phytoestrogen reduced diet containing <10 μ g daidzein (D) and (G)/g diet and given RO/DI water ad libitum. Mouse pups were weaned at post-natal day (PND) 15 and rat pups were weaned at PND 19 and randomly assigned to cages. The weaned pups were fed the AIN-76A diet spiked with genistein at 0, 150, 300, or 450 μ g/g diet. Animals were observed daily and the time of VO was recorded daily. Body weights were determined at weaning, at weekly intervals, and at the time of VO. The CD-1 mice showed significant (p<0.05) differences in the mean time of VO between the control and all treatment groups. The F344 rat showed significant differences in the mean time of VO between the control and the 300 and 400 μ g/g diet groups. The SD rat showed significant differences in the mean time of VO only at the 450 μ g/g diet level. Significant differences in body weights at weaning and at all other time points were observed between the F344 and SD rat. It was concluded that: 1) the SD rat was less sensitive to (G) than the CD-1 mouse or the F344 rat, 2) the estrogenic effects were not due to total metabolizable energy, 3) species and strains significantly differ in their sensitivity to genistein, and 4) a phytoestrogen reduced diet (<10 μ g D&G/g diet) and the strain used should be stated in VO assays evaluating the hormonal activity of EDCs.

128 VARIATIONS IN PHYTOESTROGEN CONTENT BETWEEN DIFFERENT MILL DATES OF THE SAME DIET PRODUCES SIGNIFICANT DIFFERENCES IN THE TIME OF VAGINAL OPENING IN F344 RATS BUT NOT IN CD SPRAGUE DAWLEY RATS.

J. E. Thigpen¹, J. Haseman¹, K. Setchell², H. Saunders¹, G. Caviness¹, E. Padilla-Banks¹, M. Grant¹ and D. Forsythe¹. ¹NIEHS, Research Triangle Park, NC and ²Children's Hospital Medical Center, Cincinnati, OH. Sponsor: W. Jefferson.

The selection of the animal species, strain and optimum diet for conducting uterotrophic assays for the evaluation of the hormonal activity of Endocrine Disruptor Compounds (EDC) is a subject of current concern. This report describes the effects of a fourfold variation of the phytoestrogen content of three different mill dates of the PMI #5002 diet on the time of vaginal opening (VO) in F344 rats and Sprague Dawley (SD) rats. Dams with standardized litters of 10 female pups were fed the Zeigler phytoestrogen-reduced diet II containing < 10 µg daidzein and genistein (D&G)/g diet and given RO/DI water ad libitum. Rat pups were weaned at post-natal day (PND) 19 and were randomly assigned to the PMI #5002 test diets or control PMI #5K96 phytoestrogen-reduced diet (at least 16 pups/diet). The time of VO was recorded daily from PND 19 to time of VO. Body weights were determined at weaning, at time of VO and at weekly intervals until PND 46. Different mill dates of the same diet produced significant ($p < 0.05$) differences in the time of VO in F344 rats. In contrast, no significant differences were observed in the time of VO in SD rats fed different mill dates of the same diet even though the concentration of the D&G in the plasma of SD rats was twice as high as the plasma concentration in the F344 rat. Significant differences were observed in the body weight at PND 19, at time of VO, and at all time points between the two species. It was concluded that 1) the F344 rat was more sensitive to D&G than the SD rat; 2) the variation in the D&G content in different mill dates of the same diet produced significant ($P < 0.05$) differences in the time of VO in F344 rats, but not in SD rats; 3) a standardized open formula phytoestrogen reduced diet (<10µg of D&G/g diet) containing ~ 3.1 Kcal/g diet should be considered for studies evaluating the hormonal activity of EDCs.

129 BATCH TO BATCH VARIABILITY IN ESTROGENIC ACTIVITY IN COMMERCIAL ANIMAL FEED: IMPORTANCE AND IMPLICATIONS FOR LABORATORY ANIMAL RESEARCH.

J. J. Heindel², F. vom Saal¹, J. Thigpen², K. Setchell³ and E. Yetley⁴. ¹University of Missouri, Columbia, MO, ²NIEHS/NIH/DHHS, Research Triangle Park, NC, ³University of Cincinnati, Cincinnati, OH and ⁴Office of Dietary Supplements, NIH/DHHS, Bethesda, MD.

Significant undefined batch-to-batch variability in estrogenic components of commercial rodent feeds can influence phenotype. To address this issue, the NIEHS and the NIH Office of Dietary Supplements convened two workshops. The first determined the extent of the problem from the scientist's perspective and the second addressed solutions with feed manufacturers. Workshop discussions documented that batch to batch variability in estrogenicity of diets is responsible for failures to replicate results both within and between laboratories. In addition, variability in estrogenicity of animal diets will require a larger number of laboratory animals for adequate bio-statistical power. This will increase the cost of scientific research and significantly influence estrogenic effects of diets on positive controls, species, strain and life stage differences. Investigators will benefit from the availability of commercial soy- and casein-based animal diets for which manufacturers have identified the components responsible for the variability in estrogenic activity and applied appropriate manufacturing quality control procedures to assure control of the variability between batches of the feeds. Documentation of the estrogenic activity in these diets by chemical analysis coupled with bioassays of batch to batch estrogenic composition and activity can effectively meet this need. In summary, scientists should be aware of the implications of undefined phytoestrogens and other estrogenic components in the rodent diets used, to document the estrogenic content of the diets used by reporting the identity and details of diet composition and mill dates in publications, by using positive controls in every experiment, and by keeping historical samples of diets for future analyses.

130 INTERACTION OF RETINOID X RECEPTOR WITH ENVIRONMENTAL CHEMICALS.

Y. H. Wang, G. Wang and G. A. LeBlanc. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.*

The retinoid X receptor (RXR) is a pleiotropic transcription factor that functions both independently and in concert with other nuclear receptors. RXR is highly conserved among the metazoa and regulates a variety of activities critical to normal physiology. Despite its important roles in regulating aspects of development, growth, and reproduction, little is known of the susceptibility of this receptor to

xeno-agonists or antagonists. We have undertaken the cloning, expression, and characterization of RXR isolated from the water flea (*Daphnia magna*) in an effort to provide a definitive in vitro assessment of the interaction of this receptor with environmental chemicals and establish in vivo consequences of such chemical-receptor interactions. The full length cDNA of the daphnid RXR was cloned by RACE yielding a 1888 bp product that coded for a 400 amino acid protein. The RXR protein shared significant identity with RXR from other species. Expression profiling revealed that daphnid RXR mRNA levels were greatest in embryos that were early in development and progressively declined through the five stages of embryo development. Adult females expressed higher levels of RXR mRNA than did males and exposure of females to the terpenoid hormone mimic pyriproxyfen reduced RXR mRNA in females to levels approaching males. Presently, recombinant RXR protein is being expressed for the assessment of xenobiotics-binding interactions with the receptor. Candidate xeno-ligands then will be evaluated for effects on development, growth, and reproduction in daphnids. Preliminary data suggests that some insect growth regulating insecticides activate RXR with consequences on sex determination of offspring.

131 EFFECTS OF BISPHENOL A AND CADMIUM ON GENOMIC AND NON-GENOMIC ACTIONS OF THE ESTROGEN RECEPTOR.

Y. Zang, S. A. Odwin-DaCosta and J. D. Yager. *Department of Environmental Health Sciences, Division of Toxicology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Various hormonal and environmental estrogens activate the estrogen receptor (ER) and stimulate cell proliferation. The ER is a member of the nuclear steroid receptor family, and mediates the regulation of numerous estrogen-responsive genes such as the progesterone receptor (PgR). Recent evidence supports the existence of a plasma membrane ER, which, upon ligand binding activates various second messenger and protein kinase signaling pathways such as mitogen-activated protein kinase (MAPK) pathways. In this study, we investigated two environmental compounds, bisphenol A and cadmium, both of which had been shown to bind ER, on their abilities to activate the genomic (through nuclear ER) and non-genomic (through membrane ER) actions, as well as their abilities to stimulate breast cancer cell proliferation. ER positive T47-D breast cancer cells were cultured in stripped serum for 5 days before treatment with different concentrations of bisphenol A or cadmium chloride. Cells were harvested after 6 days for a proliferation assay, or at different time points for determination of a) PgR mRNA levels by real time RT-PCR, b) ERK1/2-MAPK phosphorylation by western blot. Our results showed that Bisphenol A increased PgR mRNA level by 18 hours, and 100 nM bisphenol A induced maximal transcriptional activation. No significant ($p > 0.05$) PgR up-regulation was induced by cadmium, even at 10 µM. Different from their effects on genomic action, 1 nM concentrations of bisphenol A and cadmium activated ERK1/2-MAPK phosphorylation as early as 5 minutes. Bisphenol A and cadmium displayed different capability to modulate T47-D cell proliferation. The former increased cell proliferation at 10 nM, while the later did not, even at a concentration as high as 1 µM. These findings suggest that different ER ligands show different patterns of ER activation, and that genomic and non-genomic pathways of ER signaling may play different roles in breast cancer cell proliferation. Supported by Grants CA77550 and P30 ES 03819.

132 EVALUATION OF AN IN VITRO PRE-SCREENING STRATEGY TO PRIORITIZE ENVIRONMENTAL CHEMICALS FOR FURTHER TESTING: ANDROGEN AND ESTROGEN RECEPTOR MEDIATED ACTIVITY.

V. S. Wilson¹, J. E. Schmid¹, D. P. Blakeman², J. F. Pregezer², J. M. McKim², J. M. Goldman¹ and L. E. Gray¹. ¹Reproductive Toxicology Division, U.S. EPA, ORD, NHEERL, Research Triangle Park, NC and ²CeeTox, Inc., Kalamazoo, MI.

This project evaluated an in vitro pre-screening strategy to identify chemicals that may act as androgen or estrogen receptor agonists or antagonists and prioritize them for further testing as potential endocrine disrupting compounds. Specifically, the approach was to examine the interaction of 117 chemicals with the androgen (AR) and estrogen receptor (ER) with in vitro cell-based transcriptional activation (TA) assays using the MDA-kb2 and T47D-KBluc cell lines, respectively. The chemicals identified as positive in TA assays were then examined for competitive receptor binding to confirm their ability to act via that receptor. Solubility and cytotoxicity assessments were also performed on all chemicals. Initially, seventeen compounds with varying, but well-established, affinities for either AR or ER were evaluated in cell-based TA and receptor binding assays to establish the methods and to demonstrate satisfactory performance of those methods. Then fifty chemicals were chosen that were primarily from the ICCVAM list of Proposed Substances and Selection Criteria for Assay Validation. Finally, fifty unknowns were evaluated in the final phase of the work. Taken together, the results of this project demonstrated the feasibility of this approach for chemical prioritization and identified several important issues that must be considered in evaluating in vitro data. In addition, these methods have the potential to be used in high through-put screening.

Disclaimer: This abstract does not necessarily reflect US EPA policy.

133 COMPOUNDS OF DIFFERENT CHEMICAL CLASSES ELICIT SUPRAMAXIMAL RESPONSES IN IN-VITRO ANDROGEN AND ESTROGEN RECEPTOR MEDIATED ACTIVITY ASSAYS.

J. F. Pregenzer¹, D. P. Blakeman¹, J. McKim¹, V. S. Wilson², J. Schmid², J. Goldman² and L. Gray². ¹CeeTox, Inc., Kalamazoo, MI and ²U.S. EPA, Research Triangle Park, NC.

In vitro assays designed to identify estrogen and androgen activity were evaluated as an efficient high throughput method for screening a wide range of environmentally significant chemicals for endocrine activity. In the present study more than 120 chemicals were tested for androgen (AR) and estrogen receptor (ER) mediated activity using a cell-based transcriptional activation (TA) model consisting of MDA-kb2 and T47D-KBluc cell lines, respectively combined with competitive receptor binding assays. Receptor binding assays used a human recombinant receptor in combination with polarographic fluorescence detection. Chemicals that were positive in the TA assay were tested in the receptor binding assay as a confirmation of the chemical's ability to elicit response via ER or AR. Solubility and cytotoxicity assessments were also performed. Several of these compounds, which included cadmium chloride, genistein, benzoic acid, 2-hydroxy-, 4-(1,1-dimethylethyl)phenyl ester, benzyl salicylate, 1,3-benzenedicarboxylic acid, and diphenyl ester produced a supramaximal response in both assays with response values ranging from 0.5 to 3-fold greater than that obtained from endogenous high affinity ligands, such as estradiol. This supramaximal response was most pronounced when the compound was co-incubated with the reference agonist (Estradiol or DHT). One exception to this occurred with genistein which caused a 2- to 3- fold increase both with and without agonist co-incubation. Supramaximal responses have been observed by others in reporter gene assays. Possible explanations for this phenomenon, depending on the chemical class, could be ligand-dependent differences in the ability of receptor to bind co-activators or interaction of ions with transcription factors. Further study in light of these observations could help elucidate the mechanism of this phenomenon in transactivation models.

134 ESTROGEN RECEPTOR ACTION: GLOBAL GENE EXPRESSION PROFILING IN HUMAN ISHIKAWA CELLS WITH DISTINCT ESTROGEN RECEPTOR EXPRESSION REVEAL DISTINCT ESTROGEN PATHWAYS.

S. O. Mueller, S. Simon and S. Susanne. *Toxicology, Merck KGaA, Darmstadt, Germany.*

Estrogens regulate diverse physiological processes in various tissues including the mammary gland and reproductive organs. Estrogenic effects are mediated by the estrogen receptors belonging to the superfamily of ligand-inducible transcription factors. We analyzed cellular responses to estrogens at the gene expression level in a time and dose-dependent manner. For that, global gene expression profiling (Illumina® Sentrix® BeadArray) was done in Ishikawa cells expressing endogenous estrogen receptor (ER) alpha (Ishikawa-plus) or lacking ER (Ishikawa-minus). Cells were treated with 17β-estradiol (E2) and a combination of E2 and the anti-estrogen ICI 182,780 (ICI) and harvested after 2, 24 and 72 hours. Principle component analysis (PCA) showed that the two cell lines accumulate in two well-defined, separate clusters, confirming their different properties in gene expression. We were able to identify more than 1300 significantly deregulated genes in response to E2 in Ishikawa-plus with a clear time-dependent pattern. The deregulation of the majority of these genes was suppressed by ICI, indicating their ER-dependent modulation. In contrast, only 374 genes were deregulated in Ishikawa-minus. Interestingly, eight genes were deregulated in both Ishikawa-plus and -minus and showed diametric directions of deregulation. These eight genes are therefore putative marker genes to discriminate ER-dependent from ER-independent signals. Overall, these results show that Ishikawa cell lines with distinct ER expression provide a suitable model system to screen for and to analyze estrogenic effects with respect to ER-dependent or ER-independent signalling pathways.

135 FOOD ASSOCIATED ESTROGENIC COMPOUNDS INDUCE ER-MEDIATED LUCIFERASE GENE EXPRESSION IN TRANSGENIC ER-LUC MALE MICE.

M. G. ter Veld^{1,2}, E. Zawadzka^{2,4}, J. H. van den Berg², P. T. van der Saag³, I. M. Rietjens² and T. J. Murk². ¹Toxicology and Drug Disposition, Organon, Oss, Netherlands, ²Toxicology section, Wageningen University, Wageningen, Netherlands, ³Hubrecht Laboratory/NIOB, Utrecht, Netherlands and ⁴Department of Andrology and Reproductive Endocrinology, Medical University of Lodz, Lodz, Poland. Sponsor: H. Joosten.

The current research project reveals the in vivo estrogenic potency of seven in vitro estrogenic food associated compounds in ER-luc male reporter gene mice.

Estradiol-propionate (EP, positive control) was dosed at 0.3 and 1 mg/kg body-weight (bw), bisphenol A (BPA) or nonylphenol (NP) at 10 and 50 mg/kg bw, p,p'-DDE at 5 and 25 mg/kg bw, quercetin at 1.66 and 16.6 mg/kg bw, and diisooheptyl phthalate (DIHP), di (2-ethylhexyl) phthalate (DEHP) or di (2-ethylhexyl) adipate (DEHA) all at 30 and 100 mg/kg bw. DMSO was used as the solvent control. Generally, IP dosing caused higher inductions after 8 hours compared to oral dosing after 14 hours, except in the liver where the responses were comparable. Maximum induction was reached up to 20,000 times in the liver at 1 mg EP/kg bw. DDE, NP, DEHA and DIHP did not induce luciferase in any tissue. BPA induced luciferase in the liver via both exposure routes and after IP exposure in the testis, kidneys and tibia at 50 mg/kg bw. Orally dosed 100 mg DEHP/kg bw, induced luciferase in the liver 3-fold but reduced luciferase in the testis. Orally dosed 16.6 mg quercetin/kg bw induced luciferase 1.4 fold in the liver.

The results of this study show that food associated compounds can be estrogenic in vivo. Oral exposure generates lower estrogenic activity compared to IP exposure, thereby lowering the risks for orally ingested food associated estrogenic compounds. Luciferase levels were induced in livers of ER-luc male mice after exposure to BPA at levels 2300 times the TDI in humans. Based on these results no effects are expected upon average human exposure to estrogenic food associated compounds.

136 LONG-TERM ESTROGEN EXPOSURE (LTEE) UP-REGULATES ARYL HYDROCARBON (AH) RESPONSIVENESS IN MCF-7 BREAST CANCER CELLS.

D. C. Spink, B. T. Pentecost and B. C. Spink. *Wadsworth Center, New York State Department of Health, Albany, NY.*

The long-term presence of estrogen is known to imprint gene expression patterns. In this study, the effects of LTEE on Ah responsiveness to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in MCF-7 cells were investigated. MCF-7 cells were continuously cultured in Dulbecco's-based medium containing 5% bovine calf serum (DC5 medium), which contains minimal estrogen, or DC5 medium supplemented with 0.01, 0.1 or 1.0 nM 17β-estradiol (E2). At passages 4 and 12, basal and TCDD-induced ethoxyresorufin O-deethylase activities (EROD) were determined, and samples from control and TCDD-induced (10 nM TCDD, 72 h) cultures were taken for isolation of total RNA, whole-cell extracts were prepared for Western immunoblot analysis of soluble proteins, and microsomal fractions were prepared for analysis of cytochrome P450 (CYP) expression. The results showed significant (P<0.01) elevations of basal and TCDD-induced EROD activities at the 0.01, 0.1 and 1.0 nM E2 levels. Western immunoblots showed up-regulation of Ah receptor protein expression and enhanced induction of CYP1A1 and CYP1B1 proteins by TCDD in LTEE compared with the long-term estrogen-deprived (LTED) cells maintained in DC5. Total RNA isolated from these cultures was subjected to reverse transcription and real-time polymerase chain reactions (PCR). These PCR results showed up-regulation of Ah receptor mRNA and enhancement of the induction of CYP1A1 and CYP1B1 mRNAs consistent with the Western blot and EROD activity measurements. These RNA samples were subjected to gene expression analysis on Affymetrix HG U133A 2.0 chips, and the data were analyzed for global changes in gene expression. The results revealed that LTEE enhanced TCDD-induced expression of a number of members of the Ah gene battery in MCF-7 cells. These studies suggest that LTEE, through the enhancement of Ah responsiveness, may ultimately affect the toxicity and carcinogenicity of environmental Ah receptor ligands and CYP1 substrates.

137 TIER-1 SCREENING CLASSIFICATION SYSTEM FOR ESTROGENIC EDCS USING THE LUMI-CELL® ER BIOASSAY.

J. D. Gordon¹, M. S. Denison², A. C. Chu¹, M. D. Chu³, C. Matherly¹, F. Kayama⁴ and G. C. Clark¹. ¹Xenobiotic Detection Systems, Inc., Durham, NC, ²Department of Environmental Toxicology, University of California, Davis, Davis, CA, ³Analytical Perspectives, Wilmington, NC and ⁴Department of Health Science, Jichi Medical School, Minamikawachi, Tochigi, Japan.

There is a growing need for a reliable tier-1 screening classification system for estrogenic endocrine disruptor chemicals (EDCs). The concern for EDCs arises from the detrimental effects on human and wildlife populations resulting from its bioaccumulation in the food chain. A classification system would help researchers and regulators determine which compounds pose the greatest potential threat to human and wildlife populations. Here we report a possible method for classification of xenoestrogenic EDCs based on dose response criteria using the LUMI-CELL® ER bioassay. Fifty compounds, which were on ICCVAM's priority list to validate an estrogen receptor transcriptional activation (ER TA) assay, were analyzed using the LUMI-CELL® ER bioassay. We evaluated gene induction data for all compounds to establish a classification scheme based on dose dependent response and induction efficacy. The data allowed chemicals to be divided into 4 classes depending on their EC50: Class IV (greater than 10⁻³M); Class III (10⁻³M to 10⁻⁷M); Class II (10⁻⁷M to 10⁻¹¹M); and Class I (10⁻¹¹M to 10⁻¹⁵M).

⁷M to 10⁻⁹M); and Class I (less than 10⁻⁹M). Compounds were further classified by the efficacy of their agonist ER TA response. Group D includes compounds with a maximal response of less than or equal to background. Group C includes compounds with a maximal response of greater than background, but less than 50% of the relative light unit (RLU) response for 17 β -estradiol (E2). Group B includes compounds with a maximal response of greater than 50% of the E2 response but less than 100% of the E2 response. Group A compounds include responses greater than 100% of the response of E2. This system of in vitro classification should help prioritize compounds for subsequent analysis in animal and cell systems and will help determine initial doses reducing animal use. Supported by NIEHS SBIR ES10533-03 and Superfund Basic Research Grant ES04699.

138 COMPARISON OF VISUAL INSPECTION TO CELLTITER-GLO® IN EVALUATING CYTOTOXICITY IN THE LUMI-CELL® ER BIOASSAY.

G. C. Clark¹, J. D. Gordon¹, M. S. Denison², A. C. Chu¹, M. D. Chu³, C. Matherly¹, F. H. Deal⁴, P. Ceger⁴, J. M. Charles⁴, R. R. Tice⁵ and W. S. Stokes⁵.
¹Xenobiotic Detection Systems, Inc., Durham, NC, ²Department of Environmental Toxicology, University of California, Davis, Davis, CA, ³Analytical Perspectives, Wilmington, NC, ⁴ILS, Inc., Research Triangle Park, NC and ⁵NICEATM/NIEHS/NIH/DHHS, Research Triangle Park, NC.

There is a need to determine if a decreased response observed (for agonist and in particular antagonist testing) in an endocrine disruptor screening assay is a result of lower activity due to a chemical-receptor response or whether the compound is cytotoxic, resulting in a lower observed response. A comparison study was conducted in cooperation with NICEATM to compare cytotoxicity measured using the Visual Inspection assay with that obtained using Promega's CellTiter-Glo® assay which is a method of estimating viable cell number based on quantitation of ATP. Visual Inspection viability score codes were developed with: 1 = normal cell morphology and cell density, 2 = altered cell morphology and small gaps between cells, 3 = altered cell morphology and large gaps between cells and, 4 = few (or no) visible cells. Comparison of the Visual Inspection and CellTiter-Glo® assays demonstrate that, a score of 1 corresponded to greater than 80% viability, 2 corresponded to 80 – 60% viability, 3 corresponded to 60 – 40% viability and 4 corresponded to less than 40% viability. Eight coded compounds were selected to test for estrogenic activities and eight coded substances to test antagonist activities in the LUMI-CELL® ER assay, a cell based assay in which estrogenic chemicals induce firefly luciferase. The CellTiter-Glo® and Visual Inspection assays both were able to detect cytotoxicity, with a significant correlation between the two techniques for determining cytotoxicity. Accordingly, either of these methods may be useful in determining cytotoxicity of chemicals and extracts tested in the LUMI-CELL® ER assay, thereby eliminating cytotoxicity-dependent false positives. Supported by NIEHS Contract N01-ES-85424, NIEHS SBIR ES10533-03 and Superfund Basic Research Grant ES04699.

139 MIXTURES OF THYROID DISRUPTING CHEMICALS: TESTING ADDITIVITY OF HEPATIC INDUCERS AND THYROID PEROXIDASE INHIBITORS.

J. L. Flippin¹, K. M. Crofton², G. A. LeBlanc¹, J. M. Hedge² and M. J. DeVito¹.
¹Department of Environmental and Molecular Toxicology, NCSU, Raleigh, NC and ²ORD, NHEERL, U.S. EPA, Research Triangle Park, NC.

Humans are exposed to chemical mixtures via diet, occupation, and the environment. Previous data demonstrated that low doses of polycyclic halogenated aromatic hydrocarbons (PHAHs) acting through similar mechanisms result in an additive reduction of thyroxine (T4). If xenobiotics acting through the same mechanism are able to disrupt thyroid hormone homeostasis, it is reasonable to expect that chemical mixtures acting through different mechanisms but targeting the same endpoint (i.e. serum thyroid hormone levels) would exert additive effects on T4. Along with PHAHs, which induce T4-eliminating hepatic enzymes, certain pesticides are shown to decrease production of T4 by inhibiting thyroid peroxidase in the thyroid gland. Female Long-Evans rats, 28 days of age, were dosed with a mixture of 18 PHAHs (2 dioxins, 4 dibenzofurans, and 12 PCBs, including dioxin-like and non-dioxin like PCBs) and a mixture of 3 pesticides (thiram, pronamide, and mancozeb) for 4 consecutive days. Stock solutions were prepared with concentrations of the PHAH mixture and each individual pesticide that individually produce a 20% decrease in circulating T4 levels. Six serial dilutions (66, 33, 10, 6.6, 3.3, and 1%) and a control were administered in the 4-day bioassay. Tissues were collected 24 hours after the last dose and serum total T4 was quantified via radioimmunoassay. Animals exposed to the four highest doses resulted in serum T4 decreases between 3 and 45% compared to control animals; the two lowest doses

showed a slight increase in circulating T4. Dose and response addition models fit to the data suggest that the combination of UGT-inducers and TPO inhibitors are antagonistic. The results of this research suggest that environmentally complex chemical mixtures interact in a complicated fashion to disrupt thyroid hormone homeostasis. (Funded by the EPA NHEERL/NCSU Cooperative Training Program in Environmental Sciences Research, CT826512010. This abstract does not represent USEPA policy).

140 BRAIN, LIVER, AND THYROID BIOMARKERS REFLECT ENHANCED SENSITIVITY OF THE DEVELOPING RAT TO THYROID HORMONE DEPLETION.

M. A. Taylor¹, M. Stramiello¹, N. Paolino¹, N. Jennings¹, J. Swant¹, J. Fisher¹, J. Wagner¹, M. Gilbert² and D. Ferguson¹.

Many developmental events are regulated at least in part by thyroid hormones. It was hypothesized that tissue biomarkers of thyroid status would be more accurate predictors of neurotoxicity than serum biomarkers in rats treated with the goitrogen propylthiouracil (PTU). Over several studies, timed pregnant rats were dosed 0, 0.3, 1, 3 or 10 ppm PTU solutions in drinking water from day 2 of gestation until weaning. Dams and pups were studied at 21-30 days after birth for thyroid status and hippocampal electrophysiology, focusing on synaptic potential and weak and strong long term potentiation (LTP). Brain tissue from animals dosed with 0, 1, 2, or 3 ppm PTU at the USEPA was studied. Cerebrocortical Type 2 5'-deiodinase (D2), which converts thyroxine(T4) into the metabolically active 3',3',5'-Triiodothyronine (T3), was found to be a very sensitive indicator of T4 depletion, and provided robust protection of brain T3 levels. Cortical T3 concentrations were reduced further in pups than in dams. Serum T3 concentrations were better protected than serum T4 concentrations. Serum T4 was more affected by doses >0.3ppm in PND4 and 14 pups than older animals. Serum T4 and cortical D2 activity correlated strongly, and results from two rat strains were nearly identical, strengthening the utility of D2 as a biomarker of thyroid disruption in the brain. In our first study, effects on synaptic potential in PND 21 pups showed a strong linear correlation to cerebrocortical D2(R=.75, p<.0001). In that study, synaptic potential decreased with increasing D2 and decreasing serum T4, and LTP was impaired in PND100 animals. Overall, exposure to PTU doses >0.3ppm had effects on at least serum T4 at PND4-21. This data will assist researchers developing a biologically based pharmacokinetic model of thyroid disruption in the developing rat. Funding was provided by USEPA STAR cooperative agreement #R832134. 141 EVALUATION OF THE REPRODUCTIVE TOXICITY OF A MIXTURE OF ANTI-ANDROGENIC COMPOUNDS IN FEMALE WISTAR RATS.

A. E. Engell-Kofoed, U. Hass, M. Axelstad and A. Vinggaard. Department of Toxicology and Risk Assessment, Danish Institute for Food and Veterinary Research, SVÉ-11borg, Denmark. Sponsor: E. Gray.

Earlier studies have shown that anti-androgenic compounds elicit severe developmental effects on the male reproduction system and generate feminised male rats after perinatal exposure. However, the literature on effects of anti-androgenic compounds on female offspring is limited, and more research is needed in order to elucidate effects on endocrine endpoints in females. Furthermore, in vitro studies have revealed that several of these substances can have multiple effects on the endocrine system in addition to anti-androgenic effects, and only few studies in general have evaluated mixture effects of endocrine disruptors. The objective of this study was to evaluate whether prochloraz (PRO), vinclozolin (VIN), di-2-ethyl-hexyl-phthalate (DEHP) and finasteride (FIN) affected female offspring. Pregnant dams were given the test substances both singly and in a mixture at 'No Observed Adverse Effect Level' (PRO: 5 mg/kg, VIN: 5 mg/kg, DEHP: 3 mg/kg, FIN: 0.01 mg/kg) and 5 to 10 times higher doses. The dosages were given daily by gavage for a period of 31 days from gestation day 7 until postnatal day (PND) 16. Birth weights, anogenital distance (AGD), organ weights, ovarian steroidogenesis, uterine effects (histology, immunohistochemistry and gene expression) and hormone levels at PND6 and PND16 were evaluated. Furthermore onset of puberty (time of vaginal opening) and oestrous cyclicity were analyzed as end points for long-term effects. The results of this study showed only small effects on the female offspring. The highest dose of prochloraz (50 mg/kg) caused an increased AGD and so far no other significant short-term effects have been observed. With regard to long-term effects, no detectable effect on onset of puberty was observed. However, the highest mixture dose caused a disturbed oestrous cyclicity, which may be regarded as a sensitive endpoint for endocrine disruptors.

142 ARSENIC-INDUCED TOXICITY AND THE PROTECTIVE ROLE OF ASCORBIC ACID IN MOUSE TESTIS.

D. Ryu¹, S. Chang¹ and J. Park². ¹College of Veterinary Medicine, Seoul National University, Seoul, South Korea and ²College of Medicine, Chung-Ang University, Seoul, South Korea.

Oxidative stress has been suggested to be a major cause of male reproductive failure. Here, we investigated whether arsenic, which impairs male reproductive functions in rodent models, acts by inducing oxidative stress. Male 8-week-old ICR mice were given drinking water containing 20 or 40 mg/l sodium arsenite with or without 0.75 or 1.5 g/l of the antioxidant ascorbic acid for 5 weeks. The arsenic-treated mice showed decreased epididymal sperm counts and testicular weights compared to untreated mice. These effects were reversed in mice that were co-treated with ascorbic acid. Similarly, arsenic treatment lowered the activities of testicular 3 β -hydroxysteroid dehydrogenase (HSD) and 17 β -HSD, which play important roles in steroidogenesis, and this was reversed by co-treatment with ascorbic acid. The testes of arsenic-treated mice had decreased glutathione (GSH) levels (which correlate inversely with the degree of cellular oxidative stress) and elevated levels of protein carbonyl (a marker of oxidative damage to tissue proteins). Ascorbic acid co-treatment reversed both of these effects. Thus, ascorbic acid blocks both the adverse effects of arsenic on male reproductive functions and the arsenic-induced testicular oxidative changes. These observations support the notion that arsenic impairs male reproductive function by inducing oxidative stress.

143 A FIVE GENERATION REPRODUCTIVE TOXICITY ASSESSMENT OF ETHINYL ESTRADIOL (EE) IN CD SPRAGUE-DAWLEY RATS.

K. B. Delclos¹, C. C. Weis¹, G. Olson², T. J. Bucc² and R. R. Newbold³. ¹NCTR, Jefferson, AR, ²Toxicologic Pathology Associates, Jefferson, AR and ³NIEHS, Research Triangle Park, NC.

The toxicity of dietary EE (0, 2, 10, and 50 ppb), a potent estrogen, has been evaluated in a multigeneration design with NCTR CD rats. These concentrations led to ingested doses of approximately 0, 0.2, 1, and 5 μ g/kg/day in females and 0, 0.1, 0.7, and 4 μ g/kg/day in males. This study was one of a series examining estrogens of varying potencies, including the carryover and magnification of subtle effects across generations, reversibility of effects, and chronic effects. The parental generation was exposed to EE in a low phytoestrogen diet (Purina 5K96) from 28 days prior to mating until necropsy at PND 140, the age at which all generations were terminated. The F₁ and F₂ generations were exposed continuously from conception, F₃ from conception until wean, and F₄ was not exposed to EE. Body weight was lower than controls in the 50 ppb dose group for both sexes in the continuously exposed F₀ through F₂ generations, with terminal body weights 8-15% lower than controls. Body weights in all groups were similar after dosing was discontinued at weaning in the F₃ generation. Fertility and litter parameters did not show consistent dose-related effects. The primary effects observed in females were at 50 ppb: an acceleration of the time of vaginal opening by 4, 6, and 3 days in the F₁, F₂, and F₃ generations, respectively, and disrupted estrous cycles, which were approximately doubled in length, in the F₁ and F₂ generations. No clear adverse histopathological effects were observed in females at 140 days. In males, an increase in renal tubule mineralization was observed in the 50 ppb dose group of the continuously exposed F₁ and F₂ generations. Increases in alveolar/ductal hyperplasia of the male mammary gland were observed in the 50 ppb dose group of the F₀ through F₃ generations, with significant effects at 10 ppb in the F₁ and F₂ generations, and at 2 ppb in the F₁ generation. These effects overlap those observed previously at near 10,000-fold higher doses of the phytoestrogen genistein.

144 ALTERED UTERINE GENE EXPRESSION IN RATS IN RESPONSE TO P-TERT-OCTYLPHENOL EXPOSURE.

S. K. Sahambi and P. J. Devine. , INRS-Institut Armand-Frappier (Université du Québec), Pointe Claire, QC, Canada.

P-tert-octylphenol (OP) is an environmental contaminant possessing estrogenic properties found to alter gene expression, interrupting the normal course of development and reproduction. OP, the most estrogenic among the alkylphenols, is an environmentally persistent industrial by-product, present in food, drinking water and household products. Multiple studies show that high doses of OP induce interruption of the estrous cycle, changes in uterine, prostate and epididymal weights and dose-dependent alterations in estrogen-responsive gene expression in vitro and in vivo. Exploiting uterine sensitivity to estrogens, we tested uterine response and gene expression as a biomarker of estrogenicity, using OP as a purported estrogenic chemical. Sprague-Dawley rats were given vehicle (propylene glycol) or OP (125mg/kg bw/day) by gavage either once or for 35 days. Uteri collected after 24hrs or 35 days were weighed and processed for microarray gene expression studies. OP did not affect uterine weights but altered uterine expression of certain genes re-

sponsive to estrogens, toxicants or stress. Acute exposures changed the expression of 21 genes (p<0.05, >2-fold, 12 up- and 9 down-regulated), 3 of which have been related to estrogen changes (cytochrome P450 Cyp1a2, heterogeneous ribonucleoprotein Hnrpa1 and sulfotransferase Sult1c1). In the sub-chronic treatment, 8 genes had a >2-fold change in expression (p<0.05, 3 down- and 5 up-regulated), one of which (cysteine rich protein Cyr 61) was responsive to estrogenic changes. Expression of expected estrogen-responsive genes in uterine tissues was not affected by OP exposures. Thus, results do not support that OP has estrogen-like activity in uterus at the dose tested here. Low oral bioavailability, rapid elimination, and route of exposure to OP may underlie these negative results, since previous studies required higher doses to observe estrogenic effects. However, altered expression of several other genes suggests that OP could alter uterine physiology through estrogen-independent mechanisms. (Funded by NSERC)

145 ACUTE DIMETHYDITHIOCARBAMATE (DMDC) EXPOSURE ALTERS NEUROENDOCRINE CONTROL OF OVULATION (OV) BUT CONTINUED DOSING DOES NOT.

R. L. Cooper, A. Buckalew, J. Ferrell and T. Stoker. Endocrinology Branch, RTD, U.S. EPA, Research Triangle Park, NC.

Our laboratory has shown previously that a single exposure to dithiocarbamate pesticides on the morning of proestrus will block the OV surge of luteinizing hormone (LH), an effect attributed to a DMDC-induced decrease in hypothalamic norepinephrine (hNE) and decreased pulsatile release of gonadotropin releasing hormone (GnRH). Blocking the LH surge delays OV, alters oocyte viability, delays embryonic development and reduces litter size. We also reported that continued dosing (21 days) is without effect on pregnancy, indicating that any adverse reproductive effect observed following one treatment dissipates with repeated dosing. Here, we examined the underlying neuroendocrine changes associated with DMDC and pregnancy disruption to better define the events responsible for the initial adverse effects and characterize how these measures change with repeated dosing. Groups of ovariectomized (OVXed), estrogen-primed rats were dosed with DMDC at 1300 h (50 mg/kg, i.p.) for 1, 5 or 21 days. The induction of the surge was timed to occur on the last day of treatment. On day 1, DMDC decreased LH secretion and hNE. On day 5 and 21, LH secretion was not different from controls. hNE was still lower in treated rats on day 5 but not day 21. In a second experiment we examined the pulsatile release of LH in long-term OVXed females treated with DMDC for 1, 5 and 21 days using a cardiac catheter. Again, DMDC decreased the pulsatile LH release on 1 day, but not 5 and 21 days. These results demonstrate that the neuroendocrine mechanisms underlying the generation of the OV surge of LH are initially impaired by DMDC, but these adverse effects are ameliorated after only 5 days of exposure and appear to be completely compensated after 21 days later. This would explain our observation of pregnancy loss after acute but not subchronic DMDC treatment and emphasizes the importance of tolerance in the risk assessment process. This abstract does not necessarily reflect EPA policy.

146 PPAR GAMMA AND OVARIAN TOXICITY: AN ENDOCRINE STORY.

M. R. Robbins, V. L. Reynolds, G. D. Williams and I. R. Cohen. Eli Lilly and Co., Greenfield, IN.

Previous work in rats with PPAR (peroxisome proliferator-activated receptor) γ agonists has shown a clear association between treatment and the loss of corpora lutea. Recently, we also identified an increase in atresia of secondary follicles in rats treated with the gamma-weighted PPAR α,γ dual agonist, naveglitazar. The present study was designed to elucidate the interplay between PPAR γ activation and the endocrine system on ovarian function. Naveglitazar was administered daily by oral gavage to female F344 rats for 4 weeks. Serial blood samples were collected on the final day of dosing from unrestrained rats via an atrial cannula. Circulating levels of hormones including LH, FSH, Inhibin A, and progesterone (P4) were measured. The ovary, uterus, cervix, and vagina were examined for morphological changes. Treatment with naveglitazar resulted in normal levels of basal LH and elevated FSH. Decreased levels of P4 were associated with depletion of corpora lutea. Increased atresia was noted in follicles from the secondary follicle stage of development through the Graafian stage with associated decreases in Inhibin A levels. It is clear, given the corpora luteal depletion, that in spite of sufficient gonadotropin support, ovarian follicles failed to reach an ovulatory state. Further, the increase in circulating FSH levels did not result in an increased rate of follicular development. The increase in follicular atresia was observed in the same developmental stages at which PPAR γ expression in the follicle is increasing during normal follicular development. Additionally, previously reported evidence suggests that activation of PPAR γ is associated with factors favoring apoptosis such as induction of p53, inhibition of bcl-2, and interference with estradiol binding its receptor. Thus, the interpretation of the present study concludes that activation of PPAR γ in the ovary interrupts follicular development at early stages inducing apoptotic events and atresia resulting in a loss of follicles that are functionally able to undergo ovulation.

147 EFFECTS OF THE DITHIOCARBAMATE FUNGICIDE THIRAM ON THE REPRODUCTIVE AND THYROID AXIS FOLLOWING EXPOSURE IN THE JUVENILE AND ADULT MALE RAT.

T. E. Stoker, E. Kaydos, J. M. Ferrell and R. L. Cooper. *Endocrinology Branch, U.S. EPA, Research Triangle Park, NC.*

Thiram inhibits the synthesis of norepinephrine (NE) by inhibiting dopamine-beta-hydroxylase in the hypothalamus. NE is important for the regulation of gonadotropin releasing hormone and subsequent luteinizing hormone (LH) secretion. Thiram has been shown previously in our laboratory to inhibit the proestrous surge of LH in the female rat. Therefore, we hypothesized that thiram would disrupt testosterone secretion and affect pubertal onset in the juvenile rat. We exposed weanling males from postnatal day (PND) 23 to 53 by oral gavage with 0, 12.5, 25 and 50 mg/kg/d thiram. Preputial separation was delayed at 50 mg/kg. Lateral and ventral prostate and seminal vesicle weight at PND 53 was decreased by the same dose. There were no effects on testes or epididymal weights. Serum LH was decreased by 25 and 50 mg/kg, while testosterone was decreased at all doses on PND 53. These results demonstrate that thiram is able to alter pubertal progression in the male rat, which can be attributed to effects on LH. We also observed a dose-dependent decrease in serum thyroid stimulating hormone (TSH) at 25 and 50 mg/kg, while T4 was only decreased by 50 mg/kg. Since this pattern of effect on thyroid homeostasis indicated that thiram may be altering the pituitary or hypothalamic regulation of TSH, an additional study was conducted in the adult male rat to evaluate TSH release more closely. We dosed 60 day old male rats daily by gavage with 0, 25, 50, or 100 mg/kg thiram for 1, 7 or 21 days and measured TSH six hours after dosing. TSH was decreased 6 hours after either 1, 7 or 21 days of exposure to thiram or at doses of 50 and 100 mg/kg. These results demonstrate that effects are seen on TSH after only a single dose and that the brain or pituitary are likely target sites. Further studies are planned to evaluate this effect of thiram on the pituitary or hypothalamic regulation of TSH. This abstract does not necessarily reflect EPA policy.

148 EFFECT OF SIMAZINE (SIM) ON TESTICULAR FUNCTION IN THE JUVENILE WISTAR RAT.

E. Kaydos, J. Ferrell, R. Cooper and T. E. Stoker. *Endocrinology Branch, U.S. EPA, Research Triangle Park, NC.*

Chlorotriazine herbicides, such as SIM, are used extensively in the U.S. each year and both the parent compound and the metabolites are detected in ground water in areas of major usage. Previously we found that SIM exposure from postnatal day 23 to 53 increased serum testosterone (T) on postnatal day (PND) 53 in the rat. We hypothesized that SIM was either advancing the hypothalamic-pituitary-gonadal (HPG) activation of puberty by targeting the hypothalamic regulation of pituitary luteinizing hormone (LH) release or inducing the secretion of testosterone by altering testes function. The present study examines the effects of SIM on testes function more closely. We measured intra-testicular T concentrations and ex-vivo T production following a 20 day exposure to 0, 3.125, 6.25, 25 and 100 mg/kg of SIM by gavage (PND 23 to 43). Specifically, we measured interstitial fluid (IF) and seminiferous tubule fluid (SNF) in one testis of each rat and determined T content. There were no significant differences in testis weight or IF and SNF volume or T content. The other testis was incubated in supplemented Med 199 based upon the sliced testes assay and baseline and challenged collections (100 mIU/ml hCG) were obtained at seven 30 minute intervals. In the initial baseline collection, the concentration of T in the media was increased at simazine doses of 25 mg/kg or higher. All other incubation media T concentrations were not different from controls in the baseline or hCG stimulated collections. Lactate dehydrogenase activity from the last collection indicated no cytotoxicity. In conclusion, SIM did not alter testicular function and suggests that the previously observed effects of SIM on serum T concentrations are not due to any direct effects on the testes, but may be due to increased LH stimulation. Further studies are ongoing to determine the effect of simazine on the hypothalamic-pituitary regulation of LH secretion during the pubertal period. This abstract does not necessarily reflect EPA policy.

149 EFFECTS OF DI(N-BUTYL)PHTHALATE ON DEVELOPMENT OF REPRODUCTIVE ORGANS AND STEROIDOGENESIS IN SPRAGUE DAWLEY FEMALE RATS.

T. Kim, H. Moon, I. Kang, K. Jung, B. Lee, E. Choi, T. Kang, S. Kim and S. Han. *Endocrine Toxicology, KFDA/NITR, Seoul, South Korea.*

The purpose of this study was to evaluate the effect of di(n-butyl)phthalate (DBP), a widely used plasticizer, on the reproductive organ development in F1 Sprague-Dawley (SD) female rats following in utero exposure. Development of female reproductive organs and vagina opening were dose-dependently delayed by DBP

treatment. High-dose DBP (700 mg/kg/day) increased the number of days in proestrus, whereas DES 50 ug/kg/day produced a persistent estrus state. In granulosa cells of ovary follicle, expressions of aromatase and ER α were decreased by DBP treatment, but were increased in the DES treatment group. In uterus epithelium cells, expression of ER α was increased in the DBP treatment group and was proliferated more than control group similar to DES treatment. The serum estradiol and IGF-I levels were significantly decreased by the DBP treatment but were significantly increased in the DES treatment groups. In the expression of peroxisome proliferator-activated receptors α was increased by the DBP treatment in ovary. These results showed that ER α , IGF-I and aromatase may be significantly involved in DBP-induced disruption of ovary development and estradiol synthesis. These results demonstrate that exposure to DBP during gestation days 10-19 causes several abnormal developments of female reproductive organs, and these effects may be due to disruption of the stage and tissue specific expression of genes and growth factors related to development of organs.

150 COMPARISON OF CYCLOSARIN (GF) AND SARIN (GB) TOXICOKINETICS AND TOXICODYNAMICS FOLLOWING A SINGLE INHALATION EXPOSURE IN THE GUINEA PIG.

C. E. Whalley¹, L. A. Lumley², J. M. McGuire¹, D. B. Miller¹, C. Robison², W. T. Muse¹, C. Clark², J. C. O'Donnell², B. Somsamayong², T. Dill², E. M. Jakubowski¹, J. H. McDonough², R. J. Mioduszewski¹, T. M. Shih² and S. A. Thomson¹. ¹ECBC, Aberdeen Proving Ground, MD and ²USAMRICD, Aberdeen Proving Ground, MD.

It is necessary to generate mathematical models of the adsorption, distribution, and elimination of nerve agents to improve toxicity estimates from sub-lethal exposures to chemical warfare nerve agents (CWNA). However, such models are based on representative data sets generated with different routes of exposure and in different species and are designed to interpolate between limited laboratory data sets to predict a wide range of possible human exposure scenarios. This study was performed to integrate CWNA sub-lethal toxicity data using different nerve agents in male Duncan Hartley guinea pigs (GP). Animals had a single whole body inhalation (IH) exposure of either GF or GB (0.1 or 0.4 x LC₅₀). Arterial catheterization allowed repeated blood sampling from the same animal at various time periods. Blood and tissue levels of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE), as well as blood and tissue levels of regenerated GF (rGF) or GB (rGB) were determined at various time points during and following low level nerve agent exposure. The following pharmacokinetic parameters were calculated from the graph of plasma or RBC regenerated nerve agent concentrations versus time: time to reach the maximal concentration (t_{max}), maximal concentration (C_{max}), mean residence time (MRT), clearance (Cl), volume of distribution at steady state (V_{ss}), terminal elimination phase rate constant (k_{elim}), and the area under the plasma concentration time curve extrapolated to infinity (AUC) using WinNonlin[®] analysis program 5.0. The plasma and RBC t_{1/2} for rGF and rGB was also calculated. These data will be used to develop a mathematical model of the absorption of sub-lethal doses of GF and GB and its distribution into susceptible tissues. A specific goal was to compare uptake and clearance kinetics of similar sub-lethal doses of GF or GB in the blood and tissue of GP exposed to agent by acute inhalation exposure.

151 EVALUATION OF TOXICOKINETICS OF SUBCUTANEOUS EXPOSURE TO SUB-LETHAL DOSES OF CYCLOSARIN (GF) AND SARIN (GB) IN THE GUINEA PIG.

L. A. Lumley¹, C. E. Whalley², J. M. McGuire², C. L. Robison¹, J. C. O'Donnell¹, C. R. Clark¹, B. Somsamayong¹, T. I. Dill¹, L. J. Burr¹, E. M. Jakubowski², D. B. Miller², J. H. McDonough¹, R. J. Mioduszewski², S. A. Thomson² and T. Shih¹. ¹Pharmacology, USAMRICD, Aberdeen Proving Ground, MD and ²U.S. Army Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD.

Mathematical models of the absorption, distribution and elimination of chemical warfare nerve agents can be used to improve toxicity estimates, extrapolate to humans and predict response to a range of nerve agent exposures. The current study was performed to compare toxicity data of subcutaneous exposure to different nerve agents in male guinea pigs. Animals were given a single low-level subcutaneous (SC) dose of either GB or GF (0.1 & 0.4 x LD50). Blood levels of acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE), as well as of regenerated GB (rGB) or GF (rGF) were evaluated at multiple time points following exposure. In plasma, for each respective LD50 exposure of either GF or GB, toxicokinetic parameters such as the AUC, C_{max}, t_{max} and clearance were similar for each respective dose irrespective of the agent used; however, the t_{1/2} for rGF in plasma was

twice as long compared to rGB. In RBC, similar toxicokinetic results occurred except that clearance from RBCs was higher for rGF than rGB and the $t_{1/2}$ for the 0.1 x LD50 GB dose was higher than the other RBC $t_{1/2}$ values. Also the t_{max} was higher for RBCs than plasma. In summary, it appears that GF has greater inhibitory action upon guinea pig AChE activity that occurs earlier and persists longer than does GB. Although toxicokinetic parameters were similar for rGB and rGF, some differences did occur. These data will be utilized in a physiologically based pharmacokinetic model that was developed to simulate low level nerve agent exposures in guinea pigs.

152 THE EFFECTS OF MEDICAL COUNTERMEASURES ON SURVIVAL AND BEHAVIOR OF GUINEA PIGS EXPOSED TO REPEATED DOSES OF SARIN OR VX.

T. Shih¹, F. N. Bader and B. J. Jung. *Pharmacology Branch, U.S. Army Med. Res. Inst. Chemical Defense, Aberdeen Proving Ground, MD.*

This study assesses the therapeutic effectiveness of standard medical countermeasures against repeated exposures to the organophosphorous nerve agents sarin (GB) or VX. Male guinea pigs were subcutaneously injected once daily with 0.7 x LD50 GB or VX (LD50 for GB and VX are 42 and 9 µg/kg, respectively) for two weeks (5 days per week, Mondays–Fridays). During the exposure period, animals were pretreated with pyridostigmine bromide (PB) or treated with the countermeasures (CM) atropine sulfate/2-PAM. PB (25 mg/L) was provided in drinking water for the duration of GB or VX exposure to inhibit ~25% of basal blood cholinesterase activity. A single MARK I injector equivalent dose (by body weight) of atropine sulfate (0.03 mg/kg, im) and 2-PAM (8.5 mg/kg, im) was injected immediately following daily GB or VX. Toxic signs (TST) were collected at selected exposure and recovery days. The TST measures cholinergic toxicity in response to nerve agents. CM decreased mortality in GB- and VX-exposed guinea pigs from 55.6% (GB alone) to 9.1% (GB+CM) and 81.8% (VX alone) to 9.1% (VX+CM), respectively. PB pretreatment with GB and VX exposure reduced mortality rate from 55.6% (GB alone) to 0% (PB+GB) and from 81.8% (VX alone) to 40.0% (PB+VX). GB exposure alone produced higher TST scores ranging from mild to moderate only during the first week. Countermeasures failed to lower GB toxicity during the exposure period. VX exposure alone produced moderate levels of toxicity starting on the fifth day and continuing through the rest of the exposure period. With VX exposure, CM reduced TST scores, producing mild levels of toxicity below the TST scores of the VX alone and PB+VX groups. PB pretreatment of the GB-exposed group prevented the toxicity produced by either GB alone or GB+CM. Conversely, PB pretreatment with VX exposure did not reduce TST scores. In summary, pretreatment with PB or treatment with atropine sulfate/2-PAM had variable effects upon toxic signs. However, regardless of whether VX or GB was tested, PB or CM decreased mortality rates.

153 LOW LEVEL VX INCREASES HIPPOCAMPAL NEUROTROPHIN EXPRESSION INDEPENDENT OF BRAIN PATHOLOGY IN MOUSE HIPPOCAMPUS.

W. E. Chang², J. M. Petras³, H. Smith², C. L. Robison¹, D. M. Cerasoli¹, S. M. Johnson¹, A. Zheng³, T. Shih¹ and L. A. Lumley¹. ¹Pharmacology, USAMRICD, Aberdeen Proving Ground, MD, ²Emerging Technologies Office, MITRE, McLean, VA and ³Psychiatry and Neuroscience, Walter Reed Army Institute of Research, Silver Spring, MD.

The chemical warfare nerve agent VX is an irreversible inhibitor of the enzyme acetylcholinesterase and leads to neurotoxicity at nerve synapses and neuromuscular junctions through the accumulation of excess acetylcholine. Although high doses of VX and other nerve agents induce seizures, excitotoxicity and brain pathology, less is known about the effects of exposure to low doses of nerve agents. Brain derived neurotrophic factor (BDNF) is associated with neuronal development, synaptic plasticity, and cell survival, and is neuroprotective for certain types of hippocampal neurons following brain trauma. In the current study, we evaluated the effects of low-level VX exposure on protein levels of BDNF in a dose (0.1, 0.2, 0.4 LD50 VX (1/day x 5 days/wk x 2 wk)) and time course study (range 2 hr to 2 wk). In a parallel study, we assessed whether there was any hippocampal pathology three weeks following the same dose regimen of low-level VX exposure. A significant increase in the level of BDNF protein was observed in the hippocampal formation at 72 hr post-exposure compared with saline control mice. Pathology was not observed when evaluated 3 wk after the final VX exposure. The increase in BDNF protein expression in hippocampus is consistent with our previous observation of increased BDNF mRNA in the hippocampal formation following multiple VX exposures. This increase in BDNF may be an adaptive response to VX, since we do not observe brain pathology following exposure. Funding was provided by DTRA to LA Lumley.

154 ANALYSIS OF FREE AND BOUND VX FROM MINIPIG BLOOD FOLLOWING WHOLE BODY VAPOR EXPOSURE.

E. Jakubowski¹, J. M. McGuire¹, R. A. Evans¹, S. W. Hulet¹, C. E. Byers¹, J. A. Renner², A. L. Totura², D. B. Miller¹, K. L. Matson¹, C. L. Crouse², R. J. Mioduszewski¹ and S. A. Thomson¹. ¹U.S. Army ECBC, APG Edgewood, MD and ²SAIC, Abingdon, MD.

Recent developments to improve nerve agent biomarker and dose-metric techniques include methods for measuring fluoride ion regenerated VX G-analog (VX-G) in blood and tissue. Protein bound V-series nerve agents regenerate a G-series analog upon addition of fluoride ion. In the case of VX, the regeneration product is O-ethyl methylphosphonofluoridate. Blood samples were taken serially before, during, and after whole body VX vapor exposures from Gottingen minipigs via venous catheter allowing agent exposure profiles to be generated. After processing the samples with fluoride ion and extracting with C-18 solid phase extraction cartridges the ethyl acetate extract was analyzed by GC/MS/MS. In addition to VX-G, significant levels of free VX were recovered from plasma using hexane solvent extraction and GC/MS/MS analysis. Plasma levels of VX-G maximized relatively soon after the end of the exposure. However, RBC levels rose for hours after the end of the exposure.

155 INVESTIGATION OF HAIR FOLLICLE AND PLASMA BIOMARKERS FOR LOW-LEVEL VX VAPOR EXPOSURE.

E. M. LaFiandra¹, A. E. Chambers¹, A. Higgins², B. J. Benton¹, J. J. Valdes¹ and J. W. Sekowski¹. ¹Edgewood Chemical and Biological Center, U.S. Army Research Development and Engineering Command, Aberdeen Proving Ground-EA, MD and ²Icoria, Inc., Research Triangle Park, NC.

Currently, there are no field-ready, expedient, and simple assays available that can determine whether someone has been exposed to very low levels of chemical warfare agent (CWA). Our laboratory has begun work to identify protein biomarkers in hair follicles and metabolite biomarkers in the plasma of rats exposed to low-level VX vapor. Both blood plasma and the active hair follicle carry a large number of easily accessible proteins that are responsive to toxicant exposure and are therefore excellent candidates from which to mine biomarkers. We identified more than 20 potential protein targets that are reportedly altered as a result of OP agent exposure and, using Western blotting, determined which of these potential targets are found in the rat whisker hair follicle. Using a novel whole mount immunohistochemistry (IHC) technique we investigated which proteins are responsive to VX exposure. Growth stage corrected expression of estrogen receptor (ER-α) was significantly lower in both male and female VX-exposed rats. Expression of androgen receptor (AR) was also reduced in VX-exposed male rats. Rats exhibiting physical symptoms of exposure (miosis) one hour post exposure had significantly lower expression of a cytochrome P450 enzyme (CYP1A1) in the whisker follicle bulb. The metabolomic profiles of the blood plasma of the same VX-exposed rats were determined using liquid chromatography coupled with mass spectrometry (LC/MS). The LC/MS data were analyzed using unsupervised hierarchical clustering to identify groups of perturbed metabolic components in the plasma. A panel of plasma metabolite biomarkers that can discriminate between VX exposure and control as well as level of VX exposure was identified. We have identified several potential biomarkers of low-level VX exposure that, once validated, may allow more rapid screening for exposure to a toxic agent.

156 ALTERATIONS IN BRAIN GENE AND PLASMA PROTEIN EXPRESSION IN SOMAN VAPOR-EXPOSED RATS.

J. W. Sekowski¹, E. LaFiandra¹, J. Horsmon¹, J. J. Valdes¹, P. Dabisch¹, M. Horsmon¹, R. Mioduszewski¹, S. Thomson¹, C. Evans² and O. Crasta². ¹Edgewood Chemical Biological Center, U.S. Army, APG-EA, MD and ²Virginia Bioinformatics Institute, Virginia Polytechnic University, Blacksburg, VA.

Since the end of the first Gulf War, there has been concern that there may be unknown consequences of low-level exposure to a number of military compounds, including nerve agents. In particular, it was not known whether exposures to chemical nerve agents, at peri- and sub-symptomatic levels, may have potential to induce measurable immediate and/or persistent neurological effects. It is widely accepted that small molecular level changes are often amplified by participation in larger biochemical networks. The aim of this study was to link gene and protein expression alterations with biochemical pathways that may have important operational or longer-term health implications. To begin to address this aim, transcriptomic and proteomic alterations in the brain and blood plasma of male and female Sprague-Dawley rats exposed to low-level doses of the aerosolized nerve agent soman (GD) were assessed. The transcriptomic changes in the brains were measured using DNA

microarray analysis and real-time RT-PCR. The proteomic analysis of the blood plasma was carried out using LC-MS-MS. To date, our results indicate that: 1) low-level inhalation exposure to Soman results the differential expression of a number of neuronal genes, including some that participate in neurological injury mediation and regeneration and 2) there are a number of key protein alterations in the blood plasma of soman-exposed animals, and 3) there are significant gender-associated differences in the degree and type of gene and protein expression alterations.

157 NEBULIZED SULFUR MUSTARD CAUSES ACUTE LUNG INJURY IN ANESTHETIZED RATS.

A. M. Witriol, T. S. Moran, S. Richards, B. Boyd, B. Capacio and A. Sciuto. *Analytical Toxicology Division, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (SM) is an alkylating chemical warfare agent used during World War I and in the Iran-Iraq (1984-88) conflict. SM poses a threat to the respiratory tract with short duration exposure resulting in acute lung injury. The detection of acute lung injury is important for therapeutic countermeasures to reduce toxicity in a timely manner. This study was designed to deliver nebulized dilute SM in a dose-response manner to investigate possible markers of lung injury. SM was delivered to male rats (240-270g) by a small animal ventilator set for a volume of 2.5 mL x 60-80 breaths/minute. SM was administered at doses of 0, 25, 50, 75, 125, 175, 225, 275, and 300 µg/min x 10 minutes. The effects from doses between 25-125 µg/min were not different from saline-exposed controls for any parameter measured. In euthanized animals, the trachea was excised, 5 mL of saline was instilled into the lungs which were washed five times, and bronchoalveolar lavage fluid (BALF) was taken at 0.5, 1, 3, 6, and 24 hours post-exposure. BALF was analyzed for protein concentrations, LDH, GSH, and GPx. Lung wet and dry ratios showed no change across dose and time. As a validation of exposure, blood levels of SM were analyzed; increasing plasma levels of SM were significantly higher across all time points and doses vs. saline-exposed controls. BALF results at doses 175-300 µg/min showed an increase in protein and LDH in a dose- and time-response manner. The protein data indicated a marked alteration in the air-blood barrier, with significance at 24 hours post-exposure for 225 and 300 µg/min ($p < 0.05$). The LDH data indicated an increase in cell lysis and tissue injury at 1, 6 and 24 hours post-exposure ($p < 0.05$). BALF GSH indicated signs of oxidative stress with significance at 6 and 24 hours post-exposure ($p < 0.05$). BALF GPx, another indicator of oxidative stress showed significance at 0.5, 6, and 24 hours post-exposure to SM ($p < 0.05$). These data indicate that nebulized SM exposure causes acute lung injury across dose and time.

158 NITROGEN MUSTARD-INDUCED ALTERATIONS OF MATRIX METALLOPROTEINASE-9 IN MOUSE KERATINOCYTES.

M. P. Shakarjian¹, D. V. Ajibade¹, A. T. Black^{2,3}, Y. Chang³, M. K. Gordon³, D. E. Heck³, J. D. Laskin², D. J. Riley¹ and D. R. Gerecke². ¹Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, ²Environmental & Occupational Medicine, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and ³Pharmacology & Toxicology, EOHHSI, Ernest Mario School of Pharmacy, Rutgers University, Piscataway, NJ.

Cutaneous exposure to sulfur mustard (SM) produces delayed vesication by targeting basal keratinocytes and causing blistering at the epidermal-dermal junction. MMPs, enzymes that degrade extracellular matrix proteins, play important roles in inflammatory and immune responses. We have previously observed that SM upregulates matrix metalloproteinase-9 (MMP-9, gelatinase B) in the mouse ear vesicant model (MEVM). To reduce animal testing and bridge the MEVM and in vitro human models, we have established primary murine epidermal keratinocyte (MEK) cultures. We tested whether nitrogen mustard (HN-2), a surrogate for SM, alters MMP expression in MEK as in the MEVM. Primary MEK were grown on collagen I, IV, or laminin 332 (formerly laminin-5) matrices. Cells were cultured in low and high calcium concentrations to induce differentiation. This was verified by monitoring biomarkers keratin 1 and profilaggrin. HN-2 produced a dose-dependent toxic effect between 1 and 100 µM. Undifferentiated cultures were more susceptible to HN-2 than differentiated cultures. At 100 µM, HN-2 increased the relative level of MMP-9 mRNA and the expression of the active protein form in differentiated, but not undifferentiated MEK, as evidenced by RT-PCR and gelatin zymography. The changes in MMP-9 were similar to our previous observations in the MEVM. MEK grew and differentiated equally well on each of the matrices tested. In conclusion, exposure of differentiated MEK to HN-2 produces effects similar to those of SM in the MEVM. This model may be useful for high-throughput testing of vesicant countermeasures such as anti-proteinases and for exploiting transgenic technology for mechanistic studies.

159 MECHLORETHAMINE TOXICITY IN SKIN CELLS IS INHIBITED BY BUTYLATED HYDROXYANISOLE.

M. A. Pino, D. Hardej and B. Billack. *Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Mechlorethamine (HN2) is a nitrogen mustard alkylating agent used clinically to treat Hodgkin's lymphoma. HN2 produces toxic effects on the eyes, respiratory tract and skin. Presently, there is no effective treatment for HN2 poisoning. Butylated hydroxyanisole (BHA) is a fat-soluble phenolic compound commonly used as a food preservative. The present study evaluated the ability of BHA to reduce HN2 toxicity in the A431 human epidermoid carcinoma cell line. Cellular viability was measured by the reduction of 3-[4,5-dimethylthiazol-2-yl]-2, 5-diphenyl tetrazolium (MTT). The cytotoxicity of HN2 after either 24 hr or 48 hr of treatment was found to be concentration-dependent (LC50 ~25 µM). At both experimental periods, a co-treatment with BHA (75 µM) resulted in significant protection against the cytotoxic effects of HN2 (LC50 > 50 µM). Scanning electron microscopy (SEM) confirmed viability results with cells co-treated with BHA and HN2 showing a reduction in morphological alterations when compared to cells treated with HN2 alone. Cells depleted of glutathione (GSH) with the γ-glutamyl-cysteine synthase inhibitor di-buthionine-S,R- sulfoximine (BSO) were found to be more sensitive to HN2 after 24 hr (LC50 < 12.5 µM). The effect of HN2 on cellular levels of GSH and its potential to induce lipid peroxidation were investigated. GSH levels were found to be elevated in a concentration-dependent manner 3 hr after a treatment with 50 µM HN2, an effect that was partially reversed by co-treatment with BHA (75 µM). Furthermore, thiobarbituric acid reactive-substances (TBARS) were observed in skin cells at 48 hr after treatment with 50 µM HN2 but not in control cells. A co-treatment with BHA (75 µM) reduced the formation of TBARS to a significant extent. Taken together, these results indicate that BHA is effective at protecting skin cells from the toxicity of nitrogen mustard *in vitro*, perhaps, by reducing lipid peroxidation.

160 INFLAMMATORY CYTOKINE RELEASE IN HUMAN ISOLATED CELL CULTURE AND TISSUE CONSTRUCTS FOLLOWING *IN VITRO* EXPOSURE TO SULFUR MUSTARD.

A. L. Miller, O. E. Clark, E. W. Nealley, V. L. Fuller and W. J. Smith. *Research Division, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (2,2'-dichlorodiethyl sulfide, SM) is a cytotoxic chemical warfare agent known for its vesicating properties. Prior to visible blister formation, observable edema and redness are prevalent within SM-exposed tissues. To elucidate these inflammatory effects, we examined cytokine production in normal human epidermal keratinocytes (NHEK) and normal human bronchial epithelial cells (NHBE). These cell types serve as principal target sites for *in vivo* toxicity in response to SM exposure. In addition we compared cytokine secretion by these cell cultures to commercially available skin and airway tissue constructs (EpiDermFT and EpiAirway, MatTek Corp.) Cytokines were measured by Luminex technology using Biosource Human Cytokine Inflammatory 10-plex kits. Media samples were collected at 0, 2, 4, 6, 8, and 24 hours following exposure to 0, 1, 10, 50, 100 and 300 µM concentrations of SM. Increases of IL-1β, IL-6, IL-8 and TNF-α were routinely detected in cell cultures at SM concentrations greater than 10 µM. Additionally, our results indicate that some tissue constructs appear to be releasing cytokines into the media prior to SM exposure. This high background level can mask SM-specific release of cytokines. The data obtained with isolated cell cultures confirms the ability of SM to initiate inflammatory cascades in skin and airway tissue. Further studies will determine if skin and airway tissue constructs can be routinely incorporated as working models for future SM research.

161 PROTECTIVE EFFECT OF A NOVEL ANTI-INFLAMMATORY PEPTIDE AGAINST SULFUR MUSTARD-INDUCED LUNG INJURY AND THERMAL BURNS.

U. Wormser, A. Rosengarten, E. Shapira, E. Proscura and B. Brodsky. *Pharmacology, The Hebrew University, Jerusalem, Jerusalem, Israel.*

Exposure of airway to sulfur mustard (SM) causes bronchitis, chemical pneumonia and lung edema. The present study demonstrates the protective effect of a 9 amino acid fragment of histone H2A against SM-induced lung injury. Mouse trachea was instilled with 50 µl saline containing 6 µg SM. Bronchoalveolar lavage (BAL) was carried out 24 hours after SM exposure. The animals received a single iv injection of the peptide (1 mg/kg) 7 days prior to SM exposure. We observed a significant reduction in Interferon gamma and Tumor Necrosis Factor alpha levels in the BAL fluid of peptide-treated mice as compared to controls. The anti-inflammatory/counter-irritating effect of the peptide was also demonstrated in heat burns induced by exposure of guinea pig skin to hot water. Intradermal injection of a peptide analog 5 min prior to heat exposure resulted in a significant reduction in

skin irritation score as compared to control animals injected with the vehicle. The anti-inflammatory effects of the peptide may be useful in prophylactic treatment of chemical and thermal injuries (supported by the US Army Medical Research and Material Command under Cooperative Agreement DAMD17-03-2-0013).

162 MATHEMATICAL MODEL FOR REGIONAL BRAIN DISPOSITION OF CHEMICAL WARFARE AGENTS AND IMPACT ON CHOLINESTERASES.

E. A. Merrill, P. J. Robinson and J. M. Gearhart. *Applied Biotechnology Branch, AFRL, Henry M. Jackson Foundation, Wright-Patterson AFB, AL.*

Inhibition of red blood cell acetylcholinesterase (AChE) activity has been previously used as a correlate of AChE inhibition in the brain. Recently, however it has been shown to be a poor predictor of AChE inhibition in nervous tissues (Anderson et al., 2005). Heterogeneity and complexity of cell types and function of the CNS are impediments in the prediction of neurotoxicity. Unfortunately, predictive physiologically-based pharmacokinetic (PBPK) models often represent the brain as a single well-mixed compartment, ignoring its regional variations. A better understanding of regional toxicant distribution could better illuminate the understanding of mechanisms behind differential vulnerability. Little research has been devoted to the inclusion of regional brain specificity in PBPK/PD modeling efforts. Here, a PBPK model for sarin, developed in our laboratory by Gearhart et al. (2006), is expanded to include regional brain specificity. Brain compartments included cerebrospinal fluid, frontal and parietal cortex, hippocampus, cerebellum, brain stem, and thalamus. Volumes and blood flows of brain regions for the rat and other species were obtained from the literature. Preliminary parameterization was based on limited published regional brain measurements of basal cholinesterase (ChE) synthesis and irreversible inhibition after sarin exposures. The potential for integrating a functional PBPK/pharmacodynamic (PD) model with an appropriate PD model to characterize excitotoxicity, namely the evolution of excessive intracellular calcium resulting from acetylcholine (ACh) overload, and a possible role for improving neuroprotecting therapeutics are discussed.

163 THE PROTECTIVE EFFECT OF CAPSAICIN ANALOGS ON NORMAL HUMAN EPIDERMAL KERATINOCYTES (NHEK) FOLLOWING *IN VITRO* EXPOSURE TO SULFUR MUSTARD.

O. E. Clark, E. W. Nealley, A. L. Miller, K. W. Leiter and W. J. Smith. *Research Division, USAMRICD, Aberdeen Proving Ground, MD.*

Sulfur mustard (2, 2'-dichlorodiethyl sulfide, SM) is a cytotoxic alkylating agent with mutagenic and vesicating properties. Our research focus is the mechanism of toxicity of SM for the purpose of developing medical countermeasures to this chemical threat agent. A major feature of SM tissue injury is inflammation. Capsaicin is known to block neurogenic inflammatory pathways. It has been reported that the capsaicin analogs, octyl homovanillamide and retro-ovaniol, have limited ability to prevent SM damage in the mouse ear model. We have evaluated the ability of capsaicin analogs to prevent SM-induced changes in cultured NHEK. Three capsaicin analogs were obtained from the Korea Research Institute of Chemical Technology (KRICT). These compounds are identified as KR-22010, KR-24095, and KR-25018. Retro-ovaniol and octyl homovanillamide were also included in this study. NHEK were pretreated with these compounds 15 minutes prior to SM exposure. Cellular viabilities were determined 24 hours post SM exposure via vital dye (propidium iodide, PI) uptake as measured by flow cytometry. Morphological changes were documented via light microscopy. SM at 300 μ M for 24 hrs caused significant up-take of PI. Retro-ovaniol, while preserving good cellular morphology, failed to prevent SM-induced vital dye uptake. KR-24095 and KR-22010 significantly reduced the uptake of vital dye following SM exposure. Further studies with KR-24095, a water soluble analog, will be done to determine the efficacy of this compound as a medical countermeasure against the sulfur mustard injury.

164 INTERACTION OF CYANIDE AND NITRIC OXIDE AT THE CYTOCHROME C OXIDASE BINUCLEAR CENTER BINDING SITE.

H. B. Leavesley, L. Li, P. Krishnan, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN.*

Cyanide induces neurotoxicity by inhibiting mitochondrial respiration by binding to the cytochrome c oxidase (COX) binuclear center ($\text{Fe}_{3+}\text{-Cu}_{2+}$). Previous studies have shown that nitric oxide (NO), which also inhibits COX and is metabolized by the enzyme, antagonizes cyanide. The interaction of NO and cyanide at the binu-

clear center was studied by monitoring cellular oxygen uptake and COX enzymatic activity in the immortalized rat mesencephalic cell line N27. KCN (10-60 μ M) inhibited cellular respiration in a concentration-dependent manner, in competition with O_2 . The KCN IC_{50} for cellular respiration ($15.5 \pm 2.1 \mu\text{M}$) was slightly greater than that for COX inhibition ($9.9 \pm 0.7 \mu\text{M}$). A respiratory threshold analysis indicated that KCN had to inhibit a 45 % excess of COX before decreasing cellular respiration. The NO donor SNAP (100 μ M) enhanced the KCN inhibition of cellular respiration and COX at 2 to 15 μ M cyanide, but reversed it at higher cyanide concentrations (15-60 μ M). When endogenous NO generation was blocked by treatment with a NOS inhibitor (L-NMMA, 100 μ M), the KCN IC_{50} for cellular respiration and COX increased to $88 \pm 6.8 \mu\text{M}$ and $110 \pm 11 \mu\text{M}$, respectively. This suggested that under normal cell conditions, endogenous NO contributes to KCN-mediated COX inhibition. To further evaluate the interaction of cyanide and endogenous NO, mitochondrial NO and nitrite levels were examined in the presence of KCN. KCN dose-dependently (15-60 μ M) decreased mitochondrial NO levels, while increasing mitochondrial nitrite (metabolite of NO) production. The results indicate that exogenous NO can antagonize cyanide-mediated inhibition of COX, whereas endogenous NO may contribute to the enzymatic inhibition. A triphasic model is proposed to characterize cyanide binding at the binuclear center in the presence of endogenous NO and O_2 . (This study was supported by NIH grant ES04140.)

165 RICIN IC_{50} AS DETERMINED BY A BALB/c MURINE FIBROBLAST NEUTRAL RED UPTAKE ASSAY.

J. Madren-Whalley¹, V. Bevilacqua², A. M. Schenning³ and J. S. Rice².
¹Molecular Engineering Team, Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD, ²Chemical Methodology Team, Edgewood Chemical Biological Center, Aberdeen Proving Ground, MD and ³SAIC, Gunpowder, MD. Sponsor: J. Sekowski.

Ricin is well recognized as a potential bioterrorism agent and the identification of this protein toxin in a powder found in a U. S. Senate office (2004) has served to keep ricin in the public eye. Proteins may be denatured and inactivated by fairly mild factors (e.g. temperature or pH change), necessitating the ability to ascertain the activity as well as the identity of protein toxins in such unknown samples. The well-known Neutral Red Uptake (NRU) assay has been previously employed for ricin cytotoxicity using bovine pulmonary endothelial cells [JN Hughes *et al.*, *Human & Exp. Tox.* 1996, 15, 443]. However, because of ricin's potential impact as a bioterrorism agent, a protocol previously validated for use with other chemicals is desirable for standardization purposes. Here we report ricin toxicity as determined by the NRU assay using BALB/c murine fibroblasts (3T3). We chose to follow the NICEATM/ECVAM protocol involving 3T3 cells, which was part of a recently completed multi-laboratory validation study for the determination of IC_{50} values for 72 coded chemicals [MW Paris *et al.*, SOT06 poster V5]. The NICEATM/ECVAM protocol required minor modification for use with a protein toxin as opposed to other non-protein toxic chemicals to which it was applied in the multi-laboratory study. Triplicate assays showed that ricin (Vector Laboratories, product L-1090) has an IC_{50} of $1.75 \times 10^{-03} \mu\text{g/mL}$ as determined by NRU using 3T3 cells. In addition, preliminary experiments indicate quick-freezing on liquid nitrogen does not affect ricin's cytotoxicity. Support: Defense Threat Reduction Agency Project BA05TAS080. NICEATM/ECVAM: The National Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological Methods/European Centre for the Validation of Alternative Methods.

166 DEVELOPMENT OF HUMANE END POINTS IN RICIN INHALATION TOXICOLOGY.

T. Mann and G. D. Griffiths. *Biomedical Sciences, DSTL, Porton Down, United Kingdom.* Sponsor: A. Sciuto.

Ricin is a potent protein toxin produced by the seeds of the castor oil plant, *Ricinus communis* and has been of concern for some time as a potential agent in connection with warfare or terrorist attacks, particularly in relation to inhalation. In animal models, lung damage leads to pulmonary oedema which can be fatal. Exposure to lethal quantities of ricin (10 – 20 $\mu\text{g/kg}$ bodyweight) by inhalation leads to the development of toxic signs and symptoms, typically around 24 h following challenge, depending upon the dose. Symptoms of intoxication typically occur around 24h post inhalation exposure of a supra-lethal quantity of ricin aerosol, and mice or rats become less active, show signs of piloerection, begin to show signs of respiratory distress by panting, which gradually worsens over the next 12 – 24h. Appetite appears to be lost, animals lose weight and body temperature falls, eventually accompanied by cyanosis of ear lobes and footpads. When an animal is moribund, it may have lost as much as 33% of its original bodyweight and, as well as being cyanotic,

feels cold to the touch. These symptoms follow the progressive lung damage and corresponding increase in pulmonary oedema, accompanied by reduction in respiratory gaseous exchange and congestive impairment of blood circulation. At Dstl, we have been interested in developing humane endpoints following inhalation of ricin, focusing on the decrease in body temperature. Initial studies using intraperitoneally-implanted transponders measuring deep body temperature have been used, in freely moving mice. Animals were group housed in cages, 6 to a group. Each cage was equipped with a perimetric antenna, enabling almost continuous temperature recording from each animal simultaneously, without human intervention. Results of a small preliminary study were most encouraging and suggested that temperature fall could be an early predictor of mortality. Confirmatory studies are required to consolidate preliminary data.

167 CYCLOTRIMETHYLENETRINITRAMINE (RDX) CAN INCREASE CALCIUM FLUORESCENCE IN HUMAN NEUROBLASTOMA CELLS.

M. Ehrlich¹, X. Wu¹, G. Reddy² and M. A. Major². ¹Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA and ²U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.

Cyclotrimethylenetrinitramine (RDX) has use as an explosive. Past studies in animals have demonstrated spontaneous seizures as an adverse effect of oral administration (Burdette et al., TAAP 92, 436, 1988). Mechanisms for seizure production, however, have not been delineated. In the present study we examined the ability of RDX applied to human neuroblastoma SH-SY5Y cells to increase cellular calcium, as increased calcium levels are a possible contributing mechanism for excitotoxicity. For these experiments, cells were loaded with calcium-indicating fluorescent dye one hour before application of RDX in concentrations between 1.5 μ M and 7.5 mM. Fluorescence was immediately measured on a kinetic fluorescent microplate reader with autoinject, and recordings made for a total of 30 cycles of 11 seconds each. A concentration response was noted, with even the lowest concentration of RDX tested capable of raising calcium fluorescence above baseline. A return toward baseline was noted by the end of the observation period. The effect of 7.5 mM RDX was significantly greater than the effects of the other concentrations tested ($p < 0.05$; $n=4$). Glutamate could also increase calcium fluorescence, but incubations of neuroblastoma cells with RDX for 1 hr did not result in a significant effect on cellular glutamate levels as indicated by GC-MS. These experiments suggest the possibility that increased cellular calcium concentrations could be a contributing factor to RDX-induced neuronal excitability (Abstract does not reflect U.S. Army Policy).

168 GLOBAL GENE EXPRESSION IN RAT BRAIN FOLLOWING ACUTE ORAL HEXAHYDRO-1, 3, 5-TRINITRO-1, 3, 5-TRIAZINE (RDX) EXPOSURE.

D. I. Bannon¹, J. F. Dillman², W. Bao³, C. Phillips², R. D. Wolfinger³ and E. J. Perkins⁴. ¹Center for Health Promotion and Preventive Medicine, Directorate of Toxicology, U.S. Army, APG, Aberdeen, MD, ²Medical Research Institute of Chemical Defense, Cellular and Molecular Biology Branch, U.S. Army, Aberdeen Proving Ground, MD, ³SAS Institute, Inc., Cary, NC and ⁴Environmental Genomics and Genetics Team, Environmental Laboratory, Engineer Research and Development Center, U.S. Army, Vicksburg, MS.

Hexahydro-1,3,5-trinitro-1,3,5-triazine is a synthetic, high-impact, relatively stable compound commonly known as Rapid Detonation Explosive (RDX) and has been used in munitions and formulations since World War II. Humans can be exposed to RDX in several ways: during the manufacturing process, at contaminated soils at or near military facilities, or in groundwater. The primary symptom of acute exposure to high doses of RDX in humans is transient and reversible seizure, often accompanied by nausea, muscle spasms, and disorientation, which are also reported in experimental animals. The occurrence of these preventable effects in humans is most often reported in occupational settings that lack standard industrial hygiene practices, resulting in high airborne exposures. For lower exposures in water, a chronic oral reference dose of 0.003 mg/kg/day has been derived by EPA-IRIS (Integrated Risk Information System), based on rat prostate inflammation. Though several important studies have correlated measurements of RDX in the brains and plasma of dosed animals with the occurrence of seizures, little work has been carried out on the effects of RDX at the molecular level. Previously, we examined temporal gene expression of rat brain at single doses of 3 and 18 mg/kg RDX and times 0, 4, 24, and 48 hours. Recently, two additional doses of 9 and 36 mg/kg were added to the dataset and the gene expression profiles reexamined. The combined results of both experiments are presented here and a tentative hypothesis for the mechanism of RDX induced neurotoxicity is proposed, based on in vitro work and gene expression analysis.

169 HEMATOTOXICITY OF MUNITIONS COMPOUND HEXAHYDRO-1, 3, 5-TRINITRO-1, 3, 5-TRIAZINE (RDX) AND ENVIRONMENTAL DEGRADATION PRODUCT MNX.

V. M. Kale¹, M. M. Aycock¹, M. S. Wilbanks¹, L. S. Inouye², E. J. Perkins² and S. A. Meyer¹. ¹Toxicology, University of Louisiana-Monroe, Monroe, LA and ²Engineer Research and Development Center, U.S. Army Corps of Engineers, Vicksburg, MS.

RDX, a military explosive and contaminant of munitions manufacturing and artillery training sites, undergoes anaerobic metabolism by nitroreductases of environmental microbes to hexahydro-1-nitroso-3,5-dinitro-1,3,5-triazine (MNX). Previous acute toxicity studies determined comparable potency for RDX and MNX (LD50 187 mg/kg; Meyer et al., 2005; J. Appl. Toxicol. 25: 427-34). Survivors of the MNX study exhibited normochromic anemia accompanied by splenic hemosiderosis (NOAEL 47 mg/kg). Because anemia persisted for 14 days after a single exposure, we hypothesized that hematopoiesis was impaired due to bone marrow toxicity and that RDX would have comparable effects. The objective of the present investigation was to determine and compare effects of RDX and MNX on bone marrow cellularity and hematopoietic progenitor cells. Acute exposure effects on peripheral blood and bone marrow cells after 14 days for MNX and RDX at various doses (vehicle, 12, 24, 47 and 94 mg/kg) were studied. RDX was more potent than MNX in reducing bone marrow cellularity and peripheral blood leukocytes, in particular granulocytes. Further, RDX and MNX were found equipotent in decreasing Burst Forming Units-Erythroblasts, BFU-E (NOAEL 12 mg/kg), while RDX and MNX at all doses decreased Granulocyte/Macrophage-Colony Forming Units (CFU-GM). In conclusion, our studies support the hypothesis that RDX and MNX toxicity to bone marrow hematopoietic progenitors effects a persistent depletion of peripheral blood cells and further indicates that both erythroid and myeloid lineages are involved. (Support: DoD; W914Z-05-P-0145 and W81XWH-05-1-0537).

170 ACUTE RENAL FAILURE ALTERS THE KINETICS OF PRALIDOXIME IN RATS.

F. J. Baud¹, M. Kayouka¹, P. Houze¹, C. Monier¹, P. Risede¹, C. Martin² and J. Warnet². ¹UMR 7157, INSERM U705, Paris, France and ²Toxicology Laboratory, University Paris 5, Paris, France. Sponsor: G. Isom.

Objective: Pralidoxime (PX), the antidote to organophosphate poisoning, is eliminated unchanged by the renal route. This study assessed the effect of acute renal failure (ARF) on the kinetics of PX.

Methods: In a male Sprague-Dawley rat model of ARF induced by potassium bichromate, PX (50 mg.Kg-1 as PX base) was administered intramuscularly. Control rats received isotonic sodium chloride solution instead of bichromate. Plasma PX concentrations were measured by HPLC, urine concentrations using capillary electrophoresis. Pharmacokinetics were determined using Apis® program. Results are expressed as mean $\pm$ SEM. Statistical analysis was performed using Mann-Whitney test.

Results: Maximal plasma creatinine levels occurred 48 hours following bichromate injection (22.4 $\pm$ 1.8 μ mol.L-1 control vs 169.6 $\pm$ 26.5 μ mol.L-1 ARF). No significant difference was observed regarding the Cmax (24.4 $\pm$ 1.1 vs 35.2 $\pm$ 4.9 mg/l). In contrast, the areas under the curve (AUC) in the treated group were about 3 times greater than in the control group 2661.0 $\pm$ 535.6 ARF vs 976.3 $\pm$ 29.7 mg.min.L-1 control ($p < 0.01$). The volumes of distribution were not modified 3.3 $\pm$ 0.3 control vs 3.6 $\pm$ 0.7 l/kg-1 ARF. The total clearances were significantly reduced in ARF (1.5 $\pm$ 0.2 vs 3.1 $\pm$ 0.1 l.kg-1.h-1; $p < 0.01$) resulting in a significant increase in the elimination half-life (102.8 $\pm$ 7.9 ARF vs 44.0 $\pm$ 1.1 min control; $p < 0.01$). A positive correlation ($r^2 = 0.7665$) existed between the AUCs and the plasma creatinine values.

Discussion - Conclusion: The kinetics are significantly different between control and ARF groups. Acute renal failure did not modify PX distribution but decreased significantly its plasma elimination. PX kinetics was correlated with creatinine clearance. From a clinical viewpoint, our data suggest that the dosage regimen of PX should be modified in patients with severe acute renal failure. Further investigations are required to determine whether the antidotal efficacy of PX is modified in ARF.

171 BIOANALYTICAL METHOD VALIDATION OF 2, 3-BUTANEDIONE MONOXIME (DAM) IN HUMAN SERUM AND WHOLE BLOOD.

B. Burbach¹, B. Harritos¹, S. Graves¹, T. Hayes² and J. D. Johnson¹. ¹Chemistry Technical Center, Battelle, Columbus, OH and ²MREF, Battelle, W. Jefferson, OH.

2, 3-Butanedione monoxime (diacetyl monoxime or DAM) may have therapeutic uses as a cardioprotective agent against ischemia and/or an antidote following exposure to organophosphorus compounds. A validated bioanalytical method was

needed for conducting non-clinical studies and clinical trials. A GC/MSD method was developed and validated for DAM in human serum with a limited validation in human whole blood. Standards, quality control samples (QCs), and blanks were treated with acetonitrile containing the internal standard (IS): 1, 4-dichlorobenzene (d4). A best fit curve was determined using a quadratic regression model weighted $1/x$. The coefficients of determination were greater than 0.99 over a concentration range of 50 to 10,000 ng/mL. There were no interfering peaks in the retention times of the analyte or IS (specificity). Serum standard accuracy (%RE) ranged from -1.9 to 2.3% and precision (%RSD) from 0.2 to 3.1%. The limit of quantitation was 50 ng/mL (sensitivity). Human serum or QC samples with DAM concentrations greater than 10,000 ng/mL diluted linearly. Storage stability was determined using spiked human serum/whole blood samples (150 and 5000 ng DAM/mL). DAM in serum stored frozen (-20 degrees C) was stable for up to 69 days and through three freeze/thaw cycles. DAM in whole blood stored refrigerated (2-8 degrees C) decreased at least 30 percent for the 150 ng/mL samples whether using acetonitrile or saline. The decrease was less pronounced at the higher concentration. These results indicated that a method for quantitation of DAM in human serum and whole blood was able to be validated. The method was used to quantitate serum and blood DAM concentrations in a human clinical trial.

172 ADMINISTRATION OF GENISTEIN PROMOTES NEUTROPHIL AND PLATELET RECOVERY IN IRRADIATED MICE.

M. R. Landauer¹, S. R. Mog¹, T. K. Clarke¹ and T. A. Davis². ¹Armed Forces Radiobiology Research Institute, Bethesda, MD and ²Naval Medical Research Center, Silver Spring, MD.

Genistein is a non-toxic isoflavone from soybeans. We previously reported that a single subcutaneous injection or repeated daily oral administration of genistein, significantly increased survival of lethally irradiated mice. In this experiment, we investigated the mechanism for genistein-induced radioprotection by evaluating the recovery of bone marrow cells and peripheral blood hematology in lethally irradiated mice. CD2F1 male mice received a single non-toxic subcutaneous injection of genistein (200 mg/kg), 24 hr prior to a lethal total body irradiation dose (8.75 Gy) of cobalt-60 gamma radiation. Survival and hematopoietic reconstitution were evaluated over 9 weeks postirradiation. Hematopoietic progenitor colony forming cell assays and an endogenous splenic CFU assay were performed to assess the reconstitution of the bone marrow after radiation-induced myelosuppression. In this study, 97% of genistein treated mice survived after 30 days, while 31% of vehicle-treated mice survived. The improvement in survival was related to accelerated neutrophil and platelet recovery resulting from earlier and more pronounced multilineage hematopoietic progenitor cell reconstitution in the femoral marrow compartment. Hematopoietic recovery in the marrow compartment was observed primarily 9-28 days postirradiation. Myeloid and erythroid progenitor cell numbers at day 15 postirradiation were 6-20 fold higher and the number of endogenous pluripotent hematopoietic splenic stem cells on day 11 postirradiation were 14-fold higher in genistein-treated than in vehicle control animals. These results demonstrate that a single subcutaneous administration of genistein 24 hr before irradiation provides significant radioprotection to the hematopoietic progenitor and stem cell compartment. Pretreatment with genistein may be useful in mitigating radiation-induced hematopoietic injury associated with radiotherapy or exposure to radiation by first responders entering contaminated areas.

173 ENVIRONMENTAL AND INDUSTRIAL CHEMICAL HAZARD ANALYSIS SYSTEM.

G. Diamond, T. Gray and J. Stickney. Syracuse Research Corp., Cincinnati, OH.

A prototype risk assessment system, Environmental and Industrial Chemical Hazard Analysis System (EICHAS) has been developed. In its final form, EICHAS will predict exposure concentrations associated with specific types of military operations and will estimate and display the threat to military personnel, including those impacts that threaten the success of a mission (e.g., disabling health effects). Information and predictions provided by EICHAS will inform military planners in their decisions about targeting industrial facilities as well as where and how to deploy troops in areas where contamination is likely, so that potential exposures and chemical casualties are minimized. The current prototype system is designed to estimate residual concentrations and human health risks associated with exposure to chemicals remaining at a chemical manufacturing or storage site, after its destruction. Human health threats are based on a risk assessment methodology specifically developed for this application that incorporates into Human Toxicity Doses (HTDs): 1) severity of adverse effects (minimally adverse, clinically adverse, life threatening; 2) dose route (ingestion, inhalation, dermal); 3) dose duration (acute, intermediate, chronic); 4) carcinogenicity; and 5) gender-specificity/sensitivity. An

HTD represents the most certain estimate possible of the lowest-observed-adverse-effect level for a given severity category. The method used to estimate residual chemical concentrations includes modeling and simulation approaches to incorporate into Exposure Point Concentrations (EPCs): 1) time-varying chemical concentrations in soil and air; 2) geographic extent of the contamination; 3) extent of any chemical reactions (e.g., hydrolysis); 4) degree of migration into the soil profile over time; and 5) extent of volatilization into the air from a spill. The latter two elements were developed over time frames most likely to be encountered during military operations.

174 UPREGULATION OF GCLM EXPRESSION RESTORES GLUTATHIONE AND PROTECTS AGAINST APAP-INDUCED LIVER INJURY IN GCLM NULL MICE.

D. Botta, M. B. McGrath, H. D. Neff-LaFord and T. J. Kavanagh. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

The tripeptide antioxidant, glutathione (GSH), has many functions including promoting cell growth, maintaining cellular redox status, protecting cells against oxidative damage from reactive oxygen species, and playing a crucial role in the detoxification of xenobiotics. The rate-limiting enzyme in the biosynthesis of GSH is glutamate-cysteine ligase (GCL), consisting of two subunits, a catalytic subunit (GCLC) and a modifying subunit (GCLM). We have previously demonstrated that by conditionally over-expressing GCL, acetaminophen (APAP) induced hepatic injury is attenuated. Our present hybrid model is a cross between the GCLM null mouse and conditionally restored GCLM utilizing the liver specific transactivator GLVP in the presence of mifepristone (RU486). Restoring GCLM expression with RU486 elevates GSH levels in these mice approximately 3-fold compared to control mice. APAP administration resulted in serum ALT levels averaging over 5000 U/ml in hybrid mice not receiving RU486. When given RU486 in addition to APAP, hybrid mice increased GSH levels 3.5 fold and ALT levels were down nearly 16-fold. We propose that restoring GSH in GCLM null mice by upregulating GCLM results in diminished APAP-induced hepatotoxicity. Furthermore, this model demonstrates the importance of varying GCLM levels with regard to toxicant-induced liver injury.

175 PPAR α -REGULATED MOLECULAR NETWORKS ARE RESPONSIBLE FOR THE DIFFERENTIAL EFFECTS OF DIETARY FATTY ACIDS ON OXIDATIVE STRESS AND DNA DAMAGE IN MOUSE LIVER.

C. L. Powell, P. K. Ross, C. G. Woods, B. U. Bradford and I. Rusyn. University of North Carolina, Chapel Hill, NC.

Epidemiological and animal model research shows that ω -3 and ω -6 polyunsaturated fatty acids (PUFA) can attenuate or enhance cancer risk, respectively. Mechanisms underlying the differential effects between these PUFA are not well understood but are thought to include the ability to generate bioactive lipids, modulate gene expression through nuclear receptors, and increase cellular oxidant injury. To identify potential mechanistic differences between the two PUFA, C57BL/6J mice were administered a high fat diet containing corn (ω -6) or fish oil (ω -3) for up to 3 weeks and gene expression profiling was performed on liver. Pathway mapping of significantly altered genes showed that fish oil induced biological processes related to fatty acid oxidation, glutathione metabolism and oxidative stress; in contrast, corn oil repressed these processes while inducing inflammatory response. These data suggested that the type of dietary fat may influence the cellular anti-oxidant capacity. Thus, oxidative stress biomarkers were evaluated. It was determined that a corn oil diet lead to significant increase in expression of DNA repair genes and the number of 8-OH-dG DNA adducts with concomitant decrease in reduced GSH content. Fish oil lead to significant reduction in 8-OH-dG DNA adducts while no induction of DNA repair genes was observed. Comparison of PUFA gene expression data with a potent PPAR α pan-agonist, WY-14,643, determined that over 50% of the significantly altered genes from fish oil treatment were driven by PPAR α . Moreover, the increases in gene expression for glutathione-S-transferases, heat shock and proteasome proteins by fish oil could also be attributed to PPAR α . In summary, dietary fatty acids can modulate the cellular redox state and the direction may be dependent on their ability to trans-activate PPAR α . The ability of nutrients to exacerbate or attenuate oxidative stress and DNA damage, processes linked to carcinogenesis, warrants further study as its implications for human health could be significant.

176 EFFECT OF FESCUE TOXICOSIS AND ACUTE HEAT STRESS ON HEPATIC OXIDATIVE ACTIVITIES.

R. S. Settivari¹, T. Evans², E. Antoniou¹, M. Sutovsky¹, P. Sutovsky¹ and D. Spiers¹. ¹Animal Sciences, University of Missouri, Columbia, MO and ²Veterinary Medical Diagnostic Laboratory, University of Missouri, Columbia, MO.

Much of tall fescue grass in the US is infected with an endophytic fungus. Intake produces fescue toxicosis, characterized by reduced productivity and hyperthermia during heat stress (HS). A rat model for this condition was used to evaluate the ef-

fect of endophyte toxins on hepatic gene expression under thermoneutral (TN) and HS conditions. Core temperature (T_c) was monitored continuously in rats ($n=24$) implanted with telemetric transmitters. Rats were fed ad libitum either endophyte-infected (E+) or uninfected (E-) diets and maintained under TN conditions (21°C) for five days, followed by TN or HS conditions (31°C) for three days. Feed intake (FI) and body weight (BW) were measured daily; selected visceral organ weights and serum chemistry were evaluated at the end. Liver sections were either fixed in 10% formalin or frozen at -80°C . Protein expression of hepatic CYP3A4 was evaluated using immunohistochemistry. Hepatic enzyme activities of antioxidants, superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) were determined spectrophotometrically. Hepatic apoptosis rates were determined using TUNEL assay. Both E+ and HS induced alterations in liver-specific genes were evaluated using DNA microarrays. Intake of E+ reduced FI and BW under TN and HS conditions. Core temperature at TN decreased from pretreatment level, but increased during HS. Serum prolactin decreased with E+ treatment at TN, and increased during HS. Heat stress, E+, and the combination reduced liver weight relative to BW. Protein level of CYP3A4 was greater in E+ liver compared to E-. In addition, rats exposed to E+ and HS had less amounts of SOD, CAT and GPx; and greater apoptosis rates. Microarray analysis is being used to evaluate genes associated with antioxidant, detoxification and immune functions. Present findings suggest that rats respond to E+ and HS by inducing CYP3A4 expression and suppressing hepatic antioxidant enzymes, which could ultimately increase oxidative stress and damage.

177 EFFECTS OF MIXTURES OF THE CHLOROACETATES ON THE INDUCTION OF OXIDATIVE STRESS IN HEPATIC TISSUES OF MICE.

E. A. Hassoun and B. Dougan. *Pharmacology, The University of Toledo, Toledo, OH.*

Dichloroacetate (DCA) and trichloroacetate (TCA) are byproducts produced during the process of chlorination of the drinking water. The two compounds were found to be hepatotoxic and hepatocarcinogenic in rodents, with oxidative stress considered as one of the possible mechanisms of toxicity. Since the compounds always exist in the water as mixtures, rather than individual, it is very important to determine the interactivities between the two compounds. To achieve that, the compounds were administered to groups of male B6C3F1 mice, p.o., at doses of 150 and 300 mg/kg and in two mixtures, DCA+TCA 150, and DCA+TCA 300, that correspond, respectively to 75 and 150 mg/kg of each of the two compounds. The animals were sacrificed 8 h later, and changes in the biomarkers of oxidative stress, including production of superoxide anion (SA) and lipid peroxidation (LP), as well as activities of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GSH-Px) were determined in hepatic tissues. The compounds caused significant production of SA and LP, with Potentiation/ synergistic effects observed with the mixtures. Also, the compounds and the mixtures caused dose-dependent suppression of SOD and GSH-Px activities, and had slightly smaller effects on CAT activity. The results suggest that oxidative stress play an important role in the hepatotoxicity of the chloroacetates, with more effects produced when the compounds exist in mixtures.

178 ATP SYNTHASE AND UBIQUINONE ARE TARGETS FOR TCDD MITOCHONDRIAL TOXICITY.

H. Shertzer, M. Genter, D. Shen, D. W. Nebert, Y. Chen and T. P. Dalton. *Environmental Genetics & Molecular Toxicology, Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.*

Mitochondria generate ATP and participate in signal transduction and cellular pathology and/or cell death. TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) decreases hepatic ATP levels and generates mitochondrial oxidative DNA damage, which is exacerbated by increasing mitochondrial glutathione redox state and by inner-membrane hyperpolarization. This study identifies mitochondrial targets of TCDD that initiate and sustain reactive oxygen production and decrease ATP levels. One week after treating mice with TCDD, liver ubiquinone (Q) levels were significantly decreased, while rates of succinoxidase and Q-cytochrome c oxidoreductase activities were increased. However, the expected increase in Q reduction state following TCDD treatment did not occur; instead, Q was more oxidized. These results could be explained by an ATP synthase defect, a premise supported by the unusual finding that TCDD lowers ATP/O ratios without concomitant changes in respiratory control ratios. Such results suggest either a futile cycle in ATP synthesis, or hydrolysis of newly-synthesized ATP prior to release. The TCDD-mediated decrease in Q, concomitant with an increase in respiration, increases complex 3 redox-cycling. This acts in concert with glutathione to increase membrane potential and reactive oxygen production. The proposed defect in ATP synthase explains both the greater respiratory rates and the lower tissue ATP levels.

179 VITAMIN E DEFICIENCY ENHANCES PULMONARY INFLAMMATORY RESPONSE AND OXIDATIVE STRESS INDUCED BY SINGLE WALLED CARBON NANOTUBES IN C57BL/6 MICE.

A. A. Shvedova¹, E. R. Kisin¹, A. R. Murray¹, O. Gorelik², S. Arepalli², V. Castranova¹, S. H. Young¹, F. Gao³, Y. Y. Tyurina⁴, T. Oury³ and V. E. Kagan⁴.
¹PPRB, NIOSH, Morgantown, WV, ²GBTech, Inc., NASA-JSC, Houston, TX, ³Pathology, University of Pittsburgh, Pittsburgh, PA, ⁴CFRAH, University of Pittsburgh, Pittsburgh, PA and ⁵GSPH, University of Pittsburgh, Pittsburgh, PA.

Exposure of mice to single walled carbon nanotubes (SWCNT) induces an unusually robust pulmonary inflammatory response with a very early onset of fibrosis, which is accompanied by a significant oxidative stress and antioxidant depletion. The role of specific components of the antioxidant protective system, specifically vitamin E, the major lipid-soluble antioxidant of membranes and lipoproteins, in the SWCNT induced reactions required further investigation. We used C57BL/6 mice, maintained on a vitamin E-sufficient diet as well as on a vitamin E-deficient diet, to explore and compare the pulmonary inflammatory reactions to aspirated SWCNTs. The induced vitamin E-deficiency (a 90-fold depletion of α -tocopherol in the lung) resulted in a significant decline of other antioxidants as well as in accumulation of lipid peroxidation products. A more severe decrease of pulmonary antioxidants was detected in SWCNT treated vitamin E-deficient mice as compared to controls. Exposure of vitamin E-sufficient mice to SWCNTs markedly shifted the ratio of low to high molecular weight forms of extra-cellular SOD (EC-SOD) such that approximately 3-4 times greater amounts of this neutrophil-associated enzyme were present. This effect was enhanced in vitamin E-deficient animals. Lowered levels of antioxidants in vitamin E-deficient mice were associated with a higher sensitivity to SWCNT-induced acute inflammation (PMNs number, released LDH, protein content, pro-inflammatory cytokines level) as well as pro-fibrotic pathways (TGF- β elevation and collagen deposition). Given that pulmonary levels of vitamin E can be manipulated through diet, its effects on SWCNT responses may be of practical importance in optimizing protective anti-inflammatory strategies.

180 LUNG EXTRACELLULAR THIOCYANATE LEVELS ARE MODULATED BY CFTR AND CAN AMELIORATE MYELOPEROXIDASE-MEDIATED INJURY.

L. W. Velsor², C. T. Kariya^{1,2}, S. Gauthier² and B. J. Day^{1,2,3}. ¹Molecular Toxicology and Environmental Health Sciences, University of Colorado HSC, Denver, CO, ²Medicine, National Jewish Medical & Research Center, Denver, CO and ³Immunology, National Jewish Medical Research Center, Denver, CO.

The cystic fibrosis transmembrane conductance regulator (CFTR) has been shown to transport a wide variety of anions into the lung epithelial lining fluid (ELF). We wanted to examine the effect of defective CFTR on thiocyanate levels in the lung ELF and adaptive responses to *Pseudomonas aeruginosa* (PA) challenge. Wild type and CFTR KO mice were challenged intratracheally with PA, and on the 3rd day of infection bronchoalveolar lavage fluid was obtained and analyzed for thiocyanate levels using a colorimetric assay. Basal levels of lung ELF thiocyanate were similar in both wild type and CFTR KO mice. PA infection increased the levels of lung ELF thiocyanate 4-fold in the wild type but only 2-fold in the CFTR KO mice. In separate studies, we measured the basal thiocyanate levels in human lung epithelial cell lines sufficient (C38) and deficient (IB3) in CFTR grown in transwells. CFTR sufficient cells had significantly higher basal levels of thiocyanate in apical compartment as compared to CFTR deficient cells. To test for the functional importance of thiocyanate, we exposed human lung epithelial (A549) cells to a MPO system that generates hypochlorous acid in presence of different concentrations of thiocyanate. Thiocyanate significantly decreased the MPO-induced cytotoxicity in dose-dependent manner. These data suggest that CFTR is partially responsible for thiocyanate transport in the apical compartment. Furthermore, our data also indicates that the lung adapts to infectious agents with elevated ELF thiocyanate levels which may protect the lung against MPO released from activated neutrophils. Individuals with cystic fibrosis may lack the ability to adequately adapt to lung infections resulting excessive injury. (This work was supported in part through funding by NIH HL75523).

181 A ROLE FOR GLUTATHIONE TRANSPORT IN THE ATTENUATION OF OXIDATIVE INJURY BY HYPERTONIC SALINE.

B. J. Day^{1,2}, J. Huang^{1,2} and C. T. Kariya². ¹Molecular Toxicology and Environmental Health Sciences, UCHSC, Denver, CO and ²Medicine & Immunology, National Jewish Medical & Research Center, Denver, CO.

The lung is continually exposed to environmental agents and pathogens. The lung epithelial lining fluid (ELF) is first to encounter these agents and GSH is a major antioxidant found in this apical fluid. The cystic fibrosis transmembrane conductance regulator protein (CFTR) is the only known GSH transporter that maintains

lung ELF GSH levels. Cystic fibrosis (CF) patient have low levels of GSH in their ELF and have copious and viscous mucus. Hypertonic saline is used in CF patient to help clear mucous and improve lung function however the mechanism(s) by which it does so are poorly understood. The purpose of these studies was to examine whether hypertonic (3.0%) saline can modulate apical GSH levels and protect lung epithelial cells against the oxidant, t-butyl hydroperoxide (t-BOOH). We used human lung epithelial cell lines sufficient (C38) and deficient (IB3) in CFTR. The CFTR deficient IB3 cells have 40% lower basal levels of apical GSH as compare to CFTR sufficient C38 cells. Cells were exposed separately and in combination to 3% saline, and t-BOOH (100 μ M) for 48 hours. The CFTR deficient IB3 cells were much more sensitive to t-BOOH-mediated oxidative injury as measured by lactate dehydrogenase (LDH) release. Hypertonic saline exposure was associated with an increase in apical GSH levels in both CFTR sufficient and deficient cells and decreased t-BOOH-mediated oxidative injury in both cells lines. Hypertonic saline increased GSH in the apical compartment, which appeared to be largely CFTR mediated. This data suggests that CFTR and GSH adaptive responses play an important role in lung's reaction to oxidants. We propose that factors, which interfere with the lung's capability to mount and maintain an adequate adaptive apical GSH response, may compromise and sensitize the lung to oxidative injury. (Supported in part from NIH grant HL075523).

182 DIFFERENTIAL MODULATION OF STRESS SIGNALING PATHWAYS BY CADMIUM IN CULTURED MOUSE LUNG FIBROBLASTS HETEROZYGOUS FOR GPX4.

M. R. Garry^{1,2}, S. S. Deeb³, T. J. Kavanagh², X. Yu², M. A. Vredevoogd², E. Kim² and E. M. Faustman². ¹Exponent, Bellevue, WA, ²Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and ³Medicine and Genome Sciences, University of Washington, Seattle, WA.

Cadmium is a widely dispersed environmental and occupational toxicant and has been associated with mutagenic, carcinogenic, teratogenic and neurotoxic endpoints. Inhalation exposure to cadmium has been associated with airway inflammation, pulmonary edema, emphysema, and cancer. Cadmium causes oxidative stress in cells by formation of reactive oxygen species (ROS), induction of lipid peroxidation, binding to protein thiols, and alteration of intracellular glutathione status. Glutathione peroxidase 4 (GPx4) is a member of the family of selenium dependent enzymes that catalyze the reduction of peroxides. GPx4 specifically reduces mitochondrial membrane-bound phospholipid hydroperoxides in situ and thus, protects against membrane peroxidative damage. Mouse lung fibroblasts deficient in GPx4 have increased susceptibility to cadmium-induced cytotoxicity. In the present study cultured mouse lung fibroblasts from wild-type (+/+) and GPx4 heterozygous (+/-) mice were exposed to cadmium chloride (CdCl₂), and cell extracts were analyzed for stress (p38, JNK) and survival (Akt) pathway activation by Western blot analyses. Levels of phosphorylated p38 and JNK were increased following CdCl₂ treatment in GPx4+/+ cells, but less so in GPx4+/- cells. Phosphorylated Akt levels, though decreased slightly, remained high in GPx4+/+ cells, but dropped to only 10% or less of control in GPx4+/- cells. However, GPx4+/- cells exhibited an attenuated survival response, as measured by the ratio of survival pathway activation (Akt) to stress pathway activation (p38 and JNK). These results implicate the involvement of survival and stress signaling pathways in cadmium-induced cytotoxicity, and the potential involvement of these pathways in defining the differential susceptibility to cadmium-induced stress in cells deficient in GPx4.

183 DIESEL EXHAUST PARTICLE-INDUCED OXIDANT INJURY AND CELLULAR RESPONSES IN WILD TYPE AND INDUCIBLE NITRIC OXIDE SYNTHASE-DEFICIENT (iNOS KO) MICE: ROLES OF PARTICLE CORE AND ADSORBED ORGANICS.

J. Y. Ma¹, L. Millicchia¹, M. Barger¹, J. K. Ma² and V. Castranova¹. ¹HELD, NIOSH, Morgantown, WV and ²School of Pharmacy, WVU, Morgantown, WV.

Studies have shown that diesel exhaust particle (DEP) exposure induces lung inflammation and injury, which are mediated through reactive oxygen/nitrogen species (ROS/RNS) generation by alveolar macrophages (AM). The present study examines the differential roles of DEP particle core, represented by carbon black (CB), and DEP organic extract (DEPE) in ROS generation and nitric oxide (NO) production through inducible nitric oxide synthase (iNOS)-related cellular responses using C57B/6J wild type (WT) and iNOS knockout (iNOS KO) mice. Mice (8-10 weeks old) were exposed to saline, CB (35 mg/kg), or DEPE by aspiration and sacrificed at 1, 3 and 7 days post-exposure. AM were isolated by bronchoalveolar lavage (BAL). CB, but not DEPE, significantly induced neutrophil infiltration in both WT and iNOS KO mice. CB-exposed AM also exhibited enhanced hydrogen peroxide and superoxide anion generation, peaking at 3 d post exposure. This CB-induced oxidative stress was correlated with mitochondrial damage, involving reduction of mitochondrial mass and membrane potential in

AM from both WT and iNOS KO mice. These results suggest that NO did not play a major role in modifying CB-induced mitochondrial damage in AM. In contrast, the organic component of DEP, DEPE, only slightly induced ROS generation and did not significantly affect mitochondrial function in AM. Measurement of macrophage ATP content showed that CB and DEPE did not significantly affect ATP levels in either WT or iNOS KO mice. This is due to the fact that mitochondrial oxidative phosphorylation pathway is not the major energy source for AM. In summary, this study shows that CB, but not DEPE, plays a major role in DEP-induced pulmonary inflammation and AM mitochondrial dysfunction by a mechanism independent of NO. (The findings and conclusions in this abstract have not been formally disseminated by the NIOSH and should not be construed to represent any agency determination or policy.)

184 BLOCKADE OF HMGB1 INHIBITS HYPEROXIA-INDUCED PRO-INFLAMMATORY LUNG INJURY.

L. Mantell^{1,2}, M. Javdan², H. Wang², K. Tracey², T. Entezari-Zaher^{1,2}, E. Miller² and J. Romashko III². ¹Pharmaceutical Sciences, St John's University College of Pharmacy, Queens, NY and ²The Feinstein Institute for Medical Research, North Shore-LIJ Health System, Manhasset, NY.

Prolonged exposure to hyperoxia results in acute lung injury (ALI) with markedly elevated levels of proinflammatory cytokines and infiltrated leukocytes in lungs. However, the mechanisms underlying hyperoxia-induced proinflammatory ALI remain poorly understood. Here we report our studies on determining the role of high mobility group box protein 1 (HMGB1), a newly discovered proinflammatory cytokine, in hyperoxic lung injury. Exposure of adult mice to >99% oxygen increased the accumulation of HMGB1 in the bronchoalveolar lavage fluid, which preceded the onset of severe lung injury. Neutralizing anti-HMGB1 antibodies, administered to mice 24 hours prior to hyperoxic exposure, significantly mitigated ALI, indicated by the levels of the wet/dry ratio, lung permeability and total leukocyte infiltration. This protection was also observed when the treatment with HMGB1 inhibitors was delayed until after the onset of the oxidative stress. In addition, ethyl pyruvate, a stable aliphatic antioxidant, not only inhibited HMGB1 secretion from hyperoxic macrophages, but also mitigated hyperoxic lung injury when administered post hyperoxic exposure. The contribution of HMGB1 to the initiation of hyperoxic lung injury was further confirmed using purified recombinant HMGB1 (rHMGB1) protein instilled intratracheally. Administration of rHMGB1 caused a marked increase in the levels of leukocyte infiltration into the lung of these mice compared to those that were treated with the same amounts of non-specific peptide ($31 \pm 4.8 \times 10^4$ vs. $14 \pm 3.4 \times 10^4$, $p < 0.05$). Taken together, these results indicate that HMGB1 plays a critical role in mediating hyperoxic lung injury through the recruitment of leukocytes into the lung, and support the potential clinical application of HMGB1 inhibitors as therapeutic interventions against oxidative lung injury in patients receiving hyperoxia.

185 METABONOMIC SIGNATURES OF SILICA NANOPARTICLE RESPIRATORY TRACT TOXICITY IN NORMAL AND DISEASED ANIMALS.

J. A. Villa, K. Thrall and C. M. Carosino. Center for Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA.

Characterizing the hazard potential of the significant number of nanomaterials that have been or will be produced is one of the most noteworthy challenges faced by the regulatory, research, and producer communities. Ultrafine (aerodynamic diameter d_{ae} , 0.1 μ m) and fine (d_{ae} , 2.5 μ m) particulate matter is associated with decreased lung function in child and adult asthmatic populations and increased cardiovascular morbidity and mortality in the general population. One weakness of occupational studies is they generally do not consider effects on sensitive populations. The Wistar-Kyoto (WKY) derived spontaneously hypertensive (SH) rat is a useful model of cardiovascular disease with underlying chronic pulmonary injury, inflammation, and oxidative stress. Metabonomic analysis involves the quantitation of the multivariate response of an organism to a pathological event. To provide a metabonomic comparison of the biological response to nanoparticle exposure between the normal (WKY) and sensitive (SH) rat, male rats were given a single dose of amorphous silica (16 nm) at either 0.12 or 5 mg/kg via intratracheal instillation. Bronchoalveolar lavage fluid (BALF) and blood were collected 24 hours after exposure. Screening of small molecule biomarkers less than 1400 atomic mass units was accomplished using LC-ESI-MS. Comparison of peak areas from spectra of blood and BALF samples showed clear differences in endogenous levels of compounds associated with oxidative stress between nanoparticle exposed and control animals of both strains. More subtle changes in peak areas of endogenous compounds were observed in comparison of BALF and blood collected from hypertensive versus normotensive animals. This study indicates that non-invasive monitoring of readily available biofluids using mass spectrometry holds promise as a rapid methodology for tracking metabonomic changes and identification of biomarkers of nanomaterial induced respiratory and cardiovascular toxicity.

186 POST-TRANSLATIONAL MODIFICATION OF SURFACTANT PROTEIN-D IN OZONE-INDUCED LUNG INJURY: AN INFLAMMATORY SIGNAL.

A. Groves, V. Sunil, K. Patel, E. Powell, J. Laskin, D. L. Laskin, A. J. Gow and C. Guo. *Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.*

Ozone is a ubiquitous urban air pollutant known to induce damage to the lower lungs. This is associated with an accumulation of macrophages in the tissue and the release of reactive nitrogen intermediates (RNIs) which we have previously demonstrated contribute to tissue injury. However, the molecular mechanisms by which RNIs induce cell death and injury are unclear. Surfactant Protein-D (SP-D), a pulmonary collectin, possesses both pro and anti-inflammatory functions; these functions are controlled via two cysteine residues in the hydrophobic tail. Here we examined whether SP-D was a target for NO-mediated modification within a mouse model of ozone-induced injury. Mice were exposed to air or ozone (0.8 ppm) for 3 hr. Bronchoalveolar lavage (BAL) fluid was collected 0-72 hr later. Utilizing a biotin-switch method we identified that SP-D is nitrosylated to form SNO-SP-D. SNO-modification peaked 24-48 hr following exposure and resolved by 72 hr. SNO-modification was accompanied by disruption of the multimeric structure of SP-D, as shown by native gel-electrophoresis. In vitro these modifications can be replicated within BAL from control animals or recombinant protein by transnitrosation with S-nitrosocysteine. Utilizing a modified Boydin chamber we showed that SNO-SP-D, but not control SP-D can induce RAW 264.7 macrophage chemotaxis. Further, while SP-D suppresses calcium influx in response to bradykinin in A549 lung epithelial cells, this was not observed with SNO-SP-D. These studies suggest that nitrosylation of SP-D may be a mechanism whereby RNIs induce pulmonary injury and inflammation. Supported by NIH grants, ES004738, ES005022, ES007148, and HL074115

187 MASS SPECTROMETRIC ANALYSIS OF PHOSPHOLIPID MOLECULAR SPECIES AND THEIR HYDROPEROXIDES IN APOPTOTIC NEURONS AND INJURED RAT BRAIN.

V. A. Tyurin¹, H. Bayir^{2,1}, Y. Y. Tyurina¹, W. Feng¹, R. Viner⁵, A. Amoscato⁴, Q. Zhao¹, K. Janesko-Feldman², H. Alexander², P. M. Kochanek², S. T. DeKosky³ and Y. E. Kagan¹. ¹EOH, CFRAH, University of Pittsburgh, Pittsburgh, PA, ²CCM, University of Pittsburgh, Pittsburgh, PA, ³Neurology, University of Pittsburgh, Pittsburgh, PA, ⁴Pathology, University of Pittsburgh, Pittsburgh, PA and ⁵Thermo Electron Corp, San Jose, CA.

We applied oxidative lipidomics approach (that includes quantitative HPLC fluorescence-based assessment of lipid hydroperoxides) and mass spectrometry (MS) (electrospray ionization, ESI-MS and matrix-assisted laser desorption ionization, MALDI-MS) to characterize individual molecular species of phospholipid classes and their hydroperoxides in neurons and brain. In in vitro experiments, rat primary cortical neurons were triggered to apoptosis by staurosporine (STS). Traumatic brain injury (TBI) was employed as an in vivo model in which mitochondrial fraction from rat brain cortex was utilized for phospholipid analysis. In both models MS analysis revealed the formation of several oxygenation products of two major anionic phospholipids - phosphatidylserine (PS) and cardiolipin (CL). Selective oxidation of CL and PS with highly oxidizable molecular species C22:5 and C22:6 were detected. We identified one major molecular cluster for PS and at least 12 different molecular species of CL. Detailed analysis of doubly-charged peak of CL ions at m/z 790 after TBI demonstrated that it corresponds to several CL species containing fatty acid residues with m/z 281 (C18:1), 283 (C18:0), 327 (C22:6), and 359 (C22:6+OOH). Notably, two most abundant phospholipids, phosphatidylcholine and phosphatidylethanolamine, did not reveal any oxidation products induced by either STS in neurons or after TBI in brain in spite of the presence of polyunsaturated molecular species. Thus, phospholipid oxidation products can be successfully detected and characterized in vitro and in vivo by MS analysis. Support: AHA0535365N, NIH HL70755, AI068021, PA Dept of Health, DAMD 17-01-2-0038.

188 STUDIES OF O₂ TOXICITY IN RAT CORTICO-HIPPOCAMPAL TISSUE SLICES.

J. Hollyfield¹, N. V. Reo¹, R. W. Putnam² and J. B. Dean³. ¹Biochemistry & Molecular Biology, Boonshoft Sch Med., Wright State University, Dayton, OH, ²Neuroscience, Cell Biology & Physiology, Boonshoft Sch Med., Wright State University, Dayton, OH and ³Molecular Pharmacology & Physiology, University of South Florida, Tampa, FL. Sponsor: D. Mahle.

Brain O₂ levels can vary from near hypoxia during ischemia, to hyperoxia during hyperbaric oxygen (HBO) events, to episodic changes in sleep apnea. We are studying brain sensitivity to O₂ using measures of reactive oxygen species (ROS), electrophysiology, and NMR-based metabolomics. Rat cortico-hippocampal slices were incubated in artificial CSF with 0.95 ATA O₂ (atmospheres absolute) for 1h, then

transferred to a pressure chamber at 36 °C for 1h at either: 0.40 ATA (n=6), 0.95 ATA (n=6), or 4.5 ATA O₂ (HBO, n=6). Slices were rinsed, blotted dry, and frozen in liq N₂. Aqueous and lipid extracts were prepared and analyzed using a Varian INOVA 600 NMR. Previous work shows ROS increases as normobaric O₂ increases, and excitability is reduced at 0.40 vs 0.95 ATA O₂. To examine the metabolic effects, 1H and 31P spectra of aqueous extracts were analyzed for lactate, N-acetylaspartate (NAA), creatine (Cr), phosphocreatine (PCr), ATP, and inorganic phosphate (Pi). These reflect neuronal viability (NAA/Cr ratio) and cellular energy status. Principal Component Analysis (PCA) of 1H aqueous spectra and 13C lipid spectra showed data clustering in the scores plot and clear separation for the 0.40 ATA O₂ vs HBO groups. The PCr/ATP ratios vs [O₂] show a positive linear correlation (r²=0.95), and the value for 0.95 ATA (2.2±0.2) compares favorably with values in vivo. PCr/ATP at 0.40 ATA (1.4±0.2) may indicate early signs of metabolic stress. But ATP/Pi and NAA/Cr ratios at 0.40 vs 0.95 ATA were not different suggesting that cells are not yet energy compromised and show no significant loss of neurons. Thus the reduced excitability observed at 0.40 vs 0.95 ATA O₂ may be normal, and activity at 0.95 ATA may reflect a hyperoxic state. Indeed, HBO shows >2-fold higher PCr/ATP (3.5±0.2) and 2-fold lower lactate/Cr (0.71±0.1) vs 0.40 ATA, suggesting that the cellular energy charge may be augmented under high O₂.

189 DFP-INDUCED OXIDATIVE INJURY AND DENDRITIC DAMAGE IN RAT BRAIN.

D. Milatovic¹, R. C. Gupta², S. Milatovic³, R. Lu¹ and M. Aschner¹. ¹Pediatrics, Vanderbilt University, Nashville, TN, ²Breathitt Vet. Center, Murray State University, Hopkinsville, KY and ³Cancer Biology, Vanderbilt University, Nashville, TN.

Increasing evidence suggests that in addition to excessive cholinergic stimulation, organophosphates, such as DFP (diisopropylphosphorofluoridate) induce glutamatergic activation, inflammatory responses as well as generation of reactive oxygen (ROS) and nitrogen (RNS) species, leading to neuronal degeneration. In order to establish the relevance of these mechanisms to structural neuronal injury, we studied multiple effectors of DFP exposure, which are critical in causing oxidative damage. Rats treated with DFP developed onset of toxicity signs within 10-15 min, which progressed to maximal severity of seizures and fasciculations within 60 min. At this time point, biomarkers of ROS, F₂-isoprostanes (F₂-IsoPs) and F₄-neuroprostanes (F₄-NeuroPs) were significantly increased (p<0.001) to 196% and 756% of control, respectively. Severe seizures also induced 2-5 fold increase in citrulline, a marker of RNS in discrete brain regions (cortex, amygdala, and hippocampus) but no changes in cerebral pro-inflammatory prostaglandins E₂ (PGE₂) were seen at 1 h following DFP compared to control (1.71 ng/g tissue). Significant elevations in PGE₂ levels were seen at a later time point (6 h) with the highest increase (340%) at 24 h. Quantitative morphometric analysis of pyramidal neurons of the hippocampal CA1 region 1 h following DFP exposure revealed significant decreases (p<0.01) in dendritic lengths and spine density to 64% and 60% of control, respectively. These findings support the involvement of ROS, RNS and PGE₂ as mediators of seizure-induced neuronal injury. (Supported by NIH P30 ES000267)

190 ANGIOTENSIN II-INDUCED RENAL OXIDATIVE STRESS IN CHRONIC ALCOHOL-INDUCED HYPERTENSION.

K. Husain, M. Vazquez, R. Carrero, J. Mejia and J. Lalla. *Physiology, Pharmacology and Toxicology, Ponce School Of Medicine, Ponce, Puerto Rico.*

The link between chronic alcohol consumption and the prevalence of hypertension is well established in clinical as well as experimental studies. However, molecular mechanisms implicated with alcohol-induced increases in blood pressure (BP) remain elusive. The aim of this study was to investigate the relationship of chronic ethanol-induced increase in blood pressure (BP) with angiotensin II-induced renal oxidative injury response in rats. Male Fisher rats were divided into two groups of seven animals each and treated as follows: (1) Control (5% sucrose, orally) daily for 12 weeks; (2) ethanol (4 g kg⁻¹, orally) daily for 12 weeks. The BP (systolic, diastolic and mean) was recorded every week through tail-cuff method. The animals were sacrificed after 12 weeks blood and kidney were isolated and analyzed for angiotensin II levels and oxidative stress parameters. The results show that the systolic and mean BP was significantly elevated 6-12 weeks after ethanol ingestion, whereas diastolic BP was significantly elevated 8-12 weeks post ethanol ingestion. The increased BP was related to elevated angiotensin II levels in the tissues of alcohol treated group compared to control. The renal oxidative stress parameters such as NADPH oxidase activity, ratio of oxidized and reduced glutathione (GSSG/GSH) and lipid peroxidation significantly increased in alcohol group compared to control. The renal antioxidant enzyme activities such as superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPX) were significantly depressed in alcohol-treated rats compared to control. The study concluded that chronic ethanol ingestion induces elevations in systolic, diastolic and mean BP which are correlated with elevated tissue angiotensin II levels. Elevated angiotensin II levels induced superoxide production via activation of NADPH oxidase activity causing increased

lipid peroxidation and depletion of antioxidants (glutathione levels and antioxidant enzyme activities) leading to oxidative renal injury in rats (supported in part by NIH grant #2 G12 RR03050-19).

191 PREVENTION OF HYPEROXIA-INDUCED RETINOPATHIES AND ABNORMAL NEOVASCULARIZATION IN THE NEWBORN RAT BY RETINOIC ACID.

X. I. Courrouchi¹, Y. Wei-Liang¹, L. Kong¹, P. Chevez-Barrios², W. Jiang¹ and B. Moorthy¹. ¹Pediatrics, Baylor College of Medicine, Houston, TX and ²Pathology, The Methodist Hospital, Houston, TX.

Supplemental oxygen administration to premature infants contributes to the development of retinopathy of prematurity (ROP). In this study, we tested the hypothesis that neonatal exposure of rats to a combination of all-trans retinoic acid (RA) and hyperoxia would alleviate retinopathy and abnormal neovascularization compared to those exposed to hyperoxia alone. Newborn Fisher 344 rats were maintained in room air or exposed to hyperoxia ([gt] than 95% O₂) for 7 days. Some animals were treated i.p. with RA (1 mg/kg) or vehicle (saline), once daily for the first 5 days of hyperoxic exposures. Animals were sacrificed at selected time points after termination of hyperoxia. Retinal histopathology and vascular densities of flat mounted retinas were assessed. mRNA expression of VEGF and its receptors (VEGFR-1/sFLT-1 and VEGFR-2), and HIF-1 α was determined by real time RT-PCR. Immediately after 7 days of exposure to hyperoxia or to hyperoxia + RA, we observed constricted retinal vessels, compared to air breathing animals. Seven to thirty days after termination of hyperoxia, the animals displayed formation of abnormal retinal vessels and capillaries, whereas animals given RA+ hyperoxia showed significantly lesser extent of neovascularization. At these time points, VEGF mRNA expression in the hyperoxia group was much higher than that of the RA+ hyperoxia group. On the other hand, the expression of VEGFR-1 and sFLT-1, but not VEGFR2, was differentially regulated by RA + hyperoxia, compared to those animals exposed to oxygen alone. EMSA and supershift experiments suggested that CREB plays an important role in the modulation of VEGFR-1 by RA. In conclusion, our results suggest that RA protects retinas from oxygen-induced retinopathy with abnormal neovascularization, and that modulation of VEGFR-1 via CREB contributes to the retinoprotective effects of RA. Future studies to elucidate the mechanisms of RA action could lead to the potential use of RA in infants with the risk of developing ROP.

192 MITOCHONDRIAL THIOREDOXIN-2 OVEREXPRESSION INHIBITS OXIDATIVE DAMAGE IN AGED MICE.

J. M. Hansen¹, S. Moriarty-Craige² and D. P. Jones². ¹Pediatrics, Emory University, Atlanta, GA and ²Medicine, Emory University, Atlanta, GA.

Numerous studies have shown an increase in oxidative stress biomarkers and damage as a consequence of aging. While antioxidant supplementation does not show beneficial effects in slowing the aging process, a decrease in mitochondrial reactive oxygen species (ROS) inversely correlates with lifespan duration. Thioredoxin-2 (Trx2) is an antioxidant system particular to the mitochondria and is capable of participating in the elimination of ROS. To evaluate the effects of mitochondrial health and aging, we generated a Trx2 transgenic (Trx2 Tg) mouse and measured parameters of oxidative stress in young mice (~3 months) and old mice (~24 months). For measurement of reactive oxygen metabolites, a dROMs (reactive oxygen metabolites) assay was performed. There was not a significant difference between young wild-type and Trx2 Tg mice. While both old wild-type and Trx2 Tg mice showed an increase of ROMs with age compared to respective young mice, old wild-type mice showed an increase of nearly 130% while the old Trx2 Tg mice showed a 58% increase. These differences approached statistical significance (p=0.07). Plasma nitrotyrosine (N-Tyr) and protein carbonyls (PC) were determined by mass spectrometric and colorimetric assays, respectively. Plasma N-Tyr concentrations between young wild-type and Trx2 Tg mice were not different but plasma N-Tyr was significantly less (approximately 50%) in old Trx2 Tg mice as compared to old Wild-type mice. Plasma PC showed a similar pattern, where significant differences were observed between old wild-type and Trx2 Tg mice measuring an approximate difference of 55%. Plasma redox status was measured via HPLC and showed no significant differences in the glutathione/glutathione disulfide redox potential (Eh) between any of the groups. Significant oxidation of the cysteine/cystine Eh was observed and appears to be a consequence of a significant decrease in plasma cysteine concentrations. In summary, the overexpression of Trx2 protects against oxidative damage that occurs during aging and may contribute to increase in lifespan.

193 INDUCTION OF OXIDATIVE STRESS AND OXIDATIVE DNA DAMAGE IN RATS BY ACRYLONITRILE.

X. Pu, L. M. Kamendulis and J. E. Klaunig. *Pharmacology and Toxicology, Indiana University, Indianapolis, IN.*

Acrylonitrile, widely used in the manufacture of plastics, acrylic fibers, and synthetic rubber, resulted in a dose-related increase in gliomas in rats following chronic exposure. Studies have provided evidence supporting that the mechanism for the induction of brain tumors by acrylonitrile involves the induction of oxidative stress. The present study examined the ability of acrylonitrile to induce oxidative stress and DNA damage in the rat. Male Sprague-Dawley rats were treated with 0, 3, 30, 100 ppm acrylonitrile in drinking water for 28 days; and in a time-response study, rats were treated with 0 or 200 ppm acrylonitrile in drinking water for 14 and 28 days. Direct DNA strand breakage in white blood cells was measured using the alkaline Comet assay. Oxidized DNA damage was evaluated using the formamidopyrimidine-modified Comet assay and HPLC with electrochemical detection in white blood cells and brain cortex, respectively. No increase in direct DNA strand breaks were observed in white blood cells from any of the treated rats, however, oxidative DNA damage was increased in white blood cells in a dose- and time-dependent manner (up to 3.8 fold over control). Similarly, dose- and time-dependent increases in the level of 8-hydroxy-2'-deoxyguanosine in brain cortexes (up to 3.9 fold over control) and hydroxyl free radicals in plasma (up to 9.8 fold over control) were observed in rats treated with acrylonitrile. A slight but significant decrease in the GSH/GSSG ratio was seen in the brain cortexes of rats receiving 30, 100, 200 ppm acrylonitrile in drinking water for 28 days, and 200 ppm for 14 days. These results show that ACN dose not produce direct damage to DNA, but does cause oxidative stress and oxidative DNA damage in rats, and supports that oxidative DNA damage may be involved in acrylonitrile-induced tumorigenicity.

194 WHICH RISK FACTOR IS IMPORTANT FOR INCINERATOR WORKERS: EXPOSURE TO DIOXINS OR POLYCYCLIC AROMATIC HYDROCARBONS?

Y. Ogawa¹, I. Mori¹, S. Hiroyuki¹, Y. Rie¹ and M. Ichiba². ¹National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan and ²Social and Environmental Medicine, Saga Medical School, Saga, Japan.

Incinerator workers are well known to be at the risk of exposure to dioxins and the cancer is considered to be a critical outcome. On the other hand combustion of carbon materials produces polycyclic aromatic hydrocarbons (PAH) as well as dioxins and PAH are also well known as mutagens or carcinogens. We intended to evaluate the effects on oxidative stress level among workers exposed to dioxins or PAH. We studied workers from four factories, which were three municipal solid waste incinerators (MSWI) A, B, and C and one industrial waste incinerator D. Subjects were 97 male, aged from 22 to 64 and mean 44.7. Blood were collected from cubital vein before the work shift and 7 polychlorinated debenzo-para-dioxins, 10 polychlorinated dibenzofurans, and 12 non-ortho and mono-ortho coplanar polychlorinated biphenyls were measured. Urine samples were collected before and end of the work shift and 1-hydroxypyrene (1-OHP), 2-naphthol (2-N), 8-hydroxy-2'-deoxyguanosine (8-OH-dG) and creatinine were measured. 1-OHP was highest for factory A workers, 2-N was highest for factory B workers, dioxins were highest for factory D workers and 8-OH-dG was highest for factory B. These results suggested that oxidative stress was highest for workers of factory B who were exposed to rather high naphthalene and rather low pyrene. Dioxin levels did not influence the oxidative stress level. Factory B is ordinary MSWI and workers have not dealt with industrial chemicals or house building materials. Emitted PAH from the incinerator must be produced mainly from the combustion of municipal solid waste. Although low molecular PAH were considered not to have significant effect to carcinogenicity and the increased exposure of factory B workers to naphthalene does not directly relate to increased oxidative stress level, the relation needs to be examined further.

195 HMGB1 IN HYPEROXIA-INDUCED IMPAIRMENT OF PSEUDOMONAS AERUGINOSA PHAGOCYTOSIS.

T. Entezari-Zaher¹, E. Miller², H. Wang², K. Tracey², J. Li² and L. Mantell^{1,2}. ¹Pharmaceutical Sciences, St. John's University College of Pharmacy, Queens, NY and ²The Feinstein Institute for Medical Research, North Shore-LIJ Health System, Manhasset, NY.

Pseudomonas aeruginosa (PA) is a leading cause of nosocomial pneumonia in patients receiving mechanical ventilation with hyperoxia. Alveolar macrophages are instrumental in bacterial clearance in the lung. Previously, we have shown that hyperoxic exposure ($\geq 95\%$ O₂) results in a significant impairment of phagocytosis of PA in both alveolar macrophages that were isolated from hyperoxic mice and in cultured macrophages. Since patients are weaned from these high concentrations of oxygen at the earliest possibility, we tested whether the magnitude of the impairment of PA phagocytosis depends on the concentrations of oxygen. RAW 264.7

cells were exposed to different concentrations of oxygen, ranging from 95% down to 40%. Hyperoxia ($\geq 95\%$ O₂)-induced cell proliferation-arrest was diminished when the concentration of oxygen was 65% or lower. However, this differential effect on cell proliferation was not reflected in the macrophage's ability to phagocytose PA. Exposure to $\geq 40\%$ O₂ induced similar extents of PA phagocytosis impairment. Corresponding to the reduction in PA phagocytosis, similar levels of HMGB1, a newly discovered cytokine and an important contributor to the pathogenesis of hyperoxic acute lung injury, were accumulated in the cultured media of RAW cells exposed to various concentrations of hyperoxia. To test whether HMGB1 contributes to hyperoxia-induced reduction of PA phagocytosis, RAW cells were exposed to recombinant HMGB1. Compared to RAW cells treated with a control peptide or trypsinized HMGB1, recombinant HMGB1 caused a reduction of PA phagocytosis at a similar level as those exposed to hyperoxia. These data suggest that HMGB1 plays a critical role in hyperoxia-induced impairment of PA clearance.

196 A DIFFERENTIAL EFFECT OF HYDROGEN PEROXIDE ON THE ABILITY OF MACROPHAGES TO PHAGOCYTOSE MICRO-ORGANISMS.

B. Phan¹, T. Entezari-Zaher¹, R. Lockshin² and L. Mantell^{1,3}. ¹Pharmaceutical Sciences, St. John's University College of Pharmacy, Queens, NY, ²Biology, St John's University, Queens, NY and ³Cardiopulmonary Research, The Feinstein Institute for Medical Research, Manhasset, NY.

Prolonged exposure to hyperoxia during mechanical ventilation causes acute proinflammatory responses. Nosocomial pneumonia in patients receiving mechanical ventilation is a related problem and one of the major causes for mortality and morbidity in Intensive Care Units. Hydrogen peroxide, generated by phagocytes during inflammation to kill the invading microorganisms, impairs the macrophage's ability to phagocytose. However, hydrogen peroxide exhibits differential effects on cell proliferation and cell death in a concentration-dependent manner. In this study, we tested whether the impairment of macrophage phagocytosis by hydrogen peroxide depends on its concentration in cultured macrophages. RAW 264.7 cells were exposed to various concentrations of hydrogen peroxide from 1mM to 1 μ M for up to 3 hours. Consistent with the previous studies, hydrogen peroxide significantly reduced macrophage phagocytosis of microbeads at concentrations higher than 500 μ M. In addition, loss of mitochondria dehydrogenase activity, as evidenced by the MTT assay, and reduced total actin polymerization were observed in these cells. In contrast, the ability of RAW cells to phagocytose was significantly ($>50\%$) increased when the cells were treated with <200 μ M hydrogen peroxide. Furthermore, actin polymerization was markedly more pronounced in cells treated with low concentrations of hydrogen peroxide. These results suggest that a moderate amount of hydrogen peroxide can stimulate actin polymerization and improve phagocytosis in macrophages although high concentrations of hydrogen peroxide are detrimental to macrophage functions.

197 IN VITRO TOXICITY AND OXIDATIVE STRESS STUDY WITH NANO- VS. FINE-SIZED ZNO PARTICLES IN HUMAN LUNG CANCER CELLS.

Y. Huang³, W. Lin¹ and Y. Ma². ¹Chemistry, University of Missouri-Rolla, Rolla, MO, ²Chemistry and Environmental Research Center, University of Missouri-Rolla, Rolla, MO and ³Biological Sciences and Environmental Research Center, University of Missouri-Rolla, Rolla, MO.

Cytotoxicity of 71 nm ZnO nanoparticles and 0.48 μ m ZnO fine-sized particles was investigated in cultured human bronchoalveolar carcinoma-derived cells. The physicochemical properties of these two nanoparticles were well characterized using TEM, XRD, and BET. The results demonstrated that exposure to both particles at 10-14 μ g/mL dosage levels for 24-hr decreased cell viability in a dose-dependent manner. Dosage levels less than 8 μ g/mL resulted in no cell viability while dosage levels higher than 18 μ g/mL caused approximately 95% cell viability reduction. The 71 nm ZnO nanoparticles (IC₅₀=13.3 μ g/ml) showed only slightly higher cytotoxicity than that of 0.48 μ m ZnO particles (IC₅₀=13.9 μ g/ml). In the subsequent mechanistic study, both particles were used to determine levels of cellular oxidative stress. Indicators of oxidative stress and cytotoxicity, including total reactive oxygen species (ROS), glutathione, malondialdehyde, and lactate dehydrogenase, were assessed quantitatively. Significant oxidative stress was observed after cells had been exposed to 10-14 μ g/ml of 71 nm or 0.48 μ m ZnO particles for 24-hr, as indicated by elevated cellular ROS levels and reduced GSH. Elevated malondialdehyde levels indicated lipid peroxidation, a consequence of elevated oxidative stress due to ZnO exposure. The increased lactate dehydrogenase levels in the cultured medium indicated cell membrane damage ($p < 0.05$). In addition, results from single cell gel electrophoresis (Comet Assay) showed DNA damage was induced by ZnO particles. In general, the extent of oxidative stress induced by 71 nm ZnO nanoparticles was higher than that of 0.48 μ m ZnO particles.

198 THE MOUSE CLARA CELL AS A TARGET FOR STYRENE-INDUCED TOXICITY.

J. Harvilchuck, R. Zurbrugg, N. Mantick and G. Carlson. School of Health Sciences, Purdue University, West Lafayette, IN.

Styrene is widely used in the manufacturing industry. In mice and rats, it is both hepatotoxic and pneumotoxic. It causes lung tumors in mice but not in rats. The Clara cell is the main target for the toxicity of styrene and its metabolites, and it also has the highest activity in the lung for styrene metabolism. Therefore, adverse effects of styrene and its metabolites on Clara cells isolated from CD-1 mice were investigated. Cytotoxicities due to styrene and its metabolites were compared in vitro in Clara cells at concentrations ranging from 0.1 to 10 mM. The cytotoxicity of styrene was greater in vitro than that of its metabolites styrene oxide (SO) (racemic, R- and S-) and 4-vinylphenol (4VP) in contrast with what has been observed in vivo in previous studies on hepatotoxicity and pneumotoxicity. Levels of the antioxidant glutathione were measured in mouse Clara cells following treatment with styrene and its metabolites in vitro and in vivo at doses of 600 mg/kg for styrene, 300 mg/kg for SO, and 100 mg/kg for 4VP. Decreases in glutathione concentrations were seen even at doses which did not cause the death of mouse Clara cells. Decreases in Clara cell glutathione were observed 3 hours after treatment with all compounds and were significant with racemic SO and R-SO. At 12 hours, rebound effects were seen for all compounds, with all but R-SO rebounding above controls. Reactive oxygen species were measured in vitro in Clara cells using 2',7'-dichlorodihydrofluorescein diacetate, with small but significant increases observed 3 hours after treatment with racemic SO, S-SO, R-SO, and styrene. Using agarose gel electrophoresis, DNA fragmentation was observed 3 hours after treatment of mice with racemic SO and R-SO. These studies suggest that the in vitro cytotoxicities of styrene and its metabolites do not strictly follow in vivo effects and that the toxicity of styrene and its metabolites to Clara cells may be related to oxidative stress. (This work was supported in part by a grant from the Styrene Information and Research Center.)

199 MYCOPLASMA PNEUMONIAE INFECTION INCREASES OXIDATIVE STRESS AND INHIBITS THE LUNG'S GLUTATHIONE ADAPTIVE RESPONSE TO CIGARETTE SMOKE IN IN VIVO AND IN VITRO.

C. T. Kariya^{1,2}, H. Chu², R. Martin² and B. J. Day^{1,2,3}. ¹Molecular Toxicology, UCHSC, Denver, CO, ²Medicine, NJRMC, Denver, CO and ³Immunology, NJRMC, Denver, CO.

The lung epithelial lining fluid (ELF) serves as the first line of defense against environmental agents (EA) and potential pathogens. It has been speculated that antioxidants play important roles in protecting the lung against these agents. Cigarette smoke (CS) is known to elevate the levels of glutathione (GSH) in the ELF, although it is unclear what role this plays in the lung's ability to adapt to the damaging effects of CS. Little is currently known about how the lung regulates the levels of these antioxidants in the ELF. Recent studies suggest that the cystic fibrosis transmembrane conductance regulator protein (CFTR) is involved in the maintenance of the high levels of GSH in the ELF. Lung pathogens such as Mycoplasma pneumoniae (Mp) have been shown to exacerbate airway inflammation associated with asthma. The purpose of these studies was to examine the role of CFTR in adaptive responses following CS and Mp exposures both in vitro and in vivo. Human lung epithelial cell lines sufficient (C38) and deficient (IB3) in CFTR were exposed separately and in combination to cigarette smoke extract (CSE) and Mp for 48 hours. CSE elevated the extracellular levels of GSH in IB3 & C38 cells as compared to controls and these increases were blocked in the Mp treatment groups. BALB/c mice were exposed separately and in combination to CS and Mp for 2 and 4 months. CS exposure resulted in a 3.5-fold elevation in ELF GSH levels, which was completely blocked in the Mp exposed mice. In addition, the CS/Mp exposed mice had elevated oxidized glutathione (GSSG) and dramatic change in their ratio of GSH/GSSG ratios. Furthermore, CS/Mp exposed mice also had high levels of DNA oxidation as measured by 8OHdG. These studies suggest Mp infection may interfere with the lung's ability to respond appropriately, resulting in lung inflammation and injury. The role of GSH transporter(s) requires further studies to better understand these mechanism(s). (Supported in part from NIH grant HL075523)

200 INDUCTION OF OXIDATIVE STRESS BY URANIUM IN LUNG EPITHELIAL CELLS.

A. Periakaruppan, F. Kumar, S. Sarkar, C. S. Sharma, R. Yog and R. Govindarajan. Molecular Neurotoxicology Laboratory/Proteomics Core, Department of Biology, Texas Southern University, Houston, TX.

Uranium compounds are widely used in the nuclear fuel cycle, antitank weapons, tank armor, and also as a pigment to color ceramics and glass. Effective management of waste uranium compounds is necessary to prevent exposure to avoid adverse health effects on the population. Health risks associated with uranium exposure includes kidney disease and respiratory disorders. In addition several published

results have shown uranium or depleted uranium causes DNA damage, mutagenicity, cancer and neurological defects. Oxidative stress induces DNA damage and also changes in related signaling cascade. Therefore to evaluate the role of oxidative stress induced by uranium in rat lung epithelial cells was studied. The study shows uranium induced significant oxidative stress in rat lung epithelial cells followed by concomitant decrease in the antioxidant potential in the cells. Treatment with uranium to the cells decreased cell proliferation after 72h in culture. The decrease in cell proliferation was attributed to loss of total glutathione and superoxide dismutase in presence of uranium. The supplementation of antioxidants counteracted the oxidative stress induced by uranium. In presence of NAC, GSH and vitamin E, uranium induced oxidative stress was considerably decreased suggesting loss of cellular antioxidants. Thus the results indicate that oxidative stress is induced by uranium in the rat lung epithelial cells. This work was supported by NSF-HRD 0401587; NIH RR03045-19 (GR).

201 ATTENUATION OF CADMIUM-INDUCED TOXICITY BY MONOISOAMYL 2, 3-DIMERCAPTOSUCCINATE ON CRL-1439 NORMAL RAT LIVER CELLS.

R. Buggs¹, C. O. Odewumi¹, V. D. Badisa¹, L. M. Latinwo¹, L. T. Ayuk-Takem¹, C. Ikediobi², U. T. Le¹, B. Jones¹, T. Sanders¹ and M. R. Soliman³.

Cadmium (Cd) is a non-essential heavy metal that is found in environment and industry. Cadmium causes severe human health problems, and also causes deleterious effects on antioxidant enzymes. Monoisoamyl 2,3-dimercaptosuccinate (MiADMS) is an ester of DMSA containing two sulfhydryl (SH) groups. MiADMS is potent chelator of cadmium and also provides an antioxidant function by removing cadmium from the site of deleterious oxidation reactions. Therefore, we studied the protective effect of MiADMS on cadmium induced oxidative stress by evaluating the activities of the antioxidant enzymes catalase, glutathione reductase (GR), and glutathione peroxidase (GPx) in cultured normal rat liver CRL-1439 cells. The cells were treated with 150 μ M cadmium chloride and co-treated with 300 μ M MiADMS at the same time, 2-hrs post or 4-hrs post for 24 hrs. Cd concentration of 150 μ M decreased cell viability by 61.9% compared to untreated control cells. MiADMS increased cell viability by 45.3%, 42%, and 26.25% in the same time, 2-hrs post, and 4-hrs post treatments, respectively. In the presence of 150 μ M Cd, GR, catalase, and GPx activities decreased by 87.6%, 82.1% and 18.2% respectively compared to the untreated control. GR activity was increased by 110.4%, 144.7%, and 66.2% in MiADMS treated cells, respectively. Catalase activity was also increased by 53.85%, 82.55%, and 71.55% in MiADMS treated cells, respectively. GPx activity was increased by 24.3% and 5.2% in same time and 2-hrs post MiADMS treated cells, while in 4-hrs post MiADMS treated cells activity decreased by 74.35%. These results show that MiADMS protects the cells by increasing the activity of GR and catalase enzymes, while GPx showed a slight increase in activity.

202 ATTENUATION OF CADMIUM-INDUCED TOXICITY BY CO-TREATMENT OF N-ACETYL-CYSTEINE AND CADMIUM ON CRL-1439 RAT LIVER CELLS.

U. T. Le¹, C. O. Odewumi¹, V. D. Badisa¹, L. M. Latinwo¹, C. Ikediobi², R. Buggs¹, B. Jones¹, T. Sanders¹ and M. R. Soliman³. ¹Department of Biology, Florida A & M University, Tallahassee, FL, ²Department of Chemistry, Florida A & M University, Tallahassee, FL and ³College of Pharmacy, Florida A & M University, Tallahassee, FL.

Cadmium (Cd), a ubiquitous heavy metal is listed among the top seven of the 275 most hazardous substances in the environment, and it is classified as a Type I carcinogen. Human exposures to cadmium are usually through inhalation, dermal or oral routes. Although, the quantity of cadmium exposure is usually low, accumulation and long half-life of cadmium in animals and humans are responsible for the initial high health effects of cadmium. N-acetyl-cysteine (NAC), a sulfur-containing amino acid and precursor of glutathione is used as an antioxidant to protect the cells from oxidative stress. Therefore, we studied the protective effect of NAC on cadmium-induced oxidative stress in cultured normal rat liver CRL-1439 cells by evaluating the activities of antioxidant enzymes such as catalase, glutathione reductase (GR), and glutathione peroxidase (GPx). Cd concentration of 150 μ M decreased cell viability by 57% compared to untreated control cells. Cells that were pre-treated with 5 mM NAC for 2-hour, or post treated for 2-hour, or co-treated with 150 μ M Cd exhibited improved viability by 36%, 43%, and 34.8% respectively. There is was no catalase activity detected in the 150 μ M Cd treated cells compared to untreated cells. Catalase activity increased by 39.7%, 33.8% and

13.5% respectively in pre, same, and post NAC treatment than 150 μ M Cd treated cells. GR and GPx activity decreased by 43.9% and 21.7% respectively in the presence of 150 μ M Cd compared to untreated cells. Interestingly, in the presence of NAC, GR activity for each treatment increased by 34.9%, 34.4%, and 43.4%, respectively. In the presence of NAC, GPx activity increased by 66.3%, 61.6%, and 66% respectively. These results clearly show NAC protects cells by increasing the activities of antioxidative enzymes.

203 ALLOXAN REDOX CYCLING IS NOT REQUIRED FOR INHIBITION OF GLUCOSE-STIMULATED OXYGEN FLUX IN ISOLATED PANCREATIC BETA ISLETS.

J. P. Gray¹, E. Heart³, P. J. Smith³, D. E. Heck² and J. D. Laskin¹.

Alloxan (1,3-diazinane-2,4,5,6-tetrone) is commonly used as a model to induce type II diabetes in rodents. In addition to inhibiting the glucose responsiveness of beta islet cells, it has been suggested that alloxan undergoes redox cycling. We speculate that this leads to the generation of cytotoxic reactive oxygen intermediates (ROI), and that this contributes to its diabetogenic actions. For these studies, self-referencing oxygen microensors were used to measure oxygen flux from intact islets isolated from female CD1 mice. Menadione (100 μ M), a non-diabetogenic redox cycling agent was used as a control. We found that menadione caused a rapid increase (2-4 fold) in oxygen utilization by islets. In contrast, alloxan (1 mM) had no effect on basal oxygen consumption suggesting that it was not redox cycling. However, both menadione and alloxan were able to inhibit the glucose-stimulated respiratory burst in intact beta islets. Using purified cytochrome P450 reductase in an enzymatic system for redox cycling that generates hydrogen peroxide, we found that menadione effectively stimulated production of ROI, while alloxan had no effect on cytochrome P450 reductase basal activity. Unlike menadione, alloxan non-enzymatically generated ROI in the presence of cellular reducing agents, including NADPH, cysteine and glutathione in a process that utilizes molecular oxygen. However, this redox cycling activity is unlikely to occur in islets since alloxan treatment was not associated with alterations in oxygen utilization in beta islets. Taken together, these data indicate that alloxan and menadione alter islet cell functioning by distinct mechanisms and that inhibition of the glucose-stimulated respiratory burst alone is not sufficient for islet cell toxicity leading to diabetes. Supported by NIH grants ES05022, CA093798, P41 RR001395, and CA100994.

204 DIFFERENTIAL EFFECTS OF Ca^{2+} -INDEPENDENT PHOSPHOLIPASE A_2 INHIBITION ON OXIDANT-INDUCED CELL DEATH IN PRIMARY NEOCORTICAL CELLS.

B. Peterson and B. S. Cummings. University of Georgia, Athens, GA.

Our previous studies demonstrated that inhibition of Ca^{2+} -independent phospholipase A_2 (iPLA₂), a phospholipid metabolizing enzyme, increased oxidant-induced (hydrogen peroxide (H_2O_2), and tert-butylhydroperoxide (TBHP)) cell death in human glioblastoma (A172) cells. The goal of this study was to determine the effect of iPLA₂ inhibition on oxidant-induced cell death in primary cultures of mouse neocortical neurons. Immunoblot analysis demonstrated that these neurons expressed both cytosolic (iPLA₂ β) and microsomal (iPLA₂ γ) isoforms of iPLA₂, and that these isoforms were inhibited by bromoenol lactone (BEL), an iPLA₂ selective inhibitor. Exposure of neurons to H_2O_2 (0-1000 μ M) and TBHP (0-800 μ M) induced concentration-dependent increases in cell death as determined by cell morphology (36 hr) and 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) staining (24 hr). To examine the mechanism of cell death, adenosine 5'-triphosphate (ATP) levels and production of reactive oxygen species (ROS) were measured using bioluminescent and dichlorofluorescein assays, respectively. Both oxidants induced concentration-dependent decreases in ATP levels (50-75%) at 24 hr. H_2O_2 treatment did not induce ROS production compared to control, while TBHP treatment induced a 200% increase after 2 hr. Treatment of cells with 2.5 μ M BEL prior to exposure to 500 μ M H_2O_2 increased ATP levels (~30%), increased MTT staining (~10%), but did not increase ROS formation in comparison to H_2O_2 -treated cells. In contrast, treatment of neurons with BEL prior to exposure to 100 μ M TBHP did not prevent ATP depletion, decrease MTT staining or alter the formation of ROS. Collectively, these data demonstrate that both iPLA₂ isoforms are expressed in primary cultures of neocortical neurons. iPLA₂ inhibition appeared to protect against H_2O_2 -induced neuronal cell death but not TBHP-induced cell death. This suggests the novel hypothesis that inhibition of iPLA₂ plays differential roles in cell death induced by different oxidants.

205 ROLE OF REACTIVE OXYGEN SPECIES, NFKAPPAB AND CASPASE-3 IN PESTICIDE-INDUCED NEURONAL CELL CYTOTOXICITY.

Z. Jia and H. P. Misra. *Edward Via Virginia College of Osteopathic Medicine, Blacksburg, VA.*

A number of epidemiological studies have demonstrated a strong association between the incidence of Parkinson's disease and factors that increase the likelihood of exposure to pesticides. We and others have demonstrated that exposure to endosulfan and zineb causes dopaminergic system dysfunction in vivo. Reactive oxygen species (ROS) has been implicated in neurotoxicity, based on its role in the cascade of biochemical changes that lead to dopaminergic neuronal cell death. We, therefore, examined the role of ROS in pesticides (endosulfan and zineb)-induced neurotoxicity in human neuroblastoma cells (SH-SY5Y) in culture. The generation of intracellular hydrogen peroxide and superoxide anion was monitored using spectrofluorometric analysis in combination with dichlorofluorescein diacetate and hydroethidine dyes, respectively. SH-SY5Y cells exposed to pesticides (50-200 μ M) were found to generate both superoxide anion and hydrogen peroxide in a dose- and time-dependent manner. Mixtures of the pesticides significantly enhanced the production of these reactive oxygen species compared to individual pesticide exposures. Exposure to these pesticides individually or in mixtures decreased the activities of antioxidant enzymes such as superoxide dismutase, glutathione peroxidase, and catalase in SH-SY5Y cells. Additionally, these pesticides augmented lipid peroxide formation in these cells. While both pesticides individually (at 100 μ M) increased caspase-3 activity, cells exposed to a mixture of the pesticides exhibited significantly low levels of this protein, probably due to excessive necrotic cell death. Furthermore, exposure to these pesticides increased nuclear transcription factor NFkappaB activity. Taken together, these findings suggest that the cytotoxicity of endosulfan and zineb, both individually and in mixtures may, at least in part, be associated with the generation of reactive oxygen species with concomitant increased expression of NFkappaB.

206 QUINONE-THIOETHER MEDIATED STRESS RESPONSES IN HUMAN PROXIMAL TUBULAR EPITHELIAL CELLS.

R. Xie, T. J. Monks and S. S. Lau. *Pharmacology and Toxicology, University of Arizona Health Sciences Center, Tucson, AZ.*

Hydroquinone (HQ) is a rodent carcinogen and a potential human carcinogen. HQ is metabolized in the liver to 2,3,5-tris-(glutathion-S-yl)HQ (TGHQ), a redox active and potent toxic quinone- thioether. The kidney is a known target organ of HQ toxicity and is critical for TGHQ biotransformation. We are utilizing an immortalized human proximal tubular epithelial cell line, HK-2, to serve as an in vitro model for the human exposure to TGHQ. Consistent with data obtained in a porcine renal cell model (LLC-PK1), TGHQ generated reactive oxygen species (ROS) in HK-2 cells. Catalase abolished ROS production and efficiently prevented TGHQ-mediated cell death, as determined by leakage of LDH from cells. No molecular markers of apoptosis, annexin V - propidium iodide staining, were observed following TGHQ exposure, indicating that HK-2 cells undergo necrotic cell death. The mitogen-activated protein kinases (MAPKs), including ERK, JNK and p38, and another serine/threonine kinase, Akt, were all activated by TGHQ. In addition, HK-2 cells were more susceptible to TGHQ when maintained in Keratinocyte medium with EGF and bovine pituitary extract, than when cultured in DMEM-F12 medium with 10% FBS. HK-2 cells have similar doubling times and express the same level of γ -glutamyl transpeptidase in both culture media. However, ROS generation was more rapid and greater in cells cultured in Keratinocyte medium. Current studies focus on dissecting the cellular signaling pathways leading to TGHQ-mediated oncotic cell death. Moreover, elucidating the factors contributing to differences in sensitivity of HK-2 in response to TGHQ will be useful for designing mechanism-based strategies to attenuate TGHQ-mediated cell death. (RO1 DK59491, P30 ES 06694)

207 MITOCHONDRIA TARGETED HEMI-GRAMICIDIN S CONJUGATED NITROXIDES INHIBIT APOPTOSIS AND CARDIOLIPIN OXIDATION IN MOUSE EMBRYONIC CELLS.

J. Jiang^{1,2,3}, N. A. Belikova^{1,2,3}, J. Xiao^{2,4}, Q. Zhao^{1,2,3}, I. V. Kurnikov^{1,2,3}, M. P. Fink^{2,5}, P. Wipf^{2,4}, J. S. Greenberger^{2,6} and V. E. Kagan^{1,2,3}. ¹Center for Free Radical and Antioxidant Health, University of Pittsburgh, Pittsburgh, PA, ²Center for Medical Countermeasures against Radiation, University of Pittsburgh, Pittsburgh, PA, ³EOH, University of Pittsburgh, Pittsburgh, PA, ⁴Chemistry, University of Pittsburgh, Pittsburgh, PA, ⁵Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA and ⁶Radiation Oncology, University of Pittsburgh, Pittsburgh, PA.

Reactive oxygen species (ROS) generated by disrupted electron transport in mitochondria are involved in irradiation induced intrinsic apoptosis. Removal of superoxide, a major form of ROS in mitochondria, has been suggested as an effective intervention strategy against irradiation. Although nitroxides have been proven as ideal candidates for their unique electron scavenging features and recycling ability, they are not effective in ameliorating oxidative stress due to the poor accumulation in mitochondria. Here we evaluated the effect of a hemi-gramicidin S conjugate of 4-amino-TEMPO (4-AT), (GS-TEMPO), on γ -irradiation induced mouse embryonic cell apoptosis. We report that GS-TEMPO accumulated in cells and mitochondria orders of magnitude more efficiently than 4-AT. Treatment of cells with GS-TEMPO, either pre- or post- (1h) irradiation, inhibited irradiation induced cytochrome c release, caspase-3 activation, and phosphatidylserine externalization. Further studies revealed that GS-TEMPO suppressed irradiation induced superoxide generation and accumulation of cardiolipin hydroperoxides. Finally, the comparative study of GS-TEMPO derivatives and Monte-Carlo simulations of GS-TEMPO in model lipid membranes indicated that the conservation of the DPhe-Pro reverse turn in hemi-GS analogs ensure the specific positioning of the nitroxide moiety at the mitochondrial membrane interface and maximize their protective effects. In conclusion, GS-TEMPO can be effectively delivered into mitochondria and act as radioprotectors preventing irradiation induced mitochondrial ROS production, oxidative damage and apoptosis. Supported by NIAID U19-AI068021

208 NAD(P)H:QUINONE OXIDOREDUCTASE 1 (NQO1)-MEDIATED INDUCTION OF OXIDATIVE STRESS AND DNA DAMAGE BY LAVENDAMYCIN ANTI-TUMOR AGENTS.

M. Hassani¹, W. Cai², C. Bolin¹, F. Cardozo-Pelaez¹, M. Behforouz² and H. D. Beall¹. ¹Center for Environmental Health Sciences, The University of Montana, Missoula, MT and ²Department of Chemistry, Ball State University, Muncie, IN.

Lavendamylicins are quinone antitumor agents with structural similarity to streptonigrin, a redox cycling substrate for the two-electron reductase, NQO1. Therefore, we hypothesized that efficient lavendamylicin substrates for NQO1 could also undergo redox cycling with concomitant production of reactive oxygen species (ROS) resulting in the formation of the biological marker of oxidative DNA damage, 8-hydroxy-2'-deoxyguanosine (8-oxo-2dG) and depletion of reduced glutathione (GSH). NQO1-rich BE-NQ and NQO1-deficient BE human colon adenocarcinoma cells were treated with MB-353 (good substrate) and MB-323 (poor substrate) to investigate 8-oxo-2dG generation. An HPLC-based analysis was utilized to determine levels of 8-oxo-2dG, 2'-deoxyguanosine (2-dG) and the molar ratio, 8-oxo-2dG (fmol)/2-dG (nmol). Among MB-353 treated cells, a significant increase in the molar ratio of 8-oxo-2dG to 2-dG was observed only in BE-NQ cells suggesting a NQO1-mediated selective induction of oxidative DNA damage in BE-NQ cells by MB-353. No significant increase in the corresponding molar ratio was observed in either cell line treated with MB-323 implying that NQO1-mediated induction of oxidative DNA damage in BE-NQ cells was specific to good NQO1 substrates. Our laboratory previously determined that bioactivation of MB-353 by NQO1 caused selective depletion of GSH in NQO1-rich cells. To determine whether GSH depletion was specific to good substrates of NQO1, we measured levels of GSH in BE-NQ and BE cells after treatment with MB-323, the poor substrate. No difference was observed in GSH levels in either cell line treated with MB-323 suggesting that GSH depletion in BE-NQ cells was specific to good lavendamylicin substrates. Overall, only the good lavendamylicin substrate, MB-353, caused significant oxidative stress and DNA damage in NQO1-rich cells. Supported by NIH grants RR17670 (HDB) and CA74245 (MB).

209 ERYTHROPOIETIN PROTECTS CELLS FROM OXIDATIVE STRESS BY REDUCING OXIDATIVE DNA DAMAGE.

I. N. Rich and K. Hall. *HemoGenix Inc., Colorado Springs, CO.*

Erythropoietin (EPO) was, at one time, considered only as an erythropoietic lineage-specific regulator. The production of EPO is under the influence of a complex molecular signal detection system influenced by the partial oxygen pressure. More recently, EPO has been shown to exhibit multifunctional properties and its receptor has been found not only on erythropoietic cells, but also on cells from many different tissues and organs. Erythropoietin is a proliferation factor for primitive erythropoietic cells, but a differentiation/survival factor for late erythroid cells due to its anti-apoptotic function. We now demonstrate that EPO also exhibits anti-oxidative effects. Fresh, human bone marrow cells were incubated in the absence or presence of 0.1, 1 and 10U/ml human recombinant EPO. At the time cultures were prepared and after 24h incubation, the cells were incubated in the absence or presence of 1mM methylene blue (MeB), which, when illuminated with bright light, induces oxidative DNA damage (ODD) and the production of 8-oxoguanine residues. Additional controls included the absence or presence of light. After incubation, oxidative DNA damage was detected by OxyFLOW™, a flow cytometric detection system that uses a fluorescence isothiocyanate (FITC)-conjugated 8-oxoguanine – specific binding protein to measure changes in median fluorescence intensity. The results indicate that at 0h, EPO reduced ODD, but not in a dose dependent manner. In contrast, 10U/ml EPO significantly reduced ODD by more

than 40% compared to cells without EPO. These results demonstrate that EPO has an anti-oxidative function by acting to reduce oxidative DNA damage. This may occur in a number ways, e.g. iron store depletion, increase in glutathione peroxidase. The net result is protection against free radicals and oxidative stress for a large number of cell types that express the EPO receptor.

210 AMINOGLUTETHIMIDE METABOLISM BY MYELOPEROXIDASE RESULTS IN PROTEIN FREE RADICAL FORMATION THAT CORRELATES WITH CASPASE ACTIVATION AND PROTEASOME INHIBITION: A POSSIBLE MECHANISM OF AGRANULOCYTOSIS.

A. Siraki and R. P. Mason. *Laboratory of Pharmacology and Chemistry, NIH/NIEHS, Research Triangle Park, NC.*

Aminoglutethimide (Cytadren®, AG) is a drug used for estrogen-dependent breast cancer, adrenal gland tumors, and also as an adjuvant to prostate tumor treatment. Agranulocytosis, an unpredictable loss of neutrophils, occurs in 1% of patients undergoing AG administration. The loss of neutrophils increases the susceptibility of the patient to bacterial infection and sepsis. We hypothesize that AG may induce this harmful side-effect by metabolism to a reactive metabolite catalyzed by myeloperoxidase (MPO), an enzyme found within neutrophils. Using purified human MPO, we have found that MPO metabolism of AG resulted in protein free radical formation on MPO itself. The protein free radical was identified by using DMPO to trap the unstable radical, which was detected using an anti-DMPO antibody. The formation of the protein free radical was likely mediated by a phenyl radical metabolite of AG (detected by electron paramagnetic resonance spectroscopy). HL-60 cells, which express MPO, were used to determine if protein free radical detection also occurred in living cells. We found that protein free radical formation occurred in a time- and drug-dependent manner when cells were treated with AG and a H₂O₂-generating system. The absence of H₂O₂ did not result in protein free radical formation. Cytotoxicity, assessed using MTT, was greatest with 5 mM AG treatment. However, Caspase 3/7 activity was greatest with 1 mM AG. Interestingly, 1 mM AG also produced the most intense protein radical formation as determined by anti-DMPO western blot analysis. To determine the effect of this protein modification, we determined proteasomal activity as a possible mechanism of AG-induced cytotoxicity. Both 1 and 5 mM AG resulted in a significant inhibition of proteasomal activity both with and without the presence of DMPO. We speculate that that proteasomal inhibition may be a signal for apoptosis as a result of AG treatment, and could be a possible mechanism for AG-induced agranulocytosis.

211 IMMUNO-SPIN TRAPPING OF DNA RADICALS: A SENSITIVE DETECTION OF OXIDATIVELY GENERATED GENTOTOXIC DAMAGE.

D. C. Ramirez, S. E. Gómez-Mejiba and R. P. Mason. *Lab. Pharmacology Chem., National. Inst. Environment Hlth. Sciences., Research Triangle Park, NC.*

Reactive oxygen species can directly or indirectly affect the structure and function of biomolecules. Most of the techniques used to study oxidatively generated damage to the DNA are based on the detection of final oxidation products such as 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxo-dG). However, 8-oxo-dG can be repaired, excreted, and/or artifactually generated during sample work-up and analysis. We thought that by detecting DNA radicals it must be possible to achieve an early and more sensitive and specific characterization of the oxidatively generated damage to the genome than detecting final products of DNA oxidation. To detect DNA radicals we have developed immuno-spin trapping (IST) that involves three main steps: i) trapping, in situ and in real time, DNA radicals with DMPO, thus forming DMPO-DNA nitron adducts (nitron adducts); ii) purification of nitron adducts; and iii) analysis of nitron adducts by heterogeneous immunoassays using antibodies against DMPO. The nitron spin trap DMPO possesses low toxicity and excellent pharmacokinetics in cells and whole animals. Indeed, DMPO accesses the cell and traps, in situ and in real time, DNA radicals in the nucleus and/or mitochondria of cells under oxidative stress forming DMPO-DNA radical adducts (radical adducts). However, the analysis of the unstable radicals and radical adducts, which only can be achieved by electron spin resonance, is difficult in biological systems due to the time required to isolate the DNA from the biological matrix relative to their decay. Radical adducts decay to nitron adducts, in which DMPO is stably bound to the DNA facilitating their extraction and analysis. Applications of IST to investigate genotoxic damage to the DNA are empowered by its sensitivity, specificity, affordability, and reliability. Theoretical and practical considerations for the successful IST analysis of DNA radicals in toxicological models are presented.

212 THE MOLECULAR MECHANISM OF NRF2 ACTIVATION BY SODIUM ARSENITE AND MONOMETHYL ARSONOUS ACID.

Y. Li, Z. Sun, J. A. Gandolfi and D. Zhang. *University of Arizona, Tucson, AZ.*

Epidemiology studies have correlated arsenic exposure to various human diseases including cancer of the skin, lung, and bladder. Following uptake, inorganic arsenic is converted primarily in the liver to methylated metabolites, including monomethylarsonous acid [MMA(III)], which has been found to be 20x more toxic than arsenite and able to transform human cells. Both arsenite and MMA(III) have been found to generate an oxidative response even at environmentally relevant, low levels of exposure. The transcription factor Nrf2, through the antioxidant responsive element (ARE) in the regulatory regions of its downstream genes, regulates a cellular defense response against environmental toxicants and carcinogens. Degradation of Nrf2 is blocked and Nrf2-dependent genes are expressed in cells under oxidative stress. In this study, the induction of Nrf2 by arsenite and MMA(III) was examined. Steady state levels of Nrf2 and its transcriptional activity were increased in a breast cell line (MDA-MB-231) at concentrations as low as 2 µM for sodium arsenite and 250 nM for MMA(III), as evaluated by immunoblot analysis and the ARE-luciferase reporter gene assay. Elevated levels of the endogenous Nrf2 protein in response to sodium arsenite and MMA (III) were also observed in a human urothelium cell line. It appears both arsenite and MMA(III) exposures trigger induction of Nrf2 at low concentrations in both of these human cell lines. The mechanism of this induction is under investigation. (NIEHS 1R01ES015010-01 and NIEHS 04940)

213 MULTIPLEXED FLUORESCENT METHODS FOR MEASURING OXIDATIVE MODIFICATIONS OF PROTEIN/NON-PROTEIN THIOLS IN THE LUNG: APPLICATION TO THE STUDY OF CYTOTOXIC AROMATIC HYDROCARBONS.

P. Spiess, D. Morin and A. Buckpitt. *Vet. Med. Molecular Biosciences, University of California, Davis, Davis, CA.*

Oxidative stress caused by agents undergoing redox cycling or which are metabolized to electrophilic metabolites may alter both protein and non protein thiols. These processes have been implicated as key events in cellular toxicity. Naphthalene (NA) and 1-nitronaphthalene (NN) are metabolized to glutathione depleting metabolites in the lung and the formation of these metabolites has been associated with Clara cell toxicity. In these studies we examined alterations in murine pulmonary epithelial protein thiols (PSH) and the formation of more oxidized proteins (PSSP, PSSG, PSOH, PSO3) in response to diethylmaleate, a well known glutathione depleting agent. Reduced and oxidized protein thiols were measured using a multiplexed fluorescent two-dimensional gel electrophoresis labeling method developed by our laboratory. Briefly, proteins selectively isolated from lung epithelium using a method modified from Wheelock et al. (Am. J. Physiology, LCOMP 286: L399, 2004) were labeled with the sulfhydryl reactive maleimide dye Cy-3, excess label removed, disulfides were reduced and labeled with Cy-5 maleimide. Proteins were separated by 1 or 2D gel electrophoresis to examine loss of protein sulfhydryl associated with sulfhydryl oxidation. Preliminary validation studies with purified proteins containing both free SH and disulfide bridges demonstrated that the method yields data which accurately mirrors the number of free SH and PSSP in the protein. Treatment with diethylmaleate decreases PSH and increases the number of protein disulfides relative to control. Additional work to determine the identity of susceptible proteins is currently underway. We conclude that our method provides an assessment of the status of individual cellular proteins that may reveal key mechanistic features associated with the cytotoxic responses of aromatic hydrocarbons. Supported by NIEHS 04311, 04699, and T32ES07059.

214 TAQMAN LOW DENSITY ARRAYS: TESTING THE POTENTIAL FOR USE AS A HIGHER THROUGHPUT MOLECULAR TOXICOLOGY SCREEN FOR OXIDATIVE STRESS.

J. M. Hitchcock¹, A. Marcelino² and F. J. Spence¹. ¹*Drug Safety Research and Development, Pfizer Ltd., Sandwich, Kent, United Kingdom and* ²*School of Biomedical and Molecular Sciences, University of Surrey, Guildford, Surrey, United Kingdom.*

Reactive oxygen species are highly toxic by-products of aerobic respiration and can lead to oxidation and damage of cellular constituents. This damage has been implicated in the cause of a number of diseases including Parkinson's, diabetes, Hepatitis B and cancer, hence there is a need for earlier detection of oxidative stress in drug development. The aim of this work was to design and test the feasibility of a higher throughput molecular toxicology screen for oxidative stress.

There are currently a large number of biochemical assays available for the measurement of oxidative stress, however these are all relatively low throughput. Multiplex gene expression analysis, using TaqMan low density arrays (TLDA), could potentially enable increased throughput, coupled with greater insight into the mechanism of oxidative stress. The following work describes the study of 2 cell lines namely HepG2 and Hela cells, treated with a known oxidant Diethyl Maleate (DEM) and non-oxidant Oubain, for 24 hours. The cells were then evaluated using a routinely used viability assay and GSH depletion assay before gene expression analysis.

Standard TaqMan qRT-PCR and TLDA were employed to analyse gene expression. A total of 23 genes were selected by review of the literature and knowledge of a previous study performed in HepG2 cells (Morgan et al, 2002). HepG2 gene expression data from this study showed high concordance with the investigation of 7 genes, by Morgan et al. Data from both cell lines suggest the 23 genes chosen are capable of differentiating between an oxidant and non oxidant to some extent. In summary, the preliminary data generated, has shown that it may be feasible to differentiate compounds based on a set of genes related to oxidative stress. Also a comparison of the standard TaqMan assay and the TLDA has demonstrated a consistency in data generated and thus the potential to use TLDA in higher throughput molecular screens for toxicology.

215 ANALYSIS OF LIPID ALDEHYDE MODIFICATION OF PEROXIREDOXIN 6 USING MASS SPECTROMETRY.

J. Roede, P. Reigan and D. Petersen. *Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.*

Peroxiredoxins are a class of antioxidant enzyme that possess peroxidase activity. These enzymes are placed into two classes, 1-cys or 2-cys, based on the number of conserved cysteine residues in their active sites. Peroxiredoxin 6 (Prx6) belongs to the 1-cys class (TRENDS in Biochemical Sciences. 28(1): 32-40). This specific peroxiredoxin has been shown to protect the lung from paraquat induced oxidative stress using wild type and Prx6 $-/-$ knockout mice (Journal of Biological Chemistry. 278(27): 25179-25190). Collectively, these reports demonstrate that Prx6 has the ability to protect the cell from oxidative damage by scavenging hydrogen peroxide. Preliminary in vivo data has shown that PRX6 is adducted by 4-hydroxynonenal (4-HNE) in the livers of rats chronically fed an ethanol containing diet; therefore, the goal of this study was to identify specific aldehyde modifications of peroxiredoxin 6 (PRX6) using various mass spectrometry techniques. This analysis was carried out using both matrix-assisted laser desorption/ionization – time of flight mass spectrometry (MALDI-TOF) along with liquid chromatography and tandem mass spectrometry (LC-MS/MS). Molecular modeling technologies were also employed to investigate active site accessibility, solvent accessible residues and changes in conformation due to aldehyde adduction. After incubations with various concentrations of 4-HNE, Prx6 was analyzed for adducts using MALDI-TOF and tryptic peptides were analyzed via MALDI-TOF and LC-MS/MS. Analysis of the intact protein and peptides demonstrated multiple sites of modification, including the active site, Cys47. Also, analysis of solvent accessible residues utilizing the molecular modeling software showed that virtually all lysine residues and Cys47 are accessible to solvent, while the ring structures of the three histidine residues are buried within the globular protein. These observations support previous activity data that demonstrated a concentration-dependent loss of peroxidase activity due to aldehyde adduction and cross-linking.

216 STRESS PATHWAY-BASED REPORTER ASSAYS TO ASSESS TOXICITY OF ENVIRONMENTAL CHEMICALS.

S. O. Simmons¹ and R. Ramabhadran². ¹NTD/NHEERL/CMTB, U.S. EPA, Durham, NC and ²NHEERL/NTD, U.S. EPA, Research Triangle Park, NC.

There is an increasing need for assays for the rapid and efficient assessment of toxicities of large numbers of environmental chemicals. To meet this need, we are developing cell-based reporter assays that measure the activation of key molecular stress pathways. We are using promoter regions from various stress-responsive genes such as heme oxygenase I (HO), heat shock protein 70 (hsp70), and nuclear factor-kappa B, etc. with the ultimate goal of building and characterizing a panel of reporter assays that can be multiplexed within the same cell line for use in high-throughput chemical screening. Our preliminary work towards this goal with the heme oxygenase 1- reporter shows that several toxic compounds can activate HO expression of a in a dose-dependent manner. Cadmium sulfate significantly activated HO expression at a LOAEL concentration of 250 nM, compared to hsp70, which was activated at a LOAEL concentration of 10 uM, indicating the differential sensitivities of these two stress pathways. Less toxic metallic compounds such as copper sulfate did not appreciably affect HO activity at identical concentrations. Additionally, HO expression was induced by a polychlorinated biphenyl (PCB) mixture, Aroclor 1254, at a LOAEL concentration of 10 uM indicating the broad responsiveness of the HO-1 promoter to metal and non-metal stressors. The data

presented will show that in vitro stress reporter assays can discriminate toxic compounds at sub-lethal concentrations, provide a quantitative method to assess cellular toxicity and infer mechanism(s) of toxicity. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy).

217 GENETIC PATHWAY ANALYSIS FOR RISK ASSESSMENT OF EXPOSURE TO OXIDATIVE STRESSORS.

C. N. Giroux, J. Fu and K. Skrzypek. *Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.*

A broad spectrum of drugs and environmental agents exert toxicity by the induction of oxidative stress in target cells. Oxidative stress is also implicated in the etiology of complex diseases such as cancer, diabetes, and the neurodegenerative syndromes. Therefore, the identification of genetic risk factors for susceptibility to oxidative stress and the corresponding development of pathway-targeted drugs represent a key area of focus for mechanism-based strategies in personalized medicine. To support these strategies, we have previously reported development of a high throughput Bioscreen assay to quantify cellular oxidative stress responses in a conserved yeast genetic model. In our Bioscreen assay, a quantitative cell growth / death profile is collected in the presence or absence of a dose series of hydrogen peroxide. Comparison of this Bioscreen stress profile for a wild type yeast strain to those obtained from a whole-genome collection of knockout mutant strains allows us to identify conserved genetic risk factors that confer either susceptibility or resistance to oxidative stressors. To further validate our assay system, we demonstrate that genetic ablation of either of the two major anti-oxidant defense pathways, glutathione or the peroxiredoxin family, results in hypersensitivity to low doses of hydrogen peroxide. Hydrogen peroxide induces apoptotic cell death in mammalian systems. We similarly observe that ablation of either of the conserved caspase "executioner" or the AIF death signaling pathways confers resistance to the hydrogen peroxide-induced apoptotic death response in the Bioscreen assay. In contrast, we observe that ablation of the autophagy / lysosomal stress response confers sensitivity to hydrogen peroxide. Significantly, we report for the first time that ablation of the yeast ortholog of the human beclin1 tumor suppressor / autophagy gene also sensitizes a cell to oxidative stress. In conclusion, our Bioscreen assay allows the separation and quantitative evaluation of the individual component pathways that mediate oxidative stress-induced toxicity.

218 α -SYNUCLEIN INTERACTS WITH VMAT2 TO REGULATE VMAT2 ACTIVITY.

E. D. Dean^{1,2}, G. E. Torres³ and G. W. Miller^{1,2}. ¹Center for Neurodegenerative Disease, Emory University, Atlanta, GA, ²Department of Environmental and Occupational Health, Emory University, Atlanta, GA and ³Department of Neurobiology, University of Pittsburgh School of Medicine, Pittsburgh, PA.

Mutations in α -synuclein (ASYN) are associated with familial forms of Parkinson Disease (PD). Although ASYN is expressed throughout the brain, dopaminergic neurons are preferentially affected in PD. This may be due to the ability of dopamine (DA) to readily oxidize in the cytosolic environment. Oxidized DA is believed to stabilize a toxic protofibril aggregate form of ASYN. Therefore, DA neurons' ability to prevent protofibril-induced toxicity may rely on the ability to protect DA from oxidation. The vesicular monoamine transporter 2 (VMAT2) is responsible for the transport of cytosolic DA into synaptic vesicles for sequestration and subsequent release at synaptic terminals. Since the storage of DA also protects DA from the oxidative environment of the cytosol, factors responsible for the maintenance of normal VMAT2 activity may be necessary to protect dopaminergic neurons from cell death. In order to understand how ASYN promotes dopaminergic cell death, we must first understand ASYN's cellular function. One possible role for ASYN in dopaminergic neurons is the maintenance of DA homeostasis. Recently, we have identified an interaction between ASYN and the C-terminus of VMAT2 by yeast two-hybrid assay. We also show that this interaction leads to functional changes in VMAT2 activity in transiently transfected SHSY5Y cells. Coexpression of VMAT2 and either human wild-type or the disease-associated mutant A53T ASYN increases tetraabenazine sensitive-VMAT2 sequestration of 3H-DA in cell lysates by 33% and 77%, respectively as compared to empty vector control and VMAT2 cotransfected cells. These data suggest that one function of ASYN may be to maintain proper storage of DA via regulation of VMAT2.

219 4-HYDROXYNONENAL COVALENTLY MODIFIES TUBULIN AND INHIBITS MICROTUBULE ASSEMBLY.

B. Stewart and D. Petersen. *University of Colorado Health Sciences Center, Denver, CO.*

Chronic ethanol consumption causes oxidative stress and lipid peroxidation in the liver, which is associated with the accumulation of lipid droplets in hepatocytes, a condition known as steatosis. The mechanisms by which steatosis occurs remain

elusive. Intact microtubules are critical to a number of cellular transport processes, including the secretion of triglycerides as VLDL particles. Disruption of the microtubule cytoskeleton in hepatocytes could contribute to steatosis by reducing the secretion of triglycerides. Our in vitro experiments show that the lipid peroxidation product 4-hydroxynonenal (4-HNE) inhibits polymerization of purified tubulin in a dose-dependent manner. The inhibitory effect of 4-HNE on tubulin polymerization is greater than the effect of acetaldehyde, the proximate metabolite of ethanol, but less than the effect of the cysteine-specific modifier N-ethylmaleimide (NEM). Immunoblotting experiments have shown that 4-HNE Michael adducts can form on intact microtubules as well as on the tubulin heterodimer. Treatment of tubulin dimers with 4-HNE in vitro causes the formation of high molecular weight cross-links. 4-HNE does not induce depolymerization of microtubules, whereas cysteine specific modification of tubulin results in a modest degree of depolymerization. The microtubule binding and ATP hydrolysis of the anterograde motor protein kinesin to taxol-stabilized microtubules is not affected by 4-HNE. Mass spectrometry data indicate that 4-HNE adducts of tubulin occur on cysteine residues, as well as on other nucleophilic amino acids, suggesting cysteine-lysine cross-links between alpha and beta tubulin subunits. Because microtubules are dynamic structures in the cell, impairment of polymerization by 4-HNE may reduce microtubule-based lipid transport, and could contribute significantly to the accumulation of lipid droplets observed in alcoholic livers.

220 CO INTERACTS WITH CYTOCHROME C/CARDIOLIPIN COMPLEXES AND INHIBITS THEIR PEROXIDASE ACTIVITY: A POSSIBLE PROTECTIVE ROLE IN APOPTOSIS.

S. W. Ryter², I. I. Vlasova¹, A. M. Choi², B. R. Pitt¹ and V. E. Kagan¹. ¹Center for Free Radical and Antioxidant Health, EOH, University of Pittsburgh, Pittsburgh, PA and ²Department of Medicine, Division of Pulmonary, Allergy and Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA.

CO has been shown to protect cells against apoptosis in vivo and in vitro through yet to be identified pathways. A number of biological effects of CO are associated with its binding hemo-proteins including the reduced cytochrome c oxidase in mitochondria. Cytochrome c (cyt c) is another abundant heme-containing protein of the inter-membrane space of mitochondria. The hexa-coordinate organization of heme-iron effectively accommodates electron-transporting function of cyt c, however, hinders its binding and chemical interaction with small molecules thus precluding its peroxidase activity. Recently, we demonstrated that interaction of cyt c with a mitochondria-specific phospholipid, cardiolipin (CL), induced protein unfolding accompanied by an exchange and loss of axial ligands of heme iron resulting in an increased accessibility for H₂O₂ and appearance of the peroxidase activity. The latter caused selective CL oxidation during apoptosis. Using optical spectroscopy and measurements of tryptophan fluorescence we now demonstrate CO binding with ferrous heme in cyt c/CL complexes. In triple CL/cyt c/CO complexes, the heme is likely less accessible for the interaction with H₂O₂ or lipid hydroperoxides as evidenced by EPR-detectable delayed and inhibited oxidation of ascorbate and etoposide. We speculate that CO contributes to regulation of the peroxidase activity of cyt c/CL in mitochondria, particularly during apoptosis-associated oxidative stress. Supported by NIH HL070807.

221 GAMMA-GLUTAMYL-CYSTEINE SYNTHETASE OPTIMIZATION AND USE IN WILDLIFE CHEMICAL EFFECTS ASSESSMENTS.

H. Wu¹, T. J. McBride¹, J. P. Isanhardt¹, T. J. Kavanagh² and M. J. Hooper¹. ¹The Institute of Environmental Health, Texas Tech University, Lubbock, TX and ²Department of Environmental Health, University of Washington, Seattle, WA.

Gamma-Glutamylcysteine synthetase (GCS), catalyzes the binding of glutamate and cysteine, the first and rate-limiting step of glutathione (GSH) biosynthesis. In this study, tissues from Sprague Dawley rats, deer mice and mallard ducks were used to characterize GCS activity and responsiveness to chemical exposure. Varying glutamic acid concentrations from 5mM to 80mM did not affect the GCS activities, whereas cysteine concentrations from 2.5mM to 40mM influenced GCS activities substantially. The optimal cysteine concentrations for GCS activities were tissue and species dependent. Generally, the maximum and linear range of hepatic GCS activities of each species was obtained between 10- and 30- fold dilution. The reaction rates of GCS decreased with longer time with an optimum reaction period of 30 minutes. Intra-assay variation of GCS activity demonstrated coefficients of variation ranging from 5.0% to 8.0%. Deer mice GCS activities differed among tissues with the highest activity in liver, followed by kidney, brain and heart sequentially. Carbon tetrachloride decreased both hepatic total GSH concentration and GCS activity. In kidney, however, GCS activities were induced with increased GSH (reduced form). Mixed-metal-dosed deer mice had increased GSH forms. Duck studies with mixed-metals will also be described.

222 IRON-CATALYZED OXIDATIONS OF TRYPTOPHAN RESIDUES IN W-E SEQUENCES OF APOB-100 IN LOW DENSITY LIPOPROTEINS.

C. V. Smith¹, H. Chen², C. Chen³, L. Chow⁴, H. Chu³, Y. Lee³ and C. Yang². ¹Center for Developmental Pharmacology and Toxicology, Children's Hospital & Regional Medical Center, Seattle, WA, ²Medicine, Baylor College of Medicine, Houston, TX, ³Medicine, National Taiwan University Hospital, Taipei, Taiwan and ⁴Biochemistry and Molecular Biology, National Taiwan University, Taipei, Taiwan.

To test the hypothesis that iron-catalyzed oxidations of LDL in vitro produce diagnostic biomarkers of oxidation of the apoprotein that could be applied to studies of LDL oxidation in vivo, LDL were oxidized in 200 μM Fe+2, 60 μM EDTA, 5 mM ascorbic acid at 37°C for up to 40 h. Following delipidation and trypsin digestion, the peptides were separated by HPLC, with four peaks detected at 365 nm, whereas none were observed in peptides from unoxidized LDL. Treatment of Fe-oxidized LDL with 2,4-dinitrophenylhydrazine prior to trypsinization and HPLC did not yield peptides detected at A365 nm. The peptides were purified by three consecutive buffer systems (ammonium acetate, phosphate, and 0.1% TFA). The four peptides were identified by MALDI-Q-TOF, as YH(W+4)EHTGLTLR (AA: 4061-4071), IYSL(W+4)EHSTK (AA:3532-3541), IVQILP(W+4)EQNEQVK (AA: 550-563), and FEGLQE(W+4)EGK (AA: 3937-3946), respectively, with (W+4) signifying (W plus 4 Da) in place of the W residues in the unoxidized protein. The mass gains and the absorbances at 365 nm indicate kynurenines, which were found in trypsin-releasable peptides that are thought to be motifs exposed on the surface of LDL particles. All four peptides thus characterized also share the sequence of WE, with glutamate residues immediately C-terminal to W. Of the 4 peptides identified in the present studies with Fe, 2 were among the 9 characterized in our previous studies with Cu oxidation. The results demonstrate marked differences in products from different methods of LDL oxidation in vitro and suggest potential biomarkers of iron-mediated oxidation for studies in vivo. The preferential oxidation of W residues in WE sequences suggest contributions from the C-proximate glutamate residues in chelation of the iron species, thereby influencing site selectivities of oxidation.

223 TYROSINE NITRATION AND OXIDATION OF MNSOD: COMPETITION AND TOXICOLOGICAL CONSEQUENCES.

R. Rafikov, Z. Huang, A. Glumac, H. Bayir and V. E. Kagan. Center for Free Radical and Antioxidant Health, Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.

Mitochondria are the major source of superoxide radicals and other reactive oxygen species produced mostly by components of disrupted respiratory chains. Extremely high reactivity of superoxide with NO and resulting production of a potent and toxic oxidant, peroxynitrite are prevented by MnSOD, a unique enzyme of the mitochondrial matrix. Sufficiency of catalytically competent MnSOD is essential for integrity of mitochondria and cell survival. However, nitration of catalytically important tyrosine residues leads to inactivation of the enzyme. Tyrosine residues in MnSOD may also be involved in the formation of intra- or inter-molecular di-tyrosine crosslinks leading to protein oligomerization whose ability to support enzymatic activity is not well characterized. Using recombinant protein, rat brain and liver mitochondria as well as HL-60 cells we found that nitration and dimerization of tyrosine residues represent two competing pathways of stress-mediated modification of MnSOD. Oxidative stress mediated di-tyrosine formation induces covalent oligomerization of MnSOD which does not substantially affect its catalytic activity. Moreover, the oligomerized enzymatic complexes are resistant to unfolding and protein degradation. In contrast, nitration of tyrosines leads to loss of dismutase activity, protein unfolding, and confers a new catalytic quality on the enzyme, a peroxidase activity. Further, nitration prevents di-tyrosine formation and thus oligomerization of MnSOD. These results are discussed in the context of tetrameric organization and interactions of 36 tyrosine residues in catalytically active hMnSOD with emphasis on crystallographic data indicating that Tyr45 and Tyr166 are within contact distances with respective Tyr45 and Tyr166 of adjacent subunits of MnSOD.

This work was supported by NIH U19 AI068021 and AHA 0535365N.

224 THE EFFECTS OF NITRATION USING PEROXYNITRITE ON PROTEIN FUNCTION AND DEGRADATION.

T. V. Curry-McCoy¹, E. Bendlin¹ and T. M. Donohue^{1,2}. ¹Pathology/Microbiology, University of Nebraska Medical Center, Omaha, NE and ²U.S. Department of Veterans Affairs Medical Center, Omaha, NE.

Ethanol induces oxidative stress in the liver, which can negatively impact cell function and bring about hepatic injury. Ethanol metabolism increases mitochondrial release of superoxide, which reacts with nitric oxide to form peroxynitrite.

Peroxynitrite can injure the cell by its ability to react with proteins and alter structure, which could disable proteins from performing their function and alter their susceptibility to degradation. In order to determine whether protein nitration enhances or inhibits a protein's ability to undergo degradation, we performed *in vitro* experiments to determine whether nitration of proteins with peroxynitrite affects their susceptibility to degradation by the proteasome, an important cellular protease, which regulates protein homeostasis. Preparations of both highly purified lysozyme, and HepG2 cell lysate, which was radiolabeled with $[3H]$ leucine, were nitrated to varying degrees. Nitration was performed by increasing the molar ratio of peroxynitrite to lysozyme and radiolabeled proteins 0, 1, 2, 4, 8, 16 times. Proteolytic susceptibility was measured by incubating nitrated lysozyme or radiolabeled proteins with either trypsin, pronase, or purified rat liver proteasome. As nitration of lysozyme increased, its catalytic activity decreased by three-fold at 16x peroxynitrite. The, proteolytic susceptibility of lysozyme to degradation by the proteasome generally increased by as much as three-fold as nitration of lysozyme increased. Although some nitrated radiolabeled cellular proteins showed a two-fold increase in proteolytic susceptibility by the proteasome compared with its un-nitrated control, the results were not always related to the degree of nitration. We conclude that peroxynitrite altered the structure of lysozyme and those of radiolabeled cellular proteins by the formation of nitrotyrosine adducts, which decreased the ability of nitrated proteins to function properly and generally enhanced their susceptibility to degradation by the proteasome.

225 INHIBITION OF NADPH OXIDASE ACTIVITY SUPPRESSES GROWTH AND PROMOTES DIFFERENTIATION OF B16 MELANOMA CELLS.

Y. Zhao¹, D. K. St. Clair², J. Liu¹ and K. E. McMartin¹. ¹Pharmacology, LSU Health Science Center, Shreveport, LA and ²Toxicology, University of Kentucky, Lexington, KY.

Oxidative stress has been recognized as a mediator for cell proliferation and implicated in playing an important role in cancer development. Oxidative stress is accompanied by overproduction of reactive oxygen species. The activity of DADPH oxidase, an enzyme capable of generating superoxide radicals, is increased in malignant skin keratinocytes after a tumor promoter treatment. Herein we demonstrated that inhibition of DADPH oxidase activity by diphenyleneiodonium (DPI) suppressed free radical production, inhibited cell growth while promoted cell differentiation of B16 melanoma cells as indicated by cell morphology and increased production of melanin. Biochemical studies revealed that pERK expression was induced whereas PKC α expression was reduced by DPI treatment, suggesting ERK and PKC α may play opposite roles in the event. In addition, the protein levels of tumor suppressor p53 were suppressed by DPI, suggesting that p53 is activated by oxidative stress and it may negatively regulate differentiation in melanoma cells. Taken together, these results suggest three folds of the effects of inhibiting NADPH oxidase activity in melanoma cells: halting cell proliferation, promoting cell differentiation, and suppressing the tumor suppressor p53.

226 DESIGN, SYNTHESIS AND APPLICATION OF A HYDRAZIDE-FUNCTIONALIZED ISOTOPE-CODED AFFINITY TAG (HICAT) FOR THE IDENTIFICATION AND QUANTIFICATION OF OXYLIPID PROTEIN CONJUGATES.

B. Han¹, F. Stevens² and C. S. Maier¹. ¹Chemistry, Oregon State University, Corvallis, OR and ²College of Pharmacy, Oregon State University, Corvallis, OR. Sponsor: W. Chung.

Reactive oxygen species (ROS) chemically modify a variety of biological molecules, including polyunsaturated acyl chains of membrane phospholipids to generate a variety of α , β -unsaturated acyl aldehydic intermediates, such as keto aldehydes, 2-alkenals, and 4-hydroxy-2-alkenals. Especially, 4-hydroxy-2-alkenals such as 4-hydroxy-2-nonenal (HNE) and 4-hydroxy-2-hexenal (HHE) are prominent aldehydes generated during peroxidation. HNE has a high stability and reactivity, and is largely responsible for many types of cellular damage associated with oxidative stress. HNE-induced modification was found to occur mainly on histidine, cysteine, and lysine residues via a Michael addition preserving the aldehyde functionality on the targeted protein, rather than by Schiff's base formation. Therefore, the purpose of this study was to develop an analytical method which can assist us to identify and quantify the oxylipid-damaged mitochondrial proteins on a proteome-wide scale. In this study, we are developing a mass spectrometry-based quantitative proteomics approach using hydrazide-functionalized isotope-coded affinity tag. We designed the isotopomers, $^{12}C_6$ -HICAT and $^{13}C_6$ -HICAT, as the 'light' and the 'heavy' labeling reagents. To demonstrate the feasibility of using the HICAT probes to selectively target and potentially quantify carbonylated proteins, we de-

scribe the modification of thioredoxin (Trx) with HNE, followed by $^{12}C_6$ and $^{13}C_6$ -HICAT labeling and the selective affinity enrichment from tryptic digests of HNE-conjugated Trx. The HICAT-labeled peptides were identified and quantified by MALDI tandem mass spectrometry. Successful results also have been obtained from *in vitro* treated HNE mitochondrial adducts, showing the potential of HICAT as a new tool in proteome wide screens for identifying and quantifying LPO-modified proteins.

227 CHARACTERIZATION OF RAT ALANINE AMINOTRANSFERASE ISOENZYMES ALT1 AND ALT 2.

R. Goldstein¹, R. Yang², W. J. Reagan¹, D. Nettleton¹, F. Rajamohan¹, M. Lawton¹, L. Nelms¹, S. Park² and D. Gong². ¹DSRD-Investigative Toxicology, Pfizer, Groton, CT and ²University of Maryland, Baltimore, MD.

ALT has been used as an indicator of hepatocellular damage and is an important enzyme involved in gluconeogenesis and amino acid metabolism and thus may be an indicator of metabolic adaptation and not just hepatocellular damage. The purpose of this study was to clone and sequence rat ALT 1 and 2 (rALT1 and rALT2) genes as well as to produce and characterize recombinant ALT proteins to better understand their role in metabolic processes. Full length rALT1 cDNA was amplified by PCR from a liver cDNA library and rALT2 was obtained from IMAGE clone 7113147 of the Mammalian Genome Collection. ALT isoenzymes are well conserved between rodents in that rALT1 and rALT2 share 97% and 98% homology at the amino acid level with their murine counterparts. The amino-terminus of ALT2 peptide is 28-amino acids longer than ALT1 which represents a putative mitochondrial targeting signal sequence. Northern analysis of normal Sprague-Dawley rat tissues showed ALT1 mRNA was highly expressed in liver, colon and moderate levels in small intestine, brown fat, heart and skeletal muscle. ALT2 mRNA was expressed in high levels in skeletal muscle and liver and moderate levels in brain. Recombinant ALT1 and ALT2 enzymes were expressed and purified from SF9 insect cells as His-tag fusion proteins using nickel affinity chromatography, followed by the removal of His tag for functional analysis. rALT1 and rALT2 had molecular masses of 56,613 and 58,507 Da respectively. The Km values for rALT1 with the substrates L-alanine and 2-oxoglutarate were: 48 mM and 11.3mM respectively with a Vmax of 10.5 μ mol/min per mg protein. The Km values for rALT2 with the substrates L-alanine and 2-oxoglutarate were: 13.3 mM and 54.1 mM, respectively with a Vmax of 7.2 μ mol/min per mg protein. Functional and mass based assays are in development to measure these isoenzymes in tissues and blood and will lead to a more effective use of these markers in safety risk assessment.

228 INHIBITION OF THE EPIDERMAL PERIPHERAL NEUROPATHY BIOMARKER PGP9.5 IN DIFFERENTIATED PC12 NEURONAL CELLS BY PROTEASOME INHIBITION.

V. Csizmadia¹, A. Raczynski¹, J. Pradines³, K. Tsui², S. Badola², E. Csizmadia¹, E. Fedyk¹, S. Coleman¹, S. Barros¹, R. DeCoster⁴, V. J. Kadambi¹ and C. L. Alden¹. ¹Drug Safety and Disposition, Millennium Pharmaceuticals, Inc., Cambridge, MA, ²Expression Profiling, Millennium Pharmaceuticals, Inc., Cambridge, MA, ³Computational Sciences, Millennium Pharmaceuticals, Inc., Cambridge, MA and ⁴Global Preclinical Development Oncology, Johnson and Johnson Pharmaceutical Research and Development, Beerse, Belgium.

Anti cancer therapy is a common cause of peripheral neuropathy in the clinic. pgp 9.5 immunohistochemistry on epidermal biopsies represents an important tool in peripheral neuropathy diagnosis in patients. pgp 9.5 is an ubiquitin protein ligase/hydrolase representing about 2% of the total protein in neuronal cells and is used as a marker for quantifying free nerve endings in epidermal tissues during neuropathy assessment in patients. In a gene expression study using differentiated PC12 neuronal cells an experimental proteasome inhibitor (EPI) down regulated the UCHL1 gene coding for pgp9.5 protein in a concentration dependent manner without affecting protein levels. However, proteasome inhibition resulted in the appearance of ladder-type pattern in Western blots, indicating post-translational modifications of pgp9.5 (ubiquitination). This observation prompted us to analyze the intracellular localization of pgp9.5 in cultured rat dorsal root ganglion. Following proteasome inhibition in this system, pgp9.5 translocated and accumulated in the perinuclear areas resulting in weakened signals in the neurites. In conclusion, EPI induced down regulation of pgp9.5 gene expression, had no effect on total protein, but induced changes in pgp9.5 intracellular localisation. These findings indicate a potential complexity factor of intraepidermal free nerve ending quantification. Thus, in parallel with intraepidermal free nerve end counting for proteasome inhibitor-induced peripheral neuropathy an assessment of the direct effect on pgp9.5 gene and protein expression should be included.

229

COMPARISON OF COMMERCIAL CARDIAC TROPONIN (CTN) ASSAYS FOR EVALUATION OF MYOCARDIAL INJURY IN THE LABORATORY RAT, DOG AND CYNOMOLGUS & RHESUS MONKEY, AND KINETIC PROPERTIES OF SERUM CTN IN RATS WITH ACUTE CARDIOTOXICITY.

S. Pettit¹, M. York², D. B. Walker³, F. Apple⁴, E. Herman⁵, S. Brady⁶, J. Turton⁶, B. Berridge⁷, R. Nicklaus⁸, P. Clements² and I. Mikaelian⁸. ¹HESI Biomarkers Committee, Cardiac Troponins Expert Working Group, Washington, DC, ²GlaxoSmithKline, Ware, United Kingdom, ³Bristol-Myers Squibb, Syracuse, NY, ⁴Hennepin Co Med. Ctr, Minneapolis, MN, ⁵CDER-FDA, Rockville, MD, ⁶School of Pharmacy, London, United Kingdom, ⁷GlaxoSmithKline, Research Triangle Park, NC and ⁸Hoffman-La Roche, Nutley, NJ.

Cardiac troponins have valuable utility as biomarkers that bridge monitoring for myocardial injury in laboratory animals to humans. The HESI Troponins Expert Working Group sponsored studies to advance the analytical qualification of assays for, and biological characterization of serum cTn in animals. In these studies, commercial assays (n=9) were compared for cross-reactivity, linearity, precision and lower limits of detection for measurement of serum cTn I and T in common laboratory species. In addition, in vivo time-course evaluation of serum cTn in rats administered an acutely cardiotoxic dose of isoproterenol (0.1 or 4 mg/kg SC) was compared with concurrent cardiac histopathology. Results of the analytical study showed inherent differences among assays in cross-reactivity, precision and dynamic range with cTn-positive serum from the test species. Results also indicated that some assays were suboptimal for measurement of serum cTn in select species. In the in vivo study, good correlation in kinetics of serum cTn I and T in the animals occurred with 3 different assays, although sensitivity and dynamic range varied. Increases in serum cTn occurred coincident with early histologic changes of myofiber injury at 0.5 hrs post dose; however, more progressive histologic changes were seen at later intervals (24-48 hrs) when cTn values were in decline. Sensitivity of cTn over traditional serum markers of myocardial injury was also shown in this model. These results support the need for adequate qualification of each cTn assay for each species, and further define the utility of cTn as a cardiac injury biomarker.

230

DRAMATIC REDUCTION OF GLUCOCORTICOID RECEPTOR EXPRESSION IN RAT AND HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC) TREATED WITH THE HEAT SHOCK PROTEIN (HSP)90 INHIBITOR 17-DIMETHYLAMINOETHYLAMINO-17-DEMETHOXYGELDANAMYCIN (17-DMAG) *IN VITRO*.

D. Zhou, S. Qin, X. Zhang, L. Li, J. Ye, X. Zhang, W. Ying and J. Barsoum. Biology, Synta Pharmaceuticals Corp., Lexington, MA. Sponsor: E. Kitayama.

Hsp90 is an important chaperone protein that regulates the folding of key signaling proteins and maintains their function. One of the Hsp90 client proteins is the glucocorticoid receptor (GR) that plays multiple critical roles in development, glucose homeostasis, metabolism, proliferation, and anti-inflammatory responses. Although inhibition of Hsp90 promotes degradation of its multiple oncogenic client proteins and demonstrates anti-tumor activity, the effects of inhibition of Hsp90 on GR expression in normal cells have not been fully investigated. In this study, we evaluated the expression of GR in rat and human PBMCs after treatment with the Hsp90 inhibitor, 17-DMAG, in vitro. The fresh isolated rat and human PBMCs were treated with 17-DMAG at 0, 1, 5, 25, and 100 nM for 2 or 16 hours. Immunoblot analysis was performed to measure and compare the levels of the GR protein expression. We found that 17-DMAG caused a dose-dependent decline in GR expression when compared with the vehicle after normalization to gapdh levels in both rat and human PBMCs. There were 3- and 6-fold reductions in rat PBMCs 16 hours after the treatment at 25 nM and 100 nM, respectively. However, GR protein expression was not significantly affected after a 2-hour treatment. In human PBMCs, GR protein levels were decreased 2-fold after a 16-hour treatment at 25 nM, and further reduced 5-fold at 100 nM. In both rat and human PBMCs, 17-DMAG only affected the GR α , not β , isoform. In conclusion, our data show a dose- and time-dependent degradation of GRs in both rat and human PBMCs after the treatment with 17-DMAG. The changes could impact GR function in tumor and normal cells. The results suggest that the GR α isoform, one of the Hsp90 client proteins affected by 17-DMAG, could be used as a biomarker to monitor the activities or toxicities of Hsp90 inhibition.

231

FAT-SOLUBLE VITAMIN ANALYSES BY LC/MS IN THE TISSUES OF RATS AND DOGS.

K. Navetta, P. Quintas and J. Colangelo. Drug Safety Research and Development, Pfizer, Groton, CT. Sponsor: M. Aleo.

Fat-soluble vitamins are lipophilic molecules stored in liver and fatty tissue. Depletion of fat-soluble vitamins has been observed during weight loss, use of some drug therapies, or with specific diseases and clinically results in conditions such as

coagulopathy, decreased infection resistance, and peripheral neuropathy. During the drug development process, information concerning fat-soluble vitamin levels has become increasingly valuable for understanding the potential involvement of changes in vitamin levels and toxicity. An assay to measure vitamins A, D, E and K in rat and dog tissues has been developed. Extraction of the fat-soluble vitamins from the tissue was performed by combining ~ 10 mg of tissue, hexane, and internal standard with subsequent processing on the Fastprep bench top homogenizer. The analytes of interest were separated from matrix components on a Gemini C18 (2.0 x 50 mm) HPLC column with isocratic elution and a total runtime of 5 minutes. The vitamins were detected on a triple quadrupole mass spectrometer coupled with atmospheric pressure photoionization. The linear range for all four vitamins was 1 to 500 ng vitamin/mg wet tissue. Inter- and intra-assay precision was within 22 % and 20 %, respectively, for all of the vitamins. The assay was applied to measure fat soluble vitamins in dog and rat peripheral nerve and adipose tissue. The combination of the Fastprep homogenization system with the hexane extraction increased sample throughput (5-fold) and decreased sample preparation time (4-fold) over assays previously used for vitamin tissue analyses.

232

VALIDATION OF THREE ENZYME-LINKED IMMUNOSORBENT ASSAYS FOR THE QUANTITATIVE DETERMINATION OF TOTAL IGG, IGM AND IGE ANTIBODIES IN CYNOMOLGUS MONKEY SERUM.

S. Lavallee, C. Gelinas, T. Ragavan, N. Rouleau, M. Oetelaar, F. Bouzar, A. St-Pierre and L. LeSautour. Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.

The validation of three enzyme-linked immunosorbent assays (ELISA) for the quantitative determination of Total IgG, IgM and IgE antibodies in Cynomolgus monkey serum was performed in order to monitor the Cynomolgus monkey total immunoglobulin concentration during the course of toxicology studies. Validation parameters included selectivity, intra- and inter-batch precision and accuracy, prozone effect, parallelism and stability. The validated concentration range for all three methods is from 3.91 ng/mL to 200.00 ng/mL. The methods were successful at detecting IgG, IgM and IgE antibodies when spiked in ten different lots of diluted Cynomolgus monkey serum at concentrations between QC1 and QC2 while taking the endogenous concentrations of IgG, IgM or IgE into account. The intra and inter precision and accuracy met the acceptance criteria. No assay deficiency was detected when samples spiked at a high concentration of IgG, IgM or IgE antibodies were analyzed. The parallelism between the standard curve and an ex-vivo sample was demonstrated for sample dilutions of up to 1/320000 and 1/128000 for the IgG and IgM methods respectively. Parallelism could not be assessed for IgE since no Cynomolgus monkey serum sample with a suitably high concentration of IgE was available. IgG, IgM and IgE antibodies in Cynomolgus monkey serum samples were shown to be stable at room temperature for approximately 6 hours, at approximately 4°C for approximately 24 hours and after 4 freeze-thaw cycles at approximately -80°C. IgG, IgM and IgE antibodies in Cynomolgus monkey serum samples were shown to be stable when stored for up to 124, 102 and 160 days respectively, at approximately -80°C. The quantitation of Total IgG, IgM and IgE antibodies using these validated ELISA methods will be valuable endpoints for toxicology studies.

233

COMPETITIVE ELISA FOR FATTY ACID ETHYL ESTERS AS BIOLOGICAL MARKERS FOR THE DIAGNOSIS OF FETAL ALCOHOL SYNDROME.

H. Kim^{1,2}, E. S. Roberts-Kirchhoff^{1,3}, J. Chun¹, V. Hornik-Rosinski³, B. Jiang¹ and Y. Yuan¹. ¹Detroit R&D, Inc., Detroit, MI, ²Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and ³Department of Chemistry and Biochemistry, University of Detroit Mercy, Detroit, MI.

Fetal alcohol syndrome (FAS) is a serious disease that can affect children born to mothers who have consumed alcohol during their pregnancy and is best treated with early diagnosis. One of the consequences to children with this disorder is that they have altered fatty acid metabolism. 13-Hydroxyoctadeca-9,11-dienoic acid (13-HODE), a metabolite of linoleic acid, was converted to an ethyl ester with lipase from *Candida antarctica* and ethanol. The ethyl ester was converted to a succinate derivative via its C13 hydroxyl group in the presence of succinic anhydride. Identification of the ethyl ester of 13-HODE and the succinate derivative was achieved with gas chromatography/mass spectrometry of the trimethylsilyl derivatives. The succinate product was conjugated to keyhole limpet hemocyanin (KLH) and bovine serum albumin (BSA). The KLH conjugate was then used to immunize a goat. IgG was isolated from the KLH-immunized goat serum and used in im-

munoassays with the BSA-conjugate. Western blot analysis revealed that, whereas the IgG did not bind to BSA, the IgG strongly bound to BSA conjugated with ethanol-esterified 13-HODE. A competitive ELISA using a plate coated with the IgG was carried out with various concentrations of BSA conjugated with ethanol-esterified 13-HODE and horseradish peroxidase (HRP) conjugated with ethanol-esterified 13-HODE. A negative control for this ELISA was BSA without conjugated ethanol-esterified 13-HODE. Whereas BSA did not compete for its binding to the IgG with HRP conjugated with ethanol-esterified 13-HODE, BSA conjugated with ethanol-esterified 13-HODE competed with the HRP conjugate in a dose-dependent manner. This result demonstrated that the IgG recognized the ethanol-conjugated fatty acids in Western blot analysis and competitive ELISA. (Supported by NIAAA SBIR Phase I R43 AA014535).

234 A POTENTIAL BIOMARKER FOR DEOXYNIVALENOL INTOXICATION AND EXPOSURE: PLASMA HAPTOGLOBIN.

J. Cho, S. Jeong, E. Kim, H. Ku, H. Pyo, H. Kang and Y. Jean. *Toxicology & Chemistry Division, National Veterinary Research & Quarantine Service, Anyang, KyungGi, South Korea.*

Deoxynivalenol (DON) is a foodborne mycotoxin contaminated in cereal crops such as wheat, barley, oats and etc. DON induces systemic health problems and reduces immune functions in both human and farm animals but there have not been convincing markers for diagnosis or exposure assessment until now. The present study was aimed to find out sensitive biomarkers for the determination of DON intoxication and exposure. B6C3F1 male mice, 8 weeks old, were exposed orally with 0.83, 2.5 and 7.5 mg/kg bw DON for 8 days and plasma was collected at the day of sacrifice. Protein expression patterns were examined using SELDI-TOF (Surface Enhanced Laser Desorption/Ionization) Mass Spectrometer. 9.7 kDa copper immobilized protein and 11.7 kDa hydrophobic protein were significantly increased and 17.4 kDa weak cationic protein was decreased by DON with dose-dependent manner. Among those proteins, 11.7 kDa hydrophobic plasma protein captured on H50 chip was expressed the most sensitively. This protein was purified by the methyl ceramic Hyper D F column optimized with 1M ammonium sulfate, 50mM sodium phosphate pH 7.0 for adsorption and with 50mM sodium phosphate pH 7.0 for desorption. The purified 11.7 kDa protein was identified as haptoglobin precursor by peptide mapping using LC/Q-TOF and MALDI-TOF and confirmed by western blotting and ELISA.

To confirm the specificity of haptoglobin as a biomarker for DON intoxication or exposure, we measured the amount of haptoglobin in plasma of rat orally administered with other mycotoxins (Aflatoxin 1.0 mg/kg bw, and Zearalenone 240 mg/kg bw for 8days) using ELISA. Haptoglobin was increased only by DON 7.5 mg/kg bw while decreased by Zearalenone 240 mg/kg bw compared to control and not detected by Aflatoxin 1.0 mg/kg bw.

These results show that plasma haptoglobin could be a potential biomarker for DON exposure and intoxication.

235 BIOMARKER LEVELS IN FEMALE F-344 RAT TISSUES AFTER 28-DAY ORAL TREATMENT WITH SR16157.

L. Rausch¹, P. Catz¹, S. LeValley¹, L. Dousman¹, K. L. Steinmetz¹, C. E. Green¹, J. Tomaszewski², K. Schweikart², N. Zaveri¹ and J. C. Mirsalis¹.
¹Toxicology, SRI International, Menlo Park, CA and ²National Cancer Institute, Bethesda, MD.

SR16157 is a potent novel dual-acting breast cancer therapy agent that inhibits both estrogen biosynthesis directly and the estrogen receptor by its metabolite, SR16137. In a GLP toxicity study, rats received SR16157 by daily gavage for 28 days at 10, 33 or 100 mpk (150, 300, 600 mg/m²) with 14 days recovery. Blood was collected to determine plasma drug levels of SR16157 and SR16137, the metabolite released after SR16157 binds to estrone sulfatase (ES). Liver and uterus were flash frozen at necropsy and evaluated for estrone, estradiol, and estrone sulfate levels, and ES activity (liver only). Mortality was observed at 100 mpk by Day 12. ES activity in the liver was completely inhibited after 28 days at 10 and 33 mpk/d SR16157, or after 14 days of 100 mpk/d SR16157. At recovery, ES activity was 23%, 7%, and 4% of control at 10, 33, and 100 mg/kg, respectively. Estrone, estrone sulfate, and estradiol levels in the liver and uterus were unremarkable from controls and do not appear to be reliable biomarkers of SR16157 activity. Repeated administration resulted in increased exposure to SR16157, based on AUC and C_{max}, suggesting accumulation. SR16137 was also detected in plasma and its AUC was ~2-4% of SR16157 AUC. Histopathology findings included changes in liver (fatty changes in all treated groups; hyperplasia at 100 mpk/d), kidney nephrosis, atrophy in thymus and reproductive organs, and lymphoid depletion; cholesterol

and triglyceride changes were likely due to marked changes in body weight and food consumption of treated animals. In conclusion, daily oral gavage administration of SR16157 for 28 days in female F-344 rats was associated with dose-related changes in body weight, food consumption, clinical observations, clinical chemistry parameters, toxicokinetics, and histology. ES inhibition is a very sensitive indicator of the pharmacologic action of SR16157. Work supported by NCI Contract N01-CM-42203.

236 IDENTIFICATION OF PROBABLE BIOMARKERS FOR PHOSPHODIESTERASE INHIBITOR INDUCED VASCULAR INJURY USING TOXICOGENOMICS.

Y. Gu¹, E. Wang¹, R. J. Smith¹, K. Keane², B. S. McIntyre², N. Collins² and R. D. Snyder¹. ¹Molecular and Genetic Toxicology, Schering-Plough, Summit, NJ and ²Drug Safety, Schering-Plough Research Institute, Summit, NJ.

Phosphodiesterase inhibitors are used for erectile dysfunction (ED) and have the potential for other clinical indications such as asthma and COPD. Vascular injury induced by phosphodiesterase inhibitors is a frequent observation in preclinical toxicology studies. The deficiency in understanding of its mechanism of toxicity as well as the lack of available biomarkers presents obstacles for development of this class of compounds. To develop probable biomarkers of toxicity, we treated rats with Minoxidil, SCH 351591 (a PDE4 inhibitor) and Vardenafil (a PDE5 inhibitor), and examined gene expression changes upon compound treatment using the Affymetrix GeneChip platform. The biomarker candidates identified through microarray were confirmed for their expression changes using RT-PCR. A set of probable biomarkers is proposed for their potential application in toxicity assessment in preclinical drug development. Some of these probable biomarkers are expressed in peripheral blood cells, suggesting potentials of non-invasive assays for clinical applications.

237 A SURVEY OF PROBABLE NEPHROTOXICITY BIOMARKERS FROM THE LITERATURE THROUGH GENE EXPRESSION ANALYSIS.

E. Wang, Y. Gu, R. Smith and R. Snyder. *Molecular and Genetic Toxicology, Schering-Plough, Summit, NJ.*

Nephrotoxicity is a recurring impediment in drug development. The existing biomarkers of nephrotoxicity serum creatinine and blood urea nitrogen (BUN) are not sensitive enough to indicate early renal injury. In an effort to search for better nephrotoxicity biomarkers, we did a literature survey and identified 49 probable biomarker candidates. These candidates were screened for their kidney gene expression changes in rats following treatments of either nephrotoxins (n=4) or hepatotoxins (n=3) using RT-PCR technology. A set of genes emerged from this screen as probable biomarkers whose expression is regulated significantly by nephrotoxins but not by hepatotoxins. The range of gene expression changes ranges from several fold to thousands compared with control. The genes displaying most expression changes upon treatment of nephrotoxins include kidney injury molecule 1 (KIM1), lipocalin 2 (LCN2) and osteopontin (SPP1). The identification of this gene set offers a new tool in risk assessment for nephrotoxicity.

238 IDENTIFICATION OF OXIDATIVELY-MODIFIED PROTEINS IN CEREBROSPINAL FLUID BY A TARGETED PROTEOMICS APPROACH.

W. Chung, C. L. Miranda and C. S. Maier. *Chemistry, Oregon State University, Corvallis, OR.*

A targeted proteomics approach was employed for the identification of oxidatively-modified proteins in human cerebrospinal fluid (CSF) using an aldehyde reactive probe, N^ε-aminooxymethylcarbonylhydrazino-D-biotin (ARP). Ten proteins in 2-dimensional (2D) gels of CSF from healthy and Alzheimer's disease (AD) subjects have been identified with MALDI-MS/MS analysis. The proteins were serotransferrin, serum albumin, hemoexin, Ig gamma chain C region, transthyretin, prostaglandin D-synthase, α -2 microglobulin, Ig kappa chain C region, α -1-antitrypsin and adducin gamma. Some proteins, such as serum albumin, serotransferrin and prostaglandin D-synthase were found in several spots indicating extensive post-translational processing. There was an overlap of adducin gamma with serotransferrin in the 2D gels. Avidin affinity stained blots of CSF protein samples revealed that 6 of the 10 proteins reacted with ARP. Protein spots that were identified in 2D gel

spots and corresponded to the ARP-reactive protein spots were serotransferrin, serum albumin, transthyretin, prostaglandin D-synthase, α -1-antitrypsin, and aducin gamma.

The use of ARP coupled with mass spectrometry represents a novel approach for the identification of carbonylated CSF proteins. The identified proteins might potentially lead to the development of novel markers for AD and other neurodegenerative diseases.

239 IN SITU BREAST CANCER METASTASIS CHARACTERIZATION BY MALDI MASS SPECTROMETRY.

S. Schwartz¹, L. A. Greene¹, P. A. Veno², J. Zhao², L. F. Bonewald² and S. L. Dallas². ¹Midwest Research Institute, Kansas City, MO and ²School of Dentistry, University of Missouri-Kansas City, Kansas City, MO. Sponsor: B. Astroff.

Breast cancer frequently metastasizes to bone, causing bone destruction, hypercalcemia, fracture and pain. To examine the mechanisms responsible for breast cancer metastasis and growth in bone, and study the tumors in their metastatic microenvironment, tumorigenic bone sections from nude mice inoculated with MDA-231 human breast cancer cells were analyzed by direct-tissue protein profiling using matrix assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI TOF MS). This technique allows "in situ" mass spectrometry analysis to be performed directly on tissue sections, and protein profiles are generated from discrete tissue subregions such as bone, marrow, tumor and muscle. The described approach is applicable to a variety of studies including monitoring small molecule localization within tissues and identifying key biomarkers indicative of disease state, tissue response to exposure or therapy, or patient outcome.

Tissue from five control mice and five mice containing breast cancer metastases were harvested, processed and analyzed, including tumor-bearing bone, tumor-bearing adrenal gland, muscle, liver and kidney. To optimize mineralized tissue preparation techniques, specimens were either fresh frozen or fixed in 70% ethanol and decalcified, sectioned, and analyzed by MALDI MS. The resulting protein profiles were evaluated. Comparable protein patterns were generated for the two tissue preparation methods, with the fixation/decalcification procedure giving better histology and the fresh frozen preparation yielding enhanced tumor protein patterns. The fresh frozen sample preparation method was then applied to characterizing breast cancer metastasis to bone and adrenal gland. Comparison of the protein patterns from tumor metastatic regions demonstrated greater than 20 protein signals with potential differential expression between the tumor and surrounding non-tumor regions as well as between tumor metastases in different tissues.

240 URINARY PROTEOMIC-BASED BIOMARKER DEVELOPMENT FOR EVALUATION OF OCCUPATIONAL EXPOSURE USING SELDI-TOF MASS SPECTROMETRY.

P. I. Mathias and K. L. Cheever. DART BHAB MGM, CDC NIOSH, Cincinnati, OH.

The utility of four types of Ciphergen ProteinChips were evaluated by comparing protein profiles in control, and in in vitro acrylamide or glycidamide exposed urine using Surface Enhanced Laser Desorption Ionization Time of Flight (SELDI-TOF) mass spectrometry. Acrylamide (CAS 79-06-1), a widely used industrial chemical, which also may be formed in thermally processed food, can produce peripheral neurotoxicity and reproductive effects. Acrylamide has been classified as a probable human carcinogen. Changes in the levels of potential protein biomarkers in serum and urine have been reported in exposure to toxic agents, and bioactivation of acrylamide to glycidamide (5694-00-8), a reactive epoxide, suggests that urinary protein levels would be affected in acrylamide exposure. This work was designed to identify molecular biomarkers in human urine for use to assess acrylamide exposure or detect early disease onset. Urinary proteins were processed on NP20, CM10, H50, and IMAC30 chips having normal phase, cationic exchange, hydrophobic, and ionic surface chemistries, respectively. The number of peaks and mean peak intensity varied significantly with IMAC30 > CM10 > NP20 > H50. Various factors were optimized during the development of binding protocols for each chip, including surface pretreatment, sample binding time and washing methods. The data from this work suggest that the detection and further characterization of urinary protein levels using SELDI-TOF mass spectrometry can provide specific proteomic-based biomarkers of exposure for acrylamide.

241 IDENTIFICATION OF PROTEIN EXPRESSION PROFILES AFTER TREATMENT WITH THE HEAT SHOCK PROTEIN (HSP)90 INHIBITOR, 17-DIMETHYLAMINOETHYLAMINO-17-DEMETHOXYGELDANAMYCIN (17-DMAG) IN HUMAN AND RAT PBMCs USING THE SELDI PROTEIN CHIP SYSTEM.

S. Qin, D. Zhou, X. Zhang, L. Li, J. Ye, X. Zhang and J. Barsoum. Synta Pharmaceuticals Corp., Lexington, MA. Sponsor: E. Kitayama.

Proteomic techniques hold the promise to improve efficiency of protein profiling and biomarker identification for treatment-responsive proteins. In this study, we use a surface-enhanced laser desorption/ionization time-of-flight mass spectroscopy (SELDI TOF-MS) system to identify protein profiles in normal PBMCs treated with Hsp90 inhibitor in vitro. The fresh human and rat PBMCs were isolated and treated with 17-DMAG overnight at different concentrations from 1 to 100 nM. The cells were harvested and proteins were extracted, quantified, and then applied to weak cation exchange (CM10) and strong anion exchange (Q10) ProteinChip® arrays for protein profiling by SELDI-TOF MS. Ciphergen Express and Biomarker Patterns Software package was used to compare the protein profiles from different samples acquired from different protein chips. When the peak intensity was calculated as a fold increase or decrease vs. control in a range from 1-13 kDa, 49 protein picks were identified in rat and human PBMCs, which all relevant to the treatment of 17-DMAG. Among those, 29 (16 from Q10 and 13 from CM 10 chips) proteins identified in the treatment groups were differentially by 3 folds or greater relative to the vehicle control with a trend of dose-dependency. Overall, the number of protein picks identified in the rat was higher than that in the human PBMCs based on the peak intensity. Our results suggest that SELDI-TOF-MS has the potential to identify a protein profile that distinguishes action of the testing compounds vs. vehicle controls in both rat and human PBMCs. These protein expression profiles determined by SELDI TOF-MS can provide a new resolution to identify drug-responsive biomarkers and potentially lead to a better understanding of mechanisms related to the activity/toxicity of Hsp90 inhibitors.

242 DEVELOPMENT OF A PROTEOME DATABASE FOR QUANTITATIVE ANALYSIS OF MACROPHAGE RESPONSES TO NANOMATERIALS AND ENVIRONMENTAL PARTICULATES.

L. M. Masiello, J. M. Jacobs, K. M. Waters, R. C. Zangar, D. Smith, C. Sacksteder and B. Thrall. Pacific Northwest National Laboratory, Richland, WA.

The increase in industrial use of engineered nanoparticles and the link between particulate matter exposure and cardiovascular and respiratory effects in humans has created a need to understand the biological pathways stimulated by these agents. Identification of protein biomarkers of exposure to particulates and nanomaterials may aid in early detection of toxicity and highlight differential mechanisms of action. Toward this goal, we have established a reference macrophage proteome database for comparison of responses to different activating stimuli, which can be applied for future quantitative comparisons. We used a global proteomic approach to identify proteins in the extracellular compartment following treatment with particulate, biological, and biochemical stimuli. Conditioned medium from RAW 264.7 cells treated with urban particulate matter (UPM), crystalline silica, lipopolysaccharide (LPS), phorbol ester (PMA), or serum-free media (control) was analyzed by LC-MS/MS following tryptic digestion. We confidently identified 623 proteins, which is a significant increase in coverage compared to previous 2-D gel based studies of the extracellular proteome. Based on spectral counts, we found proteins that were differentially detected compared to control for UPM (80), silica (84) LPS (87), and PMA (117), as well as several proteins that were unique to each stimulus. We identified proteins associated with inflammatory (74), proteolytic (55), and apoptotic (15) processes among other biological pathways. Several of the proteins responses identified by MS/MS have been validated by orthogonal protein microarray analysis. This study established a reference database that is being applied for high-throughput investigations of macrophage responses to an array of nanomaterials using quantitative mass spectrometry-based approaches.

243 METABOLOMIC DETERMINATION OF BIOMARKER CANDIDATES OF PHOSPHOLIPIDOSIS USING CAPILLARY ELECTROPHORESIS TIME-OF-FLIGHT MASS SPECTROMETRY.

N. Masutomi¹, T. Ishikawa², J. Abe², A. Hirayama², N. Tsutsui² and T. Soga^{2,3}. ¹Toxicology Laboratory, Mitsubishi Pharma Corporation, Chiba, Japan, ²Human Metabolome Technologies, Inc., Yamagata, Japan and ³Institute for Advanced Biosciences, Keio University, Yamagata, Japan. Sponsor: J. Sugimoto.

We conducted a metabolomic analysis based on capillary electrophoresis time-of-flight mass spectrometry (CE-TOF-MS) to find biomarker candidates of phospholipidosis (PLD). SD rats received oral doses of a vehicle, amiodarone or MPC1 (a

Mitsubishi Pharma Compound) for two weeks. PLD was evaluated by histopathology and lung phospholipids (PL) contents. Amiodarone (150mg/kg) induced microscopically visible PLD in the lungs with 2.1-fold increase in PL content in the organ. On the other hand, MPC1 had no effect on the histopathology with 1.4-fold increase in the PL contents, demonstrating MPC1 induced milder PLD compared with amiodarone. CE-TOF-MS metabolomic analysis was conducted on urine and blood plasma collected after 2-weeks of treatment. Thousands of peaks detected by each assay were aligned from sample to sample to facilitate differential analysis between groups. Application of filtering with correlation coefficient to the lung PL contents as well as statistical significance between groups successfully extracted potentially valuable peaks from huge data sets. Tandem mass spectrometry with CE-Q-TOFMS clarified the identities of these peaks by confirmation of the exact molecular weight, migration time and MS/MS fragmentation pattern. Metabolites identified included phenylacetylglycine (PAG), a benchmark metabolite reported to be altered by PLD. Comparison with PAG showed that many of the metabolites newly discovered had superior property as biomarkers of PLD, especially in detection of milder PLD in terms of statistical significance and magnitude of changes. Moreover, the metabolomic analysis detected metabolic shift of a particular metabolic pathway, which exhibited more pronounced detection of PLD than each single metabolite. The results demonstrated the power of CE-TOF-MS based differential metabolome analysis to find multiple biomarker candidates simultaneously.

244 USE OF METABONOMICS TO DEFINE MECHANISMS OF TOXICITY: CONSORTIUM FOR METABONOMIC TOXICOLOGY-2 (COMET-2) PROJECT.

J. D. Vassallo¹, C. M. Rohde², D. G. Robertson², M. Coen³, H. C. Keun³, J. C. Lindon³, E. C. Holmes³, V. Baker⁴, A. Amberg⁴, B. Walther⁵, F. Goldfain-Blanc⁵ and J. K. Nicholson³. ¹Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ, ²Metabonomics Evaluation Group, Pfizer, Ann Arbor, MI, ³Biomolecular Medicine, Imperial College, London, United Kingdom, ⁴Sanofi-Aventis, United Kingdom, Germany and ⁵Servier, Orléans, France.

COMET-1 was formed to develop a comprehensive database of toxicologically important changes in metabolic patterns determined by NMR analysis of rat urine and serum. Although metabonomics is a powerful approach for evaluating toxicity, its application to determining mechanisms of toxicity and ultimately human risk remains limited. COMET-2 was developed to apply metabonomic data (now both NMR and MS) to defining mechanisms of toxicity and assessing risk factors for toxicity. Two projects are underway. 2-Bromoethanamine (BEA), an acute papillary toxicant, induces renal injury in rats within 24 hours (>150 mg/kg) but the mechanism is not fully established. In initial COMET-2 studies, BEA markedly increased the urinary excretion of glutaric acid in rats, suggesting possible inhibition of glutaryl CoA dehydrogenase. This was observed at both non-toxic (< 50 mg/kg) and toxic (>150 mg/kg) doses indicating a lack of concordance with histopathologic changes. In contrast, metabonomic data indicate correlative changes in deoxynucleoside and N-methylnicotinic acid pathways, providing new mechanistic leads. The second project is to understand the metabolic basis of inter-individual variability in response to toxicant exposure using the highly variable hepatotoxicity of galactosamine (Gal) as an exemplar. At a dose of 415 mg/kg, ca 75% of rats showed hepatotoxicity ranging from minimal to marked necrosis, while 25% showed no toxicity. A mechanistic understanding of the basis for this variation is a current objective of COMET-2. Ultimately, results of these studies will be used to develop and test hypotheses regarding toxic mechanisms to position the utility of metabonomic data in investigative toxicology and risk assessment.

245 METABONOMIC ANALYSIS BY 1H-NMR SPECTROSCOPY OF CONTROL URINES OF DIFFERENT TOXICOLOGICAL ANIMAL MODELS.

E. Troesken¹, S. Byard², J. Morsman³, V. Baker³, I. Stammberger¹, M. Kurz⁴ and A. Amberg¹. ¹Drug Safety Evaluation, Sanofi-Aventis, Frankfurt, Germany, ²Chemistry Manufacturing and Control, Sanofi-Aventis, Alnwick, United Kingdom, ³Drug Safety Evaluation, Sanofi-Aventis, Alnwick, United Kingdom and ⁴Discovery Analytics, Sanofi-Aventis, Frankfurt, Germany. Sponsor: B. McCullough.

Metabonomic studies investigate a wide range of low-molecular mass endogenous metabolites present in biological samples and the influence of administered compounds on these profiles. However, the concentration of many urinary endogenous metabolites fluctuates as a result of normal physiological variation. The number of control samples analysed per individual metabonomic study is limited. To have a broader database and to better distinguish between physiological and compound induced variation, control urine samples of different toxicological species were analysed. Standard 1H-NMR spectroscopy and Principal Component Analysis (PCA) and Partial Least Squares Discriminant Analysis (PLS-DA) were utilised to determine the influence of species, gender and age. Overnight urine samples from male and female rats, minipigs, beagle dogs and cynomolgus monkeys were

analysed. The results of these studies showed that many physiological conditions influence the composition of urine samples. A clear distinction between the four species was noted. Gender differences could easily be detected in rats and minipigs, but not in dogs or cynomolgus monkeys according to PCA analysis of urinary metabolic profiles. In rats, discrimination between male and female urines was due to the amount of citrate present, with females having far higher levels than males. The poster further discusses the influence of age on endogenous metabolic profiles. A broader understanding is necessary to avoid misinterpreting the natural fluctuation of endogenous metabolites as potential markers of toxicity.

246 NMR-BASED METABONOMIC EVALUATION OF GALACTOSAMINE HEPATOTOXICITY AND THE PROTECTIVE ROLE OF GLYCINE.

M. Coen¹, C. M. Rohde², J. T. Pearce¹, H. C. Keun¹, T. D. Ebbels¹, E. C. Holmes¹, J. C. Lindon¹, J. K. Nicholson¹, M. D. Reilly² and D. G. Robertson². ¹Biomolecular Medicine, Imperial College, London, United Kingdom and ²Metabonomics Evaluation Group, Pfizer Global R&D, Ann Arbor, MI.

Galactosamine (GalN) has been shown to alter gut permeability and increase bacterial translocation leading to endotoxemia which is believed to be primarily responsible for the hepatic effect. It has been postulated that glycine protects against GalN toxicity as it counteracts the activation of Kupffer cells and prevents cytokine release. Rats were acclimatised to a 0 or 5% glycine diet for 6 days and subsequently administered vehicle, GalN (500 mg/kg), glycine (via the diet), or both GalN and glycine. Urine was collected over 12 days prior to administration of GalN and for 24 hours thereafter. The metabolic profiles of biofluids and tissues were determined using NMR methodologies. The multivariate classification method, orthogonal-projection on latent structures (O-PLS), which pre-filters classification-irrelevant variation from data, was applied to model the NMR spectral data. O-PLS loadings enabled the urinary and serum metabolites that discriminated between control and treated classes to be determined. The urinary metabolic effects of GalN treatment were increased levels of N-acetylglucosamine together with decreased levels of 2-oxoglutarate, isoleucine, leucine, valine, deoxycytidine, N-methylnicotinamide and creatinine. The corresponding serum data revealed elevated levels of tyrosine, 3-hydroxybutyrate, TMAO, lactate, phenylalanine and reduced levels of lipid triglyceride and glucose. The metabolic effects of treatment with both GalN and glycine were significantly different; N-acetylglucosamine urinary levels were not elevated and the serum profile remained very close to that of controls. Histopathological data and clinical chemistry measurements confirmed the protective effect of glycine. These novel data highlight the applicability of NMR-based metabonomics in elucidating the metabolic consequences of toxicity and protection from toxicity, and lead to understanding a mechanism of toxicity.

247 METABOLOMIC RESPONSE PROFILE FOR SURGERY AND RADIATION.

M. Milburn¹, C. Guha², M. W. Mitchell¹ and E. Milgram¹. ¹Metabolon, Inc., Durham, NC and ²Albert Einstein College of Medicine, Toronto, ON, Canada. Sponsor: S. Borghoff.

The goal of the study was to determine small molecule biochemical markers for both surgery and radiation treatment. There were four treatment groups: untreated mice; surgery treated mice; surgery treated mice with livers exposed to low radiation [10 grays (gy)]; and surgery-treated mice with livers exposed to high radiation [50 grays (gy)]. 24 hours later, blood samples were taken from the mice and complete biochemical profiles were obtained. The relative concentrations of over 150 small molecules were measured using GC and LC mass spectrometry. Statistical analysis consisted of looking for specific compounds with treatment effects and looking for sets of compounds indicative of changes in biochemical pathway response. The results found two sets of natural, small molecules, e.g., citric acid, were discovered that allowed for classification of the treatments, surgery effects, and radiation effects.

248 METABONOMICS EVALUATION OF URINE FROM RATS DOSED WITH ACETAMINOPHEN USING NMR AND UPLC/MS.

R. D. Beger¹, L. K. Schnackenberg¹, J. Sun¹, R. D. Holland¹, M. D. Reilly², D. G. Robertson³, G. H. Cantor³ and Y. P. Dragan¹. ¹Systems Toxicology, National Center for Toxicological Research, Jefferson, AR, ²Metabonomics Evaluation Group, Pfizer Global Research & Development, Ann Arbor, MI and ³Discovery Toxicology, BMS, Princeton, NJ.

Urinary metabolic perturbations associated with acetaminophen induced hepatotoxicity were investigated using NMR and ultra performance liquid chromatography-mass spectrometry (UPLC/MS). Single low and high doses of acetaminophen

were administered to male Sprague-Dawley rats in groups of 10. Pre-dose urine samples and urine samples from days 1 to 7 were collected for each rat and monitored by NMR and UPLC/MS. The PCA clustering of NMR and UPLC/MS spectra were shown to be associated with the measured clinical chemistry and histopathology findings. Many of the metabolic changes observed were due to dietary changes in the animals that received the high dose of acetaminophen. Both phenylalanine and pantothenic acid, which are derived from the diet, were decreased after the high dose of acetaminophen was administered. Furthermore, concentrations of ferulic acid and glycine both decreased as expected since they both play a role in detoxifying the reactive intermediates of acetaminophen. General biomolecules, including hippurate, phenylacetylglutamine, kynurenic acid, N-acetylsuccinyl, citrate, α -ketoglutaric acid, pipercolinic acid and other unknown metabolites were also observed as altered components in urine. As such, metabolomics based on NMR and UPLC/MS analysis has provided complimentary information concerning acetaminophen-induced liver injury.

249 EVALUATING DRUG-INDUCED HEMOLYSIS EFFECTS USING A WHOLE BLOOD-LIVER SLICE CO-CULTURE MODEL.

J. R. Sinclair, W. Way and A. E. Vickers. *Drug Safety Evaluation, Allergan Inc., Irvine, CA.*

In this study, we demonstrate the utility of an in vitro model to determine drug induced effects on the hemolysis of red blood cells (rbc) and the expression of liver genes involved in heme turnover. After pre-incubation in media alone, precision-cut rat liver slices are transferred to fresh media mixed with whole blood plus compound or vehicle for up to 72 hr. The release of hemoglobin from rbc and levels of ATP and GSH in rbc and liver slices are quantitated over the culture time. Additionally, changes in the expression of liver genes involved in heme metabolism (e.g., heme-binding protein 23, heme-oxygenase 1, and ferroportin 1) are determined by quantitative RT-PCR. One test compound, aniline, which is known to require metabolism to induce hemolysis, causes hemolysis in a time- and concentration- dependent manner. For example, at 48 hr, a single dose of 10 and 25 mM, resulted in 30% and 70% hemolysis respectively. Similarly, another test compound, methimazole, administered as a single dose up to 1.5 mM for up to 72 hr, induces up to 60% hemolysis in a time- and concentration- dependent manner. Preceding hemolysis, levels of GSH in the blood declined, while ATP levels remained stable. The expression of heme metabolism related liver genes positively correlated with hemolysis. In the absence of a liver slice but in the presence of aniline or methimazole, the percent hemolysis is similar to cultures with no drug exposure, <5%. This study demonstrates that the whole blood-liver slice co-culture model is a useful tool for the investigation of liver generated drug metabolites leading to hemolysis. Furthermore, the model can be extended across species, including human, for the characterization of species susceptibility to drug-induced hemolysis and the identification of the metabolic pathways involved.

250 NEWBORN MICE EXPOSED TO HYPEROXIA EXHIBIT INCREASES IN LIPID OXIDATION PRODUCTS AND CYTOSOLIC PHOSPHOLIPASE A2.

L. K. Rogers, S. E. Welty and L. D. Nelin. *Pediatrics, Columbus Children's Research Institute, Ohio State University, Columbus, OH.*

Respiratory failure, lung inflammation, and alterations in lung development are serious clinical complications associated hyperoxic lung injury in premature infants. We tested the hypothesis that exposure to hyperoxia is associated with increases in lipid inflammatory mediators and the enzymes involved in their formation and that these increases would be associated with changes in lung concentrations of nuclear receptors PPAR α and/or γ . Newborn mice were placed in either room air (RA) or >95% O₂ for 1, 3, or 7 days and subsequently lung tissues were harvested for lipid and protein analyses. Histological analysis indicated no detectable lung injury in these mice through 7 days of exposure. In the phospholipid fractions of lung tissues, levels of 5-HETE, 8/12-HETE, and 11-HETE were greater in the O₂ exposed animals than the RA controls at all days tested (5-HETE: day1, 472+65 vs 275+71; day 3, 235+64 vs 129+43; day 7 235+64 vs 119+26 pmol/g tissue), (8/12-HETE: day1, 123+46 vs 77+21; day 3, 61+8 vs 34+8; day 7, 73+26 vs 39+14 pmol/g tissue), (11-HETE: day1, 231+25 vs 93+11; day 3, 127+11 vs 95+23; day 7, 124+24 vs 91+26 pmol/g tissue). Western blots indicated that cPLA2 levels were greater in the O₂ exposed mice than RA controls by day 7 but 15-lipoxygenase (15-LO) levels were dramatically less at 7 days in O₂, than day 1 or 3 in O₂ or in all RA controls. Neither PPAR α nor PPAR γ protein levels were different in the tissues from oxygen treated animals than tissues from the room air controls. However, PPAR γ protein levels indicated an age dependent decrease in expressions in both the treated and control tissues. Our data indicate that increases in specific lipid oxidation products are detectable as early as 1 day of exposure and may be relevant in the course of lung injury. Levels of cPLA2 were increased by 7 days of hy-

peroxia and are likely to contribute to the increases in oxidized lipids. Levels of 15-LO were decreased and may be associated with both inflammatory resolution and growth in the newborn lung.

251 TOTAL HOMOCYSTEINE CHANGES IN ADULT MALE MICE AFTER EMBRYONIC EXPOSURE TO 5-AZA-2'-DEOXYCYTIDINE (5-AZA-CdR): ROLE OF EPIGENETICS.

F. J. Cisneros¹, S. Branch², J. Gulbinski¹ and M. Snyder¹. ¹Charles River Laboratories Preclinical Services PA, Horsham, PA and ²Djehuty Biomed Consulting, Leasburgh, NC.

Homocysteine is considered a risk factor marker for several pathologies, mainly cardiovascular diseases. It is produced by intracellular demethylation of the essential amino acid methionine. Its remethylation ensures the provision of S-adenosylmethionine, the main methyl group donor in the body. DNA methylation, the most understood epigenetic mechanism, controls at least in part gene expression during embryonic and post-natal life. To investigate if an embryonic exposure to 5-AZA-2'-Deoxycytidine (5-AZA-CdR) – a demethylating agent- affects the total homocysteine levels in postnatal stages. CD-1 mice at gestation day (GD) 10 were administered one dose of 1 mg/kg of 5-AZA-CdR via intra peritoneal injection. Blood samples from male offspring were collected at post natal days (PD) 70 and 154 by cardiac puncture. Levels of total homocysteine were analyzed using the Microplate STE-Based Assay of homocysteine. Total homocysteine levels for control and exposed mice were 14.19 (+/- 2.17) and 13.4635 (+/- 1.29) at PD 70 and 16.5369 (+/-1.46) and 16.0117 (+/-1.47) at PD 154. While the ANOVA (0.95 confidence) did not identify statistical differences among experimental groups, there was a trend in which embryonic exposed mice exhibited lower levels of total homocysteine. Further studies are needed to elucidate the effects of altered methylation during embryogenesis on homocysteine levels during adult life and the subsequent implications.

252 MULTIPLEXING FLUORESCENT-BASED OXYGEN AND PH SENSING FOR THE ANALYSIS OF MITOCHONDRIAL FUNCTION AND DYSFUNCTION.

J. Hynes², D. Papkovsky² and Y. Will¹. ¹Drug Safety Research and Development, Pfizer, San Diego, CA and ²Luxcel BioSciences, Cork, Ireland.

Mitochondrial dysfunction is a major mechanism of drug-induced toxicity. Our goal is to identify NCEs that exhibit the capacity to perturb mitochondrial function early within the drug discovery process. Recently, we have demonstrated in the suitability of the MitoXpress™ approach for HTS analysis of mitochondrial respiration in (Toxicological Sciences, 2006, 92(1):186-200). Here, we present a multiplexed approach to obtain an even more detailed and complete picture of cellular metabolism via parallel monitoring of aerobic and non-aerobic metabolism. Knowledge of the effect of NCE treatment on both glycolysis and oxidative phosphorylation allows inferences to be drawn regarding the site of metabolic insult; allowing glycolytic inhibition to be delineated from direct mitochondrial effects, increasing the confidence with which mitochondrial toxicity can be detected. Currently this is achieved in our laboratory through screening in HepG2 cells which are either anaerobically or aerobically poised, respectively (The Toxicologist 2005). However, dictating metabolic poise via substrate restriction is not feasible for all cell lines, many of which are grown in proprietary culture media. In an attempt to adapt the measurement of extracellular acidification to a convenient, high throughput assay, capable of multiplexing with the Luxcel MitoXpress™ oxygen sensing assay, we evaluated the use of new pH sensitive fluorescent probes. Data to be presented includes the spectral characterisation of both O₂ and pH probes in the presence of each other and assessment of probe performance in multiplexed assay

253 ASSESSMENT OF DRUG-INDUCED MITOCHONDRIAL TOXICITY IN DRUG SAFETY.

J. A. Dykens and Y. Will. *Drug Safety Research and Development, Pfizer, San Diego, CA.*

Mitochondrial integrity is essential for viability of aerobically poised cells; when mitochondria fail, the cell dies. The evidence is accumulating that many ethical drugs have deleterious mitochondrial effects that are manifest as tissue toxicity in liver, cardiovascular system, skeletal muscle, nervous system, and kidneys, among others. In some cases, such as antiviral therapy, toxicity results from coincident interference with mitochondrial replication. In others, however, the drug acutely and directly undermines mitochondrial function. Importantly, not all drugs within a class have mitochondrial liabilities, indicating that the therapeutic objective can be accomplished while circumventing cytotoxicity due to mitochondrial impairment.

We present here mitochondrial assessments of several families of drugs used for treatment of diabetes and hyperlipidemia, including statins, thiazolidinediones, and fibrates. Respiration of isolated rat liver mitochondria during State 2 (oxidizable substrate) and State 3 (substrate plus ADP) was monitored using a fluorescent probe that reports PO₂. Of the 6 statins evaluated, 4 uncoupled State 2 respiration, and also inhibited OXPHOS. Of the 6 thiazolidinediones, 3 profoundly uncoupled State 2 respiration, 2 showed intermediate uncoupling, and one was without effect. However, all 6 thiazolidinediones inhibited State 3 respiration. Of the 5 fibrates examined, 1 showed modest uncoupling of State 2 respiration, and 2 modestly inhibited State 3. Because these drugs are frequently co-prescribed, we also evaluated their mitochondrial effects when combined at half the previously tested concentration. In several cases, although neither drug alone elicited a mitochondrial response, the combination additively uncoupled or inhibited respiration, suggesting that some combinations are more likely to yield drug-induced mitochondrial side effects.

254 CURRENT DEVELOPMENTS IN REAL-TIME FOURIER TRANSFORM INFRARED SPECTROSCOPIC ANALYSIS OF THE CELLULAR RESPONSE TO NANOMATERIALS.

S. K. Sundaram, B. J. Riley, R. S. Addleman, L. S. Fifield, A. A. Schepmoes and T. J. Weber. *Environmental Technology Directorate, Pacific Northwest National Laboratory, Richland, WA.*

There is considerable uncertainty surrounding the toxicity of nanomaterials and associated mechanisms of action. Cost effective technologies that can provide real-time screening of nanomaterials and provide information regarding the mode of action are needed to reduce this uncertainty. Here we are investigating the application of Fourier Transform Infrared (FTIR) spectroscopy as a tool to screen the cellular response to nanomaterials rapidly. Initial efforts have focused on the activation of macrophage cells (RAW 264.7) by lipopolysaccharide (LPS) as a model proinflammatory stimulus, a mode of action that is widely implicated in nanomaterial toxicity. LPS induces a proinflammatory state in RAW 264.7 cells, characterized by up-regulation of cyclooxygenase-2 (Cox-2) and inducible nitric oxide synthase (iNOS). FTIR data on LPS-treated macrophages indicated a marked increase in a peak detected at wave number 1652, characteristic of the protein carbonyl bond. Pretreatment of RAW 264.7 cells with indomethacin, a Cox-2 inhibitor, fully suppressed the increase in this peak, suggesting a link between this spectroscopic change and Cox-2 activity. Additionally, we overexpressed Cox-2 in RAW 264.7 to explore this link further. Treatment of Cox-2 expressing cells with arachidonic acid, the substrate for Cox-2, was associated with an increase in the peak occurring at the same wave number 1652, providing additional evidence to this link. Dehydration experiments were investigated to reduce interference by water revealing additional FTIR observable features masked in live cell experiments. Treatment of RAW 264.7 cells with multiwalled carbon nanotubes (MWNs) resulted in a reproducible change in a peak observed at wave number 1083. These data illustrate the most recent advances in the application of FTIR spectroscopy to interrogate the cellular response to nanomaterials. This research was supported by U.S. DOE funding (Contract DE-AC05-76RL01830).

255 DEVELOPEMENT OF A CIGARETTE SMOKE MODEL OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) IN THE MOUSE.

K. Norton, M. Freke, S. Groom and S. Mason. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.* Sponsor: *C. Banks.*

The purpose of this study and its preceding work was to develop a model that adequately replicated several of the physiological and molecular characteristics of COPD that could be used to evaluate the efficacy of new chemical entities to delay disease onset. Changes in gene expression, inflammatory biomarker levels and lung remodeling were evaluated in smoke sensitive A/J mice. Mice were exposed to vehicle, 4% smoke, 4% smoke + LPS (known for inducing neutrophilia) or 4% smoke + rolipram (a PDE4 inhibitor shown to decrease the influx of inflammatory cells to the site of inflammation) for 2 hours daily, over a 3 month period. Mild changes in lung pathology, increased alveolar airspace along with chronic macrophage infiltration were noted in smoke and smoke + LPS treated groups; whilst macrophage infiltration was decreased in Rolipram treated animals. Bronchoalveolar lavage fluid cytokine levels indicated increased levels of MDC, MCP-1 and MPO, consistent macrophage accumulation. However changes in TNF α , INF γ , IL10, IL18, KC (Gro- α /CXCL1), normally associated with COPD were not present. Lung tissue expression showed significant upregulation of 186 probe sets, which included oncogenes and cardiac myosin genes, possible indicators of cancer and heart disease. A comparison of gene expression changes observed in 5 human patient microarray/SAGE studies identified 32 genes with similar upregulation. However no changes in tissue expression were noted for Metalloproteases, Serpine or RTP801 which would normally be altered in COPD. The data indicates that although the

model does not fully mimic COPD, some common characteristics, i.e alveolar enlargement and chronic macrophage inflammation were noted. The next stage of this model development will be to increase the total smoke concentration and/or exposure period, in order to upregulate expression of other markers commonly associated with COPD.

256 DEVELOPMENT AND APPLICATION IN A NEPHROTOXICITY MODEL OF A NOVEL ENZYME IMMUNOASSAY FOR THE QUANTIFICATION OF URINARY CLUSTERIN IN RATS.

C. G. Kilty³, D. Magee², M. Shaw¹ and K. Schuster². ¹Senior Scientific Officer, Biotrin International, Co Dublin, Ireland, ²Research and Development, Biotrin International, Co Dublin, Ireland and ³Chief Scientific Officer, Biotrin International, Co Dublin, Ireland. Sponsor: *D. Bounous.*

Clusterin / Apolipoprotein J (ApoJ) is a secreted glycoprotein found in numerous mammalian tissues and biological fluids. Although clusterin has been implicated in numerous biological processes, the localised over-expression of clusterin at sites of tissue damage or stress suggests that clusterin acts as a molecular chaperone displaying cytoprotective characteristics. The marked induction of clusterin in several renal disease states, such as glomerulonephritis, cystic renal disease and renal tubular injury suggests the possibility that urinary clusterin could be a useful biomarker of nephrotoxicity.

Biotrin International has developed a novel enzyme immunoassay (EIA) for the detection and quantification of urinary clusterin levels in rats. Here, we present the development and performance characteristics of this EIA together with data from a study on urinary clusterin release in laboratory rats during and after treatment with the non-steroidal anti-inflammatory drug, indomethacin (9 rats, 10mg/kg body weight/day over a period of 4 days). For all animals treated, the post-treatment urinary levels of clusterin were significantly higher than pre-treatment levels. These preliminary findings corroborate results from previous nephrotoxicity studies and support the use of urinary clusterin as a biomarker of nephrotoxicity.

257 A CHEMOGENOMIC ANALYSIS OF THE DRUG-DRUG INTERACTION BETWEEN STATINS AND FIBRATES.

M. D. Lee, B. Ganter, K. Jarnagin and D. N. Halbert. *Iconix Biosciences, Mountain View, CA.*

The incidence of HMG-CoA reductase inhibitor (statin) associated rhabdomyolysis increases with co-administration of a PPAR α agonist (fibrate) due to drug-drug interaction (DDI) between these two classes of lipid lowering agents. This DDI was initially considered to be a pharmacodynamic effect since both classes of drugs can cause myopathy when administered alone; however, recently gemfibrozil was reported to increase the plasma concentration of cerivastatin by 5-fold. We have analyzed drug-induced gene expression changes in liver and skeletal muscle tissues of statin or fibrate-treated rats and found that the DDI may alternatively be attributed to insufficient hepatic glucose output resulting from synergistic down-regulation of key genes involved in hepatic gluconeogenesis, PEPCK and glucose-6-phosphatase, by fibrates and statins, respectively. The state of glucose-insufficiency in skeletal muscles of statin-treated (MTD) animals was reflected in i) the up-regulation of PDK4 - known to be induced both under conditions of starvation and by PPAR α agonists and serving to facilitate entry of acetyl-CoA derived from β -oxidation into the TCA cycle, and ii) increased expression of mitochondrial HMG-CoA synthase, the rate limiting enzyme for ketogenesis. Thus, in skeletal muscles, statins and fibrates synergistically increase the consumption of fatty acids. This leads to an hypothesis that under conditions where the individual's circulating serum triglyceride level is low, the triglyceride and fatty acid store in muscle could be depleted leading to muscle protein break-down, increased serum creatine kinase, and rhabdomyolysis. We have also found that fibrates suppress drug-metabolizing enzymes and transporters such as CYP2C, CYP3A, PAPSS2 and ABCC2 that are involved in the metabolism and excretion of the statins, potentially leading to increased plasma concentration of co-administered statins. In conclusion, chemogenomic analysis allowed us to develop a mechanistic understanding of the DDI between fibrates and statins and postulate testable molecular hypotheses for these DDIs.

258 MUSCLE CREATINE DEPLETION EXACERBATES CERIVASTATIN-MEDIATED TOXICITY.

D. F. Wells, C. M. Rohde, L. A. Egnash, L. C. Robosky, M. L. Manning, S. A. Roys, M. D. Reily and D. G. Robertson. *Pfizer, Ann Arbor, MI.*

One clinically noted side effect of statin therapy is an adverse effect on muscle, ranging from aches and weakness to rhabdomyolysis. In an effort to discover new biomarkers of myotoxicity, a metabonomics evaluation of statin-mediated myotoxicity was conducted. Female Sprague-Dawley rats (n=5-6/gp) were given daily oral

doses of 0, 0.03, 0.1, 0.3, and 1 mg/kg cerivastatin (CVA) for 14 consecutive days. On Day 15, rats given 1 mg/kg CVA exhibited increased serum creatine kinase (CK) and transaminase levels as well as liver and muscle histopathology, primarily in Type 2 (fast-twitch) muscles. Correspondingly, urinary creatine levels increased while creatinine levels decreased. As creatine plays a key role in energy utilization in Type 2 muscles, we investigated whether CVA was affecting muscle creatine levels. In a separate study, rats (n=6/gp) were fed Certified Rodent Diet 5002 (5002), a 1% β -guanidinopropionic acid (β -GPA)-supplemented diet, or a 2 % creatine-supplemented diet and then dosed orally with 0 or 1 mg/kg CVA daily for 14 days. β -GPA is a creatine analog that is commercially available as a health-food supplement and competes with creatine for uptake into muscle, thus depleting muscle creatine levels. Dietary creatine supplementation did not ameliorate the myotoxicity associated with CVA treatment. However, dietary β -GPA supplementation exacerbated CVA toxicity (moribundity) relative to rats administered CVA alone, although the toxicity was not necessarily via muscle or liver damage. This effect may in part be due to an increase CVA exposure levels (2-fold) in the presence of β -GPA. Muscle extracts of rats fed 5002 and dosed with CVA exhibited a marked decrease in muscle creatine content as did animals treated with β -GPA. These data suggest that CVA affects muscle creatine levels and that decreases in tissue creatine exacerbates CVA toxicity, but depletion of creatine in itself is not sufficient to induce muscle toxicity.

259 AIN-93G DIET EXACERBATES CERIVASTATIN-MEDIATED MYOTOXICITY.

C. M. Rohde, D. F. Wells, L. C. Robosky, L. A. Egnash, M. L. Manning, S. A. Roys, M. D. Reily and D. G. Robertson. *Metabonomic Evaluation Group, Pfizer, Inc., Ann Arbor, MI.*

While looking for new biomarkers of cerivastatin (CVA)-mediated myotoxicity, a novel dietary interaction was observed in female rats being fed AIN-93G, a defined, casein-based diet, and orally dosed with 0 or 1 mg/kg/day CVA. Markers of muscle and liver toxicity were markedly increased relative to effects seen in previous study where rats were given 1 mg/kg CVA and fed Certified Rodent Diet 5002. The AIN-93G study had to be terminated two days early due to moribundity and mortality, with only 3 rats surviving to Day 13. To confirm this dietary interaction, a second study was performed. Rats (n=6/gp) were fed 5002 or AIN-93G and orally dosed with 0 or 1 mg/kg CVA once daily for 11 days. All rats fed 5002 and dosed with CVA survived to Day 11. Except for one rat, all the animals in this group (5/6) showed no indications of CVA-mediated toxicity. One rat (1/6) had high serum creatine kinase (CK) and transaminase levels as well as signs of minimal muscle necrosis. In comparison, rats that received AIN-93G and CVA had markedly increased clinical and clinical pathologic evidence of toxicity. One rat (1/6) in this group died just prior to study termination on Day 11. All of the surviving rats in this group exhibited signs of CVA-mediated myotoxicity, including maximal serum CK levels (32000 U/L), transaminase levels and early indications of muscle necrosis. The markedly increased severity of CVA-induced myotoxicity could not be explained by an effect of AIN-93G on CVA exposure levels, as exposures (AUC) were comparable in rats fed the two diets. In conclusion, the AIN-93G diet exacerbated CVA-mediated myotoxicity by a mechanism that remains to be elucidated.

260 INVESTIGATION OF THE EFFECTS OF A LIPOPHILIC ANTI-INFLAMMATORY AGENT ON BILE ACID TRANSPORTER PROTEIN FUNCTION.

P. Duffy, J. Hopwood, C. Summers, H. Powell and E. Pognan. *Global Safety Assessment, AstraZeneca, Macclesfield, Cheshire, United Kingdom.*

Several molecules affect bile acid excretion patterns *in vivo* however the mechanisms by which these effects are mediated are not fully understood. We investigated these mechanisms using a lipophilic anti-inflammatory compound (logP=3.29) from a series of molecules that we have shown to modify biliary excretion patterns in the rat. We have investigated the effects of the compound on bile acid transporter biology *in vitro* as a possible explanation for the observed *in vivo* effects. We have used *in vitro* rat hepatocyte sandwich cultures to study the effects of the compound on the canalicular efflux of cholesteryl lysyl fluorescein (CLF) by the bile salt efflux protein (Bsep), the multidrug resistance protein 2 (Mrp2)-mediated canalicular efflux of carboxydichlorofluorescein (CDF), and the basolateral uptake of [^{3} H]-taurocholate via the sodium taurocholate co-transporter protein (Ntcp). The compound decreased the efflux of CLF by Bsep, increased the Mrp2-mediated efflux of CDF and slightly increased the uptake of [^{3} H]-taurocholate via Ntcp. Further studies, using immunocytochemistry techniques, indicated that transporter expression and the distribution of Bsep and Mrp2 in hepatocyte cultures was also modified following exposure. These data suggest that subtle effects on hepatocyte transporter biology may underpin the observed modification in bile acid excretion patterns seen with other compounds in this series *in vivo*.

261 BERBERINE AND BERBAMINE MODULATE P-GLYCOPROTEIN.

Y. Fan¹ and R. R. Proteau^{1,2}. ¹Pharmaceutical Sciences, Oregon State University, Corvallis, OR and ²Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.

Oregon Grape Root (OGR), *Mahonia aquifolia*, is native to the west coast of North America, and is also known by the names Mountain Grape and Holly-Leaved Barberry. Berberine as an alkaloid found in the OGR as well as berbamine which have been reported to have significant anticancer activity. The hypothesis of our study is that berberine and berbamine can modulate P-glycoprotein (P-gp), thereby, altering the bioavailability of drugs that are substrates of P-gp, such as cyclosporine A (CSA) and digoxin using Caco-2 and MDCKII-MDR1 drug transport models. Cytotoxicity was evaluated by measuring LDH levels and by assessing mitochondrial function using the MTT assay. Cells were exposed to various concentrations of OGR extract, berberine or berbamine for 0 - 4 hr. There were no significant increases in LDH leakage or decreases in MTT reduction for OGR extract at 4 h. However, there was a significant increase in LDH leakage and decrease in MTT reduction as early as 2 h for 300 μ M berbamine and 4 h for 150 μ M berberine (p<0.05). [^{3} H]-CSA/[^{3} H]-digoxin (0.5 μ M) transport experiments were performed with and without co-exposure of OGR extract, berberine or berbamine. OGR extract inhibited the efflux of CSA and digoxin in a dose-dependent manner with a significant effect at 0.1 mg/ml. Ten μ M berberine and 30 μ M berbamine significantly reduced the apparent permeability coefficient's (P_{app}) efflux of CSA ($3.31 \pm 0.32 \times 10^{-6}$ to $1.79 \pm 0.40 \times 10^{-6}$ cm/sec and $2.18 \pm 0.46 \times 10^{-6}$ cm/sec for berberine and berbamine, respectively), while there was no measurable effect of berberine with digoxin. In the MDCKII-MDR1 cells, 10 μ M berberine and 30 μ M berbamine were capable of inhibiting the efflux of CSA (from $1.31 \pm 0.19 \times 10^{-5}$ to $5.34 \pm 0.16 \times 10^{-6}$ cm/sec and $2.55 \pm 0.11 \times 10^{-6}$ cm/sec, respectively) and digoxin (from $3.30 \pm 0.13 \times 10^{-6}$ to $1.56 \pm 0.43 \times 10^{-6}$ cm/sec and $1.71 \pm 0.66 \times 10^{-6}$ cm/sec, respectively). Thus, these data suggest that OGR extract, berberine and berbamine can inhibit P-gp thereby increasing the bioavailability of drugs that are substrates of P-gp.

262 COMBINATION TOXICITY STUDIES: SCIENTIFIC NECESSITY OR A REGULATORY REQUIREMENT? A CASE STUDY WITH DARUNAVIR-BOOSTED RITONAVIR.

A. Raoof¹, J. Verbeeck¹, S. Lachau-Durand¹, K. Steemans², M. Bouche² and B. Willems². ¹Tibotec, Mechelen, Belgium and ²Johnson & Johnson Pharmaceutical Research and Development, Beerse, Belgium. Sponsor: W. Coussement.

The need for nonclinical safety evaluation for combination therapy of non co-formulated products is unclear. The treatment of HIV-infection, unlike many other diseases, necessitates multi-drug therapy to prevent viral replication. Darunavir is a protease inhibitor used for the treatment of HIV-infection and like most drugs in its class it is used in the clinic in-combination with ritonavir to increase its oral bioavailability. In order to assess the pharmacokinetics and the safety of each molecular entity alone and in-combination, two 6-month repeated dose toxicity studies were conducted in rats. Animals were dosed orally with darunavir alone at 20, 100 and 500 mg/kg and in a separate study with darunavir/ritonavir at 0/75, 20/50, 100/50, 500/75 and 1000/75 mg/kg. Observations were made for clinical signs, body weight, food consumption, blood and urine chemistry and animals were subjected to necropsy and histopathological examination. Blood samples were taken for toxicokinetic evaluation. Systemic exposure to darunavir decreased with repeated administration due to metabolic autoinduction. The enhancement of systemic exposure of darunavir by ritonavir was limited. Exposure to ritonavir was decreased in rats when administered with darunavir. The target systems identified with darunavir were the hematopoietic system, the blood coagulation system, liver and thyroid. No new target organs of toxicity were identified when darunavir was combined with ritonavir. To conclude, combination toxicology studies allow for the assessment of nonclinical safety of drugs clinically used in-combination and thus fulfill the recommendations of regulatory authorities by providing a comprehensive data-package for drug approval. However, the scientific value of such studies can be limited especially for compounds that exhibit a different pharmacokinetic interaction in animals relative to humans.

263 ADAPTIVE RENAL WEIGHT CHANGES IN DOGS FOLLOWING IV ADMINISTRATION OF THE NOVEL NEURO-PROTECTANT DRUG-NEU2000-K.

D. Dandekar¹, L. Sheets¹, W. Bomann¹, L. Elcock², D. Phipps¹, K. Willard¹ and P. McKinney¹. ¹Toxicology, Bayer CropScience, Stilwell, KS, KS and ²Pathology Associates, Kansas City, MO.

Increase in renal weights in pre-clinical toxicity studies should be scrutinized carefully for accurately defining the toxicity of the drug.

Intravenous (slow bolus) administration of Neu2000-K for 28-days at 25, 50, 125 mg/kg/day in Beagle dogs, resulted in increases in absolute and relative weights of kidney.

The parameters examined to identify the plausible cause of increased renal weights following Neu2000-K administration were: serum chemistry parameters, micropathology, special histochemical staining of kidney sections (lipofuscin and Prussian blue) and transmission electron microscopy (EM).

Microscopic pathology assessment revealed test-article related findings (brown pigmentation of renal tubular epithelial cells, minimal to moderate severity) in the kidney of dogs at 50 and 125 mg/kg/day, no microscopic lesions were observed at 25 mg/kg/day. No alterations were observed in any of the serum chemistry parameters determined during the study. The results of special staining histology procedures revealed that the brown pigment in the proximal tubular epithelium was due to the accumulation of iron positive material (interpreted as hemosiderin, a metabolic product of hemoglobin break-down). Transmission EM evaluation corroborated the findings of special staining and confirmed that the pigment present in the renal tubule was consistent with hemosiderin. In addition, EM evaluation also revealed occasional presence of small lipid droplets which were interpreted as lipofuscin (residual bodies). Based on these observations, increase in renal weights at 50 and 125 mg/kg may be due to pigment/droplet accumulation in the proximal tubular epithelium and the numerical increase in kidney weight, at the 25 mg/kg/day is an adaptive response of the renal tissue following repeated IV dosing with the test-article. Overall, observed increased renal weights at all the dose levels did not induce any alterations in serum chemistry parameters indicating that, the renal function was not affected.

264 HEMATOLOGICAL EFFECTS OF PLURONIC F127 AND HYDROXYPROPYL METHYLCELLULOSE UTILIZED AS DELIVERY VEHICLES FOR HEMATOPOIETIC GROWTH FACTORS.

J. M. Blonder, S. Taylor, B. Lin, E. Verderber, C. Balliu, Y. Jiao, C. Coeshott and G. J. Rosenthal. *RxKinetics, Inc., Boulder, CO.*

Pluronic and cellulosic polymers have been utilized experimentally as injectable drug delivery vehicles to provide a single dose format for pharmaceuticals that typically require multiple dosing to be pharmacologically active. A combination of Pluronic F127 and hydroxypropyl methylcellulose (HPMC) polymers have been used to deliver the hematopoietic growth factors, fms-like tyrosine kinase 3 ligand (Flt3L) and granulocyte colony stimulating factor (G-CSF), so that efficacy was achieved after single dose administration to mice. The goal of the current study was to evaluate the activity of F127 and HPMC vehicles, administered in combination or alone, on hematological parameters. In this regard, potential acute adverse actions or contribution to expected drug effect by these vehicles would be addressed. Mice received a single subcutaneous injection of F127/HPMC, F127, or HPMC vehicles or F127/HPMC + G-CSF and hematological parameters were assessed from 1 to 5 days after injection. F127/HPMC + G-CSF increased neutrophil numbers while decreasing lymphocyte and bone marrow nucleated cell numbers. In addition, the numbers of splenic nucleated cells were increased, a common effect following high dose G-CSF in mice. These effects differed significantly ($p < 0.05$) from non-injected control mice or mice injected with buffer or F127/HPMC vehicles. A single administration of F127 and HPMC vehicles, alone or in various combinations, did not significantly alter numbers of neutrophils, lymphocytes, spleen cells, or bone marrow cells compared to controls. Furthermore, F127 and HPMC vehicles neither significantly affected body weight nor numbers of red blood cells. Therefore, F127 and HPMC did not induce acute adverse effects on these hematological endpoints nor generate drug-related responses. Assessment of additional toxicological and hematopoietic endpoints, including hematopoietic stem cell numbers and function, would allow further critical evaluation of the safety profile of these polymers.

265 QUANTITATIVE ANALYSIS OF OPIOID DRUGS AND PEPTIDES IN HUMAN PLASMA BY MALDI-LINEAR ION TRAP MASS SPECTROMETRY (LITMS).

S. Pk¹, S. Ramagiri^{2,1}, H. Kosanam³ and R. K.c¹. ¹Chemistry, Osmania University, Hyderabad, Andhra Pradesh, India, ²Pharmaceutical Sciences, University of Tennessee, Memphis, TN and ³Chemistry, University of Memphis, Memphis, TN.

Rapid quantitative analysis of 5 opioid drugs, morphine, codeine, oxycodone, fentanyl, hydromorphone and 4 opioid peptides, Met-enkephalin, Leu-enkephalin, alpha neo endorphins and beta neoendorphin in plasma was performed by MALDI-Linear ion Trap Mass Spectrometry (LITMS). Identification of opioid drugs and peptides was traditionally performed by gas chromatography-mass spectrometry (GC/MS) and liquid chromatography-mass spectrometry (LC/MS) techniques. However, these processes require chromatographic separation followed by mass spectrometry identification which are tedious and time consuming. This

paper describes a quick quantification method using meso-tetrakis (pentafluorophenyl) porphyrin as MALDI matrix for opioid drugs and α -cyano-4-hydroxycinnamic acid (CHCA) and dihydroxy benzoic acid (DHB) for peptides. Porphyrin (MW 974.57) was identified as the preferred matrix for small molecules due to a lack of interfering matrix peaks at lower mass range (m/z 100-700). Spiked plasma samples were processed by solid phase extraction (SPE) using Bond Elute Certify cartridge. Validation of the methodology was demonstrated for each compound in plasma by selective reaction monitoring method. Quantitative analyses were performed through the use of a deuterium labelled analog of each analyte as an internal standard. Linearity was observed for the analysis of 5 opioid drugs (5-1000 ng/ml) and for peptides (10-1000 ng/ml) in plasma with a limit of detection ranging from 1-4 ng/ml. In general, the observed concentrations showed good linearity and reproducibility with coefficients of variation of within 15%. This is the first time MALDI-Ion Trap MS has been reported as a potential means for quantification of opioid drugs and peptides. We conclude that MALDI-Ion Trap MS improved sensitivity, speed and throughput for complex mixture analysis of opioid drugs and peptides in human plasma and is ideally suited as a reliable and complementary technique to GC/MS and LC/MS.

266 A MODEL OF POST-OPERATIVE AND OPIOIDS INDUCED ILEUS FOR ASSESSMENT OF GASTRO INTESTINAL TRANSIT IN RATS.

A. Kirouac, S. Mason and C. Banks. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.*

Post-operative ileus (POI) is a transient impairment of bowel motility. The pathophysiology of POI is multifactorial and causes include, but are not limited to, surgical manipulation of the bowel, post-surgical inflammation and a generalized stress response. The use of postoperative opioids also appears to contribute to ileus. In order to better comprehend the invasive association of abdominal surgery and use of opioids with POI, this study was conducted to investigate the effects of exposure of abdominal contents to manual handling (specifically the cecum) and of exposure to morphine. POI was quantified by measurement of gastric emptying through dilution of a phenol red dye. A first group of Sprague-Dawley rats was anesthetized with isoflurane gas and the abdomen opened. Half of the animals had the cecum exteriorized and gently patted for 1 minute, while the second half were exposed to surgery, but with no cecum manipulation. Another group of rats was administered a subcutaneous dose of either 1 or 4 mg/kg of morphine. A group of rats was administered the phenol red alone and served as a control. Phenol red served as a gastrointestinal marker and was administered orally post-surgery or post morphine injection, and was assayed colorimetrically 30 minutes post administration. Increases in stomach content of phenol red in cecum-manipulated and non-manipulated surgical groups were approximately 19% and 31%, respectively, when compared to control group (absorbance of 1.9 and 2.1, respectively vs 1.6 for control). The stomach content of phenol red in the cecum-manipulated group was approximately 9.5% lower than the non-manipulated group. Exposure to morphine alone significantly reduced the stomach motility and equivalent increases of approximately 88% in stomach content were seen at both dose levels (absorbance of 3.0). These responses confirm that POI is a response to surgery and administration of opioids and its magnitude is not unilaterally dependent on the degree of surgical manipulation or dose dependent on the exposure of opioids.

267 TRANSPORT KINETICS OF THENORPHINE INTO RAT BRAIN BY THE BLOOD-BRAIN BARRIER.

Y. Guan¹, H. Qu¹, B. Yuan¹ and W. Zheng². ¹Beijing Institute of Pharmacology and Toxicology, Beijing, China and ²Purdue University, West Lafayette, IN.

Thenorphine is a newly developed partial agonist of μ -opioid receptor. Recent pharmacological studies have shown that the drug may be of a great potential for treatment of opioids addiction in clinics. However, few pharmacokinetic and toxicokinetic studies have been performed to elucidate brain transport properties of thenorphine. In the current study, we used an in situ brain perfusion technique coupled with the capillary depletion method to investigate the transport kinetics of thenorphine into rat brain. Wistar rats of both sexes were divided into 3 dosage groups, each of which was perfused with 12.5, 25, and 50 μ g/mL of thenorphine, respectively, for 2, 5, 8, or 10 min. At the end of perfusion, the brain was harvested and homogenized, and the cerebrocapillary was removed. The concentrations of thenorphine in the brain parenchyma were then extracted and analyzed by HPLC. Data showed that thenorphine could be detected in brain parenchymal fractions, suggesting the capability of the drug in passing across the blood-brain barrier. Concentrations of thenorphine in brain parenchyma increased with the perfusion time and were positively associated with thenorphine concentrations in the perfusate. The influx transfer coefficient (K_{in}) values for thenorphine at three perfusion concentrations were 0.162, 0.207 and 0.205 mL/min/g, respectively. Our results demonstrate that thenorphine can pass across the blood-brain barrier to reach its brain targets. Since the influx values does not change with the increase of the

thenorphine concentration in the perfusate, the transport of thenorphine across the blood-brain barrier appears to be rate-limited by yet-unknown mechanism(s), but not likely a passive diffusion. These data may help better design the drug for treatment of opioid addiction.

268 CORRELATION OF RENAL TOXICITY OF A NOVEL ANTI-INFLAMMATORY COMPOUND IN CYNOMOLGUS MONKEYS WITH PRIMARY CULTURES OF KIDNEY PROXIMAL TUBULAR CELLS AND TRANSFECTED CELL LINES.

H. Cai¹, K. Datta², A. Agrawal¹, D. Putt³, M. Hashim⁴, A. Reddy¹, R. Guzman², L. H. Lash³, J. Brodfuehrer¹ and N. Surendran¹. ¹Pfizer Global R&D, Ann Arbor, MI, ²DSRD, Pfizer Global R&D, Ann Arbor, MI, ³Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI and ⁴ADME Biology, Research Technology Centre, Boston, MA.

PF1, an exploratory drug candidate, demonstrated nephrotoxicity at the lowest dose of 50 mg/kg, QD for 14 days in cynomolgus monkeys. In the mid and high dose groups (300 and 750 mg/kg, QD) monkeys were euthanized after 7 days of dosing due to significant clinical signs and indication of renal failure detected by increased serum creatinine level. In this study, the observed toxicity was found to be qualitatively comparable to nephrotoxicity observed with the two previous drug candidates (PF2 and PF3). Based on the severity of nephrotoxicity, PF1 ranked between the other two compounds: PF2 induced mortality at all doses (up to 1000 mg/kg, BID) from 3 to 6 days of dosing and PF3 elicited mild renal toxicity at all doses (up to 2000 mg/kg, QD). Primary human and monkey renal proximal tubular cell cultures with functional drug metabolizing enzymes and transporters were developed and evaluated as an in vitro tool to predict nephrotoxicity. A positive correlation between in vitro model and vivo toxicity findings in monkeys was established using LDH-release as the toxicity marker. Based on these results, several related compounds were screened in hOAT1 and hOAT3 transfected cell lines to evaluate their interaction potential with these transporters. PF2 was a strong hOAT3 substrate with an IC₅₀ of 18 μ M in this in vitro model. This presentation will discuss the results of this study and highlight the potential role of the organic anion uptake transporters in the observed renal toxicities of these compounds.

269 AN ANIMAL MODEL FOR SELECTION OF CETP INHIBITORS LACKING BLOOD PRESSURE CHANGES BASED ON EXPERIENCE WITH TORCETRAPIB.

A. Benardeau, E. Niesor, J. Mizrahi, O. Kuhlmann, D. Callend and L. Mueller. *Toxicology, F. Hoffmann-La Roche Ltd., Basel, Switzerland.* Sponsor: M. Stephan-Gueldner.

Following the very successful control of low density lipoproteins in dyslipidemia with HMG CoA reductase inhibitors ("statins"), the next step in therapeutic intervention in this area is considered to be elevation of HDL cholesterol, the "good cholesterol". Inhibition of the cholesteryl ester transfer protein (CETP) is considered a promising target to achieve this goal and the compound torcetrapib is in late stage clinical trials. However, torcetrapib has been reported to increase blood pressure in man. This finding triggered concerns that this may be a target-associated finding and would consequently pose a toxicity issue for other CETP inhibitors. Hence, an animal model was designed to investigate the blood pressure changes observed in man with torcetrapib. Mean arterial (MAP), systolic arterial (SAP) and diastolic arterial (DAP) pressures, and heart rate (HR) were measured by telemetry in normotensive and spontaneously hypertensive (SH) rats treated with CETP inhibitors from different chemical classes (Torcetrapib 10, 40, 80 mg/kg/day; RO4607381 (JTT-705) 100, 300, 500 mg/kg/day). In SH rats, torcetrapib dose-dependently increased MAP, SAP, and DAP. Torcetrapib induced significant MAP increases (approx. +7 to +11 mmHg) over the 24h recording period, which were greater and more persistent in hypertensive than in normotensive rats. In both cases HR did not change significantly. Interestingly, the other CETP inhibitor RO4607381 (JTT-705) neither changed BP nor HR. These results show that SH rats are a relevant model for assessing the potential for CETP-inhibitor-related BP changes and suggest that torcetrapib-induced hypertensive effects do not appear to be a class effect of CETP inhibition; may not be observed with other CETP inhibitors and is not linked to CETP inhibition (since rats do not express CETP).

270 INTRAVENOUS CARDIOVASCULAR SAFETY PHARMACOLOGY STUDY IN DOGS ON A PDE4 INHIBITOR (TOFIMILAST).

D. J. Ball¹, C. Hassler², M. Brooker², M. Stonerook² and R. Hamlin³. ¹Drug Safety Research & Development, Pfizer, Groton, CT, ²Bartelle Memorial Institute, Columbus, OH and ³The Ohio State University, Columbus, OH.

Tofimilast is PDE4 inhibitor that is being studied for the treatment of asthma/COPD. In this study, 12 dogs received a single 6 hour IV infusion of tofimilast, 4 dogs received vehicle only and 4 dogs were administered norepinephrine

over a 5 hour IV infusion and served as the positive control. Dogs were anesthetized with morphine/chloralose and were mechanically ventilated with room air so that arterial blood gases remained within physiological limits. Dogs were instrumented to monitor physiological variables of cardiovascular function. Markers of myocardial injury were measured from samples collected at the coronary sinus and peripheral venous blood. Myocardial oxygen consumption were either measured or calculated from intravascular pressures and echocardiographic images. Coronary arterial to coronary sinus oxygen differences were measured to determine oxygen demand. Systemic exposure of tofimilast was measured from plasma samples collected during the study. Gross examination and histopathologic evaluation of the heart was performed on each dog in the study.

There were no gender differences in exposure to tofimilast. Control and low dose dogs did not exhibit an imbalance in myocardial oxygen consumption, myocardial injury or signs of cardiotoxicity. High dose tofimilast dogs had increases in myocardial oxygen consumption indices without evidence of cardiotoxicity. There were no drug-related histopathological changes in the hearts of the tofimilast treated dogs. Norepinephrine exposed dogs exhibited a greater increase in myocardial oxygen consumption with corresponding increases in potassium, troponin I and T in both coronary sinus and peripheral venous blood. Three of 4 norepinephrine exposed dogs had slight to mild degeneration of the subendomyocardial and papillary muscles of the left ventricle and septum.

These data demonstrated that the hemodynamic effects of tofimilast when administered IV are mild and related to the pharmacology of the test article.

271 ARIPIRAZOLE: 18-MONTH ORAL INVESTIGATIVE RETINAL STUDY IN FEMALE RATS.

W. M. Peden, J. W. Rhodes, T. P. Sanderson, B. E. Schilling and M. A. Dominick. *Drug Safety Evaluation, Bristol-Myers Squibb Co., Mt. Vernon, IN.*

The study investigated whether the increased incidence and severity of retinal degeneration seen in albino Sprague-Dawley (SD) rats treated with aripiprazole (Abilify®), a dopamine D2 partial agonist marketed for treatment of schizophrenia and related disorders) was a consequence of increased light exposure or a direct effect of aripiprazole. Aripiprazole was administered orally at 0 or 60 mg/kg/day (75 rats/group) to Long-Evans (LE) and SD female rats (strains with and without photoprotective ocular melanin, respectively) for up to 18 months followed by a 3-month recovery period. Study endpoints included clinical observations; electroretinogram (ERG) measurements; and histopathologic, morphometric, and ultrastructural retinal evaluations. Predose hyperactivity was seen in drug-treated SD and LE rats after 3 months and persisted to the end of the study. Time-dependent, light-induced retinal injury was noted in treated SD rats and included ultrastructural findings of condensed photoreceptor nuclei in outer nuclear layer (ONL) and vesiculated photoreceptor disk membranes in the outer segments at 3 months, qualitative/quantitative microscopic findings of decreased ONL thickness beginning centrally at 6 months, and progressive degeneration of central and peripheral retina through the recovery period. Progressive ERG abnormalities (decreased a/b-wave amplitude and increased implicit times) were also noted in treated SD rats beginning at 12 months. Treated LE rats with systemic drug exposure comparable to those in treated albino SD rats had no evidence of light-induced retinal injury, demonstrating the photoprotective effect of ocular melanin. These data indicate the exacerbation of light-induced retinal degeneration in treated albino SD rats was likely a consequence of pharmacologically mediated hyperactivity during the animal room light phase, resulting in increased light exposure, rather than a direct effect of aripiprazole on the retina. Importantly, this finding of retinal degeneration in treated SD rats has no established relevance to humans.

272 THE USE OF DIETARY ADMINISTRATION FOR TOXICITY EVALUATION OF THE NOVEL ANTI-HIV DRUG DARUNAVIR.

A. Raoof¹, J. Verbeeck¹, S. Lachau-Durand¹, K. Steemans², M. Bouche² and B. Willems². ¹Tibotec, Mechelen, Belgium and ²Johnson & Johnson Pharmaceutical Research and Development, Beerse, Belgium. Sponsor: W. Coussement.

Darunavir (Prezista TM) is a novel protease inhibitor that is used for the treatment of HIV-infected patients. It has a limited solubility and a high metabolic first-pass effect following oral administration in animals and humans. These characteristics lead to low drug bioavailability and dosing limitations when assessing safety in non-clinical species. In order to increase systemic exposure to darunavir and evaluate its safety profile at high doses, a repeated-dose toxicity study was performed via dietary administration in rats. The results obtained were compared to findings observed with gavage administration. Rats were treated daily with darunavir via oral gavage in polyethylene glycol (vehicle) at 20, 100 and 500 mg/kg (n= 10/sex/group) and in a separate study via dietary admixture at 260, 1040 and 2600 mg/kg (n= 20/sex/group), for up to 3 months. Observations were made for clinical signs, body weight, food consumption, blood and urine biochemistry and animals were sub-

jected to necropsy and histopathological examination. Blood samples were also taken for toxicokinetic evaluation. The toxicity profile of darunavir was similar following both routes of administration. Target organs identified were the hematopoietic system (increase in red blood cell turnover), the coagulation system (prolongation in clotting time), liver and the thyroid (cellular hypertrophy as a result of enzyme induction). Systemic exposure to darunavir was similar following both routes of administration. Dietary administration did not increase darunavir exposure in spite of the higher daily doses given to animals relative to oral gavage. This indicates that dietary administration has a limited use in enhancing systemic exposure and assessing the safety of drugs such as darunavir, as high metabolic clearance remains the main limiting factor preventing the achievement of high plasma levels regardless of the method of drug administration.

273 EFFECTS OF A LONG-ACTING GROWTH HORMONE RELEASING FACTOR ANALOGUE, CJC-1295, ON MALE FERTILITY.

V. Iordanova¹, S. Wen¹, E. M. Lewis², S. Morseth³ and J. Castaigne¹.
¹ConjuChem Biotechnologies, Inc., Montréal, QC, Canada, ²Charles River Laboratories Preclinical Services, Horsham, PA and ³Morseth Consulting, LLC, Jefferson, MD.

CJC-1295 is a synthetic analogue of growth hormone releasing factor (GRF) which stimulates the pulsatile release of growth hormone and the secretion of insulin-like growth factor 1 (IGF-1). By applying the Drug Affinity Complex (DACTM) technology to GRF, the peptide selectively and covalently binds to circulating albumin after subcutaneous (SC) administration, thus prolonging its $t_{1/2}$ from 10-12 min to approximately one week in humans. The fertility and general reproduction toxicity effects of CJC-1295 were evaluated in male CD rats (25/group) following every other day (q2d) SC administration at dose levels of 0, 0.5, 3, or 16 mg/kg/q2d. Treatment of the male rats began 28 days before cohabitation with untreated female rats and continued for a total of 49-50 days. There were no CJC-1295-related effects on survival. Clinical findings were limited to injection site irritation at 16 mg/kg/q2d, and increased body weights or body weight gain, and increased food consumption at ≥ 3 mg/kg/q2d. Increases in cauda epididymal sperm count and sperm density, and reductions in the absolute and relative weights of the seminal vesicles were noted at ≥ 3 mg/kg/q2d at the end of the treatment and recovery periods. Irrespective of the noted changes, treatment with CJC-1295 did not affect any mating or fertility parameters and the embryonic viability was not affected up to the highest dosage tested. Thus, the No-Observed-Adverse-Effect Level (NOAEL) for general and male reproductive toxicity was determined to be ≥ 16 mg/kg/q2d of CJC-1295.

274 TC-2696-12: PRE-CLINICAL SAFETY ASSESSMENT OF A SELECTIVE $\alpha 4\beta 2$ NEURONAL NICOTINIC RECEPTOR AGONIST.

V. M. Traina and J. K. Wamsley. *Toxicology, Targacept Pharmaceuticals, Winston-Salem, NC.*

TC-2696-12 is currently under development in Phase I clinical trials for the treatment of acute post-operative pain. To support human safety, preclinical toxicology studies were conducted: in mice, rats, and dogs in acute oral and intravenous studies; in rats and dogs in 14-day range finding and in 28-day definitive subacute studies; in 3 genotoxicity bioassays; and in safety pharmacology studies evaluating 5 functional tests. The above assays provide sufficient support for the compound's further development:

- Absence of GI toxicity after repeated administration in toxicology studies
- Non specific functional changes in safety pharmacology studies
- No major pathologic findings in definitive toxicity studies at high dosages and blood levels
- Absence of genotoxicity
- Favorable TK profile in animals.

In safety-evaluation studies, animals tolerated high oral doses and the majority of the side effects were an extension of the compound's pharmacologic action: in the rat: ataxia, hyperactivity, rapid respiration, and circling; and in the dog: tremors and emesis, which is a commonly observed finding in the dog model with nicotinic compounds.

The only functional changes were:

- Increased alkaline phosphates or alanine aminotransferase and liver weights in rats, primarily at the high oral doses of 50 mg/kg and greater, but without definitive histopathologic alterations in the 14 - and 28 - day studies
- Increased blood pressure and bradycardia in dogs at single oral doses of 3 mg/kg and higher in safety pharmacology studies, but not observed when evaluated in the repeat dose subacute 14 - and 28 - day studies. There were no changes in ocular, ECG's, gross necropsy, or histopathology at any dose level in the definitive 28 - day studies.

TK evaluation showed rapid absorption; peak plasma levels at about one hour and dose proportional C_{max} and AUC plasma levels. Clinical Phase I studies are currently ongoing and TC-2696-12 is well tolerated at single doses up to and including 150 mg and at 10 day multiple dosing at 25 and 50 mg.

275 POTENT ANTI-INFLAMMATORY EFFECTS OF NOVEL QUINOLINEDIONE DERIVATIVES, OQ1 AND OQ21, MEDIATED BY DUAL INHIBITION OF INOS AND COX-2.

J. Chung, K. Lim, S. Lee, O. Bae, J. Noh and S. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Induction of nitric oxide synthase and cyclooxygenase-2 (COX-2) and resultant increased productions NO and prostaglandins have been suggested as the key components in inflammatory processes, contributing to progression and maintenance of various inflammatory diseases. Dual inhibitory effects against nitric oxide (NO) synthesis and inflammatory prostaglandin, prostaglandin E₂ (PGE₂) production by novel quinolinedione derivatives, 6-(4-fluorophenyl)-amino-5,8-quinolinedione (OQ1) and 6-(2,3,4-trifluorophenyl)-amino-5,8-quinolinedione (OQ21) were found in lipopolysaccharide (LPS)-stimulated macrophage cell line, RAW264.7. NO production was inhibited by OQ1 and OQ21 by affecting the expression of inducible nitric oxide synthase (iNOS) as well as iNOS activity itself. LPS-induced expression of iNOS was down-regulated by OQ1 and OQ21 in concentration-dependent manners as determined by western blot analysis of iNOS. Down regulation of iNOS was mediated by the blockade of NF κ B activation pathway as shown by attenuation of LPS-induced I κ B degradation in western blot analysis. De novo synthesis and cellular accumulation of PGE₂ were also suppressed in a concentration dependent manner by OQ1 and OQ21. Western blot analysis and enzymatic assay results suggested that enzymatic activity was inhibited by OQ1 and OQ21 without any suppressive effect on COX-2 expression. Consistent with these in vitro anti-inflammatory effects, OQ1 showed significant anti-inflammatory effects in in vivo topical inflammation model, 12-O-tetradecanoylphorbol 13-acetate (TPA)-induced mouse ear edema. OQ1 derivatives with dual inhibitory effects against COX-2 activity and iNOS expression will provide a powerful therapeutic tool for the cure of chronic inflammatory diseases, which has been resistant to conventional drug therapies.

276 DETERMINATION OF PHOSPHOLIPIDOSIS IN HUMAN CELL CULTURES USING A FLUORESCENTLY TAGGED PHOSPHOLIPID PROBE.

S. P. Sawant, K. Abele, M. Sonee, P. Lord and M. McMillian. *Mechanistic Toxicology, Johnson and Johnson PRD, L. L. C., Raritan, NJ.*

Several cationic amphiphilic drugs (CADs) cause local or systemic phospholipidosis after exposure in preclinical species and humans. Phospholipidosis is characterized by the accumulation of CADs, phospholipids, and concentric lamellar bodies within cells. The objective of this study was to develop a human white blood cell line model for detecting phospholipidosis. This is particularly important since most of the phospholipid accumulation in humans is observed in the lymphatic tissues and immune cells, and these cells are routinely monitored. To select a suitable cell type, we examined the phospholipidosis-detection sensitivity of three human cell lines, Jurkat (human T-lymphocyte-derived cell line), THP-1 (human monocyte-derived cell line), and C3 (microglial) cells, with four CADs (amiodorone, amitriptyline, perhexiline, and fluoxetine) as phospholipidosis inducers and a negative control (tetracycline). We used 96-well microplate cell-culture method for detecting phospholipidosis, using a fluorescently tagged phospholipid, N-(7-nitrobenz-2-oxa-1, 3-diazol-4-yl)-1,2-dihexadecanoyl-sn-glycero-3-phosphoethanolamine (NBD-PE). Drug concentrations were used in a range from 1 to 100 μ M. After 24 h incubations, NBD-PE uptake was quantified in controls and treated cells. The NBD-PE fluorescence intensity was normalized to that of ATP content, used as an indicator of viable cells, to obtain the uptake of NBD-PE in the living cells. Phospholipid accumulation was observed in all the three cell lines at higher concentrations (30 and 100 μ M) of the four CADs, but due to cytotoxicity at these concentrations, these are false positive results. Interestingly, only in the THP-1 cells significant phospholipidosis (~ 2 to 5 fold) was observed at non-cytotoxic concentrations of the four drugs compared to the controls. Thus, these results indicate that the THP-1 model can be used as an in vitro screen for testing the phospholipidogenic potential of drugs and compounds on human cells.

277 CJC-1134-PC, A LONG-ACTING EXENDIN-4 ANALOGUE, IS WELL TOLERATED IN RATS AND MONKEYS FOR UP TO 28 DAYS.

S. Wen¹, T. Najarian¹, C. Papagiannis², Y. Fukushima¹, J. Woo¹ and J. Castaigne¹. ¹ConjuChem Biotechnologies, Inc., Montréal, QC, Canada and ²MPI Research, Mattawan, MI.

CJC-1134-PC is being developed for the control of Type II diabetes using ConjuChem's DACTM technology by the in vitro conjugation of modified exendin-4 peptide to recombinant human albumin (rHA). In doing so, it prolongs the $t_{1/2}$

and activity of the peptide. The toxicity of CJC-1134-PC was evaluated following subcutaneous (SC) 28-day repeat dosing at 0, 1, 5 or 25 mg/kg/day in rats (10/sex/group) and at 0, 0.4, 2 or 10 mg/kg/day in monkeys (3/sex/group), with 2 weeks recovery. All animals survived to study termination and there were no treatment-related effects on ophthalmology, coagulation, clinical chemistry or urinalysis in either species, or on ECG in monkeys. Treatment-related clinical signs were reversible in both species, including decreased activity and fecal output in rats (≥ 5 mg/kg/day), and decreased activity, hunched posture (≥ 2 mg/kg/day), and decreased fecal output (≥ 0.4 mg/kg/day) in monkeys. Transient, dose-dependent decreases in food consumption in both species correlated with decreases in body weight gain at ≥ 1 mg/kg/day in rats and body weight loss at ≥ 0.4 mg/kg/day in monkeys. Mild reversible decreases in erythrocyte counts, Hb and Hct were seen in male (≥ 2 mg/kg/day) and female (10 mg/kg/day) monkeys. Compared to controls, decreased thymus weight was noted in females (10 mg/kg/day) and decreased thymus to body weight ratio was seen in both sexes (≥ 0.4 mg/kg/day), correlating to stress-related lymphoid depletion in spleens and thymus glands, which were reversible. The $t_{1/2}$ of CJC-1134-PC was ~ 35 -67 h in rats and ~ 79 h in monkeys, which is similar to the $t_{1/2}$ of albumin of their respective species. Treatment with CJC-1134-PC produced antibodies in both species predominantly against the human albumin portion of CJC-1134-PC with lesser reactivity to the peptide portion. The NOAEL was established to be 5 mg/kg/day in rats and 2 mg/kg/day in monkeys. In conclusion, SC administration of CJC-1134-PC to rats and monkeys up to 28 days was well tolerated with expected pharmacologically-related effects.

278 KSR AS-214231 (NSC-731442) TARGET ORGAN TOXICITY AND ITS REVERSIBILITY IN CYNOMOLGUS MONKEYS FOLLOWING 14 DAYS OF CONTINUOUS INTRAVENOUS DOSING (CIV).

P. J. Tosca¹, J. Merrill¹, D. Vasconcelos¹, M. J. Ryan¹, J. D. Johnson¹, R. Zhang², D. Hill², P. Giclas³, R. Kolesnick⁴ and J. Peggins⁵. ¹Battelle, Columbus, OH, ²University of Alabama at Birmingham, Birmingham, AL, ³National Jewish Center for Immunology, Denver, CO, ⁴Memorial Sloan-Kettering Cancer Center, New York, NY and ⁵National Cancer Institute, Bethesda, MD. Sponsor: E. Glaze.

KSR AS-214231 (KSR), an antisense phosphorothioate oligonucleotide that inhibits KSR1 thereby abrogating of RAS-mediated tumorigenesis, may be useful in the treatment of pancreatic and/or lung cancer. A toxicity study using Cynomolgus monkeys was conducted to identify target organs and whether identified toxicities were reversible. Male and female Cynomolgus monkeys were dosed by CIV at 14 and 28 mg/kg/day (280 and 560 $\mu\text{g}/\text{m}^2/\text{day}$) for 14 days followed by a 14-day recovery period. Control animals were infused with vehicle (PBS). There were no drug-related clinical observations and no effects on body weight, coagulation, or clinical chemistry endpoints. Reversible hematological findings attributed to KSR included increased total white cell, neutrophil, monocyte, and/or lymphocyte counts. KSR appeared to elevate complement breakdown product Bb, indicating complement activation. KSR plasma concentrations were generally stable over the infusion period, and increased in a dose-related manner, suggesting that at the doses tested, the disposition of KSR was linear. Target organs included the kidneys, liver, and lymph nodes. Microscopic findings were generally dose-related and included accumulation of basophilic granules in renal tubular epithelium and hyperplasia of granule-bearing macrophages in liver sinusoids and lymph nodes. The granules were interpreted to be KSR. After a 14-day recovery period, all microscopic findings were still present. A no-observed effect level (NOEL) could not be determined. However, the maximum tolerated dose (MTD) was 28 mg/kg/day. (Supported by N01-CM-42200)

279 SEXUAL MATURITY AND AGE OF ANIMALS IN PRE-CLINICAL STUDIES TO SUPPORT 'FIRST IN MAN' STUDIES.

D. J. Mitchell¹ and D. M. Creasy². ¹Huntingdon Life Sciences, Eye, Suffolk, United Kingdom and ²Huntingdon Life Sciences, East Millstone, NJ.

The poster discusses the problems associated with using sexually immature animals to screen for toxicity in repeat dose preclinical pharmaceutical studies prior to first human exposure. The issues relate to the inability of assessing testicular toxicity in immature animals and the difficulties of identifying test article related changes in peripubertal animals. The age of sexual maturity for all routinely used rodent and non-rodent species is discussed but, by way of example, the poster focuses upon the complications of using sexually immature dogs. Of the species routinely used in preclinical toxicity studies, dogs and monkeys cause the most concern because these species are frequently immature or peripubertal at the end of the study. Male dogs mature anywhere between 7-12 months of age but it is not uncommon to start studies with dogs 4-6 months of age. Therefore, depending on study duration, dogs coming to necropsy at the end of the study may be immature, peripubertal, fully mature or a mixture of all three. If dogs are immature testicular toxicity cannot be

identified since there are no germ cells present. Dogs that are peripubertal cannot be distinguished from mature dogs that are undergoing spermatogenic degeneration. As small group sizes of only 3/group are routinely used it is quite likely that dogs of different maturity status will be unequally distributed in the control and treated groups. Examples will be provided to show how these confounding factors can result in generation of false positive, false negative or uninterpretable results. In accordance with guidance from the Society of Toxicologic Pathologists, it is strongly recommended that rodents be at least 10 weeks, and dogs be at least 10 months of age at the end of a study. In the case of primates, where males do not mature until >4 yrs of age, supply problems dictate that most studies are conducted with totally immature animals. It should be appreciated that adverse effects on spermatogenesis will not be detected in this age of animal.

280 A 1-MONTH TOXICITY STUDY IN DOGS TREATED WITH NAVEGLITAZAR (LY519818), A NON-TZD GAMMA-WEIGHTED PPAR ALPHA, GAMMA DUAL AGONIST.

V. L. Reynolds, L. I. Boone, M. A. Carfagna and D. A. Cooper. Eli Lilly and Co., Greenfield, IN.

Peroxisome proliferator-activated receptor (PPAR) gamma agonists [e.g., thiazolidinediones (TZDs) such as pioglitazone and rosiglitazone] are insulin sensitizers used clinically to treat Type 2 diabetes while PPAR alpha agonists (e.g., fenofibrate) are beneficial in controlling dyslipidemia. This study evaluated the toxicity of naveglitazar when given orally (capsules) to beagle dogs ($n=3/\text{sex}/\text{group}$) at doses of 100, 30, 3, 0.3, or 0 (vehicle control) mg/kg/d for 1 month. Clinical signs of toxicity (abnormal feces, thinness, sporadic emesis), body weight loss, and decreased food consumption occurred in a dose-related fashion. Despite the body weight effects, physical and neurological exams were normal. Target organs for toxicity included the heart, liver, hematopoietic system, and male reproductive tissues. Cardiac effects included ECG changes (QT prolongation), elevated heart weights, and an increase in pericardial fluid. Liver changes included increased CYP4A activity (without significant changes in peroxisomal beta-oxidation activity and with an overall decrease in total cytochrome P450 content), increased liver weights, variable increases in ALT (and AST in some cases) with no clear dose- or duration-dependence, and a variety of histologic changes that did not explain the transaminase elevations. These adverse liver findings are not consistent with human clinical experience with the marketed TZDs, supporting the view that dogs are not predictive for humans regarding target organ toxicities with this class of drugs. Hematologic changes (decreased hematocrit, reticulocytopenia, neutropenia, and/or thrombocytopenia) were likely due, at least in part, to plasma volume expansion. Additional hematopoietic effects included bone marrow hypocellularity and splenic extramedullary hematopoiesis. Decreased testes and prostate weights, testicular degeneration, decreased spermatogenesis, and/or prostatic atrophy were noted at 30 and 100 mg/kg, but may have been secondary to inanition and weight loss. The NOAEL was 0.3 mg/kg.

281 SAFETY EVALUATION OF SYSTEMIC HEDGEHOG PATHWAY INHIBITION.

K. Flagella, A. Bricarello, E. Choo, H. La and N. Dybdal. Genentech, South San Francisco, CA.

Hedgehog (Hh) signaling is an important regulator of normal development and tissue homeostasis. Mutations in the Hh pathway are common in human basal cell carcinomas (BCC), resulting in pathway activation and uncontrolled basal cell proliferation. To support development of a topical therapeutic for BCC, the safety of a Hh pathway antagonist, Cur-61414, was evaluated in rodent and non-rodent species. Mini-pigs were selected as the non-rodent species since their skin is morphologically similar to human skin. Topical application of Cur-61414 was well tolerated and resulted in minimal systemic exposure in mini-pigs (reported previously). To evaluate the systemic effects of Hh inhibition, Cur-61414 was administered intravenously (IV) to rodents and mini-pigs in single- and multiple-dose toxicity studies. The maximum tolerated IV dose was 66, 35, and 5 mg/kg for mice, rats, and mini-pigs, respectively. Effects after single-dose IV administration of >17 mg/kg to rodents included decreased activity, labored breathing, and/or injection site irritation. Transient decreases in heart rate occurred after IV dosing of ≥ 25 mg Cur-61414/kg/day for 7 or 28 days in rats and 6.6 mg Cur-61414/kg in a dose escalation study in mini-pigs; however, no heart weight changes or microscopic abnormalities were observed. Cur-61414 was generally well tolerated at IV doses up to 2.5 and 5 mg/kg/day in rats and mini-pigs treated for 28 days, respectively. Moreover, in mini-pigs, no effects on heart rate or other electrocardiogram parameters, blood pressure, or changes in troponins T and I or creatine kinase levels were detected. In vitro screening, 84% inhibition of the L-type calcium channel was observed with 3 μM Cur-61414, levels achieved in vivo, suggesting that heart rate

decreases observed following Cur-61414 administration may be related to calcium channel inhibition rather than Hh pathway antagonism. In summary, Cur-61414 was well tolerated systemically in rodents and mini-pigs at therapeutically relevant doses. These findings are consistent with a limited role of Hh signaling in most normal adult tissues.

282 TOXICITY OF AN ADENOVIRUS VECTOR (AD-KD3) ADMINISTERED INTRAVENOUSLY TO SYRIAN HAMSTERS.

C. Hebert¹, R. Fulton¹, J. Mann¹, J. Page¹, P. Noker¹, K. Schweikart² and W. Wold³. ¹Southern Research Institute, Birmingham, AL, ²NCI, Bethesda, MD and ³St. Louis University School of Medicine, St. Louis, MO.

The objective of this study was to assess the toxicity of a replication-competent adenovirus vector (Ad-KD3), compared to wild-type adenovirus (WT-Ad5), in male Syrian hamsters. Ad-KD3 is derived from the human serotype 5 adenovirus, and is being investigated as a potential treatment for cancer. Hamsters were given single jugular vein doses of Ad-KD3 (3.0×10^9 , 3.0×10^{10} , or 1.9×10^{12} viral particles (vp)/kg), WT-Ad5 (1.9×10^{12} vp/kg), or vehicle. Necropsy, clinical and microscopic pathology evaluations were performed on Days 2, 7, and 29. All animals survived to scheduled necropsy, and no clinical signs of toxicity were noted. Animals in the highest Ad-KD3 dose group had a mild decrease in body weight on Day 7. Hematology changes associated with administration of Ad-KD3 or WT-Ad5 included increases in neutrophil, WBC, monocyte, and platelet counts; decreases in HCT values; and decreases in lymphocyte and reticulocyte counts. Clinical chemistry changes associated with administration of Ad-KD3 or WT-Ad5 included decreases in total protein and albumin values and increases in ALT, ALP, and GGT values. Microscopic liver changes seen on Day 2 in animals treated with WT-Ad5 or Ad-KD3 included hepatocellular viral intranuclear inclusion bodies, hepatocellular karyomegaly, cytoplasmic alteration, and bile stasis; these changes were attributed to virus administration. Other potential virus-related lesions, observed at the dosing site on Day 7 in animals treated with WT-Ad5 or with the low or middle doses of Ad-KD3, included venous endothelial cell hypertrophy and venous inflammation and chronic inflammation of overlying tissues. Overall, adverse clinical and microscopic effects were similar in animals receiving equivalent doses of WT-Ad5 and Ad-KD3. With few exceptions, none of the effects observed on Days 2 or 7 were evident on Day 29. Under the conditions of this study, the No Observed Adverse Effect Level for Ad-KD3 was considered to be 3.0×10^{10} vp/kg. Supported by NCI Contract N01-CM-42201

283 DATA EVALUATION OF PRE-CLINICAL INCURRED SAMPLE REPEAT ANALYSIS.

L. Kendall¹, D. M. Fast², O. Kavetskaia¹ and D. M. Grant¹. ¹PDM, Pfizer Global Research & Development, Groton, CT and ²PDM, Pfizer Global Research & Development, Ann Arbor, MI.

As a result of discussions at the 2006 Quantitative Bioanalytical Methods Validation and Implementation: Best Practices for Chromatographic and Ligand Binding Assays (Crystal City III), we reviewed pre-clinical studies that included reanalysis of incurred samples which were conducted both in our laboratories and in contract bioanalytical laboratories from 2000 through 2006. We determined the frequency of change for reassay results, the magnitude of those changes, the effect on TK parameters, and overall effect on study results from those changes. Data from two separate Pfizer sites, Ann Arbor (AA) and Groton (GR) were analyzed. From AA, 363 total samples were reassayed (3% of total study samples) and 90% (327 of 363) changed by <10-fold in concentration, while from GR, 96% (292 of 303) changed by <10-fold. From AA, 69% (147 of 214) of drug in control, pre-dose and/or reassayed in error samples confirmed the original concentration. From GR, 92% (91 of 99) confirmed that quantifiable concentrations of drug were in the control or pre-dose samples. The remaining 204 samples from GR (TK outliers) resulted in 195 of the 204 samples (96%) changed by <10-fold in concentration. The impact of the GR data that changed upon reanalysis was further evaluated for impact on TK parameters. Because some profiles contained reanalyzed samples from multiple time points, TK parameters for only 30 profiles were recalculated for C_{max} and AUC estimates. In the 30 profiles, C_{max} changed by <15% in 29 of 30 profiles (97%). In addition, AUC values changed by <15% in 28 of 30 profiles (93%). In conclusion, in general the data obtained after reanalysis did not differ substantially from the original data, thus confirming that reanalysis of incurred samples will yield similar bioanalytical results. Further, the overall impact on the TK parameters used to estimate exposure for pre-clinical safety studies was minimal and did not change the overall interpretation of the TK data or the pre-clinical toxicology or safety pharmacology study.

284 EFFECT OF TRICYCLIC COMPOUNDS ON BASAL AND SECRETAGOGUE-INDUCED AMYLASE RELEASE FROM ISOLATED MOUSE PANCREATIC ACINI.

M. Tai¹, S. R. Hootman¹, M. Orteno² and L. J. Fischer³. ¹Physiology, Michigan State University, East Lansing, MI, ²Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE and ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Cyproheptadine and structurally-related compounds such as cyclizine and chlorcyclizine have been shown in previous studies to cause pancreatic islet cell toxicity. Whether these tricyclic compounds also induce toxicity of pancreatic acini or alter digestive enzyme secretion has not been investigated. We examined the effects of these three compounds on basal amylase release and release in response to carbachol and to cholecystokinin octapeptide (CCK8) from isolated mouse pancreatic acini. In the absence of tricyclics, both carbachol and CCK8 caused a dose-dependent increase in amylase secretion which was maximal for carbachol at a concentration of 1 μ M and for CCK8 at 0.01 nM. In the absence of secretagogues, cyproheptadine did not appreciably alter basal amylase release at concentrations below 0.1 mM. At concentration above 0.1 mM, cyproheptadine caused massive release of amylase from acini which was accompanied by a nearly 100% cellular uptake of trypan blue. Cyproheptadine abolished carbachol-stimulated amylase release with an IC₅₀ of 60 nM, consistent with earlier reports of its antimuscarinic properties. Cyclizine and chlorcyclizine also inhibited carbachol-induced amylase release, with IC₅₀'s of 2.5 μ M and 5.4 μ M, respectively. As with cyproheptadine, at concentrations above 0.1 mM, chlorcyclizine caused massive amylase release and near total trypan blue uptake, although cyclizine did not. By contrast to its effects on carbachol-stimulated amylase release, 0.1 mM cyproheptadine slightly reduced amylase release stimulated by CCK8, while cyclizine and chlorcyclizine at the same concentration were somewhat more effective inhibitors. The present results suggest that these tricyclic compounds have inhibitory effects on pancreatic exocrine as well as endocrine secretion and that these effects may be caused by combination of receptor-mediated signaling pathways and more generalized mechanisms of cellular toxicity.

285 MINIMALIST SAMPLING STRATEGIES FOR TOXICOKINETICS: A RETROSPECTIVE ANALYSIS – PART 2.

M. J. Miller, K. C. Lee, L. Kendall and D. M. Grant. *Pharmacokinetics, Dynamics, and Metabolism, Pfizer, Inc., Groton, CT.*

As part of the regulatory process for IND and NDA submissions to the FDA, ICH Guidelines require that non-clinical safety studies characterize the Toxicokinetics (TK) of all NCE's at the dose range used during the non-clinical safety assessment program. The purpose of this retrospective analysis was to determine whether four sampling time points could adequately estimate exposure (C_{max} and AUC). TK data from more than 150 legacy studies (dose range-finding, multiple dose, bid dosing, and large animal cardiovascular safety pharmacology), comprising more than 1000 data sets were included in the analyses. Two different approaches were used: 1) Four optimized time points were chosen for each compound after evaluating full profiles and early TK data. 2) Four pre-defined, standardized time points (1, 4, 7, and 24 hr) were used for all studies. TK parameters were calculated and the data were compared to the original TK data. The recalculated parameters were considered similar to the original parameters if they were within $\pm 15\%$ of the original estimates. The data from this analysis indicated that C_{max} was adequately described in 92% of the data sets analyzed using four optimized time points, and in 74% of the data sets using the four standardized time points. AUC was adequately described in 84% of the data sets analyzed using either approach. However, a number of profiles were eliminated from the analysis because the time points collected were too dissimilar to those used in the standardized approach, therefore the comparison overestimated how well using 4 standardized time points described the TK parameters. In conclusion, four optimal time points accurately described C_{max} and AUC for most studies. Four standardized time points accurately estimated AUC in 84% of the studies, however it failed to adequately estimate C_{max} in over 25% of the studies. Neither strategy adequately described TK parameters following bid dosing, shifting T_{max}, or when T_{max} differs for different analytes (i.e. parent/metabolites).

286 POTENTIAL ROLE OF THE PLASMA MEMBRANE H⁺-ATPASE IN THE ANTI-MICROBIAL PROPERTIES OF EBSELEN AND ITS 3-PYRIDINYL ANALOG.

B. Billack, G. Chan, M. Santoro, D. Hardej and C. Lau-Cam. *Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY.*

Ebselen (2-phenyl-1,2-benzisoxselenazol-3(2H)-one) is a selenium-containing antioxidant demonstrating anti-inflammatory and cytoprotective properties in mammalian cells and cytotoxicity in lower organisms. In the present study, the antimicrobial activity of this compound and its analog,

2-(3-pyridinyl)-1,2-benziselenazol-3(2H)-one, was evaluated. *Saccharomyces* sp. were found to be more sensitive to ebselen (IC₅₀ ~3 µM) than to the 3-pyridinyl analog (IC₅₀ ~16 µM). Wash-out experiments and scanning electron microscopic analysis revealed that the fungicidal effects of ebselen were irreversible. Previous work in the lab found that ebselen inhibits medium acidification by several *Saccharomyces* strains. Medium acidification by yeast is achieved by the action of the plasma membrane H⁺-ATPase pumps PMA1 and PMA2, respectively. Of the two pumps, PMA1 is more highly expressed and is more critical to yeast survival. To ascertain how ebselen blocks medium acidification, its effect on PMA1 was examined. Ebselen inhibited medium acidification by PMA1-proficient yeast in a concentration-dependent manner without altering the ATPase activity of the pump. Additional studies using PMA1 (+/-) and PMA1 (+/+) yeast cells revealed the mutant to be more sensitive to a treatment with ebselen than the wild type. Because of its propensity to react with free thiol groups in mammalian cells, the inhibition of medium acidification by ebselen may be the result of binding to one or more cysteine residues on PMA1. To this end, an *in vitro* interaction of ebselen and free cysteine was detected by thin-layer chromatography, inferring that inhibition of proton pumping via this ATPase may be the result of ebselen binding to critical cysteine residues in the protein structure. Taken together, the data suggest that the fungicidal action of ebselen to be due, at least in part, to interference with the proton translocating function, and not with the ATPase activity, of the plasma membrane H⁺-ATPase.

287 DEVELOPMENT AND VALIDATION OF A PCR-BASED ASSAY FOR THE DETECTION OF ADENOVIRAL INTEGRATION INTO HOST GENOME.

A. Steff, J. Ng and A. T. Nelson. *Immunology Department, LAB Research Inc., Laval, QC, Canada.* Sponsor: G. Washer.

Genomic integration studies are warranted when gene therapy products are detected in the germ-line or when a vector has potential to integrate. Although adenoviruses (Ad) generally do not integrate into the host genome a few studies report Ad integration at very low frequency. In addition, efforts are being made to develop integrating Ad that could provide long-term gene expression. We have developed and validated a sensitive method for the detection of integrated Ad in mouse tissues in support of preclinical studies.

Detection of integrated Ad was accomplished by differential amplification of integrated and free particles in genomic DNA. The entire genome was amplified using primers specific for repetitive sequences (mouse B1 elements) along with a single Ad-specific primer. This specifically amplifies integrated but not free Ad. A quantitative PCR assay (QPCR) was used to measure the total number of Ad particles both before and after the B1 PCR step. The post-B1/pre-B1 ratio determines if any integrated particles are present. In theory, a ratio of 1 or below indicates that no integrated particles are present. In practice, a cut-off of 1.4 was determined to account for the variability observed within integration-negative samples. A spiked positive control Ad integrant was used with each sample to control for potential PCR inhibition. The assay achieved 100% specificity for samples containing up to 700,000 free Ad particles/µg of DNA. The assay allowed the detection of as few as 5.3x10⁻⁷ integration events per gene, even in the presence of free Ad particles. This is 20 times lower than the spontaneous mutation rate observed in mammalian cells. This validated method was successfully applied to preclinical studies. It shows great sensitivity and specificity. Furthermore, this assay would be easily applicable to other gene transfer products, viral or non-viral, and to other toxicology species.

288 A MODEL OF POST-OPERATIVE AND OPIOIDS INDUCED ILEUS FOR ASSESSMENT OF GASTRO INTESTINAL TRANSIT IN RATS.

A. Kirouac, S. Mason and C. Banks. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.*

Post-operative ileus (POI) is a transient impairment of bowel motility. The pathophysiology of POI is multifactorial and causes include, but are not limited to, surgical manipulation of the bowel, post-surgical inflammation and a generalized stress response. The use of postoperative opioids also appears to contribute to ileus. In order to better comprehend the invasive association of abdominal surgery and use of opioids with POI, this study was conducted to investigate the effects of exposure of abdominal contents to manual handling (specifically the cecum) and of exposure to morphine. POI was quantified by measurement of gastric emptying through dilution of a phenol red dye. A first group of Sprague-Dawley rats was anesthetized with isoflurane gas and the abdomen opened. Half of the animals had the cecum exteriorized and gently patted for 1 minute, while the second half were exposed to surgery, but with no cecum manipulation. Another group of rats was administered a subcutaneous dose of either 1 or 4 mg/kg of morphine. A group of rats was administered the phenol red alone and served as a control. Phenol red served as a gastrointestinal marker and was administered orally post-surgery or post morphine in-

jection, and was assayed colorimetrically 30 minutes post administration. Increases in stomach content of phenol red in cecum-manipulated and non-manipulated surgical groups were approximately 19% and 31%, respectively, when compared to control group (absorbance of 1.9 and 2.1, respectively vs 1.6 for control). The stomach content of phenol red in the cecum-manipulated group was approximately 9.5% lower than the non-manipulated group. Exposure to morphine alone significantly reduced the stomach motility and equivalent increases of approximately 88% in stomach content were seen at both dose levels (absorbance of 3.0). These responses confirm that POI is a response to surgery and administration of opioids and its magnitude is not unilaterally dependent on the degree of surgical manipulation or dose dependent on the exposure of opioids.

289 FOUR WEEK ORAL TOXICITY STUDY OF THE RETINOIC ACID DERIVATIVE 9-CIS-UAB-30, IN FEMALE DOGS.

M. Lindeblad¹, L. M. Kaperanovic⁵, T. Martin-Jimenez³, R. Morrissey², Y. Chen¹, J. Crowell⁵, D. D. Muccio¹, W. Brouillette⁴ and A. V. Lyubimov¹. ¹Pharmacology, University of Illinois at Chicago, Chicago, IL, ²Pathology Associates, Charles River Laboratories, Chicago, IL, ³College of Veterinary Medicine, Comparative Medicine, University of Tennessee, Knoxville, TN, ⁴University of Alabama at Birmingham, Birmingham, AL and ⁵National Cancer Institute, Bethesda, MD.

The purpose of this study was to assess the toxicity of 9-cis-UAB-30 [(2E,4E,6Z,8E)-8-(3',4'-Dihydro-1'(2'H)-naphthalen-1'-ylidene)-3,7-dimethyl-2,4,6-octatrienoic acid] in female dogs following four weeks of daily oral treatment by capsule administration at doses of 0, 10, 30 and 100 mg/kg/day. No mortalities occurred and no treatment-related clinical signs were seen. No treatment-related changes in body weights, food consumption, clinical pathology parameters, ophthalmology or electrocardiology were seen. Total body weight gains were dose-dependently decreased, although not significantly, in the dose groups administered 9-cis-UAB-30 compared to the control group. No treatment-related changes in organ weights, gross pathology or histopathology were seen. Thymus weights were dose-dependently decreased, although not significantly, in groups administered 9-cis-UAB-30. An increase in kidney weights was seen in the 10 mg/kg/day dose group. These changes were considered sporadic and not biologically meaningful. These data indicate that administration of 9-cis-UAB-30 to female dogs did not result in treatment-related toxicity. Blood was collected for pharmacokinetics from all dogs at 0, 1, 2, 4, 8, and 24 hours post-dosing. The value of AUC_{0-∞} did have an increase with each increasing dose, but not proportionally to the dose administered. The value of AUC₀₋₂₄ increased approximately in proportion to the dose when dose groups of 30 mg/kg/day and 100 mg/kg/day were numerically compared. The values of AUC_{0-∞} ranged between 5250.0 ng*hr/mL and 13421.3 ng*hr/mL for the different dose groups. The half-life ranged between 2.68 and 4.01 hours. Based on the results obtained from this study, the no-observed adverse effect level (NOAEL) was at least 100 mg/kg/day for 9-cis-UAB-30.

290 THE LACK OF GENOTOXICITY IN AN UNPREDICTED CASE OF RAT LIVER CARCINOGENICITY.

A. J. Olaharski¹, P. Caplazi¹, P. Escobar², L. VanderVeen¹, P. Stefan¹ and K. Kolaja¹. ¹Investigative Toxicology, Roche - Palo Alto, Palo Alto, CA and ²BioReliance, Rockville, MD.

RO-450 is an alpha adrenoreceptor agonist developed for urinary incontinence that represents an interesting example of a rat hepatocarcinogen with no clear genotoxic signals of carcinogenesis. The data described herein detail the efforts to elucidate the potential genotoxicity of this compound. Non-GLP genotoxicity testing conducted during early compound development resulted in negative results (micro ames and the *in vitro* micronucleus test) with subsequent GLP genotoxicity also testing negative (ames, human lymphocyte chromosome aberration test, and *in vivo* mouse micronucleus test). A 2-year carcinogenicity study was conducted using Sprague-Dawley rats treated with RO-450 once daily at dose levels of 0, 5, 50, or 100 mg/kg/day. Treatment for 2 years was directly related to the development of hepatocellular adenomas (male and female, trend test p-values <0.001) and carcinomas in male rats (p-value = 0.008). A no-effect level for hepatocellular neoplastic changes was not achieved in male rats. Clinical development of RO-450 was halted but subsequent work has focused on identifying whether the mechanism by which hepatocellular neoplastic transformation occurs is via a genotoxic mechanism. RO-450 tested negative in the *in vitro* PPAR, *in vivo* rat bone marrow MNT, *in vivo* kidney and liver rat comet assay, and SHE cell assays. The weight of evidence of the existing data indicates that the increased incidences of rodent hepatocellular adenomas and carcinomas are likely not related to a genotoxic mechanism. Re-evaluation of short term studies indicates that only negligible changes in liver weight and hepatocellular pathological changes occur following RO-450 dosing. Hepatocellular

focal lesions however were identified in all dose groups during a 6- month repeat dose study suggesting an early indicator of the hepatocellular carcinogenicity finding. Investigations are currently focused on identifying RO-450-specific changes in shorter term studies that might yield insight into the nonogenotoxic mechanism by which hepatocellular neoplasia develop.

291 REDOX REGULATION OF GAMMA-IRRADIATION INDUCED APOPTOSIS BY CYTOCHROME C-CARDIOLIPIN COMPLEX IN HELA CELLS.

N. A. Belikova^{1,2}, J. Jiang^{1,2}, Y. Y. Tyurina^{1,2}, Q. Zhao^{1,2}, M. W. Epperly^{2,3}, J. Greenberger^{2,3} and V. E. Kagan^{1,2}. ¹Center for Free Radical and Antioxidant Health and Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, ²Center for Medical Countermeasures against Radiation, University of Pittsburgh, Pittsburgh, PA and ³Department of Radiation Oncology, University of Pittsburgh, Pittsburgh, PA.

In apoptosis, cytochrome c (cyt c) released from mitochondria into the cytosol, is central to apoptosome formation and caspase activation. Recently, we established that cyt c participates in apoptosis acting as a cardiolipin (CL)-specific peroxidase. The CL oxidation products thus formed are essential for the release of pro-apoptotic factors from mitochondria. While assembly of apoptosomes requires only minimal amounts of cyt c, catalysis of CL oxidation is strongly dependent on its content and availability for CL in mitochondria. Thus we hypothesized, the concentration of cyt c can be a determinant of cell's sensitivity to irradiation induced apoptosis. To test the hypothesis, we used siRNA approach to engineer HeLa cells with a lowered content of cyt c (14% of its amount in parental cells), HeLa 1.2 cells. γ -irradiation (in doses up to 40 Gy) induced apoptosis - as revealed by caspase-3/7 activation and phosphatidylserine externalization - was proportional to the cyt c content in HeLa 1.2 cells. Using a fluorescence HPLC-based Amplex Red assay and ESI-MS analysis, we found that irradiation caused selective accumulation of CL hydroperoxides. HeLa 1.2 cells responded by a lower irradiation-induced accumulation of CL oxidation products. No release of a pro-apoptotic factor Smac/DIABLO was detected in cyt c-deficient cells after irradiation, whereas Bax translocation was the same as in HeLa cells. Combined, our results demonstrate that cyt c is an important catalyst of CL peroxidation, critical to the execution of apoptotic program. This redox catalytic role of cyt c in irradiation induced apoptosis can be useful for the development of new radioprotectors and radiosensitizers. 292 PEROXIDASE COMPLEXES OF CYTOCHROME C WITH ANIONIC LIPIDS: STRUCTURAL PRE-REQUISITES, MECHANISMS, AND CYTOTOXIC EFFECTS.

I. I. Vlasova, A. A. Kapralov, J. Jiang, L. V. Basova, N. A. Belikova, V. A. Tyurin, Y. Y. Tyurina, J. Martin, A. Glumac, H. Bayir and V. E. Kagan. *Center for Free Radical and Antioxidant Health, EOH, University of Pittsburgh, Pittsburgh, PA.*

Interaction of cytochrome c (cyt c) with a mitochondria-specific cardiolipin (CL) confers peroxidase activity on the protein resulting in selective CL oxidation and release of proapoptotic factors. Because the complex cyt c/CL is stabilized by a combination of electrostatic and hydrophobic interactions, we determined the extent to which other anionic lipids - phosphatidic acid (PA), phosphatidylserine (PS), phosphatidylinositolphosphates (PIP), and phosphatidylcholine (PC) as a control - are effective in inducing the peroxidase activity of cyt c. EPR spectroscopy of nitrosylated cyt c, optical spectroscopy and measurements of tryptophan fluorescence demonstrated that cyt c interaction with anionic lipids induced protein unfolding accompanied by an exchange and loss of axial ligands of heme iron so that cyt c heme became more accessible for the interaction with small molecules like NO or H₂O₂. Using several peroxidase substrates we showed that all anionic lipids activated peroxidase activity of cyt c in a dose-dependent manner with the efficiency decreasing in the row: CL>PA>PIP>PIP₂>PS. Recombination of protein-derived radicals formed in peroxidase reaction caused oligomerization of cyt c and formation of protein-lipid aggregates detectable by PAGE and Western blotting. In line with this, Western blotting revealed the formation of cyt c aggregates after its incubation in the presence of H₂O₂ with membrane (but not cytosolic S-100) fraction of brain homogenates. Oxidation products of anionic lipids were detected after induction of apoptosis in HeLa cells and mouse embryonic wild type cells but not in cyt c-deficient cells. Overall, our study identified anionic lipids as physiologically relevant regulators of peroxidase activity of cyt c in mitochondria and other cell compartments, particularly during apoptosis. Supported by NIH U19 AI068021, HL 070807, NIOSH OH008282, AHA0535365N, PA Dept. of Health SAP 4100027294.

293 FREE FATTY ACIDS FORM PEROXIDASE COMPLEXES WITH CYT C: ROLE IN MITOCHONDRIAL OXIDATIVE STRESS AND DAMAGE.

A. Kapralov, I. Vlasova, N. Belikova, W. Feng, L. Basova, J. Martin, A. Glumac, H. Bayir and V. Kagan. *Center for Free Radical & Antioxidant Health, EOH, University of Pittsburgh, Pittsburgh, PA.*

Recently, we reported that negatively charged phospholipids- cardiolipin, phosphatidylserine-form strong complexes with cyt c in which the hemoprotein acts as a potent peroxidase capable of selective oxidation of respective phospholipids (Kagan et al., *Nature Chem. Biol.*, 2005). Both electrostatic and hydrophobic interactions were found essential for the complexes formation. Free fatty acids (FFAs) carry both a negatively charged carboxy-group and long chain hydrophobic moiety. Because FFA accumulation occurs in membranes and biofluids in many dyslipidemias and other disease conditions, we hypothesized that they can stimulate peroxidase activity of cyt c. Here we report, that oleic acid effectively stimulated peroxidase activity of cyt c as evidenced by oxidation of three typical peroxidase substrates: Amplex Red, etoposide, and luminol. The peroxidase activation of cyt c occurred only at ratios of oleic acid/cyt c exceeding 50:1. Generation of characteristic protein-derived radicals was confirmed by EPR spectroscopy of cyt c/oleic acid incubated with H₂O₂. Oligomerization of cyt c/FFA complexes was demonstrated by Western blotting. By utilization of immuno-spin trapping technique, we found the production of protein-immobilized DMPO nitron adducts in the PAGE bands corresponding to oligomeric forms of cyt c. Two lines of evidence suggest interaction of cyt c with oleic acid unfolds the protein resulting in a greater accessibility of its heme: 1) in low temperature EPR spectra of heme-nitrosylated oleic acid/cyt c complexes, a signal of penta-coordinate heme-iron was detectable, and 2) increased fluorescence of tryptophan quenched in native enzyme by the heme moiety. Increased levels of cyt c-associated peroxidase activity were found in isolated mitochondria and in cells incubated with oleic acid suggesting that the complexes may function as a peroxidase in vivo. Supported by grants from NIH U19 AI068021, NIOSH OH008282, AHA0535365N, Pennsylvania Department of Health SAP 4100027294.

294 OXIDIZED CARDIOLIPIN AS A NEW BIOMARKER OF GAMMA-IRRADIATION-INDUCED APOPTOSIS.

Y. Y. Tyurina¹, V. A. Tyurin¹, M. W. Epperly², J. S. Greenberger² and V. E. Kagan¹. ¹Center for Free Radical and Antioxidant Health and Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and ²Department of Radiation Oncology, University of Pittsburgh, Pittsburgh, PA.

Recently, we demonstrated that cytochrome c acts as a cardiolipin (CL) - specific peroxidase in mitochondria early in apoptosis and that CL oxidation products are required for the release of proapoptotic factors. Accordingly, gamma-irradiation initiates apoptotic response in HeLa cells and CL oxidation is critical to the execution of apoptotic program in these cells. We hypothesized that accumulation of oxidized CL can potentially be used in vivo as an early biomarker of apoptosis initiated by total body irradiation (TBI). As intestines are one of sensitive targets of irradiation, we studied phospholipid oxidation in guts isolated from control and irradiated mice. To this end C57BL/6NHsd female mice were subjected to 10 and 15 Gy of TBI and sacrificed 24 h thereafter. We found that TBI caused a dose-dependent apoptosis as revealed by caspase-3/7 activation. Moreover, a significant dose-dependent decrease in sphingomyelin content was detected in guts of TBI exposed mice thus confirming activation of sphingomyelinase typically involved in ceramide-dependent apoptotic pathway. TBI induced apoptosis was accompanied by oxidative stress as evidenced by depletion of two major intracellular antioxidants - ascorbate and GSH. Using our new protocol, oxidative lipidomics, we characterized and quantitatively assessed the formation of hydroperoxides of different classes of phospholipids and found that only CL, a mitochondria specific phospholipids (but not other phospholipids) undergo significant oxidation in mouse guts after TBI. Thus, early accumulation of CL hydroperoxides can be used in vivo as a biomarker of TBI induced apoptosis, useful for the development of new radioprotectors and radiosensitizers. Supported by NIH NIAID U19 AI068021, NIH HL70755.

295 UNMASKING PEROXIDASE ACTIVITY OF CYTOCHROME C IN MITOCHONDRIA: ROLE OF CARDIOLIPIN.

Redox properties of cyt c are critical to its normal electron transport function in mitochondria, as well as to its participation in apoptotic signaling via the peroxidase oxidation of two anionic phospholipids, cardiolipin (CL) and phosphatidylserine

(PS). Peroxidation of CL contributes to the permeabilization of mitochondrial membranes, and subsequent cyt c release into the cytosol. How cyt c changes its role from an electron shuttle to a peroxidase is currently unknown. Previous work has established that upon interaction with CL, cyt c loses its tertiary structure, and its peroxidase activity dramatically increases. During apoptosis, the fraction of CL-bound cyt c markedly increases. Consequently, we have hypothesized that binding of CL to cyt c acts as a switch that turns off its electron transport function, while simultaneously turning on its peroxidase catalytic function. The redox behavior of cyt c bound to CL-containing membranes was studied using direct voltammetry of cyt c adsorbed on alkanethiol monolayers and equilibrium redox titrations in the presence and absence of CL. The effects of CL binding on the redox potential of cyt c in liver and brain mitochondria, as well as on the regulation of electron transport activity in the mitochondrial electron transport chain, were examined by EPR and UV-Vis spectroscopy. The data shows that binding of cyt c to CL causes: 1) significant (-350-400 mV) negative shift of the redox potential of cyt c; 2) inhibition of cyt c reduction in mitochondria, 3) interruption of mitochondrial electron transport; and 4) inability to oxidize superoxide and ascorbate. These findings suggest that CL acts as a switch and regulates cyt c's mitochondrial redox functions. This work was supported by NSF (CHE-0415457), NIH (HL 70755, U19 AI 068021), NIOSH (OH 008282), The Human Frontier Science Program and PA Department of Health SAP 4100027294.

296 P38 MAP KINASE MEDIATES APOPTOSIS THROUGH PHOSPHORYLATION OF BIMEL AT SER65 AFTER SODIUM ARSENITE TREATMENT.

B. Cai¹, S. H. Chang¹, E. B. Becker², A. Bonni² and Z. Xia¹. ¹University of Washington, Seattle, WA and ²Harvard Medical School, Boston, MA.

The stress activated c-Jun N-terminal protein kinase (JNK) and p38 mitogen-activated protein (MAP) kinase (p38) regulate apoptosis induced by several forms of cellular insults. Potential targets for these kinases include members of the Bcl-2 family proteins which mediate apoptosis generated through the mitochondria-initiated, intrinsic cell death pathway. Indeed, the activities of several Bcl-2 family proteins, both pro- and anti-apoptotic, are controlled by JNK phosphorylation. For example, the pro-apoptotic activity of BimEL, a member of the Bcl-2 family, is stimulated by JNK phosphorylation at Ser65. In contrast, there is no reported evidence that p38-induced apoptosis is due to direct phosphorylation of Bcl-2 family proteins. Here we report evidence that sodium arsenite-induced apoptosis in PC12 cells may be due to direct phosphorylation of BimEL at Ser65 by p38. This conclusion is supported by data showing that ectopic expression of a wild-type, but not a non-phosphorylatable S65A mutant of BimEL, potentiates sodium arsenite-induced apoptosis and experiments showing direct phosphorylation of BimEL at Ser65 by p38 in vitro. Furthermore, sodium arsenite induced BimEL phosphorylation at Ser65, which was blocked by p38 inhibition. This study provides the first example whereby p38 induces apoptosis by phosphorylating a member of the Bcl-2 family, and illustrates that phosphorylation of BimEL on Ser65 may be a common regulatory point for cell death induced by both JNK and p38 pathways.

297 APOPTOSIS INDUCED BY LOW CONCENTRATIONS OF DOMOIC ACID IS MEDIATED BY THE P38 AND JNK MAP KINASE PATHWAYS IN MOUSE CEREBELLAR GRANULE NEURONS.

G. Giordano¹, H. M. Klintworth¹, T. J. Kavanagh¹ and L. G. Costa^{1,2}. ¹Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA and ²Department of Human Anatomy, Pharmacology and Forensic Medicine, University of Parma Medical School, Parma, Italy.

In cerebellar granule neurons (CGN) domoic acid (DomA) induces neuronal cell death, either by apoptosis or by necrosis, depending on its concentration. Necrotic damage predominates in response to concentrations above 0.1 μ M while apoptotic cell death (assessed by Hoechst staining) is evident after exposure to lower concentration of DomA (0.1 μ M). The AMPA/kainate receptor antagonist NBQX, but not the NMDA receptor antagonist MK-801, prevented DomA-induced apoptosis. To evaluate the role of oxidative stress in DomA-induced apoptosis, experiments were carried out in CGN from wild-type mice [Gclm (+/+)] and mice lacking the modifier subunit of glutamate-cysteine ligase [Gclm (-/-)]; the latter have very low levels of GSH, and were found to be more sensitive to DomA-induced apoptosis. The antioxidants catalase and GSH ethylester (GSHEE) completely prevented DomA-induced apoptosis, and DomA caused an increase in reactive oxygen species in CGN.

The p38 MAP kinase and the c-Jun NH2-terminal protein kinase (JNK) have been shown to be preferentially activated by oxidative stress. The p38 inhibitor SB203580 and a JNK inhibitor (SP600125) protected CGNs from DomA-induced apoptosis. DomA increased p38 MAP kinase and JNK phosphorylation and this effect was more pronounced in Gclm (-/-) CGNs. This early event was fol-

lowed by an increase in caspase-3 activity as assessed by both fluorescence microscope and activity assay. The ability of NBQX, catalase and GSHEE to prevent DomA-induced phosphorylation of JNK and p38 MAP kinase suggests that the activation of these kinases is mediated by oxidative stress through the AMPA/kainate receptor. These data indicate the importance of oxidative stress-activated JNK and p38 MAP kinase pathways in DomA-induced apoptosis. (Supported by ES012762/NSF-OCE-0434087, ES 07033, and ES 04696).

298 THE ROLE OF THE I κ B KINASE (IKK) IN ARSENIC TOXICITY.

Z. Peng, L. Peng, H. Shertzer and Y. Xia. University of Cincinnati, Cincinnati, OH.

The role of the I κ B kinase (IKK) in arsenic toxicity

Zhimin Peng, Li Peng, Howard Shertzer and Ying Xia

Department of Environmental Health and Center of Environmental Genetics, University of Cincinnati Medical Center, Cincinnati, OH.

Abstract:

Arsenic is a widely spread environmental agent that exerts diverse toxicity in humans. In cultured cells, high concentrations (>5 μ M) arsenic induces cell death. The present study is to investigate the role of the I κ B kinase (IKK) in arsenic toxicity using cells deficient in the α , β and γ subunit of the IKK complex. Cells were exposed to sodium arsenite at various concentrations (0.01 - 200 μ M) and times (30 min to 48 hr). Cell death was determined by measuring lactate dehydrogenase (LDH) release and nuclei condensation. Cellular reactive oxygen species (ROS) accumulation was measured by the CM-H2DCFDA and the activation of the c-Jun N-terminal kinases (JNKs) and NF- κ B pathways was monitored by Western Blot analyses. We found that arsenic at 50 μ M did not activate NF- κ B; however, it caused apoptosis of the IKK α - and IKK β -null, but not of the IKK γ -null and wild type cells, at 6 hour of exposure. In the IKK α - and IKK β -null cells, arsenic induced higher levels of ROS accumulation and JNK activity. Pretreatment of the IKK β -null cells with ROS scavengers, vitamin E and N-acetylcysteine, and a JNK inhibitor, SP600125, significantly decreased arsenic-induced apoptosis. These results suggest that the IKK α and IKK β , but not IKK γ , offer protection against arsenic-induced oxidative and apoptotic damage. Because all the IKK-null cells were impaired in I κ B α degradation and NF- κ B nuclear translocation, we suggest that the protective role of IKK α and IKK β against arsenic toxicity cannot be simply explained by the I κ B-NF- κ B pathway activation and that other IKK downstream effectors may be involved. -Supported by NIH ES 11798

299 SPLICING VARIANTS OF HUMAN FKBP8 GENE IN OXIDANT-INDUCED APOPTOSIS.

Y. Chen, P. Sternberg and J. Cai. Department of Ophthalmology & Visual Sciences, Vanderbilt University Medical Center, Nashville, TN.

Regulation of apoptosis involves the interaction between Bcl-2 family proteins and components of other signaling pathways. FKBP8 is a member of the FK506 binding proteins and is a potent inhibitor of apoptosis by targeting Bcl-2 and Bcl-XL to mitochondria. The current study investigates the transcriptional regulation of the fkbp8 gene and the potential functional roles of the splicing variants in response to oxidative stress. Human fkbp8 gene is composed of 9 exons located on chromosome 19p12. The full length mRNA was cloned and sequence verified by RACE PCR. In both cultured human neuroblastoma cells and retinal pigment epithelial cells, two splicing variants were identified. The alternative splicing resulted in loss of three exons but otherwise did not cause a frame shift in the coding sequence. The ratio between the long and short forms was regulated by exposure to oxidants and other environmental toxicants. Overexpression of the long form with an N-terminal FLAG tag showed mitochondrial localization and protection against apoptosis. In contrast, the short form was found to have distinct subcellular distribution and function. The data suggest that FKBP8 is a potential sensor protein to oxidative stress and its alternative splicing is a potential mechanism regulating oxidant-induced apoptosis. (Supported by NIH grant ES 014668, American Health Association Foundation, and Research to Prevent Blindness, Inc.)

300 CYANIDE INDUCES MITOCHONDRIAL DYSFUNCTION AND DEATH IN MESENCEPHALIC DOPAMINERGIC CELLS EXPRESSING BNIP3.

K. Prabhakaran, L. Li, L. Zhang, X. Zhang, H. B. White Leavesley, J. L. Borowitz and G. E. Isom. Medicinal Chemistry & Molecular Pharmacology, Purdue University, West Lafayette, IN.

BNIP3 is a member of the Bcl-2 family proteins that displays pro-apoptotic activity. BNIP3 has been linked to both apoptotic and necrotic death involving mitochondrial dysfunctions. In this study we demonstrate that forced over-expression of

BNIP3 by transient transfection (BNIP3⁺) induced significant apoptotic death in an immortalized mesencephalic dopaminergic cell line (N27 cells) as determined by cell viability and TUNEL assays. Cyanide, a neurotoxicant that produces mitochondrial dysfunction and death of brain cells, did not induce apoptosis or alter constitutive BNIP3 expression in wild type N27 cells. In BNIP3⁺ cells exposure to cyanide (400 μ M) for 24 h a marked increase in BNIP3 expression and apoptotic cell death was noted. KCN-induced death in BNIP3⁺ cells was caspase independent since an increase in cellular caspase activity was not detected or pretreatment with the pan caspase inhibitor z-VADfmk did not alter the BNIP3-mediated death. On the other hand, cell death was accompanied by a reduction of mitochondrial membrane potential ($\Delta\Psi$ m) that was enhanced by KCN. Knockdown of BNIP3 by RNAi or suppression of BNIP3 activity by a transmembrane-deleted dominant-negative mutant (BNIP3 Δ TM) markedly reduced the level of KCN-induced cell death. Similarly pretreatment with cyclosporine A, an inhibitor of the mitochondrial pore transition blocked the reduction of $\Delta\Psi$ m and decreased cell death. It is concluded that a high expression level of BNIP3 can mediate apoptotic death in a mesencephalic cell line through mitochondrial dysfunction without involving the caspase cell death cascade. The cytotoxic effect mediated by BNIP3 is potentiated by KCN through upregulating the protein expression level. (Supported in part by NIH grant ES04140)

301 IDENTIFICATION AND CHARACTERIZATION OF FACTORS INVOLVED IN DELAYED EFFECTS OF RADIATION.

D. L. Springer¹, J. S. Peters¹, D. S. Daly¹, R. J. Moore¹, S. Jin², R. E. Johnson¹, W. F. Morgan³ and J. H. Miller². ¹Fundamental Science Division, Pacific Northwest National Lab., Richland, WA, ²School Electrical Engineering and Computer Science, Washington State University, Richland, WA and ³Department Radiation Oncology, University of Maryland, Baltimore, MD. Sponsor: Z. Richard.

Evidence from in vitro tissue culture studies, in vivo animal models, and radiotherapy patients, indicated that a variety of biological effects, including genomic instability, occur outside the radiation field and to the progeny of irradiated cells. Media conditioned by the growth of transformed GM10115 cells, made genomically unstable by radiation exposure, is toxic to the parental cell line, the Death Inducing Effect (DIE). We hypothesized that the transformed cells release (through protein shedding and/or secretion) one or more factors into the media that cause stable cells to die primarily through apoptotic processes. We are using biochemical approaches to determine the nature of the factor(s) responsible for DIE activity. Our results indicate that the DIE activity can be diluted 2-4 fold without loss of activity. Dialysis using 2- and 10-KDa pore sizes retained DIE activity indicating that the factor(s) are large molecules and unable to escape through the pores. When DIE media was treated with proteases, DIE activity was reduced. Similarly DIE activity was unaffected by temperatures as low as -20°C; however, activity was mostly lost when media was boiled. While not yet completed, these biochemical studies are consistent with DIE factors being proteins and likely derived from either shedding or secretory processes. Current efforts are focused on implementing mass spectrometry based proteomics approaches that will allow us to identify proteins in DIE medium and determine whether they are up- or down-regulated relative to controls.

Supported by the US Department of Energy Low Dose program.

302 SUITABILITY OF A CYNOMOLGUS MONKEY KIDNEY CELL LINE, JTC-12, AS A MODEL TO INVESTIGATE LIGAND-MEDIATED APOPTOSIS.

D. D. Baker¹, S. Sawant¹, M. Rocca², C. Afshari¹ and R. T. Dunn¹. ¹Investigative Toxicology, Amgen, Inc., Thousand Oaks, CA and ²Regulatory Toxicology, Amgen, Thousand Oaks, CA.

Cynomolgus monkeys (Cyno) are used in toxicological studies to determine toxic effects of therapeutics. Unfortunately there is limited availability of in-vitro cell assay systems from non-human primates (NHP) for use in studies of drug candidates. Typically, in-vitro experiments are carried out in primary cells, most often hepatocytes, derived from suitable NHP models including Cyno monkey. However, hepatocytes from primates are subject to limited availability and their inability to proliferate limits applicability to discrete therapeutic areas. We investigated the utility of a cyno-derived cell line, JTC-12, for potential application in lead optimization studies for drugs that act by inducing apoptosis. Tumor necrosis factor related apoptosis-inducing ligand (TRAIL) is a TNF family member that interacts with at least four membrane receptors that all belong to the TNF receptor family. TRAIL receptor 1 (TRAIL-R1 or DR4) and TRAIL receptor 2 (TRAIL-R2, DR5, TRICK2, or KILLER) have cytoplasmic death domains and activate caspases in most tumorigenic but not normal cell lines. Two other receptors, TRAIL-R3 (DcR1) and TRAIL-R4 (DcR2), have truncated death domains and are considered "decoy" receptors as they do not activate caspases. We evaluated the response of

JTC-12 cells to commercially available TRAIL reagents compared to a human tumorigenic colon derived cell line, Colo205. In addition, we evaluated the response of the JTC-12 cells with the addition of a sensitizer, actinomycin D. Experiments confirmed that JTC-12 cells do respond to TRAIL reagents by activating caspase cascades though not to the same extent as the Colo205 cells. The addition of a sensitizer increases the induction of caspase 3/7 with a subsequent reduction in cell viability. Thus, JTC-12 cells may be used to evaluate candidate therapeutics for TRAIL or TNF-mediated toxicities.

303 KINETICS OF NASAL INFLAMMATION AND NEUROTOXICITY IN MICE EXPOSED TO MACROCYCLIC TRICHOHECENE MYCOTOXIN.

Z. Islam¹, C. J. Amuzie¹, K. N. Corps², J. R. Harkema² and J. J. Pestka¹. ¹Food Science and Human Nutrition, Michigan State University, East Lansing, MI and ²Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

Inhaled macrocyclic trichothecene (MTMs) mycotoxins may cause airway inflammation and neurotoxicity. Histopathology after exposure to roridin A (RA), a representative MTM, was related to apoptotic and inflammatory gene expression in murine nasal airways. C57Bl/6 mice were intranasally instilled with RA (500 μ g/kg bw) in 50 μ l saline or saline alone (controls) and sacrificed 6, 12, 24, or 72 h post instillation (PI). Both nose and brain were subjected to histopathologic and mRNA analyses. RA-induced apoptosis of olfactory sensory neurons (OSNs) resulted in marked atrophy of olfactory epithelium (OE) that peaked at 72 h PI. Elevated expression of proapoptotic genes Fas, PKR, p53, Bax, and CAD, as well as caspase-3 activation, preceded microscopic detection of OSN apoptosis and OE atrophy. Concomitantly, there was elevated mRNA expression of proinflammatory cytokines (TNF-alpha, IL-6, IL-1) and the chemokine MIP-2. Elevated mRNA expressions of IL-6 and MIP-2 were also detected in the olfactory bulb of the brain from 6 to 24 h PI. Simultaneous exposure to E. coli lipopolysaccharide (LPS; 500 ng/kg bw) and a lower dose of RA (250 μ g/kg bw) amplified nasal inflammation and apoptosis of OSNs induced by RA or LPS alone. Thus, a single intranasal exposure of RA induces both inflammation and loss of OSNs in the nose and brain of mice. RA-induced lesions were similar in character and severity to those previously reported in mice that were intranasally exposed to satratoxin G, an MTM found in *Stachybotrys chartarum*. These findings suggest that MTMs may have common cellular and molecular mechanisms of toxicity.

304 BEHAVIORAL DEFICITS AND NEURONAL APOPTOSIS FOLLOWING EARLY VPA EXPOSURE IN A MOUSE MODEL OF AUTISM.

C. Yochum¹, X. Ming², K. Reuhl³ and G. C. Wagner^{1,3}. ¹Psychology, Rutgers University, New Brunswick, NJ, ²Neuroscience, Rutgers University-UNDMJ, Newark, NJ and ³Pharmacology & Toxicology, Rutgers University, New Brunswick, NJ.

Previous studies have demonstrated neurobehavioral deficits following P14 administration of 400mg/kg of sodium valproate (VPA) to BALB/c mice. Our objective is to create a histopathological correlate for the behavioral deficits seen in mice following treatment. The time course of VPA-induced hippocampal and cerebellar apoptosis was examined using TUNEL staining. Mice were examined from P5 through P40 using a developmental behavioral battery consisting of motor, cognitive and social tests. VPA- and saline-injected mice were sacrificed at several time points following treatment, and their brains paraffin embedded and analyzed for apoptosis. VPA caused deficits in a number of neurobehavioral tests, most notably a reduction in play behavior starting on day 30, 16 days after the P14 injection. VPA-injected pups exhibited apoptotic cells in both the cerebellar and hippocampal regions with peak effects at 12 and 24 hrs, respectively (reflecting up to a 30-fold increase in apoptotic cells in cerebellum and a 10-fold increase in hippocampus over baseline). Cerebellar and hippocampal apoptosis provides an excellent biomarker for the behavioral deficits associated with VPA treatment. Both the behavioral deficits and damaged regions have been associated with autism.

305 BISPHENOL A INDUCES APOPTOSIS IN MOUSE HIPPOCAMPAL (HT-22) CELLS: ROLE OF CALCIUM-INDUCED REACTIVE OXYGEN SPECIES, MITOGEN-ACTIVATED PROTEIN KINASE AND NUCLEAR FACTOR- κ B.

S. Lee, H. Son, H. Park and S. Kim. Kyungpook National University, Daegu, South Korea.

Bisphenol A [BPA, 2, 2-bis-(4 hydroxyphenyl) propane], known to be xenoestrogen, is used in production of water bottles, baby bottles, cans, and teeth suture materials. Xenoestrogen causes adverse effects on the reproductive functions of human

and animals, similar to estrogen by binding estrogen receptor. In this report, we studied neurotoxicity of BPA and underlying mechanisms of action in mouse hippocampal cell lines (HT-22 cells). BPA treated HT-22 cells showed higher cell viability than control at below 100 μ M of BPA, but lower cell viability at over 100 μ M. BPA induced apoptotic cell death indicated by staining with Hoechst 33258, co-staining with Annexin V/propidium iodide, and activation of caspase 3. BPA-induced intracellular calcium modulated reactive oxygen species (ROS) production, which resulted in apoptotic cell death. Calcium antagonists abolished ROS production. BPA activated the phosphorylation of extracellular signal-regulated kinase (ERK) and c-Jun N-terminal kinase (JNK), and nuclear translocation of nuclear factor (NF)- κ B. Pretreatment with specific inhibitors for Ca, ROS, ERK, and JNK decreased BPA-induced cell death; however inhibitor for NF- κ B increased BPA-induced cell death. Results suggest that calcium, ROS, ERK, and JNK involve in BPA-induced apoptotic cell death in HT-22 cells. On the contrary, NF- κ B cascade is activated for survival signaling after BPA treatment. This work was supported by Brain Korea 21.

306 IMMUNOLOGICAL ALTERATIONS IN CHICKS FOLLOWING IN OVO EXPOSURE TO A BROMINATED FLAME RETARDANT MIXTURE: DE-71.

J. Stuckey¹, K. Bryant², J. Pangello³, J. Berger³, J. EuDaly⁴, D. Keil³, P. Jodice² and M. Peden-Adams⁴. ¹College of Charleston, Charleston, SC, ²Clemson University, Clemson, SC, ³UNLV, Las Vegas, NV and ⁴Medical University of South Carolina, Charleston, SC.

Polybrominated diphenyl ethers (PBDEs) are one of five major classes of currently used brominated flame retardants (BFRs). This study examined the effects of the commercial PentaBDE mixture DE-71 in white leghorn hatchlings on various developmental parameters and aspects of the immune system, including antibody responses, lymphocyte proliferation, PHA-skin test responses, white blood cell differential counts, and plasma lysozyme activity. DE-71 was dissolved in DMSO and added to Safflower oil at 10% to yield the dose concentrations. Gestation day (GD) 0 eggs were injected with either safflower oil/10%DMSO or DE-71 in safflower oil/10% DMSO at 0, 1, 10 or 25 mg/kg egg weight, and the chicks were grown to post hatch day (PHD) 14. Hatch rate was not effected by DE-71 treatment. A decrease in crown-rump length was observed but only at the 10 mg/kg egg weight treatment. Body mass, brain mass were not altered by DE-71 treatment while liver mass was increased only in the 19 mg/kg egg weight treatment. No significant differences in organ cellularity or mass were observed in the spleen, thymus or bursa. Lymphocyte proliferation was not altered by DE-71 treatment. Plasma antibody titers, as measured by hemagglutination, were not significantly altered by DE-71 treatment. Plasma lysozyme activity was significantly increased compared to control in the 10 mg DE-71/kg egg. The most striking response was suppression of the PHA skin response at the 10 and 25 mg/kg egg weight treatments. These data suggest alterations in cell-mediated immunity may occur following in ovo exposure to PDBEs in avian species and further studies should continue to characterize this in wild species.

307 IMMUNOLOGICAL ALTERATIONS IN CHICKS FOLLOWING IN OVO EXPOSURE TO PERFLUOROOCTANE SULFONATE (PFOS).

J. Berger¹, J. Stuckey², J. Pangello¹, J. EuDaly³, T. Scott⁴, K. Bryant⁴, D. Keil¹, P. Jodice⁴ and M. Peden-Adams³. ¹UNLV, Las Vegas, NV, ²College of Charleston, Charleston, SC, ³Medical University of South Carolina, Charleston, SC and ⁴Clemson University, Clemson, SC.

Perfluorinated hydrocarbons have been manufactured for over 40 years and have numerous applications in industry. Studies show that these perfluorinated compounds cause various toxicological effects; however, effects on immune function have not been addressed at length. This study examined the effects of PFOS in white leghorn hatchlings on various developmental parameters and aspects of the immune system, including antibody responses, lymphocyte proliferation, PHA-skin test responses, T-cell immunophenotypes, and plasma lysozyme activity following in ovo exposure. PFOS was dissolved in DMSO and added to Safflower oil at 10% to yield the dose concentrations. Gestation day (GD) 0 eggs were injected with either safflower oil/10%DMSO or PFOS in safflower oil/10%DMSO at 0, 1, 2.5 or 5 mg/kg egg weight, and the chicks were grown to post hatch day (PHD) 14. No decrease in hatch rate was observed in the PFOS treated eggs. Following in ovo exposure chicks exhibited increased liver and spleen weights at all treatment levels and at the 5 mg/kg treatment, body length (crown-rump length) was increased compared to control. For all three treatment groups, plasma IgG titers were increased compared to control as was lysozyme activity while no effect was seen in the cell mediated response in the PHA skin test. This is the first study to assess developmental and immune modulation following PFOS exposure in an avian species. These data indicates that immune alterations can occur in birds following in ovo

exposure to environmentally relevant concentrations of PFOS and demonstrates the need for further research on the effects of perfluorinated compounds on immune function.

308 IMMUNOLOGICAL ALTERATIONS IN WESTERN FENCE LIZARDS FOLLOWING ORAL EXPOSURE TO PFOS.

P. Guiney¹, L. Talent², D. Melson², J. EuDaly³, K. Kannan⁴ and M. Peden-Adams³. ¹SC Johnson, Racine, WI, ²Oklahoma State University, Stillwater, OK, ³Medical University of South Carolina, Charleston, SC and ⁴Wadsworth Center, Albany, NY.

Perfluorinated hydrocarbons have been manufactured for over 40 years and have numerous industrial applications. This group of compounds has recently generated considerable interest as some of these compounds (i.e., perfluorooctane sulfonate, PFOS) are ubiquitously persistent in the environment and widely detectable in blood samples of both wildlife and humans. Studies have shown that these perfluorinated compounds cause various toxicological effects; however, potential impacts on immune function have not been adequately addressed nor have effects in reptilian species been studied. In this preliminary study, adult male western fence lizards, an ideally small and environmentally sensitive species, were exposed to PFOS orally for 28 days (0, 1, 10, 100, 250 mg/kg total dose). Plasma, liver and spleen PFOS concentrations, T- and B-cell proliferation, the PFC response, hemagglutination, and lysozyme activity were assessed. The calculated LD50 (Trimmed Spearman-Kärber) in this experiment was 178.4 (95% CI: 162.9, 195.4). SRBC-specific IgM responses were increased compared to control in the 1 mg/kg treatment in both the hemagglutination assay and the PFC response. However, the PFC response was suppressed compared to control in the 250 mg/kg treatment group. Plasma lysozyme activity and T-cell proliferation were not significantly altered by any PFOS treatment. B-cell proliferation was suppressed compared to control at the 250 mg/kg treatment. Whether these changes in immune function are a direct effect of PFOS exposure on the immune system or a secondary effect related to other systemic toxicity remains to be investigated. Overall, this data indicates that immune alterations can occur in reptiles following exposure to PFOS and demonstrates the need for further research on the effects of perfluorinated compounds at more environmentally relevant concentrations on immune function.

309 PFOS-INDUCED IMMUNE MODULATION IN B6C3F1 MICE FOLLOWING ORAL EXPOSURE.

D. Keil¹, J. EuDaly², J. Berger¹, J. Pangallo¹ and M. Peden-Adams². ¹UNLV, Las Vegas, NV and ²Medical University of South Carolina, Charleston, SC.

Perfluorinated hydrocarbons have been manufactured for over 40 years and have numerous applications in industry. This group of compounds (i.e., perfluorooctane sulfonate (PFOS)) have recently generated much interest as they are persistent in the environment and detectable in blood samples of both wildlife and humans. Studies show that these perfluorinated compounds cause various toxicological effects; however, effects on immune function have not been fully characterized. We have previously shown the PFC response is suppressed in adult B6C3F1 mice. This expanded study includes assessment of splenic and thymic T-cell populations, hemagglutination, and plasma lysozyme activity. Adult male and female B6C3F1 mice were exposed to PFOS orally for 28 days (0, 0.005, 0.05, 0.1, 0.5, 1, 5 mg/kg total dose). The PFC cell response, as we have shown previously, was suppressed in males beginning at 0.05 mg/kg while female mice were affected beginning at 0.5 mg/kg. Numbers of splenic CD4+ and CD8+ cells were increased in female mice at all treatment levels while CD4+/CD8+ and CD4-/CD8- cells were increased beginning at 0.05 mg/kg. Splenic CD8+ and CD4-/CD8- cells in males were increased while CD4+/CD8+ lymphocytes were decreased in the 0.1, 0.5, 1, and 5 mg/kg treatments. Furthermore, CD4+ cells were significantly decreased in male following 0.1, 0.5 and 5 mg/kg exposures. In females, thymic CD8+ cells were increased in the 1 and 5 mg/kg treatments, while no alterations in thymic CD4/8 lymphocyte subpopulations were observed in males. Plasma lysozyme activity was not altered compared to controls in male mice but was significantly increased in the females at 5 mg/kg. These data suggests that at environmentally relevant ranges PFOS alters immunological function.

310 AMELIORATING POTENTIAL OF EMBLICA OFFICINALIS ON LEAD-INDUCED IMMUNOSUPPRESSION AND OXIDATIVE STRESS IN CHICKENS.

N. Singh and S. K. Hore. *Department of Pharmacology and Toxicology, College of Veterinary and Animal Sciences, G.B.Pant University of Agriculture and Technology, Pantnagar, India.* Sponsor: M. Ehrlich.

Lead(Pb) is one of the major industrial pollutants, which adversely affects animal health. They act as inducers of oxidative stress & disrupt the normal immune system of the body making animals prone to many disease processes. There are certain

medicinal plants known to resist diseases in human by reducing oxidative stress or stimulating immune system. The present study evaluates the ameliorating potential of emblica officinalis on lead induced toxicity in chickens. 50% ethanolic extract of *E. officinalis* fruit (EFE) was assessed for its effect on Pb-treated chickens. Six groups of day old chicks were used in this trial. Group I birds served as control. Group II birds received EFE @ 150mg/kg /day. In Group III to VI, day-3 birds were allowed to receive Pb-treated feed @ 660ppm. The birds of group IV & V were treated with EFE @ 50 and 150 mg/kg/day, respectively in drinking water. Thiamine hydrochloride (100 mg/kg/day) was given to group VI birds. Immunological & oxidative profiles were recorded after 5 & 8 weeks of feeding trial. Immunological parameters like Macrophage function test (MFT), lymphocyte stimulation test (LST), DTH & antibody (Ab) titre (ELISA) were measured. For oxidative profile malondialdehyde, catalase and reduced glutathione was measured in blood & tissue samples. Pb significantly decreased the value of MFT, LST and DTH and Ab titre against RD-vaccine birds. EFE and thiamine significantly increased the value of ELISA, MFT, LST & skin thickness (DTH) in normal & Pb treated broilers after 5 weeks of trial. The 8 weeks of Pb resulted in increase in lipid peroxidation and decrease in the activity of GSH and catalase in RBC, liver & brain. EFE & thiamine normalized the levels in Pb treated birds. As compared to Pb-treated group, there was reduction in blood Pb level in EFE and thiamine treated groups. It can be concluded that EFE have the potential to provide protection in broilers from lead-induced alterations in the immunological and oxidative profiles.

311 DELTA-9-TETRAHYDROCANNABINOL MODULATES LEVELS OF VIRAL H1, HOST IMMUNE CELL POPULATIONS, AND AIRWAY MORPHOLOGY IN A MODEL OF HOST-RESISTANCE TO INFLUENZA.

J. P. Buchweitz^{1,2}, P. W. Karmaus², J. R. Harkema^{3,2}, K. Williams³ and N. E. Kaminski^{1,2}. ¹Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

Delta-9-tetrahydrocannabinol (THC) is recognized for its role in modulating host-immune responses, in particular those mediated by T lymphocytes. Accordingly, the present study was designed to examine the effects of THC on: 1) immune cell recruitment and release of soluble mediators in response to a challenge with a non-lethal dose of influenza virus A/PR/8 (PR8) in the lower airways, and 2) associated changes in the morphology of the epithelium lining the main axial airway. Three separate studies were conducted wherein C57BL/6 mice were gavaged with one of three different concentrations of THC (25, 50, or 75 mg/kg) or corn oil for 5 consecutive days. On day three, mice were intranasally instilled with 50 plaque forming units of virus or vehicle, saline, 4 hours prior to THC exposure, and then sacrificed 7 days post-infection (dpi). In these studies, THC increased hemagglutinin 1 mRNA in a dose-dependent manner above PR8 controls. Retrievable populations of inflammatory cell types in bronchoalveolar lavage fluid, in particular monocytes and CD4+ and CD8+ T cells, were attenuated with THC treatment. Likewise, inflammation scores obtained from histopathology were suppressed by THC by 10 dpi. THC had little to no effect on protein levels of chemokines and cytokines. However, THC influenced epithelial morphology associated with inflammation at 10 dpi by decreasing mucous cell metaplasia (MCM), which was not correlated with levels of neutrophil-derived elastase. Collectively, the findings in this study suggest that THC exposure increased viral burden through modulation of the host-immune response while decreasing the overall inflammatory response. (Supported in part by NIH DA007908 and MSU Foundation SPG)

312 CHARACTERIZATION OF THE HOST IMMUNE RESPONSE TO AN INFLUENZA CHALLENGE IN CB1/CB2 RECEPTOR-NUL MICE AND C57BL/6 WILD TYPE MICE TREATED WITH DELTA-9-TETRAHYDROCANNABINOL (THC).

P. W. Karmaus², J. P. Buchweitz^{1,2}, J. R. Harkema^{3,2} and N. E. Kaminski^{1,2}. ¹Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

It has been previously shown that THC modulates host-immune responses to influenza infection in a concentration-dependent manner. Therefore, we hypothesized that THC exerted these modulatory effects through a cannabinoid receptor-dependent mechanism. Accordingly, the present study was designed to examine the effects of THC on host-immune responses to an influenza infection in wild-type (WT) mice as compared to cannabinoid receptor (CB1/CB2) knockout (KO) mice. Mice received THC (75 mg/kg) and/or corn oil (CO) by oral gavage. On the third

day of exposure, mice were intranasally instilled with 50 plaque forming units (pfu) of virus or vehicle, saline (SAL), 4 hours prior to THC exposure, and then sacrificed at 7 days post-infection (dpi). KO mice exhibited marked decreases in the numbers of retrievable monocytes and neutrophils in bronchoalveolar lavage fluid (BALF) with THC treatment. Additionally, background CD4+ T cells were elevated in BALF from KO mice. KO mice receiving both THC and PR8 had increased levels of CD4+ T cells. No effect of THC was observed with PR8 treatment as compared to PR8 controls for CD8+ T cells. Additionally, no difference was observed between strains. The levels of soluble chemokines (MCP-1) and cytokines (TNF- α and IFN- γ) in the BALF were elevated with PR8 treatment alone in KO mice as compared to WT. Interestingly, THC treatment resulted in enhanced numbers of mucin-positive epithelial cells lining the main axial airway in KO mice that was not associated with inflammation. Collectively, this study suggests that THC, in part, modulated host-immune responses to PR8 in a CB1 and CB2 receptor-independent manner. (Supported in part by NIH DA007908 and MSU Foundation SPG)

313 TWO SELECTIVE CB2 CANNABINOID RECEPTOR AGONISTS DO NOT EXHIBIT IMMUNOTOXICITY IN RAT KLH ELISA AND HOST RESISTANCE STUDIES.

D. L. Shuey¹, F. G. Burleson², G. R. Burleson², A. Makriyannis³ and R. J. Gerson¹. ¹Endo Pharmaceuticals Inc., Chadds Ford, PA, ²Burleson Research Technologies Inc., Morrisville, NC and ³MakScientific LLC, Storrs, CT.

Selective agonists of the CB2 cannabinoid receptor have demonstrated potent activity in various animal models of pain, including acute antinociception, inflammatory and neuropathic pain. CB2 cannabinoid receptors are peripherally located and found primarily on immune cells, although their role in immune function is not clear. Studies were undertaken to evaluate the potential immunotoxic effects of two potent and selective CB2 agonists, AM1241 and MAK1400. Both compounds were tested in the rat Keyhole Limpet Hemocyanin (KLH) ELISA Assay; AM1241 was also evaluated in the Rat Influenza Host Resistance Model. All studies were conducted in female F344 rats. Compounds were administered by intraperitoneal injection. Doses selected (AM1241: 0.3-3.0 mg/kg; MAK1400: 0.2-6 mg/kg) were within to several-fold higher than the range found to be effective in various pain models. Compounds were administered once daily by intraperitoneal injection in all studies. In the KLH assay, compounds were administered for 14 days. Reconstituted KLH was injected intraperitoneally on Day 9 and KLH-specific IgM determined on Day 14. Cyclophosphamide was included as a positive control. In the Host Resistance Study, AM1241 was administered for up to 28 days. Animals were infected intranasally with rat-adapted influenza virus after 7 days of AM1241 administration; lung infectious virus titer was determined 1, 3, 6, 8 and 21 days after infection. Dexamethasone was included as a positive control. No overt toxicity (mortality, clinical signs, body weight effects) was observed in any study. There were no effects of either compound on spleen weight or KLH-specific IgM production in the KLH ELISA studies. AM1241 did not affect viral clearance in the Host Resistance Study. Results of these studies indicate that repeated administration of selective CB2 receptor agonists does not adversely impact immune system function in rats.

314 EXPRESSION LEVELS OF I κ B α PLAY AN IMPORTANT ROLE IN 3'IGH RR ACTIVATION.

R. Salisbury, E. J. Romer and C. E. Sulentic. *Pharmacology & Toxicology, Wright State University, Dayton, OH.*

Transcriptional regulation of the immunoglobulin heavy chain (IgH) gene involves several regulatory elements including the 3'IGH regulatory region (3'IGH RR). The 3'IGH RR is composed of four distinct enhancers (hs3A, hs1.2, hs3B, hs4) and contains DNA binding sites for several transcription factors including NF- κ B/Rel proteins. A recently identified DNA binding motif the dioxin responsive element (DRE) may also contribute to the regulation of the 3'IGH RR. 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), a known disrupter of B cell differentiation, induces binding of the aryl hydrocarbon receptor (AhR) nuclear complex to a DRE motif within the hs1.2 and hs4 enhancers. Interestingly, TCDD profoundly inhibits the activation of the 3'IGH RR by the B cell activator lipopolysaccharide (LPS) but enhances LPS-induced activation of the hs4 enhancer. Within the hs4 enhancer, the DRE overlaps an NF- κ B/Rel binding motif (κ B) and site directed mutational analysis demonstrated a cooperative interaction between proteins binding to these motifs. The objective of the current studies was to evaluate the expression of NF- κ B/Rel proteins including their negative regulator I κ B α following LPS stimulation and TCDD treatment and to compare these results to 3'IGH RR activity under the same treatment conditions. For these studies we utilized the CH12.LX B cell line and its variant, CH12.I κ B α AA, that expresses an inducible I κ B α super repressor (I κ B α AA). Western blot analysis demonstrated a marked decrease in endogenous I κ B α with a reciprocal increase in nuclear RelA in the CH12.LX cells one hour after LPS stimulation. In the CH12.I κ B α AA cells endogenous I κ B α was also

decreased by one hour after LPS stimulation and maximal expression of the IkB α AA could be induced by one hour. Furthermore, expression of the IkB α AA partially attenuated the LPS-induced activation of the 3'IgH RR and the activation of the h δ 4 following LPS and TCDD cotreatment. These results suggest that NF- κ B/Rel proteins are at least partially responsible for 3'IgH RR modulation by LPS and TCDD. (Supported by Boonshoft School of Medicine, WSU)

315 MIXTURES EXPOSURE WITH PHOSPHORO-ORGANIC PESTICIDES AND RADIONUCLIDES (89-SR, 144-CE) AND CHANGE OF PHAGOCITARY ACTIVITY OF NEUTROPHILS IN RATS.

Z. D. Paskalev¹, D. B. Apostolova² and I. B. Pejankov³. ¹Radiotoxicology, National Center of Radiobiology and Radiation Protection, Sofia, Bulgaria, ²Occupational Toxicology, Clinic of Occupational Diseases, Sofia, Bulgaria and ³Radiobiology, National Center of Radiobiology and Radiation Protection, Sofia, Bulgaria. Sponsor: Z. Paskalev.

Organophosphorous pesticides (PhO) represent one of the most widely used classes of pesticides. Development of the nuclear energy determines a migration of radionuclides (RA) in the environment. The both factors are with high potential for human exposure and respectively immune system. We investigated the interaction of the PhO and the RA with the organisms of rats. The study was carried out on the changes in the liver function of rats and the kinetics of 89-Sr and 144-Ce after treating with PhO. The chemical and radiation factors were applied one by one or in combination between them. Chronic administration (during 4 months) of RA and PhO in the rats line Wistar perorally (89-Sr) and intraperitoneally (144-Ce) were introduced in two concentrations (370kBq and 3,6kBq for the two isotopes) each in combination with the PhO, introduced in an amount of 1/60 and 1/20 out of a lethal dose LD50/30. With a 30-day period have traced the kinetics of RA in the femur, liver and gastrointestinal tract of the experimental and the control animals and determined the phagocitary activity of neutrophils. The results obtained show that a certain tendency is observed to smaller quantities in the bones and liver and longer retaining in the gastrointestinal tract of 89-Sr and 144-Ce, introduced in the rats in combination with the PhO compared to the control groups. It was established that the effect of radiation and non-radiation factors in chronic treatment increased, expressed in inhibition of the phagocitary activity of neutrophils. This effects may become grave in doses causing approximately equal biological changes. These recent data are beginning to shape risk assessment. They will be used to regulate and provide assurance of health and environment protection, and more appropriate perspective to human risk assessment.

316 NEUTROPHIL DEPLETION DELAYS OR ALTERS AIRWAY EPITHELIAL REPAIR FROM 1-NITRONAPHTHALENE INDUCED LUNG INJURY.

L. M. Sullivan, L. M. Davison, E. D. Wallis and C. G. Plopper. University of California, Davis, Davis, CA.

Neutrophils play an important role in airway epithelial repair. In response to oxidant injury, neutrophils have been shown to have a beneficial role through clearance of damaged cells. However, the role of neutrophils in repair from bioactivated toxicants is unclear. 1-Nitronaphthalene (INN) is a bioactivated toxicant that causes a significant inflammatory response in the rat lung. Earlier studies have shown that airway epithelial repair appears to be complete 4 days post INN treatment in neutrophil-sufficient rats. Airway epithelial cell composition is still altered in neutrophil-depleted rats at 4 days post INN treatment. Neutrophil-depleted rats had greater mass of nonciliated cells than neutrophil-sufficient rats and control rats. Nonciliated cells are known to be progenitor cells of ciliated cells and we believe that this altered epithelial cell composition is due to delayed repair of airway epithelial cells. In order to test this hypothesis, we compared proliferation between neutrophil-sufficient and neutrophil-depleted rats at 4 days post INN treatment. To deplete circulating neutrophils, rats were injected with an anti-neutrophil antibody 14 hours before INN exposure. Proliferation, as determined by bromodeoxyuridine incorporation, was quantified between neutrophil-depleted and neutrophil-sufficient rats in 2 different airway generations. In proximal and distal airway epithelium of neutrophil-sufficient rats, the labeling index was 2.67 and 0.69 respectively, indicating that cellular proliferation was near control levels. However, in the proximal and distal airway epithelium of neutrophil-depleted rats, the labeling index was 13.00 and 9.87 respectively. These data combined with the morphological observations of incomplete epithelium suggest that repair is delayed or altered following INN-induced lung injury without the presence of neutrophils. Supported in part by NIH grants ES 004311, ES06700, ES04699 and USEPA grant RD-8324 1401-0. This abstract does not reflect EPA policy.

317 1-BROMOPROPANE-INDUCED INDUCIBLE NITRIC OXIDE SYNTHASE AND PROINFLAMMATORY CYTOKINES EXPRESSION IN MACROPHAGES.

E. Han^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

1-Bromopropane (1-BP) is an isomeric chemical of 2-bromopropane (2-BP). 2-BP was used as an alternative to chlorofluorocarbons in a Korean electronics factory and caused reproductive and hematopoietic disorders in male and female workers. After identification of 2-BP toxicity, 1-BP was introduced to the workplace as a new alternative to ozone-depleting solvents. But, the influence of 1-BP on cytokine production or the functions of macrophages is unclear. This study examined the effects of 1-BP on the production of nitric oxide (NO) and the proinflammatory cytokines, and analyzed the molecular mechanism in mouse macrophages. The addition of 1-BP to macrophages induced the NO and proinflammatory cytokines (IL-1 β , IL-6, and TNF- α) and expression levels of inducible nitric oxide synthase (iNOS) and these cytokine genes in a dose-dependent manner. The NF- κ B sites were identified in the promoter of the iNOS and proinflammatory cytokines genes. The transient transfection and electrophoretic mobility shift assays revealed that the NF- κ B transcription factor mediated the 1-BP-induced increase in the iNOS and proinflammatory cytokines expression levels. Overall, this study provides evidence showing that 1-BP has inflammatory potential that is previously unrecognized immunomodulating activity.

318 DEVELOPMENTAL IMMUNOTOXICOLOGY OF A COMMERCIAL POLYBROMODIPHENYLETHER (PBDE) MIXTURE.

G. S. Bondy, W. Cherry, L. Coady, E. MacLellan, K. Rutherford, C. Armstrong, M. Parenteau, M. Barker, P. Bellon-Gagnon, D. Arnold and J. Shenton. Bureau of Chemical Safety, HPFB, Health Canada, Ottawa, ON, Canada.

Polybromodiphenylethers (PBDEs) are used as flame retardants in a wide variety of textiles and plastics and are found at ppb levels in human blood, milk and tissues. To assess the impact of these chemicals on the developing immune system, adult (F0) rats (8/sex/group) were administered PBDEs (DE-71 technical mixture) by oral gavage at doses of 0, 0.5, 5 or 25 mg/kg body weight/day for 10 weeks, after which the rats were bred. Oral exposure of F0 rats continued through breeding, gestation and lactation. Weanling (F1) rats (13-18 rats/sex/group) received corresponding doses of the DE-71 mixture by gavage until post-natal day 42, at which time pups from each dose group were sacrificed to assess clinical, hematological and histopathological changes. Although dose-dependent increases in apoptotic lymphocytes and tingible macrophages were evident in the thymus and mesenteric lymph nodes of F1 males and females, there were no significant changes in numbers of circulating white blood cells, including lymphocytes and lymphocyte subsets. There were no histopathological changes in spleen from F1 pups as a result of PBDE exposure; however, tritiated thymidine incorporation into spleen lymphocytes was elevated in a dose-dependent manner in unstimulated and mitogen-stimulated cultures. To assess the functional effects of immune changes a further group of F1 rats was challenged with the T-dependent antigen keyhole limpet hemocyanin (KLH). Humoral (anti-KLH IgG) responses were not significantly altered by PBDE exposure. Delayed type hypersensitivity (DTH) responses to footpad injections of heat-inactivated KLH were significantly elevated in female rats exposed to 0.5 mg PBDE/kg bwt/day, but not in rats exposed to 5 or 25 mg PBDE/kg bwt/day. While the dichotomy between PBDE-related increases in immune function in conjunction with histopathological changes indicative of immunosuppression remains to be clarified, the results point to the potential for PBDEs to modulate immune function in developing animals.

319 ROLE OF GLUTATHIONE CONJUGATION IN THE HEPATOTOXICITY AND IMMUNOTOXICITY INDUCED BY 1, 3-DIBROMOPROPANE IN FEMALE BALB/C MICE.

M. Kang, S. Lee, D. Lee, C. Kim, H. Jeong, S. R. Bista and T. Jeong. Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, South Korea.

The effects of 1,3-dibromopropane (1,3-DBP) on the hepatotoxicity and immunotoxicity were investigated in male ICR mice. 1,3-DBP is a clear, colorless to yellow liquid used in industry and employed to stabilize wool. In this study, based on the LC/ESI-MS analyses, S-bromopropyl glutathione (GSH) were observed at m/z 427.9 and 429.9 in the positive ESI spectrum with a retention time of 5.29 and 5.23 min, respectively. Following treatment of mice with 150, 300 and 600 mg/kg of 1,3-DBP once for 12 h, the amounts of S-bromopropyl GSH was detected maximally in liver homogenates at the 600 mg/kg and the hepatic GSH level was significantly decreased. In a time course study, the production of S-bromopropyl GSH was detected maximally 6 h after the treatment and the hepatic GSH level de-

creased at 6 and 12 h. Oral 1,3-DBP significantly suppressed the numbers of antibody-forming cells in response to a T-dependent antigen in a dose-dependent manner. The formation of GSH conjugate with 1,3-DBP might be related to the increased oxidative stress following the depletion of GSH in liver, by which it leads to serious hepatotoxicity and immunotoxicity in female BALB/c mice. (Supported by a grant from KFDA and a BK 21 grant)

320 ROLE OF GLUTATHIONE CONJUGATION IN 1-BROMOBUTANE-INDUCED HEPATOTOXICITY AND IMMUNOTOXICITY IN FEMALE BALB/C MICE.

H. Jeong¹, D. Lee¹, C. Kim¹, T. Jeon¹, S. R. Bista¹, S. Lee¹, M. Kang¹, D. Kim² and T. Jeong¹. ¹Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, South Korea and ²BBRC, KIST, Seoul, South Korea.

1-Bromobutane (1-BB) was used as an alkylating reagent or a material of dehalogenation study by bacteria. In the present study, the hepatotoxic and immunotoxic effects of 1-BB were investigated in female BALB/c mice. The animals were treated once orally with 375, 750 and 1500 mg/kg of 1-BB in corn oil for a dose response study or treated orally with 1500 mg/kg of 1-BB for 6, 12, 24 and 48 hr for a time course study. The hepatic contents of GSH were significantly reduced by 1-BB at the highest dose and the splenic contents of GSH were slightly reduced by 1-BB in a dose-dependent manner. The S-butyl GSH was identified in livers following the treatment with 1-BB by liquid chromatography-electrospray ionization tandem mass spectrometry. When the production of conjugates from 1-BB was investigated in livers following an oral treatment with 1500 mg/kg of 1-BB for 6, 12, 24 and 48 hr, the GSH conjugates were detected maximally 6 hr after the treatment. The hepatic contents of malondialdehyde were significantly increased at 1500 mg/kg of 1-BB, 12 and 24 hr after the treatment. An oral 1-BB treatment significantly suppressed the antibody response to a T-dependent antigen and the production of splenic intracellular IL-2 in response to Con A in dose-dependent manners. Our present results suggested that 1-BB could cause hepatotoxicity and immunotoxicity due to the depletion of GSH content following the formation of GSH conjugates with 1-BB in female BALB/c mice. (Supported by the grant from National Institute of Toxicological Research, KFDA and the BK 21 grant)

321 DEVELOPMENTAL AND EARLY-LIFE EXPOSURE OF AUTOIMMUNE-PRONE MRL+/+ MICE TO TRICHLOROETHYLENE ALTERS CENTRAL AND PERIPHERAL IMMUNE FUNCTION.

S. J. Blossom¹ and J. C. Doss². ¹Pediatrics, University of Arkansas for Medical Sciences/Arkansas Children's Hospital Research Institute, Little Rock, AR and ²Pathology, University of Arkansas for Medical Sciences, Little Rock, AR.

Trichloroethylene (TCE) is a widespread environmental toxicant known to promote CD4+ T lymphocyte activation and autoimmunity in adult MRL+/+ mice. Because developing tissues may be more sensitive to toxicant exposure, it was hypothesized that continuous TCE exposure beginning at the onset of gestation might induce even more pronounced CD4+ T cell effects and exacerbate the development of autoimmunity in MRL+/+ mice. In the current study, MRL+/+ mice were exposed to occupationally-relevant doses of TCE from conception until adulthood. The CD4+ T cell effects in the thymus and periphery were evaluated. Serum antibody levels were also tested as indicators of early signs of autoimmunity. TCE exposure altered the number of thymocyte subsets, and reduced the capacity of the most immature thymocytes to undergo apoptosis *in vitro*. In the periphery, T cell IFN- γ production was monitored in the blood prior to sacrifice by intracellular cytokine staining and flow cytometry. TCE induced a dose-dependent increase in T cell IFN- γ as early as 4-5 weeks of age. In addition, the serum levels of anti-histone autoantibodies (autoabs) and total IgG2a were significantly elevated in the TCE-exposed offspring. The data illustrated that occupationally-relevant doses of TCE administered throughout development until adulthood affected central and peripheral immune function in association with early signs of autoimmunity. It is possible that early-life exposure to TCE may alter some aspect of self tolerance in the thymus, leading to autoimmune disease later in life.

322 AUTO-IMMUNE RESPONSE IN REFRIGERATION MECHANICS EXPOSED TO HALOGENATED HYDROCARBONS.

S. Gunnare¹, M. Vidali², L. Lillienberg³, L. Ernstgård¹, B. Sjögren¹, M. Hagberg³, E. Albano² and G. Johanson¹. ¹Work Environment Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, ²Department of Medical Sciences, University of East Piedmont, Novara, Italy and ³Occupational and Environmental Medicine, Sahlgrenska University Hospital, Göteborg University, GÖ-teborg, Sweden.

Hydrofluorocarbons (HFC) and hydrochlorofluorocarbons (HCFC) have replaced the chlorofluorocarbons (CFC) in e.g. refrigeration installations and air-conditioning systems. During the substitution period, refrigeration mechanics reported

symptoms like asthma, influenza-like reactions, and joint troubles. These symptoms resemble those of chronic inflammatory diseases with an autoimmune component. Exposure to gases similar to the new refrigerants (e.g. halothane) may result in development of antibodies against proteins modified by their reactive metabolites as well as auto-antibodies against CYP2E1, which is the main enzyme metabolizing these compounds. The aim of this study was to determine if occupational exposure to halogenated hydrocarbons used as refrigerants generates autoimmune responses against CYP2E1.

Venous blood was collected from 44 Swedish refrigeration mechanics who were occupationally exposed to halogenated hydrocarbons. Thirty of these men had asthma, joint- or influenza-like symptoms and the remaining 14 individuals were free from such symptoms. Unexposed, healthy Swedish (n=35) and Italian (n=26) persons were used as controls. The anti-CYP2E1 reactivity in serum was measured by ELISA. Non-parametric tests were used for group comparisons (Kruskal Wallis, Wilcoxon rank-sum) and correlations (Spearman's Rho). The significance level was set to 0.05. The study was approved by Swedish and Italian ethics committees.

No increase in CYP2E1 antibody titer was seen among refrigeration mechanics with symptoms, neither compared with healthy controls, nor with asymptomatic workers. Further, no relation between antibody titer and severity of symptoms, smoking or age was detected.

In conclusion, no autoimmune response against CYP2E1 was detected in refrigeration mechanics exposed to halogenated hydrocarbons.

323 DEOXYNIVALENOL IMPAIRS RESISTANCE TO RESPIRATORY REOVIRUS INFECTION AND PROMOTES VIRAL BRONCHOPNEUMONIA.

M. Li^{1,2}, J. R. Harkema^{2,3}, C. F. Cuff⁴ and J. J. Pestka^{1,2}. ¹Food Science and Human Nutrition, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI, ³Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI and ⁴Microbiology and Immunology, West Virginia University, Morgantown, WV.

The capacity of the trichothecene mycotoxin deoxynivalenol (DON), a frequent contaminant of cereal grains, to interfere with the murine respiratory reovirus infection was assessed. Balb/c female mice (5 wk old) were orally gavaged with DON (10 mg/kg body weight) or saline vehicle and then intranasally instilled with reovirus serotype 1, strain Lang (T1/L). Both viral titers and reovirus L2 gene expression were 10-fold higher in lungs of DON-treated mice than in saline controls at 10 d post-instillation (PI). As little as 2 mg/kg bw DON impaired viral clearance. DON amplified reovirus-induced IFN-beta and IFN-gamma mRNA responses in lung, however, the toxin suppressed mRNA expression for IFN-alpha beta receptor (IFNAR) and IFN-gamma receptor (IFNGR). Decreased IFNAR expression corresponded to impaired induction of two Type 1 IFN-dependent antiviral genes, double-stranded RNA protein kinase (PKR) and oligoadenylate synthase 2 (OAS2). Respiratory reovirus infection caused a mild bronchopneumonia in mice which was markedly exacerbated by DON as evidenced by severe inflammatory cell infiltration, marked alveolar damage and a higher volume density of intraepithelial mucous substances in pulmonary airways. DON also enhanced viral-induced elevations of protein, MCP-1, TNF-alpha and inflammatory cells in the bronchoalveolar lavage fluid (BALF). Furthermore, DON exposure upregulated induction of reovirus-specific IgA in BALF, fecal pellets and serum. DON's effect on BALF IgA was preceded by elevated IL-6 expression and secretion in the lung. Accordingly, the results suggest that DON compromised resistance to respiratory viral infection.

324 THE RED BLOOD CELL PROTEOME IS ALTERED BY PRIMING WITH 2-BUTOXYETHANOL.

P. Palkar¹, M. C. Korrapati¹, D. G. Kakhniashvili², S. R. Goodman² and H. M. Mehendale¹. ¹Department of Toxicology, The University of Louisiana at Monroe, Monroe, LA and ²Department of Molecular & Cell Biology, The University of Texas at Dallas, Dallas, TX.

Administration of a low priming dose of 2-butoxyethanol (BE, 500 mg/kg, po) 7 days prior to a LD90 dose (1500 mg BE/kg, po) offers protection against the lethal dose-induced hemolysis and death in female Sprague Dawley rats due to efficient replacement of RBCs with new resilient red blood cells (RBCs). *In vitro* incubation of RBCs isolated from vehicle-treated (distilled water, 5 ml/kg, po, V-RBCs) and primed rats (500 mg BE/kg, 5 ml/kg, po, P-RBCs) on day 7 with 2-butoxyacetic acid (1 to 10 mM BAA, hematotoxic metabolite of BE) over a time course (1 to 4 h) revealed resiliency of P-RBCs to hemolysis as compared to V-RBCs (Sivarao *et al. Arch. Toxicol.* 69:526-532, 1995). The objective of the present work was to test the hypothesis that the resiliency of P-RBCs to hemolysis is due to the appearance of survival proteins in P-RBCs. The cytosolic and membrane fractions were prepared from V-RBCs and P-RBCs. The fractions were labeled with Cy3 and Cy5 fluorescent dyes and subjected to 2-dimensional differential gel electrophoresis (2-DIGE) to perform protein profiling studies on V-RBCs versus P-RBCs. Owing to

high amount of hemoglobin, cytosolic samples had to be sub-fractionated into three different fractions (I, II, and III) by size exclusion chromatography. While the protein profiling in P-RBCs cytosolic fraction III is underway, separation and quantitation of other fractions revealed 11 membrane proteins, 9 (fraction I) and 25 (fraction II) cytosolic proteins increased significantly (≥ 2.5 fold) in P-RBCs as compared to V-RBCs. Our preliminary studies with membrane proteins suggest that the increased protein spots might be identified as ankyrin, adducin, anion exchange, 4.1 or 4.2 proteins. Identification of the increased proteins by LC-MS/MS and their functional categorization is in progress.

325 LUNG INFLAMMATION AND CARDIOVASCULAR OUTCOMES - WHOLE BLOOD GENE EXPRESSION STUDIES IN A LIPOPOLYSACCHARIDE (LPS) PHARYNGEAL ASPIRATION MOUSE MODEL.

A. Erdely, R. Salmen, R. Chapman, T. Hulderman and P.P. Simeonova. *HELD, CDC/NIOSH, Morgantown, WV.*

Recent animal and epidemiological studies suggest that pulmonary inflammation (e.g. ultrafine particulates) can trigger negative cardiovascular outcomes although the mechanism(s) resulting in systemic effects are not well established. Expression profiling of blood samples is becoming a useful tool for disease screening and identification of new biomarkers. In this study, it was hypothesized that lung inflammation results in activation of systemic gene expression related to cardiovascular disease. Prior to analyzing models of occupational exposure, pharyngeal aspiration of LPS was characterized with intraperitoneal (IP) injection as a positive control. C57BL/6 mice were treated with LPS (0.1mg/kg) and sacrificed 2hr post exposure. Whole blood and tissues were harvested for analysis of mRNA transcripts related to inflammation and coagulation. Expectedly, IP LPS resulted in a marked inflammatory response in the blood, heart and lung and pharyngeal aspiration of LPS resulted in a significant lung inflammation. Interestingly, whole blood showed similar gene expression induction of macrophage-inflammatory protein-2 (MIP-2) and tumor necrosis factor alpha (TNF α) following LPS by pharyngeal aspiration or IP injection. Extrapulmonary tissues were mostly unaffected by instillation of LPS into the lung. In conjunction with inflammation, changes in tissue factor (TF) and plasminogen activator inhibitor-1 (PAI-1) have been associated with increased risk of cardiovascular disease. Neither TF nor PAI-1 gene expression was elevated in blood following IP LPS although PAI-1 was strongly induced in the heart and lung. Following pharyngeal aspiration of LPS, both TF and PAI-1 were significantly increased in the lung and whole blood but not in the heart. In conclusion, lung inflammation results in activation of inflammatory and coagulation biomarkers associated with cardiovascular diseases and blood gene expression studies can identify biomarkers which predict cardiovascular outcomes in occupational-related respiratory exposures.

326 OVINE MATERNAL STRESS DURING LATE PREGNANCY ALTERS OFFSPRING FEBRILE RESPONSIVENESS TO SYSTEMIC ENDOTOXIN CHALLENGE LATER IN LIFE.

R. E. Fisher¹, H. A. Drake¹, E. J. Finegan¹, S. P. Miller¹, J. L. Atkinson¹, H. J. Boermans² and N. A. Karrow¹. ¹Animal and Poultry Science, University of Guelph, Guelph, ON, Canada and ²Biomedical Science, University of Guelph, Guelph, ON, Canada.

Epigenetic programming of the neuroendocrine-immune axis during fetal development may contribute to variation in the febrile response and subsequently influence an individual's resistance to pathogenic infection later in life. In this study gender-specific changes in the ovine febrile response to systemic *Escherichia coli* lipopolysaccharide (LPS) were examined over time using infrared imaging, and an assessment was carried out to determine if maternal inflammatory stress experienced during late pregnancy influences febrile responsiveness of the offspring later in life. Pregnant sheep were allocated to 3 treatment groups and challenged with saline, or *E. coli* LPS (400 ng/kg x 3 consecutive days, 1.2 μ g/kg) commencing on gestation day 135. Offspring of these stressed sheep were challenged with 400 ng/kg of LPS at six months of age and infrared energy emitted from the ear and eye was measured hourly for 6 hours post challenge to determine tissue temperatures; these measurements were compared with rectal temperatures. As expected, eye and rectal temperatures increased and then returned to basal levels within 6 hours of the LPS challenge. Ear temperature measurements on the other hand, decreased rapidly and then increased such that basal measurements were exceeded. This response was more pronounced in the females and is likely attributed to peripheral vasoconstriction. Female eye and rectal temperature was also higher than male offspring during LPS challenge, and the change in eye temperature was significantly different between the two different female LPS treatment groups. Overall, these results demonstrate that prenatal stress alters the ovine febrile response to LPS later in life, females have higher body temperatures than males, and infrared imaging is sufficiently sensitive to detect these subtle changes in body temperature.

327 EXPOSURE OF MICE TO CIGARETTE SMOKE *IN UTERO* INDUCES AIRWAY HYPER-RESPONSIVENESS (AHR) IN EXPOSED OFFSPRING LATER IN LIFE.

S. P. Doherty, C. Hoffman, E. Brush and J. T. Zelikoff. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

More than a million infants are born each year in the U.S. after *in utero* exposure to maternal cigarette smoke (CS). Accumulating epidemiologic data suggest that exposure to CS *in utero* poses a substantial risk for respiratory disease/asthma in the next generation. While these findings carry extensive clinical consequences, few studies are available to provide insight into the possible mechanisms by which these effects might occur. Thus, a toxicologic study was performed to test the hypothesis that prenatal exposure to CS from maternal smoking persistently enhances airway reactivity (a defining feature of asthma) and related biologic parameters in the exposed offspring, and that these effects were sex-dependent. Pregnant CD1 mice were exposed daily (by inhalation) for 4 hr/d (5 d/wk) from gestational day 4 to parturition to mainstream CS at a concentration equivalent to smoking <1 pack of cigarettes per day (PM = 16 mg/m³; CO = $\leq$ 25 ppm). In the absence of effects on maternal weight gain, litter size or offspring sex ratio, prenatal exposure to mainstream CS significantly enhanced airway reactivity (compared to the sex/age-matched, air exposed controls) in 5-wk-old female (but, not male) offspring in response to bronchoprovocation challenge with acetylcholine (ACH); AHR was observed in the absence of any pulmonary inflammation, lung cell damage, overt pulmonary pathology, or elevated serum IgE levels. In contrast, airways of prenatally exposed older female offspring (4-mo-old) were significantly less responsive to ACH challenge (compared to controls). These studies suggest that: prenatal exposure to CS has long-term effects on offspring respiratory health; effects of prenatal CS exposure on offspring airway function are gender-dependent; mechanisms other than airway inflammation may underlie changes in offspring bronchial reactivity in response to *in utero* CS exposure; and, even modest smoking during pregnancy may increase the offspring's risk of respiratory dysfunction later in life. Funded by IFSH.

328 AGE-RELATED CHANGES IN ADRENAL RESPONSIVENESS, GRANULOCYTE TRAFFICKING, AND SERUM IL-6 CONCENTRATIONS IN FEMALE SHEEP SYSTEMICALLY CHALLENGED WITH *ESCHERICHIA COLI* LIPOPOLYSACCHARIDE.

K. A. Phillips¹, N. A. Karrow², C. M. McNicoll², E. Courtney², J. Hay⁴ and H. Boermans³. ¹Food Science, University of Guelph, Guelph, ON, Canada, ²Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, ³Biomedical Sciences, University of Guelph, Guelph, ON, Canada and ⁴Immunology, University of Toronto, Toronto, ON, Canada.

The production of inflammatory mediators has been associated with senescence of both the neuroendocrine and immune systems and may contribute to a number of age-related diseases. In this study, this process of "inflamm-aging" was investigated using an ovine model of acute systemic inflammation. Seven mature ewes (4-5 years old) and 7 ewe lambs (6 months old) were challenged intravenously with 400 ng/kg *Escherichia coli* lipopolysaccharide (LPS). Temperature measurements and venous blood samples were obtained at baseline, and 2, 4, 6, and 24 hours post-LPS administration to assess changes in serum interleukin-6 (IL-6), cortisol, and haptoglobin concentrations, the percentage of blood granulocytes, and biochemical markers of hepatotoxicity and liver function. Basal IL-6 concentrations in the adult sheep were dramatically higher than those of the younger animals, and the response to LPS challenge was significantly different over time between age groups. Serum cortisol concentrations increased in both age groups in response to LPS challenge however, the response was significantly greater in the adult versus the young animals. In both age groups the percentage of blood granulocytes decreased 2 hours, and increased 6 hours post LPS challenge. The 2-hour decrease however, was significantly more pronounced in the young versus adult sheep. Significant differences between the age groups were not observed for either haptoglobin, or temperature, and there was no evidence of hepatotoxicity in either group of animals. Overall, these results indicate that inflamm-aging also occurs in ruminants, and that the sheep may be useful large animal model for studying the ageing neuroendocrine and immune systems.

329 EFFECTS OF LATENT *IN UTERO* AND PERINATAL TCDD EXPOSURE IN POST-NATAL C57BL/6 AND SNF1 MURINE OFFSPRING.

M. B. Goff², A. Mustafa², R. Kerr², S. D. Holladay² and R. M. Gogal^{1,2}. ¹Biomedical Sciences, EVVCOM, VA Tech, Blacksburg, VA and ²Biomedical Sciences and Pathobiology, VA Tech, Blacksburg, VA.

TCDD [2,3,7,8-tetrachlorodibenzo-p-dioxin] and its congeners have a long and well-documented history of causing damage from both acute and chronic exposure. However, the potential risks associated with latent *in utero* and perinatal exposure

to dioxin have not been investigated. In this prefatory study, we evaluated the latent effect of TCDD exposure in utero on select immune parameters of murine offspring on postnatal day 1 (PND1), postnatal day 14 (PND14), and postnatal day 21 (PND 21). C57BL/6 mice, a known TCDD-ArH receptor sensitive strain, and SNF1 mice, an autoimmune disease predisposed strain, were used in this study. In an ongoing study, murine mothers (C57BL/6 and SWR) were acutely exposed to either corn oil vehicle or TCDD (C57BL/6, 5 & 10 µg/kg; SNF1, 40 & 80 µg/kg) on gestation day 12. Post-parturition, the murine mothers nursed the first litter for 21-25 days after which the pups were weaned. At approximately 32 days post-exposure, TCDD-exposed C57BL/6 and SWR mothers were rebred. The pups from these litters were randomly evaluated on PND 1, PND 14, and PND 21. Endpoints examined included body weight, organ weight/body weight ratio, splenic cellularity, thymic cellularity, hepatic cellularity, splenic cell surface marker expression, thymic cell surface marker expression and hepatic cell surface marker expression. Data from this preliminary study suggest that latent exposure as previously defined increases the incidence of immune dysregulation in both C57BL/6 and SNF1 mice.

330 COMPARISON OF ON AND OFF ROAD DIESEL EXHAUST SOURCES ON SUSCEPTIBILITY TO INFLUENZA INFECTION IN MICE.

K. Gowdy¹, J. Cienciewicki², I. Jaspers², E. Boykin³, Q. T. Krantz³, W. P. Linak⁴ and M. I. Gilmour³. ¹NCSU, Raleigh, NC, ²UNC, Chapel Hill, NC, ³ETD, NHEERL, Research Triangle Park, NC and ⁴NRMRL, Research Triangle Park, NC.

Diesel exhaust particulate (DEP) is a major component of urban air pollution and its influence on susceptibility to respiratory infection is of concern. DEP is emitted from various types and ages of engine and the toxicity is dependent upon fuel, and combustion conditions which influence the physico-chemical characteristics of the emission. The purpose of this study was to evaluate the effects of an on- and off-road source of DEP exposure on the severity of acute influenza infection in mice. BALB/c mice were exposed (4 hrs/day, 5 days) to air or 0.5 mg/m³ DEP from engines powering a compressor (C-DEP) or a diesel truck (T-DEP). One hour after the final diesel exposure, mice were intra-tracheally instilled with 10 HA units of influenza A/Bangkok/1/79 virus. 18 hours later mice were euthanized and lung tissue was assessed by RT-PCR for mRNA expression of viral hemagglutinin antigen, IFN-β, IL-6, and surfactant protein A and D (SP-A and SP-D). Lung injury was measured by differential cell counts and the production of LDH, microalbumin, and protein in lung lavages (BAL). Exposure to 0.5 mg/m³ DEP from either source in conjunction with infection caused increased protein levels and neutrophil numbers as well as enhanced IFN-β expression relative to air/flu controls. Mice exposed to C-DEP had significantly higher viral HA mRNA suggesting greater viral proliferation that was not seen with mice exposed to T-DEP. This effect was also associated with decreased expression of SP-A and SP-D, which is an important in defense against respiratory infections. We conclude that while exposure to the on road (T-DEP) emission produced additive effects of lung injury during influenza infection, exposure to the DEP from the off road source (C-DEP) also enhanced susceptibility to infection in association with decreased production of SP-A and SP-D. Further studies will clarify the physico-chemical elements associated with this effect. (Funded by EPA CT829470. This abstract does not reflect EPA policy).

331 ENHANCEMENT OF CONTACT HYPERSENSITIVITY BY EXPOSURE OF TETRABROMOBIPHENOL A IN MICE.

H. Nagase¹, T. Onoda¹, H. Usuda¹ and M. Satoh². ¹Gifu Pharmaceutical University, Gifu, Gifu, Japan and ²School of Pharmacy, Aichi Gakuin University, Nagoya, Aichi, Japan.

Increase of allergic patients has become a social problem. We have paid attention to the contact hypersensitivity among the allergic reaction, and have thought that exposure of some chemicals enhances the reaction. We screened the enhancing effect of chemicals, such as fire retardants, on contact dermatitis. Test chemical was painted on the back of mice everyday for 14 days. On the day 7, the mice sensitized by painting of 2,4-dinitrofluorobenzene (DNFB) on the shaved abdomen, then on the day 14 DNFB was painted on the right ear just one hour after the last painting of test chemical. The ear thickness was measured with an engineer's micrometer. We found that tetrabromobisphenol A (TBBPA) enhanced the contact hypersensitivity. To investigate the mechanism, the female BALB/c mice were challenged by TBBPA 25 µg/body/day for a week before and after sensitization. Lymph node cells and liver from mice were collected. We carried out antigen-specific T cell proliferation assay and the proliferation was significantly enhanced in TBBPA-treated mice than in the vehicle-treated. The IFN-γ production from lymph node cells was increased in the TBBPA-treated mice in comparison with the vehicle-treated, but no difference was observed on the IL-10 production. Concentrations of glutathione in the ears and

the livers were increased in the TBBPA-treated mice in comparison with the vehicle-treated. From these results, TBBPA exposure via skin affect immunocytes and possibly exacerbates contact hypersensitivity reaction.

332 TRICHLOROETHENE-MEDIATED AUTO-IMMUNE RESPONSE: ROLE OF LIPID PEROXIDATION-DERIVED ALDEHYDES.

G. Wang, R. Konig, G. Ansari and M. Khan. University of Texas Medical Branch, Galveston, TX.

Lipid peroxidation is implicated in the pathogenesis of various autoimmune diseases. Lipid peroxidation-derived aldehydes (LPDAs) such as malondialdehyde (MDA) and 4-hydroxynonenal (HNE) are highly reactive and bind proteins covalently, but their potential to elicit autoimmune responses and to contribute to disease pathogenesis remains unclear. To investigate the role of lipid peroxidation in the induction and/or exacerbation of autoimmune responses, 6-week-old autoimmune-prone female MRL +/+ mice were treated with trichloroethene (TCE; 10 mmol/kg, i.p., once a week), an environmental contaminant known to induce lipid peroxidation, for 4 weeks. Sera from TCE-treated mice showed significant levels of antibodies against MDA- and HNE-adducted proteins along with anti-nuclear antibodies. This suggested that TCE exposure not only caused increased lipid peroxidation, but also accelerated autoimmune response. Furthermore, stimulation of cultured splenic lymphocytes, isolated from both control and TCE treated mice, with MDA-adducted mouse serum albumin (MDA-MSA) or HNE-MSA adducts for 72 h showed significant increases in the percentage of activated CD4+ T cells in TCE-treated mice, as analyzed by flow cytometry. Also, splenic lymphocytes from TCE-treated mice released more IFN-γ and IL-2 into cultures when stimulated with MDA-MSA or HNE-MSA, suggesting a Th1 T cell activation. Thus, our data suggest a role for lipid peroxidation-derived aldehydes in TCE-mediated autoimmune responses, and involvement of Th1 T cell activation. Supported by NIH ES013510.

333 LOW MERCURY BURDENS ATTENUATE BCR MEDIATED SIGNAL TRANSDUCTION.

M. McCabe¹, M. Laiosa¹, L. Li², S. Menard², R. Mattingly² and A. Rosenspire². ¹Environmental Medicine, University of Rochester, Rochester, NY and ²Immunology and Microbiology, Wayne State University, Detroit, MI.

The ubiquitous environmental heavy metal contaminant mercury (Hg) is a potent immunomodulator that has been implicated as a factor contributing to autoimmune disease in animal models as well as in humans. The mechanisms whereby Hg initiates autoimmune responses, especially at the biochemical/molecular level, remain poorly understood. Signal strength through clonotypic antigen-specific receptors present on developing lymphocytes is a key determinant that shapes the immune repertoire and establishes tolerance to self antigens. Strength of signals through the antigen specific receptors on B lymphocytes (i.e., the BCR) determines many of the decisions that B cells have to make including whether, or not, they proliferate, differentiate or survive. Recent work has established a relationship between impaired BCR signal strength and autoimmune disease. In previous studies we have shown that in mouse WEHI-231 B cells, non-cytotoxic concentrations of inorganic mercury (iHg) interfered with BCR-mediated growth control, suggesting that BCR signal strength was impaired by iHg. ERK 1,2 MAPK is responsible for the activation of several transcription factors in B cells. Phosphorylation of ERK serves as an essential node of signal integration for the BCR. Thus, the magnitude of ERK activation serves as an operational metric for BCR signal strength. Using Western blotting and phosphospecific flow cytometry, we now show that the kinetics and magnitude of BCR mediated activation of ERK MAP kinase are markedly attenuated in WEHI-231 cells and splenic B cells that have been exposed to low and non-toxic burdens of iHg. However, iHg does not seem to act directly on ERK MAP kinase but rather on an upstream element of the BCR signal transduction pathway, above the level of the key protein tyrosine kinase Syk. Preliminary data suggest that the site of action of iHg may very well be localized on the plasma membrane. These findings support a connection between iHg and attenuated BCR signal strength in the etiology of autoimmune disease.

334 TIMING IS EVERYTHING: LOW DOSE INORGANIC MERCURY BEFORE THE TRIGGERING EVENT INCREASES SEVERITY AND FREQUENCY OF AUTO-IMMUNE MYOCARDITIS IN MICE.

J. F. Nyland¹, D. Fairweather¹, N. R. Rose^{2,3} and E. K. Silbergeld¹. ¹EHS, Johns Hopkins Medical Institutions, Baltimore, MD, ²MMI, Johns Hopkins Medical Institutions, Baltimore, MD and ³Pathology, Johns Hopkins Medical Institutions, Baltimore, MD.

Mercury is a widespread environmental contaminant with neurologic and immunotoxic impacts observed at low dose exposures. Inorganic mercury (iHg) has a range of immunotoxic effects, including both immune suppression and induction

of autoimmunity. Epidemiological studies have demonstrated an association between Hg exposure and risks of autoimmune disease. In some rodent strains, iHg at relatively high doses can induce lupus-like disease; much lower doses can accelerate lupus-like disease in nonsusceptible mice that are challenged with an appropriate trigger. We have utilized this model in studies of low doses of iHg and induced autoimmune cardiac disease using coxsackievirus B3 (CVB3) in BALB/c mice. CVB3 is a cause of dilated cardiomyopathy (DCM) in human populations and in mice, induces a biphasic cardiac disease which is characterized by a primary acute phase, peaking at day 12 post-infection (pi), and a chronic phase, peaking at about day 35 pi, often with accompanying DCM. In these studies, the animals were treated with iHg either before infection (200 ug/kg, every other day for 15 days) or after CVB3 infection, in the interim (every other day for 7 days) between the acute and chronic phases. We found that only pre-treatment exacerbated the chronic disease. With iHg pre-treatment the percentage of mice with dilated cardiomyopathy (DCM) was increased; however, this increased pathology was not accompanied by changes in heart cytokine profiles. In contrast, iHg exposure following infection did not change the incidence or severity of disease, but increased IL-12 and IL-4 in the heart. These results suggest that Hg lowers the threshold of activation for autoreactive cells before encountering autoantigen (presumably the "trigger" event in this induced autoimmune disease).

This work was supported by NIH training grants (MMI and EHS) and donations from the Heinz Family Foundation.

335 GLOBAL GENE EXPRESSION PROFILING OF MACROPHAGES IN RESPONSE TO D-PENICILLAMINE TREATMENT.

J. Li and J. Uetrecht. *Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada.*

Rationale: At present idiosyncratic drug reactions are impossible to predict largely because the mechanisms involved are unknown. The previous studies in our lab have demonstrated the involvement of macrophages in pathogenesis of D-Penicillamine-induced autoimmune disease in Brown Norway rats. Meanwhile, literature evidence has implicated a reversible imine bond formation between carbonyls and amines on APCs and T-cells respectively in T-cell activation.

Hypothesis: D-penicillamine binds irreversibly with aldehyde groups activating macrophages, which in some patients and rats might lead to the autoimmune reaction. **Experimental Procedures:** Brown Norway rats (n=3) were given 150 mg/kg of D-Penicillamine by oral gavage while the control group (n=3) received the same volume of water. At 6 h post-dosage, spleen macrophages were purified by using an immunomagnetic separation column and monoclonal antibody CD163, and total RNA was isolated. Microarray analysis was performed using the rat expression array 230 2.0. Quantitative real time PCR was used to confirm the gene expression changes detected by microarrays.

Results: All three D-Penicillamine treated rats were separately compared to each individual control rat. The criteria for defining whether genes were up- or down-regulated were if at least comparisons between 2 treated rats with 2 control rats were different and the fold change for up and down-regulation was no less than 1.2 and no more than 0.7. A comparison of the observed changes of genes and the literature macrophage activation markers lead us to focus on 20 genes. Out of these 20 genes, 14 associated with inflammatory reactions, recruitment of immune cells, and regulation and polarization of macrophages, natural killer cells, and T helper cells were chosen for additional testing by RT-PCR and about 95% of the observed changes were confirmed.

Conclusions: Microarray data in this study demonstrated very early activation of macrophages by D-Penicillamine treatment, which suggests that macrophages play a critical role in initiation of immune responses to D-Penicillamine leading to autoimmune disease.

336 ARSENITE INDUCES CD14 AND HLA-DR STRONG POSITIVE DENDRITIC MACROPHAGE (ARSENITE-INDUCED MACROPHAGE; AS-MP) GENERATION WITH GM-CSF FROM HUMAN PERIPHERAL BLOOD MONOCYTES.

T. Sakurai, C. Kojima and S. Himeno. *Laboratory of Molecular Nutrition and Toxicology, Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Japan.*

A trivalent inorganic arsenic, arsenite, has been recently developed as a potent therapeutic agent for acute promyelocytic leukemia (APL), while, it is also causing chronic poisoning through the consumption of contaminated well water. The total peripheral blood arsenic concentrations of two APL patients who underwent complete remission by intravenous injection of arsenite and chronic arsenic poisoning patients who had inflammatory-like immune responses are less than 1 μM , thus, nM concentrations may be very importance to induce both therapeutic and chronic

toxic effects by arsenite. We demonstrate in this study the effect of nM concentrations of arsenite on human peripheral blood monocytes. Arsenite significantly inhibited the cytokine-induced *in vitro* normal maturation of monocytes into macrophage species at nM levels. Surprisingly, arsenite induced the generation of a unique nonadherent dendritic macrophages (arsenite-induced macrophages; As-Mp) which strongly expressed CD14 and HLA-DR at nM levels together with GM-CSF. They were responded more strongly to bacterial lipopolysaccharides by inflammatory cytokine, TNF α and IL-1 α , release and more effective at inducing T cell responses as compared to normal macrophages induced by GM-CSF alone. On the other hand, As-Mp expressed lower levels of cell membrane adhesion molecules, such as CD11b and CD54, and phagocytic ability was less efficiently. We also demonstrated that the optimum amount of cellular reactive oxygen species induced by nM arsenite might play an important role in this As-Mp generation. As-Mp could be still responded to M-CSF and GM-CSF and were differentiated into partially abnormal adherent macrophages. This work may have implications in both the chemotherapeutic use and in chronic poisoning of this remarkable metalloind. Ref.; Sakurai *et al. Int. 337 DISTINCT EICOSANOID RESPONSE OF LIVER AND LUNG MACROPHAGES TO ACUTE ENDOTOXEMIA: ROLE OF TOLL-LIKE RECEPTOR 4.

A. Jankowski Connor, L. C. Chen, J. D. Laskin and D. L. Laskin. *Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.*

Exposure to excessive quantities of bacterially-derived endotoxin (ETX) is associated with injury to the liver and the lung. Macrophages (MP) play a key role in the pathogenic response to ETX by releasing excessive quantities of inflammatory mediators including reactive oxygen and nitrogen intermediates and eicosanoids. In the present studies, we examined the role of TLR-4 in the regulation of MP expression of prostaglandin synthase (cyclooxygenase [COX]-1 and COX-2) and the prostaglandin-catabolizing enzyme, 15-hydroxyprostaglandin dehydrogenase (PGDH) during acute endotoxemia. Treatment of control C3H/OuJ with ETX (3 mg/kg) was associated with a significant increase in the number of MP recovered from both the liver and the lung. In the lung this occurred within 12 hr, while in the liver it was delayed for 24 hr. This was not observed in TLR-4 mutant C3H/HeJ mice. Acute endotoxemia also resulted in a dramatic upregulation (140-fold) in COX-2 expression in liver MP from control, but not in TLR-4 mutant mice. This was maximum within 3 hr and persisted, although at reduced levels for at least 24 hr. No significant effects of ETX on expression of COX-1 were observed in either mouse strain. ETX-induced increases in COX-2 in liver MP were correlated with increases in PGE2 and PGE1. This was also evident within 3 hr and persisted for at least 24 hr. In contrast, PGDH was down-regulated in liver MP from both control and TLR-4 mutant mice. In control mice this persisted for 24 hr. When compared to liver MP, lung MP were relatively unresponsive to ETX. These results demonstrate that functional TLR-4 is essential for hepatic MP responses to ETX. Moreover, the effects of TLR-4 are mediated in part via regulation of prostaglandin levels in the liver. Supported by NIH ES004738, ES005022, ES007148, GM03410 and APERG.

338 EVALUATION OF THE EFFECTS OF ORGANOCHLORINE PESTICIDES ON MACROPHAGE FUNCTIONS.

F. Wang, S. M. Roberts and E. S. Sobel. *University of Florida, Gainesville, FL.*

Macrophages play important roles in immunological responses, especially in removal of cell debris, antigen presentation, and cytokine secretion. Defects in macrophage function are related to many disorders, including autoimmune disease. Organochlorine pesticides can accelerate autoimmunity in the classic (NZB x NZW)F1 [NZBWF1] mouse model of systemic lupus erythematosus, but their effects on macrophage function have not been well studied. To determine whether there may be a class effect, we examined five organochlorine pesticides (chlordecone, dieldrin, DDE, toxaphene and methoxychlor) for their effects on a series of macrophage functions using the RAW 264.7 macrophage cell line. Cell proliferation and apoptosis rates were measured by CFSE and annexin-V/7AAD staining, respectively, while cytokine secretion was determined by ELISA. Macrophage clearance of apoptotic cells was conducted using dexamethasone-induced apoptotic thymocytes from BALB/c mice as targets. Furthermore, *ex vivo* studies were conducted with peritoneal macrophages obtained from two-month-old ovariectomized NZBWF1 mice treated with chlordecone sustained release pellets for six weeks. All five pesticides at 1 μM and 10 μM concentrations reduced RAW cell proliferation (after 72 hrs) and apoptosis (48 hours). Chlordecone, dieldrin, DDE and toxaphene treatment all caused a concentration-dependent augmentation in TNF- α secretion by RAW cells. One μM chlordecone, DDE and toxaphene reduced RAW cell clearance of apoptotic cells. *In vivo* exposure to chlordecone increased the

expression of MHC class II molecules on peritoneal macrophages and caused a dose-dependent decrease in clearance of apoptotic cells, a source of self antigen. Taken together, these results indicate organochlorine pesticides can affect macrophage functions, and suggest a role in the augmentation of autoimmune responses in NZBWF1 mice through adverse effects on tolerogenic, autoantigen clearance mechanisms. (Supported by NIH ES07375)

339 METALLOTHIONEIN GENE DOSE AFFECTS LISTERIOSIS IN MICE.

X. Yin¹, R. Emeny², G. Marusov¹, D. A. Lawrence² and M. A. Lynes¹.
¹Molecular and Cell Biology, University of Connecticut, Storrs, CT and ²Wadsworth Laboratory, Albany, NY.

Metallothioneins (MTs) are small cysteine-rich proteins with a wide range of functions including ROS scavenging, chemokine activity, immunomodulation, essential cation management and metal sequestration. MT-I and MT-II are the most widely studied isoforms. C57/BL6 wild-type mice (WT), congenic MT-I/II knock-out mice (MTKO), and congenic MT-I transgenic mice (MTTG) were used to evaluate the effects of MT gene dose on antioxidant, chemotactic, and immunomodulatory activities. *Listeria monocytogenes* is a Gram-positive bacterium that is pathogenic in all mammals, and is commonly used as a model of mammalian immune response to infection. Immunocompromised individuals, neonates, and women in their third trimester are particularly vulnerable to listeriosis. Here we have used an in vivo model of listeriosis to evaluate the effects of MT gene dose on the course of *Listeria* infection in mice. Our results suggest that either over-expression of MT or a lack of functional MT I and II will significantly alter the course of intravenous *Listeria* infection. Both MTTG and MTKO mice showed significantly lower *Listeria* burdens in both liver and spleen three days post-inoculation. A time course study suggested that this difference is most prominent in the first 48 hours of infection, after which *Listeria* clearance occurs at comparable rates in all three strains. Lymphocytes from MTKO mice exhibited both increased levels of surface thiols and increased apoptosis compared to WT and MTTG mice. DHR fluorescence assays revealed that lymphocytes from the MTTG mice exhibit an increased oxidative burst compared to both WT and MTKO strains. Macrophages from both MTTG and MTKO mice exhibited increased oxidative burst compared to WT, suggesting a possible mechanism by which these strains maintain a lower *Listeria* burden in this model of infection. These results indicate that MT gene dose can have dramatic influences on the course of disease. * co-first authors. Supported by R01 ES07408.

340 METALLOTHIONEIN GENE DOSE INFLUENCES T-DEPENDENT HUMORAL IMMUNITY IN MICE EXPOSED TO ZN AND CD.

D. Unfricht, X. Yin, G. Jin, K. Frostad, K. Zaffuto and M. A. Lynes. *Molecular and Cell Biology, University of Connecticut, Storrs, CT.*

Metallothionein (MT) is a stress response protein with significant influences on immune activities. To understand the immunomodulatory function of MT and the role of MT in heavy metal detoxification, we employed three C57BL/6J congenic strains of mice in these studies: wild-type (WT) mice, MT transgenic (TgN) mice and MT knockout (KO) mice. In vivo ovalbumin (OVA) challenge of each strain fed water, with or without 100 uMCdCl₂ or 100 uM ZnCl₂ revealed (1) at 4 weeks, TgN mice express higher levels of MT mRNA irrespective of treatment but only cadmium induces significantly higher levels of MT protein in liver; (2) KO mice exhibit increased anti-OVA antibody compared to WT controls in the latter stages of the 45 day experiment and KO mice had more anti-OVA secreting splenocytes; (3) cadmium suppressed anti-OVA antibody (IgG1 isotype) levels in both KO and TgN mice, while zinc only suppressed anti-OVA antibody production in TgN mice; (4) neither metal exposure (at the exposure level in this experiment) affected the anti-OVA response in WT mice; (5) TgN mice have less splenocytes compared with their counterparts; (6) there are significantly less B cells among the splenocytes of TgN mice compared to both wild-type and KO mice, and metal-treatment did not change the subpopulation distribution of the splenocytes. In vitro cytokine profiles from stimulated splenocytes revealed that: (1) KO splenocytes produced higher levels of IL-4 and lower levels of IFN- γ compared to WT and TgN splenocytes; (2) TgN splenocytes produced lower levels IL-2, IL-4, and IFN- γ compared to WT splenocytes; (3) the higher dosage of CdCl₂ (25 uM) used in these in vitro cultures decreased IL-2, IL-4 levels in all three strains, but the lower (6.25 uM) dosage of CdCl₂ decreased IL-2, IL-4, and IFN- γ only in KO splenocytes. Taken together, this data suggests that KO mice express a Th2 cytokine profile that favors B cell class switching to the IgG1 isotype, and that splenocytes from KO mice are more sensitive to cadmium treatment. (NIEHS grant R01 ES07408).(*=co-first authors)

341 DIFFERENCES IN THE APOPTOTIC RESPONSE IN ACUTE AND CHRONIC SILICOSIS.

R. J. Langley, N. C. Mishra, J. C. Philippides, S. Razani-Boroujerdi and M. L. Soper. *Immunology, LRRI, Albuquerque, NM.*

Silicosis is characterized by lung granulomas and generally develops by chronic occupational inhalation of crystalline silica. Chronic silicosis has a long asymptomatic latency and, similarly, Lewis rats, exposed chronically to occupationally realistic doses of silica inhalation, show limited lung inflammation and injury, and delayed granuloma formation. Acute silicosis, a relatively rare form of the disease, usually resulting from massive accidental exposures, and is associated with severe lung inflammation, apoptosis, and tissue injury. While the cellular and molecular mechanisms of silicosis are largely unknown, inferences from animal models of acute silicosis are commonly extrapolated to human silicosis. Using the rat model of chronic silicosis (6.2 mg/m³, 5 days/wk for 6 wk), and single intratracheal instillation of 35 mg silica/rat for acute exposure, we present evidence that acute and chronic silicosis are mechanistically distinct diseases. Thus, unlike acute exposure, chronic silica inhalation produces a strong anti-apoptotic response, characterized by dramatic increases in Bcl-2 and procaspase-3, and loss of Jun-N-terminal Kinase in bronchoalveolar lavage cells. Lungs exhibit total lack of TUNEL staining and Bcl-2 is highly exaggerated in the epithelioid macrophages of developing granulomas. Changes in Bcl-2 are associated with increased protein expression of NF κ B-p50, but not the p65 subunit. Moreover Bcl-3, which regulates Bcl-2 expression through interaction with NF κ B-p-50, shows strong nuclear localization. Thus, unlike acute silicosis, apoptosis is not a critical event in chronic silicosis, and NF κ B-p50/Bcl-3 interaction may play an important role in inducing the anti-apoptotic phenotype in chronic silicosis.

342 GENE EXPRESSION PROFILING OF XENOBIOTIC METABOLIZING ENZYMES (XMEs) IN THE AGING MALE FISHER RAT.

J. S. Lee, D. C. Wolf, J. W. Allen, W. O. Ward and C. Corton. *NHEERL, U.S.-EPA, Research Triangle Park, NC.*

Detoxification and elimination of xenobiotics is a major function of the liver and is important in maintaining the metabolic homeostasis of the organism. The degree to which aging affects hepatic metabolism is not known. The expression of XMEs, in part, determines the fate of the xenobiotic and whether exposure will result in toxicity. This project was designed to examine the changes in XMEs during the aging process in male Fisher rats. Gene expression profiles for XMEs in male Fisher rats (6, 11, 18, 24 months of age) were generated using Affymetrix Rat 230 2.0 arrays. Four animals per age group were profiled. Principal component analysis showed a clear age-dependent separation in expression profiles between 6 and 24 month hepatic transcripts. Differentially expressed genes (DEG) were identified using the following algorithm: background correction was performed using MAS5 followed by a quantile normalization, perfect match adjustment, median polish, Loess normalization and Cyber T statistics. 1135 genes were found to be significantly altered in a 24 versus 6 month comparison, and 155 genes were significantly altered in a 18 versus 6 month comparison. No significant gene changes were observed between 11 and 6 month old rats. In the 24 versus 6 month comparison, we found 23 phase I, 10 phase II, and 20 phase III metabolism genes significantly altered. In the 18 versus 6 month comparison, we found 3 phase I and 2 phase III metabolism genes significantly altered. qRT-PCR was performed to confirm altered expression. These data confirm an age-dependent change in XME gene expression in male Fisher rats. This information can be used to adapt pharmacokinetic models to reflect age-dependent differences in xenobiotic metabolism. (This abstract does not necessarily reflect US EPA policy).

343 EVALUATION OF PATHWAY-FOCUSED PCR ARRAY FOR EXPRESSION PROFILING OF DRUG METABOLIZING GENES.

L. Guo¹, S. Dial¹, L. Shi¹, B. Ning¹, Y. Sun², J. Wang², J. Yang² and Y. P. Dragan¹. ¹National Center for Toxicological Research, Jefferson, AR and ²SuperArray Bioscience, Frederick, MD.

Side effects and toxicities of drugs are the main reasons for the termination of drug development and withdrawal of approved drugs. Drug metabolizing enzymes are an important battery of genes involved in drug-induced toxicities. In this study, the performance of the pathway-focused PCR arrays for expression profiling of 84 human drug metabolizing genes were evaluated for intra-, inter-laboratory and cross-platform comparability by using two reference RNA samples, Universal Human Reference RNA and Human Brain Reference RNA established in the MicroArray Quality Control project. For each of the two laboratories, the experiment was conducted in five technical replicates for each RNA sample and repeated

three months later. Therefore, data from 40 PCR arrays were generated. The reproducibility of PCR arrays was measured by the Pearson correlation coefficients of ΔCT and $\Delta\Delta CT$, and the overlap of differentially expressed genes (DEGs). The intra- and inter-laboratory correlation coefficients of ΔCT were 0.995 and 0.976, and the intra- and inter-laboratory correlation coefficients of $\Delta\Delta CT$ were 0.987 and 0.9744. The overlap between the two DEGs from the repeated experiments within a laboratory was about 90%, and over 90% of the DEGs generated in two laboratories were in common. The data from SYBR Green based PCR arrays were also compared with those from TaqMan assays generated in MAQC project, and there was a high level of concordance between PCR arrays and TaqMan. Finally, the PCR arrays were validated by observing the expected gene expression changes in biological samples resulting from dosing primary human hepatocytes with known drug metabolizing enzymes inducers. In conclusion, the high throughput PCR arrays can be used as a reliable tool for the quantification of expression levels of drug metabolizing genes.

344 TISSUE DISTRIBUTION, GENDER DIFFERENCE, ONTOGENY, AND CHEMICAL INDUCTION OF MULTIPLE DRUG RESISTANCE GENES (MDR1A, MDR1B, MDR2) IN MICE.

Y. Cui, X. Cheng and C. D. Klaassen. *Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Multi-drug resistance (Mdr) transporters are ABC transporters that efflux amphipathic cations from cells, and thus aids in protecting tissues from xenobiotics. Unfortunately, Mdr transporters also efflux cancer chemotherapeutic drugs from some tumor cells, resulting in drug resistance. There are two groups of Mdr genes in mice: group I includes Mdr1a and Mdr1b, which transport xenobiotics; whereas group II consists of Mdr2 only, which excretes phospholipid into bile. Little is known about the regulation of Mdr genes in vivo. Therefore the purpose of this study was to determine the regulation of three Mdr genes by tissue, age, gender, and chemicals. The data indicate that Mdr1a mRNA is mainly expressed in the gastrointestinal tract, Mdr1b mRNA is highest in ovary and placenta, and Mdr2 mRNA is mainly expressed in liver. Gender differences in expression of the three Mdr transporters were observed in several tissues: Mdr1a in kidney; Mdr1b in lung, kidney, and brain; and Mdr2 in lung. The ontogeny of mouse Mdr1a in duodenum and brain, as well as Mdr1b in brain, kidney, and liver, all share a similar pattern, which is low mRNA expression at birth, which gradually increases to mature levels at about 30 days of age. The developmental pattern of Mdr2 is different, in that there is a marked up-regulation at birth, a return to low levels by 5 days of age, and then an increase to mature levels with a similar pattern of the other transporters. None of the three Mdr mRNA levels were significantly up-regulated by all three chemicals in any class of selected microsomal enzyme inducers. Moreover, down-regulation was produced in Mdr1b by Nrf2 ligands, and in Mdr2 by AhR ligands. In conclusion, the expression of Mdr transporters in mice is tightly regulated by age and gender, the distribution of which indicates a tissue-specific pattern, and Mdr genes are not readily up-regulated by xenobiotics. (Supported by NIH grants ES-09649 and ES-09716)

345 HUMAN SULT2A1 IS TRANSCRIPTIONALLY REGULATED BY THE NUCLEAR RECEPTOR CONSTITUTIVE ANDROSTANE RECEPTOR (CAR).

G. Chen. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Sulfotransferase (SULT) catalyzed sulfation regulates hormone activity and detoxifies xenobiotic toxicants. Human dehydroepiandrosterone sulfotransferase (hSULT2A1) is a major SULT catalyzing the sulfation of hydroxysteroids and xenobiotic alcohols. In our previous studies, we have shown that the anti-folate drug methotrexate (MTX) can up-regulate several major human SULTs. To determine the mechanisms controlling the regulation of hSULT2A1, we cloned the 5'-flanking region of hSULT2A1 and investigated its transcriptional regulation using Caco-2 cell line based reporter gene assay. Nuclear receptor co-transfection indicates that CAR and RXR α were involved in the transcriptional regulation of hSULT2A1. RNA interference experiments further prove the positive role of CAR in hSULT2A1 regulation. Progressive promoter deletion, DNA sequence alignment, and site directed promoter deletion suggest that an imperfect inverted repeat DNA motif, IR2 (-186AGCTCAGATGACCC-173), within the hSULT2A1 5'-flanking region mediates the hSULT2A1 induction. Furthermore, electrophoretic mobility shift assay and super shift assay have been exploited to characterize the interactions of CAR and RXR α with the IR2 element. In summary, we identify an IR2 DNA cis-element located at -186/-173 of hSULT2A1 promoter region. The IR2 element mediates the MTX induction of hSULT2A1 by interacting with CAR and RXR α .

346 INDUCTION OF HUMAN SULFOTRANSFERASES BY ISOFLAVONES IN HEP G2 CELLS.

Y. Chen¹ and G. Chen¹. ¹Physiological Sciences, Oklahoma State University, Stillwater, OK and ²Physiological Sciences, Oklahoma State University, Stillwater, OK.

Sulfotransferases (SULTs) are phase II drug-metabolizing enzymes. Their induction by hormones and endogenous molecules is relatively well known, although xenobiotic induction of SULTs has not been well studied. Isoflavones are naturally occurring phytoestrogens that mainly exist in soy food products. They have been described as health-promoting, disease-preventing dietary supplements, and have activity as cancer preventive agents. Recently, isoflavones have been reported interacting with nuclear receptors, including those that have been well known to mediate the induction of drug metabolizing enzymes. In the present investigation, isoflavones are shown to be xenobiotic inducers of human SULTs in transformed human liver (Hep G2) cells. Following isoflavone (Genistein, Biochanin A and Daidzein) treatments, two isoforms of SULTs were induced in Hep G2 cells. Enzyme assay, Western blot, reverse-transcription polymerase chain reaction (RT-PCR) and Real-Time RT-PCR results demonstrated that protein and mRNA expressions of human simple phenol sulfotransferase (P-PST, hSULT1A1) and human dehydroepiandrosterone sulfotransferase (DHEA-ST, hSULT2A1) were significantly induced in Hep G2 cells. Inductions of hSULT1A1 and hSULT2A1 in Hep G2 cells by these isoflavones were time- and dose- dependent. Enzyme activity and Western blot results were in good agreement with RT-PCR and Real-Time RT-PCR results, suggesting that the induction is at the gene transcription level. These isoflavones are the first nutritionally related phytoestrogens to show induction of SULTs.

347 INVESTIGATION OF NEW SULFUR DONORS FOR CYANIDE ANTAGONISM.

I. Petrikovics^{1,2}, K. M. Beigel¹, G. Rockwood¹ and S. I. Baskin¹. ¹USAMRICD, Aberdeen Proving Ground, MD and ²Sam Houston State University, Huntsville, TX.

This study focuses on developing effective cyanide (CN) antidotal systems with selected sulfur donors (SDs) having superior efficacy and pharmacokinetic characteristics to sodium thiosulfate (TS). TS is the standard antidote for CN intoxication. It is recognized that utilization of SDs that serve as substrates for sulfurtransferases (STase) (e.g. rhodanese, mercaptopyruvateSTase, TS reductase) is inefficient. Our approach is based on the idea of converting CN to the less toxic thiocyanate before it reaches the target organs.

Stealth liposomes and polymeric nanocapsules have been chosen to provide protective environments for the enzymes employed to destroy CN in the body. Sulfane sulfur containing molecules with three major sources a) endogenous (e.g. sulfur containing amino acids), b) naturally occurring plant components (e.g. allyl-, diallyl-, alkyl disulfides, and trisulfides; allylmercaptocysteine, ajoene), and c) synthetic sulfur donors designed from SAR studies have been chosen as SDs for present studies. The in vitro investigations, based on a) determining kinetic constants (KM and Vmax) for enzymatic reactions between the SDs and CN, b) cytochrome c oxidase inhibitions by CN in the presence of SDs with an STase and/or nitrites, and c) lipophilicity studies serve as tools to predict the in vivo efficacy. The in vivo efficacy studies are focused on determining LD50 values for CN and brain cytochrome c oxidase activity and inhibition.

Alkyl thiosulfonates (R-SO₂-S-) with longer alkyl chains showed greater lipophilicity, chemical reactivity, and in vivo efficacy than their methyl- and ethyl- counterparts. Butane thiosulfonate in combination with encapsulated rhodanese and sodium nitrite showed a 14 x LD50 protection against cyanide intoxication, while TS with sodium nitrite protect only 6 x LD50 on Balb/C mice.

Previous and ongoing studies show the potential usefulness of enzyme encapsulation in developing antidotal therapeutic agents.

348 THE REACTION KINETICS OF PARAOXONASE BOUND TO AN HPLC STATIONARY PHASE.

K. M. Bell-McGuinn² and W. McGuinn¹. ¹U.S. FDA, Beltsville, MD and ²Memorial Sloan-Kettering Cancer Center, New York, NY.

The purpose of this project was to determine the enzyme kinetics of a purified organophosphorus acid anhydride (paraoxon hydrolase, E.C. 3.1.1.3). During this process, we developed a simple and more precise HPLC based method for determining enzyme kinetics at steady state. We then compared this HPLC method to the traditional spectrophotometric method for determining enzyme kinetics. First, the enzyme was eluted onto an anion exchange HPLC column under conditions that allowed the enzyme to bind reversibly. Enzyme substrate, paraoxon, in dilute aqueous solution was eluted past the bound enzyme at determined concentrations. The enzyme hydrolyzed the substrate to the products 4-nitrophenol and diethyl phosphate. The concentration of the 4-nitrophenol determined at 400 nm in the effluent was constant with constant flow. From these 4-nitrophenol concentrations

at different flow rates, the reaction rates for the bound enzyme were determined by multiplying the product concentration ($\mu\text{mol/mL}$) by the flow (mL/sec). The reaction rates determined by this method demonstrated Michaelis-Menten behavior (linear double reciprocal plot, correlation coefficient 0.97). The K_m of the reaction was $0.421 \pm 0.007 \text{ mM}^{-1}$. The V_{max} was $0.0585 \pm 0.004 \mu\text{mol/sec/mL}$. The values for these parameters determined by a traditional spectrophotometric method were similar but the HPLC method achieved a 10-fold increase in the precision of measurement. This method of enzyme kinetic analysis offers the benefits of a true reaction steady state (change in concentration of the reactive intermediate is 0 at constant flow), the elimination of product inhibition (product is carried away from the enzyme by the effluent), rapid analysis times and the potential for simulating many different enzyme environments not obtainable in stirred solutions.

349 EXAMINATION OF THE PROPOSED "SIDE DOOR" IN THE XENOBIOTIC METABOLIZING ENZYME CARBOXYL ESTERASE.

T. M. Streit, A. Borazjani, S. E. Lentz and M. K. Ross. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

Carboxylesterases (CEs) are involved in the metabolism of a wide range of endobiotics and xenobiotics containing ester bonds, including several classes of pesticides. Recently, the structure of a mammalian CE suggested that a side door was located adjacent to the active site. The side door has been proposed to act as an entrance/exit pore for substrates and products, with four amino acid residues identified as "gate keepers" to this side door. The purpose of this study was to investigate the role of one of these residues, leucine(L) 362, in the CE-catalyzed hydrolysis of several esterified substrates. Recombinant CE enzymes (wild-type and L362 site-specific mutants) were purified and tested for their hydrolytic activity toward simple esters and both pyrethroid and organophosphate insecticides. Mutation of position L362 into various residues decreased k_{cat} values by 1.5–3-fold compared to wild type when the kinetics of 4-nitrophenyl valerate hydrolysis was examined. In contrast, the same L362 mutants enhanced the hydrolysis rate of 4-methylumbelliferyl acetate. In this instance, the mutant enzymes exhibited k_{cat} values that were increased by 1.2–2-fold compared to wild type, which suggested that the mutant proteins were correctly folded. All mutant CEs exhibited decreased k_{cat} values (between 3.2- and 7-fold) when hydrolysis of the pyrethroid insecticide *trans*-permethrin was examined. CEs covalently react with organophosphate oxons and are inhibited by these compounds. Reactions of enzymes with chlorpyrifos oxon demonstrated that mutant enzymes were less sensitive to inhibition compared to wild type, as indicated by 3–5-fold increases in the half-maximal inhibitory concentration (IC_{50}) values. Taken together, our results demonstrate that the side door residues of CEs can influence the rate of catalysis and degree of inhibition by interactions that are dependent upon the charge of the residue at position 362 and the structure of the substrate. [Supported by NIH P20RR017661]

350 EVALUATION OF THE CARBOXYL ESTERASE PHENOTYPE IN HUMAN LIVER.

M. K. Ross¹, A. Borazjani¹, J. A. Crow¹ and M. P. Patricelli². ¹Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS and ²ActivX Biosciences, La Jolla, CA.

Carboxylesterases (CEs) of the serine hydrolase superfamily are xenobiotic metabolizing enzymes that hydrolyze esterified substrates to alcohol and carboxylic acid products. Two CE isoforms are expressed in human liver and are termed hCE1 and hCE2. Human liver microsomes (HLMs) are often used in reaction phenotyping studies to discern interindividual variability in xenobiotic metabolism. We have begun studies to evaluate the 'CE phenotype' of human liver samples using traditional western blotting and hydrolytic assays to ascertain both the levels of hCE1 and hCE2 protein and their hydrolytic activities. We have further extended these studies using an 'activity-based' fluorophosphonate fluorescent probe (FP-TMR), which covalently reacts with catalytically-active serine residues of serine hydrolases but not with inactive enzymes. Quantitative immunoblotting of pooled HLMs using antibodies raised against hCE1 or hCE2 demonstrated that the amount of hCE1 protein expressed in liver was far more abundant than hCE2 protein (46-fold, $64.4 \pm 16.5 \mu\text{g}$ hCE1/mg microsomal protein compared to $1.4 \pm 0.2 \mu\text{g}$ hCE2/mg microsomal protein). Moreover, the FP-TMR probe robustly labeled the hCE1 proteins in HLMs, while hCE2 proteins were labeled weakly. The hCE1 enzyme was by far the most active serine hydrolase labeled in the HLMs studied. Furthermore, differences were observed in the extent of hCE1-specific labeling by FP-TMR between individual HLM samples; however, the differential labeling by FP-TMR appeared to be specific to hCE1 since another robustly active serine hydrolase in the same HLMs (arylacetamide deacetylase) exhibited a similar degree of labeling in all individuals. We are currently identifying the cause of the differential hCE1 activities among the individual HLMs. Identification of the factors that lead

to altered CE activities in HLMs will be important to characterize since several therapeutic drugs and toxicants are metabolized by these enzymes. [Supported by NIH P20RR017661]

351 DOSE-DEPENDENT PANCREATIC AND HEPATIC INJURY BY ETHANOL IN HEPATIC ALCOHOL DEHYDROGENASE-DEFICIENT DEER MICE.

K. K. Bhopale¹, H. Wu¹, G. S. Ansari¹ and B. S. Kaphalia¹. ¹Pathology, University of Texas Medical Branch, Galveston, TX, ²Pathology, University of Texas Medical Branch, Galveston, TX, ³Pathology, University of Texas Medical Branch, Galveston, TX and ⁴Pathology, University of Texas Medical Branch, Galveston, TX.

Alcoholic pancreatitis and liver disease are the two major health problems associated with chronic alcohol abuse and cause high morbidity and mortality among alcoholic patients. The mechanisms of both the diseases are not well understood. In previous study, we found a greater pancreatic and hepatic injury in hepatic ADH-deficient (ADH-) vs. hepatic ADH-normal (ADH+) deer mice fed 4% ethanol in Lieber-DeCarli liquid diet. Therefore, present study was undertaken to evaluate the dose-dependent ethanol-induced pancreatic and hepatic injury in ADH- and ADH+ deer mice fed 1, 2 and 3.5% ethanol in Lieber-DeCarli liquid diet for 2 months. Control animals of both strains were provided an isocaloric liquid diet. A total of 6/22 animals died in the ADH- deer mice vs. none in ADH+ deer mice fed 3.5% ethanol during the 2 months of ethanol exposure. However, no deaths occurred in groups of deer mice fed 1 and 2% ethanol. All the animals were sacrificed on day 60 and toxicity and histological changes for pancreata and livers were evaluated. Dose-dependent increases in hepatic and pancreatic injury markers were observed in both strains, but the increases were significantly higher in ethanol-fed ADH- vs. ADH+ deer mice. Similarly, histological and electron microscopic changes such as vacuolization, apoptosis and endoplasmic swelling were more prominent in pancreata and livers of ADH- vs. ADH+ deer mice fed 3.5% ethanol. Overall, the pancreatic and hepatic toxicity of ethanol in the ADH- deer mice appears to be dose-dependent and indicates the role of ethanol metabolism in ethanol-induced pancreatic and hepatic pathologies. This work was supported by NIH grant AA13171.

352 DOSE-DEPENDENT METABOLISM OF ETHANOL AND RELATED PANCREATIC INJURY IN HEPATIC ALCOHOL DEHYDROGENASE-DEFICIENT DEER MICE: SIGNIFICANCE OF FATTY ACID ETHYL ESTERS.

B. S. Kaphalia. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Impaired hepatic alcohol-dehydrogenase (ADH) is an important metabolic condition during chronic alcohol abuse that facilitates nonoxidative metabolism of ethanol to fatty acid ethyl esters (FAEEs). Inhibition of hepatic ADH by 4-methyl pyrazole is reported to induce nonoxidative metabolism of ethanol to FAEEs and cause pancreatitis-like injury in rat model. Pancreatic injury and cytotoxic effects of FAEEs are also reported in vitro and in vivo. However, events leading from early pancreatic injury to pancreatitis are not well known. In the present study, we studied a dose-dependent biosynthesis of FAEEs in the pancreata of hepatic ADH-deficient (ADH-) deer mice and compared with that in the pancreata of hepatic ADH-normal (ADH+) deer mice fed Lieber-DeCarli liquid diet containing 1, 2 and 3.5% ethanol for 2 months. Individual and total pancreatic FAEEs analyzed in the pancreata of both strains of deer mice fed 1 and 2% ethanol in the liquid diet showed negligible or trace amount of individual and total FAEEs. However, the levels were significantly high in the pancreata of ADH- vs. ADH+ deer mice fed 3.5% ethanol. Ethyl esters of oleic (18:1), linoleic (18:2) and arachidonic (20:4) fatty acids were very prominent and significantly high in the pancreata of ADH- deer mice fed 3.5% ethanol. The pancreatic injury assessed by measuring trypsinogen activation peptide and histology was also observed only in the 3.5% ethanol-fed ADH+ deer mice. These results suggest a dose-dependent formation of FAEEs and 18:1, 18:2 and 20:4 FAEEs could be reliable markers of pancreatic injury and alcohol exposure in chronic alcohol abusers. This work was supported by NIH grant AA13171.

353 EFFECT OF CAFFEINE AND ALCOHOL ON THE TOXICITY AND METABOLISM OF METHACRYLONITRILE (MEAN) IN MALE SPRAGUE-DAWLEY RATS.

M. Y. Farooqui, M. Trevino, B. Robles and I. Garcia. *Biology, University of Texas Pan American, Edinburg, TX.*

We have studied the relationship between the toxicity of MeAN and its metabolism to cyanide using normal rats and those pre-treated with caffeine or alcohol or both. One group of experimental rats received an oral dose of 6 % MeAN solution in corn oil (equivalent to 0.5 LD50). Other three groups of rats were pre-treated with alcohol (2 ml of 50 % solution in water), caffeine (1 ml of 2 % solution in water) or both alcohol and caffeine twelve hours before receiving MeAN dose. The rats

were closely observed for known signs of toxicity of nitriles. Six and twelve hours after the treatments the rats were sacrificed under ether anesthesia for collection of blood, urine, liver, kidney and brain. The concentrations of cyanide, thiocyanate and glutathione (GSH) were determined in blood, liver, kidney and brain. In the rats treated with MeAN alone and those pre-treated with alcohol and alcohol + caffeine the GSH concentrations decreased in liver, brain and kidney by 23-36 %. In the rats pre-treated with caffeine alone the concentrations of GSH were not significantly different from controls. In the rats treated with MeAN alone and those pre-treated with alcohol and alcohol + caffeine the cyanide and thiocyanate concentrations increased in the blood and other organs up to 2-4 fold whereas in rats pre-treated with caffeine alone the concentrations of cyanide and thiocyanate were not significantly different from controls. These results suggest that caffeine inhibited and alcohol enhanced metabolism of MeAN resulting in a significant decrease in organ GSH and increase in cyanide concentration in blood and organs. When rats were pre-treated with both caffeine and alcohol, caffeine could not provide this protection. The opposite effects of caffeine and alcohol may be through opposite modulation of microsomal activity. (Supported by NIH South Texas Doctoral Bridge Program Grant # 2 R25GM50080).

354 GENDER AND SPECIES DIFFERENCES IN DNA DAMAGE PRODUCED BY THE CARCINOGEN 2-ACETYLAMINOFLUORENE IN RAT LIVER AND CULTURED RAT HEPATOCYTES AND IN CULTURED HUMAN HEPATOCYTES.

J. Duan¹, A. M. Jeffrey¹, M. J. Iatropoulos¹, C. E. Perrone² and G. M. Williams¹. ¹Department of Pathology, New York Medical College, Valhalla, NY and ²Orentreich Foundation, Cold Spring-on-Hudson, NY.

The potent DNA-reactive hepatocarcinogen 2-acetylaminofluorene (AAF) is more carcinogenic to the livers of male rats than female rats of several strains. To elucidate further the basis for rat gender differences, DNA reactivity of AAF was studied in livers and cultured hepatocytes of both genders of Sprague-Dawley rats and cultured human hepatocytes of both genders. Rats were administered oral doses of AAF at 3 mg/kg for up to 8 weeks. This dose produces liver neoplasms in male F344 rats by 36 weeks, when given 3 times per week for 8 weeks. The levels of adducts were 25.3 ± 1.54 in 10^8 normal nucleotides in males and 4.3 ± 1.4 in 10^8 in females, comprising 3-(deoxyguanosin-*N*²-yl)-2-acetylaminofluorene and *N*-(deoxyguanosin-8-yl)-2-aminofluorene together with other minor adducts. In cultured rat hepatocytes exposed to AAF at a concentration of about 100 μ M, the levels of DNA adducts formed in male hepatocytes were 14 times greater than that in female hepatocytes and the level of DNA repair synthesis was greater. In contrast, in human hepatocytes of both genders, AAF at the same concentration, produced similar levels of adducts and DNA repair synthesis, which were intermediate between those of male and female rats. Thus, the greater susceptibility of male rats to AAF-induced liver neoplasia is due at least in part to greater levels of genotoxicity. Moreover, it would appear that livers of both human genders are not as susceptible as those of male SD rats to the formation of AAF DNA adducts and hence cancer susceptibility to a carcinogen of this type would be anticipated to be lesser.

355 COMBUSTION-DERIVED PAHS CONCENTRATE IN LIPID DROPLETS AND UPREGULATE BIOTRANSFORMATION ENZYMES IN HUMAN RESPIRATORY EPITHELIAL CELLS.

G. Murphy¹, W. Henk¹, S. Barker¹, E. Floyd² and A. Penn¹. ¹Comp. Biomed. Sciences., LSU-School of Vet. Med., Baton Rouge, LA and ²Pennington Biomedical Research Center, Baton Rouge, LA.

Cytoplasmic lipid droplets sequester lipids for subsequent cell activities (membrane synthesis and eicosanoid production). Here we report that these droplets concentrate hydrophobic components from combustion-derived ultrafine particles and this coincides with up-regulation of AhR-associated genes. Butadiene soot (BDS) generated from the combustion of 1,3-butadiene is a model mixture and a real-life example of a petrochemical product of incomplete combustion. BDS is a metals-poor, organic-rich mixture of carbonaceous particles to which numerous polynuclear aromatic hydrocarbon (PAH) species are adsorbed. We previously described the characteristics of BDS (EHP, 109: 965-71, 2001; *ibid*, 113: 956-63, 2005): 1) Fresh BDS particles are in the ultrafine respirable range (PM 0.1); 2) A wide range of PAHs, including several carcinogens, is adsorbed to the surface of the particles; 3) Cultured human bronchial epithelial cells (BEAS-2B) exposed to BDS exhibit a similar spectrum of PAHs as the soot particles. Cells exposed to BDS in culture display a time- and concentration-dependent fluorescence pattern that begins as diffuse blue fluorescence and progresses to punctate, perinuclear fluorescence. Here, we show that the punctate blue BDS-associated fluorescence and a red fluorescent cholesterol analog, cholesteryl-BODIPY, co-localize in BEAS-2B cells. Deconvolution of fluorescence microscopy images of BDS-exposed cells transfected with a lipid droplet surface protein construct (pDsRed-ADFP) confirmed this co-localization. Cultured adipocytes exposed to BDS develop blue fluorescence in their large lipid droplets, further supporting the localization of fluorescent PAHs to

lipid stores within cells. Quantitative RT-PCR results revealed a time-dependent upregulation of Phase I biotransformation enzymes (CYP1A1, CYP1B1 and ALDH3A1) secondary to PAH exposure. TCDD-inducible poly(ADP-ribose) polymerase (TIPARP) and plasminogen activator inhibitor 2 (PAI-2 or SERPINB2) also were up-regulated.

356 MONO-FUNCTIONAL MUSTARDS FORM FREE RADICALS WHEN ENZYMATICALLY REDUCED MAKING THEM USEFUL AS MODEL COMPOUNDS FOR MECHANISTIC STUDY AND DRUG SCREENING FOR SULFUR MUSTARD.

A. A. Brimfield and A. M. Mancebo. USAMRICD, Aberdeen Proving Ground, MD.

During the past twenty years it has been the prevailing opinion among many who study sulfur mustard (2,2'-bis-chloroethyl sulfide) toxicity that tissue damage arises from the alkylation and cross linking of chromatin in affected tissues driven by sulfonium ion formation. That theory led to the conclusion that monofunctional mustards such as mechlorethamine (HN1), chloroethylthyl sulfide (CEES) and chloroethylmethyl sulfide (CEMS) could not act via the same mechanism as sulfur mustard because they lacked the capacity to cross link DNA and, therefore, could not serve as model compounds for the study of sulfur mustard toxicity. Current work from our laboratory, however, indicates that the toxicity of mustards is a consequence of free radicals arising from enzymatic reduction of the immonium and sulfonium ions which form as intermediates in the hydrolysis of nitrogen and sulfur mustards, respectively. Electron paramagnetic resonance (EPR) spectroscopy using a Bruker ESP 300E instrument can detect these free radicals in an *in vitro* system consisting of 2.4 mM NADPH, up to 4.0 mM sulfur mustard, CEES, or HN1, a 1.03 M concentration of the spin trap α -(4-pyridyl-1-oxide)-N-t-butyl nitron, and 0.016 μ M human NADPH cytochrome P450 reductase in 490 μ L 0.1 M potassium phosphate buffer, pH 7.5 containing 250 mM NaCl in an EPR flat cell with a capacity of 0.5 mL. The work presented here indicates that monofunctional mustards are also activated to free radicals by enzymatic reduction. As such they offer an excellent model to study the toxic mechanism of sulfur mustard and the usefulness of potentially therapeutic and prophylactic compounds without use of the chemical warfare agent itself. Some variance between the monofunctional compounds and the behavior of sulfur mustard may arise from slight differences in solubility.

357 EFFECTS OF DAIDZEIN ON TCDD-INDUCED IMMUNOSUPPRESSION IN MURINE SPLENOCYTES IN VITRO.

C. Kim¹, T. Jeon¹, S. Lee¹, D. Lee¹, H. Jeong¹, S. R. Bista¹, M. Kang¹, H. Jeong², E. Lee¹ and T. Jeong¹. ¹Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, South Korea and ²Pharmacy, Chosun University, Gwangju, South Korea.

Phytochemicals have various pharmacological properties including antioxidant activity, anticancer, and immunomodulatory effects. In this study, we evaluated the immunomodulatory effects of 13 phytochemicals, such as daidzein, genistein, formononetin, biochanin A, kaempferol, galangin, quercetin, myricetin, chrysin, baicalein, luteolin, naringenin and hesperetin, on 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-induced immunosuppression in splenocyte cultures from female BALB/c mice *in vitro*. Daidzein, kaempferol, galangin, quercetin, myricetin and luteolin recovered TCDD-induced inhibition of lymphoproliferative response by LPS. In contrast, only daidzein recovered TCDD-induced suppression of proliferative response by Con A. Moreover, the number of intracellular CD4⁺IL-2⁺ cell and IL-2 mRNA expression reduced by TCDD were recovered by daidzein. Taken together, the present results indicated that daidzein might interact with the Ah receptor in TCDD-induced immunosuppression. (Supported by a grant from KOSEF and a BK 21 grant)

358 STUDY ON DOXORUBICIN-INDUCED CARDIOTOXICITY IN RATS USING UPLC-MS-BASED METABONOMICS.

S. Peng¹, L. Chen¹, J. Wang² and G. Xu². ¹Beijing Institute of Pharmacology and Toxicology, Beijing, China and ²Dalian Institute of Chemical Physics, Chinese Academy of Science, Dalian, China.

The use of Doxorubicin (DOX) as anticancer drug is limited by its cardiotoxicity. Until now the precise mechanisms of DOX-induced cardiotoxicity is not entirely clear. Metabonomics, the study of metabolites and their roles in various disease states, is a novel methodology arising from the post-genomics era. The present study investigated the cardiotoxic effects of DOX in male Wistar rats by using

UPLC/MS-based metabolomics of urine, as well as clinical chemistry and heart histopathology. Through single intraperitoneal injection, DOX is administered to the rats at the doses of 5mg/kg, 10mg/kg and 20mg/kg respectively, and the rats in control group are treated with equal volume of saline. Urine samples were collected from 0 to 4 days after treatment. Results of clinical chemistry and histopathology examinations prove the appearance of cardiotoxic effects with a dose-time-dependant manner. After the UPLC analysis, the retention time and m/z data pair for each peak was detected. Partial least squares discriminant analysis (PLS-DA) and coefficient of correlation analysis were used for marker selection and identification. The scatter for different groups is centralized in different places and is related to the administered dose. One day after administration, the changes of the metabolite spectrum of the rats treated with DOX have appear, which are correlative with the rat's weight, changes of clinical chemistry and histopathology. With the dose and time increased, such contents in the urine get augmented as uric acid, tryptophan, phenylalanine and bile acid, at the same time the hippuric acid and glucuronate conjugates are decreased. Based on above results, these metabolites may be involved in DOX-induced cardiotoxicity, but the role of them need more research. Metabonomics proves more sensitive than traditional method for toxicity evaluation, and thus can be applied to the selection of drug toxicity and early diagnoses of disease. Supported by China Natural Science Foundation grant 30572281, 30371705.

359 BEAT-TO-BEAT QT VARIABILITY CORRELATES WITH PRO-ARRHYTHMIC RISK IN CONSCIOUS PRIMATES.

P. Lainée, R. Galy, A. Bétat, G. Froget and R. Forster. *CIT, Evreux, France.*

The appearance of the ICH S7B guideline, requiring the investigation of arrhythmogenic potential of candidate drugs prior to the initiation of clinical studies, has highlighted the need for improved predictors of pro-arrhythmic potential other than QT prolongation. Recent approaches to identify the risk of arrhythmia have been proposed based on parameters to quantify beat-to-beat QT variability (BBQTV) and the correlation of these parameters with the induction of arrhythmia has been examined in anesthetised dog preparations (Thomsen et al, 2004; Van der Linde et al, 2005). In the present study we have evaluated this approach in a conscious telemetered monkey study, using astemizole (AST) as a model pro-arrhythmic drug. Six female cynomolgus monkeys implanted with telemetry transmitters were orally dosed with either astemizole (30 mg/kg) or the vehicle (methylcellulose) and ECG signals monitored from 1h before to 12h after dosing. QTc (Bazett) was estimated from the QT and RR intervals. Estimates of BBQTV were provided by Short Term Instability (STI) Long Term Instability (LTI) and Total Instability (TI) (Van der Linde et al, 2005). The frequency and severity of arrhythmia induction was graded for each animal. Treatment with Astemizole resulted in QTc prolongation and the occurrence of large U waves in all animals and arrhythmic events were detected in two animals. Increases in values for STI, LTI and TI correlated with the severity of arrhythmia observed and these parameters returned to the normal range after recovery from the arrhythmic periods. Our results demonstrate a good correlation between BBQTV and pro-arrhythmic potential in monkeys treated with AST. Further studies are warranted with different classes of pro-arrhythmic and pure QT prolonging drugs. Furthermore, data is also required on the sensitivity of these markers at lower dose-levels, where arrhythmias are not observed, in order to evaluate the predictive potential of this approach in safety studies.

360 THE CARDIOVASCULAR HEMODYNAMICS OF THE ACUTE TOXICITY OF RECOMBINANT HUMAN ACID SPHINGOMYELINASE ADMINISTERED TO ACID SPHINGOMYELINASE KNOCKOUT MICE AND THE MODIFICATION OF THIS TOXICITY WITH THE ADMINISTRATION OF L-N6-(IMINOETHYL) LYSINE-5-TETRAZOLE-AMIDE.

A. M. D'Angona, C. Brown, J. Murray, A. D'Angona, M. Huff, P. Finn, K. Culm-Merdek, L. Andrews and K. Karey. *Pharmacology and Toxicology, Genzyme, Framingham, MA.*

Acute toxicity of recombinant human acid sphingomyelinase (rhASM) in acid sphingomyelinase knock-out (ASMKO) mice occurs following a 20 mg/kg dose of rhASM. Several studies designed to establish cardiovascular biomarkers/ mechanism of toxicity for use in clinical trials, have observed dose responsive changes in heart rate, blood pressure and activity.

We have designed studies to provide supplementary analysis of cardiovascular hemodynamics and have noted significant changes in the P-R and Q-T interval on the electrocardiograph (ECG) and increases in nitric oxide (NO) production, following a 20 mg/kg dose of rhASM, but not a 10 mg/kg dose of rhASM. NO is a key homeostatic biological messenger in the cardiovascular system. Under normal conditions, NO mediates vasodilatation and therefore normal heart rate/blood

pressure parameters. To investigate the possible role of NO, in the observed changes in cardiovascular hemodynamics, L-N6-(Iminoethyl) Lysine-5-Tetrazole-Amide (L-Nil), a selective interstitial nitric oxide synthase (iNOS) inhibitor, was co administered with 20 mg/kg rhASM. Under the conditions of the studies, L-Nil modified observations of toxic lethargy.

Changes in cardiac hemodynamics, specifically blood pressure, are paramount as the mechanism of action is unclear. Further characterization of the role of NO and specifically, iNOS in the modification of toxicity following a 20 mg/kg dose of rhASM, is underway.

361 EMBRYONIC ZEBRAFISH EXPOSED TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN EXHIBIT DEFECTS IN CARDIAC VALVE FORMATION AND FUNCTION.

V. Mehta¹, R. E. Peterson^{1,2} and W. Heideman^{1,2}. ¹Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI and ²School of Pharmacy, University of Wisconsin-Madison, Madison, WI.

Zebrafish embryos develop cardiac valves at three sites: the sinus venosus (SV) valve at the inflow to the heart; the atrioventricular (AV) valve between the atrium and the ventricle, and the bulbo-ventricular (BV) valve at the outflow. The valves originate from endocardial cells that migrate to form an endocardial ring and prevent blood regurgitation at presumptive valve locations at approximately 48 hours post fertilization (hpf). These endocardial cells then undergo a process termed epithelial to mesenchymal transformation [60-72 hpf] in which the endothelial cells delaminate into the cardiac jelly to form cardiac cushions [96 hpf]. The cushions are subsequently remodeled to form valve leaflets [120-168 hpf]. High-speed video microscopy showed that zebrafish embryos exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) develop blood cell regurgitation at the nascent valve sites [72 hpf], suggesting that TCDD induces a defect in cardiac valve formation or function. GFP labeled vascular endothelial cells showed that TCDD (1 ppb) disrupts the normal endothelial cell congregation at the presumptive AV valve site. Although TCDD did not prevent the initial formation of the ring of endothelial cells [48 hpf], the ring lost spatial restriction and became progressively diffused in TCDD exposed hearts. Similar results were observed at the BV valve. In-situ hybridization using AV valve-specific markers *bmp4* and *notch1b* indicates that valve specification was not initially prevented by TCDD at early time points [48 hpf]. However, these markers became significantly less restricted in pattern as heart development progressed in TCDD exposed embryos [72 hpf]. Confocal microscopy of TCDD exposed larvae showed no evidence of cushion formation or AV valve leaflets. This is the first report of TCDD affecting cardiac valve formation and function in a vertebrate species. (Supported by NIH RO1 ES012716 and UW Sea Grants R/BT17, R/BT20 and R/BT22).

362 BETA-NAPHTHOFILAVONE INDUCED INHIBITION OF BETA 2-ADRENERGIC RECEPTOR PROMOTER DRIVEN LUCIFERASE ACTIVITY IS NOT MEDIATED VIA PUTATIVE DIOXIN RESPONSE ELEMENTS.

K. M. Gonsalves, M. W. Carmody and R. J. Sommer. *Bates College, Lewiston, ME.*

Beta-adrenergic receptor (β -AR) signaling plays an important role in several cardiovascular system processes that are disrupted by TCDD exposure. We hypothesized that TCDD directly alters β -AR gene expression via putative dioxin response elements (DREs) that are located in the 5' enhancer regions of the β_1 - and β_2 -AR genes. Electromobility shift assays (EMSAs) were performed using [³²P]-labeled hCYP1A1 (positive control) or h β_1 - or h β_2 -AR oligos incubated with *in vitro* translated hAhR and hARNT proteins in the presence or absence of cold competitor oligos, with or without β NF. EMSA data indicate that AhR and ARNT do not bind the five putative DREs of the h β_1 -AR gene, however, strong binding was observed with one of the three putative DREs of the h β_2 -AR gene. Luciferase reporter activities of a positive control vector, hCYP1A1 DRE luciferase construct, pGudLuc6.1 (generous gift from M. Denison, UC-Davis), and of a pGL3-Basic vector (Promega, Madison, WI) containing a 660 nucleotide piece of the h β_2 -AR promoter were determined in transiently transfected HepG2 cells and were normalized to protein concentrations and to renilla transfection control vector expression levels. As expected, exposure to 5 or 10 μ M β NF for 24 hrs increased pGudLuc6.1 vector's luciferase activity 7- or 20-fold over vehicle treatment alone. In contrast, β NF exposure for 8 hrs decreased β_2 -AR promoter driven luciferase activity 30-fold below vehicle treatment levels. Promoter constructs containing a single point mutation in the one putative β_2 -AR DRE that exhibited AhR/ARNT binding in EMSAs; or in all three of the putative β_2 -AR DREs also exhibited similar magnitude decreases. Thus, the β NF-induced inhibition of β_2 -AR promoter driven luciferase activity does not appear to be directly mediated by AhR and ARNT at the

putative DREs of the β_2 -AR gene. The inhibition is, however, specific to β -AR promoter constructs and is not due to overt toxicity. Supported by NIH R15 ES011806 and RR16463-04.

363 MICRO-ELECTRODE ARRAY CHARACTERIZATION OF PHARMACOLOGICAL RESPONSES OF CRYOPRESERVED NEONATAL RAT CARDIOMYOCYTES IN CULTURE: CARDIAC CELL CHIP

T. Tam¹, A. Krantis^{1,3}, K. Kajiura³, A. Chichirau³, W. Staines^{1,3}, B. Foster^{4,1}, T. Meyer² and K. Boven². ¹Center for Research in Biopharmaceuticals and Biotechnology, University Ottawa, Ottawa, ON, Canada, ²Multi Channel Systems GmbH, Reutlingen, Germany, ³QBM Cell Science, Ottawa, ON, Canada and ⁴Health Canada, Ottawa, ON, Canada. Sponsor: M. Aschner.

Primary cells in culture are an important tool for investigating physiological mechanisms and responses to pharmaceuticals or toxicants. Cryopreservation of large batches of dissociated embryonic cells has proven to be a valid and convenient substitute for fresh dissections as a source of cells for primary neuronal cultures of cortex, hippocampus, striatum and dorsal root ganglia. We sought to expand on previous reports that benefits of convenience, animals care concerns and economies of scale could be derived from the cryopreservation of neonatal rat cardiomyocytes. Using our method for isolation and cryopreservation of cardiomyocytes we obtained rat cardiomyocytes that could be subsequently thawed and plated in a variety of multi-well formats and in MultiElectrode Array (MEA) chambers. At intervals from 1 to 5 weeks cultures were fixed and immunostained for alpha-actinin and connexin 43 (Cx43). MEA recordings were made at comparable time points. In some experiments cultures were treated with drugs directed toward gap junction coupling. The effect on Cx43 immunofluorescence and the time of coupling events in the MEA were observed. The cardiomyocytes were observed to beat and to show electrical activity 24 to 48 hours after plating. Correlation of activity across individual electrode points of the MEA and Cx43 immunofluorescence indicated formation of an electrical syncytium. Treatment with isoproterenol and carbachol caused predictable alterations in excitation-contraction. These data show that cryopreserved neonatal cardiomyocytes when thawed and cultured, maintain the important characteristics of freshly cultured cardiomyocytes.

364 IN VIVO ASSESSMENT OF TEMPORAL AND TRANSMURAL VARIABILITY OF CARDIAC REPOLARISATION AS A TOOL FOR EVALUATING PRO-ARRHYTHMIC RISK

G. Hanton, P. Bonnet and C. Loiret. *Drug Safety Research and Development, Pfizer Global Research and Development, Amboise Cedex, France.* Sponsor: M. Doubouetvsky.

Drug-induced prolongation of the QT interval of the ECG, in laboratory animals and humans, is generally considered as indicative of a pro-arrhythmic risk. However there is now evidence that the prolongation of QT interval as such is not an accurate predictor of this risk and that other parameters of cardiac repolarisation are more reliable. In particular instability of action potential duration and increase in transmural heterogeneity of myocardial repolarisation are considered as key parameters. The former can be evaluated as changes in beat-to-beat variability of the QT interval and the latter can be evaluated by changes in T wave morphology. This study was aimed at testing these changes in dogs treated orally with the I_{K_r} blocker astemizole (AST: 3 to 15 mg/kg), the adrenergic agonist isoproterenol (ISO: 2.5 to 10 μ g/kg) or in hypokalemic conditions (hypoK⁺: plasma K⁺ = 3.1 to 3.5 mmol/L) induced by furosemide.

Beat-to-beat variability of QT, was evaluated by 2 formulas: the coefficient of variation of QT as $CVQT = SD_{QT}/mean_{QT}$ and the formula of QT temporal dispersion described in the literature and used in clinical investigations: $QTdt = \log_{10}(CVQT/CVRR)^2$. QTdt formula was found inappropriate for dogs in which the sinus arrhythmia is generally marked and therefore QTdt reflects more the change in RR than in QT variability. In contrast, CVQT showed that AST increased the beat-to-beat variability of QT.

The T wave recorded in CV5RL lead, which is positive and monophasic in untreated healthy animals, was notched after treatment with AST or ISO and in hypoK⁺, which all modify transmural heterogeneity of repolarisation. Notching was characterized by a second peak in the T wave. In hypoK⁺, the changes were most marked, with occasional biphasic or inverted T wave, in addition to various degrees of notching.

In conclusion, we have established a method for in vivo assessment of transmural and beat-to-beat variability of cardiac repolarisation, which may help in evaluating the pro-arrhythmic risk of drugs.

365 SEX DIFFERENCE IN ELECTROPHYSIOLOGICAL PROPERTIES OF CYNOMOLGUS MONKEY PAPILLARY MUSCLES.

A. Suzuki, K. Yunomae, J. Matsuo, M. Haruyama, M. Ban, T. Nakamura, T. Sukamoto, K. Fukuzaki, R. Nagata and G. Kito. *Shin Nippon Biomedical Laboratories, Ltd., (SNBL), Kagoshima, Kagoshima, Japan.*

It's reported that women have longer QTc intervals than men and are at greater risk of associated arrhythmia, such as drug-induced torsades de pointes (TdP). Female gender is also a risk factor for the occurrence of syncope and sudden death in congenital long QT syndrome. The purpose of this study was to investigate whether there are sex differences in action potential (AP) repolarization and responses to proarrhythmic drugs in cynomolgus monkey papillary muscles. Ion channel expressions in cynomolgus monkey left ventricles were evaluated to elucidate the mechanisms of sex differences. [Methods] AP in cynomolgus monkey papillary muscles was measured using the microelectrode recording technique. Ion channel protein (KvLQT1, ERG and Cav1.2) expressions were evaluated by Western blot technique. [Results] APD90 in female cynomolgus monkey papillary muscles was approximately 15% longer than that in males. At stimulation of 0.2 Hz, but not at 1.0 Hz, E-4031 at 1 μ M elicited a significantly higher increase in APD90, incidence of early after depolarizations (EADs) and triggered activities (TAs) in papillary muscles from females compared with those from males. In low potassium conditions at stimulation of 0.2 Hz, EADs and TAs were induced at a lower concentration of E-4031 in papillary muscles from females compared with those from males. KvLQT1 and Cav1.2 expressions were higher in female left ventricles than those of males. [Conclusion] In the present study, we provide experimental evidence suggesting sex differences in cynomolgus monkey AP repolarization, and this might be attributable to ion channel protein expression differences. Our electrophysiological findings are consistent with the clinical observations that women have longer QTc intervals and that female gender is a risk factor for drug-induced TdP. Therefore, papillary muscles from the female cynomolgus monkey could be a useful test model for safety pharmacological assessment in evaluating potential proarrhythmic events.

366 CARDIOPULMONARY EFFECTS OF INHALED OZONE AND PARTICULATE MATTER IN TWO MOUSE STRAINS.

A. K. Hamade, E. Abston, A. Rule, R. Rabold and C. Tankersley. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Ozone, a potent oxidant gas with established pulmonary toxicity is a principal air pollutant that coexists with particulate matter (PM) in urban ambient air. While human and animal studies are replete with associations between PM exposure and adverse pulmonary and cardiovascular events, ozone has received little attention outside the realm of pulmonary toxicity. We tested the hypothesis that ozone has a potent cardiopulmonary effect and that variation in interindividual responses occur with specific air pollutants. After implanting radiometers to measure heart rate (HR), we exposed two different mouse strains (i.e. C3H/HeJ, C3 [n=3] and C57Bl/6J, B6 [n=3]) to 3 different daily exposure protocols for 3 consecutive days each. The order of the exposure protocols was as such: 1) 2 hrs of filtered air (FA) followed by 3 hrs of FA; 2) 2 hrs of FA followed by 3 hrs of carbon black (CB, CMD = 0.7 μ m, MMAD = 1.01 μ m); and 3) 2 hrs of ozone (O3, 550 ppb) followed by 3 hrs of CB. We observed predictable strain differences in HR following 2 hrs of FA between C3 and B6 mice (507 $\pm$ 27 vs. 406 $\pm$ 11 bpm). We also observed a notable decline in HR after O3 exposure in both C3 and B6 mice (313 $\pm$ 17 vs. 292 $\pm$ 13 bpm). The O3-induced HR response in C3 mice appeared to be more persistent over time compared with that in B6 mice. Selected heart rate variability (HRV) parameters in the time domain were also altered with O3 exposure. The O3-induced HRV changes are associated with altered parasympathetic activity in regulating HR. Using whole-body plethysmography, we observed striking strain differences in the O3-induced ventilatory response. The C3 mice responded by increasing respiratory rate following ozone exposure while the B6 mice showed no significant changes in respiratory rate when compared to the FA exposure. Further analyses and future studies will focus on the adverse mechanisms of O3 and PM exposure on cardiopulmonary function. Moreover, we aim to elucidate genetic factors that may modify individual responses and susceptibility to these air pollutants.

367 SUBCHRONIC EFFECTS OF ENVIRONMENTAL TOBACCO SMOKE (ETS) EXPOSURE ON CARDIAC FUNCTIONS IN APOE^{-/-} MICE.

Q. Li¹, X. Jin¹, M. Zhong¹, J. Hwang² and L. Chen¹. ¹Nelson Institute of Environmental Medicine, NYU School of Medicine, Tuxedo Park, NY and ²Statistics Institute, Academia Sinica, Taipei, Taiwan.

ETS exposure has been associated with increased cardiac morbidity and premature mortality. However, cumulative effects of long-term ETS exposure have yet to be fully explored and systematically monitored. This subchronic study therefore evaluated alterations in cardiac functions in ApoE^{-/-} mice during a 6-mo series of daily 6-hr side stream smoke (SS) exposures.

Thirty-two ApoE^{-/-} mice, fed with either high-fat chow (HFC) or normal chow (NC), were exposed to SS (a surrogate for ETS, avg. 450 µg/m³) or filtered air, 6 hours per day, 5 days per week for 6 months. Electrocardiogram (ECG), Heart Rate (HR), Deep Body Temperature, and Activity Counts data were constantly sampled for 35 seconds/5 minutes throughout the experiment using implanted DSI telemetry transmitters (TA10ETA-F20). Heart Rate Variability (HRV) analyses, and methodologies for assessing cardiac vulnerability and mortality, were conducted using conventional methods (SDNN, standard deviation of RR intervals; RMSSD, root mean square of successive RR-differences; PSD, power spectral analysis.) and a new method that was developed in our laboratory.

The results showed that: (1) HR was significantly reduced in both high-fat and normal chow mice over the 75 days of SS exposure; and (2) the effects of SS exposure varied across different time segments of the day. Although no significant HRV alterations were found in NC-fed mice exposed to SS, the HFC-fed mice exposed to SS had greater acceleration in HRV reduction than those in the NC-fed control group.

Our results showed that subchronic SS exposures at concentrations encountered in human environments, could produce abnormal cardiac functions in ApoE^{-/-} mice. Our results provide additional information for elucidating pathophysiologic pathways between ETS exposure and cardiac diseases.

368 ACUTE CARDIOVASCULAR EFFECTS OF NICKEL AEROSOL IN APOE^{-/-} MICE.

G. Kang, Q. Li, X. Jin, Z. Mianhua, M. Lippmann and L. Chen. New York University, Tuxedo, NY.

Although exposure to fine ambient particulate matter (FPM) is known to be associated with excess daily mortality and morbidity, the major component responsible for these effects remain unknown. Our recent study using a mouse model of atherosclerosis (ApoE^{-/-}) exposed to concentrated (10X) ambient air FPM (CAPs) for 6hr/d, 5d/w, for 6 mo showed that Ni concentration was significantly associated with acute changes in heart rate (HR) and HR variability (HRV). The objective of this pilot study was to investigate if a similar pattern of acute changes in HR and HRV could be seen when ApoE^{-/-} mice were exposed specifically to Ni.

Male ApoE^{-/-} mice, 16 weeks-old, were fed with high fat chow for 2 months and implanted with ECG transmitters three weeks before the start of the exposure. They were exposed either to filtered air or 0.2 µm NiSO₄ aerosol at ~300 µg/m³ for 3h/d, 5d/w for 2 weeks. ECG, HR, activity, and body temperature data were sampled for 30 sec every 5 min throughout the experiment.

We found that average HR decreased in 3 out of 4 Ni-exposed mice between midnight and 6 am, an effect consistent with previous findings in mice exposed to CAPs. HRV, expressed as log standard deviation of normal-to-normal beat intervals (SDNN), decreased significantly during the exposure period in both Ni- and sham-exposed mice. However, decreases in HRV persisted in Ni-exposed mice for at least 3 more h after the exposure, while HRV returned to normal shortly after in the sham-exposed animals.

Our results indicated that Ni aerosol could produce changes in HR and HRV in mice susceptible to atherosclerosis and confirmed our earlier observations that Ni could be an important component of ambient FPM in eliciting alterations in cardiac functions. Further study is needed to explain the biological mechanism of this phenomenon, and of chronic effects of Ni exposure at environmentally relevant levels.

369 HIGH DOSE PRENATAL ARSENIC EXPOSURE DECREASES CORONARY ARTERY DENSITY AND INCREASES CARDIAC FIBROSIS IN ADULT MICE.

L. L. Philbrook, J. M. Shulan and R. J. Sommer. Bates College, Lewiston, ME.

Arsenic is a naturally occurring groundwater contaminant found at levels higher than 10 ppb in more than 30% of the private wells in Maine. Epidemiological studies have associated arsenic exposure with cardiovascular disease. The goal of this study was to determine whether prenatal arsenic exposure could adversely impact the adult cardiovascular system. Pregnant mice were exposed to high levels of

sodium arsenite (10, 20, 40, or 80 ppm) via drinking water, *ad libitum*, starting on day 5 of gestation and continuing until the day of birth. Hearts from one male and one female offspring from four different litters were collected in adulthood and processed for histochemical analysis. Coronary arteries and arterioles were visualized with α -smooth muscle actin staining. Arteries and arterioles >5 µm in diameter were counted from a single section at each of the lower, middle and upper areas of the midventricular region. Incidence and severity of cardiac fibrosis were observed by Masson trichrome stain of ten sections evenly distributed from the apex to base of each heart. Only data from male offspring have been analyzed. In males, increasing arsenic exposure decreased artery densities for all areas of the midventricular region with the largest effect observed in the lower midventricular region. Lower midventricular artery densities (mean $\pm$ SE) were 12.5 $\pm$ 2.1, 10.5 $\pm$ 2.5, 9.8 $\pm$ 3.7, 7.9 $\pm$ 3.0, and 8.1 $\pm$ 3.3 no./mm² for the 0, 10, 20, 40 and 80 ppm treatment groups, respectively. Likewise, a trend for increasing fibrosis was observed with increasing arsenic exposure. Mean ($\pm$ SE) total area of fibrosis was 1.58 $\pm$ 0.40, 1.32 $\pm$ 0.42, 3.32 $\pm$ 2.04, 3.62 $\pm$ 2.37, and 4.62 $\pm$ 3.60 1x10³ pixels for the 0, 10, 20, 40 and 80 ppm treatment groups, respectively. Cardiomyocyte hypertrophy was observed adjacent to areas of fibrosis. Thus, prenatal exposure to arsenic may increase risk of cardiovascular disease in adulthood.

370 METHODS FOR THE ASSESSMENT OF CARDIOVASCULAR PARAMETERS IN THE MINIPIG.

H. Penton, M. Vezina, S. Mason and C. Banks. Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.

The dog and primate are the usual large animal species for evaluating test article effects on the cardiovascular system, however they may not always be suitable for some compounds. As an alternative species, the minipig may be used given their many similarities to humans. A telemetered model was prepared to assess simple parameters such as blood pressure (BP), heart rate (HR) and ECG, in addition to a more complex cardiovascular profile in both anesthetized and conscious animals. In the telemetry study, treatment with dl-Sotalol induced prolongation of PR and QT-intervals of the ECG, with telemetry demonstrating to be an accurate method for long-term collection of cardiovascular data in this species. Additional parameters including pulmonary artery pressure (PAP), left ventricular pressure (LVP) and cardiac output (CO) were also assessed in male minipigs (Yucatan and Gottingen) administered Saline, Diphenhydramine or Isoproterenol. Large volumes of saline resulted in a small transient elevation in BP in anesthetized animals with no effect in the conscious restrained model. Diphenhydramine caused a small transient decrease in HR and elevated systemic BP, which was contrary to results in conscious unrestrained animals. Isoproterenol dosing resulted in acute elevations in HR, LVP, PAP and decreased systemic BP. The minipig is therefore considered an appropriate model for use as an indicator of potential effects on the cardiovascular system.

371 A COMPARISON BETWEEN COMPOUND POTENCY IN AN IN VITRO PHOSPHOLIPIDOSIS ASSAY AND AT THE HERG-ENCODED POTASSIUM CHANNEL.

L. Barone¹, B. Small², J. Valentin², C. Pollard² and P. Ciaccio¹. ¹Safety Assessment U.S., AstraZeneca, Wilmington, DE and ²Safety Assessment UK, AstraZeneca, Alderley Park, United Kingdom.

Inhibition of the Human Ether-a-go-go Related Gene (hERG) encoded K⁺ channel and phospholipidosis (PLD) are potential safety concerns and liabilities to early compound progression in the drug discovery process. Although PLD has not been causally linked to aberrant cellular function and its clinical implications are not well understood, the association of PLD with frank toxicity within a given tissue is common; and presence of PLD in cells/tissues is an issue to regulatory agencies and for the drug development process. The hERG - encoded K⁺ channel underlies the repolarising I_{Kr} current of the cardiac action potential, inhibition of the I_{Kr} current can lead to potentially fatal cardiac arrhythmias. Cationic, amphiphilic drugs (CADS) are reported to cause local or systemic PLD after chronic exposure in preclinical studies and, in very broad terms, inhibitors of the hERG-encoded K⁺ channel also fall into this chemical category. In view of this and the observation that some CADs that induce PLD *in vivo* have also been reported to prolong the QT interval, it was considered to be worth testing whether a larger list of agents known to prolong QT interval are phospholipogenic and whether there was any correlation between potency of CADS in *in vitro* PLD and hERG-encoded channel assays. Forty-five compounds representing various therapeutic indications were tested in an *in vitro* PLD assay using the mouse splenic I-13.35 cell line and in the IonWorks™ HT hERG assay using the Chinese hamster ovary K1 cell line. Potency values were obtained in both assays for 33 of these, 26 of which are known to cause QT prolongation, with 24 of the 26 causing PLD *in vitro*. Correlations between hERG potency (IC₅₀) and either PLD induction (EC₅₀) (r=0.04) or extent (% PLD maximal response) (r=0.4) were not observed. Lack of a potency correlation indicates that hERG data cannot be used as a quantitative indicator of *in vitro* PLD potency or vice versa.

372 A DOSE RANGE-FINDING STUDY TO DETERMINE THE HEMODYNAMIC EFFECTS OF A SINGLE IV INFUSION AND A 14-DAY CONTINUOUS INTRAVENOUS (CIV) OF KSR-1 AS-214231 (NSC-731442) IN CYNOMOLGUS MONKEYS.

C. R. Hassler², M. Hawk², R. Lordo², B. Wood², J. Johnson², R. Kolesnick³ and J. Peggins¹. ¹National Cancer Institute, Bethesda, MD, ²Battelle, Columbus, OH and ³Memorial Sloan-Kettering Institute, New York, NY. Sponsor: E. Glaze.

The objectives of this study were to determine the hemodynamic effects and cardiovascular (CV) toxicity of KSR AS-214231 (KSR) when administered as a single 15-minute IV infusion at 9, 18, or 27 mg/kg and as a 14-day ambulatory continuous intravenous infusion (CIV) at 0, 14, or 28 mg/kg/day in cynomolgus monkeys. This compound is a phosphorothioated antisense oligonucleotide to KSR-1 being developed for use in the treatment of pancreatic cancer. The animals were instrumented with telemetry for blood pressure (BP), heart rate (HR), and electrocardiograms (ECG). For the 15-minute infusion groups (2 to 4/group), there were no BP or HR alterations (9 mg/kg). At 18 mg/kg, three of four animals exhibited variable CV alterations, including BP increases (15 to 25 mmHg) peaking at 2 hours post dosing and HR increases (50 BPM). At 27 mg/kg one of two animals responded with BP increases (50 mmHg) and apparent reflex bradycardia (50 BPM) associated with the end of dosing. There were no ECG alterations attributed to the test article. For the CIV groups of 1 male[M]/1 female[F] were used. At 14 mg/kg/day there were alterations of HR and BP primarily in the F that were not considered test article-related. At 28 mg/kg/day, the M exhibited acute hypotension with apparent reflex tachycardia at dosing start. HR and BP were stable through Day 6 and then progressively declined until the end of the infusion. HR decreased (35 BPM) and BP decreased (25 mmHg) across the dosing period. The F exhibited HR increases (30 BPM) and BP increases (20 mmHg) from Day 7 to Day 14. There were no ECG alterations. The no effect levels were 9 mg/kg (single IV infusion) and 14 mg/kg/day (CIV infusion). All dose levels were potentially tolerable. [Supported by NCI Contract NO1-CM-42200].

373 VALIDATION OF GUINEA PIG LANGENDORFF HEART ASSAY TO EVALUATE CARDIOVASCULAR TOXICITY OF DRUG CANDIDATES.

L. Guo, Z. Dong and H. Guthrie. *Non-clinical Drug Safety, Hoffmann-La Roche Inc., Nutley, NJ*. Sponsor: K. Pendino.

Cardiovascular toxicity of pharmaceuticals is a major concern in public healthcare. As such, effective methods must be established to detect unwanted, off-target cardiovascular signals during early drug development. The current study was conducted to validate the sensitivity and specificity of the isolated guinea pig Langendorff heart assay for detection of cardiovascular toxicity of drug candidates. Isolated guinea pig hearts were perfused in Langendorff mode under either sinus rhythm or paced at 200 and 300 beats per minute via the right atrium, and multiple parameters of hemodynamic function (coronary and left ventricle pressure), cardiac electrical function (electrocardiogram and monophasic action potential (MAP)), and indices of arrhythmogenic propensity (MAP triangulation, reverse-use dependence, increased repolarization dispersion and beat-to-beat instability), together with overt arrhythmia (ventricular tachycardia, Torsades de Pointes, etc.) were simultaneously evaluated with 26 reference compounds that possess diverse QT liability/arrhythmogenic potential, inotropy, chronotropy and vasodilatory actions. Ascending concentrations up to either 100-fold the hERG IC50 value or 100 μ M were routinely tested utilizing 4-6 hearts for each reference compound. The validation results revealed that each reference compound exhibited a unique cardiovascular profile; compounds associated with high arrhythmogenic risk in the clinic often exhibited more than two "positive signals" on parameters linked to arrhythmogenesis at concentrations within 30-fold of their maximal therapeutic free plasma concentration. A scoring system was then developed to assist in rank-ordering the cardiovascular toxicity of these cardiotoxicants as well as new drug candidates. The arrhythmogenic potential predicted by this scoring system generally correlated well with that observed in the clinic, suggesting that the isolated Langendorff heart assay in conjunction with the newly developed scoring system may be a useful tool in early cardiac risk assessment.

374 A HESI STUDY OF DOXORUBICIN INDUCED CARDIOTOXICITY IN RATS.

Q. Huang, J. Lyon, H. Hamadeh, E. Herman, M. Embry, S. Pettit, B. Gollapudi, S. Lipshultz, R. Roth, P. Ciccio, T. Auman, Y. Bauer, M. Cunningham, J. Davis, G. Gibson, W. Harrouk, R. Haworth, M. Holsapple, A. Klenk, J. Leighton, G. Orphanides, R. Paules, F. Staedtler, S. Thurmond and J. Tugwood. *Mechanism-Based Markers of Toxicity Working Group, HESI Committee on the Application of Genomics in Mechanism-Based Risk Assessment, International Life Sciences Institute, Washington, DC.*

This study was initiated by the Mechanism-Based Markers of Toxicity Working Group as part of the HESI Committee on the Application of Genomics in Mechanism-Based Risk Assessment. Doxorubicin (Dox), a broad spectrum anthracycline antineoplastic agent, is associated with a cumulative dose-dependent cardiomyopathy in patients. In the current study, the cardiotoxicity potential of Dox was investigated and compared with the effects of etoposide (Etop), a pharmacologically comparable negative control. Sprague Dawley rats received weekly intravenous dosing of Dox (0.5, 1, 2, and 3 mg/kg/week) or Etop (0.5, 1, and 3 mg/kg/week) for 6 consecutive weeks. The highest dose of Dox was associated with low incidence of mortality and dose-dependent decrease in body weight gain was observed in animals that received Dox. Dox treatment caused profound pancytopenia (RBC, WBC and lymphocyte), and prominent changes in various serum chemistry parameters (BUN, CREA, ALKP, CHOL, and ALB). Cardiotoxicity markers, such as creatinine kinase (CK), CKMM and troponin T, were elevated in the animals receiving Dox at doses of 2 and 3 mg/kg. Dexrazoxane (Dex), a protective agent for Dox induced cardiotoxicity, significantly ameliorated Dox's effects on body weight, serum parameters, and cardiotoxicity markers. Histopathological examination of toluidene-blue stained heart sections revealed macrovesicular vacuolation of atrial and ventricular myocytes following high dose Dox. High-density gene expression profiles will be analyzed to study the molecular mechanisms underlying the cardiotoxic effects mediated by Dox and inform for potential safety biomarkers.

375 EFFECT OF β -BLOCKERS ON LEFT VENTRICULAR FUNCTION IN HEALTHY AND DISEASE HEARTS OF NON-HUMAN PRIMATES USING REAL-TIME THREE-DIMENSIONAL ECHOCARDIOGRAPHY.

H. Okatani¹, H. Yamashita¹, K. Fukuzaki¹, H. Iwao², R. Nagata¹ and G. Kito¹. ¹Drug Safety Research Laboratories, Shin Nippon Biomedical Laboratories (SNBL), Kagoshima, Japan and ²Department of Pharmacology, Osaka City University Medical School, Osaka, Japan.

β -Blockers remain a cornerstone in the therapy of all stages of ischemic heart disease, albeit the negative inotropic effect of acute β -blockade. The purpose of this study was to examine whether effects of β -blockers on left ventricular (LV) function are different between healthy and diseased hearts in monkeys. Male cynomolgus monkeys (n=25) were used in this study. To induce acute cardiomyopathy as diseased heart, animals received two repetitive epinephrine infusions (10 μ g/kg/min for 3 h) at an interval of 24 hours. LV function was measured using real-time three-dimensional echocardiography (RT3DE, SONOS 7500). End-diastolic and end-systolic volumes (EDV and ESV) significantly ($p<0.01$) increased in monkeys treated with epinephrine. Thereby, LV ejection fraction (EF) was significantly ($p<0.01$) depressed ($<40\%$) compared with pre-value (60%). In healthy hearts, propranolol and metoprolol (0.1 and 0.3 mg/kg/10 min, iv; n=3-4) caused a dose-dependent increase in ESV, but little effect on EDV, resulting in a decrease in EF as an indication of heart contractability. On the other hand, propranolol and metoprolol (each 0.3 mg/kg/10 min, iv; n=4-6) ameliorated a reduction in EF associated with a decrease in ESV in monkeys with LV dysfunction. These results demonstrated that β -blockers might present a different action mode in the diseased heart compared with effect on the healthy heart. Additionally, RT3DE provides the feasibility and accuracy for the detection of the deterioration of LV function.

376 EVIDENCE FOR ISOPRENOID DEPLETION PRIOR TO NECROSIS IN A RAT MODEL OF STATIN-INDUCED MYOPATHY.

R. C. Scott¹, H. S. Jones², P. D. Graves¹, F. Westwood¹, A. M. Marsden¹, T. C. Orton¹ and J. E. Sidaway¹. ¹Safety Assessment, AstraZeneca, Macclesfield, United Kingdom and ²University of Birmingham, Birmingham, United Kingdom.

Statins are lipid-lowering agents that inhibit HMG-CoA reductase, the rate-limiting enzyme in the synthesis of isoprenoids and cholesterol. The isoprenoid pyrophosphates of farnesol (FPP) and geranylgeranyl are attached to proteins by three prenyl transferases (with different substrate/protein specificities) and act as membrane anchors. Rare instances of myopathy are associated with statin use, and this may involve depletion of isoprenoids and FPP-derived products such as the respiratory chain intermediary ubiquinone. We have indirectly assessed isoprenoid level in

a rat model of statin-induced myopathy by measuring the appearance of unprenylated Ras, Rap1A and Rab5A (representing substrates for each prenyl transferase) in skeletal muscle cytoplasmic fractions. Female Han-Wistar rats were administered simvastatin (80 mg/kg/day) and skeletal muscle necrosis (defined by histopathology) was induced after 10-14 days in glycolytic fibres (predominant in gastrocnemius muscle) but not in oxidative fibres (predominant in soleus muscle). Unprenylated Ras, Rap1A and Rab5A were increased in gastrocnemius muscle of rats with necrosis but not in matched soleus muscle. Changes in protein prenylation also occurred prior to the induction of necrosis, as unprenylated Rab5A was evident in gastrocnemius muscle after two days of simvastatin administration and continued to increase for the duration of the study. Combined oral administration of simvastatin with farnesol (220 mg/kg/day) or geranylgeranyl (145 mg/kg/day) failed to prevent skeletal muscle damage. Unprenylated Rab5A was comparable in the gastrocnemius muscle of all groups, implying that insufficient exposure of isoprenoids was achieved in skeletal muscle. In conclusion, these data suggest that isoprenoids are decreased in glycolytic skeletal muscle several days prior to the initiation of statin-induced myopathy in the rat. This could be as a prelude to depletion of ubiquinone or more directly implicate protein prenylation in the mechanism.

377 EFFECTS OF MODERATE DIET RESTRICTION AND HIGH FAT DIET-INDUCED OBESITY ON DOXORUBICIN-INDUCED CARDIOMYOPATHY.

M. S. Mitra¹, S. Donthamsetty¹, J. R. Latendresse² and H. M. Mehendale¹.
¹University of Louisiana at Monroe, Monroe, LA and ²NCTR, Jefferson, AR.

Clinical use of doxorubicin (DOX, Adriamycin[®]) is limited due to its oxyradical-mediated cardiomyopathy. Susceptibility of the obese sensitive population to drug-induced cardiomyopathy has been sparsely investigated. Moderate diet restriction (DR) has a plethora of beneficial health effects. Our objective was to investigate the potentially opposing effects of obesity and DR on DOX-induced cardiomyopathy (DOXIC). Challenge of male SD rats (250-275 g) maintained on DR [35% less food than ad libitum (AL), 42 d], with a LD₁₀₀ dose of DOX (12 mg/kg, ip) on d 43, led to 100% mortality in AL rats between 7 to 13 d, whereas all the DR rats survived. Serum creatine kinase-MB (CK-MB), cardiac troponin-I, cardiac MDA, and histopathology revealed progressive cardiac injury in AL rats in stark contrast to the DR rats. Accumulation of DOX and its toxic metabolite, doxorubicinol, did not differ in the AL and DR rat hearts. Further mechanistic studies revealed that DR rats were protected due to: (1) increased cardiac antioxidants leading to markedly lower oxyradical stress decreasing cardiac uncoupling proteins 2 & 3; (2) lowered cardiac triglycerides leading to higher adiponectin, higher mitochondrial AMPα2 protein kinase, and 2-fold higher cardiac ATP levels; and (3) increased cardiac erythropoietin and decreased SOCS3 resulting in upregulation of cardioprotective JAK/STAT3 pathway. For the obesity studies, male SD rats (250-275 g) were maintained on 40% high fat diet for 42 d. Upon challenge with a normally LD₁₀ dose of DOX (8 mg/kg, ip) on d 43, 10% of the AL rats died by d 19 compared to 80% mortality in obese rats between d 7 to 18. Serum CK-MB and cardiac MDA levels were significantly higher in obese rats compared to AL rats. These results indicate that obesity sensitizes, while DR renders high resiliency to DOXIC. Moreover, the remarkable cardioprotection against DOXIC by DR appears to be due to a combination of lower oxyradical stress and favorable cardioprotective cellular signaling.

378 ENHANCED SUSCEPTIBILITY OF MYOCARDIAL FAILING RABBIT HEART TO DOFETILIDE-INDUCED TORSADES DE POINTES.

R. L. Hamlin¹, A. Kijawornrat¹, S. Viatchenko-Karpinski², B. M. Roche³, Y. Nishijima³, J. L. Lolly³ and S. Gyorke². ¹Department of Veterinary Biosciences, The Ohio State University, Columbus, OH, ²Department of Physiology and Cell Biology, The Ohio State University, Columbus, OH and ³QTest Labs, LLC, Columbus, OH.
Sponsor: M. Hejtmancik.

Cardiac remodeling after myocardial infarction is associated with increased risk of ventricular arrhythmias and susceptibility to proarrhythmic effects of torsadogenic drugs. The rabbit model of myocardial failing has been shown to be prone to develop torsades de pointes (TdP) when exposed to torsadogens. However, there are little data concerning the cellular basis of arrhythmias in this model. This study was aimed to investigate the dispersion of repolarization and the myocyte action potential duration (APD90) of the normal and myocardial failing rabbit heart in response to dofetilide. Comparison with normal conscious rabbits, rabbits with myocardial failing hearts had a slower heart rate (228±10vs244±10bpm; p=ns), prolongation of QT (p<0.001) and QTc (p<0.001) intervals (154.3±4.5vs133.3±2.4ms and 280.9±6.2vs243.4±6.1ms, respectively). Short-term variability was increased (p<0.05) in myocardial failure group (0.38±0.02ms) when compared with normal conscious group (0.29±0.01ms) whereas long-term variability tended to increase (0.39±0.03vs0.33±0.02ms; p=ns). Myocytes isolated

from border zone of infarcted area could be separated into two groups: non-hypertrophic cells and hypertrophic cells with pathological parameters of EC coupling. APD90 of hypertrophic failing myocytes (912±44ms) was prolonged (p<0.01) compared with action potentials from the same area of normal rabbits (388±19ms). In normal myocytes, dofetilide increased APD90 (p<0.01) at 0.1 μM (from 388±19to921±68ms) with evidence of EADs. In hypertrophic myocytes, dofetilide (1.0 μM) increased APD90 21±8 % from baseline (p<0.05) and EADs were observed both before and after applied dofetilide. It can be concluded that (1) the re-entrant circuit from different APD profiles, (2) EADs triggered activity and (3) increase dispersion of repolarization are responsible for genesis of TdP in the failing rabbit heart.

379 ATTENUATION OF ANGIOTENSIN II-INDUCED EARLY CELL DEATH BY METALLOTHIONEIN RESULTS IN A PREVENTION OF THE LATE DEVELOPMENT OF CARDIOMYOPATHY.

G. Zhou, J. Y. Kang and L. Cai. University of Louisville, Louisville, KY.

Angiotensin II (Ang II) plays a critical role in the diabetic cardiovascular diseases including cardiomyopathy. We have demonstrated that cardiomyocytes with high levels of metallothionein (MT) are significantly resistant to diabetes- and Ang II-induced apoptotic cell death mediated by NADPH oxidase (NOX) activation. To investigate the effects of MT on Ang II - induced cardiac injury in vivo, we administered the cardiac-specific MT-overexpressing transgenic (MT-TG) and WT mice with a single injection of Ang II at 1 mg/kg body weight and collected the cardiac tissues 7 hr after the treatment. Ang II caused a significant increase in apoptotic cell death, examined by TUNEL assay and Western blotting for the caspase-3 activation along with an increased 3-NT formation in the heart and an increased expression of NOX isoform p47phox in the membrane proteins, examined by Western blotting. All of these effects of Ang II were significantly prevented in the heart of Ang II-treated MT-TG mice, indicating the protective effect of MT on Ang II-induced apoptosis via suppression of NOX activation. To further evaluate antiapoptotic effect of MT on Ang II, MT-TG and WT mice were chronically infused with Ang II at a subhypertensive dose of 0.5 mg/kg body weight for two weeks and then cardiac tissues were collected at 3 and 6 months. Ang II chronic treatment caused a significant increase in cardiac fibrosis, shown by increased collagen content and up-regulation of connective tissue growth factor, an important profibrotic factor, in the heart of WT, but not in MT-TG, mice. These results suggest that Ang II induces cardiac apoptosis through activation of NOX and subsequent generation of peroxynitrite. MT prevents Ang II-induced cardiac cell death through suppression of NOX activation, peroxynitrite formation and nitrosative damage. The protection of Ang II-induced early cell death by MT leads to a prevention of the late development of cardiomyopathy (Supported in part by ADA, NIH and AHA research grants).

380 METALLOTHIONEIN PREVENTS DIABETES-INDUCED TRIGLYCERIDE AND LIPIDS ACCUMULATION IN THE HEART: EFFECT ON STIMULATING AKT-DEPENDENT GLUCOSE METABOLISM.

Y. Wang. Medicine, University of Louisville, Louisville, KY. Sponsor: L. Cai.

Yuehui Wang, Y. James Kang and Lu Cai, Medicine, University of Louisville, Louisville, KY

Cardiac-specific metallothionein (MT)-overexpressing transgenic (MT-TG) mice were highly resistant to diabetes-induced oxidative damage and the development of diabetic cardiomyopathy. Increasing evidence indicates that diabetic lipotoxicity plays a critical role in initiating the oxidative damage at the early stage, leading to cardiac dysfunction at the late stage. Therefore, the present study was aimed at investigating mechanism by which MT protects the heart from diabetes-induced lipotoxic damage. Both MT-TG and wild-type (WT) mice were given a single dose of streptozotocin to induce hyperglycemia. Two and three weeks after the treatment, cardiac triglyceride and lipid accumulation were significantly increased, along with increases in lipid peroxidation in the heart of the WT diabetic mice, but not in the MT-TG diabetic mice. To explore the underlying mechanisms, Akt abundance and phosphorylation was examined at two weeks and two months after the onset of diabetes. Although Akt abundance was not significantly changed, Akt phosphorylation was significantly decreased in the heart of WT diabetic mice under basal condition or in response to insulin stimulation. The decreased phosphorylation of Akt in the hearts of WT diabetic mice at two weeks and two months after the onset of diabetes was accompanied by decreases in phosphorylation of GSK-3b, a critical kinase related to glucose metabolism. However, neither phosphorylation of Akt nor GSK-3b kinase was decreased in the MT-TG diabetic mice, suggesting the preservation of normal glucose metabolism. Therefore, these results suggest that MT prevents diabetes-induced increases in cardiac triglyceride and

lipids accumulation, likely through preservation of the Akt-dependent glucose metabolism (Supported, in part, by research grants from ADA, Philip Morris USA, Inc. and NIH).

381 ACIZOL EFFICACY IN EXPERIMENTAL CARDIOLOGY.

S. P. Nechiporenko, M. A. Zaytseva, S. A. Kiril and M. V. Melikhova. *The Institute of Toxicology, St Petersburg, Russian Federation.* Sponsor: K. Khamidulina.

Acizol, an antidote to carbon monoxide belonging to the series of zinc organic compounds, is an effective antioxidant. We studied Acizol specific pharmacology activity at intragastric introduction on cardiac ischemia. Two experimental models were used - cardiac infarction and calcium arrhythmia. Acizol dose was 60 mg/kg. Survival rate, electrocardiography and histology indices were registered. Experimental studies showed that Acizol can increase experimental animals survival rate by 20%, decrease heart attack frequency by approximately 2 times, increase cardiac tonus 2 times, and accelerate atrioventricular conductivity by 25% in comparison with the controls. Acizol has antiarrhythmic properties: lengthening of the latent period by 70% and lengthening of the fibrillation time by 80%. Increasing time of life of experimental animals by 40% in comparison with the control was registered. Acizol is a perspective drug for prophylaxis and cardiac ischemia treatment.

382 IDENTIFYING CARDIOTOXIC DRUGS USING A TWO CELL MODEL COMBINED WITH MULTI-PARAMETRIC ANALYSIS: APPLICATIONS FOR *IN VITRO* TOXICITY SCREENING.

P. C. Wilga, D. K. Petrella, A. J. Swanson, J. F. Pregoner, S. Thompson, K. Rutherford-Root and J. McKim. *CeeTox, Inc., Kalamazoo, MI.*

In vitro cell-based models able to predict toxicity specific to the heart would be of considerable value in early drug development. Predicting organ-specific toxicity requires cells from different tissues and a test set of drugs with known organ-specific toxicity. Drugs considered primarily toxic to the heart (anthracyclines) were compared to those considered primarily toxic to the liver (camptothecin and rotenone). Rat cardiomyocytes isolated from 1-2 day old neonates and a rat liver hepatoma (H4IIE) cell line were used as the cell models. Both cell systems were exposed to 1, 5, 10, 20, 50, 100, and 300 μ M of the test drugs for 1, 3, 6, or 24 hr. Cytotoxicity was assessed using markers for general toxicity, oxidative stress, apoptosis, and hypertrophy. Mitochondria were the most sensitive targets in both cell models. However, the TC50 values were 2-to-3 fold lower in the liver cells when compared to the heart cells. The average TC50 value for adriamycin in cardiomyocytes at 24 hr was 5 μ M versus 18 μ M in H4IIE cells. In addition, a reduction in reduced glutathione was observed in cardiomyocytes with a concomitant dose- and time-related increase in ROS as measured by DCFDA. Cardiac hypertrophy markers ANP and BNP were also measured. At 3 hr, adriamycin showed a 2-fold increase in BNP at 50 μ M, and Endothelin-1 at 0.1 μ M showed a 2-fold increase in ANP and a 4-fold increase in BNP. Camptothecin and rotenone were more toxic in the H4IIE cells. A decrease in cell proliferation and reduction in mitochondrial function were observed in H4IIE cells that was much greater than in the cardiomyocytes. The average TC50 value for camptothecin in H4IIE cells at 24 hr was 77 μ M versus 298 μ M in cardiomyocytes. The average rotenone TC50 was 0.3 μ M in H4IIE cells versus 32 μ M in cardiomyocytes. These data suggest that a two cell model may allow *in vitro* screens to predict cardiac versus non-cardiac toxicity. Thus, the incorporation of a two cell model for identifying organ specific toxicity appears to be a useful tool.

383 STRAIN DIFFERENCES IN SERUM CARDIAC TROPONIN-I CONCENTRATION AND MYOCARDIAL NECROSIS AFTER ISOPROTERENOL TREATMENT IN MICE.

S. K. Engle¹, J. L. Zimmerman², W. H. Jordan², M. L. Pritt¹, M. A. Davis¹, A. Schultze² and D. E. Watson¹. ¹*Investigative Toxicology, Eli Lilly and Company, Greenfield, IN* and ²*Pathology, Eli Lilly and Company, Greenfield, IN.*

Cardiac troponin-I (cTnI) is a common biomarker of cardiac injury in humans, but satisfactory application of cTnI in toxicologic pathology requires greater characterization of its properties. Increases in the concentration of cTnI in serum are thought to be diagnostic of myocardial cell membrane disruption and breakdown of myofiber. Interpretation of cTnI concentration across different mouse strains has not been described. This study evaluated cTnI in age-matched female CD1 and balb/c mice after beta-adrenergic stimulation. Subcutaneous administration of isoproterenol (10 mg/kg) to CD1 mice produced a peak cTnI concentration of 5.5 ± 2.1 ng/ml 4 hr after dosing and returned to baseline (0.1 ng/ml ± 0.03) after 24 hr. CK activity in serum was increased and returned to normal within 24 hr in these animals. These mice exhibited dose-dependent increases in myocardial necrosis,

graded as minimal to slight, which was restricted to the left ventricle, and characterized by myofiber hyalinization, fragmentation and karyorrhexis. In contrast, balb/c mice treated with 10mg/kg isoproterenol reached a peak cTnI concentration of 27.5 ± 13.1 ng/ml 4 hr post dose and did not return to baseline (0.1 ng/ml ± 0.03) for 72 hr. CK activity in serum was markedly increased 1 hr post-dose, and by 24 hr, some mice still had marked increases in the activity of CK. Myocardial necrosis, graded as minimal to moderate, was characterized by hyalinization and karyorrhexis, and varied in distribution from a few myocytes in the left ventricles to necrosis of a majority of the myocytes in the left ventricle and several in the right ventricle. Collectively these data demonstrate the sensitivity of cTnI as a biomarker of cardiac injury, and suggest that balb/c mice are more susceptible to isoproterenol induced cardiac injury.

384 FABP3 AS A BIOMARKER OF CARDIAC AND SKELETAL MUSCLE INJURY IN THE RAT.

M. L. Pritt¹, A. Schultze², K. M. Credille², K. Rodocker², D. D. Brown² and D. E. Watson¹. ¹*Investigative Toxicology, Eli Lilly and Company, Greenfield, IN* and ²*Pathology, Eli Lilly and Company, Greenfield, IN.*

Striated muscles are subject to compound-mediated toxicity, including injury caused by statins, PPARs, and other lipid-altering drugs. Histopathologic assessment of muscle is the most definitive method to confirm injury but is resource intensive and lesions that occur at low incidence and in specific fiber types can be difficult to detect. Clinical pathology biomarkers of muscle injury, such as CK and AST, are useful, but tend to be less sensitive than is desired. As part of a broader effort to develop additional biomarkers of muscle injury, we investigated the use of fatty acid binding protein 3 (Fabp3) as a biomarker of both cardiac and skeletal muscle injury. Fabp3 is abundant in heart and skeletal muscle and is released into circulation with muscle injury. When quantified in a panel of markers with cardiac troponin I (cTnI) concentration, the cardiac or skeletal muscle source of serological Fabp3 may be inferred. Histologic sections of muscle were examined and serological Fabp3 and cTnI concentrations were quantified in Sprague Dawley and F-344 rats following treatment with compounds that cause cardiac and/or skeletal muscle injury. The kinetics and treatment-dependant increases in Fabp3 concentration were evaluated and compared with histologic assessments and clinical pathology parameters. Those doses producing histologic muscle lesions had corresponding serological Fabp3 concentrations up to 70 times control values. Specifically, nine compound treatments that produced skeletal muscle necrosis in rats at an incidence of 80-100% had Fabp3 concentrations increased 7.5 to 70 times control (mean = 32.2x). Ten compound treatments that produced skeletal muscle necrosis at an incidence of 33-66% had Fabp3 concentrations increased up to 17.3 times control (mean = 6.7x). The correlations between histologic muscle lesions and serological Fabp3 concentrations suggested that Fabp3 is a sensitive and predictive biomarker of cardiac and skeletal muscle injury in the rat in pre-clinical safety studies.

385 EFFECTS OF CALCIUM CYCLING ALTERATION ON THE GENESIS OF TORSADES DE POINTES IN MYOCARDIAL FAILING RABBIT HEART.

A. Kijawornrat¹, B. M. Roche³, R. Hamlin¹, M. T. Ziolo², Y. Nishijima³ and J. L. Lolly³. ¹*Department of Veterinary Biosciences, The Ohio State University, Columbus, OH.* ²*Department of Physiology and Cell Biology, The Ohio State University, Columbus, OH* and ³*QTest Labs, LLC, Columbus, OH.* Sponsor: M. Hejtmancik.

QT interval prolongation may be antiarrhythmic, but also may be associated with increased risk of arrhythmias, in particular torsades de pointes (TdP). Early afterdepolarizations (EADs) and transmural dispersion of repolarization have been known to serve as a physiological substrate and predictor for TdP. It is thought that abnormal calcium cycling is the proximate cause of EADs, and it is known that calcium cycling is abnormal in heart failure. However, the mechanisms for drug-induced TdP in heart failure are not well understood. The purpose of this study was to search for torsadogenic-modifying effects of verapamil, ryanodine and KB-R7943 on ventricular premature depolarizations (VPD) and TdP in the conscious failing rabbit heart, a model known to be prone to develop TdP. Failing rabbit hearts were pretreated with propranolol followed by test articles before continuous infusion of dofetilide, used to induce TdP. In the vehicle control hearts, VPD and TdP were induced in all rabbits (8 of 8) and the onset of VPD and TdP were 3.6 ± 1.3 min and 10.3 ± 1.4 min, respectively. Intravenous infusion of dofetilide was associated with lengthening of RR, QT and QTc interval. Verapamil and ryanodine significantly delayed onset of VPD ($p < 0.05$) and suppressed occurrence of TdP ($p < 0.01$). On the other hand, KB-R7943 accelerated onset of TdP. Blockade of L-type calcium channel and blockade of calcium release channel of the sarcoplasmic reticulum prevent dofetilide-induced TdP, suggesting roles of intracellular calcium overload in drug-induced TdP. Also, our data indicates that blockade of sodium/calcium ex-

change (NCX) may favor the development of TdP in the setting of heart failure, and suggests potential new avenues for development of antiarrhythmics in the presence of heart failure.

386 PHYSIOLOGICALLY-MOTIVATED PHARMACOKINETIC MODELING OF SATURABLE, RENAL RESORPTION OF PERFLUOROALKYLACIDS IN MONKEYS AND RATS.

Y. Tan¹, H. Clewell¹, J. Butenhoff², G. Olsen² and M. Andersen¹. ¹Center for Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC and ²Medical Department, 3M Company, St. Paul, MN.

Perfluorooctanoate (PFOA) and perfluorooctanesulfonate (PFOS) are xenobiotic amphiphilic surfactants that are present in human blood, likely from the wide variety of commercial and product applications that they have been used in or can be derived from. Both are unreactive, essentially unmetabolized, distributed primarily in extracellular space, and largely protein bound in serum; however, both have elimination half-lives in human serum of several years. The combined properties of biopersistence, potential bioaccumulation, and evidence of toxicity have resulted in international scientific and regulatory attention. Human elimination rates are much lower than those determined in monkeys and rodents. Previous pharmacokinetic (PK) analyses and risk characterizations for these compounds have been performed using a one-compartment model; however, PFOA and PFOS in the monkey have kinetic behaviors that are not consistent with a single-compartment model. We developed a physiologically-motivated pharmacokinetic (PK) model for PFOA and PFOS was developed to evaluate quantitative evidence for a role of renal resorption in controlling persistence (*Toxicol* 227, 156-64, 2006). Here we extend this model by adding time-dependent changes in distribution in monkeys and in rats that appear to be due to pharmacodynamic properties of these compounds. Observed changes in kinetics appear to be associated with altered distribution within the body, coupled with reductions in elimination clearance on single doses. Higher, repeated dosing leads to saturation of resorption and more rapid excretion. The physiological basis of this model makes it feasible to develop a human model that can be used to estimate the exposures associated with blood levels of PFOA and PFOS measured in a population, as well as to evaluate the potential role of variability in renal function on potential individual susceptibility.

387 BAYESIAN ANALYSIS OF PARAMETERS FOR PHARMACOKINETIC MODELS.

J. F. Wambaugh, W. Setzer and H. A. Barton. *National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.*

Bayesian statistical approaches are increasingly being used to estimate the distributions of parameters for physiologically-based pharmacokinetic (PBPK) models. These models introduce many parameters for which there is often little, if any, knowledge. Bayesian analysis estimates all parameters simultaneously using data sets of various types along with any prior parameter estimates. When we assume that the kinetic parameters for individuals are drawn from the same probability distributions, we may both estimate the population distributions (by estimating their parameters) and use information about the population to refine the individual estimates. This hierarchical approach to the statistics also allows us to distinguish between error and biological variability. We examine the results of a series of experiments [Kemper (2003), DuPont-7473, USEPA AR-226.1499] observing the concentration of perfluorooctanoic acid (PFOA) in adult rats. We jointly analyzed time-courses for plasma concentration in some experiments and fecal and urinary elimination in others to estimate the distributions of PK parameters for PFOA in the overall population of rats. In some subjects, plasma concentration declines in two distinct phases, indicating the need for multi-compartmental analysis. We analyzed one- and two-compartment models with separate urinary and fecal clearances and determined the information gained with the two-compartment model. For example, in male rats using plasma data alone we can only estimate a mean total clearance of 0.7 mL/kg/h. The inclusion of elimination data allowed by our hierarchical analysis found that the mean urinary and fecal clearances could be estimated as 0.65 and 0.08 mL/kg/h respectively. Though we observed large biological variability, the estimated errors are relatively small. By simultaneously using both the plasma and elimination data, we obtained a more complete characterization of the distribution of model parameters. This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy.

388 PHARMACOKINETIC/PHARMACODYNAMIC MODELING OF PERMETHRIN IN THE RAT.

R. Tornero-Velez¹, E. J. Scollon², J. Starr³, M. E. Hughes², M. J. DeVito² and C. C. Dary¹. ¹NERL, U.S. EPA, Las Vegas, NV, ²NHEERL, U.S. EPA, Research Triangle Park, NC and ³NERL, U.S. EPA, Research Triangle Park, NC.

Pyrethroid insecticides typically represent complex mixtures of isomers, both diastereomeric and enantiomeric in form, some more potent than others in eliciting their neurotoxic effects. Isomer potency is thought to be a function of intrinsic ac-

tivity at the target site as well as susceptibility to detoxication through biotransformation. For example, trans-permethrin is hydrolyzed in vitro approximately 20 times faster by mouse liver microsomal esterases than cis-permethrin. Consequently, it is unclear whether pharmacokinetic models used to predict target tissue dose following exposure must account for the individual isomers to reasonably predict response. A coupled pharmacokinetic/pharmacodynamic (PK/PD) model was used to characterize potential bias in predicted response. A physiologically-based pharmacokinetic (PBPK) model was used to describe the pharmacokinetics of permethrin and calibrated using experimental data on concentration time-course of cis- and trans-permethrin in rat blood and brain tissues following oral administration. A pharmacodynamic model was proposed based on a Hill equation representation of the fractional population of modified sodium channels. Dissociation constants were varied to simulate varying potency. The PK/PD model was employed to test three scenarios: (i) accounting for the isomers individually; (ii) lumping of the isomers as one; (iii) considering only the 'active' form of the isomers. Initial modeling results suggest that both diastereoisomers, cis- and trans-permethrin, must be accounted for individually to accurately predict response. (Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.)

389 A QUANTITATIVE STRUCTURE-ACTIVITY-BASED PREDICTION OF ACUTE INHALATION TOXICITY FOR NON-REACTIVE VOLATILE ORGANIC COMPOUNDS (VOCs).

E. P. Petkova¹, G. D. Veith² and K. B. Wallace¹. ¹Department of Biochemistry and Molecular Biology, University of Minnesota, Medical School, Duluth, MN and ²International QSAR Foundation, Two Harbors, MN.

A large majority of the chemicals used in occupational settings are volatile non-reactive compounds for which inhalation concerns mandate an assessment of respiratory toxicity. Unfortunately, comprehensive toxicity testing is not available for all chemicals and convenient, accurate screens are needed. Attempts to develop reliable quantitative structure-activity relationship (QSAR) models for inhalation toxicity that are suitable both within and across species have been largely unsuccessful due to a large variability in the quality of test data and an integrated thermodynamic approach. The objective of this project was to compile a high quality toxicity database from which we can develop QSAR-based models for predicting inhalation toxicity. A comprehensive rodent inhalation toxicity database was developed that includes entries for over 150 chemicals, each of which conform with a stringent standard for quality assurance. From this, a correlation was established wherein the acute toxicity of non-reactive VOCs can be predicted with an accuracy comparable to the reproducibility of the testing methods. In conclusion, it is possible, based on QSAR principles, to accurately estimate the acute toxicity of non-reactive chemicals based strictly on thermodynamic principles that govern dosing metrics. For reactive chemicals, the derived value represents a baseline of minimum toxicity from which points of departure can be identified and further explored. The success of the model demonstrates the potential for deriving rapid, inexpensive and biologically-derived in silico screens for estimating inhalation toxicity for incompletely characterized chemicals.

390 DEVELOPMENT OF QUANTITATIVE STRUCTURE ACTIVITY RELATIONSHIP (QSAR) MODELS TO PREDICT CARCINOGENIC POTENCY OF CHEMICALS.

R. Venkatapathy^{1,2}, R. Bruce² and C. Moudgal³. ¹Pegasus Technical Services, Cincinnati, OH, ²NCEA, U.S. EPA, Cincinnati, OH and ³NHSRC, U.S. EPA, Cincinnati, OH. Sponsor: H. Choudhury.

Two important disadvantages of long-term animal bioassays are that testing involves substantial amounts of time and money, and that high doses are usually used in the testing process. These disadvantages can be circumvented using QSARs. Most carcinogenicity QSAR models relate the carcinogenic potency to measures of carcinogenicity such as mutagenicity, lethal dose (LD50) or the MTD. In one such QSAR, Krewski et al. demonstrated a good correlation ($r = 0.952$, $N = 191$) between tumor dose (TD50) and the MTD. The objective of this study was to predict the carcinogenic potency of a wide variety of chemicals. Initially, this study aimed to duplicate the results of Krewski et al. (1989) using TD50 data published in the Carcinogenic Potency Data Base (CPDB). The MTDs, LD50s and LOAELs of 467 chemicals from the CPDB were estimated using TOPKAT, a QSAR software for toxicity prediction. The correlation between TD50 and MTD for the 467 CPDB chemicals ($N = 467$, $r = 0.538$) was poor compared to the result from the study by Krewski et al. (1989). This study also developed QSAR models using both TD50 and oral slope factor (from USEPA's IRIS database; 95% upper bound on the dose-response slope) as measures of carcinogenic potency. The lowest energy conformers of the chemicals were obtained using CAChe software. Four descriptor-generating programs were used to generate the descriptors for the QSAR model: Dragon,

Molconn-Z, CAChe and CODESSA. Results of this research indicate that sex, species, and mechanism-specific QSARs have a greater predictive ability than generic QSARs that considered all chemicals irrespective of sex, species or mechanism of action. In addition, while the QSARs developed in this study may predict the carcinogenic potency of a wide variety of chemicals, they may not be able to differentiate between carcinogens and non-carcinogens. Hence, separate discriminative QSAR models may need to be developed to differentiate carcinogens from non-carcinogens.

391 A GENERALIZED CONCENTRATION ADDITION MODEL PREDICTS JOINT EFFECTS OF TCDD AND PARTIAL-AGONIST PCBs.

G. J. Howard, J. J. Schlezinger and T. F. Webster. *Department of Environmental Health, Boston University School of Public Health, Boston, MA.*

The Toxic Equivalency Factor (TEF) method used to assess the joint effects of mixtures of dioxin-like chemicals is a special case of the method of concentration addition. However, the TEF method implicitly assumes that the individual agents are full agonists with parallel dose-response curves that differ only by potency. We have derived a generalization of concentration addition (GCA), intended to more accurately describe interactions of combinations of full and partial agonists, and which is supported by kinetic models of simple receptor systems.

The GCA and TEF models were compared to AhR-dependent expression of EGFP by binary combination doses of TCDD and each of two mono-ortho partial agonist PCBs (2,3,3',4,4'-pentachlorobiphenyl, PCB105, and 2,3',4,4',5-pentachlorobiphenyl, PCB118) in the H1G1.1c3 (mouse hepatoma) cell line. The GCA model performed better than TEF at predicting the observed data. Each assay showed a reduced effect at the highest-dose combinations; this reduction is not predicted by the TEF method, but in the GCA model can be seen as the result of competition by the partial agonist for free receptors. While the TEF method overpredicts combination effects at the highest combination doses, it may also underpredict the joint effects of lower (more environmentally relevant) doses, depending on the specific TEF values chosen.

392 QUANTITATIVE MODELING OF THE EFFECTS OF MEMBRANE FLUIDITY ON THE ONSET OF TYPE-2 DIABETES.

P. J. Robinson, E. A. Merrill and I. Hauge. *HEPB, Air Force Research Laboratory, Dayton, OH.*

Type-2 diabetes represents one of the highest health care costs based on VA data. Multiple mechanisms leading to this disease have been identified, such as insufficient insulin sensitivity, genetic factors, and oxidative stress from environmental insults. Interventions need to be focused for uncovering specific mechanisms of disease onset and progression. Our working hypothesis is that decoupling between insulin levels and glucose uptake into cells (insulin resistance) is largely the result of reductions in cell membrane fluidity leading to reductions in glucose transporter capacity. Further, that such changes are the result of changes in the fatty-acid (FA) composition of the membrane phospholipids, e.g. as a result of diet and/or oxidative stress and other toxicological processes. Experimental support of this hypothesis includes Read and McElhaney (1975), who demonstrated that uptake of *n*-glucose by the bacterium *A. laidlawii* is dependent on the FA and cholesterol content of the plasma membrane and exhibits a direct dependence on the fluidity of the membrane lipids. Our analysis of their glucose uptake shows that V_{max}/K_m is reduced by a factor of ~4X due to the experimentally induced changes in membrane fluidity. More recent work by Napoli et al. (1995) shows changes in V_{max} in skeletal muscle of streptozotocin diabetic rats decreases about 6X from a baseline of 7.5 to a value of 1.2 nmol/(mg-sec) as diabetes is induced over 10 days. Thus, changes in membrane fluidity are capable of producing the magnitude of change in glucose transport V_{max} observed in an animal model of diabetes. These quantitative relationships can be exploited to develop a biologically-based pharmacokinetic/dynamic (BBPK/PD) model for the disposition of glucose and insulin. The specific benefits of a mechanistic understanding of the processes underlying diabetes incidence include: early identification of insulin resistance, identification of susceptible individuals and potential environmental stressors, identification of potential biomarkers, and development and screening of more effective and/or novel treatments.

393 INTEGRATION OF TOXICOKINETICS AND TOXICODYNAMICS BY MECHANISM-BASED MATHEMATICAL MODELING.

S. Lee, W. Geng and T. D. Steele. *Nonclinical Drug Safety, Hoffmann-LaRoche, Nutley, NJ.*

A mechanism-based mathematical modeling approach was applied to integrate and analyze data from safety studies in rats of an experimental drug for use in diabetes. Based on the postulated mechanism that the pathological finding (i.e., sciatic nerve

degeneration) was associated with glucose-lowering effects of the test article, the model was designed to explore this relationship using toxicokinetic and toxicodynamic data. The toxicokinetic process was depicted by a physiologically-based toxicokinetic model, which also considered reversible hepatic biotransformation between the parent and its major metabolite. A mathematical toxicodynamic model was constructed to mimic the glucose-lowering effect in the plasma compartment, which considered glucose production, elimination and positive and negative feedback mechanisms that are responsible for maintaining euglycemia. In the toxicodynamic model, the extent and duration of glucose-lowering in the treated animals were described as reductions in the glucose AUC as compared to the control animals. The degree of sciatic nerve degeneration was translated into numerical data for each dose level using both the individual incidence and the severity of the findings. A sigmoidal Emax model was used to describe the relationship between reductions in glucose AUC and sciatic nerve degeneration. Simulation outputs showed good agreement with the experimental findings. The modeling efforts demonstrated a clear relationship between glucose-lowering effects and sciatic nerve degeneration. This approach suggests that mechanism-based mathematical modeling could be a useful tool for integration of experimental findings and for quantitative safety assessment in preclinical drug development.

394 BBPK MODEL OF THE HYPOTHALAMIC-PITUITARY-THYROID AXIS IN ADULT MALE RATS.

E. D. McLanahan¹, M. E. Andersen², M. Mumtaz³ and J. W. Fisher¹.

¹Interdisciplinary Toxicology Program, University of Georgia, Athens, GA, ²Division of Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC and ³Division of Toxicology and Environmental Medicine, ATSDR, Atlanta, GA.

Some environmental chemicals affect endocrine function and may alter hormone systems at low doses. The hypothalamic-pituitary-thyroid (HPT) axis controls many physiologic functions, including metabolism, development, and reproduction. Here we present the approach for development of the biologically-based pharmacokinetic model (BBPK) euthyroid HPT axis model, its features, and model simulations. The model for the adult male rat includes sub-models for dietary iodide, thyroid stimulating hormone (TSH), as well as thyroid hormones, thyroxine (T4) and 3,5,3'-triiodothyronine (T3). First, the individual sub-models were developed independently of one another using radiolabeled tracer studies to estimate various model parameters. Then, the models were combined to form one endogenous model that includes (1) feedback of T4 on TSH production, (2) stimulation of T4/T3 production and thyroidal iodide uptake by TSH, and (3) the use of available thyroidal iodide in hormone production. Further model development will include linking the HPT axis model with BBPK models for thyroid active chemicals to predict HPT axis disturbances based on the primary mode of action of the chemicals. Key model features have already been built into the HPT axis model to facilitate this linkage. Hepatic UDPGT conjugation of T4 in the liver was described because HPT axis disturbances may result from an increase T4-glucuronide formation. Active uptake of iodide into the thyroid at the sodium/iodide symporter was included because environmental chemicals may inhibit thyroidal iodide uptake, decreasing the amount of iodide available for hormone production. This mechanistically formulated HPT axis model integrates a variety of physiologic processes that will be used predict complex, non-linear dose responses resulting from exposure to thyroid toxic chemicals, alone and in combination. Funded by ATSDR #U61/ATU472105 and EPA STAR Fellowship #FP916793.

395 DEVELOPMENT OF BBPK RADIOLABELED SUB-MODELS FOR THE HPT AXIS IN PND 14 SD RAT PUPS.

L. Myers¹, E. D. McLanahan¹, J. W. Fisher¹ and M. Andersen². ¹Environmental Health Science, University of Georgia, Athens, GA and ²Division of Computational Biology, CIIT, Centers for Health Research, Research Triangle Park, NC.

To assess the developmental neurotoxicity of chemicals that act by disruption of the HPT axis, we are developing a BBPK model for the PND 14 SD rat pup. This model includes integration of feedback mechanisms among thyroxine (T4), triiodothyronine (T3), and thyroid-stimulating hormone (TSH). Growth equations will expand the model to all developmental stages. To begin the model, submodels for iodide, T4 and T3 were created using radiolabeled kinetic data for each material. These models establish kinetic parameters such as metabolic rate constants and distribution behavior. The submodel for iodide included flow-limited compartments for plasma and liver and diffusion-limited compartments for thyroid and GI tract. Active uptake via the sodium-iodide symporter was accounted for in the thyroid and GI tract. The model predictions compared well with experimental data for radiolabeled iodide in the thyroid, GI tract, and plasma. Both the T4 and T3 models include a flow-limited volume of distribution compartment and diffusion-limited brain (cortex) and liver compartments. Active transport and metabolism via glucuronidation and Michaelis-Menton (MM) Type 1 5' deiodination was accounted for in the T4 model liver. 1st order clearance of T4 from the brain was in-

cluded. In the T3 model, active transport and 1st order clearance were included in the liver and MM Type III 5' deiodination was included in the brain. The BBPK model predictions compared well with experimental radiolabeled brain, liver, and plasma data. A submodel for TSH was created to establish kinetic parameters to describe the feedback relationships between serum concentrations of both TSH and T4. The BBPK model predictions were compared to endogenous TSH and T4 data. Pup submodel parameterization allows comparison with kinetic behavior of the axis in adults. Future efforts includes integration of submodels to create an HPT axis BBPK model with homeostatic feedback processes and chemical induced disruptions.(USEPA RD832134)

396 CRITICAL CELL-CYCLE-EVENTS IN CANCER DEVELOPMENT.

A. O. Chiu¹, ¹NCEA, U.S. EPA, Washington DC, DC, ²OST OW, U.S. EPA, Washington, DC and ³OPPTS, U.S. EPA, Washington, DC.

Cancer can result from interactions between genetic elements and genotoxic agents in the ambient environment. Population density of animal populations, and especially human populations, is affected by age specific cancer mortality rates. Decrease in latency from initiation to frank tumor correlates with a decrease in the number of cell-cycle steps or a reduction in control by targeted tumor suppressor genes independently and in combination with expressed macromolecular p53, p27, H2AX, Blm, etc. We have systemically examined the decrease in steps to cancer development based on estimates from survival analysis and Weibull's model of the combinations of these targeted antioncogene-knockout mice. Thus, the multistage and multistep carcinogenic process at the organismic level finds its counterpart at the cellular level. The cause-and-effect relationship between cancer development and the loss of these genetic functions can be explicitly shown in p53-MDM2 demonstrating escape from apoptosis- senescence as the initiation-transformation-immortality process of cancer development. The importance of these initiating events is confirmed by further mathematical modeling with targeted knockouts in Rb-p107-p130, and Arf-myc-p53.

397 COMPUTATIONAL MODELING OF NRF2-MEDIATED OXIDATIVE/ELECTROPHILIC STRESS RESPONSE.

Q. Zhang, J. Pi and M. E. Andersen. CIIT Centers for Health Research, Research Triangle Park, NC.

To limit excessive accumulation of reactive oxygen species (ROS) and electrophiles, mammalian cells have a transcription factor Nrf2-mediated gene regulatory network, which is activated in the face of oxidative and electrophilic stressors. In this study, we analyzed the antioxidant gene regulatory network from an engineer's perspective. We decomposed the network into transducer, controller, and plant, which are functional units often seen in a classical negative control system. We then formulated a computational model to study the systems behavior of oxidative/electrophilic stress responses. This model reproduced the response profile of a variety of intracellular species including ROS, electrophiles, Nrf2, GSH, GSSG, and antioxidant/phase II enzymes (e.g. GCL, GPx, GST, etc.), in both normal and impaired conditions such as GSH depletion. The model predicted that prior exposure to small-doses of oxidative stressors would protect cells from damage by a subsequent large-dose exposure. These predictions were confirmed experimentally using hypochlorous acid as the oxidant stressor in RAW 264.7 macrophages. For species such as hydrogen peroxide and lipid peroxide, which are removed by reactions converting GSH into GSSG, detoxification is limited by glutathione reductase and the pentose pathway supplying NADPH. In contrast, for electrophiles which are primarily removed by conjugating with GSH either enzymatically or non-enzymatically, the ability of *de novo* GSH synthesis is the limiting factor. Model simulations indicate that the steady-state dose response between intracellular electrophiles and stressors is likely to follow a superlinear-to-sublinear transition as the dose increases. This study represents one of the first efforts to understand cellular control systems related to a key oxidative stress pathway in a quantitative manner and to use the control module to understand expected dose-response relationships.

398 A HYBRID CFD-PBPK MODEL OF CHLORINE GAS UPTAKE AND TISSUE DOSIMETRY IN THE UPPER RESPIRATORY TRACT (URT) OF F344 RATS.

A. M. Jarabek¹, J. D. Schroeter², M. E. Andersen² and J. S. Kimbell². ¹NHEERL ETD, U.S. EPA, Research Triangle Park, NC and ²CIIT CHR, Research Triangle Park, NC.

Chlorine (Cl₂) is very reactive in water and an irritant. Nasal extraction of Cl₂ is high and resultant lesions in the respiratory tract show a proximal to distal distribution indicating that airflow and exposure concentration play a key role in patho-

genesis. Our hypothesis for the mode of action (MOA) for Cl₂ is that its irritant effects are caused by oxidative stress mediated by hypochlorous acid (HOCl). HOCl would be formed in epithelial tissues by hydrolysis of Cl₂, and to a lesser extent, by downstream biological responses including inflammation. To describe tissue dose metrics associated with different endpoints of this proposed MOA for use in dose response analysis, a recent computational fluid dynamics-physiologically based pharmacokinetic (CFD-PBPK) model of inhaled hydrogen sulfide (Schroeter et al., Toxicol. Sci., 2006, 90(1), 198) was modified to address experimental dosimetry data on Cl₂. These data included gas uptake of Cl₂ delivered unidirectionally at 3 different flow rates and concentrations, measured in situ in the isolated URT of both sexes of F344 rats; and tissue chlorotyrosines (Cl-Tyr; 3-chloro- and 3,5-dichlorotyrosine) in samples obtained from 4 different regions representing respiratory and olfactory tissues in both the septal and lateral airstreams. Cl-Tyr were used as an internal dosimeter. The CFD mesh was segmented to provide estimates of Cl₂ flux in each of the 4 regions. The PBPK model of the tissue in each region describes rates for Cl₂ hydrolysis, reaction of HOCl with proteins, and scavenging of reactive species by soluble anti-oxidants, including glutathione, obtained by both evaluation of the literature and fitting to dosimetry data. This model can be used to estimate flux to the URT, and tissue HOCl or Cl-Tyr as improved dose metrics for risk assessment. Correlation of these dose metrics with lesion incidence and location will provide insights on their utility in characterizing oxidative stress as the MOA for inhaled Cl₂ in the respiratory tract. (This abstract does not reflect Agency policy.)

399 INTER-SPECIES EXTRAPOLATION OF HYDROGEN SULFIDE NASAL DOSIMETRY USING PHARMACOKINETIC-DRIVEN COMPUTATIONAL FLUID DYNAMICS MODELS.

J. D. Schroeter, J. S. Kimbell, M. E. Andersen and D. C. Dorman. CIIT Centers for Health Research, Research Triangle Park, NC.

Human exposure to hydrogen sulfide (H₂S) gas results in cardiovascular, neurological, and respiratory effects that increase in severity with increased exposure level. Animal studies show that the olfactory epithelium is especially sensitive to H₂S inhalation. Subchronic exposure of rats to 30 or 80 ppm H₂S results in olfactory neuron loss and basal cell hyperplasia (with a No-Observed-Adverse-Effect-Level (NOAEL) of 10 ppm). These lesions commonly border main airflow streams, indicating that differential epithelial tissue responses likely result from increased tissue dose. Anatomically accurate computational fluid dynamics (CFD) models of the rat and human nasal passages were developed to predict H₂S tissue dose in the olfactory regions. Air-tissue flux was defined in terms of H₂S solubility, diffusivity, and reaction kinetics in nasal tissue. Kinetic parameters for the rat were estimated from an air-tissue pharmacokinetic model that was fit to experimental nasal extraction data. Using this pharmacokinetic-coupled CFD model, there was a close correlation of predicted air-tissue flux with lesion incidence within olfactory epithelium. Kinetic parameters were allometrically scaled from rats to humans to predict olfactory tissue dose with the human nasal CFD model. Assuming that equivalent H₂S flux values induce similar tissue responses in rats and humans, a NOAEL Human-Equivalent-Concentration was estimated to be 5 ppm. This estimate was based on quantitative interspecies extrapolation of olfactory tissue dose estimates from the CFD models and is approximately 10-fold higher than the current estimate used by the U.S. EPA that relied on default dosimetric assumptions.

400 ESTIMATION OF GAS-PHASE MASS TRANSFER COEFFICIENTS FOR DOSIMETRY CALCULATIONS IN THE RAT NASAL PASSAGES.

J. S. Kimbell¹, J. D. Schroeter¹, D. L. Kalisak¹ and P. M. Schlosser². ¹CIIT Centers for Health Research, Research Triangle Park, NC and ²NCEA, U.S. Environmental Protection Agency, Washington, DC.

Dosimetry of inhaled gases in the upper respiratory tract depends on nasal geometry and airflow patterns. Recently, hybrid computational fluid dynamics-physiologically based pharmacokinetic (CFD-PBPK) models were developed to estimate nasal tissue dose and systemic transport of inhaled chemicals. In this approach, a CFD model of the rat nose was used to compute gas-phase mass transfer coefficients (MTCs) for implementation in a PBPK model. Specifically, a model developed by Frederick et al. (Toxicol. Appl. Pharmacol. 152:211-231, 1998) divided the rat nose into compartments based on airflow patterns and epithelial type. MTCs were estimated for each compartment. However, the CFD model used in that study contained only the anterior rat nose so some MTCs had to be estimated by other means. In this study, a CFD model of the entire rat nose was used to estimate localized MTCs using a zonal approach (Jarabek et al., Toxicol. Sci. 60(1-S):150, 2001). Airflow simulations were conducted at inhalation flow rates of 100, 300, and 500 ml/min with FIDAP (Fluent, Inc.). The rat nasal passages were partitioned into 16 zones separated by coronal cross-sections including the compartment boundaries defined by Frederick et al. (1998). Gas uptake simulations were

conducted in which anterior zones were progressively made non-absorbing, with all distal regions being completely absorbing. Localized MTCs were then calculated in each zone and used to compute compartmental MTCs. This approach avoids the problem of high extraction efficiency in the rat nose as a whole under maximal uptake conditions, and estimates the filtering efficiency of different regions of the nose. These updated MTCs can be implemented in future CFD-PBPK models for improved dosimetry estimates of inhaled gases. This research was funded by the U.S. EPA (Req. No. 06262W5E48). The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency.

401 EXPERIMENTAL AND COMPUTATIONAL APPROACHES TO EVALUATE RESPIRATORY TRACT UPTAKE AND DOSIMETRY OF HEXAMETHYLENE DIISOCYANATE IN RATS.

B. Asgharian, J. D. Schroeter, J. S. Kimbell and M. E. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Hexamethylene diisocyanate (HDI) is a reactive chemical used in the commercial production of polyurethanes. Human exposure to HDI may initiate occupational asthma. Toxic effects in animals exposed to HDI vapor include respiratory tract irritation and degeneration of olfactory epithelium. Olfactory degeneration was observed at 0.025 ppm HDI in a chronic two-year inhalation study, and pathological changes were seen in the alveolar airways at higher exposure concentrations. These observations suggest that inhaled HDI results in dose dependent effects that permeate throughout the respiratory tract. In this study, a dosimetry model was developed to predict HDI tissue dose in the rat respiratory tract. The model consisted of an anatomically accurate computational fluid dynamics (CFD) model of the rat nasal passages that was linked to a lung dosimetry model. Airflow and HDI transport in the nasal passages were simulated using the finite element software FIDAP (Fluent, Inc.). Transport of HDI through lung airways was simulated by convection and axial dispersion and was implemented in MATLAB (Mathworks, Inc.). The nasal and lung components of the dosimetry model included tissue phases where elimination of HDI was governed by diffusion and first-order clearance. HDI nasal extraction was experimentally measured in the surgically isolated upper respiratory tract of anesthetized F344 rats. The CFD model was used to fit a first-order clearance term to the nasal extraction data that was subsequently used throughout the respiratory tract lining. Tissue dose was predicted in the nasal passages and in all generations of the lung. The simulations predicted that the upper respiratory tract and upper bronchial airways received the highest tissue dose, yet there was still penetration of HDI vapor to the pulmonary airways. These results allow more accurate estimation of the relationship of tissue dose with adverse responses from a chronic HDI inhalation study in rats and can be scaled to human inhalation.

402 COMPUTATIONAL FLUID DYNAMICS PREDICTIONS OF HYPER-POLARIZED HELIUM FLOWS.

A. P. Kuprat, D. R. Einstein, K. R. Minard, J. E. Richard, C. Timchalk and R. A. Corley. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Seattle, WA.*

Computational fluid dynamic (CFD) simulations of respiratory airflow provide a quantitative basis for optimizing inhaled drug delivery, understanding the risks posed by airborne pollutants, and predicting human health effects. However, to have confidence in the model it must be validated against experimental data. We have previously demonstrated the feasibility of validating CFD predictions with magnetic resonance (MR) imaging of hyperpolarized (HP) ^3He . However, the direct comparison between measured and predicted flows with HP remains challenging, due to the high degree of helium self-diffusion which blurs the predicted velocities. The forward problem of applying a probabilistic blurring to predicted data is possible and accurate but remains computationally expensive even in simple geometries. In the current study, the forward problem is efficiently and accurately solved on arbitrary geometries. The approach is based on physical arguments which show each component of the velocity field is blurred independently via convolution with a diffusion propagator which obeys the diffusion equation and whose solutions can be linearly superposed; thus each component of the blurred velocity field can be solved for independently and simultaneously over the whole domain. To illustrate the approach, comparisons were made between measured and predicted flows in a phantom. Two dimensional maps of HP gas flow at select imaging planes were created using two phase-sensitive images acquired with different bipolar gradient strengths. The phantom geometry was derived from separate ^1H MR images. The steady-state Navier-Stokes equations were solved with a commercial finite-volume solver (Star-CD). Each solution was then evolved with a custom solver to account for statistical blurring over the acquisition window. Results showed good correlation between measured and predicted flows. Larger airways showed a greater level of detail in the velocity profile than smaller airways in keeping with theoretical considerations. Funded by NHLBI RO1 HL073598-01.

403 PARTICLE DEPOSITION IN AN IMAGING-BASED GEOMETRY OF THE SPRAGUE-DAWLEY RAT.

D. R. Einstein, M. C. Richmond, W. A. Perkins, A. P. Kuprat, K. R. Minard, R. E. Jacob, C. A. Timchalk and R. A. Corley. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Seattle, WA.*

Many investigators have modeled the physics of particles in order to investigate potential interactions between respiratory diseases and environmental challenges. Most of these early simulations were based on idealized geometries and the approach to particle deposition was likewise idealized. However, the details of 3D geometries are strong determinants of micro-dosimetry, particularly in upper airways. In this study, laminar vs. turbulent flow assumptions were compared with fine and ultra-fine particle deposition in an imaging-based rat lung. Cast imaging was performed using an Avance MRI spectrometer and a 11.7-Tesla magnet. Airway geometry was extracted as an isosurface and subjected to volume-conserving smoothing. A paved, boundary-fitted CFD-compatible tetrahedral mesh was generated directly from the isosurface with a novel scale-invariant meshing algorithm (LaGriT-PNNL) that creates cells orthogonal to the boundary. A transient inhalation/exhalation case was simulated using a commercial finite-volume solver (Star-CD). The inlet pressure was prescribed from plethysmograph data; outlet pressures were prescribed 0.0 kPa. Turbulent simulations were performed with the Reynolds averaged k- ω model. Particles were assumed to have one-way interaction with the pulmonary flow. Particle trajectories and deposition patterns were predicted with the PNNL Lagrangian particle tracking code PT6. Turbulent influence on particle trajectories is based on the eddy-interaction model and accompanied by a near-wall correction. Results from a grid refinement study show our solution has acceptably small discretization error. Deposition efficiencies and patterns were a function of particle size, flow rates, and the addition of turbulence. Capabilities of the particle tracking code include the handling of particle dynamics in moving meshes, and we hope to extend our analysis to moving airways to better predict the in vivo data we are currently acquiring to validate these predictions. Funded by NHLBI RO1 HL073598-01.

404 ADVANCES IN CANCER RISK ASSESSMENT FOR INHALATION EXPOSURES TO ASBESTOS.

S. Foster¹, E. Hofmann¹, W. Brattin² and T. Barry¹. ¹*U.S. EPA, Washington, DC* and ²*Syracuse Research Corporation, Denver, CO.*

Efforts are underway to develop a new approach to assessing cancer risk associated with inhalation exposures to asbestos at contaminated sites. The draft methodology is based on a meta-analysis of available epidemiological studies that provide quantitative exposure-response information on relative risk of lung cancer or incidence of mesothelioma. The influence of mineral type (amphibole or serpentine) and fiber dimensions are considered by "binning" fibers, and a number of different binning strategies are evaluated. An over-dispersed Poisson model is used to fit the predicted number of deaths to the observed number in each exposure group using maximum likelihood estimation (MLE), rather than fitting individual studies. Probability distribution functions are used to address uncertainty in the data, including cumulative exposure, disease, and estimation of bin-specific concentration values. The output of the model includes uncertainty distributions for each bin-specific potency factor and for any specified mixture of asbestos bins.

405 MULTISCALE CARDIAC MODEL OF NANOPARTICLE DRIVEN ATHEROSCLEROSIS.

J. C. Carson, D. R. Einstein, A. P. Kuprat, K. R. Minard and C. Timchalk. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Seattle, WA.*

There is growing evidence that exposure to particulates may be involved in lesions of the coronary endothelium that lead to atherosclerosis. It is also well known that deleterious alterations in fluid shear stress and coronary transmural pressure perturb endothelial biochemistry and exacerbate the local inflammation at the root of plaque formation. We have initiated a program to develop a multiscale computational model of the heart to investigate the relationship among atherosclerosis, the presence of nanoparticles and the secondary perturbations of respiratory inflammation. The project aims to link cardiovascular function with respiratory function and biomechanics with biochemistry. A preliminary mouse heart geometry with cellular resolution was reconstructed from serial cryomicrotome images via serial nonlinear co-registration. In addition, a high-contrast, high resolution, whole mouse, contrast-infused magnetic resonance (MR), dataset was acquired. A detailed segmentation of both tissue and blood domains was performed with custom algorithms including fuzzy connectivity, and a network preserving algorithm for extracting the coronary vasculature. Work is currently underway to co-register the cryomicrotome data with the MR data. To create a computational mesh, tissue surfaces, blood surfaces and blood-tissue interface were extracted with a multi-material marching

cubes algorithm. This was followed by application of a novel scale-invariant, multi-material mesh-generation algorithm that produces a quality, nearly orthogonal paving of biological geometries based on the concept of local scale. Finally, we have developed efficient constitutive models for myocardium, papillary muscle, chordae tendinae, cardiac valve tissue and coronary artery. Much work remains to be done. However, we believe that a predictive computational model that links circulation to respiration can become an important tool for predicting regional deposition of ultrafine particulates and site selectivity of atherosclerotic plaque formation. 406 *IN VITRO* 2-METHOXYACETALDEHYDE ADDUCT FORMATION USED FOR PROTEOMIC-BASED GLYCOL ETHER BIOMARKER DEVELOPMENT WITH SURFACE ENHANCED LASER DESORPTION IONIZATION (SELDI) ANALYSIS.

K. L. Cheever. *Molecular and Genetic Monitoring, NIOSH, Cincinnati, OH.*

The protein adduct formation of 2-Methoxyacetaldehyde (MALD, CAS 10312-83-1) was tested as a potential biomarker of glycol ether exposure. MALD is a reactive intermediate in the metabolism of 2-methoxyethanol (2ME, CAS 109-86-4), a glycol ether known to produce reproductive effects in laboratory animals and is a potential carcinogen. Bioactivation of 2ME is reported to occur via oxidation by alcohol dehydrogenase to MALD and subsequent aldehyde dehydrogenase to methoxyacetic acid (MAA, CAS 625-45-6). Protein and DNA adducts have been reported for 2ME, and MALD has been suggested as the likely source of macromolecular adduct formation. In the current study MALD, along with 2ME and MAA were tested *in vitro* to evaluate adduct formation using human hemoglobin or albumin. Surface Enhanced Laser Desorption Ionization (SELDI) with Time of Flight mass spectrometry was used to detect adduct formation in 0.1 µg hemoglobin or albumin incubates. The study showed that the reactivity of MALD with albumin was several fold greater than for hemoglobin. The reaction of MALD with the alpha-globin chain was greater than that of the beta-globin portion of hemoglobin. After 3 hours the MALD-adduct levels for albumin > alpha-globin > beta-globin. The MALD adduct levels did not continue to increase further during the 24-hour test period, and no corresponding adduct formation was noted for 2ME or MAA. Tryptic digests of the proteins may be utilized for specific proteomic-based biomarkers of exposure to glycol ethers.

407 (2-METHOXYETHOXY)ACETIC ACID: A URINARY BIOMARKER OF EXPOSURE TO JP-8 JET FUEL.

M. A. Butler¹, C. B. B'Hymer¹, K. L. Cheever¹, E. Krieg¹, C. A. Toennis¹, J. C. Clark¹ and R. L. Gibson². ¹*Biomonitoring and Health Assessment Branch, National Institute for Occupational Safety and Health, Cincinnati, OH* and ²*Armed Forces Epidemiological Board, USAF, Falls Church, VA.*

(2-Methoxyethoxy)acetic acid (MEAA), the major urinary metabolite of the deicing agent 2-(2-methoxyethoxy)ethanol (diEGME) added to JP-8 jet fuel, was used to measure exposure to JP-8 in air force personnel at six airbases in the United States. JP-8 is a kerosene based fuel containing over 200 different compounds, including aliphatics, aromatics, benzene, and naphthalene, all of which vary in concentration depending upon the specific batch of JP-8. DiEGME is always present at 0.1 %. Post-shift urine specimens were obtained from personnel who performed fuel tank maintenance and their attendants (high category, n = 98), fuel handlers (moderate category, n = 38) and personnel with no direct JP-8 contact (low category, n = 61). Urine containing a deuterated (2-butoxy)acetic acid internal standard was extracted with ethyl acetate, followed by esterification to the ethyl ester. The ethyl ester was extracted with methylene chloride and concentrated. Quantitation was by a gas chromatograph equipped with a mass spectrometer. The mean urinary MEAA level was significantly greater in the high (6.9, SD = 15.5 µg/ml) category, as compared to the means of the moderate (0.4, SD = 0.9 µg/ml, p = 0.0024) and low (0.1, SD = 0.02 µg/ml, p = 0.0002) categories. The maximum concentrations of urinary MEAA were 110.0 µg/ml, 4.8 µg/ml, and 0.2 µg/ml and the percent of measurements below the limit of detection (0.1 µg/ml) were 6%, 67%, and 97% for the high, moderate, and low categories, respectively. This study demonstrated that urinary MEAA can be used as a biomarker of exposure to JP-8.

408 URINARY 2-BUTOXYACETIC ACID: DEVELOPMENT OF AN EFFECTIVE GAS CHROMATOGRAPHIC TEST METHOD FOR QUANTIFICATION.

C. B'Hymer and K. L. Cheever. *BHAB, NIOSH, Cincinnati, OH.*

A simple and effective general test method for 2-butoxyacetic acid (2-BAA) in urine samples was developed. 2-Butoxyacetic acid is a metabolite and biomarker for exposure to 2-butoxyethanol (2-BE), a glycol ether and is of concern because of the general toxicity of this class of compounds. Glycol ethers have been frequently reported to damage the male reproductive system, hematopoietic system, and fetal/embryonic development. Occupational exposure by these widely used glycol ethers is likely, since they are readily absorbed through the skin. Specifically, 2-BE is used as a component in paints, inks and common household cleaning products, and is of interest to this laboratory for exposed populations. For the use of this test on urine, specimens were first spiked with deuterated 2-BAA; the deuterated analog was used as a procedural internal standard. The samples were extracted with ethyl acetate, concentrated, and treated by acid catalyzed esterification to produce the corresponding ethyl esters of 2-BAA. Subsequently, the ethyl ester derivatives were extracted using methylene chloride and concentrated to produce the final solution for gas chromatographic analysis. A mass selective detector (MSD) using a 50-m X 0.20-mm (id) HP-1 capillary column and a temperature program of 60 to 150°C was used for the gas chromatographic measurement. Ion m/z 57 was monitored for the ethyl ester of 2-BAA and ion m/z 66 was monitored for the internal standard. A series of recovery studies using 1, 5, 10 and 20 µg/ml 2-BAA spiked urine samples demonstrated good accuracy and precision; recovery varied between 100-102% of theory. The limit of detection (LOD) was found to range from 0.005 to 0.015 µg/ml for this analysis method.

Disclaimers: Mention of company names and/or products does not constitute endorsement by the Centers for Disease Control and Prevention (CDC). The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy.

409 EXCRETION OF URINARY BIUREA IN WORKERS EXPOSED AZODICARBONAMIDE.

J. Lee¹, B. Choi¹, J. Shin¹, B. Kim² and J. Jeong². ¹*Center for Occupational Lung Diseases, WAMCO, Ansan, South Korea* and ²*Occupational Safety & Health Research Institute, KOSHA, Incheon, South Korea.* Sponsor: L. Yu.

Azodicarbonamide (ADCA), a causative agent of occupational asthma in plastics and rubber industry workers, is an organic low molecular weight agent used as a blowing agent in the manufacture of expanded foam plastics. ADCA is rapidly converted to biurea and that biurea is then eliminated rapidly from all tissues through urine. The urinary biurea has been used as biomarker of ADCA exposure, yet limited studies have been done. Accordingly, we measured airborne ADCA in workplace, urinary biurea, and total IgE in serum, and analyzed the relationship among indices. The study population contained 14 exposed and 14 non-exposed workers in a ADCA manufacturing plant. Urine samples were obtained at prior to shift (PS) and the end of shift (EOS) on the survey day and blood samples collected on the survey day. Analysis for biurea was achieved by oxidation of biurea to ADCA prior to derivation with triphenylphosphine. The derivative was extracted with dichloromethane, and then evaporated. The dried sample was reconstituted in acetonitrile, and quantified using HPLC. Total IgE in serum was analyzed via immunoassay. The mean of environmental ADCA was 1.553±1.930 TWA mg/m³, and 80 percent among the collected samples were higher than 1 mg/m³, recommend level of Health and Safety Executive. The mean of PS biurea, EOS biurea, and total IgE were 0.19±4.68 mg/g creatinine, 0.18±4.02 mg/g creatinine, and 163.78±4.09 IU/mL, respectively. There was significant correlation between the urinary EOS biurea and the airborne ADCA (r=0.733, p<0.05) and PS biurea (r=0.574, p<0.05) in the exposure group. From the results of simple regression analysis about the urinary concentration of EOS biurea and that of ADCA in the exposed group, coefficient of determination was 0.34 (p<0.05). There was significant correlation between the urinary EOS biurea and the airborne ADCA. The urinary biurea was an effective index as a biomarker of airborne ADCA in workplace, despite the limitation of sample size and variables.

410 GENOTOXIC EFFECTS IN WORKERS EXPOSED TO FUMES AND AEROSOLS OF BITUMEN (FAB).

B. Marczyński¹, K. Foerster², A. Spickenheuer¹, M. Raulf-Heimsoth¹, R. Bramer¹, D. Breuer³, J. Hahn³, B. Pesch¹, J. Angerer², H. U. Kaefferlein¹ and T. Bruening¹. ¹*BGFA, Ruhr-University, Bochum, Germany.* ²*Institute of Occupational Medicine, Friedrich Alexander University, Erlangen, Germany* and ³*BGIA, BG Institute of Occupational Safety, St. Augustin, Germany.*

Recently, DNA damage in form of increased strand break frequencies could be determined in white blood cells (WBC) of 66 workers exposed to FAB (Marczyński et al., *Cancer Epidemiol. Biomarker & Prev.* 15: 645; 2006). Meanwhile, 202 exposed

workers were studied using a cross-shift design. 1-hydroxypyrene (1-OHP) and the sum of 1-, 2-, 3-, 4- and 9-hydroxyphenanthrenes (OHPhe) in urine as well as 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-OHdG) and DNA strand breaks in WBC were analysed before and after the shift. Personal air sampling during shift was carried out to assess external exposure to FAB. 55 construction workers not exposed to FAB served as reference subjects. Compared to controls, exposed workers showed higher levels of 1-OHP and OHPhe after the shift. Significantly more 8-OHdG and DNA strand breaks were found before and after the shift in exposed workers. Concentrations of 8-OHdG increased ($P < 0.0001$), while DNA strand break frequencies decreased ($P < 0.05$) during shift in both, exposed and control individuals. Airborne concentrations of FAB correlated significantly with urinary concentrations of 1-OHP ($r = 0.25$, $P < 0.001$) and OHPhe ($r = 0.36$, $P < 0.001$) after the shift. In addition, 1-OHP in post-shift urine was weakly, but significantly associated with post-shift values of DNA strand breaks ($r = 0.19$, $P = 0.001$). However, no associations could be found between external exposure to FAB and genotoxic parameters as well as between OHPhe in post-shift urine and genotoxic parameters. Overall, the findings strengthen our previous results that at workplaces with exposure to FAB higher levels of DNA damage are observed. However, because of a weak association between 1-OHP and DNA strand breaks only and because of lacking associations between airborne FAB and genotoxic effects as well as between OHPhe and genotoxic effects the reasons for increased DNA damage in FAB exposed workers remains unclear.

411 PAH EXPOSURE AND BIOMARKERS IN HUMAN POPULATIONS.

R. A. Lingenfelter¹, L. Cizmas¹, Z. Naufal¹, C. Napinski¹, L. He¹, G. Zhou¹, T. McDonald¹, G. Denoux¹, R. Autenrieth¹, A. Mekhtiev², A. Islamzadeh³ and K. Donnelly¹. ¹Texas A&M University, College Station, TX, ²Institute of Physiology n.a. A.I. Karaev, Baku, Azerbaijan and ³Sumgayit Centre for Environmental Rehabilitation, Sumgayit, Azerbaijan.

Polycyclic aromatic hydrocarbons (PAH) are released from the incomplete combustion of organic materials such as gas, oil, and wood. PAH contamination occurs as complex mixtures that often contain over one hundred different chemicals. Humans may be exposed to polycyclic aromatic hydrocarbons (PAHs) in the environment from voluntary sources, such as tobacco smoke and diet, and involuntary sources, for example industrial processes. Animal studies have clearly linked exposure to PAHs with a variety of cancers. Human populations may also be at increased risk of cancer if the dose and duration of exposure are adequate. However, there is limited information regarding the absorption and distribution of PAHs from non-occupational exposures. The current study has measured biomarkers in plasma and urine from three generations in a total of 70 families (37 urban, 33 rural) from the country of Azerbaijan. Measurements collected from these populations include the concentration of PAHs in plasma, PAH-DNA adducts in peripheral lymphocytes, and 1-hydroxypyrene in urine. The median serum concentration for total PAHs in the urban population was 148 ng/mL, while a median level of 67 ng/mL total PAHs were detected in the rural population. Total DNA adduct levels were significantly higher in the urban population than in the rural population. Analyses of urine samples from urban and rural populations indicate that 1-hydroxypyrene concentrations are highly variable. The data also indicate that plasma PAH levels may reflect DNA damage in lymphocytes.

412 ASSESSMENT OF CHRONIC EXPOSURE TO PESTICIDES OF POPULATION IN HELLA, PELOPONNESUS AND CRETE, GREECE.

M. Tutudaki¹, M. Tzatzarakis¹, M. Margariti¹, C. Koutis², A. Kafatos¹ and A. Tsatsakis¹. ¹Medical School, University of Crete, Heraklion, Crete, Greece and ²Public Health, TEI, Athens, Greece. Sponsor: B. Kroes.

In the present report we assessed chronic exposure of the population to currently used (endosulfan, dimethoate, diazinon, fenthion, chlorpyrifos, methyl parathion, malathion, methidathion, phosphamidon and methomyl) and two banned organochlorine pesticides (HCHs and DDT). The population was divided to two large groups. One had current occupational exposure to pesticides and one did not. The levels of the aforementioned pesticides were measured in the head hair of the population. The organochlorine pesticides were measured as follows: The samples were analyzed by GC-ECD following distraction of the hair matrix by overnight incubation in 2 M HCl, cleanup with liquid-liquid extraction with 2ml hexane: dichloromethane (4:1) and final purification on a cartridge containing basic alumina, acidified silica and anhydrous sodium sulphate. The rest of the pesticides were measured by GC-MS following a simple methanolic extraction. The limits of detection for the currently used pesticides in the GC-MS analysis ranged from 1-40 ng/g. Currently used pesticides (diazinon, fenrthion, malathion and endosulfan) were detected at trace amounts in a very small percentage of our samples. Mean values of both organochlorine pesticides and their metabolites in the hair of whole

population were as follows: α -HCH: 0.18 ng/g, HCB: 2.34 ng/g, lindane: 0.38 ng/g, op DDE: 1.16 ng/g, pp DDE: 0.33 ng/g, op DDD: 1.6 ng/g, pp DDD+op DDT: 0.90 ng/g, pp-DDT: 0.23 ng/g.) The values observed in the present study are lower than those in one of our earlier studies. The pesticides though are still detected despite the long time that they have been banned. This report is part our ongoing population and environmental study of exposure to pesticides and assessment of its effects on public health.

413 EXPOSURE FROM ARTISANAL METAL PROCESSING AND MANUFACTURING FISHING TOOLS INCREASES BLOOD LEAD LEVELS IN CHILDREN FROM CARTAGENA, COLOMBIA.

J. Olivero-Verbel¹, D. Duarte-Amador², M. Echenique-Diaz², N. Montoya-Rodriguez³, J. Guette-Fernandez¹, B. Jhonson-Restrepo^{1,4} and P. J. Parsons⁴. ¹Environmental and Computational Chemistry Group, University of Cartagena, Cartagena, Colombia, ²Bacteriology Program, University of San Buenaventura, Cartagena, Colombia, ³System Engineering Program, Technological University of Bolivar, Cartagena, Colombia and ⁴Lead Poisoning/Trace Elements Laboratory, Wadsworth Center, Albany, NY.

Lead poisoning is one of the most frequent health concerns in children around the world. Low levels of blood lead (BPb) have been linked to impairment in neurobehavioral and growth development. In order to assess lead exposure in a Latin-American country where this metal has been removed from gasoline, BPb concentrations, morphometric and demographic parameters, as well as several hematological variables were evaluated in 189 randomly chosen children, 5-9 years old, attending primary schools located in different neighborhoods in Cartagena, Colombia. The arithmetic mean $\pm$ standard error BPb level was 5.5 ± 0.2 μ g/dL (range $<1.0 - 21.0$ μ g/dL). Fourteen children (7.4%) had BPb levels above the US Centers for Disease Control and Prevention's threshold of concern (10 μ g Pb/dL). BPb levels were weakly but significantly correlated with red blood cell count, and inversely with child stature, age, mean corpuscular volume, and mean corpuscular hemoglobin. BPb levels did not differ significantly between boys and girls, but significant differences were observed between locations ($P < 0.001$). Among the children with BPb levels greater than 10 μ g/dL, four had microcytic homogeneous and nonregenerative anemia, and an equal number also presented basophilic stippling. These children were visited at their homes, and in all cases, lead source was linked to artisanal metal melting-related processes, and fishing net sinker production by fishermen. An educational program about the health effects of Pb exposure is being implemented to prevent poisoning in children from Colombia. Supported by CICTE, UniCartagena.

414 DEVELOPMENT OF A MAGNETIC IMMUNOSENSOR TO BIOMONITOR FOR THE CHLORPYRIFOS METABOLITE TRICHLOROPYRIDINOL.

G. Liu, Y. Lin, J. A. Campbell and C. Timchalk. Pacific Northwest National Laboratory, Richland, WA.

Biological monitoring approaches are being developed using portable analytical systems to quantify dosimetry utilizing readily obtainable body fluids (i.e. blood, urine, and saliva). To assess dosimetry to the insecticide chlorpyrifos (CPF), a fast, simple, and sensitive bioelectrochemical magnetic immunosensing method was developed to measure the metabolite trichloropyridinol (TCP). Under optimal conditions the immunosensor detected a TCP concentration as low as 6 ng L⁻¹, which is 50-fold lower than the reported limit for a commercially available TCP ELISA assay. To establish the utility of the immunosensor, in vivo pharmacokinetic studies were conducted. Rats were given single oral gavage doses (1, 10 or 50 mg/kg) of CPF, and saliva and blood were collected from groups of animals (4/time-point) at 3, 6, and 12 hr post-dosing, and were analyzed for TCP. Trichloropyridinol was detected in both blood and saliva at all doses and the concentration in blood exceeded saliva; although the kinetics in blood and saliva were comparable. The results from these experiments were then used to further develop a physiologically based pharmacokinetic (PBPK) model for CPF that incorporated a compartment model to describe the blood and saliva time-course of TCP. The computational model adequately simulated the results over the dose ranges evaluated. The model was further used to simulate the blood and saliva TCP concentrations for human dietary CPF exposures in the range of the Allowable Daily Intake (ADI) or Reference Dose (RfD) for CPF (0.01-0.003 mg/kg/day). The simulations suggest that the immunoassay has adequate sensitivity to detect and quantify TCP in blood and saliva at these low exposure levels. However, further studies are needed to fully understand the pharmacokinetics of CPF and TCP, particularly at low environmentally relevant doses. These initial findings suggest that the TCP immunosensor repre-

sents a novel approach with broad application for evaluating both occupational and environmental exposures to CPF. (Supported by CDC/NIOSH grant R01 OH008173-01)

415 CHARACTERIZATION OF PROTEIN ADDUCTS OF SULFURYL FLUORIDE WITH ALBUMIN PROTEIN IN THE MALE F344 RAT.

F. Zhang¹, D. Rick¹, D. Eisenbrandt² and M. Bartels¹. ¹Toxicology, Dow Chemical, Midland, MI and ²Global Toxicology, Dow AgroSciences LLC, Indianapolis, IN.

Inhaled test materials may react with nucleophilic macromolecules (hemoglobin, albumin) following absorption. Quantitation of these adducts can provide useful information to assess exposure to xenobiotic compounds. Sulfuryl fluoride (SO₂F₂) is a structural and post-harvest fumigant used to control a wide variety insect pests. SO₂F₂ is a key alternative to methyl bromide, a stratospheric ozone depleting substance scheduled for phaseout by the Montreal Protocol. The tissue distribution of radioactivity after exposure to ³⁵S-SO₂F₂ has been shown to be highest in lungs and nasal mucosa (Mendrala 2005), suggesting significant uptake of inhaled SO₂F₂ or its metabolites in both nasal and pulmonary tissue. SO₂F₂ has also been shown to be highly reactive with endogenous nucleophiles such as hydroxide and amine moieties of protein (Mielke 1964; Cady 1974). To characterize potential covalent adducts of SO₂F₂ with albumin, a major protein in blood and nasal/lung lavage fluids, *in vitro* experiments were conducted to characterize the extent and site of alkylation to this protein. Treatment of rat albumin with high vapor concentrations of SO₂F₂ (500-50,000 ppm x 4hr) resulted in addition of 1-10 SO₂F moieties to each protein molecule, as measured by ESI-TOF-LS/MS. ESI-LC/MS/MS analysis of tryptic digests of these treated albumin samples and data analysis with MASCOT allowed for the identification of two unique peptides containing a tyrosine residue alkylated with SO₂F. Subsequent analysis of tryptic digests of plasma and lung lavage fluid from male F344 rats exposed to 300 ppm SO₂F₂ (4 hr) afforded identification of one of the alkylated peptides seen in the *in vitro* experiment in both sample matrices. These data indicate that SO₂F₂ has the potential to react with albumin present in the airways of the rat, and possibly peripheral circulation. Future studies are planned to evaluate the site- and dose-dependence of this adduct formation.

416 GLOBIN S-PROPYLCYSTEINE AND URINARY N-ACETYL-S-PROPYLCYSTEINE AS BIOMARKERS OF 1-BROMOPROPANE EXPOSURE.

W. Valentine¹, H. Valentine¹, K. Amarnath¹, W. Li³, X. Ding³ and G. Ichihara². ¹Vanderbilt University Medical Center, Nashville, TN, ²Nagoya University Graduate School of Medicine, Nagoya, Japan and ³Shanghai Institute of Planned Parenthood Research, Shanghai, China.

1-Bromopropane (1-BP), an alternative to ozone-depleting solvents, is a neurotoxin and a reproductive toxicant in animals and humans. In the study presented here, the dose response of urinary N-acetyl-S-propylcysteine (AcPrCys) and S-propylcysteine (PrCys) adduct formation on globin and neurofilament preparations were evaluated as potential biomarkers of exposure. To evaluate the response of these indices to differing exposure levels, male Wistar rats were exposed to 1-BP by inhalation for two weeks at either 0, 50, 200, or 800 ppm (8 hr/day, 5 days/week). Urinary AcPrCys and PrCys protein adducts all increased with increasing exposure levels as determined by LC/MS/MS. To evaluate the response of AcPrCys and PrCys adducts to different exposure durations male Wistar rats were either exposed to filtered air or 1-BP for 4 weeks at 50 ppm (8 hr/day, 5 days/week). Urine was collected before the first day of exposure and blood and urine collected after the fifth day of exposure each week. After 4 weeks half of the animals were euthanized and blood collected and one week later the remaining rats were euthanized and blood obtained. Urinary AcPrCys and globin PrCys adduct levels were determined using LC/MS/MS and observed to increase with duration of exposure; and a first approximation of elimination kinetics obtained. Blood was also obtained from workers in a 1-BP production facility and analyzed for globin PrCys adducts by LC/MS/MS. A significant increase in globin PrCys adducts was observed in the 1-BP exposed workers relative to nonexposed workers. These results demonstrate the ability of 1-BP to covalently modify proteins within the nervous system as well as peripheral proteins and support urinary AcPrCys and PrCys adducts as potential biomarkers of 1-BP exposure.

417 FIPRONIL URINE BIOMARKERS IN HUMANS FOLLOWING TOPICAL TREATMENT OF DOGS.

M. M. Bigelow, J. Keenan, Z. Chen, Y. Li, S. Mosadeghi, H. Vega and R. L. Krieger. *Environmental Toxicology, University of California Riverside, Riverside, CA.*

Fipronil (I; 5-Amino-1-(2,6-dichloro-4-(trifluoromethyl)phenyl)-4-(1,R,S)-(trifluoromethyl)sulfinyl)-1H-pyrazole-3-carbonitrile; CAS number 120068-37-3) is an important insecticide in 47 registered products for pest management. Pet owners

often protect dogs and cats from fleas with topical applications of liquid formulations at rates of up to 5 mg fipronil/kg dog. The extent of human exposures resulting from these applications has not been reported. We have used spot urine specimens from persons familiar with our biomonitoring research who have inquired about the extent of their I exposure. Composite samples of two persons, A and B, were created using 30 ml of urine from 15 spot samples from each person to give two 450 ml composites for protocol analysis. Composites were stored at -10C until needed for analysis. Samples were acid hydrolyzed at 24, 40, and 80 C in 0.5N HCl from 0-21 hr and passed through a Bond Elut-Certify II SPE Cartridge (Varian, Harbor City, CA). Samples were eluted with 4 mL ethyl acetate and saturated with sodium sulfate. Elutions were analyzed using HPLC with UV/Vis detection at 275 nm. Acid hydrolysates of urine contain microgram amounts of the corresponding sulfone (II) and sulfide (III). Preliminary urine biomarker indices of exposure (0-1.3 µg/mL urine and 0-2.7 µg/g creatinine) represent potential aggregate exposure following safe use of I products. Biomarkers appear within 1 day of use of I and urine elimination of progressively smaller amounts of II and III continues for several days to 2 weeks depending upon the extent of exposure. Primary contact with treated pets and secondary contact with indoor residues are likely based upon previous studies with chlorpyrifos products. When knowledge of absorption, distribution, metabolism, and elimination are available these data will be useful to estimate absorbed dosage (µg/person) for risk characterization. Alternatively, urine biomarkers may be useful to construct biological exposure indices.

418 A NOVEL APPLICATION OF N-ACETYLCYSTEINE (NAC) IN BIOLOGICAL MONITORING OF METHYLMERCURY (MEHG) EXPOSURE – A PRELIMINARY STUDY.

D. A. Aremu, M. S. Madejczyk and N. Ballatori. *Environmental Medicine, University of Rochester, Rochester, NY.*

Scalp hair is the current media of choice for assessing MeHg exposure in humans. However, the new EPA hair reference level of only 1-2 ppm is close to the background level found in hair, limiting the utility of hair in monitoring relatively low levels of exposure. Cord blood concentration is a better predictor of nervous system deficits determined during postnatal follow-up, but cord blood is not always accessible for analysis, and by the time it is obtained it is too late to reverse any damage that might have been done. The present work was embarked upon to search for a new method of bio-monitoring for MeHg exposure using NAC. We took the advantage of our previous finding that NAC is remarkably effective at enhancing urinary excretion of MeHg in mice and hypothesized that an NAC challenge dose will produce a transient increase in urinary MeHg excretion that is proportional to the MeHg body burden. Unlike other chelating agents including diethiols, NAC does not alter tissue distribution of essential metals, and has minimal side effects. Anesthetized Wistar rats (250-300g) were given different doses of NAC intravenously following intravenous injection of [14C] MeHg and urine samples were collected at 30 min intervals. In addition, a selected NAC challenge dose was applied to graded doses of [14C] MeHg that mimics the body burden of MeHg following a meal of contaminated fish. The results show that the NAC challenge dose consistently produced a transient (<2h) increase in urinary MeHg excretion that was proportional to the body burden. This rapid, reproducible, and dose-dependent response to NAC challenge makes it a promising bio-monitoring agent for MeHg exposure, and thus for predicting the MeHg body burden. Current studies are evaluating different NAC dosing regimens for applications under conditions that more closely mimic environmental MeHg exposure, with the hope that a similar protocol may eventually be tested in humans. (Supported in part by NIH grants ES01247, ES07026, and ES06484)

419 SPECIATION OF ARSENIC IN BIOLOGICAL MATRICES BY AUTOMATED HG-AAS WITH MULTIPLE MICROFLAME QUARTZ TUBE ATOMIZER (MULTI-ATOMIZER).

A. Hernandez Zavala¹, T. Matousek², Z. Drobna³, O. L. Valenzuela⁴, L. M. Del Razo⁴, B. Adair⁵, J. Dedina², D. J. Thomas⁵ and M. Styblo^{1,3,7}. ¹CEMBL, University of North Carolina, Chapel Hill, NC, ²Institute of Analytical Chemistry, Prague, Czech Republic, ³Nutrition, University of North Carolina, Chapel Hill, NC, ⁴Cinvestav, Mexico, D.F. Mexico and ⁵U.S. EPA, Research Triangle Park, NC.

Analyses of arsenic (As) species in body fluids and tissues of individuals chronically exposed to inorganic arsenic (iAs) provide essential information about the exposure level and pattern of iAs metabolism. This information facilitates the risk assessment of disorders associated with iAs exposures. We have previously described an oxidation state-specific analysis of As species in biological matrices by hydride-generation atomic absorption spectrometry (HG-AAS), using a cryo-trap for preconcentration and separation of arsines. In order to improve performance and detection limits of

the method, we have recently automated the cryotrapping and HG step and replaced a conventional flame-in-tube atomizer with a newly developed multiatomizer. Arsenines from As(III)-species are generated in a mixture of 0.75M Tris-HCl (pH 6) and 1% sodium borohydride. For generation of arsenines from As(V)-species, samples are pre-treated with 2% L-cysteine. The analytical performance of this system was characterized using cultured cells and tissues of mice exposed to iAs. Detection limits have improved significantly reaching 12 pg for iAs, 17 pg for MAs, and 13 pg for DMAs in cell lysates. Recoveries were between 92-98%. The redesigned system was used for As speciation in exfoliated bladder cells isolated from 21 individuals exposed to iAs in drinking water. All samples contained iAs, MAs and DMAs, however, the amounts and proportions of these arsenicals varied among donors and did not correlate with As levels in urine. The sum of As species in cells ranged from 4 to 18 ng. Analysis of As species in small samples from human tissues targeted by iAs exposure may provide an effective tool for risk analysis of diseases associated with this exposure. (This abstract does not reflect EPA policies.)

420 NOVEL APPROACH TOWARDS IDENTIFICATION OF BIOMARKERS FOR HORMONE EXPOSURE.

M. Heneweer¹, H. van der Voet² and A. A. Peijnenburg¹. ¹RIKILT - Institute of Food Safety, Wageningen UR, Wageningen, Netherlands and ²Biometris, Wageningen UR, Wageningen, Netherlands.

Traditional risk analysis often implies estimations by extrapolating from dose-response relations established in animal experiments. Often, physiological effects in animals can only be induced at high doses. DNA microarray technology, combined with statistical techniques, may offer the possibility to identify biomarkers for effects at lower doses.

To address this issue, we have performed an animal study in which we exposed immature female rats for 3 days to increasing doses of ethinyl estradiol (EE2, 0.03–10 µg/kg/day) and examined uterus weight and several additional parameters, including uterine gene expression profiles. Subsequently, we used flexible spline models to assess how much of the variation in uterus weight was explained by the variation of the dose. Furthermore, spline models were fitted to explain gene regulation from dose, as well as, uterus weight from gene regulation. From the two latter models the explanatory power of each gene as a biomarker for the dose–response relation was estimated and calculated over the total dose range, or restricted to the low doses. Additionally, we aimed to select biomarkers that suffice as a unique intermediate link in the causal relation from dose to response.

A general conclusion is that many genes, including Gjb2, Syk, Gfra2, apelin, calbindin and Gap43, showed high correlations with both dose and response, and also with each other. These genes could therefore be selected as sensitive biomarkers for exposure to and as biomarkers for effects of estrogenic compounds. Future applications could consist of *in vitro* systems expressing these genes in a comparable manner as the *in vivo* system, allowing for high-throughput testing of estrogenic compounds without animal testing. Furthermore, this method of biomarker identification could be applied to any group of chemicals of interest.

421 MASS SPECIFIC DISCOVERY OF DNA ADDUCTS.

R. W. Giese and P. Wang. *Pharmacology Sciences/Barnett, Northeastern University, Boston, MA.* Sponsor: R. Schatz.

Up until the present time, unknown DNA adducts in biosamples generally have been detected with low specificity, impeding their development as biomarkers for cancer, for example to help individualize cancer prevention. We are reporting a new method (IMI-MS) that broadly discovers unknown DNA adducts with high specificity by mass spectrometry. In our method, enriched adducts from a nuclease digest of DNA (50–100 µg) are phosphate-specifically tagged with an isotopic pair of benzoyl-histamines and detected by MALDI-TOF-MS. Examples of adduct data from the method are as follows. Calf thymus DNA exposed in a test tube to cigarette smoke and DNA from smoker lung share the following adducts: 355.067 (etheno-dAMP), 387.093, 401.110 and 441.105. The latter might be N7-phenylfapydGMP (exact mass 441.105) derived from exposure to benzene oxide. Adduct 359.064, that is observed in many DNA samples, may be formyl-dAMP (exact mass 359.064), a previously undetected lesion that might arise from the reported oxidative intermediate formylphosphate on DNA. In a test tube exposure, p-benzoquinone, a metabolite of the ubiquitous carcinogen benzene, is observed for the first time (perhaps with some propensity) to adduct onto 5-methylcytosine in DNA, in addition to forming known C, A and G adducts. Especially if this BQ-MeC lesion, by perturbing local DNA structure, enhances damage in one way or another to a diagonal MeC deoxynucleotide, then exposure to benzene could erase epigenetic sites. The first direct detection by the method of N6-methyladenine in mammalian DNA samples (e.g. human leukocytes) remains to be interpreted as bacterial contamination (uninteresting result), or as further evidence for this compound as the sixth base of DNA (interesting observation). The method is a new tool for studies of both simple and complex (e.g. human) exposures. It will help to determine unknown DNA adduct structures, to make precise adduct connections

between different exposures, and to formulate and test adduct-related hypotheses. (Supported by CA84641, CA106006, and the Environmental Cancer Research Program. Tissue samples were from NDRI.)

422 GCSPRI: A MULTIPLEXED MICROARRAY FOR PATHOGEN, TOXIN AND TOXICANT BIOSENSING.

G. Marusov¹, J. Samson¹, A. Sweatt¹, S. Fernandez², D. Knopp³, D. Rood⁵, L. K. Silbart⁵, M. Gladd⁴, S. J. Geary⁴ and M. A. Lynes¹. ¹Molecular and Cell Biology, University of Connecticut, Storrs, CT; ²Ciencia, Inc., East Hartford, CT; ³Inst. of Hydrochemistry, Munich, Germany; ⁴Pathobiology, University of Connecticut, Storrs, CT and ⁵Allied Health Sciences, University of Connecticut, Storrs, CT.

Surface plasmon resonance (SPR) is a technology that can measure minute changes in the optical properties of an aqueous medium close to a metal surface, represented by a shift in the SPR angle, allowing for the sensitive detection of changes in mass at that surface that result from the capture of molecules or cells. SPR analysis has been used to detect various pathogens or toxins with great sensitivity, suggesting the potential of the technology as a biosensor, but the traditional Kretschmann SPR configuration is limited in the number of analytes that can be simultaneously detected. Grating-Coupled Surface Plasmon Resonance Imaging (GCSPRI) represents a novel method for detecting a wide range of pathogens, toxins, and toxicants. Our experiments show that GCSPRI is capable of sensitive and quantitative real-time detection of multiple analytes, including viruses, bacteria, protein toxins, and toxicants. In line with the requirements of a robust environmental biosensor, we have demonstrated the capability of a single GCSPRI sensor chip to detect multiple analytes in succession, simultaneously, and from a surrogate environmental samples. By immobilizing an antigen on the chip in order to measure the amount of a cognate antibody in serum samples, it is also possible to monitor pathogen- or toxin-specific seroconversion in order to identify previous exposure to such agents. Our results demonstrate that GCSPRI technology is capable of high-throughput, real-time, label-free, sensitive detection of a broad range of representative pathogens, toxins, and toxicants highlighting the technology's numerous potential applications in the fields of biodefense and environmental monitoring. Supported by N43 ES 2490, DMI-0321646, USDA grant 58-1940-0-007

423 PLUCKED HUMAN ANAGEN HAIR IS UNIQUELY SUITED FOR BIOMARKER DEVELOPMENT; A COMPARATIVE STUDY OF PLUCKED MAMMALIAN HAIR FROM DIFFERENT SPECIES.

A. M. Fajardo¹, L. Engstrom², K. Toy², R. Rahbari², M. Bleavins² and R. Dunstan². ¹Toxicology, University of New Mexico, Albuquerque, NM and ²Drug Safety Research and Development, Pfizer, Ann Arbor, MI. Sponsor: C. Marcus.

Because the anagen (actively growing) hair follicle is such a metabolically active organ, plucked hair is being used with increasing frequency to define the efficacy of compounds, especially those that influence the cell cycle. The purpose of this study is to further define the utility of plucked hairs for biomarker development. Plucked hair from mice, rats, dogs, minipigs, cynomolgus monkeys and humans were stained with hematoxylin and characterized as being in anagen, telogen or undetermined (for humans). Telogen and anagen hairs were evaluated for morphology and cellularity. In all species, telogen hairs had differing club morphologies. In dogs, minipigs, monkeys and humans, telogen hairs were lined by a small layer of epithelial cells surrounding the club region. In anagen follicles, only human plucked hairs could be extruded intact, defined by the presence of an inner and outer root sheath. Plucked minipig hairs were sometimes surrounded by an extensive outer sheath but no inner sheath. Because plucked human anagen hairs were morphologically intact, confocal microscopy was used to further evaluate their morphology. Confocal microscopy was shown to be an improvement over standard sectioning procedures for evaluation of targets of interest that can be identified with fluorescent labels in plucked hairs. In summary, plucked human anagen hair offers considerable potential to establish tissue biomarkers; however, because only human anagen hairs can be extruded intact, this method may not be highly translatable to other species.

424 AN ASSESSMENT OF OVERALL ESTROGEN EXPOSURE FOR THE GENERAL POPULATION AND SEVERAL SUB-POPULATIONS IN THE UNITED STATES.

P. D. Anderson, B. DuPlessie and M. Hoyt. *AMEC Earth & Environmental, Westford, MA.* Sponsor: B. Magee.

Detections of estrogens in the environment have raised concerns in recent years because of their potential to affect both wildlife and human development. Often little context is provided as to whether potential drinking water exposures in the United States are large or small compared to other sources of exposure (e.g., dietary intake).

This study estimates the combined environmental and dietary exposure on a mass basis to endogenous, synthetic, natural product and plant-derived estrogens; and, quantifies the relative importance of the different types and sources of estrogens. For most of the U.S. population, greater than 99% of the total estrogen exposure comes from estrogens in the diet (most of which is comprised of phytoestrogens). The exception is women taking estrogens for contraception or hormone therapy for whom the prescribed source can be important. Drinking water exposures make a minor contribution. Moreover, estrogens derived from therapeutic use that are predicted to be present in drinking water (from excretion after human-use) represent less than 0.0001% of total exposure to estrogens for all age groups. Using the results of this study to characterize the potential effects of estrogens is challenging and complex. Because estrogens affect many endpoints and relative biological activity varies among endpoints, a detailed risk assessment would require investigating multiple endpoints and adjusting the estimated exposures presented in this study for differences in biological activity for each endpoint being investigated. Nevertheless, comparison of the relative contribution of different sources of estrogens clearly indicates: diet dominates total estrogen exposure; exposure to prescribed estrogens through drinking water is a very small fraction of total exposure; and, the contribution of prescribed estrogens via drinking water to total estrogen exposure is so small that adverse effects to human health from prescribed estrogens in drinking water are not likely to occur in the United States.

425 DEVELOPMENT OF PCDD/F AND DIOXIN-LIKE PCB SERUM CONCENTRATION REFERENCE VALUES FOR THE GENERAL U.S. POPULATION USING THE 2005-WHO TEFS AND THE 2001-2002 NHANES DATA.

L. Ferriby¹, M. Harris¹, K. Unice², P. Scott², L. Haws³ and D. Paustenbach⁴.
¹ChemRisk, Houston, TX, ²ChemRisk, Pittsburgh, PA, ³ChemRisk, Austin, TX and ⁴ChemRisk, San Francisco, CA.

The availability of serum concentration reference values has become essential as biomonitoring data is being used more often to determine if individuals have potentially been exposed to specific chemicals. Serum concentration reference values were recently published for PCDD/Fs and dioxin-like PCBs based on the 2001-2002 NHANES data and the 1998 WHO TEFS. Since that time, however, WHO has revised the TEF values for a number of congeners. In accordance with these changes, it was necessary to determine new reference statistics by applying the 2005-WHO TEFS to the weighted 2001-2002 NHANES serum concentration data. Updated summary statistics were developed for several demographic subgroups including males and females, Hispanics and non-Hispanics, smokers and non-smokers, as well as for several representative age groups. In addition, the contribution of individual congeners to the total TCDD TEQ and the effect that the revised TEFS had on total TEQ serum concentrations for the general U.S. population were also determined. The updated TEFS had little impact on the overall percent contribution of the various congeners to the total TEQ: 2,3,7,8-TCDD, 1,2,3,7,8-PeCDD, 1,2,3,6,7,8-HxCDD, 2,3,4,7,8-PeCDF, and PCB 126 still contributed the most to the total TEQ. However, both PCB 156 and PCB 157 were no longer significant contributors, instead being displaced by 1,2,3,4,7,8-HxCDF and PCB 169. The effect of the new TEFS on total TEQ was consistent with the change in magnitude of the TEFS. In general, the decrease in TEFS for the mono-ortho substituted PCBs decreased their contribution to total TEQ appreciably. Using the new TEF scheme, TEQ17-9 was approximately equal to TEQ17-3. Within groups, differences in TEQs using the two schemes were more evident in groups with higher serum levels (e.g. Age 60+) than in groups with lower levels.

426 DEVELOPMENT OF A FRAMEWORK FOR DETERMINING THE APPROPRIATENESS OF A BIOMARKER OF EXPOSURE.

M. P. Zelenka¹, M. G. Bird¹, D. B. Barr² and N. Doerrer³. ¹ExxonMobil Biomedical Sciences, Annandale, NJ, ²Centers for Disease Control & Prevention, Baltimore, MA and ³ILSI Health & Environmental Sciences Institute, Washington, DC.

The ILSI Health and Environmental Science Institute's Biomonitoring Technical Committee is sponsoring work to develop a practical method for determining the appropriateness of a biomarker for specific questions of exposure. The resulting framework is based upon the use of interpretive criteria developed for the International Biomonitoring Workshop co-sponsored by the ILSI Health and Environmental Sciences Institute. The criteria cover a wide range of attributes regarding a biomarker's characteristics; for example, how well the human pharmacokinetics of the biomarker are understood, the strength of association of the exposure to the level of the biomarker, the temporality of the biomarker, and numerous criteria dealing with analytic measurement of a biomarker. A criterion is quantifiable based upon its relationship to the marker being assessed, thus making it possible to compare the results of the criteria for different biomarkers to help the assessor determine the best choice of biomarker. Further, the framework is accessed

through a simple spreadsheet, thus making it easily assessable and user friendly. The overall framework will help assessors make a decision regarding the best choice of biomarker for specific questions of exposure; the possible application/development of a similar framework for biomarkers addressing health risk is discussed.

427 INTERPRETING HUMAN BIOMONITORING DATA IN A RISK ASSESSMENT CONTEXT: BIOMONITORING EQUIVALENTS.

S. Hays², L. Aylward¹, D. Pyatt⁵, H. Leung⁴ and R. Becker³. ¹Summit Toxicology, LLP, Falls Church, VA, ²Summit Toxicology, LLP, Lyons, CO, ³American Chemistry Council, Arlington, VA, ⁴Independent Consultant, Danbury, CT and ⁵Summit Toxicology, LLP, Boulder, CO.

Advances in analytical methodology have made it possible to detect and quantify trace amounts of synthetic and natural environmental chemicals and their metabolites in various human tissues and biological matrices. However, conventional exposure and risk assessment paradigms are structured in terms of administered dose rather than the absorbed dose or tissue concentrations. Health-based screening criteria are generally presented in terms of administered dose (e.g., reference doses or cancer slope factors) or external media concentrations (reference concentrations in air, for example). Thus, the snapshot of integrated uptake of a chemical provided by a biomonitoring sample cannot be directly interpreted in terms of these traditional risk criteria. We propose here application of pharmacokinetic modeling techniques to derive blood or urinary levels of analytes that are consistent with exposure at existing health-based screening guidelines such as reference doses. These levels are termed "biomonitoring equivalents" or BEs. Approaches for using pharmacokinetic data from a variety of sources including clinical experiments, occupational monitoring data, etc. are described. The BE approach leverages existing regulatory health-based exposure guidelines to provide a screening tool for evaluation of preliminary biomonitoring data, allowing prioritization of chemicals for further, more detailed study using epidemiological techniques or to delineate exposure pathways. BEs are presented for several case study chemicals.

428 ANALYSIS OF 1, 2,3, 4-DIEPOXYBUTANE SPECIFIC PROTEIN ADDUCT IN OCCUPATIONALLY EXPOSED WORKERS.

N. I. Georgieva¹, G. Boysen¹, P. Upton¹, R. Sram², R. Albertini³ and J. A. Swenberg¹. ¹ESE, UNC, Chapel Hill, NC, ²Laboratory of Genetic Ecotoxicology, Prague, Czech Republic and ³Bioscience, Inc., Burlington, VT.

Butadiene (BD) is an industrial chemical used in the production of synthetic rubber which is also found in gasoline and cigarette smoke. It is a multisite carcinogen in rodents, with mice being more susceptible than rats. BD is categorized by NTP and US EPA as carcinogenic to humans by inhalation. BD is metabolically activated to several epoxides that differ in their mutagenic potency by up to 200-fold and are known to form DNA and protein adducts. To advance our understanding in BD metabolism and carcinogenesis it is important to have accurate measure for the internal formation of the individual epoxides. Therefore, the internal formation of the promutagenic 1,2,3,4-diepoxybutane (DEB) in vivo was determined indirectly by analysis of the corresponding N,N-(2,3-dihydroxy-1,4-butadiyl)-valine (pyr-Val) adduct. To achieve this, globin samples from BD-styrene polymerization plant workers in the Czech Republic were analyzed for pyr-Val using a recently established method (Boysen et al 2004). Stable isotope internal standard was added to 50 mg globin, followed by hydrolysis with trypsin, purification by immunoaffinity (IA) chromatography and quantification by LC-MS/MS. The LOD and LOQ were 5 fmol and 10 fmol, respectively. Among the analyzed 104 subjects from the Czech study (26 female controls, 23 female BD exposed workers, 25 male controls and 30 male exposed workers) 12 samples had quantifiable amounts of pyr-Val ranging from 0.2 to 0.8 pmol/g globin. Mean 8-h exposure levels to BD were 0.0035 and 0.180 ppm for female controls and exposed, respectively, and 0.0032 and 0.370 ppm for male controls and exposed, respectively. At the time of abstract submission, all samples remain blinded for exposure and gender groups. Following completion of a second independent set of analyses and data submission, codes will be broken for exposure, gender and genotype assignment. These data will be available on the poster.

429 IN UTERO AND LACTATIONAL EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) PERMANENTLY ALTERS CARDIOVASCULAR MORPHOLOGY AND EXTRACELLULAR MATRIX REMODELING.

A. C. Aragon, P. G. Kopf and M. K. Walker. College of Pharmacy, University of New Mexico, Albuquerque, NM.

Studies have shown that the murine heart is a sensitive target of TCDD during fetal development. Microarray analysis demonstrates that in utero and lactational TCDD exposure significantly induces the expression of cardiac genes involved in

extracellular matrix (ECM) remodeling. We tested the hypothesis that this exposure would permanently disrupt cardiac ECM expression and be associated with cardiac remodeling in adulthood. Time-pregnant C57Bl6 female mice were treated with vehicle control (corn oil) or 1.5, 3.0, or 6.0 μg TCDD/kg on GD 14.5. Dams were sacrificed on GD 17.5 and fetal hearts were assessed for ECM mRNA expression, using quantitative RT-PCR. Additional dams from the 6.0 μg /kg group were allowed to deliver, and adult offspring were sacrificed at approximately 3 months of age and were assessed for ECM mRNA expression as well as cardiac morphology. Quantitative RT-PCR of fetal hearts revealed a significant induction of CYP1A1, endothelin (ET-1), osteopontin, and matrix metalloproteinase (MMP) 13 mRNA following exposure to 3.0 or 6.0 μg TCDD/kg, while MMP9 was significantly induced at 6.0 μg TCDD/kg, and 18s rRNA was significantly induced at all three doses. While hearts of adult offspring exposed to TCDD no longer showed induction of CYP1A1 or ET-1, they did exhibit induction of fibrosis markers and regulators of ECM, including collagen I, osteopontin, MMP2, MMP9, and MMP13. Further, TCDD-exposed offspring exhibited increased left ventricular mass and induction of cardiac hypertrophy markers, atrial natriuretic peptide and β -myosin heavy chain. These results suggest that early TCDD exposure may predispose animals to cardiac remodeling and hypertrophy with age. Future studies will determine if alterations in fetal gene expression are mediated by the aryl hydrocarbon receptor and whether early exposure increases the susceptibility to cardiovascular disease following a second cardiovascular insult in adulthood. Supported by ES012335 to MKW and ES012335-0281 to ACA.

430 ARYL HYDROCARBON RECEPTOR PARTICIPATES IN POST-TRANSCRIPTIONAL CONTROL OF WILMS' TUMOR SUPPRESSOR GENE AND MURINE NEPHROGENESIS.

A. Nanez and K. S. Ramos. *Biochemistry and Molecular Biology, University of Louisville, Louisville, KY.*

The molecular mechanisms governing ontogenesis are regulated by environmental and somatic factors in utero that activate or repress the expression of numerous genetic elements. The aryl hydrocarbon receptor (Ahr) is an important ligand-activated nuclear transcription factor during embryogenesis and throughout maturity in multiple organisms. Environmental hydrocarbons acting as Ahr ligands deregulate Ahr functions to induce deleterious developmental deficits in several systems, including the kidney. The Wilms' tumor suppressor gene (Wt-1) encodes a Cys2-His2 zinc finger protein that mediates transcriptional repression/activation of target genes involved in the regulation of mesenchymal-to-epithelial (MET) trans-differentiation during renal development. Wt-1 is regulated at the mRNA level via insertion of lysine-threonine-serine residues (KTS) between the third and fourth zinc finger resulting in modification of Wt-1 DNA binding specificity. Using a metanephric kidney organ culture system we have shown that benzo(a)pyrene (BaP), an Ahr ligand, inhibits nephrogenesis via an Ahr dependent mechanism in embryonic day 11.5 (Ell.5) C57BL/6J (C57) mouse embryos and alters -KTS/+KTS Wt-1 mRNA ratios after a consecutive four-day exposure. Altered Wt-1 mRNA ratios correlate with a reduction in mRNA for Wt-1 transcriptional targets (syndecan 1, Pax2, Egf-receptor, and RaR α), and renal differentiation markers (Sfrp1, Igf1r, Igf2r, Wnt4, Lhx1, and E-cadherin). Metanephroi from B6.D2N-Ahrd/J (D2N) a co-isogenic mouse strain expressing an Ahr variant with reduced ligand-binding affinity are protected from BaP-induced deficits in renal cell differentiation. Thus, BaP and related Ahr ligands may disrupt nephrogenesis in vivo by altering the ratio of Wt-1 mRNA splice variants and expression of downstream Wt-1 targets. These data establish a link between Wt-1 and Ahr in the regulation of transdifferentiation events for diseases of the kidney such as Wilms' tumor, Denys-Drash syndrome, Frasier syndrome and Beckwith-Wiedman syndrome.

431 DEVELOPMENTAL AND MOLECULAR INTERACTIONS BETWEEN THE HYPOXIA AND ARYL HYDROCARBON RECEPTOR (AHR) PATHWAYS IN ZEBRAFISH.

C. W. Matson, C. R. Fleming, A. R. Timme-Laragy, D. Jung, L. P. Battle and R. T. Di Giulio. *Integrated Toxicology and Environmental Health Program, Duke University, Durham, NC.*

Previous zebrafish (*Danio rerio*) studies have shown that exposure to the model PAH β -naphthoflavone (BNF) or the environmentally relevant PAH benzo[a]pyrene (BaP) substantially increases CYP1A expression and activity, while co-exposure to the CYP1A inhibitors α -naphthoflavone (ANF) or fluoranthene (FL) blocks the BNF or BaP-mediated induction of CYP1A. This reduction in CYP1A activity is thought to account for the marked synergistic developmental toxicity (e.g. pericardial edema and jaw deformities) observed in BNF/ANF and BaP/FL coexposed embryos, effects not observed in embryos exposed to these compounds independently. This synergistic embryotoxicity seems to be a generalized response to the coexposure of an AHR agonist and CYP1A inhibitor. A plausible ex-

planation for this interaction is that reduced metabolism leads to prolonged activation of the AHR, which appears to underlie the toxicities of recalcitrant AHR agonists (e.g. TCDD). We hypothesized that a hypoxia-induced reduction in CYP1A activity in BNF or BaP exposed embryos would similarly enhance pericardial effusion and other developmental abnormalities. Various combinations of BNF/ANF or BaP/FL were performed under hypoxia and normoxia. CYP1A activity in the BNF/hypoxia and BaP/hypoxia embryos was reduced by approximately 50% relative to normoxia embryos. Although CYP1A activity was reduced, we did not observe any increase in pericardial edema. However, pericardial edema increased in co-exposed embryos (BNF/ANF or BaP/FL) under hypoxic conditions compared with those under normoxic conditions. These results suggest that reduced CYP1A activity may not underlie the observed developmental toxicity, and that hypoxia may exacerbate the developmental toxicity of some PAH mixtures. This research was partially funded by the NIEHS Duke Superfund Basic Research Center (P42 ES10356) and the NIEHS-supported Integrated Toxicology and Environmental Health Program (T32 ES07031).

432 TCDD IS A POTENT DEVELOPMENTAL TOXIN, BUT FAILS TO AFFECT SPERMATOGENESIS IN OFFSPRING OF CHRONICALLY TREATED CRL:WI(HAN) RATS.

D. R. Bell¹, S. Clode², A. Fernandes⁶, P. M. Foster⁵, G. Loizou³, A. MacNicol⁴, B. Miller⁴, M. Rose⁶, L. Tran⁴ and S. White⁶. ¹School of Biology, University of Nottingham, Nottingham, United Kingdom, ²Covance, Harrogate, United Kingdom, ³HSL, Buxton, United Kingdom, ⁴IOM, Edinburgh, United Kingdom, ⁵NIEHS, Research Triangle Park, NC, United Kingdom and ⁶CSL, York, United Kingdom.

One of the most potent adverse effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is on the developing male reproductive system, after in utero exposure [1]. We have previously found that a single dose of TCDD causes no decrease in F1 sperm levels [2], and we have now undertaken a study to determine if chronic dosing of TCDD affects the developing rat.

CRL:WI(Han) rats were weaned and exposed to TCDD for 12 weeks before pairing, then during pairing until the end of gestation. Animals were killed for determination of TCDD levels, with ~30 animals per group littering. >90 F1 animals per group (67 for the high dose group) were analysed.

The high dose group had 8 animals with total litter loss (vs. 3 in control), there was an adverse effect on pup viability and a dose-related decrease in pup weight at birth. The F1 males showed a significant, dose-related delay in balano-preputial separation (BPS), and the high dose group were slightly less active in motor activity trials. There were no adverse effects of maternal treatment on seminology data at PND70 or 120, nor any effect on the fertility of the animals. Although there was a decrease in epididymis weight at PND 70 in the high dose group, there were no decreases in the weight of accessory sex organs at PND120; nor were there any significant findings in tissues examined by light microscopy at PND120.

Our data from both an acute and a chronic dosing study show that developmental exposure to TCDD does not decrease sperm counts of F1 animals. However, our chronic dosing data reveal BPS to be an extremely sensitive response to maternal TCDD exposure, and that the dosing regime is a key determinant of response.

433 670NM LIGHT TREATMENT MITIGATES DIOXIN-INDUCED HEPATIC OXIDATIVE STRESS.

J. B. Watkins¹, R. L. Yeager², R. A. Sanders¹, J. T. Eells³ and D. S. Henshel². ¹School of Medicine, Indiana University, Bloomington, IN, ²School of Public and Environmental Affairs, Indiana University, Bloomington, IN and ³College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is an acutely toxic anthropogenic chemical. Previous studies have shown that treatment with a red to near-infrared (630 – 1000 nm) light emitting diode (LED) attenuates toxicant-induced oxidative stress and energy deficit in rodent neuronal cell culture. For this study, fertile chicken eggs (*Gallus gallus*) were injected once at the start of incubation with sunflower oil vehicle or 200 pg TCDD/g egg (200 parts per trillion), an environmentally relevant dose. Daily LED treatment (670nm; 4J/cm²) from embryonic day 0 – 20 after TCDD exposure significantly reduced embryonic mortality by 47%, and doubled the probit-determined LD₅₀. Exposure to TCDD alone increased the hepatic oxidized-to-reduced glutathione ratio (GSSG/GSH) by 134%, which was accompanied by a 42% decrease in glutathione reductase (GRx) activity, the key enzyme that actively restores GSH from the oxidized state (GSSG). LED treatment of TCDD-exposed eggs completely reversed the glutathione redox imbalance by decreasing GSSG/GSH by 88% and increased GRx by 55%, restoring activity to the control levels. Our study demonstrates that 670 nm phototherapy can mitigate the oxidative stress resulting from developmental exposure to TCDD and restore he-

patric enzyme activities to control levels in TCDD-exposed embryos. The effective attenuation of TCDD-induced embryo toxicity by LED treatment could extend to mitigating the effects of other teratogens that induce oxidative and energy stress.

434 A DEVELOPMENTAL STUDY OF ENERGY AND GLUTATHIONE REDOX BALANCE IN BRAIN AFTER DIOXIN EXPOSURE AND 670NM LIGHT TREATMENT.

R. L. Yeager¹, D. A. Oleske², R. A. Sanders³, J. T. Eells⁴, J. B. Watkins³ and D. S. Henshel¹. ¹School of Public and Environmental Affairs, Indiana University, Bloomington, IN, ²Medical Sciences, Indiana University, Bloomington, IN, ³School of Medicine, Indiana University, Bloomington, IN and ⁴College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI.

Daily treatment with a red light (670 nm; 4J/cm²) emitting diode (LED) has been shown to effectively mitigate 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) embryo toxicity in the domestic chicken (*Gallus gallus*) model. Work in other organ systems suggests that TCDD decreases available energy (ATP) and suppresses antioxidant enzyme activity prior to and during hatch (embryonic day 20 - 21), as well as that daily LED treatment (embryonic day 0 - 20) mitigates toxicant induced energy deficit and improves both cytochrome c oxidase activity and energy production. The present study quantifies cellular energy production (ATP), cytochrome c oxidase activity, and glutathione in the developing brain of the chicken exposed in ovo to TCDD. In the developing chicken brain, exposure to TCDD alone (200 ppt) decreased ATP content by 5% and cytochrome c oxidase activity by 17%, and significantly increased the ratio of oxidized (GSSG) to reduced (GSH) glutathione by 178%. In TCDD-exposed chicks given LED treatment throughout development, those trends were completely reversed; ATP was significantly increased by 21% and cytochrome c oxidase activity increased by 27%. The GSSG/GSH ratio was significantly reduced by 69%, primarily by blocking the TCDD-induced 154% increase in GSSG. These results support the hypothesis that daily LED therapy *in ovo* decreases toxicant-induced oxidative and energy stress, and these changes may underlie our previous report of the LED therapy-induced decrease in embryo mortality induced by TCDD. We are currently conducting multiple studies to elucidate the mechanism(s) by which LED therapy attenuates toxicant-induced stress in the developing central nervous system.

435 THE EFFECTS OF RED LIGHT THERAPY ON TCDD-INDUCED OXIDATIVE STRESS IN CHICKEN KIDNEY DURING EMBRYOGENESIS.

J. Lim¹, R. L. Yeager¹, D. S. Millsap¹, R. A. Sanders², J. T. Eells³, J. B. Watkins² and D. S. Henshel¹. ¹School of Public and Environmental Affairs, Indiana University, Bloomington, IN, ²Medical Sciences, Indiana University, Bloomington, IN and ³College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a potent developmental toxicant that causes increased embryo mortality and sub-lethal changes in multiple organs, including the liver and the kidney. TCDD has been shown to induce oxidative and energy stress by increasing production of oxygen radicals at the cellular level. In this study, we investigated TCDD induced oxidative stress and the effects of daily red light (670nm at peak; 4 J/cm²) therapy (RLT) in the chicken kidney during development. Eggs were injected once prior to incubation with sunflower oil vehicle control, 2pg/g, 20pg/g, or 200pg/g TCDD; half of the eggs in each dose were then treated with red light once per day through embryonic day 20 (E20). Upon hatching (E21), the kidneys were collected and assayed for glutathione peroxidase [GPx], glutathione reductase [GRx], catalase [CAT], superoxide dismutase [SOD], reduced glutathione [GSH], and ATP. The effectiveness of the red light treatment at the 200 pg/g TCDD dose is evident in GPx activity (RLT:14% vs. Non-RLT: 36% decrease), GRx activity (RLT: 22% vs. Non-RLT: 32% decrease), CAT activity (RLT: 13% vs. Non-RLT: 22% decrease), SOD activity (RLT: 19% vs. Non-RLT: 29% decrease), GSH concentration (RLT: 5% vs. Non-RLT: 36% decrease), and ATP level (RLT: 6% vs. Non-RLT: 25% decrease). Our findings indicate that TCDD induced oxidative and energy stress in chicken kidneys and that daily RLT throughout development attenuated decreased ATP, GSH depletion, and lowered antioxidant enzyme activities. These changes also suggest that RLT therapy could counteract renal damage induced by increased oxygen radicals at cellular levels.

436 EXAMINATION OF METAL INDUCED TOXICOGENOMIC RESPONSE DURING NEURULATION IN RESISTANT AND SENSITIVE MOUSE STRAINS.

J. F. Robinson, X. Yu, S. Hong, E. Kim, W. C. Griffith and E. M. Faustman. Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Differential sensitivity to environmentally induced Neural Tube Defects (NTDs) has been observed between inbred mice strains. In particular, the C57BL/6(C57) is more sensitive than the SWV to Cd exposure during neurulation. We hypothesize

that Cd induces NTDs by impacting gene expression in cell cycle and apoptosis pathways and that the observed difference in Cd-sensitivity is due to its differential effect on these pathways. We used the Codelink Uniset 20K mouse I array to evaluate for gene expression alterations in embryos of C57 and SWV mice, 12 and 24 hrs post-injection (GD8.0, ip) of either vehicle or 4mg/kg(BW) Cd. To determine associations between developmental stage, treatment, and strain, we employed MAPPFinder(GenMAPP) to observe categorical and pathway-based changes in gene expression. In both the C57 and SWV, Cd induced up-regulation of genes involved in the cell cycle pathway and kinase activation(12h) as well as down-regulation of genes related to development and neurogenesis(24h). Exclusively, in the C57, Cd induced up-regulation of genes involved in apoptosis(12h). These genes included caspase 8, cyclin g1, and pmaip. In addition, in the C57 we observed down-regulation of genes responsible for cell adhesion, corresponding to dysfunctional adhesion and fusion of the neural tube(24h, GD9.0). Our initial microarray analysis suggests Cd impacts apoptotic and other cell signaling pathways differentially in the C57 compared to the SWV. In both strains, we observed Cd-induced changes in cell cycle genes. Using pathway based assessment approaches, we were able to observe differential impact in specific gene targets. Preliminary western blot analysis of p53, p21, and caspase 3 further supports these specific conclusions. Using a comparative microarray approach, we have correlated Cd-induced alterations in gene expression of these selected signaling pathways with differential neural tube closure sensitivity. 437 EFFECTS OF PERFLUORINATED ACIDS ON PULMONARY SURFACTANT PROPERTIES *IN VITRO*.

S. C. Gordon¹, S. Schürch², M. Amrein² and M. Schoel². ¹Corporate Toxicology and Regulatory Services, 3M, St. Paul, MN and ²Respiratory Research Group, University of Calgary, Calgary, AB, Canada.

Dose-dependent reductions in neonatal survival were observed in rodents treated during gestation with perfluorooctanoate (PFOA) and perfluorooctane sulfonate (PFOS) but not with perfluorohexane sulfonate (PFHS) or perfluorobutane sulfonate (PFBS). The pathophysiological basis of the neonatal mortality is unknown but clinical signs suggest impaired respiratory function. Studies with PFOS found no evidence of delayed lung maturation or altered surfactant composition or quantity in rats. In the present study, direct effects of these perfluorinated acids (PFA) on surfactant surface properties were evaluated using a captive bubble surfactometer (CBS). The CBS chamber was filled with aqueous media and an air bubble was allowed to float up to the agarose ceiling. A 1µL droplet of bovine lipid extract surfactant (BLES) was spread at the air-liquid interface to form an equilibrium film of 23 mN/m in < 1sec. PFA was added to the media at concentrations of 0.5, 0.1, 10⁻³, 10⁻⁵ and 10⁻⁶% w/w. After 5 min, 20 compression-expansion cycles at 20 cycles/min were conducted. Minimum surface tensions (ST) and the amount of film area compression needed to achieve them were determined. Minimum ST at 0.5% and 10⁻⁶% PFA (means, n=5) were: PFOA 11.9, 1.7; PFOS 16.4, 5.7; PFHS 15.6, 2.9; PFBS 11.1, 2.9 mN/m, respectively, upon film area compressions of 60-80%. The minimum ST for BLES without PFA was 1.0 mN/m (mean, n=5) on film area compressions of <20%. At 0.5% PFA, minimum ST were significantly higher than those at 10⁻⁶% (p<0.01). At 10⁻⁶% PFA, minimum ST approached normal values, but only at film area compressions well above those of normal surfactant films *in vitro* (~20%) or *in situ* in lungs (<30%). Thus, these PFA appear to directly interfere with normal surfactant properties *in vitro* even at relatively low concentrations. Further studies are needed to assess the toxicological significance of these findings. (Supported by a grant from 3M Corporation)

438 EFFECTS OF AMPHETAMINE DRUG CHALLENGE DURING AN INHIBITORY CONTROL TASK IN RATS DEVELOPMENTALLY EXPOSED TO PCBs AND/OR MEHG.

H. J. Sable^{1,2}, B. E. Powers^{1,2}, V. C. Wang^{1,2} and S. L. Schantz^{1,2}. ¹Department of Veterinary Biosciences, University of Illinois at Urbana-Champaign, Urbana, IL and ²Neuroscience Program, University of Illinois at Urbana-Champaign, Urbana, IL.

Developmental PCB exposure has been reported to produce dopamine (DA) hypo-functionality in rats. *In vitro* studies suggest MeHg exposure may exacerbate this effect. To examine this more closely, we conducted a drug challenge study to determine if developmental exposure to an environmental PCB mixture, alone and in combination with MeHg, alters catecholamine function. Female Long-Evans rats were exposed to corn oil (controls), PCBs alone (1 or 3 mg/kg/day in corn oil), MeHg alone (1.5 or 4.5 ppm in drinking water) or a combination of PCBs and MeHg (1 mg/kg PCB + 1.5 ppm MeHg or 3 mg/kg PCBs + 4.5 ppm MeHg) beginning 4 weeks prior to breeding and continuing until litters were weaned on post-natal day 21. One adult male and female per litter were trained to asymptotic performance on a differential reinforcement of low rates (DRL) operant task which has been shown to be prefrontal cortex (PFC) dependent. Rats had to wait 15 s between lever presses to obtain a food reinforcer. Presses occurring too soon reset the

timer and delayed the reinforcer. Testing occurred Monday-Saturday and replicate doses of 0, 0.5 and 1.0 mg/kg amphetamine (AMPH) were given IP 10 minutes before testing on Tuesdays and Fridays via a counterbalanced Latin square design. The 1.0 mg/kg dose of AMPH was less disruptive to responding in male rats receiving 3 mg/kg/day PCBs as well as in males receiving 1.5 ppm MeHg both alone and in combination with PCBs. Paradoxically, rats exposed to 4.5 ppm MeHg, either alone or in combination with PCBs, did not show this effect, and female rats did not differ significantly from controls in their response to AMPH. Interestingly, groups exposed to both PCBs and MeHg did not show a greater effect than groups exposed to PCBs or MeHg alone. Overall, the findings lend support to the hypothesis that either developmental PCB or MeHg exposure may produce DA hypofunctionality in the PFC. (Supported by USEPA R82939001 & NIEHS PO1 ES11263)

439 THE EFFECTS OF INHALED VAPORS OF DIMETHYL DISULFIDE ON EMBRYO/FETAL DEVELOPMENT IN RATS AND RABBITS.

D. Kirkpatrick¹, T. Thullen¹, C. Farr², M. Nemec¹, E. Slotter¹, K. Weedman¹, S. Davis¹, J. Sherman¹ and K. Foster¹. ¹DART, WIL Research, LLC., Ashland, OH and ²Arkema, Inc., Philadelphia, PA.

Dimethyl Disulfide (DMS) is a promising zero-ozone depleting, methyl bromide replacement candidate for soil fumigation applications and a known effective agent used in the sulfiding process of oil refining. These studies were designed to provide information about unique toxicities emanating in prenatal development when DMS was exposed to pregnant rats and rabbits throughout the period of major organogenesis. Four groups of 27 female Crl:CD(SD) rats were exposed to atmospheres of 0, 5, 20, and 80 parts per million (ppm) and four groups of 24 female NZW rabbits were exposed to atmospheres of 0, 15, 45, and 135 ppm. All animals were observed twice daily for morbidity and mortality, and clinical observations, body weight, and food consumption were recorded at appropriate intervals. Laparohysterectomies were performed on rats and rabbits on gestation day 20 and 29, respectively, and the following parameters were examined: Gravid uteri weights, number of early and late resorptions, number of total implantations, number of corpora lutea, number of fetuses, fetal weights, fetal sex, and fetal examination of malformations and variations (external, visceral, and skeletal). From an overall maternal toxicity perspective, the rabbits were not as sensitive as the rats, as reductions in body weight, body weight gain, gravid uterine weight, and food consumption were manifested at 80 ppm in the rats but not at 135 ppm in the rabbits. The high exposure concentration resulted in in utero growth retardation in the rats, but not in the rabbits. Other manifestations of developmental toxicity (prenatal mortality or structural malformations) were not observed in either species at all evaluated concentrations. A NOEL for both maternal and developmental toxicity in rats and rabbits was 20 ppm and 135 ppm DMS, respectively.

440 STRUCTURAL DIFFERENCES BETWEEN THALIDOMIDE AND LENALIDOMIDE CAUSE DIFFERENT DEVELOPMENTAL EFFECTS IN RATS AND RABBITS.

M. S. Christian¹, O. L. Laskin², V. A. Sharper³, A. M. Hoberman³, D. I. Stirling² and L. Latriano². ¹Argus International, Inc., Horsham, PA, ²Celgene Corporation, Summit, NJ and ³Charles River Preclinical Services, Horsham, PA.

Lenalidomide (LEN) and thalidomide (THAL) are structurally similar. Developmental toxicity (DT) studies were conducted to compare their effect patterns. LEN (oral gavage) was given to 24 Crl:CD (IGS) BR female rats/group at 0, 100, 300 or 500 mg/kg/day (MKD) on GDs 7-17 (C-section GD 20; standard evaluations). A pulse-dosing and 2 full DT studies (oral, gavage) were conducted in Crl:NZW/Kb BR or Hra:(NZW)SPF rabbits. In the pulse-dosing study (5/group), LEN (100 MKD) or THAL (250 MKD) was given on GDs 8-10. In DT study 1 (20/group), LEN was given at 0, 5, 15 or 25 MKD on GDs 7-17 (THAL: 250 MKD). In DT study 2 (25/group), LEN was given at 0, 0.3, 10, 20 MKD on GDs 7-17 (THAL: 180 MKD). Doses based on range-finding studies (5/group; LEN: 0, 5, 10, 25, 60, 100 MKD; THAL: 0, 10, 20, 60 and 180 MKD). C-section GD 29 with uterine and fetal examinations. LEN maternal and developmental NOELs in rats = 300 MKD (decreased weight gain, feed consumption and fetal weight, increased supernumerary ribs and growth retardations at 500 MKD; postimplantation loss unaffected although the classic effect of THAL in rats). In rabbits, LEN maternal and developmental NOELs = 3 MKD (decreased weight gains, feed consumption and fetal weights and increased postimplantation loss, external, soft tissue and skeletal variations but no malformations at 10 MKD; THAL at 180 MKD selectively reduced fetal weight and increased postimplantation loss, fetal limb abnormalities and other malformations/variations). In the pulse-dosing study, 100 MKD of LEN caused maternal weight loss without affecting conceptuses; at 250 MKD THAL selectively reduced fetal body weight and increased postimplan-

tation loss and limb abnormalities. Thus, despite structural similarity, in two responsive species, LEN and THAL had different developmental effects, confirming observations by Nau (1995) that minor structural differences can remarkably affect developmental outcomes.

441 EVALUATION OF THE DEVELOPMENTAL TOXICITY OF LINALOOL IN RATS.

C. Letizia¹, A. Api¹, V. T. Politano¹, E. M. Lewis², A. M. Hoberman², M. S. Christian³ and R. M. Diener³. ¹RIFM, Woodcliff Lake, NJ, ²CRL Argus Research, Horsham, PA and ³Argus International, Inc., Horsham, PA.

The developmental toxicity of linalool, a widely used fragrance ingredient, was evaluated in rats. Linalool or the vehicle, corn oil, were administered orally (via gavage) to pregnant rats (25 rats/group) once daily on days 7 through 17 of gestation at doses of 0 (vehicle), 250, 500 or 1000 mg/kg/day. The rats were observed for viability and examined for clinical signs, abortions, premature deliveries and deaths. Body weights and feed consumption were also recorded. On day 21, all rats were sacrificed and a gross necropsy of the thoracic, abdominal and pelvic viscera was performed. The uteri were removed and examined for number and distribution of implantation sites, early and late resorptions and fetal mortality. Each fetus was examined for gross external alterations. Approximately one half of each litter was examined for soft tissue alterations and the remaining fetuses were examined for skeletal alterations. No maternal deaths occurred. No clinical signs and no gross changes attributable to linalool were observed at necropsy. During the dosage period, mean relative feed consumption was significantly reduced by 7% and mean body weight gains were reduced by 11% at the highest dose level. During the post-dosage period, feed consumption values at the highest dose level were significantly higher than vehicle control values, which corresponded to the increase in body weight gains during this period. No adverse effects on embryo-fetal development were observed in this study. Caesarean-sectioning or litter parameters, as well as fetal alterations, were not affected by dosages of linalool as high as 1000 mg/kg/day. On the basis of this data, the maternal no observable adverse effect level (NOAEL) of linalool is 500 mg/kg/day and the developmental NOAEL is greater than 1000 mg/kg/day.

442 DEVELOPMENTAL AND PERI-POSTNATAL STUDY IN CYNOMOLGUS MONKEYS WITH BELIMUMAB.

D. Auyeung-Kim¹, P. Lappin¹, T. Migone², W. Cai², W. Halpern² and G. J. Chellman¹. ¹Charles River Preclinical Services, Sparks, NV and ²Human Genome Sciences, Inc., Rockville, MD.

Belimumab is a fully-human monoclonal antibody specific and antagonistic for the B-lymphocyte stimulator protein (BLyS). BLyS is a soluble protein secreted by monocytes/macrophage that stimulates B lymphocyte maturation and survival. This study assessed the potential in utero and postnatal effects of continuous belimumab exposure in cynomolgus monkeys during pregnancy. Dose levels of 0 (control), 5 and 150 mg/kg were administered intravenously bi-weekly from Gestation Day (GD) 20 to GD150 to pregnant monkeys, in a two-phase study design. In Phase 1, the adult females were evaluated for multiple endpoints of toxicity, immunological response, toxicokinetics (TK) and pharmacodynamics (PD). Fetuses were delivered by C-section on GD150 for teratologic evaluations (external, visceral, skeletal), TK and PD. In Phase 2, the adult females were allowed to deliver and were maintained with their infants for one-year postnatal and evaluated for TK and PD. Infants were evaluated for growth and development, neurobehavior, clinical pathology, immunology, and then necropsied for complete pathologic evaluation. Results showed no test article related toxicologic effects in adult females during gestation or postnatally, and no developmental or toxicologic effects in fetuses or infants. The primary effects observed were related to expected pharmacology, mainly reduced numbers of total (CD20+) and mature (CD20+/CD21+) B lymphocytes in peripheral blood and tissues. These effects were observed in the adult females during dosing, in GD150 fetuses, and in infants, and were reversible upon cessation of exposure. In conclusion, this study demonstrated that belimumab was well tolerated at pharmacologically active dose levels in pregnant cynomolgus monkeys and their infants after exposure throughout pregnancy.

443 DEVELOPMENTAL TOXICITY EVALUATION OF BIS (METHYL SALICYLATE) CARBONATE (BMSC; CAS NO. 82091-12-1) ADMINISTERED BY ORAL GAVAGE TO CD® (SPRAGUE-DAWLEY) RATS ON GESTATIONAL DAYS (GD) 6 THROUGH 19.

M. C. Marr¹, C. B. Myers¹, N. P. Castillo¹, R. W. Tyl¹, S. S. Dimond² and J. P. Van Miller³. ¹RTI International, Research Triangle Park, NC, ²GE Plastics, Pittsfield, MA and ³TRS, Charlottesville, VA.

BMSC, a chemical intermediate, was evaluated initially in a 28-day study in adult rats; there were no effects at doses ≤ 1000 mg/kg/day (mkd). Subsequently, time-mated CD® rats (25/group) were gavaged with 0, 25, 250, or 1000 mkd BMSC in

corn oil on gd 6 through 19. Maternal body weights (MBW), feed consumption (FC), and clinical observations (CO) were recorded throughout gestation. On gd 20, gravid uterine (GUW), and liver weights were recorded. Live fetuses were counted, sexed, weighed, and examined externally (E;100%), viscera (V;50%), and skeletally (S;50%). No maternal mortality or treatment-related CO occurred. At 0-250 mkd, no litters were fully resorbed. At 1000 mkd, 20 (83.3%) had fully resorbed litters. MBW and MBW gain were reduced at 1000 mkd on gd 6-19, gd 0-20, GUW on gd 20 and when corrected for GUW. At 250 mkd, reduced MBW was reduced for gd 6-19 only. MFC was reduced at 1000 mkd throughout gestation and gd 6-9 at 250 mkd. Fetal BW/litter was reduced at 250 and 1000 mkd. The % resorptions and affected fetuses/litter was increased for E, V, S, and total malformations and for E, S, and total variations at 1000 mkd. The % affected fetuses/litter was increased at 250 mkd for S and total variations. Malformations at 1000 mkd included craniorachischisis, exencephaly, abnormal forebrain and lateral ventricles, anophthalmia, anasarca, gastroschisis, umbilical hernia, dextrocardia, unossified skull plates, 15 ribs, and abnormal vertebral cartilage/bone. In conclusion, BMSC resulted in maternal and embryofetal toxicity and teratogenicity at 1000 mkd and maternal and fetal toxicity (but not embryotoxicity or teratogenicity) at 250 mkd. The NOAEL for dams and conceptuses was 25 mkd. The proposed mode of action involves monomeric methyl salicylate (from hydrolytic cleavage of BMSC). Salicylates are not teratogenic in humans. Supported by GE Plastics, Pittsfield, MA.

444 TERATOLOGY STUDIES IN NZW RABBITS FOLLOWING IMMUNIZATION WITH BONE MORPHOGENETIC PROTEIN-7 (BMP-7).

A. Pierce¹, H. Aloui-Ismaili³, N. Denison³, R. Schroeder², D. Schrier¹ and D. Falb³. ¹Preclinical Development, Stryker Biotech, Hopkinton, MA, ²RPDT, MPI Research, Inc., Mattewan, MI and ³Research & Development, Stryker Biotech, Hopkinton, MA.

Bone morphogenetic proteins are members of the TGF- β super family of proteins. BMP-7 is currently under marketing approval in trauma and spine orthopaedic indications. The objective of reproductive and developmental studies in NZW rabbits was to evaluate toxicity to dams and offspring from maternal BMP-7 antibody formation. Two separate studies were performed: prenatal and postnatal assessment. Maternal animals were treated with BMP-7 (350 μ g/animal in 0.5mL) in CFA on pre-mating day 1 and boosted with BMP in IFA on pre-mating days 14, 28, and GD12, and GD26 (postnatal only). Maternal examinations were performed in-life and at necropsy on GD 29 (prenatal) and LD 28 (postnatal). Prenatal fetal assessment included external, visceral, and skeletal exams. Postnatal kits were euthanized on LD 28 and examined. ELISA was used to measure maternal, prenatal and postnatal serum IgG and IgM antibody levels. Anti-BMP-7 antibody levels were elevated in the treated dams in both studies. Fetal and kit levels were elevated corresponding to maternal levels. Postnatal antibody to BMP-7 was detected in maternal milk. No mortality or differences in pregnancy status between BMP-7 treated and untreated dams were noted. No treatment effects in body weight, food consumption, uterine or ovarian parameters (prenatal), gestation length (postnatal), dystocia (postnatal), organ weights, and necropsy findings were noted. Fetal and kit survival rates and development were not altered by elevated antibodies in the BMP-7 treated group. In conclusion, large doses of BMP-7 (total dose = 1.4 mg in prenatal and 1.8 mg in postnatal) induced elevated anti-BMP-7 antibodies in maternal animals. These elevated antibody levels cross the placenta and were distributed among the litters. No teratogenic effects were noted in the presence of elevated anti-BMP-7 antibodies.

445 A TERATOLOGY STUDY OF ORAL GAVAGE OF SI-WU-TANG IN RATS.

H. Chen, C. Wang, Y. Yang, J. Chao, D. Wang, H. Chu, T. Yuen and S. Hsu. Development center for biotechnology, Xizhi City, Taiwan.

Si-Wu-Tang is a traditional Chinese herbal medicine has been used to improve the female reproductive function for hundred of years. However, it has been questioned used Si-Wu-Tang in pregnant women might cause adverse effect on the fetuses. The purpose of this study was to evaluate the effects of Si-Wu-Tang on maternal pregnancy, embryo-fetal developments and the fetuses in rats.

Four groups of mated Sprague-Dawley rats (21-22) were dosed daily during gestation days 6 to 15 via oral gavage with 0, 100, 300 and 500 mg/mL of Si-Wu-Tang solutions with the dosing volume of 10 mL/kg. Rats were observed daily throughout gestation days 6 to 20. The maternal body weights and food consumption were recorded at designated time intervals. At near term G20, the dams were euthanized and Cesarean sectioned. The number of viable or dead fetuses per litter was recorded. External, visceral and skeletal abnormalities of fetuses were examined.

Significant decreases of maternal food consumption during G6-G9, G9-G12 and G6-G15 were found at 5000 mg/kg/day group ($p < 0.05$). There were no other maternal significant differences among control, low, medium and high dose groups in all parameters. Low incidences of spontaneous external, visceral and skeletal abnormalities of fetus were observed in both the treated and/or control groups. The daily recommended human dose is 15-20 g for a 60-kg subject, therefore, the maximal daily recommended dose estimated is 333 mg/kg approximately. Based on the results, rats received dose up to 5000 mg/kg/day of Si-Wu-Tang did not reveal any maternal toxicity and teratogenicity in the maternal, which provided a safety margin of 15 folds over the recommended human dose basing on a conversion of body weight. It is concluded that Si-Wu-Tang is unlikely to induce detrimental embryo-fetal toxicity and teratogenicity in rats.

Key words: Si-Wu-Tang, fetus, teratogenicity, safety margin

446 ETHYLENE GLYCOL: TOXICOKINETIC STUDY IN PREGNANT NEW ZEALAND WHITE RABBITS.

E. W. Carney¹, B. Tornesi¹, D. Markham¹ and N. Moore². ¹TERC, The Dow Chemical Company, Midland, MI and ²Dow Europe GmbH, Horgen, Switzerland.

Large doses of ethylene glycol (EG) are teratogenic in rats, but not rabbits. Therefore, a rabbit toxicokinetic study was conducted to test the hypothesis that the insensitivity of rabbits is due to limited embryonic exposure to the EG metabolite, glycolic acid (GA); the proximate teratogen in rats. NZW rabbits were gavaged with 100 or 1000 mg EG/kg on gestation day (GD) 9 or 1000 mg/kg on GD 15. At various times post-dosing, rabbits were sacrificed and maternal blood and kidney, embryo, extraembryonic fluid (EEF) and visceral yolk sac were collected and analyzed for EG, GA and/or acid-base status. Data were compared to similarly conducted studies in pregnant rats, with an internal bridging control included in the present study which ensured comparability of the analytical values. In GD 9 rabbits given 1000 mg/kg, peak maternal blood EG (891 μ g/g) was almost identical to that reported for pregnant rats similarly dosed (886 μ g/g). However, peak maternal blood GA (146 μ g/g) was less than half that of rats (363 μ g/g). Levels of both EG and GA in embryo and yolk sac were much lower than maternal blood. As a result, peak levels of GA in the rabbit embryo (45.7 μ g/g) were only one-tenth that reported for rat embryos (479 μ g/g). Following a dose of 100 mg/kg on GD 9, GA was barely detectable in maternal blood, and not detected in embryo or yolk sac. GD 15 kinetics were generally similar to GD 9, except that levels of EG and GA in the embryo and yolk sac tended to be much higher on GD 15, most likely due to more efficient transfer via the chorioallantoic placental circulation relative to the yolk sac placenta of GD 9. The 10-fold difference between rabbit and rat embryos in embryonic GA exposure could be an important factor in the species-specific teratogenicity of EG, although intrinsic insensitivity of the rabbit conceptus to GA also needs to be considered as a possible explanation. Sponsored by CEFIC Ethylene Oxide and Derivatives Sector Group, Brussels, Belgium.

447 COMPARISON OF MATERNAL AND EMBRYO-FETAL DEVELOPMENT DATA AMONG AND ACROSS TWO STRAINS OF RABBITS OBTAINED FROM DIFFERENT VENDORS.

E. A. Zahalka, K. Wheeler and D. Potter. Gene Logic, Inc., Gaithersburg, MD.

Rabbit colonies at different vendors are susceptible to infection with a variety of bacterial, viral or parasitic agents, as well as subjected to variable housing conditions; therefore, it is important to investigate the impact of using same strain, time-mated rabbits obtained from different vendors on data analysis. This study was designed to compare the maternal and embryo-fetal developmental data from New Zealand White rabbits or Dutch Belted rabbits obtained from two different vendors (Covance and Myrtle's Rabbitry). Forty non-treated, time-mated female rabbits were assigned to one of four groups based on their strain and purchase vendor. Maternal and embryo-fetal development end-points were evaluated. Maternal body weight and food consumption were not statistically different between same strain rabbits obtained from different vendors. All Dutch Belted rabbits were pregnant and 9 of 10 and 8 of 10 New Zealand White rabbits obtained from Covance or Myrtle, respectively, were pregnant. No significant differences in number of corpora lutea, implantations, resorptions (early and/or late), live or dead fetuses, mean litter weights, mean fetal weights (males and/or females) or fetal morphological (external, visceral and skeletal) were noted between same strain rabbits regardless of vendors. In comparing the two different strains obtained from the same vendor, a greater number of resorptions were noted for the New Zealand White rabbits than the Dutch Belted rabbits regardless of vendor. Dutch Belted rabbits had higher pre-implantation loss and higher percentage of viable implants, lower total number of live fetuses, and mean litter weight as compared to the New Zealand White rabbits regardless of vendor. In conclusion, maternal and embryo-fetal development data were similar for the same strain of time-mated rabbits obtained from different vendors and the embryo-fetal development data was different between both strains regardless of vendor.

448 INTEGRATION OF DEVELOPMENTAL TOXICITY DATA INTO RISK ASSESSMENT: A CASE STUDY OF DIMETHOATE.

J. DeSesso¹, R. E. Watson¹, C. L. Keen², K. P. Hazleden³, L. C. Haws⁴ and A. Li⁵. ¹Mitrotek Systems, Falls Church, VA, ²University of California, Davis, CA, ³Huntingdon Life Sciences, East Millstone, NJ, ⁴ChemRisk, Austin, TX and ⁵Exponent, San Francisco, CA.

Dimethoate is an organophosphate pesticide used to control a wide variety of insects on agricultural crops and ornamentals. To ensure that dimethoate is used safely, it is important to determine exposure levels that protect against adverse effects at all life stages, including the developing fetus, infants and children. Based on an analysis of a developmental neurotoxicity study, a cholinesterase (ChE) sensitivity study, a cross-fostering study, and several single and multi-generational reproductive toxicity studies, two potential critical endpoints for dimethoate were identified: brain ChE inhibition (ChEI) and pup mortality. An initial evaluation concluded that pup mortality was a preferable endpoint, based on an increased number of pup deaths born to dams dosed with > 3 mg/kg dimethoate via oral gavage. Closer examination, however, revealed that the pup deaths were clustered in a low number of litters in which the dams providing postnatal care exhibited maternal care deficits. When the data were instead analyzed using the dam as the unit of statistical significance, the USEPA-recommended practice, a significant increase in the average litter proportion of pup deaths was only observed when dams postnatally dosed with 6 mg/kg dimethoate were raising the pups. Gestational exposure to 6 mg/kg dimethoate had no effect on pup survival. Furthermore, a benchmark dose (BMD) meta-analysis approach revealed that BMDL10 (the lower 95% bound of the dose resulting in a 10% reduction in the parameter of interest) for ChEI was >3-fold lower than the BMDL10 for pup mortality (0.19 and 0.68 mg/kg, respectively; Reiss and Gaylor, Regul. Toxicol. Pharmacol., 2005). Thus, we conclude that brain ChEI is the correct critical endpoint for assessing risk. Overall, this study underscores the importance of using the dam as the unit of statistical significance, and demonstrates the utility of the BMD approach.

449 HISTORICAL CONTROL DATA OF CRL:(WI) BR-WISTAR RATS, IN SEG II STUDY.

A. Miklos¹, K. Pal-Kutas², J. Nimer¹, C. Paculba¹, K. L. Steinmetz¹ and A. Druga². ¹SRI International, Menlo Park, CA and ²LAB International Hungary Ltd., Veszprem, Hungary.

Control data are frequently considered when interpreting teratology results from common laboratory species. The Middle Atlantic Reproduction and Teratology Association (MARTA) database includes data from studies performed using Sprague-Dawley (SD) rats, a frequently used outbred strain in the U.S. In the current study, control data are presented for the Crl:(Wi) BR-Wistar rat (WI), a frequently used outbred strain in Europe. Control groups from rat Segment II studies included 233 litters consisting of 3221 fetuses from the two study sites. Scoring evaluations were normalized by cross-site training. All studies were conducted using criteria for GLP studies and were compliant with ICH Segment II or OECD 414 guidelines. Fetuses were collected from timed-pregnant females by C-section data on GD20 and evaluated for external, visceral, and skeletal parameters. Fetal abnormalities were calculated on a per-litter basis by determining percentage of affected/total for each litter, and then calculating the overall average % for the groups. There were no incidents of an entire litter being resorbed. The mean numbers of implants and live fetuses per litter were 14.9 (range 14.3–15.1) and 13.8 (12.7–13.9), respectively, while mean % postimplantation loss 9.8% (7.6–12.0%). Comparing our results with the MARTA SD database suggests that WI rats have slightly lower mean numbers of implants and live fetuses whereas postimplantation loss was observed at a slightly higher frequency. However, numbers for all parameters are well within observed SD ranges. Morphological examinations of fetuses revealed some differences between the strains in the incidence of spontaneous malformations. For example, abnormal origin of right subclavian artery from aortic arch was found to be 0.4% in WI compared with approximately 0.1% in SD. It is not clear whether these trends will continue as additional fetuses are added to the WI database. Our findings demonstrate that although there may be slight differences between WI and SD teratology parameters, these appear to be minimal.

450 USE OF THE ZEBRAFISH FOR EMBRYOTOXICITY SCREENING.

C. Janaitis¹, T. Steger-Hartmann², A. Hill⁴, S. Albert⁴, T. Weiser³, N. Clemann³ and J. Bluemel¹. ¹Merz Pharmaceuticals GmbH, Frankfurt, Germany, ²Schering AG, Berlin, Germany, ³F.Hoffmann-La Roche AG, Basel, Switzerland and ⁴Oxford-based VASTox plc, Oxford, United Kingdom.

Several screening assays have been developed as early indicators for in vivo embryotoxicity/teratogenicity traditionally studied in rats and rabbits, but so far none of them has gained broad acceptance in drug discovery. Embryotoxicity assays in the

zebrafish (*Danio rerio*) provide several advantages compared to other screens such as the EST or the WEC: in the developing fish egg the whole embryofetal period is covered, the assay is easy and quick to perform and requires no use of higher vertebrates.

To evaluate the predictivity of the zebrafish embryotoxicity screen, 13 compounds for which in vivo data were available, were provided as blinded samples by 3 pharmaceutical companies and were screened by Oxford-based VASTox in zebrafish embryos, which were exposed to the test substances at 4 hours post fertilization (sphere stage or midblastula; equivalent to 6 days in rats/rabbits) and scored at 96 hours p.f. (free swimming larva; equivalent to 16/18 days in rats/rabbits). The score consisted of the assessment of at least 22 morphological and functional parameters at each dose tested.

Out of the 10 embryotoxic substances, 8 were classified correctly, whereas none of the 3 non-embryotoxic compounds was correctly predicted as negative. Thus, the sensitivity of the test system was found to be 80% but the specificity of the assay was only 0%. By adding VASTox's bioanalysis to check compound uptake for the 2 false negatives and an acute toxicity test in zebrafish larvae for the 3 false positives to determine embryotoxicity versus general toxicity, the predictivity may be improved considerably.

This evaluation study points towards the zebrafish embryotoxicity test being a promising method for the early screening of lead compounds during early drug discovery. However, a higher number of compounds needs to be tested to further validate and especially improve specificity of the zebrafish model in order to become an accepted early screening system for embryotoxicity/teratogenicity.

451 ROLE OF THE INHIBITOR OF DNA BINDING-6 (ID6) IN NORMAL AND ALL-TRANS RETINOIC ACID EXPOSED ZEBRAFISH EMBRYO DEVELOPMENT.

C. Villano, J. Hillegass and L. White. Joint Graduate Program in Toxicology, Rutgers University, New Brunswick, NJ.

Id proteins (Inhibitor of DNA Binding) are a class of helix-loop-helix (HLH) proteins that lack a DNA binding domain and function by forming inactive heterodimers with other HLH proteins. The Id proteins promote G1/S phase transition of the cell cycle and are important regulators of lineage commitment and terminal differentiation. Morpholino knockdown of Id6 resulted in pericardial, yolk sac, and/or brain edemas, as well as notochord herniations indicating that Id6 is necessary for proper development of these structures. In addition, we have found that all-trans retinoic acid (atRA) exposure results in increased expression of zebrafish Id6. atRA is a powerful regulator of cell growth and differentiation and is known to result in abnormal embryo development, including truncation of the heart tube and alterations in the midbrain and hindbrain. Id6 in situ hybridization data demonstrate that an increase in Id6 expression is detectable in the posterior heart of atRA-exposed embryos at 48 and 72 hpf. These data suggest that defects in zebrafish heart development following exposure to atRA may result, at least in part, from increased expression of Id6. In human endothelial cells, Ids are involved in vascular endothelial growth factor (VEGF)-induced activation of angiogenesis. Our data show that atRA also induces VEGF expression in the developing zebrafish. Injection of VEGF in zebrafish embryos causes disruption of vessel and heart development, similar to vascular defects we have observed in atRA-exposed embryos, such as pericardial edema and disruption in the formation of the subintestinal vessels and the common cardinal vein. Further evidence that Id6 expression in the developing zebrafish is a target for the atRA signaling pathway is demonstrated by exposure to DEAB, an inhibitor of atRA signaling, which results in reduced Id6 expression. Taken together, these data indicate that Id6 is a key player in atRA signaling in the embryo and that it may be acting through increased expression of VEGF.

452 MATRIX METALLOPROTEINASE-2 AND -9 ARE ESSENTIAL FOR ZEBRAFISH EMBRYOGENESIS AND SERVE AS TARGETS FOR GLUCOCORTICOID EXPOSURE.

J. M. Hillegass, C. M. Villano, L. A. White and K. R. Cooper. Joint Graduate Program in Toxicology, Rutgers, The State University of New Jersey, Piscataway, NJ.

Expression and activity of the matrix metalloproteinases (MMPs) are essential for the extracellular matrix remodeling that occurs during embryonic tissue morphogenesis. The gelatinases MMP-2 and MMP-9 catalyze the degradation of intact type IV collagen and denatured collagens (gelatins). Glucocorticoids (GCs) inhibit MMP gene expression in mammalian cell cultures systems and cause developmental abnormalities in several species. Therefore, we hypothesized that GCs impede normal development through alteration of MMP expression. Microinjection of morpholinos targeting MMP-2 and MMP-9 was utilized to transiently knock down expression and demonstrated the necessity of these genes for normal embryogenesis. Exposure to 100 mg/L dexamethasone (DX) or hydrocortisone (HC) caused an induction of MMP-2 (1.5-1.6 fold over control) and MMP-9 expression (7.6-9.0 fold over control) by 72 hours post fertilization (hpf) as measured by real-time PCR. Further, DX- and HC-treated embryos exhibited a decreased head-

trunk angle, craniofacial abnormalities, truncated body axis, altered somitogenesis, and/or modification of the yolk sac shape and size. *In situ* hybridization (ISH) confirmed GC-induced MMP-2 and MMP-9 expression in treated embryos at 72 hpf. Increased expression was seen in the brain, heart, and anterior kidney. Increased gelatinase activity was observed via *in vitro* zymography in embryos treated with 100 mg/L DX or HC through 72 hpf (3.0-3.1 fold over control). These data confirmed that increased transcript levels detected via real-time PCR and ISH resulted in increased enzyme activity. Through the addition of specific inhibitors, it was determined that this activity was due to the metalloenzymes MMP-2 and MMP-9. Based on these findings, MMP-2 and MMP-9 are critical for normal zebrafish embryogenesis and GCs are capable of modulating their expression, thereby providing insight into how this class of compounds exerts its teratogenic effects.

453 ARYL HYDROCARBON RECEPTOR REGULATED GENE EXPRESSION DURING SYNERGISTIC DEVELOPMENTAL TOXICITY OF POLYCYCLIC AROMATIC HYDROCARBONS IN ZEBRAFISH (DANIO RERIO).

A. Timme-Laragy, C. Cockman, C. Matson and R. T. Di Giulio. *Environment, Duke University, Durham, NC.*

Polycyclic aromatic hydrocarbons (PAH) are pollutants created by the incomplete combustion of carbon, and are increasing in the environment largely due to burning of fossil fuels. PAH occur as complex mixtures, and some combinations have been shown to cause synergistic developmental toxicity in fish embryos, characterized by pericardial edema and craniofacial malformations. Previous studies have indicated this toxicity is regulated by the aryl hydrocarbon receptor (AHR). In this study, we examined the model PAH and AHR agonist β -naphthoflavone (BNF) with and without the AHR partial agonist/antagonist and CYP1A inhibitor α -naphthoflavone (ANF) to determine 1) whether ANF was acting as an AHR antagonist and 2) what other alterations BNF and ANF both alone and in combination had on mRNA expression AHR regulated genes cytochromes P450 (CYP) 1A, 1B1, and 1C1, and the AHR repressor (AHRR2). Zebrafish embryos were exposed from 24-48 hours post fertilization to either BNF, 1-100 μ g/L, ANF, 1-150 μ g/L, a BNF+ANF co-exposure (1 μ g/L + 100 μ g/L), or a DMSO vehicle control. RNA was extracted and examined by quantitative reverse transcription real time PCR. Both BNF and ANF alone caused a dose dependent increase in mRNA of CYP1A, CYP1B1, CYP1C1, and AHRR2, confirming their activities as AHR agonists. In the BNF+ANF co-exposures, expression of these genes was greater than additive, and expression levels of the AHR regulated genes resembled the higher doses of BNF alone, indicating that ANF is not acting as an AHR antagonist and suggesting that ANF's inhibition of CYP1A may be increasing the half-life of the parent compound and toxicity. This study furthers a mechanistic understanding of PAH synergistic toxicity by and will be important for developing more robust tools for risk assessment. This research was supported by the NIEHS-supported Duke University Superfund Basic Research Center (P42 ES10356), Integrated Toxicology and Environmental Health Program (T32 ES07031), and EPA STAR fellowship to A.T.L.

454 OVER-EXPRESSION OF PGC-1 ALPHA DOES NOT CONFER PROTECTION BUT PROMOTES RECOVERY FROM OXIDANT INDUCED RENAL MITOCHONDRIAL AND CELLULAR INJURY.

K. Rasbach and R. G. Schnellmann. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

Renal cell death as a result of mitochondrial dysfunction and compromised bioenergetics is a common consequence of ischemia-reperfusion injury and exposure to nephrotoxins. Promoting the biogenesis of mitochondria is therefore an attractive therapeutic strategy to sustain oxidative phosphorylation and maintain ATP-dependent cellular functions. The goal of this study was to determine if increased mitochondrial biogenesis prior to or following oxidant exposure prevents cell death and/or accelerates recovery of renal proximal tubular cells (RPTC) in primary culture. Over-expression of the mitochondrial biogenesis regulator PPAR- γ cofactor-1 alpha (PGC-1 α) in control RPTC resulted in a 52% increase in mitochondrial number. However, the increased mitochondrial number did not protect mitochondrial function after t-butylhydroperoxide (TBHP) (200 μ M for 30 mins.) exposure, but rather potentiated mitochondrial dysfunction and cell death measured by cellular respiration and propidium iodide staining. In contrast, increased mitochondrial biogenesis following TBHP exposure, accelerated recovery of mitochondrial function 48 hours after TBHP injury. Control RPTC exhibited a 50% reduction in the expression of electron transport proteins (ATP-synthase β and ND), ATP, basal, uncoupled, and ouabain-sensitive respiration, whereas all measures of mitochondrial function in injured RPTC over-expressing PGC-1 α after injury returned to control values. We suggest that the up-regulation of mitochondrial biogenesis prior to oxidant exposure promotes renal cell death whereas the up-regulation of mitochondrial biogenesis following injury accelerates the recovery of mitochondrial and cellular functions.

455 LINDANE-INDUCED MODULATION OF GLUTATHIONE STATUS IN MDCK CELLS DOES NOT RESULT IN NECROTIC INJURY.

A. L. Piskac and M. A. Smith. *Environmental Science, The University of Texas School of Public Health, Houston, TX.*

Lindane (LIN), a chlorinated hydrocarbon pesticide, is toxic to the liver, kidneys, immune, reproductive, and central nervous systems. Oxidative stress has been suggested as a possible mechanism of toxicity, although the mechanism of renal toxicity has yet to be identified. Our laboratory has shown LIN-induced morphological changes indicative of apoptosis, and a concentration-dependent increase and time-dependent decrease in generation of reactive oxygen species (ROS) in distal tubule cells. To determine whether LIN exposure alters cellular glutathione (GSH) levels, MDCK cells were treated with vehicle (DMSO), a known oxidant-stress inducing compound, H₂O₂ (50 μ M), and LIN (10 & 100 μ M). Total GSH was measured using a DTNB microassay after incubating for 15 and 30 min, 1, 2, and 6 hr time points. GSH levels increased above control values 15 min after LIN exposure at both concentrations. From 30 min onward, a time-dependent decline in GSH was noted. Control, vehicle, and H₂O₂-treated cells exhibited similar GSH levels over time. Cells were pretreated with N-acetyl cysteine (NAC) or buthionine sulfoximine (BSO) to evaluate the role of GSH on LIN-induced oxidative stress. Changes in cellular response to LIN exposure were shown after pretreatment with NAC and BSO. NAC enhanced GSH levels, while BSO caused further depletion of GSH. Necrotic injury was assessed by measuring lactate dehydrogenase (LDH) leakage at 15 and 30 min, 1, 2, 4, 8, 24, and 48 hours after LIN treatment. No LDH leakage was observed for all treatments at all time points. This finding corresponds to our previous findings of LIN-induced apoptosis, as opposed to necrosis. Initial elevation in total GSH corresponds to the spike in ROS generation at 15 minutes. The time-dependent decline in ROS generation correlates to the time-dependent depletion of GSH. This decline may be attributed to quenching of free radicals by GSH, thereby decreasing the cellular stores of this antioxidant. ROS generation and alterations in cellular protective mechanisms did not result in necrotic injury.

456 TOXICOGENOMICS ANALYSIS CORRELATES ATTENUATION OF NRF2 FUNCTION WITH RENAL TOXICITY IN THE RAT.

M. D. Lee, W. Hu, D. N. Halbert and M. D. Lee. *Iconix Biosciences, Inc., Mountain View, CA.*

Renal toxicity is a significant cause for clinical failure of drug candidates and for post-marketing withdrawal of approved drugs; however, the mechanisms of chemically-induced renal toxicity are not well understood. In order to gain understanding of the mechanisms of chemically-induced renal toxicity, we first curated 4 key biological pathways focused on kidney function and injury from a thorough review of the literature. Genes in these 4 pathways were then used to systematically query and analyze kidney data in DrugMatrix®, a large-scale contextual microarray gene expression database of drug-treated rat tissues. Data mining revealed a tightly-clustered set of experiments, including treatments with compounds of well documented renal toxicity such as 4,4'-methylenedianiline, 6-mercaptopurine, cerivastatin, rifampin and thalidomide. Pathway analysis revealed that genes involved in TGF- β signaling, PI3K/MAP signaling, inflammation, and oxidative stress response are consistently up-regulated by these compounds, potentially leading to hypertrophy, proliferation, fibrosis and cell death, consistent with renal injuries such as renal tubular necrosis and acute interstitial nephritis that have been reported for some of these compounds. Surprisingly, heme-oxygenase-1 (HO-1), a key cytoprotective mediator of oxidative stress response in kidney, was not up-regulated in these experiments, while many transcription factors that activate HO-1 transcription were consistently up-regulated. In-depth analysis revealed that in these experiments, the function of Nrf2, a key transcription factor that regulates the expression of many genes including HO-1, thioredoxin, and peroxiredoxin, involved in the amplification of the mammalian defense system against oxidative stress, was compromised by the induction of Bach1, a transcriptional repressor of Nrf2. These results suggest that attenuating the anti-oxidative response mediated by Nrf2 via Bach1 induction may be an important mechanism for compound-induced renal dysfunction, and illustrates the value of using gene expression to understand mechanisms of toxicity.

457 A METHOD FOR THE EVALUATION OF SITE-SPECIFIC NEPHROTOXIC INJURY IN THE INTACT RAT KIDNEY USING ETHIDIUM HOMODIMER.

J. Edwards, M. V. Kowal, E. A. Diamantakos and W. C. Prozialeck. *Pharmacology, Midwestern University, Downers Grove, IL.*

As part of our ongoing research to identify the mechanism by which cadmium produces its nephrotoxic effects, we have developed a novel method to quantify proximal tubule epithelial cell viability that involves perfusing the intact rat kidney with

the cell membrane impermeable fluorochrome, ethidium homodimer. The objective of the present study was to determine if this procedure could be used to characterize toxic injury in other regions of the kidney. Rats were treated with the site-specific nephrotoxicants, gentamicin (proximal tubule; 100 mg/kg i.p. per day for 8 consecutive days) and indomethacin (papillus; 20 mg/kg oral gavage, single dose). At the end of the respective treatment periods, ethidium homodimer (5 μ M) was infused (3 ml/min for 10 min) into the left intact kidney while the animal was anesthetized. The kidney was then perfused with a physiologic saline solution, removed, placed in embedding medium, frozen, cryosectioned at a thickness of 5 μ m and ethidium-labeled cells counted. The gentamicin-treated animals exhibited polyuria and proteinuria with no change in urinary creatinine excretion. Indomethacin-treated animals did not show significant differences in either urine volume or urinary protein, but did show significantly lower urinary creatinine levels. Results of the viability assay indicated that gentamicin treatment resulted in proximal tubule cell death that was localized in the cortex of the kidney. Renal cell death resulting from indomethacin treatment was localized primarily in the papillus. However, the kidneys of the indomethacin-treated animals also showed modest evidence of cell death in the cortex and medulla. These results show that this *in situ* viability assay provides a sensitive and accurate way to identify cell death in different regions of the kidney following exposure to the site-specific nephrotoxicants. Supported by Grant RO1-ES006478 from the NIEHS.

458 METABONOMIC EVALUATION OF RENAL PAPILLARY NECROSIS: COMPARISON OF THREE CHEMICALLY-DIVERSE AGENTS.

J. T. Pearce¹, M. Coen¹, H. C. Keun¹, T. D. Ebbels¹, E. C. Holmes¹, J. C. Lindon¹, J. K. Nicholson¹, J. D. Vassallo², G. H. Cantor² and L. D. Lehman-McKeeman². ¹Biomolecular Medicine, Imperial College, London, United Kingdom and ²Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.

NMR-based metabolomics was used to study the metabolic consequences of renal papillary necrosis (RPN), a major cause of renal failure. The mechanism of RPN is not fully understood and is further hampered by the lack of methods to detect its development and progression. Patterns of metabolite changes elicited by three compounds, 2-bromoethanamine (BEA), 2-chloroethanamine (CEA) and N-phenylanthranilic acid (NPAA) were compared. BEA and CEA cause RPN to develop acutely while NPAA requires several days of dosing to manifest a lesion. Sprague Dawley rats (n=30) were given a single IP dose of 15 mg/kg or 150 mg/kg of BEA, or 100 mg/kg or 1000 mg/kg of CEA. NPAA was orally dosed for three days at 200 mg/kg/day. Urine and serum samples were collected at sequential time points up to 168 hours post dose and metabolic profiles were determined using high-resolution NMR. The multivariate classification method, orthogonal-projection on latent structures was applied to NMR spectral data. Passage of time was included explicitly in the models to improve separation of general and specific toxic effects from recovery effects. BEA and CEA demonstrated similar markers of toxicity but the time-course and extent of the metabolic changes differed. Urinary metabolic changes common to BEA and CEA were increased levels of glutaric acid, choline- and N-acetyl moieties together with reduced levels of 2-oxoglutarate, succinate, hippurate and dimethylglycine. In addition for BEA, increased levels of adipic acid, glucose, lactate, alanine, formate and reduced levels of N-methylnicotinamide, dimethylamine and TMAO were identified. The metabolic changes identified for NPAA were much less extensive; reduced levels of 2-oxoglutarate, hippurate and creatinine were identified. Serum metabolic profiles were also compared. These data support the conclusion that NPAA causes RPN by a mechanism distinct from that of BEA and CEA.

459 TOXICOGENOMIC INVESTIGATION OF MECHANISMS AND MARKERS OF NEPHROTOXICITY BY INCORPORATING LASER CAPTURE MICRO-DISSECTION AND A CONTEXTUAL MICROARRAY DATABASE.

A. H. Yang¹, F. Ramiro-Ibanez², C. Fuentealba², A. Vladimirova¹ and B. Jessen². ¹Iconix Biosciences, Mountain View, CA and ²Pfizer Global Research & Development, La Jolla Laboratories, San Diego, CA.

To investigate mechanisms and markers of renal tubular toxicity, SD rats were administered a single i.p. dose of a renal tubular toxicant, *p*-aminophenol (PAP), at 50 and 150 mg/kg. The major histopathological lesions observed were renal tubular dilation, necrosis, and regeneration. Microarray gene expression data from the whole renal cortex and from proximal tubular regions, isolated by laser capture microdissection (LCM), were obtained at 6, 24, and 48 hours. Applying Iconix's Drug Signatures® gene-based biomarker technology to the PAP data revealed positive Signature matches consistent with histopathological and *in-life* findings, and provided a means of addressing mechanisms of toxicity. The use of LCM was more informative than the whole cortex in providing Signature-based evidence of renal injury at low dose. Analysis of genes most consistently perturbed at low dose in LCM but not in cortex revealed prominent repression of mitochondrial oxidative phosphorylation and energy production pathways, likely due to enrichment of affected

cells by LCM. These pathways could reflect events that precede the occurrence of minimal tubular necrosis at low dose. Leveraging the contextual richness of DrugMatrix®, a large-scale reference database of rat microarray experiments, hierarchical clustering was performed on genes commonly perturbed in >60% of experiments with renal tubular injury findings, selected from all kidney experiments in the database (n=395). The majority of PAP experiments fall in a tight cluster enriched with heavy metal toxicants. Oxidative stress and mitochondrial injury are some ways heavy metals can cause renal tubular injury, and may provide additional insight into the mechanisms of PAP toxicity. Taken together, this study demonstrates the utility of genomics and LCM in unraveling mechanisms of drug-induced toxicities, and of using a contextual toxicogenomic database to enhance the depth and breadth of analysis.

460 NITRIC OXIDE-MEDIATED NEPHROTOXICITY IN RATS AFTER ACUTE EXPOSURE TO GENTAMICIN, MERCURY OR CHROMIUM.

R. P. Brown¹, P. L. Goering¹, Y. Zhou¹, T. J. Miller² and J. Zhang². ¹CDRH, U.S. FDA, Silver Spring, MD and ²CDER, U.S. FDA, Silver Spring, MD.

The present study was undertaken to morphologically characterize acute kidney injury in gentamicin (Gen)-, mercury (Hg)-, or chromium (Cr)-treated rats and explore the role of nitric oxide (NO) in renal pathogenesis. Sprague-Dawley rats were injected with Gen (100 mg/kg, sc, daily for 3 days), HgCl₂ (0.25 mg Hg/kg, iv), K₂Cr₂O₇ (5 mg Cr/kg, sc), or vehicle (control). At 24 or 72 hr after the last dose, kidneys were collected and formalin-fixed renal sections were used for histopathologic evaluation, TUNEL assay and immunoperoxidase staining with monoclonal antibodies of inducible nitric oxide synthase (iNOS), endothelial nitric oxide synthase (eNOS), and nitrotyrosine. The severity of renal lesions was assessed using a semiquantitative scale of 0 to 5. Histopathology revealed that Gen-, Hg-, or Cr-induced renal lesions were characterized by epithelial necrosis, degeneration, and regeneration of the proximal convoluted tubules (PCT), tubular dilatation, protein casts, glomerular vacuolization with or without capillary thrombosis, and interstitial lymphocytic infiltration. Renal lesion scores indicated greater severity at 72 hr compared to 24 hr (3.3 vs 1.5, 3.8 vs 3.0, and 4.8 vs 2.8 in Gen-, Hg-, or Cr-treated rats, respectively). TUNEL analysis demonstrated that epithelial apoptosis of the PCT in Gen-, Hg-, or Cr-treated rats was more frequent at 72 hr than at 24 hr. Rats treated with Gen, Hg, or Cr exhibited increased expression of iNOS and nitrotyrosine at the necrotic and apoptotic areas of the PCT, the degree of which correlated with the severity of tubular necrosis and apoptosis and increased with time. The increased expression of eNOS was identified in the endothelial cells of glomerular capillaries. These findings suggest that the cytotoxic effects of Gen, Hg, or Cr on PCT are attributable to the free radical NO formed by iNOS that induces epithelial cell necrosis and apoptosis, whereas the cytotoxic effects of these agents on the glomeruli are attributable to NO from eNOS that causes endothelial cell injury.

461 NITRIC OXIDE-ASSOCIATED NEPHRO-TOXICITY IN JUVENILE RATS TREATED WITH GENTAMICIN.

P. Espandiani¹, T. J. Miller¹, A. Nampton¹, N. P. Clayton², J. P. Hanig¹ and J. Zhang¹. ¹CDER, FDA, Silver Spring, MD and ²NIEHS, Research Triangle Park, NC.

Nonclinical studies suggest that gentamicin (Gen) induces renal tubular apoptosis in rats via several pathways (caspase-3, cytochrome C, nuclear endonuclease and Bax) and that reactive oxygen species may be responsible for Gen-induced nephrotoxicity. To explore the role of nitric oxide, different age groups of SD rats (25, 40, 80 days old) were treated with saline, 50 or 100 mg/kg/daily (ip) for 6 or 14 days. Gen-induced renal injury was evaluated using a semiquantitative scale (0-5). Histopathological evaluation showed that Gen induced degeneration, necrosis, and regeneration in the proximal and distal convoluted tubules, tubular dilatation and protein casts, glomerular vacuolization, and interstitial lymphocytic inflammation and that Gen-induced renal injury is age-, time- and dose-dependent. The immunoreactivity of apoptosis, caspase-3, cytochrome C, iNOS (inducible nitric oxide synthase), and nitrotyrosine was assessed immunohistochemically in the kidneys. The expression of caspase-3, cytochrome C, iNOS, and nitrotyrosine increased with age, time and dose and the levels of the increased immunoreactivity correlated with degree of tubular apoptosis. These findings suggest that nitric oxide may play an important role in Gen-induced nephrotoxicity.

462 KIDNEY INJURY MOLECULE-1 (KIM-1) EXPRESSION DURING ACUTE KIDNEY INJURY INDUCED BY GENTAMICIN, MERCURY, OR CHROMIUM.

P. L. Goering¹, Y. Zhou¹, R. P. Brown¹, M. A. Ferguson³, J. Zhang², T. J. Miller², J. V. Bonventre³ and V. S. Vaidya³. ¹CDRH, U.S. FDA, Silver Spring, MD, ²CDER, U.S. FDA, Silver Spring, MD and ³Brigham and Women's Hospital, Boston, MA.

We previously reported that increases in urinary Kim-1 (U-Kim-1) occurred at lower doses of the nephrotoxicants gentamicin and mercury compared to other routinely-used markers: urinary NAG, BUN and serum creatinine. The objectives

of this study were to determine 1) the temporal relationship between the appearance of U-Kim-1 with routinely-used biomarkers of nephrotoxicity; 2) the correlation of U-Kim-1 and nephropathology; and 3) whether appearance of Kim-1 in urine is specific for renal injury. Sprague-Dawley male rats were injected with a nephrotoxicant (gentamicin, 100 mg/kg, sc, daily for 3 days; HgCl₂, 0.25 mg Hg/kg, iv; or K₂Cr₂O₇, 5 mg Cr/kg, sc), or vehicle (control) and urine collected from each rat prior to and at 0-4, 4-8, 8-24, 24-48, 48-72 h after treatment for assay of Kim-1, NAG, and creatinine. At necropsy (72 h), blood (BUN, creatinine) and kidneys (histopathology) were collected. Results showed that U-Kim-1 was elevated within 24 h after exposure to each nephrotoxicant and remained elevated through 72 h. NAG responses were nephrotoxicant-dependent with elevations occurring early (gentamicin), late (Cr), or no change (Hg). At 72 h after treatment, histopathology indicated injury to ~50% tubules; however, only U-Kim-1 was significantly increased while BUN, serum creatinine and NAG were not different from controls. In rats treated with the hepatotoxicant galactosamine (1.1 mg/kg, ip), serum ALT was increased at 12 and 24 hr, but no increase in urinary Kim-1 was observed. Thus, at nephrotoxicant doses used in this time-course study, elevations in U-Kim-1 occurred within 24 h and were sustained following exposure compared to other biomarkers, correlated with the severity of renal lesions, and were specific for renal injury and not liver injury. U-Kim-1 appears to be a sensitive and tissue-specific biomarker that will improve detection of early acute kidney injury following exposure to nephrotoxic chemicals and drugs.

463 COMPARISON OF URINARY BIOMARKERS TO DETECT METAL-INDUCED NEPHROTOXIC EFFECTS IN GENTAMICIN-PRETREATED RATS.

Y. Zhou¹, V.S. Vaidya³, M. Shaw⁴, J. Keenan⁴, M. A. Ferguson³, J. Zhang², R. P. Brown¹, J. V. Bonventre³ and P.L. Goering¹. ¹CDRH, U.S. FDA, Silver Spring, MD, ²CDER, U.S. FDA, Silver Spring, MD, ³Brigham and Women's Hospital, Boston, MA and ⁴Biotrin Int'l Ltd., Dublin, Ireland.

Patients with subclinical renal injury (SRI) represent a subpopulation that is potentially more susceptible than healthy subjects to further kidney damage from nephrotoxic compounds. We have developed and validated a rat model of SRI using doses of gentamicin (Gen) that do not produce overt renal failure. Administration of mercury (Hg) or chromium (Cr) to SRI rats results in the development of acute renal failure at doses that do not produce overt effects following administration of these metal doses to healthy control animals. The objective of this study was to determine which urinary biomarkers (NAG, Kim-1, α GST, GST-Yb1 and RPA-1) are best able to detect the effects of either Hg or Cr in Gen-pretreated rats. To induce SRI, male Sprague-Dawley rats were dosed (sc) daily for 3 d with 100 or 150 mg/kg Gen; 24 h after the 3rd injection, rats were injected with HgCl₂ (0.1 and 0.25 mg Hg/kg iv) or K₂Cr₂O₇ (2.5 and 5 mg Cr/kg sc). No interactive effects were seen following administration of 100 mg/kg Gen followed by the lowest dose of either Hg or Cr. In contrast, injection of 150 mg/kg Gen followed by the lower dose of Hg resulted in a marked increase in urinary levels of α GST, GST-Yb1, and NAG. No increases in urinary levels of Kim-1 or RPA-1 were observed, although these levels were increased after exposure to Gen alone. The potentiation of Hg-induced nephrotoxicity in SRI rats would not have been observed if only traditional markers of nephrotoxicity had been used in the study (blood creatinine and BUN). A similar interactive effect was observed at the higher doses of Cr (α GST, GST-Yb1, NAG) and Hg (α GST, GST-Yb1) in rats pretreated with 150 mg/kg Gen. These results suggest that the ability to detect a potentiation of metal-induced nephrotoxic effects in animals with SRI, compared to healthy control animals, depends on the biomarker selected, the agent producing the nephrotoxicity, and the dose of the nephrotoxic agent.

464 ALPHA-GST, GST-YB1, RENAL PAPILLARY ANTIGEN-1 (RPA-1) AND KIDNEY INJURY MOLECULE-1 (KIM-1) ARE SENSITIVE BIOMARKERS OF SUB-CLINICAL RENAL INJURY IN GENTAMICIN-TREATED RATS.

M. Shaw¹, V. Vaidya⁴, Y. Zhou², M. Ferguson⁴, J. Zhang³, R. Brown², J. Keenan¹, J. Bonventre⁴ and P. Goering². ¹Biotrin International Ltd., Dublin, Ireland, ²CDRH, U.S. FDA, Silver Spring, MD, ³CDER, U.S. FDA, Silver Spring, MD and ⁴Brigham and Women's Hospital, Boston, MA.

Elevated serum creatinine and BUN are typically used as indices of acute renal failure; however, greater than 50% of the GFR could be lost before elevations of these markers are detected. Since limitations exist with the use of these markers of kidney damage, and since early detection of even subtle renal injury is important for the implementation of renal protective strategies, there is a need to identify more sensitive biomarkers of altered renal function. The objective of this study was to compare the ability of routinely used biomarkers of renal damage (blood: creatinine and BUN; urine: NAG) and a suite of relatively new urinary biomarkers, notably, α GST, GST-Yb1, renal papillary antigen-1 (RPA-1), and kidney injury molecule-1

(Kim-1) to detect renal injury in rats injected with gentamicin (Gen). Male Sprague-Dawley rats were injected with Gen at 0, 50, 100, 150, 200 or 300 mg Gen/kg, sc, daily for 3 d. Rats were placed in metabolism cages after the 3rd injection and urine collected for 24 h, after which blood and kidneys were removed. Dose-dependent increases in the severity of histopathologic lesions were observed using a semiquantitative scale of 0 to 5. Scores were controls, 0; 50-150 mg/kg, 1.5-2.5; 200-300 mg/kg, 4-5. No increases in BUN, blood creatinine, and urinary NAG were observed except at the highest dose. In contrast, dose-dependent increases in urinary α GST, GST-Yb1, RPA-1, and Kim-1 were observed at doses $\geq$ 100 mg/kg. Increases in urinary markers following injection of 100 or 150 mg/kg gentamicin (no elevation of BUN and creatinine) were 3- to 5-fold for α GST, GST-Yb1, and RPA-1, and 10- to 20-fold for Kim-1. Since elevated levels of α GST, GST-Yb1, RPA-1 and Kim-1 were detected in urine of rats after injection of Gen doses that do not produce overt renal failure, these endpoints have potential to serve as sensitive biomarkers of renal injury.

465 LOW DOSE OF DICHROMATE ALTERS PARACELLULAR AND TRANS-CELLULAR TRANSPORT ALONG THE RAT NEPHRON.

L. Arreola-Mendoza¹, J. L. Reyes², P. Poujeol³, G. Jacquillet³, M. Cougnon³ and L. M. Del Razo¹. ¹Toxicology, Cinvestav-IPN, Mexico D.F., Mexico, ²Physiology & Biophysics, Cinvestav-IPN, Mexico D.F., Mexico and ³Physiologie Cellulaire et Moléculaire, Université de Nice, Nice, France.

Potassium dichromate (PD) at mM dose induces renal transport disorders. However, there is scant information of the effects of this metal on whole kidney function at μ M dose. This study investigates the effect of PD on the transport of mono and divalent cations, glucose, total proteins and phosphate along the nephron, in rats i.v. infused. A tracheotomy was performed on anesthetized adult Wistar female rats. One catheter was inserted into the left jugular vein for infusion (inulin-FITC, with or without PD), other into the femoral artery for blood sampling and arterial blood pressure recording, and another into left ureter for urine collection. PD was infused during 1 h to attain in plasma 5 μ M. Glomerular filtration rate (GFR) was estimated from inulin-FITC clearance (fluorometric analysis), the renal solute transport was evaluated through fractional excretions (FE) of Na⁺, K⁺, Ca²⁺, Mg²⁺ (AAS), phosphate (colorimetric method), glucose (hexokinase method), proteins and urinary and serum osmolarities (vapor pressure). Experiments were performed in three stages in the same animal: 1) control (inulin-FITC), 2) exposed (PD with inulin-FITC) and 3) recovery (inulin-FITC). Infusion of PD induced a decrease in the inulin U/P ratio and GFR. Renal transport of cations was also affected: FE of Na⁺ and K⁺ increased, whereas those of Ca²⁺ and Mg²⁺ decreased. FE of glucose augmented, proteins and phosphate decreased. Reabsorption of Na⁺, glucose and phosphate were transiently decreased and transport of Ca²⁺ and Mg²⁺ were increased by PD infusion. Interestingly in the recovery period all parameters return to the control values except the FE of Ca²⁺ and Mg²⁺. These results show that the infusion of PD to low doses caused deleterious effects on the transcellular and paracellular transport along the nephron. Further studies are required to evaluate the effects of PD into the distal transport of cations across the paracellular pathway.

466 REVERSIBLE BINDING OF 14C-HEXAMETHYLDISILOXANE (14C-HMDS)/METABOLITES TO ALPHA 2U-GLOBULIN IN MALE F344 RATS.

J. Y. Domoradzki, L. M. Thackery, D. A. McNett, C. M. Sushynski and K. P. Plotzke. Health and Environmental Sciences, Dow Corning Corporation, Auburn, MI.

Studies with Fischer 344 female and male rats exposed to HMDS have demonstrated the following in male kidney; increased protein droplets, the presence of alpha 2u-globulin (α 2u) by immunohistochemical staining, increased tubular regeneration, hyaline and granular casts, tubular and papillary mineralization, kidney lesions and renal tumors. To investigate the reversible binding of HMDS/metabolites to α 2u, 14C-HMDS was administered to rats in corn oil by oral gavage at 100 mg/kg bw. Kidney cytosol was prepared using an improved procedure to minimize loss of volatile/lipophilic siloxanes. Established direct and indirect approaches that demonstrate a chemical- α 2u interaction such as gel filtration, DEAE anion exchange chromatography and headspace gas chromatography (GC) were unsuccessful in characterizing binding between HMDS/metabolites with α 2u most likely due to the extreme hydrophobic and volatile nature of HMDS. A new approach using Hydrophobic Interaction Chromatography (HIC) was developed to isolate the α 2u specifically found in the kidneys of male rats but not female rats. A dot blot using polyclonal antibodies raised against purified rat α 2u-urinary globulin was used to positively identify the presence of α 2u in the fraction isolated by HIC. Radioactivity co-eluting with the α 2u peak was monitored to determine the binding of HMDS/metabolite to the protein. D-limonene oxide, a chemical with a high

affinity for $\alpha 2u$, displaced/reversed the binding of HMDS/metabolites to $\alpha 2u$ in samples of male rat kidney cytosol. Reversed phase-high pressure liquid chromatography and GC-mass spectrometry analysis of solvent extracts of HMDS/metabolites from kidney cytosol provided additional evidence that HMDS/metabolites were indeed reversibly bound to $\alpha 2u$ in male rats. Reversible binding coupled with the observed nephropathy and renal tumors and the observation of $\alpha 2u$ in kidneys by immunohistochemical staining support the criteria of EPA and IARC for an $\alpha 2u$ mechanism of male rat kidney tumors induced by HMDS.

467 AMINOACYLASE III MEDIATED CYTOTOXICITY OF THE TRICHLOROETHYLENE-DERIVED MERCAPTURIC ACIDS IN MOUSE PROXIMAL TUBULE CELLS.

A. Pushkin¹, K. Scholz², W. Dekant², D. Newman¹, N. Abuladze¹, G. Bondar¹ and I. Kurtz¹. ¹D. Geffen School of Medicine at UCLA, Los Angeles, CA and ²University of Würzburg, Würzburg, Germany.

Trichloroethylene (TCE) and other halogenated alkenes are known environmental contaminants with cytotoxic and nephrotoxic effects, and potential carcinogens. Their metabolism via the mercapturate metabolic pathway was shown to lead to their detoxification. The final products of this pathway, mercapturic acids or N-acetyl-L-cysteine S-conjugates are secreted in the lumen in the renal proximal tubule. The proximal tubule may also deacetylate mercapturic acids, and the resulting cysteine S-conjugates are transformed by cysteine S-conjugate β -lyases to nephrotoxic reactive thiols. The specificity and rate of mercapturic acid deacetylation may determine the toxicity of certain mercapturic acids whereas enzymology of this process is not known in details. In the present study we characterized kinetics of the recently cloned and purified to homogeneity mouse aminoacylase III (AAIII) towards wide specter of halogenated mercapturic acids and N-acetylated amino acids. In general, V_{max} of AAIII was significantly larger with chlorinated and brominated mercapturic acids whereas fluorination significantly decreased V_{max} . The enzyme deacetylated the mercapturic acids derived from the TCE metabolism, N-acetyl-S-(1,2-dichlorovinyl)-L-cysteine (NA-1,2-DCVC) and at higher rate N-acetyl-S-(2,2-dichlorovinyl)-L-cysteine (NA-2,2-DCVC). Both mercapturic acids induced cytotoxicity in the mouse proximal tubule derived mPCT cells, which exogenously expressed AAIII. An inhibitor of β -lyase, aminooxyacetate, significantly decreased the cytotoxicity. The toxic effect of NA-2,2-DCVC was smaller than NA-1,2-DCVC indicating that factors other than the AAIII intracellular activity may be involved in mediating the cytotoxicity of these mercapturic acids. Our results indicate that in the proximal tubule cells AAIII plays an important role in deacetylating NA-1,2-DCVC and 2,2-DCVC and this process may be involved in their cyto- and nephrotoxicity.

468 STRUCTURE OF DIMERIC AMINOACYLASE III.

S. Ryazantsev, N. Abuladze, D. Newman, G. Bondar, I. Kurtz and A. Pushkin. D. Geffen School of Medicine at UCLA, Los Angeles, CA. Sponsor: W. Dekant.

Aminoacylase III (AAIII) plays an important role in deacetylation of acetylated amino acids and N-acetylated S-cysteine conjugates (mercapturates) of halogenated alkenes and alkanes in kidney. AAIII was recently cloned from mouse kidney and partially characterized. *In vitro* mouse AAIII (35 kDa) is a mixture of tetramers and dimers. In the present work the AAIII dimer was shown to be enzymatically active and was studied using electron microscopy, three-dimensional (3D) reconstruction and limited trypsinolysis. The 3D reconstruction of the micrographs of negatively stained AAIII dimer particles was performed using EMAN software from Steven Ludtke (Baylor College of Medicine). In the resulting 12.5 Å resolution model, the AAIII monomer was subdivided into two unequal domains. Only proximal ends of the domains participated in the dimer formation. Protein protrusions from both monomers surrounded the central cavity in the dimer, creating a "cage", which might be a substrate-binding site. In agreement with the model, limited trypsinolysis identified a ~9 and ~25 kDa fragments. By Western blotting the smaller domain was localized N-terminally and the larger domain C-terminally. These domains did not demonstrate the AAIII activity separately or together indicating that a specific structure is necessary for the catalysis.

469 MITOCHONDRIAL CALPAIN 10 REGULATES ATP SYNTHESIS IN RENAL PROXIMAL TUBULE CELLS.

M. Covington, D. D. Arrington and R. G. Schnellmann. Department of Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.

Calpains are a family of Ca^{2+} -activated cysteine proteases that have been implicated in numerous physiological and disease processes. Recently our laboratory has determined that calpain 10 is located in the mitochondria and is active in the mitochondrial matrix. We have developed an adenoviral-delivered calpain 10 shRNA to

knockdown calpain 10. To determine the physiological role of mitochondrial calpain 10, we infected renal proximal tubular cells (RPTC) with calpain 10 shRNA and examined mitochondrial function. After 3 days of infection, mitochondrial calpain 10 decreased to undetectable levels. While cytosolic calpain 10 levels did not decrease until 5 days after infection, measurement of mitochondrial membrane potential and oxygen consumption revealed no differences in control, virus-scramble, or calpain 10 shRNA infected cells. However, cellular ATP levels increased 25% four days and 50% five days after knockdown of calpain 10. Three days after calpain 10 shRNA infection there was an increase in ATP synthase β subunit of the F1 complex in the mitochondria that was not seen in the control or scramble shRNA treated cells. In addition, the loss of mitochondrial calpain 10 was correlated with increased protein expression and phosphorylation of AMP-activated protein kinase (AMPK), which is known to mediate transcription of respiratory subunits and components of the F1/F0 ATPase. In summary, we suggest that mitochondrial calpain 10 regulates cellular ATP levels under basal conditions.

470 CHLOROFORM RENAL TOXICITY DOES NOT REQUIRE HEPATIC CYTOCHROME P450-DEPENDENT CHLOROFORM METABOLISM IN MICE.

C. Fang, M. Behr, F. Xie, H. Luo, W. Yang, X. Ding and J. Gu. Wadsworth Center, Albany, NY.

Chloroform, which can be generated by chlorination of drinking water, can cause hepatic and renal toxicity in a number of species. Chloroform is believed to be metabolically activated by P450 to form phosgene, which targets cellular macromolecules to initiate toxicity. It has been proposed that nephrotoxic chloroform metabolites are produced by P450 enzymes within the kidney, leading to damages in the proximal tubule, although direct *in vivo* evidence for the contribution of renal P450s in chloroform-induced nephrotoxicity has not been reported. The aim of this study was to determine whether chloroform renal toxicity persists in a conditional knockout mouse model (the liver-Cpr-null mouse), in which there is a liver-specific deletion of the P450 reductase gene. We compared the extent of chloroform-induced renal toxicity in wild-type and the liver-Cpr-null mice. The levels of blood urea nitrogen (BUN), and histopathological changes in the kidney, were examined at 24 hr following an oral dose of chloroform at 150 or 300 mg/kg. Mice in the vehicle control groups received corn oil only. At the 150 mg/kg dose, the levels of BUN were three times higher in the exposed group than in the vehicle-treated group for the liver-Cpr-null mice, but were not different between exposed and vehicle-treated groups for the wild-type mice. Furthermore, lesions were found in the proximal tubules of the liver-Cpr-null, but not the wild-type, mice. At the chloroform dose of 300 mg/kg, kidney toxicities were observed in both mouse strains, but the severity of toxicity, as well as the extent of elevation of BUN levels, were greater in the liver-Cpr-null than in the wild-type mice. These findings indicate that the loss of hepatic P450-dependent chloroform metabolism does not protect the kidney from chloroform-induced renal toxicity, suggesting that renal P450-dependent metabolism plays an important role in chloroform toxicity in the kidney. (Supported in part by NIH grant ES07462).

471 SERINE PROTEASE INHIBITOR TREATMENT AMELIORATES ANTISENSE OLIGONUCLEOTIDES (ASO)-INDUCED RAT NEPHROPATHY.

L. Shen, R. Fey, G. Hung, S. P. Henry and A. A. Levin. Toxicology, ISIS Pharmaceuticals, Carlsbad, CA.

Glomerular proteinuria is associated with ISIS104838 treatment in rats. It does not appear to be related to ASO induced off-target effect, proinflammatory effect, immune deposition or complement activation. Inhibitors of several classes of protease were examined as part of the mechanistic studies. Rats were given single dose of ISIS104838 at 500 mg/kg on Day 1. Serine protease inhibitors (PIs) (AEBSF and Aprotinin), cysteine PI (E-64), or metallo PI (doxycycline) were given daily on week 1, and 3-times a week on weeks 2-3. Urine protein/creatinine (P/Cr) was monitored weekly. Glomerular morphology (H&E), α -dystroglycan (α -DG) staining (IHC), urine and plasma total protease activities were determined. A single dose of ISIS104838 at 500 mg/kg induced glomerular proteinuria with P/Cr>40 after 3 weeks. IHC revealed decreased staining of α -DG, prior to glomerular changes. Both plasma and urine total protease activities were elevated concurrently with urine protein increases. Non-toxic ASO ISIS141923 does not affect protease activities in either plasma or urine. Serine PI dose-response study showed a complete inhibition of glomerular proteinuria in high-dose serine PIs treated group and 60% reduction of urine protein in low-dose group after 3 weeks of treatment. Part of the high-dose group were kept for continuous monitoring urine protein changes without additional serine PI treatment. These rats briefly developed proteinuria (P/Cr=15) after 2 weeks but were able to recover eventually with P/Cr=3. In another study, daily treatment of serine PIs for the first week of the study also showed

benefit, suggesting the serine protease activation is the initiating event for ISIS104838-induced glomerular injuries. In both studies, serine PI treatment partially preserved glomerular morphology and α -DG staining, whereas cysteine or metallo PIs showed no effect. Current data suggest the causative role of serine protease in ISIS104838-induced kidney injury, most likely due to the systemic or local proteolytic events that are unique to the rats.

472 UNIQUE EFFECTS OF ANTISENSE OLIGONUCLEOTIDE (ASO) TREATMENT IN THE RAT KIDNEY.

S. P. Henry, L. Shen, K. K. Stickland, R. Fey, G. Hung and A. A. Levin.
Toxicology, ISIS Pharmaceuticals, Carlsbad, CA.

The effects of ASO on kidney in rat are distinct relative to mouse, monkey and human. Renal toxicity in the rat has been investigated using ISIS 104838, a 2nd-generation ASO targeted against human TNF α , and control ASO ISIS 141923 at 30, 60 and 150 mg/kg/wk. Kidney effects were assessed by urine chemistry and histopathology. Both ASOs induced tubular proteinuria within the first week of treatment [protein to creatinine (P/C) ratio <10]. Tubular proteinuria was independent of sequence and reversible upon cessation of treatment. ASO uptake by proximal tubule epithelial cell is an endocytic process, the same process and cell responsible for low MW protein reabsorption in kidney. ASO-induced tubular proteinuria is probably due to a competition for uptake or interference of receptor-protein interaction. Tubular proteinuria is not attributed to tubular degeneration/regeneration in these rats. A small subset of ASOs also induces glomerular proteinuria in rat at doses ≥ 30 mg/kg/wk after 4-6 weeks [P/C ratio >10]. In contrast to the tubular proteinuria, the high grade proteinuria is highly sequence dependent. The high grade proteinuria is associated with thickening of the glomerular basement membrane (GBM) and focal glomerular sclerosis. Ultrastructural changes revealed podocyte degeneration and fusion of foot processes. Decreased staining of α -dystroglycan (DG), a podocyte associated protein, has been found prior to glomerular damage. These renal effects have not been observed in mice, monkeys or man. In monkey, no increase of P/Cr ratio, no change in glomerular morphology and no decrease in α DG staining was observed after 13 weeks treatment of ISIS104838 at 35 mg/kg/wk or 4 weeks treatment at 140 mg/kg/wk. Rats in general are more sensitive to glomerular damage with aging rat nephropathy a commonly encountered lesion in laboratory rats. The present data clearly suggest the ASO-induced the kidney effects are highly sequence specific and unique to rats.

473 PROTEOMIC ANALYSIS OF THE EFFECTS OF S-(1, 2-DICHLOROVINYL)-L-CYSTEINE-INDUCED ACUTE RENAL FAILURE.

M. C. Korrapati¹, J. Chilakapati¹, F. A. Witzmann², R. Chundury², E. A. Lock³ and H. M. Mehendale¹. ¹Toxicology, ULM, Monroe, LA, ²Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN and ³Biomolecular Sciences, Liverpool John Moores University, Liverpool, United Kingdom.

It has been shown that renal tissue repair stimulated by a low dose of S-(1, 2-dichlorovinyl)-L-cysteine (15 mg DCVC/kg, ip) 72 h prior administration of a normally lethal dose (75 mg/kg, ip), protects mice from acute renal failure (ARF) and death (autoprotection). Objective of the present study was to identify the proteins indicative of DCVC-induced nephrotoxic mechanisms of autoprotection. Male mice (25-29 g) received distilled water (10 ml DW/kg), low, high, and high dose of DCVC after priming. Renal dysfunction and injury were assessed at 36 h after DCVC in low dose, high dose, and autoprotected mice (36 h after high dose of DCVC), by assessing plasma creatinine and renal histopathology, respectively. Proteins from the whole kidney homogenates at 36 h in DW-treated, low dose, high dose, and autoprotected mice were separated by two dimensional electrophoresis and quantified. Proteins significantly altered by DCVC ($p \leq 0.01$) in low dose, high dose, and autoprotected mice when compared to DW controls, were quantified. Expression of 18 common proteins was maximally changed (≥ 10 fold) in all the groups compared to controls. These proteins were conclusively identified by LC-MS/MS of peptide digests and by gel matching. These 18 proteins are involved in several biochemical processes, such as stress response, fatty acid transport, protein repair, protein turnover, and energy metabolism. ATP levels were significantly reduced after the high dose of DCVC when compared to low dose alone and autoprotected mice. These findings suggest that proteomic studies of experimental animal models like DCVC-induced ARF and nephro-autoprotection may be useful in understanding molecular mechanisms of injury and recovery following ARF-bound injury (Supported by DK 61650).

474 NEPHROTOXICITY INDUCED BY N-(3, 5-DICHLOROPHENYL)-3-HYDROXYSUCCINAMIC ACID: EFFECT OF DIMETHYL SULFOXIDE IN THE VEHICLE.

G. O. Rankin, S. K. Hong, J. G. Ball, M. A. Valentovic and D. K. Anestis.
Pharmacology, Marshall University, Huntington, WV.

The agricultural fungicide N-(3,5-dichlorophenyl)succinimide (NDPS) induces selective nephrotoxicity in male rats at intraperitoneal (ip) doses of 0.4 mmol/kg or greater. NDPS nephrotoxicity is mediated by metabolites arising from oxidation of the succinimide ring. One NDPS metabolite, N-(3,5-dichlorophenyl)-3-hydroxy-succinimide (3-NDHSA), was a nephrotoxicant at doses lower than NDPS, but heating of the sesame oil vehicle was required to achieve solution. The purpose of this study was to determine the effect of the use a combination of dimethyl sulfoxide (DMSO) in sesame oil as a vehicle that did not require heating to provide 3-NDHSA in solution prior to administration. Male Fischer 344 rats (4 rats per group) were administered 3-NDHSA (0.1, 0.2 or 0.4 mmol/kg, ip) or vehicle (25% DMSO in sesame oil; 2.5 ml/kg) and renal function monitored for 48 hr. No evidence of nephrotoxicity was observed in the 0.1 mmol/kg treatment group. In the 0.2 mmol/kg treatment group, transient diuresis and proteinuria were observed. In the 0.4 mmol/kg treatment group, marked nephrotoxicity was observed characterized by diuresis, proteinuria, increased kidney weight and blood urea nitrogen (BUN) concentration, and proximal tubular necrosis. These results demonstrate that use of a DMSO/sesame oil vehicle reduces 3-NDHSA nephrotoxicity. Supported by NIH Grant DK31210.

475 NEPHROTOXICITY OF EXTRACT FROM FUNGI DERMOCYBE SANGUINEA CONTAINING ANTHRAQUINONES.

K. V. Sivak and E. E. Lesiovskaya. *The Institute of Toxicology, St Petersburg, Russian Federation.* Sponsor: K. Khamidulina.

The toxic action of orellanine and several cortinarines from *Cortinarius speciosissimus* is very well known. Until recently the nephrotoxicity of *Dermocybe sanguinea* was at issue. The chemical composition of *D. sanguinea* presents 5.3% water soluble anthraquinones, especially emodin and dermocybin in O-glycosyl forms. Acute effects of *D. sanguinea* extract 1:1 (DSE) were evaluated on rats. Rats received a dose of DSE (10 ml/kg, p.o.) on day. At 24, 48, 96 h after the administration with DSE, urine, blood and kidney samples were collected. Normal Wistar-rat kidney, urine and blood samples were examined prior to the study. Creatinine and urea levels in urine and plasma were determined. Active tubular secretion (ATS) was determined by Rowntree-Geraity method. The kidneys were examined histologically. Exposure with DSE caused a decrease of ATS at 58 and 46% after 24 and 96 h, respectively. Plasma creatinine and urea nitrogen levels were increased after 48 h. Diuresis and urine creatinine and urea nitrogen levels were decreased after 96 h. In this dose group degenerative lesions were localized in the large segment of the proximal tubules and include lymphohistiocytic infiltrates in the interstitial area. The results of this study implicate that the extract of *Dermocybe sanguinea* was altered of rat's kidneys. The authors conclude that the acute intoxication of *Dermocybe sanguinea* may be associated with nephrotoxicity of natural anthraquinones.

476 MECHANISTIC TOXICANT PATHWAYS FOR ROTENONE AND 7-BUTYL HYDROPEROXIDE IN RAT RENAL CORTICAL SLICE CULTURES.

A. G. Aslamkhan, D. A. Meacham and J. W. Lawrence. *Safety Assessment, Merck & Co., West Point, PA.* Sponsor: N. Bhandari.

The precision-cut renal cortical slice culture model is a unique in vitro tool that maintains the 3-dimensional cell/matrix interactions found in the kidney in vivo. The purpose of this study was to characterize biochemical response of this culture model to two diverse toxicant classes, namely a mitochondrial respiratory chain inhibitor (rotenone) and a pro-oxidant (*p*-butyl hydroperoxide or tBHP). A dose response was performed in precision-cut renal cortical slices prepared from male Sprague-Dawley rats and cultured on screens in a roller incubator for 24 hours at seven concentrations between 0.1-300 μ M for rotenone and 1-10,000 μ M for tBHP. Two hours before harvesting slices, radiolabeled ³H-leucine and ¹⁴C-tetraethylammonium chloride (¹⁴C-TEA) were added to the culture media. After the incubation period, media was collected and assayed for lactate dehydrogenase (LDH) and alkaline phosphatase (ALP) activities (indices of cytotoxicity) and nitrate products [nitric oxide (NO) index]. The slices were harvested and content of ATP, GSH, protein, thiobarbituric acid-reactive substances [lipid peroxidation (LPO) index], organic cation transport (NMeN⁺-sensitive ¹⁴C-TEA uptake) and protein synthesis (acid-insoluble ³H-leucine incorporation) were determined. The LDH release response generally mimicked the ALP release response. Maximal ALP and LDH release occurred at 1 μ M rotenone and 1 mM tBHP. NO production was moderately increased by tBHP treatment (2.5 fold), but unchanged by rotenone treatment. Similarly, LPO was markedly increased (7 fold) at cytolytic concentrations of tBHP, and only moderately (2 fold) increased in rotenone treated samples. Profound declines in ATP, organic cation transport, protein synthesis, and GSH

were observed at non-cytolytic (< 20% maximal LDH release) doses (0.1 μ M) of rotenone; whereas only cytolytic concentrations (> 1 mM) of tBHP elicited these declines. This data suggests these two diverse toxicants exert effects on discrete mechanistic pathways.

477 EPIDERMAL GROWTH FACTOR RECEPTOR REGULATES DE-DIFFERENTIATION/RE-DIFFERENTIATION IN REGENERATING RENAL PROXIMAL TUBULAR CELLS FOLLOWING OXIDANT INJURY.

M. Hallman^{1,2} and R. G. Schnellmann^{1,2}. ¹Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC and ²Cell and Molecular Pharmacology, Medical University of South Carolina, Charleston, SC.

Repair of the injured renal epithelium is thought to be mediated by the surviving renal proximal tubule cells (RPTC) which must dedifferentiate to allow the proliferation and migration necessary for epithelial regeneration. RPTC then redifferentiate to restore tubular function. Current models suggest epidermal growth factor receptor (EGFR) activation, subsequent to p38 mitogen activated protein kinase (p38), or transforming growth factor- β 1 (TGF- β 1) is required for dedifferentiation characterized by vimentin expression and the spindle morphology. However, the mechanisms of the redifferentiation have not been investigated; therefore, a model of redifferentiation using rabbit RPTC in primary cultures was developed. The dedifferentiated phenotype was induced by treatment with 1 mM H₂O₂ for 5 hours and persisted > 48 hr. Redifferentiation occurs from 72 to 120 hours as indicated by a decrease in vimentin expression and the return of control epithelial morphology. Inhibition of EGFR by AG1478 during dedifferentiation (24 hr post H₂O₂) restored epithelial morphology and decreased vimentin expression to control levels at 48 hours. Conversely, EGF increased vimentin expression and produced the spindle morphology at 48 hours. The p38 and TGF- β 1 receptor inhibitors (SB 203580 and SB431542, respectively) had no effect on redifferentiation following H₂O₂ injury. These experiments represent a new model for the investigation of RPTC redifferentiation following acute injury and reveal that the dedifferentiated phenotype is maintained following injury by EGFR activation independent of p38 and the TGF- β 1 receptor.

478 COMPOUND-INDUCED CRYSTALLURIA DOES NOT PREDICT OCCURRENCE OF OBSTRUCTION NEPHROPATHY IN FEMALE RATS.

C. E. Riordan, P. Caplazi, A. Salari, K. Brown, R. Killion, M. Irwin, M. Albassam, S. Platz, S. Chanda and K. Kolaja. Roche Palo Alto, LLC, Palo Alto, CA.

Oral administration of compound A induced crystalluria in rats and dogs. Compound A contains a sulfonamide moiety, has poor, pH-dependent aqueous solubility and is renally eliminated. Urinary calculi and associated obstruction nephropathy was noted only in female rats. Administration of the compound to Beagle dogs resulted in crystalluria without renal lesions. Follow-up studies in rats were conducted to understand the association between crystalluria and calculi formation, determine the chemical nature of the urinary crystals, and identify putative biomarkers of precipitate/calculi-induced urinary tract lesions. In rats, doses $\geq$ 100 mg/kg/day resulted in marked crystalluria in all animals. Crystals were identified as compound A by confocal dispersive Raman microscopy. At high doses, lesions in the urinary tract consistent with calculus formation and obstruction nephropathy were observed in female rats after 7 days of treatment. Gross lesions included calculi and/or white precipitates in kidney, ureters and urinary bladder, renal pelvic and ureteral dilatation, and mucosal hemorrhages in ureters and bladder. Correlating microscopic renal lesions included tubular dilatation with epithelial degeneration, mucosal hemorrhages, pelvic dilatation and urothelial hyperplasia. Crystalline precipitates within the renal tubules, often sufficient enough to occlude the papillary ducts, were noted in kidney sections and visualized under polarized light in frozen sections. Urine and serum chemistry and additional renal injury biomarker panels reflected acute renal failure in affected animals; however no predictive parameters were identified as judged by absence of these markers in animals that had crystalluria but no histopathological changes. Conclusion: Precipitation of crystals and formation of calculi in the kidney, ureters, and urinary bladder in rats was due to the poor solubility of compound A at physiological pH and high concentrations of the compound achieved in the rat urine.

479 MECHANISMS OF BROMIDE- AND BROMATE-INDUCED KIDNEY AND LIVER CELL DEATH.

D. De Silva¹, J. Fisher² and B. S. Cummings¹. ¹Pharmacology and Biomed. Sciences., University of Georgia, Athens, GA and ²Environment Health Sciences., University of Georgia, Athens, GA.

The mechanisms of bromide (Br⁻) and bromate (BrO₃⁻)-induced death in Normal Rat Kidney (NRK) and liver cell (CRL1469) lines was investigated. Cell death was assessed based on the staining of 3-(4, dimethylthiazolyl)-2, 5-diphenyltetra-

zolium bromide (MTT), cell morphology, annexin V and propidium iodide (PI) staining and cell cycle analysis. Both BrO₃⁻, (added as KBrO₃) and Br⁻ (added as NaBr) induced concentration-dependent decreases in MTT staining after 48 hr in kidney and liver cells. However, BrO₃⁻ decreased MTT staining at lower concentrations (0.1 to 1.6 mg/mL) than Br⁻ (1.6 to 25.6 mg/mL). Further, BrO₃⁻, but not Br⁻, induced greater decreases in MTT staining in kidney cells compared to liver cells. These data were confirmed by analysis of cell morphology, which demonstrated that concentrations of BrO₃⁻ as low as 0.2 mg/mL induced alterations in kidney cell morphology, compared to 0.8 mg/mL in liver cells. The role of the sodium iodide symporter (NIS) in cell death was investigated by exposure of cells to the NIS inhibitor NaClO₄ (20 mM). Treatment with NaClO₄ prior to exposure to either BrO₃⁻ or Br⁻ increased MTT staining in kidney cells, but not liver cells. To study the mechanisms of cell death, the effect of BrO₃⁻ on annexin and PI staining and cell cycle was assessed in kidney cells. BrO₃⁻ exposure increased both annexin V and PI staining in tandem, suggesting that cell death was primarily mediated by necrosis as opposed to apoptosis. Cell cycle analysis demonstrated that BrO₃⁻ exposure doubled the percentage of cells in G2-M, which was not inhibited by NaClO₄. These data demonstrate that BrO₃⁻ and Br⁻ cause concentration-dependent death in kidney and liver cells, that BrO₃⁻ is a more potent toxicant than Br⁻, that kidney cells are more susceptible to BrO₃⁻-induced cell death than liver cells, and suggests that the mechanisms of BrO₃⁻-induced cell death involves both a G2-M arrest and NIS. This work was partially supported by the Awwa RF and the Georgia Cancer Coalition.

480 RESPIRATORY MEASUREMENT VALIDATION STUDY IN CYNOMOLGUS MONKEYS USING A HEAD PLETHYSMOGRAPH: EFFECTS OF MORPHINE (IV) AND HISTAMINE.

J. T. Weinberg, D. T. Kirkpatrick, R. W. Wallhead, D. S. Gumpf and J. Lambert. Inhalation Toxicology, WIL Research Laboratories, LLC, Ashland, OH.

The objective of this project was to validate procedures for inhalation exposures and respiratory measurements in nonhuman primates. In addition to inhalation exposures, the methods will be used for safety pharmacology studies and inhaled drug dosimetry estimates. A combination head-only exposure helmet/head plethysmograph system was used in conjunction with the Data Sciences International (DSI) PONEMAH® Physiology Platform. Prior to test agent treatments, the 2-3 year old male Cynomolgus monkeys were acclimated to chair restraint and the helmet system over a 6-week period. To evaluate the performance of the exposure helmet/plethysmograph and data collection system, tidal volume, breathing rate and minute volume were measured prior to, during and following intravenous dosing with morphine and inhalation of histamine. Respective mean baseline values prior to morphine and histamine treatments were 28 and 23 mL for tidal volume, 45 and 50 breaths/minute for breathing rate and 1248 and 1145 mL/minute for minute volume. Treatment with IV-injected morphine at dose levels of 100 and 1000 μ g/kg resulted in mean maximum decreases of 3% and 28% in tidal volume, 10% and 27% in breathing rate and 13% and 43% in minute volume, respectively, when compared to baseline levels. The approximate time to peak effect on respiratory parameters was 15-20 minutes post-dose for the 100 μ g/kg level and 5 minutes post-dose for the 1000 μ g/kg level. Exposure of monkeys to inhaled histamine aerosols generated from 0.02% to 0.2% saline solutions resulted in a mean maximum decrease of 42% in tidal volume and a mean maximum increase of 63% in breathing rate when compared to baseline levels. Peak effect on respiratory parameters was noted approximately 2 minutes after inhalation of histamine. These results provide a bio-phase validation for use of the exposure helmet/plethysmograph and the DSI PONEMAH® system with nonhuman primates.

481 WHOLE BODY PLETHYSMOGRAPHY IN RATS AS AN APPROPRIATE METHOD TO TEST RESPIRATORY FUNCTION ACCORDING TO THE ICH S7A GUIDELINE.

C. F. Trendelenburg¹, L. G. Meister², D. Naegelin¹, W. Classen¹ and V. Nogués¹. ¹SP&A Toxicology and Safety Pharmacology, Novartis Pharma AG, Muttens, Switzerland and ²Actelion Pharmaceuticals Ltd., Allschwil, Switzerland.

Whole body plethysmography as established in our lab is a state-of-the-art technique for quantitative routine measurements of pulmonary parameters which is considered to facilitate the detection of potential unwanted effects of new drug candidates to the respiratory system prior to first dose in man and to fulfill the requirements of the ICH guideline S7A.

A pressure signal is detected by a transducer from the animal placed into a chamber, from which respiratory parameters, i.e. respiration rate, tidal volume and minute volume, are derived using pre-determined conversion factors. The ultimate pressure signal measured results from the animal removing air from the chamber and the expansion of the thorax due to inspiration. The latter creates a signal greater than that

originating from removing air from the chamber since warming and humidifying of the inspired air are additional factors to this process. A new, internally developed study design allows the routine evaluation of respiratory parameters in combination with a functional observation battery (FOB) for neurological effects in one study without extra-use of animals. The rat was selected as an appropriate model for this type of experiments.

Baseline data confirmed the absence of any statistically significant difference in respiratory parameters between individual animals, sexes and time of recording with little evidence of habituation to repeated and/or long time exposure. Positive controls were employed (amphetamine, theophylline, baclofen) to test for adverse effects. Compared to control animals, the test articles clearly induced alterations of the respiratory function.

Our results demonstrated that changes in pulmonary parameters can reliably be detected. The experimental conditions and the equipment in use provide a basic understanding of the adverse effects on the respiratory system as a fundamental part of the safety assessment of drug candidates.

482 DEVELOPMENT OF A LCMS METHOD FOR QUANTIFYING OXIDATIVE MODIFICATIONS OF LIPIDS IN BIOLOGICAL SAMPLES.

W. Weber, M. J. Campen and J. D. McDonald. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Oxidized phospholipids have been shown to play an important pathological role in both acute and chronic vascular disease. We hypothesize that inhalation of certain toxic agents and environmental pollutants can induce oxidative modifications to endogenous phospholipids. To address this, we have developed a method to measure the specific phospholipid, 1-palmitoyl-2-arachidonoyl-sn-glycero-phosphocholine (PAPC) and its oxidized by-products in tissues and plasma. Phospholipids were eluted with an isocratic mobile phase consisting of methanol and water (90:10) with a flow rate of 1 mL/min. With reversed-phase chromatography, PAPC elutes at approximately 14 minutes. Auto-oxidation of PAPC (oxPAPC), over a 3 day period, results in the formation of a complex array of compounds eluting at approximately 6 minutes. Mass spectrometry (MS) was performed on an atmospheric pressure ionization (API) triple-quadrupole biomolecular mass analyzer (Applied Biosystems API 4000) equipped with an electrospray ionization source. Phospholipids were introduced into the electrospray MS by liquid chromatography. oxPAPC produced several signals that are both higher in molecular weight (from oxidation) and lower in molecular weight (from oxidative decomposition). PAPC was defined by the presence of a signal at m/z 782.7. The presence of PAPC could be detected as low as 100ng/mL. oxPAPC was defined by the presence of 3 previously identified molecular ions (m/z 594.3, 610.2, 828.6). These methods will enable the detection of oxidative modifications of endogenous phospholipids in inhalation toxicology studies.

483 MECHANISMS OF MECHANICAL VENTILATION-INDUCED INFLAMMATORY AND OXIDANT RESPONSES.

R. Potter¹, D. Harmon², C. Johnston³, J. Finkelstein^{1,3,5} and P. Chess^{3,4}. ¹Environmental Medicine, University of Rochester, Rochester, NY, ²School of Medicine & Biomedical Sciences, University at Buffalo, Buffalo, NY, ³Pediatrics, University of Rochester, Rochester, NY, ⁴Biomedical Engineering, University of Rochester, Rochester, NY and ⁵Radiation Oncology, University of Rochester, Rochester, NY.

Rationale: Mechanical ventilation (MV) is an unavoidable consequence in a variety of respiratory diseases. Mechanical strain associated with ventilation contributes to inflammation and ventilator-induced lung injury (VILI). Implicated in this injury are inflammatory mediators and reactive oxygen species (ROS) signaling. Tumor necrosis factor- α single and double receptor KO mice (TNF α R1-/- and TNF α R1/2-/-) and interleukin-1 β (IL-1 β) KO mice were used to investigate inflammatory and ROS signaling pathways in VILI. Methods: Wild type (WT), TNF α R1-/-, TNF α R1/2-/-, and IL-1 β -/- mice were mechanically ventilated with a 10cc/kg tidal volume, 150BPM for 6 hours. Analysis included pulmonary function testing, histological analysis, and proinflammatory cytokine and chemokine mRNA measurements by RNase protection assay. Immunohistochemistry for heme oxygenase-1 (HO-1) and 8-oxo guanine were performed to determine antioxidant and oxidant stress responses. Results: Decreased compliance and increased peak pressure were seen after 6hrs of MV, indicating a change in lung function. Ventilated mice showed no significant change in lung morphology as compared to unventilated mice. Ventilation increased alveolar expression of HO-1 protein in WT, TNF α R1/2-/-, and IL-1 β -/- mice. MV decreased 8-oxo guanine staining in all groups. mRNA message for MIP-2, IL-1 β , KC and IL-1 receptor II increased after 6hrs of MV. TNF α and IL-1 message increased in WT and KO mice. Conclusions: MV for 6hrs does not significantly alter lung morphology in all groups. Increased HO-1 protein may be contributing to decreased oxida-

tive DNA damage as seen by decreased 8-oxo guanine staining with MV. The development of ventilator-induced inflammation in TNF α R-/- and IL-1 β -/- mice demonstrates that TNF α and IL-1 β are each not solely necessary for a ventilator-induced inflammatory response.

484 COMPARATIVE EVALUATION OF RISK FACTORS FOR CARDIOVASCULAR DISEASE (CVD) IN GENETICALLY PREDISPOSED RATS.

M. C. Schladweiler¹, A. Nyska², A. D. Ledbetter¹, J. Wallenborn³, R. R. Gottipolu¹, J. H. Richards¹, R. Thomas¹, R. H. Jaskot¹, J. Shannahan¹, K. Crissman¹, G. E. Hatch¹ and U. P. Kodavanti¹. ¹NHEERL, U.S. EPA, Research Triangle Park, NC, ²NIEHS, Research Triangle Park, NC and ³UNC, Chapel Hill, NC.

Rodent CVD models are increasingly used for understanding individual differences in susceptibility to environmental stressors such as air pollution. We characterized pathologies and a number of known human risk factors of CVD in genetically predisposed, male young adult Spontaneously Hypertensive (SH), Stroke-Prone SH (SHSP), Heart Failure SH (SHHF) and Diabetic (JCR) rats. These were compared to healthy Sprague Dawley (SD) and parental Wistar Kyoto (WKY) rats. Baseline differences in pathology of the heart, lung and kidney, antioxidants and gene expression, along with levels of systemic inflammation and coagulation markers were analyzed to understand distinct disease-related phenotypes. There were various degrees of myopathy in all strains; JCR appeared to be affected the most. No major pathological lesions were apparent in the lungs of any strain. However, lavage fluid neutrophils, marker for lung inflammation, were increased in SH and SHSP relative to others. This was associated with higher baseline levels of lung glutathione but lower ascorbate. Lung ascorbate levels were highest in SD and JCR. Although having high hematocrit values, coagulation parameters in JCR were comparable to WKY. These were most affected in SHSP relative to WKY. JCR and SD rats had the highest number of circulating white blood cells and lymphocytes relative to all other strains. Further, JCR and SHHF, both with obese phenotype, demonstrated remarkable kidney lesions. Thus, each model demonstrates distinct disease- and tissue-dependent anomalies that are likely to be associated with the degree of compensatory response. Understanding the pathobiologic manifestations of the disease in the chosen animal model is essential for accurate interpretation of susceptibility data. (This abstract does not reflect US EPA policy. Supported in part by UNC/EPA CT829471 and NRC Research Associateship Award at NHEERL, EPA).

485 ACUTE CARBON MONOXIDE POISONING: TREATMENT WITH NORMOBARIC OR HYPERBARIC OXYGEN AND ITS CORRELATION WITH MITOCHONDRIAL COMPLEX IV ACTIVITY FROM PERIPHERAL BLOOD LYMPHOCYTES.

F. Cardellach¹, G. Garrabou¹, J. M. Inoriza², M. J. Martí², G. Olíu², S. López¹, J. Casademont¹ and V. E. Miró¹. ¹Hospital Clínic, Barcelona, Catalonia, Spain and ²Hospital de Palamós, Palamós, Girona, Catalonia, Spain. Sponsor: J. Domingo.

Background: Symptoms of acute carbon monoxide (CO) poisoning (ACOP) are generally attributed to hypoxia due to carboxihemoglobin (COHb), although there is also an effect on cells due to the inhibition of the mitochondrial complex IV (mCIV). Objective: To establish 1) the activity of mCIV in patients suffering from ACOP; 2) the level of its recovering depending on the treatment (normobaric oxygen -NBO- vs hyperbaric oxygen -HBO-), and 3) the correlation between mCIV activities and the severity of intoxication. Patients: 26 subjects with ACOP were distributed as: a) severe (COHb > 20%) (n:13), randomly treated with one (n:8) or two (n:5) sessions of HBO (SHBO1 and SHBO2), and b) moderate (COHb: 10-20%) (n:13), randomly treated with NBO (MNBO) (n:8) or one session of HBO (MHBO1) (n:5). Method: 1) Register of clinical manifestations, 2) COHb determination and 3) mCIV activity (spectrophotometry) in lymphocytes from peripheral blood (Ficoll technique), before and immediately after the treatment, as well as at 24 h, 1 month and 3 months later. Analysis of results: 1) analysis for intention-to-treat principle depending on the assignment of groups; 2) comparison of MNBO-MHBO1, SHBO1-SHBO2 and MHBO1-SHBO1; 3) analysis of variance for repeated measures; 4) comparison of COHb and mCIV (nonparametric test for independent data). Results: mCIV activities were decreased in severe and moderate ACOP compared to controls ($p = 0.014$ and 0.027 , respectively), but were not different to immediately after-treatment values. We did not find differences in after-treatment mCIV activities between MNBO and MHBO1, nor between SHBO1 and SHBO2. Recovery of mCIV activity along time was significant in SHBO1, SHBO2 and MHBO1 ($p = 0.036$, 0.048 and 0.016 , respectively), but not in MNBO. Conclusions: In severe ACOP one single session of HBO is enough effective in restoring mCIV activity, and it is also more effective than NBO in moderate ACOP. (FIS PI041239).

486 POSSIBLE ROLE OF ANGIOTENSIN II (ANG II) INDUCED CONNECTIVE TISSUE GROWTH FACTOR (CTGF) MEDIATED ELEVATION IN ELASTIN AND COLLAGEN LEVELS IN RAT PLEURAL MESOTHELIAL CELLS (RPMCS, CCL 216).

U. B. Doshi and J. M. Cerreta. *PHS, St. John's University College of Pharmacy and Allied Health Professions, Jamaica, NY.* Sponsor: *L. Trombetta.*

Perturbation in extracellular matrix homeostasis is the hallmark of tissue fibrosis. While many mechanisms are involved in regulation of matrix alteration, studies carried out with antagonists of Renin Angiotensin System (RAS) have implicated a role for Ang II, an effector peptide of RAS, in several fibrotic disorders. Ang II mediated increase in collagen production has been shown to occur via a peptide, CTGF, in renal and cardiac fibrosis. However, in the lung a direct link between Ang II and CTGF expression has not been established with respect to extracellular matrix perturbation. The current study in RPMC was undertaken to examine a possible link between Ang II mediated increase in elastin and collagen levels and CTGF. Cells were grown in supplemented F-12-Nutrient Mix (Ham)-media containing 50µg/ml ascorbic acid or without ascorbic acid and 5% CO₂. Cell viability was assessed by MTT assay. Sirius-red assay, ELISA and western blot analysis were carried out to measure collagen, elastin and CTGF levels respectively. Cultures were challenged with various concentrations of Ang II (10nM-1µM) for 24 hrs, following which the cells were either used for MTT assay or allowed to synthesize matrix for 7 days and then used for estimation of protein levels. At concentrations used Ang II did not show any toxicity. Ang II induced a 40 % increase in elastin and 47.1 % increase in collagen (p<0.01) levels at a concentration of 1µM by day 7 as compared to control. In western blot analysis, Ang II treatment at 1µM concentration caused an increase of CTGF as measured at day 7. These data indicate that a treatment of RPMC with 1µM concentration of Ang II causes CTGF increase between 0-7 days of treatment. Further, due to such increases the levels of collagen and elastin are elevated by day 7. These data suggest a positive correlation between Ang II, CTGF and matrix proteins synthesis.

487 LUNG PROTEIN EXPRESSION FOLLOWING ACUTE FORMALIN EXPOSURE – EFFECT OF THE SUBSTANCE P DERIVATIVE SAR⁹, MET(O₂)¹¹-SUBSTANCE P.

S. B. Mason¹, J. W. Clack², H. N. Ringham¹, A. Thomas³, *M. L. Witten³ and E. A. Witzmann¹.* ¹Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, ²Biology, IUPUI Columbus, Columbus, IN and ³Lung Injury Laboratory, Pediatrics, University of Arizona Health Sciences Center, Tucson, AZ.

Previous studies suggest that Sar⁹,Met(O₂)¹¹-Substance P (SPa) may attenuate lung injury by blocking the action of endogenous substance P at the neurokinin-1 receptor (NK1r) on pulmonary alveolar macrophages and other potential lung cell receptor sites. We sought to determine if SPa pretreatment would attenuate protein alterations associated with formalin-induced acute lung injury. F344 male rats [control; formalin-only (F); or SPa/formalin] were exposed to 67 mg/m³ (67 ppm) aerosolized formalin or air for 1.5 min while others were administered 35 ppm aerosolized 10 µM SPa over a 10 minute period just before formalin exposure. At ~42 minutes post-formalin or air exposure, rat lungs were removed for protein analysis. Replicate rats were administered pulmonary function and lung permeability tests. The F rats demonstrated a 33-fold increase in inspiratory dynamic lung compliance compared to the SPa rats. Increased compliance was matched by a 6-fold increase in F rat lung permeability versus the SPa group. Two-dimensional gel electrophoresis revealed altered abundance of 71 proteins whose formalin-mediated changes were attenuated in the SPa rats. Given the brief exposure period, the low abundance of the detected proteins (potential charge variants), and their identities, we hypothesize that this formalin effect relates to altered protein posttranslational modification and not protein synthetic/catabolic mechanisms. Conversely, immunoblotting suggests a limited set of proteins may be up- or down-regulated. Though the exact nature of the observed expression changes remains debatable, this study clearly demonstrates the protective effect of SPa against some aspects of acute formalin toxicity. Supported by AFOSR Grants FA9550-06-1-0083 & FA9550-05-1-0216 to FAW and FA9550-04-1-0231 to MLW.

488 MOUSE MODELS OF BERYLLIUM-INDUCED SENSITIZATION AND GRANULOMATOUS LUNG DISEASE.

L. M. Tarantino¹, S. S. Tinkle², A. F. Hubbs³, M. D. Hoover³ and T. Gordon¹. ¹Environmental Medicine, NYU School of Medicine, Tuxedo, NY, ²NIHES, Research Triangle Park, NC and ³NIOSH, Morgantown, WV.

Exposure to beryllium (Be) is an occupational hazard that can cause chronic beryllium disease (CBD), an irreversible, debilitating granulomatous lung disease, in as many as 3-5% of exposed workers. CBD begins as an MHC Class II-restricted,

Th1 hypersensitivity. CBD can be viewed as a biphasic disease: first peripheral sensitization occurs, and then, in some, there is progression to pulmonary granuloma formation. In order to look at both aspects of the disease, we performed a mouse ear-swelling test (MEST) to correlate with the sensitization process and a 5-month oropharyngeal aspiration study to look at granuloma development in mice. In the MEST, 21 different inbred mouse strains were utilized to see if they would exhibit varying hypersensitivity responses to Be. In two separate experiments, mice were placed into either group: C/C group (sensitized with vehicle, challenged with vehicle) or Be/Be group (sensitized with beryllium sulfate, challenged with beryllium sulfate). The SJL/J strain appeared to exhibit one of the greatest hypersensitivity responses with a 37.7% increase over the baseline ear thickness in the Be/Be group compared with a 2.6% increase in the control group. The FVB/N strain, in contrast, had statistically insignificant increases in ear thickness. The results for the hypersensitivity MEST response were as follows: SJL/J, AKR, DBA/2J>>PL/J, LG/J, MRL/MpJ>> FVB/N, 129/SvImJ, SWR/J. The data have been analyzed by haplotype mapping to uncover genes associated with sensitization to beryllium. In the aspiration study, seven inbred strains aspirated either 20µg, 35µg, or 50µg of beryllium metal powder or water vehicle monthly. Clear dose and strain differences in beryllium-induced lymphogranulomatous nodules were observed. Uncovering the genes responsible for the hypersensitive phenotype and granuloma formation in mice may prove useful in learning more about the mechanisms involved in CBD.

489 BINDING OF THE MACROCYCLIC TRICHOETECENE SATRATOXIN G TO RIBOSOMES IN RAW 264.7 MACROPHAGES AND PC-12 NEURONAL CELLS.

H. Bae^{1,2}, Z. Islam^{1,2,3} and J. J. Pestka^{1,2,3}. ¹Department of Food Science and Human Nutrition, Michigan state university, East Lansing, MI, ²Center for Integrative Toxicology, Michigan state university, East Lansing, MI and ³Department of Microbiology and Molecular Genetics, Michigan state university, East Lansing, MI.

Satratoxin G (SG), a macrocyclic trichothecene produced by the black indoor air mold *Stachybotrys chartarum*, causes both inflammation and neurotoxicity in the murine intranasal lavage model suggesting its potential to adversely affect human health. The molecular mode of action for SG and other trichothecenes is believed to involve ribosomal binding and intracellular kinase activation followed by inflammatory and apoptotic gene expression. The purpose of this research was to characterize both concentration-response and kinetics of SG binding to ribosomes in RAW 264.7 macrophage and PC-12 neuronal cell models. Following exposure of the cells to SG at various concentrations over different time intervals, ribosomal fractions were separated from cytoplasmic proteins using a sucrose gradient system. Each fraction was then measured by a competitive ELISA using anti-SG antibodies. SG was preferentially found in the monosome fraction with smaller and negligible concentrations found in the polysome and cytoplasmic fractions, respectively. When SG was incubated at 0, 2.5, 5, 10, 50, 100 ng/ml with the cells for 30 minutes, SG binding to ribosomal fractions increased in a concentration-dependent fashion up to 10 ng/ml with saturation of a single ribosomal binding site. SG binding was largely unaffected by boiling and isopropanol precipitation of the ribosomal fractions. Furthermore, exhaustive RNase treatment for removal of ribosomal RNA, failed to reduce SG content in the ribosomal protein fraction. Taken together, SG has the capacity to rapidly and tightly bind to macrophage and neuronal ribosomal proteins. Both the concentration-dependence and kinetics of this interaction were consistent with previously observed kinetics of SG-induced intracellular kinase cascade activation as well as downstream inflammatory and apoptotic sequelae.

490 ACTIVATION OF RAT ALVEOLAR MACROPHAGES AND TYPE II EPITHELIAL CELLS FOLLOWING OZONE INHALATION.

V. R. Sunil¹, K. Patel¹, J. Gray², J. Laskin² and D. Laskin¹. ¹Rutgers University, Piscataway, NJ and ²EOHSI, Piscataway, NJ.

Ozone (O₃) inhalation is associated with an inflammatory response, characterized by macrophage (AM) and neutrophil accumulation in the alveolar regions of the lung. These cells release mediators important in the pathophysiology of O₃-induced injury. We speculated that Type II alveolar epithelial cells also participate in inflammatory responses to O₃ and this was investigated. Female Wistar rats (200-225 g; 8-10 weeks) were exposed to air or O₃ (2 ppm) for 3 h. Animals were sacrificed 3-72 h later. Following O₃ inhalation, greater numbers of inflammatory leukocytes were recovered in BAL fluid 6-12 h post-exposure. This was correlated with an increase in BAL protein demonstrating that O₃ induces alveolar epithelial injury. Exposure of animals to O₃ also resulted in an increase in mRNA for the inflammatory cytokine, TNF-α, in AM and Type II cells which was evident after 3 h. Expression of COX-2, the enzyme mediating prostaglandin production, was also increased after O₃. Whereas a rapid and persistent induction of COX-2 was noted in Type II cells, increases in expression of this enzyme were delayed for 72 h in AM. Antioxidant production in the lung is critical in limiting oxidant-induced damage.

AM and Type II cells constitutively expressed SOD and HO-1 mRNA. Although SOD mRNA levels were not significantly altered by O₃, HO-1 mRNA decreased over time in AM, but not in Type II cells. Similar results were observed with SOD and HO-1 protein expression. PPAR- γ , a nuclear hormone ligand activated transcription factors, has been reported to reduce lung injury associated with inflammation. Both AM and Type II cells constitutively expressed PPAR- γ mRNA. O₃ caused a transient decrease in PPAR- γ mRNA in AM, but a rapid increase in Type II cells. Taken together, our data demonstrate that O₃ inhalation results in augmentation of genes mediating the inflammatory response. Moreover, both AM and Type II cells produce mediators that help to limit the inflammatory response and maintain normal lung homeostasis. Support: ES004738, ES005022, ALA-NJ.

491 EXPOSURE TO GASOLINE ENGINE EXHAUST CAUSES OXIDATIVE STRESS IN RATS.

J. Seagrave¹, M. J. Campen¹, S. Dunaway¹, G. Herbert¹, J. L. Mauderly¹, J. D. McDonald¹ and A. C. Rohr². ¹Lovelace Respiratory Research Institute, Albuquerque, NM and ²Electric Power Research Institute, Palo Alto, CA.

Oxidative stress is a possible mechanism for some of the adverse health effects attributed to air pollution exposure. Some effects have been reported to be greater in populations living adjacent to heavily traveled roads, consistent with the hypothesis that fresh vehicle emissions may contribute disproportionately to the hazard. Diesel engine exhaust has been widely studied, but gasoline engine exhaust (GEE) has received much less attention. We used in situ chemiluminescence to assess the effect of inhalation of GEE in rats. This technique measures the decay to ground state of singlet O₂, a highly reactive form of O₂. Rats were exposed sequentially to exhaust from two 1996 General Motors 4.3 L gasoline engines, each run for 3h (total 6h) on a cycle simulating the Unified Driving Cycle 6. This protocol thus included two "cold starts." Rats were exposed to diluted GEE containing 60 $\mu\text{g}/\text{m}^3$ (average) of total particulate matter (TPM), to similarly diluted emissions passed through a HEPA filter to remove the particles, or to filtered air as a control. TPM, NO_x, CO, and total hydrocarbons were measured. Following exposure, the rats were immediately removed from the exposure chambers, deeply anesthetized, and placed on a ventilator. The lungs, heart, and liver were exposed and covered with saline-saturated gauze and an opaque drape with a 1 cm diameter hole. The hole was aligned sequentially over the lungs, heart, and liver, and photon counting from each organ was performed using a high sensitivity photomultiplier tube and data acquisition system. The results showed a significantly higher signal in the organs (Lung > heart $\approx$ liver) of the rats that had been exposed to whole GEE, compared with those exposed to filtered air, but little effect of the filtered GEE. These results are consistent with the presence of increased reactive oxygen species due to inhalation of the particle phase of fresh GEE. Supported by the Electric Power Research Institute and the National Environmental Respiratory Center.

492 GASOLINE EMISSIONS AFFECT CLEARANCE OF INTRA-TRACHEALLY INSTILLED *PSEUDOMONAS AERUGINOSA*.

M. Reed, A. P. Gigliotti and J. A. Berger. *Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Gasoline emissions (GE) are contributors to ambient and occupational air pollution. Of the health outcomes associated with ambient pollutant exposures, respiratory infection is a major contributor to morbidity and mortality. As part of a larger health assessment of multiple anthropogenic source emissions, mice were exposed to GE and instilled with an inoculum of a common respiratory pathogen, *Pseudomonas aeruginosa*. GE was generated from two mid-mileage 1996 4.3 L GM engines operated on a simulated version of the Unified Driving Cycle 6 and fueled by national average unleaded gasoline. Groups of young C57Bl/6 mice were exposed to clean air, whole GE diluted to 18 (High), 12 (Mid), and 2 (Low) ppm oxides of nitrogen (NO_x), and a particulate matter (PM)-filtered level (18 ppm NO_x). PM concentrations were ~ 60 , 30 and $7\mu\text{g}/\text{m}^3$ at the High through Low levels respectively. Exposures were conducted for 6h/d for 7 consecutive days. Mice were instilled with bacteria subsequent to the last exposure and sacrificed after 18h in clean air. Pulmonary inflammatory histopathology and colony counts of serially diluted lung homogenate were assessed. GE had no discernable effect on exacerbation of pulmonary pathology. Similar to observations with diesel emissions, GE decreased bacterial clearance in an exposure-dependent manner. PM filtration partially attenuated the response. These results indicate that resistance to respiratory bacterial infection may be modulated by multiple on-road sources.

493 CYTOGLOBIN IMMUNOLocalISATION IN LUNG PARENCHYMA IN SEVERE COPD.

M. Graham¹, M. Carpenter², N. Hodges², K. Chipman², K. Pinnion¹ and M. Foster¹. ¹Safety Assessment, AstraZeneca, Leicestershire, Leicestershire, United Kingdom and ²School of Biosciences, Birmingham University, Birmingham, United Kingdom.

Cytoglobin is a novel member of the globin family that has a putative role as a tissue oxygen sensor. It is expressed in fibroblasts and has been shown to be an inducer of fibrosis, raising the possibility of a role in the pathogenesis of fibroproliferative toxicity and disease. In this study, we profiled cytoglobin expression in a cohort of patients with severe COPD undergoing lung volume reduction surgery, in which alveolar fibrosis and loss of vascularity are a feature. Ethically acquired COPD lung tissue was classified according to the fibroproliferative phenotype: pneumonitis (P), diffuse fibrosis (DF), marked alveolar fibrosis without loss of septation (AF) and organising fibrosis with loss of normal lung parenchyma (OF). In lung areas presenting with P, there was marked cytoglobin staining of macrophages, predominately a vesicular staining pattern suggestive of protein phagocytosis. There was little signal in adjacent areas. In DF areas, there was a diffuse signal within the interstitium, within fibroblasts and occasional mononuclear cells. As fibrosis increased from AF to OF, there was a progressive loss of cytoglobin signal from the interstitium, an increase in signal within the pulmonary vasculature and an increase in signal within pan-cytokeratin positive cells bordering areas of consolidated matrix – although typical epithelium within the conducting airways showed only a weak signal or negative signal. Additionally, a marked cytoglobin signal seen in the pulmonary vasculature was associated with vessels surrounded with fibrosis. In conclusion, cytoglobin expression in a disease cohort showing fibroproliferation and loss of vascularity shows a progressive loss of signal as the lesion matures to a more acellular phase, or where vascular structures are lost or surrounded by fibrosis. The histologically significant finding of cytoglobin expression in the peri-fibrotic cytotkeratin positive cell colony raises the possibility that this expression may be an attempt by normal lung to limit the spread of hypoxic stimuli.

494 THE USE OF A FLOW CYTOMETRY-BASED CYTOKINE ANALYSIS FOR BRONCHOALVEOLAR LAVAGE WITH CONFIRMATION BY REAL-TIME RT-PCR IN A MOUSE MODEL OF PULMONARY INFLAMMATION.

P. C. Zeidler-Erdelyi, A. D. Erdelyi, S. Young and J. M. Antonini. *Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

Bronchoalveolar lavage (BAL) provides a valuable tool for insight into the lung inflammatory state following a toxic or antigenic exposure. Toxicological injury evaluation routinely uses a concentrated first fraction BAL (<600 μl) to accurately measure various lung inflammatory parameters in mice. However, 100-250 μl of this BAL fraction is typically used in most conventional assays limiting the researcher to only a few measurements. Recently, flow-cytometry based cytometric bead arrays (CBA) have been developed to simultaneously determine concentrations of multiple analytes in a single 25-50 μl sample saving both cost and time. In this confirmatory study, we used a mouse inflammation CBA kit to analyze IL-6, IL-10, IL-12p70, MCP-1, IFN- γ , and TNF- α protein in BAL fluid obtained from A/J or C57BL/6J mice exposed to welding fume. Since inflammatory mediators are usually accompanied by both an increase in gene expression and protein, real-time RT-PCR was done on isolated RNA from whole lung homogenates to validate the findings. It was found that a limitation of the CBA kit was sensitivity. In particular, samples with low concentrations of an analyte were often reported as extrapolated below sensitivity or zero thus limiting statistical analysis. These findings made validation by some other method necessary. Real-time RT-PCR strongly supported the findings of the CBA kit by displaying similar trends in the mouse lung inflammatory response caused by welding fume exposure. Therefore, the mouse inflammation CBA kit was an acceptable method for measuring cytokines in studies involving limited sample size and represents a cost efficient screening method for pulmonary inflammation. Also, it is recommended that another method such as RT-PCR or ELISA be performed if increased sensitivity is required.

495 COMPARISON OF LUNG INJURY AND INFLAMMATION AFTER REPEATED TREATMENT WITH WELDING FUMES COLLECTED FROM DIFFERENT WELDING PROCESSES.

J. M. Antonini and J. R. Roberts. *NIOSH, Morgantown, WV.*

Welding fumes are a complex mixture of different metals. Depending on the welding process, some welders may be exposed to fumes that contain vastly different metal profiles. The goal was to compare the lung response in rats after multiple

treatments with welding fumes that are vastly different both chemically and physically. Welding fumes were collected from three different processes: gas metal arc-mild steel welding (GMA-MS); manual metal arc-hardsurfacing welding (MMA-HS); flux-cored arc-hardsurfacing welding (FCA-HS). Male Sprague-Dawley rats were treated by intratracheal instillation 1/wk x 7 wk with 0.5 mg/rat of the fume samples. Controls were treated with saline. Bronchoalveolar lavage was performed 4 days after the final treatment, and parameters of lung injury (lactate dehydrogenase and albumin) and inflammation (neutrophil influx) were assessed. Metal analysis indicated that the GMA-MS fume was primarily composed of Fe (1.08 µg Fe/gm total metal) and Mn (0.32 µg Mn/gm total metal), whereas the Mn content of the FCA-HS (2.0 µg Mn/gm total metal) and MMA-HS (1.8 µg Mn/gm total metal) fumes was ~6x higher than in the GMA-MS fume. The FCA-HS (0.07 µg Cr/gm total metal) and MMA-HS (0.304 µg Cr/gm total metal) fumes contained Cr which was present in only trace amounts in the GMA-MS fume. The FCA-HS and MMA-HS fumes were found to be more water-soluble than the GMA-MS fume. Significant elevations in lactate dehydrogenase, albumin, and the number of lung neutrophils were observed for the MMA-HS and FCA-HS groups compared to the GMA-MS and saline groups. No significant differences in lung injury and inflammation were observed between the GMA-MS and saline group. The greater lung response caused by the FCA-HS and MMA-HS fumes is likely due to the presence of Cr and higher levels of Mn. Results from this study indicate that welders who are exposed to fumes generated from specific processes may be at a greater risk for adverse pulmonary effects.

496 TOXICOKINETICS OF SURFACTANT PROTEIN AND INFLAMMATORY GENE EXPRESSION IN PRIMARY RAT LUNG ATII CELLS AND FIBROBLASTS EXPOSED TO PENICILLIUM CHRYSOGENUM AND STACHYBOTRYS CHARTARUM TOXINS.

T. G. Rand¹, A. Kading¹, J. D. Miller³, J. E. Scott² and C. Robbins¹. ¹Biology, Saint Mary's University, Halifax, NS, Canada, ²Department of Oral Biology Anatomy, University of Manitoba, Winnipeg, MB, Canada and ³Chemistry, Carleton University, Ottawa, ON, Canada. Sponsor: J. Pestka.

Not a great deal is known about the effects and modes of action of the spores and toxins of the majority of molds encountered in the indoor environment on lung biology. In vivo models of lung disease indicate that fungal spore and toxin exposures lead to a variety of species and toxin-specific inflammatory responses. However, it is unclear whether all the lung cells participate in these inflammatory changes. In this study we used gene expression profiling using custom made RT-PCR based microarrays to compare surfactant protein and inflammatory gene responses in primary fetal rat lung ATII cells and fibroblasts to atranones A&C from *Stachybotrys chartarum* (Sc) and melagrins and roquefortine C from *Penicillium chrysogenum* (Pc). In Pc-toxin exposed ATII cells, inflammatory genes were transiently up-regulated, generally in dose and time dependent ways, within 2 to 4 hr and de-expressed by 12 hr post exposure (PE), especially in melagrins exposed cells. SP-A, B & C genes were down regulated at 4 hr PE. SP-D expression was unaffected by the Pc toxin exposures. Inflammatory genes were generally up-regulated in atranone A but down regulated in atranone C exposed ATII cells from 2 to 24 hr PE, and in a dose dependent fashion. SP-A & C genes were down regulated in both atranone A & C exposed cells, while SP-B & D expression was unaffected. In fibroblasts, gene expression was generally limited to SP-D up-regulation, while MIP-3α was down regulated, from 2 to 4 hr PE. The results indicate that toxins from two mold species common on damp materials in buildings provoke compound-specific toxic responses with different toxicokinetics. They also provide further insight into molecular mechanisms of spore and toxin induced lung disease onset and development, and may be useful in the identification of fungal specific molecular biomarkers of disease.

497 REPEATED EXPOSURE TO 1→3-β-GLUCAN SUPPRESSES LUNG DEFENSE RESPONSES AND SLOWS THE PULMONARY CLEARANCE OF LISTERIA MONOCYTOGENES IN RATS.

S. Young, J. R. Roberts and J. M. Antonini. NIOSH, Morgantown, WV.

Chronic exposure to low levels of mold has been reported to increase susceptibility to respiratory infections. Currently, the mechanism is not well understood. This study investigated lung defense effects after repeated low-dose zymosan (a 1→3-β-glucan from yeast cell wall) exposure on bacterial infection (*Listeria monocytogenes*) in male Sprague-Dawley rats. On days 0, 3, 7 and 10, rats received one dose of zymosan A (0.6 mg/kg body weight each dose) via intratracheal instillation or vehicle control (saline). On day 17 (one week later), rats were intratracheally inoculated with 5x10⁵ bacteria. Rats were euthanized on days 20, 22, and 24. Bacterial clearance was determined by measuring colony-forming units cultured from the left lungs. Bronchoalveolar lavage (BAL) was performed on the right lungs.

Inflammation and lung injury were assessed by measuring (1) neutrophil (PMN) infiltration and (2) albumin and lactate dehydrogenase levels in BAL fluid. Multiple zymosan treatments induced greater lung injury and inflammation as indicated by elevations in PMN, LDH, and albumin at days 22 and 24 compared to control. In addition, repeated low-dose exposure to zymosan slowed the clearance of the bacteria at day 20 and 22 compared to controls, suggesting a possible suppression in lung immune responses. In contrast, previous results have shown that a single acute dose of zymosan at a concentration (2.5 mg/kg body-weight) equivalent to the total of the four repeated concentrations used in the current study enhanced lung immune responses and increased the rate of bacterial clearance from the lung. This study demonstrated the importance of treatment concentration and dosing regimen in understanding lung immune effects associated with 1→3-β-glucan exposure.

498 90 DAY INHALATION TOXICITY STUDY WITH DISK-SHAPED POTASSIUM OCTATITANATE PARTICLES (POT; TERRACESS TF) IN RATS.

S. Sakai¹, A. K. Tanaka¹, D. P. Kelly², G. Sykes³ and K. P. Lee⁴. ¹Otsuka Chemical Co., Ltd., Osaka, Japan, ²Haskell Laboratory, DuPont Company, Newark, DE, ³PharmPath, West Grove, PA and ⁴Pathology Consulting, Newark, DE. Sponsor: S. Loveless.

Fibrous particles such as asbestos and some man-made fibers have been known to produce carcinogenic or fibrogenic effects upon inhalation. Non-fibrous, disk-shaped potassium octatitanate particles (POT; TerraceSS TF) have been manufactured to avoid potential fiber toxicity. Four groups of 20 male and 15 female rats each were exposed to POT aerosol at concentrations of 0, 2, 10, or 50 mg/m³ for a 90 day period followed by a 15 week recovery period. The mass median aerodynamic equivalent diameter of the aerosols ranged from 2.5 to 2.9 µm. Lung burdens of POT were determined in 5 males/group at the end of the exposure period and after 3 and 15 weeks recovery. The clearance 1/2 times for POT were estimated to be in the order of 2 to 3 months for the 2 and 10 mg/m³ groups and 6 to 9 months for the 50 mg/m³ group. There were no POT related adverse effects in clinical observations, body weights, clinical pathology, or neurobehavioral measurements. At the end of the 90 day exposure, a slight increase in lung-to-body weight ratios was observed at 50 mg/m³ in males; this effect was not seen during the recovery periods. Female lung weights were normal. Microscopically, inhaled POT particles were mostly phagocytized by alveolar macrophages (AMs) in the alveoli and alveolar walls maintained their normal structure at 2 and 10 mg/m³. At 50 mg/m³, some alveoli were distended and filled with aggregates of particle laden AMs. The alveolar walls showed slight Type II pneumocyte hyperplasia but neither active inflammation nor alveolar fibrosis was present. The lung responses and lung clearance rates of POT were comparable to those of "nuisance" type dusts at these concentrations. The slower clearance rates at 50 mg/m³ and the presence of aggregated particle-laden AMs in alveoli at this level were considered signs of alveolar "overloading" and 50 mg/m³ was considered an effect level; the NOAEL was 10 mg/m³.

499 ESTABLISHMENT OF A BIOASSAY FOR DETECTION OF LUNG TOXICITY DUE TO FINE PARTICLE FROM BASED ON RESULTS OF DOSE RESPONSE STUDY.

M. Yokohira¹, K. Yamakawa¹, K. Hosokawa¹, Y. Matsuda¹, K. Sano², T. Kuno¹ and K. Imaida¹. ¹Onco-Pathology, Department of Pathology and Host-Defence, Faculty of Medicine, Kagawa University, Kita-gun, Kagawa, Japan and ²Department of Clinical and Pathological Laboratory, Kaisei General Hospital, Sakaide-Shi, Kagawa, Japan. Sponsor: S. Tomoyuki.

In order to establish an appropriate bioassay for detection of lung damage after fine particle exposure, sequential histopathological changes were examined after intratracheal instillation to quartz, as a typical lung toxic agent, into F344 male rats.

Experiment 1: A total of 60, 10-week-old male F344 rats, were randomly separated into 6 groups and each group was consisted 10 rats. Groups 1-4 were exposed to 4mg, 2mg, 1mg and 0mg (control) quartz (DQ-12) suspended in saline (0.2ml) using an aerolizer and subgroups were sacrificed 5 rats on Days 1 and 28 thereafter. Groups 5 and 6 were exposed to 4mg and 0mg (air only) quartz powder without suspension using special aerolizer and sacrificed on the same days. All groups underwent assessment of lung histopathology.

Experiment 2: A total of 72, 10-week-old male F344 rats, were randomly separated into 6 groups. 60 rats (5 groups) were exposed by intratracheal instillation to quartz, titanium dioxide, hydrotalcite and β-cyclodextrin, 2mg/rat, suspended in 0.2ml saline (established by Experiment 1) and subgroups of 6 rats were sacrificed on Days 1 and 28. 12 rats were exposed by intratracheal instillation to 0.2ml saline as control groups, remaining 12 rats were not exposed as untreated group and subgroups of 6 rats were similarly sacrificed on the same days. All groups underwent assessment of lung histopathology and immunohistochemical demonstration of BrdU and iNOS as end-point markers.

From Experiment 1, 2mg quartz suspended in 0.2ml saline were suggested to be most appropriate for sensitive detection of inflammatory changes. By histopathology and immunohistochemical assessment, the level of toxicity were considered

quartz > hydrotalcite > β -cyclodextrin > titanium dioxide from Experiment 2. This installation model can be used for more sensitive detection of acute or subchronic lung toxicity due to fine particles.

500 PARTICLE SIZE DISTRIBUTION OF NICOTINE IN MAINSTREAM SMOKE OF 2R4F CIGARETTES UNDER DIFFERENT PUFFING REGIMEN.

N. Gowadia¹, M. Oldham¹ and D. Dunn-Rankin². ¹Comm. & Env. Medicine, UC Irvine, Irvine, CA and ²Mech. & Aero. Engineering, UC Irvine, Irvine, CA.

Nicotine's dose and rate of delivery to the brain play an important role in its addiction and cardiovascular effects. Nicotine is mainly present in the particulate phase of cigarette smoke and since particle size distribution controls the deposition behavior of particles in the respiratory tract, changes in the particle size distribution can affect its regional and total dose to the lung. Variation in the regional and total dose can also change its absorption rate and delivery to the brain. The particle size distribution of mainstream smoke (MS) can be varied by changes in puffing regimen, cigarette design and composition. In this study, we measured nicotine in different particle size fractions of MS generated from 2R4F cigarettes using three puffing regimens: (1) FTC – 35 ml over 2 sec.; (2) short puff – 50 ml over 2 sec.; and (3) long puff – 100 ml over 10 sec. MS was generated in a chamber at 37°C and > 95% RH to simulate respiratory tract conditions. Size-separated particle fractions from the first puff were collected using two RJR cascade impactors. Particle size distribution of MS was determined by spectrophotometric analysis of size-segregated fractions. These particle fractions were analyzed for nicotine using gas chromatography and mass spectrometry. Quantifiable nicotine was present only on two of the impactor stages (0.4-1.1 μ m and 1.1-1.9 μ m). Although the MMAD and GSD for each puffing regimen were similar for total particulate matter (MMAD 0.9-1.1 μ m, GSD-1.6), nicotine's distribution exhibited significant differences. Using the FTC puffing regimen, nicotine was almost equally distributed between 0.4-1.1 μ m (mean $\pm$ SD; 55% $\pm$ 5) and 1.1-1.9 μ m (45% $\pm$ 5) size fractions. However, using the short puffing regimen, nicotine increased in 0.4-1.1 μ m size fraction (72% $\pm$ 0.2) and using the long puffing regimen, nicotine increased in 1.1-1.9 μ m size fraction (60% $\pm$ 5). The changes in nicotine's particle size distributions compared to total particulate matter were statistically significant (P=0.05).

501 STRAIN AND GENDER DIFFERENCES IN TOBACCO SMOKE-INDUCED PULMONARY AIRSPACE ENLARGEMENT AND MUCUS HYPER-SECRETION.

Y. Shen and K. E. Pinkerton. Center for Health and the Environment, University of California, Davis, Davis, CA.

The correlation between tobacco use and its harmful effects has been well studied; however, factors resulting in differential sensitivity to tobacco smoke are poorly understood. The objective of this study was to examine strain and gender differences in pulmonary susceptibility to tobacco smoke-induced airspace enlargement and mucus hypersecretion. Age-matched male normotensive Wistar Kyoto (WKY) rats, male spontaneously hypertensive (SH) rats, and female SH rats were exposed either to filtered air or to tobacco smoke for 6 hours/day, 3 days/week for 12 weeks at an average total particulate concentration of 90 mg/m³. The left lung lobes were then fixed with 4% paraformaldehyde and examined by hematoxylin and eosin (H&E) staining for morphometric analysis of mean linear intercept (MLI) and alcian blue/periodic acid-Schiff (AB/PAS) staining for mucus glycoconjugate measurement. The MLI of male SH rats exposed to tobacco smoke (118 microns) was significantly increased compared with their filtered air controls (93 microns), whereas no significant changes were observed in WKY rats and female SH rats when compared with their corresponding controls. In addition, the difference in MLI was significantly greater in male SH rats compared with WKY rats and female SH rats. In the airway epithelium, male SH rats also demonstrated significant elevation in positive epithelial cell AB/PAS staining (10%) following 12 weeks of smoke exposure compared with filtered air controls (0.3%). In contrast, no significant changes were found in WKY rats and female SH rats when compared with the control animals. These results not only suggest the male SH rat to be a good model for tobacco smoke-induced airspace enlargement and mucus hypersecretion, but also show strong gender differences in the classical features of tobacco smoke-induced lung disease.

502 CYTOTOXIC AND INFLAMMATORY EFFECTS OF HARDWOOD COMBUSTION PARTICLES ON MOUSE MACROPHAGE CELL LINE.

P. I. Jalava^{1,2}, R. O. Salonen¹, A. S. Pennanen¹, M. S. Happonen^{1,2}, J. M. Tissari², J. K. Jokiniemi² and M. Hirvonen¹. ¹National Public Health Institute, Kuopio, Finland and ²University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

Particles from incomplete wood combustion are a major health concern worldwide. We studied wood smoke particles from good and poor combustion of birch (*Betula spp.*) wood logs in one masonry heater. The smoke was diluted in about 1:200 with

filtered laboratory air and cooled in a dilution tunnel. The size-segregated particulate samples (PM_{10-2.5}, PM_{2.5-1}, PM_{1-0.2} and PM_{0.2}) were collected with a high volume cascade impactor. Particulate material was extracted from the sampling substrates with methanol that was subsequently evaporated. Mouse RAW 264.7 macrophages were exposed for 24 hrs to four doses of particulate samples (15, 50, 150 and 300 μ g/ml) and corresponding volumes of filter blanks. TNF α and IL-6 productions were measured immunochemically (ELISA) and cytotoxicity was measured by using the MTT test. Particulate emissions from poor combustion were 2-10 fold compared to good combustion in different size ranges. The largest emissions were measured in PM_{0.2} with good combustion and in PM_{1-0.2} with poor combustion. None of the particulate samples induced significant IL-6 production, but TNF α production was increased. Particles from poor combustion induced in all the size ranges somewhat larger TNF α responses than particles from good combustion. The PM_{2.5-1} samples caused the largest inflammatory responses in both types of combustion experiments. The PM_{1-0.2} and PM_{0.2} samples from poor combustion had higher cytotoxic activity in the macrophage cell line per unit of particulate mass than the samples in other size ranges. In good combustion, the PM_{10-2.5} samples had the highest cytotoxic activity, whereas the PM_{0.2} samples were least cytotoxic. Thus, we managed to show that combustion conditions affect not only the mass but also the toxic activity of emitted particles in different size ranges.

503 PULMONARY AND SYSTEMIC EFFECTS OF FOUR-WEEK DIESEL INHALATION IN HEALTHY AND HYPERTENSIVE RATS.

R. R. Gottipolu¹, M. C. Schladweiler², A. Nyska², J. Wallenborn³, A. D. Ledbetter¹, D. Winsett¹, D. Malarkey², J. H. Richards¹, T. Krantz¹, M. Gilmour¹, R. Thomas¹, R. H. Jaskot¹ and U. P. Kodavanti¹. ¹NHEERL, U.S. EPA, Research Triangle Park, NC, ²NIEHS, Research Triangle Park, NC and ³School of Public Health, UNC, Chapel Hill, NC.

Diesel exhaust (DE) comprises a significant fraction of near road ambient particulate matter (PM). Exacerbated cardiac and pulmonary complications are noted in individuals residing near roadways. We examined pulmonary and systemic effects of diesel exhaust (DE) in healthy and hypertensive rats to investigate potential mechanisms and susceptibility. Male Wistar Kyoto (WKY) and Spontaneously Hypertensive (SH) rats (12-14 weeks age) were exposed whole body to air or freshly generated DE (gas plus particles) at 0.5 and 2.0 mg/m³ x 6h/d x 5d/wk x 4 wks. Lung injury and inflammation were assessed by histopathology and bronchoalveolar lavage fluid (BALF) analysis while systemic effects were assessed by plasma cytokines and hematological measurements. DE caused concentration-dependent increases in BALF neutrophils in both strains but no significant net accumulation of macrophages, despite the presence of particle-laden macrophages. Pulmonary protein leakage was modest but the activity of a cell injury marker, γ -glutamyl transferase was significantly increased in both strains. Lung pathology was characterized by thickening of alveolar septa, presence of alveolar pigmented histiocytes, interstitial inflammation and focal mast cell aggregation. Plasma cytokines, fibrinogen, and hematological parameters were not altered except for modest increases in white blood cells of SH and WKY and hematocrit values of SH rats exposed to DE. Noted inherent strain differences were likely due to presence of cardiovascular disease in SH rats; however, no striking exposure-related differences were apparent in any of the measured markers. These data demonstrate that 4-wk inhalation of rats to DE causes pulmonary inflammation and pathology but only modest systemic effects in healthy and genetically hypertensive rats. (This abstract does not reflect US EPA policy. Supported in part by UNC/EPA CT829471 and NRC Research Associateship Award at NHEERL, EPA).

504 DIESEL PARTICULATE-INDUCED NEUTRAL ENDOPEPTIDASE DOWNREGULATION IS ASSOCIATED WITH CELL PROLIFERATION.

S. S. Wong¹, N. N. Sun¹, M. L. Witten¹, R. Lantz¹, B. Lu², C. Gerard² and L. Hersch³. ¹Center for Toxicology, University of Arizona, Tucson, AZ, ²Division of Respiratory Diseases, Harvard Medical School, Boston, MA and ³Department of Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY.

Neutral endopeptidase (NEP) is a key cell surface peptidase which efficiently inactivates many peptide substrates and plays a central/regulatory role in the maintenance of homeostasis or in control of many physiopathological processes including inflammatory response and carcinogenesis. Therefore, we examined the role of NEP on diesel particulate-induced cell proliferation in human airway epithelial BEAS-2B cells by using RNAi technique. NEP siRNA (small interfering RNA) transfectant cells grew in vitro slower than control siRNA transfectant cells after diesel particulates exposure. Data show that the cell proliferation of NEP siRNA-infected BEAS-2B cells was significantly inhibited at 2 days of transfection with increased DEP concentrations (P < 0.01) and the net proliferation inhibition

rates at 5, 10, 20, and 40 µg/ml DEP were 1.4%, 7.6%, 10%, and 14.4 %, respectively, when compared with their mock controls. This finding indicates that NEP per se involves in cell proliferation in the presence of DEP stimulation. It suggests that down-regulation of NEP expression genetically may be an important mechanism responsible for many pulmonary pathogenesis of diesel particulate exposure. Decrease or loss of NEP expression may indicate a greater susceptibility to the risk of lung disorders including cancer (Supported by HEI).

505 THE EFFECTS OF DIFFERENT DIESEL EXHAUST PREPARATIONS ON THE HOST RESPONSE TO RESPIRATORY VIRAL INFECTION.

J. M. Cieniewicz¹, M. Madden^{2,1}, J. Samet^{2,1}, I. Gilmour^{3,1} and L. Jaspers¹.
¹Curriculum of Toxicology, University of North Carolina, Chapel Hill, NC, ²Human Studies Division, U.S. EPA, Chapel Hill, NC and ³NHEERL, U.S. EPA, Research Triangle Park, NC.

We have previously shown that exposure of human respiratory epithelial cells to an aqueous-trapped solution of diesel exhaust (DE_{as}) enhances the innate inflammatory and anti-viral responses to influenza infections through an increase in toll-like receptor (TLR) 3 expression and signaling. The focus of the current study was to compare and contrast the effects of different DE preparations derived from different sources with differing chemical compositions. The preparations used were: Standard reference material (SRM) 2975, which is derived from a forklift and has a low organic content; DE obtained from a compressor engine (DEP), having an intermediate organic content; extracted organic material (EOM) from both SRM 2975 and DEP; and a preparation of volcanic dust from the Mt. St. Helen's eruption (MSHD), which was used as a particle control. These preparations were compared with DE_{as}, which was derived from a diesel generator. Differentiated human bronchial epithelial cells and A549 cells were exposed to DE or the respective EOM for 2 hours, subsequently infected with Influenza A or challenged with poly(I:C), a synthetic form of dsRNA, and analyzed for the expression of the viral RNA recognition receptors, TLR3, TLR7, RIG-I, and PKR, the pro-inflammatory cytokines, IL-6, IL-8, and RANTES, as well as the anti-viral cytokines IFN-α and IFN-β. When cells were exposed to these preparations prior to infection with influenza or stimulation with poly(I:C), SRM 2975 and its EOM significantly increased levels of IL-6, DEP significantly increased levels of PKR and RIG-I, while its EOM did not, and MSHD significantly increased levels of TLR3, PKR, and RIG-I. Taken together, these data suggest that DE derived from different sources significantly vary in their effects on respiratory anti-viral responses and that the amount and type of organic material as well as particulate matter within preparations may be the cause for the observed differences.

506 INHALED OXIDATION CATALYSIS TREATED DIESEL ENGINE EMISSIONS INDUCE A MARKED SYSTEMIC OXIDANT STRESS. IS NO2 MODULATION THE MAIN TRIGGER?

J. Morin¹, V. Hasson^{1,2}, D. Preterre², S. Lorient¹, J. Henry¹ and F. Dionnet².

Due to the onset of oxidation catalysis (oxycat) as a Diesel emission after-treatment strategy, the oxidant potential of Diesel emissions increased which can be probed by the NO₂/NO_x ratio which correlates with the amount of reactive oxygen species to be generated from the atmosphere to aqueous media containing CPH as a spin probe and assayed by electron spin resonance (ESR). In this study, we assess the impact of 3 consecutive daily inhalations for 3 hours of diluted untreated (UDE) (low oxidant) and Oxycat treated (ODE) (high oxidant) Euro3 Diesel engine emissions (dilution 1:50, PM=0.5mg/m³, NO₂ 0.4ppmUDE and 4ppm ODE) and air and UDE doped with NO₂ at similar concentrations to those found in ODE (4ppm). Plasma TNFα, and lung and heart SOD and GPx activity levels were assayed in healthy (H) and chronic myocardial infarction (MI). ESR measurements of ROS ranked as: AIR<UDE<NO₂=UDE+NO₂<ODE showing a significant contribution of NO₂ as a source of CPH spinprobe oxidation. NO₂ alone induced systemic oxidant stress : lung and heart GPx activities in both H and MI rats while no impact was seen on SOD. ODE had little impact on GPx activity but for increased levels in MI rat heart, while it provoked increased activities of SOD in both H and MI rat lungs and heart. A moderate impact of UDE+NO₂ was seen on SOD activities in MI lungs and hearts, while no impact was seen in H rats. In both UDE+NO₂ and ODE, impacts on lung GPx appear to be less marked than for NO₂, suggesting potential quenching of NO₂ impact by the co-presence of DE acting on SOD activity. Concerning TNFα, increased serum levels were similar in MI rats after NO₂, UDE+NO₂ and ODE, while more disparate records were found in H rats with again a net tendency to increased levels. Diesel emission treatment with oxycat provokes a marked systemic oxidant stress and elevation of serum TNFα, which cannot be totally assigned to the sole modulation of NO₂ concentrations, other ROS might be involved. MI rats appear to be more sensitive than healthy rats

507 REALISTIC ATMOSPHERIC AGING ENHANCES RESPIRATORY TOXICITY OF DIESEL EMISSIONS.

E. N. Potts¹, K. deBruijne², S. Ebersviller², K. G. Sexton², L. Jaspers² and W. M. Foster¹. ¹Duke University, Durham, NC and ²UNC-CH, Chapel Hill, NC.

Objective: Determine if photochemical aging of hazardous air pollutants (HAPS) increases toxicity of air pollution mixtures to the respiratory system.

Methods: Diesel emission particles (DEP) from a Mercedes-Benz were collected on filters as fresh DEP (FRD) or light aged DEP (AGD) after photochemical transformation with an EPA/UNC synthetic urban mixture in an outdoor smog chamber. DEP were then instilled into adult C57 male mice in 3 groups: Control (C)(PBS), FRD & AGD treated mice. DEP (30ug) or PBS (50ul) was instilled on days 1, 4, & 7 & animals were examined on day 8 for pulmonary function changes (n=4/group) or euthanized to collect bronchoalveolar fluid (BAL)(n=6/group). The photochemical aging showed a dramatic change in composition of carbonyl containing compounds (like aldehydes & ketones).

Results: DEP tx led to airway & tissue inflammation by day 8 shown by increased BAL cellularity(37,500 cells/ml in C vs 263,000 cells/ml for AGD) & an influx of neutrophils (PMNs)(<500 PMN/ml in C vs 200,000 PMN/ml for AGD). FRD also elevated cellularity & PMN in BAL(e.g. 37,000 cells/ml & 50,000 PMN/ml) but with less inflammation. Pulmonary function, indexed as total lung resistance(Rt) to methacholine (Mch) challenge (forced oscillation technique) was increased by AGD; for example, in C group the average Rt increased above baseline by 76%(0.68 to 1.20 cmH₂O/ml/s) in response to the highest dose (100 mg/ml), whereas AGD induced increases in Rt to 300% of baseline. FRD also led to an increase in sensitivity to Mch, but to a much lesser degree, increasing Rt by 122%. Additionally, more mice (n=10) were treated with dark aged DEP (non-photochemically transformed) that induced BAL cellularity and functional changes comparable to the effects with FRD & significantly less toxic to respiratory tissues than the AGD DEP.

Conclusion: Realistic atmospheric aging enhances respiratory toxicity of vehicular DEP leading to an inflammatory response (BAL cellularity & influx of PMNs) & impairment of pulmonary function. Supported by NIH: ES12496 & ES011961.

508 COMPARING THE TOXICITY OF FRESH AND AGED DIESEL EXHAUST USING A NEWLY DEVELOPED IN VITRO EXPOSURE SYSTEM.

K. de Bruijne¹, K. G. Sexton¹, S. Ebersviller¹, M. Doyle¹, H. Jeffries¹ and L. Jaspers^{2,1}. ¹Envr Sciences & Eng, University of North Carolina, Chapel Hill, NC and ²CEMALB, Chapel Hill, NC.

There is an increasing interest in examining complex urban air pollution mixtures containing both particulate and gaseous components. Our previous studies have shown that atmospheric aging of gaseous pollutants modifies the chemical composition of air pollution mixtures, ultimately affecting its toxicological potential. The goal of this current project is to determine whether aging of complex gaseous and particulate mixtures, in the presence or absence of photochemistry, alters the toxicological potential of that mixture. Specifically, we wanted to determine whether aging of diesel engine emissions (DE) would alter toxicological responses compared to fresh DE emissions. A second goal was to examine the differences between multiple diesel sources; a 1980 Mercedes and a 2005 Volkswagen Passat TDI station wagon. Each freshly emitted DE sample was injected into a 120 m³ outdoor smog chamber and aged utilizing natural sunlight and humidity. Our electrostatic aerosol sampler (EAS) system has the capability to expose human respiratory epithelial cells directly to particulate matter in its natural state across an air-liquid interface. We have compared the toxicity of unreacted "fresh" DE, dark-aged DE (reacting with itself in the absence of sunlight), and photochemically-aged DE. Cells were exposed to the various DE's for 1 hour and analyzed for cytotoxicity (LDH) and inflammatory cytokine production (IL-8) 12 hours post exposure. Both fresh and aged DE from both DE sources increased LDH and IL-8 levels as compared to the clean air control, with the Mercedes engine generating a greater response. In addition, our results suggest that aging significantly enhances the responses compared to fresh DE emissions. Taken together, these results further support the importance of considering engine type and atmospheric aging when studying the toxicity of vehicle emissions.

509 ULTRA-STRUCTURAL EVALUATION OF CYTOTOXIC EFFECTS OF COARSE AND FINE PM ON MACROPHAGES AND ALVEOLAR EPITHELIUM.

A. De Vizcaya-Ruiz¹, A. Razo-García¹, M. Uribe-Ramírez¹, S. Gonzalez-Posos², M. E. Cebrián¹ and A. R. Osornio-Vargas³. ¹Toxicology, CINVESTAV-Zacatenco, Mérida-Ciudad D.F., Mexico, ²Microscopy Unit, CINVESTAV-Zacatenco, Mérida-Ciudad D.F., Mexico and ³INCan, México-Ciudad D.F., Mexico.

Persistent exposure to high levels of airborne particles (PM) has been associated with the increase of respiratory disorders. Alveolar epithelium and macrophages resident in the airway system are some of the first cell types to be in contact with tox-

ics present in PM. We evaluated the ultrastructural cytotoxicity effects by transmission electron microscopy (TEM) on J774A.1 macrophages (MQ) and A549 alveolar epithelium (AEC) cells exposed for 24 h to 50 µg/cm² of chemically characterized coarse and fine PM collected in Mexico City. Macrophages avidly phagocytized PM. Coarse PM were observed as dense fibrous bodies inside phagolysosomes; cytoplasmic organelle lysis, increase in filopodia and chromatin condensation were also evident. The exposure to fine PM showed agglomerates of particles in cytoplasmic lysosomes and vacuoles, mitochondria swelling and crest destruction, and condensed chromatin and membrane blebbing. AEC also internalized PM. Coarse particles were observed as solid dense aggregates within lysosomes, perturbation of cytoplasmic architecture, chromatin condensation and darkness of lamellar and dense bodies were also apparent. Exposure of AEC to fine PM showed aggregates of particles in lysosomes, presence of filamentous structures in the cytoplasm, mitochondrial swelling and chromatin condensation. TEM revealed a more dramatic organelle lysis and cytoplasmic perturbation from exposure to coarse than to fine PM, yet exposure to fine PM induced mitochondrial damage. Our results indicate that ultrastructural cytotoxic effects in MQ and AEC varied according to PM physicochemical properties despite of the cell type. These observations suggest that coarse and fine PM have a direct effect on organelle structure, particularly mitochondria and cytoskeleton, thus affecting metabolic energy generation and also promoting cell death, events that could contribute to adverse health effects.

510 PULMONARY HAZARD STUDY IN RATS WITH THREE FORMS OF ULTRA-FINE-TiO₂ PARTICLE-TYPES: DIFFERENTIAL RESPONSES RELATED TO SURFACE PROPERTIES.

D. B. Warheit¹, T. R. Webb¹, K. L. Reed¹, S. Frerichs² and C. M. Sayes¹.
¹DuPont Haskell Laboratory, Newark, DE and ²DuPont Titanium Technologies, Wilmington, DE.

The aim of this study was to assess lung toxicity in rats of newly developed, well characterized, ultrafine-TiO₂ particles and compare them to TiO₂ samples in two different size ranges. Groups of rats were intratracheally instilled with doses of 1 or 5 mg/kg of either two ultrafine rutile TiO₂ particle-types (uf-1 or uf-2); rutile R-100 fine-TiO₂ (F-1); 80/20 anatase/rutile P25 ultrafine-TiO₂ (uf-3); or quartz particles. Phosphate-buffered saline (PBS) solution instilled rats served as vehicle controls. Following exposures, the lungs of PBS and particle-exposed rats were evaluated for bronchoalveolar lavage (BAL) fluid inflammatory markers, cell proliferation, and by histopathology at post-instillation time points of 24 hrs, 1 week, 1 month, and 3 months.

The range of lung inflammation/cytotoxicity/cell proliferation and histopathological responses was quartz > uf-3 > F-1 = uf-1 = uf-2. Exposures to quartz and to a lesser degree, uf-3 anatase/rutile TiO₂ particles produced pulmonary inflammation, cytotoxicity and adverse lung tissue effects. In contrast, exposures to F-1 fine-TiO₂ particles or to uf-1 /uf-2 ultrafine-TiO₂ particle-types produced transient inflammation. We conclude that differences in responses to anatase/rutile uf-3 TiO₂ particles vs. the rutile uf-1 and uf-2 TiO₂ particles could be related to crystal structure, inherent pH of the particles, or chemical reactivity. Thus, based on these results, inhaled rutile ultrafine-TiO₂ particles are expected to have a low risk potential for producing adverse pulmonary health effects. Finally, the results demonstrate that exposures to ultrafine-TiO₂ particle-types can produce differential pulmonary effects, based upon their composition, and crystal structure. Thus, the lung toxicity of anatase/rutile uf-3 should not be viewed as representative for all ultrafine-TiO₂ particle-types.

511 EFFECTS OF CONCENTRATED AMBIENT ULTRA-FINE/FINE PARTICLES IN INSULIN-RESISTANT, OBESE RATS.

A. Elder¹, N. Corson¹, R. Gelein¹, P. Mercer¹, A. Rinderknecht¹, J. Stewart², J. O'Callaghan³, R. Chapman³, P. Simeonova³, M. Frampton², M. Utell², J. Finkelstein⁴ and G. Oberdörster¹. ¹Environment Med., University of Rochester, Rochester, NY, ²Adult Crit. Care Med., University of Rochester, Rochester, NY, ³CDC/NIOSH, Morgantown, WV and ⁴Pediatrics, University of Rochester, Rochester, NY.

We hypothesize that inhaled ambient ultrafine (UF) particles can induce oxidative stress-related injury of target cells in the cardiovascular system, thus providing a plausible mechanism for adverse effects observed in sensitive populations. We measured pulmonary and cardiovascular endpoints related to inflammation and oxidative stress in a diabetic rat model after exposure to concentrated UF/fine particle-containing aerosols. The Harvard ultrafine concentrated ambient particle system (HUCAPS) was used to generate the aerosols (particle number concentration ~0.05-1.3 x 10⁶/cm³; count median diameter ~75 nm) for acute exposures (4 hrs; 3 x 6 hrs). Obese, insulin-resistant homozygous male JCR:LA-cp rats (cp/cp; 13-15

months) as well as non-diabetic, lean heterozygous males (+/?; 5-13 months) were exposed to the HUCAP aerosols; controls were exposed to particle-filtered air. We collected blood, bronchoalveolar lavage fluid, and several tissues (lungs, heart, carotid arteries, aorta, liver, pancreas, spleen, kidneys, brain) after exposure. JCR cp/cp rats had slightly higher total lung lavage cell numbers, more blood leukocytes and leukocyte aggregates, and less glial fibrillary acidic protein in brain. These parameters were not consistently affected by HUCAP exposure. Although lavage neutrophils remained unchanged, there was a trend towards elevated protein, lactate dehydrogenase, and β-glucuronidase in HUCAP-exposed rats that was independent of genotype or exposure duration. After 3 days of exposure, the amplification of aortic mitochondrial DNA (12 kb) was significantly decreased in HUCAP-exposed cp/cp rats as compared to +/? rats and air-exposed controls. These results show that small oxidant stress-related changes occur after acute exposure to real-world particles in an animal model relevant to the study of UF particle effects in humans.

512 INFLUENCE OF ENDOTOXIN AND GLUCAN ON *IN VITRO* OXIDATIVE AND INFLAMMATORY POTENTIALS OF FINE AND COARSE PM FROM PAVED ROADS.

J. L. Mauderly¹, E. J. Bedrick², J. L. Peccia³, J. Seagrave¹ and J. D. McDonald¹.
¹Lovelace Respiratory Research Institute, Albuquerque, NM, ²University of New Mexico, Albuquerque, NM and ³Yale University, New Haven, CT.

Biological materials are known to contribute to the composition and toxicity of ambient particulate material (PM), but the nature and extent of contribution are largely unknown. Similarly, PM resuspended from paved road surfaces contributes to exposures, but the nature and toxicity of road dust is poorly documented. Dust was collected from active traffic surfaces at 55 sites in 6 U.S. regions using a non-contact vacuum method. Samples were sieved and aerosolized, and the PM_{2.5} and PM_{10-2.5} fractions were collected. Samples were analyzed chemically and for endotoxin, a lipopolysaccharide marker for gram negative bacteria (limulus amoebocyte assay), and 1,3-β-D-glucan, a carbohydrate marker for fungi and some bacteria (glucatelect lysate assay). Samples were tested in vitro for oxidative potential (oxidation products from incubation with linoleic acid) and for inflammatory potential (cytokines produced by incubation with human blood). Relationships between in vitro potency ranking and endotoxin and glucan contents were examined. Mean values for both endotoxin and glucan were similar for the two PM size fractions, but values varied considerably among individual samples. Overall, neither endotoxin nor glucan were strongly correlated with either oxidative or inflammatory potential, indicating that other chemical components drove those effects. However, both size fractions of dust collected at the perimeters of cattle feedlots in Kansas and Texas were among those having the greatest inflammatory potential, and also had by far the highest endotoxin contents (4x mean value for PM_{2.5}, and 8x mean value for PM_{10-2.5}).

Supported by the National Environmental Respiratory Center with funding from multiple government and non-government sponsors.

513 ASSOCIATIONS BETWEEN CHEMICAL COMPOSITION OF FINE PARTICULATE MATTER FROM SIX EUROPEAN CITIES AND INFLAMMATORY RESPONSES IN THE MOUSE LUNG.

M. S. Happo^{1,2}, R. O. Salonen¹, A. I. Halonen¹, P. I. Jalava^{1,2}, A. S. Pennanen¹, M. Sillanpää³, R. Hillamo³ and M. Hirvonen¹. ¹Department of Environmental Health, National Public Health Institute, Kuopio, Finland, ²University of Kuopio, Kuopio, Finland and ³Finnish Meteorological Institute, Helsinki, Finland. Sponsor: M. Viluksela.

Inflammation is regarded as an important mechanism in associations between urban air fine particulate concentrations and mortality and morbidity among cardiorespiratory patients. We investigated the association of fine particulate (PM_{2.5-0.2}) chemical composition with inflammatory responses in the mouse lung. The PM_{2.5-0.2} samples were collected using an optimized high volume cascade impactor during selected seasons in six European cities. Ions (IC), water-soluble elements (ICP-MS) and PAH-compounds (GCMS-SIM) were analyzed from these samples. Healthy C57BL/6J mice were intratracheally instilled a single dose (10 mg/kg) of the PM_{2.5-0.2} samples. At 4, 12 and 24 hours after the exposure, the lungs were lavaged and the bronchoalveolar lavage fluid (BALF) was assayed for indicators of inflammation and tissue damage: cell number, total protein and cytokines (TNF-α, IL-6 and KC). The responses at the most feasible time-point for each parameter were analyzed for Spearman (ρ) correlation with the measured chemical constituents. All the measured inflammatory responses correlated strongly with each other. Significant positive correlations (ρ=0.83-1.0) of the inflammatory responses were measured with dicarboxylic acids, Ca²⁺, Ni and V. Significant negative correlations (ρ=-0.83 to -1.0) were found with NO₃⁻, NH₄⁺, K⁺, As, and total and genotoxic PAH compounds. In conclusion, the present results suggest that fine particles originating from different sources may have differential effects on the respiratory tract.

Grants of the PAMCHAR project: EC-FP5 (QLK4-CT-2001-00423), Academy of Finland, Tekes.

514 SYSTEMIC TRANSLOCATION OF PARTICULATE MATTER (PM)-ASSOCIATED METALS FOLLOWING A SINGLE INTRA-TRACHEAL (IT) INSTILLATION IN WKY RATS.

J. G. Wallenborn¹, J. K. McGee², M. C. Schladweiler², A. D. Ledbetter² and U. P. Kodavanti². ¹SPH, UNC, Chapel Hill, NC and ²NHEERL, ETD, U.S. EPA, Research Triangle Park, NC.

Ambient PM contains transition metals with differing water solubilities. Epidemiological studies show a link between PM exposure and an increased risk of cardiovascular disease. Direct translocation of PM-associated metals from the lung into systemic circulation may be partly responsible for this. We measured levels of various metals in lung, plasma, heart and liver of healthy male WKY rats (12-15 wks old) 4 and 24 h after a single IT instillation of saline or oil combustion PM (8.33 mg/kg). IT instillation was used to control for pulmonary deposited dose and nasal absorption. The selected PM contains moderate levels of metals including zinc, vanadium, nickel, aluminum, silica, iron, copper, manganese and lead, each with differing water and acid solubility. Tissues were digested in acid and analyzed for elemental content using Inductively Coupled Plasma-Atomic Emission Spectroscopy. Most PM-associated metals were detected in the lung at both time points, with lower concentrations at 24 h than at 4 h. Both essential and nonessential metals with high water solubility were translocated into extrapulmonary organs. Detection of PM-associated vanadium and nickel in plasma, heart and liver at both time points demonstrates soluble metal translocation following pulmonary exposure. Increased levels of zinc and manganese were also observed in plasma and other organs. Metals with low water solubility were not detected in extrapulmonary tissues despite their decreased level in the lung, suggesting mucociliary clearance. We have demonstrated that PM-associated water soluble metals are rapidly translocated to systemic circulation and extrapulmonary organs following an acute IT instillation, likely via vascular absorption. This process is dependent on the relative water solubility of metals. Inhalation of metal rich PM may elicit a direct effect on pulmonary and extrapulmonary organs. (Abstract does not represent USEPA policy. This research was supported in part by UNC/EPA CT829471.)

515 A NOVEL TECHNIQUE FOR QUANTITATIVE ESTIMATION OF UPTAKE OF DIESEL EXHAUST PARTICLES BY LUNG CELLS.

R. K. Saxena^{1,3}, M. D. Hays² and I. Gilmour¹. ¹Immunotoxicology, NHEERL, U.S. EPA, Research Triangle Park, NC, ²NRMRL, U.S. EPA, Research Triangle Park, NC and ³School of Life Sciences, Jawaharlal Nehru University, New Delhi, India.

While airborne particulates like diesel exhaust particulates (DEP) exert significant toxicological effects on lungs, quantitative estimation of accumulation of DEP inside lung cells has not been reported due to a lack of an accurate and quantitative technique for this purpose. In the present study, we developed a sensitive and reliable new method for quantitative estimation of uptake of DEP by lung epithelial cells and macrophages in culture. The principle of the method is to first isolate the DEP exposed cells by trypsinization and to separate them from free extracellular diesel exhaust particles by Ficoll density gradient centrifugation. Ficoll purified cells were dissolved in 1% sodium dodecyl sulfate solution and insoluble ingested DEP isolated by centrifugation. DEP pellets were subjected to an analysis on a carbon analyzer that could accurately measure the amount of elemental carbon in the sample. Since the DEP preparation used in our studies is about 90% elemental carbon, and normal cells do not have any elemental carbon, the amount of DEP taken up by the cells could be accurately estimated by this method. Using this technique, we studied the time course and dose dependence of uptake of DEP by lung epithelial cells and alveolar macrophages. Qualitative differences were found in the uptake of DEP and ultra fine carbon black (UFCB) by LA4 epithelial cells and MHS alveolar macrophages. Macrophages could ingest DEP as well as UFCB with equal efficiency, whereas epithelial cells were significantly more efficient in taking up DEP as compared to UFCB. This technique can now be used to estimate the deposition and clearance of inhaled DEP and provide correlations between particle load and toxicity. This abstract does not reflect EPA policy.

516 CADMIUM AND ELEVATED TEMPERATURE STRESS SYNERGISTICALLY AFFECT ENERGY METABOLISM IN OYSTER, CRASSOSTREA VIRGINICA.

I. Sokolova¹ and G. Lannig^{2,1}. ¹Biology, University of North Carolina at Charlotte, Charlotte, NC and ²Alfred-Wegener Institute for Polar and Marine Research, Bremerhaven, Germany. Sponsor: R. Di Giulio.

Combined effects of temperature and a toxic metal, cadmium, on energy metabolism were studied in a model marine bivalve, the eastern oyster *Crassostrea virginica*, acclimated at 20, 24 and 28°C and exposed to 50 µg/L of cadmium. Based

on the concept of oxygen-limited thermal tolerance in aquatic ectotherms, we show that a persistent pollutant, cadmium, can have detrimental effects on oyster populations by reducing thermal tolerance due to impaired energy metabolism and elevated costs of basal maintenance. At 20 and 24°C but not at 28°C standard metabolic rate of Cd-exposed oysters increased compared to respective controls. Furthermore, highest respiratory time activity was observed in Cd-exposed oysters at 28°C. The results point at a mismatch between oxygen demand and delivery supported by preliminary results that show a decrease in hemolymph oxygen partial pressure during an acute temperature rise (4°C/10h) in Cd-exposed but not control animals (20°C acclimated animals). At 28°C but not at lower acclimation temperatures glycogen content in mantle tissue of Cd-exposed oysters decreased significantly (12.2±4.2mg/g to 5.4±1.3mg/g over 14 days cadmium exposure) suggesting that the combined stressors may increase dependence on glycogen to support maintenance metabolism. Glycogen supplies energy for reproduction as well as for anaerobic metabolism. In line with the continuously decrease in condition and the nearly 50% mortality observed after 14 days of cadmium exposure in oysters acclimated to 28°C we conclude that coupled with the additional stress of cadmium, oysters are less tolerant to cope with increasing energy expenditure with increasing temperature resulting in onset of critical temperature thresholds at lower temperatures. This work was supported by the National Science Foundation IBN-0347238 and Alexander von Humboldt Foundation.

517 MITOCHONDRIAL ACONITASE IS SENSITIVE TO CADMIUM-INDUCED OXIDATIVE STRESS BUT NOT PROTECTED BY UNCOUPLING PROTEINS IN OYSTERS.

I. Sokolova¹, A. Cherkasov¹, B. Sanni¹, K. Williams^{2,1} and E. Sokolov¹. ¹Biology, University of North Carolina at Charlotte, Charlotte, NC and ²Johnson C. Smith University, Charlotte, NC. Sponsor: R. Di Giulio.

Combined effects of temperature (12, 20 and 28-30°C) and Cd stress on production of reactive oxygen species (ROS) and oxidative stress was studied in a marine poikilotherm *Crassostrea virginica* (the eastern oyster) using mitochondrial aconitase as a sensitive biomarker of oxidative damage, and potential involvement of mitochondrial uncoupling proteins (UCPs) in antioxidant protection was assessed using purine nucleotides (GDP, ATP and ADP) as specific inhibitors and free fatty acids as stimulators of UCPs. Cd exposure in vitro resulted in elevated ROS production and oxidative damage to aconitase which was particularly pronounced at elevated temperature. At higher Cd levels, oxidatively damaged aconitase became resistant to reactivation by Fe²⁺ and thiols suggesting irreversible damage and "point of no return" for this enzyme. Exposure to Cd in vivo resulted in elevated levels of aconitase expression which may indicate a compensatory response to Cd-induced aconitase inactivation. Our study also showed expression of at least three UCP isoforms in *C. virginica* gill tissues but provided no indication that UCPs protect mitochondrial aconitase from oxidative inactivation in oysters. Unexpectedly, oyster mitochondrial aconitase was inhibited by physiologically relevant levels of ATP (IC₅₀ = 1.93 and 3.04 mM at 20 and 30°C, respectively) suggesting that allosteric regulation of aconitase by ATP may be involved in regulation of the tricarboxylic acid flux in oysters. Overall, the results of this study indicate that temperature stress exaggerates toxicity of Cd leading to elevated oxidative stress in mitochondria, which may have important implications for survival of poikilotherms in polluted environments during seasonal warming and/or global climate change, and suggest a novel temperature-dependent mechanism of allosteric regulation of TCA flux in oyster mitochondria. Supported by National Science Foundation IBN-0347238 and the American Physiological Society.

518 COMBINED EFFECTS OF TEMPERATURE AND CADMIUM EXPOSURE ON HEMOCYTE APOPTOSIS AND CADMIUM ACCUMULATION IN THE EASTERN OYSTER CRASSOSTREA VIRGINICA (GMELIN).

I. Sokolova¹, S. Grewal¹, A. Cherkasov¹ and C. Taylor^{2,1}. ¹Biology, University of North Carolina at Charlotte, Charlotte, NC and ²Johnson C. Smith University, Charlotte, NC. Sponsor: R. Di Giulio.

Combined effects of acclimation temperature (12, 20 and 28°C) and exposure to a toxic metal cadmium (Cd, 50 µg/L) on hemolymph parameters related to immune defense and metal transport were studied in a model marine bivalve, *Crassostrea virginica*. Acclimation to elevated temperatures resulted in higher plasma protein concentrations and increased Cd levels in oyster hemolymph plasma and hemocytes. Cd accumulation in hemocytes was linear over the 45 days of Cd exposure and accumulation rates were 0.10, 0.53 and 0.56 µg Cd g⁻¹ dry mass at 12, 20 and 28°C, respectively. Percentage of blood Cd burden associated with hemocytes increased with increasing temperatures from 13-20% at 12°C to 26-47% at 20 and 28°C suggesting a higher role for cellular Cd transport at elevated temperatures. Cd

levels in gills and hepatopancreas were positively correlated with Cd concentration in hemocytes, but accumulation rates were considerably faster, so that after 45 days of exposure Cd levels in gills and hepatopancreas were >10-20 times higher than in hemocytes. As a result of slow Cd accumulation possibly reflecting fast hemocyte turnover rates and/or exocytosis of Cd-containing granules, hemocytes in Cd-exposed oysters did not reach threshold Cd burdens required to trigger apoptosis. This suggests that hemocyte viability is not likely to contribute to immunosuppression in the environmentally relevant Cd range. In contrast, elevated temperature (28 °C) resulted in a significant increase in the percentage of apoptotic hemocytes compared to 12°C or 20°C supporting the notion that 28 °C is physiologically stressful for *C. virginica*. Overall, our study demonstrates that effects of environmental temperature on hemocyte viability and other important blood parameters such as plasma protein content and metal transport capability override potential Cd effects and further emphasizes a key role of temperature in oyster physiology.

519 EFFECTS OF DILTIAZEM AND LANTHANUM ON COPPER INHIBITION OF O₂ CONSUMPTION IN GILL OF THE AMERICAN OYSTER, *CRASSOSTREA VIRGINICA*.

S. Collins, K. McCoy, M. A. Carroll and E. J. Catapane. *Biology, Medgar Evers College, Brooklyn, NY*. Sponsor: A. Villalobos.

Our oyster rehabilitation studies showed that *Crassostrea virginica* transplanted to Jamaica Bay, NY accumulated copper. Mitochondria are sensitive to oxidative stress caused by metal toxicity. We studied effects of copper on O₂ utilization in *C. virginica* using a YSI Micro-Biological Oxygen Monitor with continuous flow or micro-batch chambers. 5 or 50 mg of CuSO₄ decreased respiratory rates 12 and 32%, respectively. Oysters grown in Jamaica Bay or exposed to copper pretreatments were more sensitive to copper additions. 5 mg CuSO₄ decreased O₂ utilization in excess of 34% and 50 mg caused complete inhibition. We now sought to determine if channel blockers would affect copper's ability to depress mitochondrial respiration. Using micro-batch chambers we measured O₂ consumption in the mitochondrial fraction from gill tissue. Copper reduced respiratory rates in them as previously shown. Pretreating the mitochondria with diltiazem blocked the copper inhibition, while pretreating with lanthanum did not. Lanthanum had a slight inhibiting effect of its own. The study demonstrates that the diltiazem is effective in blocking copper's inhibitory effects on mitochondria and may be useful in blocking copper transport into tissues of other animals as well. The toxic effects of copper on gill mitochondrial could be of physiological significance to the growth and long-term health of oysters and other marine animals living in a copper polluted environment and a copper uptake blocker could be of benefit for preventing diseases caused by high serum copper levels in humans. This work was supported by grants 1R25GM62003 of NIGMS, 0516061071 of NYSDOE and 66288-0036 of PSC-CUNY. We thank Flower & Sons, Inc., Oyster Bay, NY for supplying oysters.

520 PRELIMINARY STUDIES ON THE ACUTE TOXICITY OF SODIUM DICHROMATE TO GOLD FISH, *CARRASSIUS AURATUS*.

R. Paverreddy¹ and P. B. Tchounwou². ¹Biology/Environmental Science, Jackson State University, Jackson, MS and ²Biology/Environmental Science, Jackson State University, Jackson, MS.

Chromium is a common contaminant in ground water and surface water. It also enters into the environment as effluent from several industrial operations such as tanneries, ceramic, mining, dying, electroplating, metal finishing, printing and pharmaceutical industries. Chromium exists in the environment in divalent, trivalent and hexavalent forms, but the hexavalent form is more toxic than the other forms. Release of chromium-containing-effluents from the industries into the aquatic environment poses a major threat to the growth and survival of ichthyofauna. In this study we evaluated the dose-response and time-response relationships of chromium (sodium dichromate) toxicity to goldfish. The study was conducted using 96 hour static renewal bioassay, according to the USEPA protocol. Study results indicated that the exposure mortality rates of gold fish were increases with increasing concentration of chromium and exposure time periods. Mortality rates of 0 %, 33.32 %, 83.33 %, and 100 % were recorded at the concentration of 0 mg/L, 250 mg/L, 500 mg/L and 750 mg/L of sodium dichromate respectively. In the time response studies, the mortality rates at 0 mg/L were recorded 0 % at all the time periods whereas at 250 mg/L the mortality rates were recorded as 16.66 % for 24 hours, 33.32 % for 48 hours, 33.32 % for 72 hours and 33.32 % for 96 hours. At 500 mg/L concentration, the mortality rates were recorded as 33.32 % for 24 hours, 50 % for 48 hours, 66.66% for 72 hours and 83.33 % for 96 hours. At 750 mg/L concentration, the mortality rates were recorded as 83.33% for 24 hours, 100

% for 48 hours, 100% for 72 hours and 100 % for 96 hours. In summary, these preliminary data indicate that the toxicity of sodium dichromate to *Carassius auratus* fish is both concentration and time dependent.

521 AN EVALUATION OF TOXICITY OF TRIBUTYL TIN OXIDE AND ZINC PYRITHIONE IN *SEPIA OFFICINALIS* (COMMON CUTTLEFISH).

C. Stevens, A. Montalvo and J. Dwivedi. *Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX*.

Since the ban of tributyltin based antifouling marine paints, new alternatives such as zinc pyrithione have been introduced to control the growth of fouling organisms on the hulls of ships. To evaluate the risk posed to non-target organisms, the toxicity and accumulation of tributyltin oxide (TBTO) and zinc pyrithione (ZPT) were examined in *Sepia officinalis* following acute exposure. *S. officinalis* is native to the coastal waters of the U.K. and Indonesia, where persistence of TBTO and more recently elevated ZPT concentrations, have been measured. This species is harvested commercially by the seafood industry in these areas, which may play a role in introducing these compounds into the human diet. Tank raised *Sepia officinalis* were exposed to environmentally relevant doses of either 50ng/L TBTO or 50ug/L ZPT for 24 hrs. A third group receiving no treatment served as a control population. Following exposure, gill tissue was examined using light, scanning and transmission electron microscopy, graphite furnace atomic absorption spectrophotometry (GFAAS), and western blot analysis. Results indicate that *S. officinalis* is sensitive to TBTO and ZPT exposure. Gill tissue from TBTO and ZPT treatment animals showed necrosis and exfoliation of epithelium as a result of membrane degradation; however damage was greater in TBTO exposed groups as compared to ZPT exposure. GFAAS results showed a significant increase in tin and zinc concentrations in respective treatment groups as compared to control animals. Western blot analysis showed an increase in 4-hydroxynonenal adduct formation in treatment groups as compared to controls, suggesting an increase in lipid peroxidation following exposure to either biocide.

522 THE TOXIC EFFECTS OF MARINE BIOCIDES COPPER PYRITHIONE (COPPER 2-PYRIDINETHIOL-1-OXIDE) ON JUVENILE BROOK TROUT, *SALVELINUS FONTINALIS*.

D. Borg and L. D. Trombetta. *Pharmaceutical Sciences, St. John's University, New York, NY*.

Copper pyrithione (CuPT)—a booster biocide developed to replace globally-banned tributyltin (TBT)—acts by disrupting cell membranes, disrupting pH-gradients, and inhibiting ATP-synthesis in target species. However, research concerning the effects of CuPT exposure on non-target species is lacking. This investigation studied the acute effects of copper pyrithione exposure on juvenile brook trout, *Salvelinus fontinalis*. Morphologic changes, as well as copper bioaccumulation in several organ systems were studied. Juvenile brook trout were housed in a 950L aquarium and acclimated to laboratory conditions for 1 month. Trout were divided into groups of 10 and exposed to CuPT (dissolved in DMSO) in separate aquaria for a duration of 2 hours. Concentrations of CuPT ranged from 1ppm to 64ppm. Following exposure, trout were sacrificed and dissected. From each fish, brain and the 2nd and 3rd gill arches were removed and either frozen in liquid N₂ or fixed in 10.0% Sorensen's buffered (pH 7.4) formalin. For light microscopy, gills were embedded in paraffin and sectioned for histological analysis. Frozen tissue was digested in concentrated nitric acid and subjected to graphite-furnace atomic absorption spectroscopy (GFAAS). Results from histological analysis showed the formation of club shaped lamella, edema, epithelial lifting and exfoliation and the fusion of secondary lamella at CuPT concentrations of 16, 32 and 64ppm. GFAAS analysis demonstrated significant increased levels of copper in the brain ($p < 0.005$) and gill arches ($p < 0.001$) of trout as compared to matched controls. These data indicate that the use of CuPT as an alternate biocide could potentially harm non-target aquatic organisms.

523 EFFECTS OF ZINC PYRITHIONE EXPOSURE ON *BUNODOSOMA CAVERNATA* (WARTY SEA ANEMONE).

A. Montalvo, J. Bixby and J. Dwivedi. *Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX*.

Zinc Pyrithione (Zinc Omadine® or Zinc 2-pyridinethiol-1-oxide) is a registered antifouling agent for incorporation into boat paints to control the growth of marine fouling organisms. There is limited documentation on the effects of zinc pyrithione

(ZPT) on anthozoans such as *Bunodosoma cavernata*. To better understand the effects of acute environmentally relevant exposure to this invertebrate, collected specimens were exposed to varying concentrations (5, 50, 100 µg/L) of ZPT for 24 hrs. An additional group served as a control population. Following exposure, anemone tissues were studied using light, scanning and transmission electron microscopy, graphite furnace atomic absorption spectrophotometry (GFAAS), and western blot analysis. Microscopy results showed that anemones exposed to ZPT had exfoliation of epithelial tissues, degradation of musculo-epithelial cells, and loss of mesoglia in a dose dependant manner. Western blot analysis showed an increase in 4-hydroxynonenal protein adducts in tissues of treatment animals as compared to controls, evidence of increased lipid peroxidation. GFAAS results confirm a significant increase in zinc concentration in tissues from treatment animals as compared to controls, indicating bioaccumulation.

524 RELEASE OF THE LIPID PEROXIDATION MARKER 8-EPI-PGF2 α FROM GILL EPITHELIAL CELLS.

E. G. Spokas¹, B. W. Spur², C. Jiang², J. Foglein⁴, S. Harshman⁴, A. Rodriguez² and G. M. Cohen³. ¹Chemistry, Rider University, Lawrenceville, NJ, ²Cell Biology, University of Medicine and Dentistry of New Jersey, School of Osteopathic Medicine, Stratford, NJ, ³Biological and Environmental Sciences, Troy University, Troy, AL and ⁴Chemistry and Biochemistry, Rowan University, Glassboro, NJ.

The aim of this study was to compare the capacities of ferric and divalent lead ions to promote lipid peroxidation in gill epithelial cells using the release of the isoprostane marker 8-epi-PGF2 α . Cell suspensions were prepared using fresh gill tissue from fathead minnows. After collagenase treatment and passage of cells through nylon sieves, epithelial cells were isolated on a 51% Percoll gradient using a method previously applied to rainbow trout gills. After centrifugation, gill pavement cells formed a band in the gradient between 1.052 and 1.074 g/mL. Cell viability was estimated as 95%. For morphological studies, paraformaldehyde-fixed cell suspensions were centrifuged and the pellet examined by light microscopy. Pellets were stained for alkaline phosphatase (ALP), because ALP specifically stains pillar cells and vascular elements. Contamination by vascular elements was estimated as < 3%. Basal levels of immunoreactive (ir) 8-epi-PGF2 α were measured by incubating pavement cells in oxygenated modified Cortland's saline and enzyme immunoassay of the supernatant after centrifugation. After 60 min, levels of free ir 8-epi-PGF2 α in medium from control cells ranged from 2.75 - 11.03 ng. The amount of ir 8-epi-PGF2 α in the medium of cells exposed to 5 and 500 µM FeCl₃ for 60 min increased to 14.1 ± 5.2 and 16.1 ± 6.6 ng (% change relative to co-incubated control cells = 149 and 185%, respectively). The enhancement of isoprostane release was statistically significant at 500 µM FeCl₃ (p<.05). By contrast, the release of ir 8-epi-PGF2 α from cells exposed to lead II nitrate (0.6 - 120 µM) did not differ from control cells. In summary, ferric ions but not divalent lead ions are potent in causing oxidant stress to gill epithelial cells as determined by the release of free ir 8-epi-PGF2 α into incubation medium.

525 GENE EXPRESSION PROFILES IN FATHEAD MINNOW EXPOSED TO 2, 4-DNT: CORRELATION WITH TOXICITY IN MAMMALS.

H. Wintz¹, L. J. Yoo², J. A. Stevens², R. D. Beger³, R. D. Holland³, E. J. Perkins² and C. D. Vulpe¹. ¹Nutritional Sciences and Toxicology, UC-Berkeley, Berkeley, CA, ²Environmental Laboratory, U.S. Army Corps of Engineer Research and Development Center, Vicksburg, MS and ³Division of Systems Toxicology, National Center for Toxicological Research, Jefferson, AR.

Toxicogenomics, the genome-wide analysis of gene expression to study the effect of toxicants, has great potential for use in environmental toxicology. Applied to standard test organisms, it has possible applications in aquatic toxicology as a sensitive monitoring tool to detect the presence of contaminants while providing information on the mechanisms of action of these pollutants. We describe the use of a cDNA microarray of the fathead minnow (*Pimephales promelas*) a standard sentinel organism in aquatic toxicology, to better understand the mechanisms of toxicity of 2,4-dinitrotoluene (2,4-DNT) which is released in the environment through military and industrial use. We have constructed a fathead minnow microarray containing 5,000 randomly picked anonymous cDNAs from a whole fish cDNA library. Expression profiles were analyzed in fish exposed to 2,4-DNT for 10 days at three concentrations (11, 22 and 44 µM respectively) below the measured LC50 (58 µM). Sequence analysis of cDNAs corresponding to differentially expressed genes affected by exposure revealed that lipid metabolism and oxygen transport genes were prominently affected in a dose specific manner. We measured liver lipids and demonstrate that lipid metabolism is indeed perturbed following exposure. These observations correlate well with available toxicological data on 2,4-DNT. We

present possible modes of action of 2,4-DNT toxicity and suggest that fathead minnow cDNA microarrays can be useful to identify mechanisms of toxicity in fish and as a predictive tool for toxicity in mammals

526 ASSESSMENT OF THE ESTROGEN ACTIVITY OF PERFLUOROOCTANOIC ACID (PFOA), PERFLUOROOCTANE SULFONATE (PFOS) AND OTHER STRUCTURALLY DIVERSE PERFLUORINATED CHEMICALS IN RAINBOW TROUT.

A. D. Benninghoff^{1,2,3}, J. A. Field^{1,2} and D. E. Williams^{1,2,3}. ¹Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, ²Environmental Health Sciences Center, Oregon State University, Corvallis, OR and ³Marine and Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR.

PFOA and PFOS, as well as other perfluoroalkyl carboxylic acids (PFCAs) and perfluoroalkyl sulfonates (PFSs), are by-products formed during the synthesis of perfluorinated chemicals (PFCs) or intermediates in the manufacture of nonstick and stain-resistant coatings. A recent toxicogenomics study suggests that PFOA acts via an estrogenic mechanism to promote hepatocellular carcinoma in rainbow trout. PFOA, perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA) and perfluoroundecanoic acid (PFUnDA) have also been shown to be estrogenic *in vivo* using the vitellogenin induction bioassay. However, it is not known whether any PFC directly binds the estrogen receptor (ER). Perfluoroheptanoic acid (PFHpA), PFOA, PFNA, PFDA, PFUnDA, perfluorododecanoic acid (PFDDA), PFOS, perfluorodecane sulfonate, 8:2 fluorotelomer alcohol (8:2 FtOH), 10:2 fluorotelomer alcohol (10:2 FtOH), 8:2 fluorotelomer acrylate (8:2 FtOAc) and N-methyl perfluorooctane sulfonamido ethyl acrylate (MeFOSEA) were tested for their ability to bind the rainbow trout hepatic ER using a standard steroid receptor competitive binding assay. All PFCAs and PFSs tested displaced [³H]-estradiol by more than 75%. Relative binding affinities (RBAs) of these ligands ranged from 0.0003 to 0.003% with PFDA, PFOS and PFDS having the highest affinities for the hepatic ER. These results are similar to those obtained for two weak xenoestrogens, indole-3-carbinol and 4-nonylphenol. Alternatively, 8:2 FtOH, 10:2 FtOH, 8:2 FtOAc and MeFOSEA did not bind the hepatic ER. These results show that multiple PFCs found in the environment are likely weak xenoestrogens. However, variations in PFC chemical structures, namely the specific end group, may influence their bioavailability *in vivo*. Supported NIH grants ES07060 and ES03850 and a DuPont gift.

527 DECREASED SURVIVAL OF RAINBOW TROUT EMBRYOS FERTILIZED WITH SEMEN FROM 17ALPHA-ETHYNYLESTRADIOL EXPOSED MALE TROUT.

J. J. Nagler¹, K. H. Brown¹ and L. R. Schultz². ¹Biological Sciences and Center for Reproductive Biology, University of Idaho, Moscow, ID and ²Marine Science Laboratory, Battelle-PNNL, Sequim, WA.

17 α -ethynylestradiol (EE2) is a potent synthetic estrogen that is found in many aquatic environments due to domestic sewage discharges. We previously demonstrated that EE2 exposure to sexually maturing male trout decreases fertility, which was not associated with changes in sperm numbers or motility. In this study, we specifically investigated the effect of EE2 exposure on early embryonic developmental success. Male rainbow trout entering spermatogenesis were exposed for 50 days to waterborne concentrations of 0, 0.8, 8.3, or 65 ng EE2/L (mean values of measured concentration). Semen was then collected from 10 randomly selected individuals in each exposure, the number of sperm quantified, and *in vitro* fertilization trials performed. All fertility trials used eggs obtained from a single unexposed female. Each semen sample was used to fertilize 150 eggs with a sperm:egg ratio of 300,000:1. All treatments were evaluated at four developmental time-points: 0.5 days post fertilization (dpf), 2.5 dpf, 7 dpf, and 14 dpf, representing first cleavage, raised blastula, embryonic keel, and eyed embryo stages, respectively. All EE2 treatments significantly decreased the number of eyed embryos relative to controls (71.8, 84.5, 77.6 % of control values for the 65, 8.3 and 0.8 ng/L treatments respectively). The highest exposure level (65 ng/L) also decreased the number of embryos at all earlier time-points of development (60 % of control). These results clearly demonstrate that trans-generational effects of EE2 are the most sensitive reproductive endpoint in trout. A parallel experiment, which exposed juvenile trout (6 months of age at time of exposure) to 100 ng/L EE2, did not cause subsequent changes in embryonic development when semen from these fish were used in fertility trials. Thus, sexually maturing trout undergoing spermatogenesis appear to be the most vulnerable life stage to EE2 exposure. Supported by NIEHS Grant 5 R01ES012446-03.

528 EFFECTS OF ALKYLANILINES AND ALKYLPHENOLS ON ESTROGEN RECEPTOR BINDING AND GENE EXPRESSION IN RAINBOW TROUT AND HUMANS *IN VITRO* MODELS.

M. Tapper¹, J. S. Denny¹, B. R. Sheedy¹, J. M. McKim², J. F. Pregoner², P. C. Wilga², B. J. Johnson¹ and P. K. Schmieder¹. ¹U.S. EPA, ORD, NHEERL, Mid-Continent Ecology Division, Duluth, MN and ²CeeTox Inc., Kalamazoo, MI.

Estrogen receptor (ER) mediated binding and gene expression assays for both rainbow trout (rt) and human (h) were used to evaluate estrogenic potential of 16 alkylphenols and alkylanilines. This work was part of a larger project to determine which chemicals of EPA concern can bind ER and be ER mediated endocrine disruptors. All 16 alkylphenols and alkylanilines tested in the cytosol rtER competitive binding and rt liver slice/VTG mRNA expression assays competitively bound to rtER and induced VTG expression. Additionally a subset of chemicals tested in the recombinant hER competitive binding assay and two hER mediated gene expression assays, expression of the endogenous estrogen-regulated pS2 gene in the human mammary carcinoma MCF-7 cell line and expression of the estrogen-responsive element luciferase reporter gene construct in the T47D-KBluc cell line, competitively bound to hER and all except high LogP p-n-octylaniline induced gene expression in both hER gene expression assays. For most alkylphenols and alkylanilines gene induction occurred at concentrations greater than or equal to those which resulted in displacement of estradiol in binding assays. The exceptions were high LogP chemicals p-n-octylphenol (5.8) and p-n-octylaniline (5.1) which were not as potent in the rt liver slice model as predicted from rtER binding results. These results suggest chemical uptake and availability are limiting the effect of these chemicals. Furthermore, the efficacy of the rt and h gene expression response for some chemicals appeared to be limited by chemically induced toxicity. Therefore, in addition to binding affinity factors such as chemical uptake, toxicity and metabolism ultimately determined estrogenic potency in rt liver slices and human cell lines.

529 REPRODUCTIVE TOXICITY OF VINCLOZOLIN AND KETOCONAZOLE IN FATHEAD MINNOW: ADVERSE EFFECTS AND COMPENSATORY RESPONSES.

D. Martinovic, L. S. Blake, E. J. Durhan, K. J. Greene, M. D. Kahl, K. M. Jensen, R. D. Johnson, E. A. Makynen, D. L. Villeneuve and G. T. Ankley. Mid-Continent Ecology Division, U.S. EPA, Duluth, MN.

The objective of this study was to characterize responses of fish reproductive systems to dicarboximide (vinclozolin [VZ]) and conazole (ketoconazole [KTC]) fungicides. Although these chemicals have been shown to alter endocrine function in vitro, either by direct interactions with androgen receptors (ARs) (VZ) or by inhibiting activities of cytochrome P450s (CYPs) that mediate steroidogenesis (KTC), little is known concerning their in vivo effects on processes mediated by hypothalamic-pituitary-gonadal axis in fish. We exposed fathead minnows, a model small fish species, for 21-d to waterborne VZ or KTC and evaluated responses at multiple levels of biological organization including: expression of AR and several CYP genes involved in steroid biosynthesis, ex vivo steroidogenic activity, plasma concentrations of sex steroids, gonad histopathology, and reproductive (spawning) success. Exposure to KTC reduced egg production, increased gonadosomatic index in both sexes, and in males caused proliferation of Leydig cells. Also, mRNA transcripts for two key steroidogenic enzymes (CYP side-chain cleavage and CYP17 α hydroxylase /17,20 lyase) were elevated. These changes are indicative of potential adaptive or compensatory responses to impaired steroidogenic capacity. Exposure to VZ resulted in reduced expression of secondary sex characteristics and decreased egg production. VZ also induced compensatory responses – it caused up-regulation of AR, 11 β -hydroxysteroid dehydrogenase mRNA transcripts, and ex vivo gonadal testosterone production. Overall, our data suggest that both VZ and KTC adversely affect endocrine function of fish, but the animals can effectively compensate for these effects to a certain degree. These compensatory responses have important implications for interpretation of data from tests with endocrine-active chemicals.

530 EFFECTS OF TRENBOLONE ON EXPRESSION OF ESTROGEN-RESPONSIVE PLASMA PROTEINS IN ADULT SHEEPSHEAD MINNOW (CYPRINODON VARIEGATUS).

M. J. Hemmer, G. M. Cripe, K. A. Salinas, B. L. Hemmer, L. R. Goodman and C. C. Walker. ORD, NHEERL, GED, U.S. EPA, Gulf Breeze, FL. Sponsor: W. Benson.

Protein profiling can be used for detection of biomarkers that can be applied diagnostically to screen chemicals for endocrine modifying activity. In previous studies using sheepshead minnows (SHM), mass spectral analysis detected four peptides

(2950.5, 2972.5, 3003.4, 3025.5 m/z) in the plasma of estrogen-treated male fish and gravid females as opposed to unexposed males. The 3025.5 m/z peptide was positively identified as SHM zona radiata protein fragment 2, an egg membrane protein, further supporting the four peptides as suitable estrogen-responsive biomarkers. In this study, a 21-day aqueous exposure of adult male and female SHM was conducted to investigate possible dose-related effects of the synthetic androgen, 17 β -trenbolone on expression of the four estrogen-responsive peptides and on expression of plasma vitellogenin (VTG). Fish were continuously exposed to 0.005, 0.05 and 5.0 μ g trenbolone/L, a vehicle control (triethylene glycol, TEG), and a seawater (SW) control using an intermittent flow-through dosing system. Plasma was analyzed for presence of the four peptide biomarkers by MALDI-TOF-MS and VTG protein by quantitative ELISA. Male fish from the trenbolone treatments and controls showed no measurable levels of VTG and absence of the four peptide biomarkers. The estrogen-responsive peptides were present in females from the SW, TEG, 0.005, and 0.05 μ g/L exposures, but all four peptide biomarkers were significantly reduced in the highest treatment of 5.0 μ g/L ($p < 0.0002$ to $p < 0.005$). Mean plasma VTG ranged from 11.8 to 4.5 mg/ml in the SW control and 5.0 μ g/L treatment, respectively. No significant difference in VTG was found between the trenbolone and control treatments ($\alpha = 0.05$) which can be explained by VTG's high accumulation and slow clearance from the bloodstream. These results demonstrate trenbolone can inhibit expression of estrogen-responsive proteins and may be capable of causing adverse reproductive effects.

531 MODULATION OF AROMATASE ACTIVITY AS A MODE OF ACTION FOR ENDOCRINE-DISRUPTING CHEMICALS IN A MARINE FISH.

L. J. Mills¹, R. E. Gutjahr-Gobell¹, S. C. Laws², D. B. Horowitz¹, C. O. Chichester³ and G. E. Zaroogian¹. ¹NHEERL, Atlantic Ecology Division, U.S. EPA, Narragansett, RI, ²NHEERL, Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC and ³Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

The steroidogenic enzyme aromatase catalyzes the conversion of androgens (androstenedione and testosterone) to estrogens (estrone and estradiol). In this study, we examine the effects that five endocrine-disrupting chemicals (EDCs) have on reproduction and aromatase activity in brains and gonads from the marine fish cunner (*Tautoglabrus adspersus*). Our goal is to investigate the hypotheses that: 1) modulation of aromatase activity is an indicator of exposure to EDCs that work through diverse modes of action; 2) activity of aromatase isozymes in fish brain and gonad are differently affected by exposures to different EDCs; and 3) modulation of aromatase activity in brains or gonads of spawning fish is linked with reproductive impairment. Spawning cunner were treated with octylphenol, atrazine, estradiol, ethynylestradiol or the aromatase inhibitor androstatrienedione (ATD) using a slow-release implant. Reproductive endpoints (egg production, fertility and viability) were monitored for 14 days, then fish were sacrificed. Brains and gonads were flash-frozen for analysis of microsomal aromatase activity. GSI, HSI and plasma vitellogenin were determined. Results indicate that male brain aromatase activity was significantly changed by exposure to all five EDCs, although not at all tested concentrations, suggesting that such changes are indicative of EDC exposure. Results also show impacts on aromatase activity are tissue-specific. Gonad aromatase activity was significantly changed only in ovaries from fish treated with estradiol or ethynylestradiol. In contrast, male brain aromatase activity was altered by all EDCs. Lastly, results suggest that significant modulation of aromatase activity in the brains of spawning males is consistently linked with reproductive impairment: a significant decrease in any reproductive endpoint was always associated with altered male brain aromatase activity.

532 VITELLOGENESIS INDUCTION IN MALE FISH EXPOSED TO WASTE WATER EFFLUENT ESTROGENS.

E. E. Singer¹, L. Gibbons², S. R. Tuberty¹ and C. Babyak². ¹Biology, Appalachian State University, Boone, NC and ²A.R. Smith Department of Chemistry, Appalachian State University, Boone, NC.

Municipal wastewater has been widely-documented to contain compounds which are introduced to aquatic systems and can significantly impact biota. We investigated environmental endocrine disruption (EED) resulting from exposure to pharmaceutical estrogens (eg, birth control, hormone therapies) from the Boone waste water treatment plant (WWTP) effluent in the S. Fork of the New River, Boone, NC. The effluent release comprises 25-40% of the downstream flow. Environmental estrogen exposure is indicated by measuring a common biomarker, the egg yolk protein vitellogenin (Vtg), in male fish. Fish and water samples (1L) were collected from two sites: the WWTP effluent release and upstream at the ASU greenway (reference). Estrogens were separated from water samples by C18 solid phase extraction columns (to concentrate samples 1000 fold) and analyzed via GC-MS. The optimized protocol resulted in a lower detection limit of 250 ppb. Fish

blood protein samples were characterized using gel electrophoresis and analyzed for Vtg presence by Western blotting, using antibodies specific to fish Vtg. Fish blood samples collected in April 2006 (university in session) indicated sixty percent of male hog suckers, *Hypentelium nigricans*, were producing Vtg (n=5). As expected, Western blots of female plasma exhibited Vtg-specific bands while males demonstrated even denser Vtg bands (likely due to the lack of oocyte uptake of the protein). Analysis of water samples collected in July (university not in session) indicated that estrogen concentrations were below detection limits. September samples (university in session) of water and several fish populations are currently being analyzed. Future sampling will include collection of monthly and quarterly water and fish samples to determine if student estrogens cause temporally increased Vtg production in exposed male fish. Occurrence of EED in fishes with various life history strategies and habitat preferences, as well as spring versus fall spawning fish populations, will be monitored.

533 ESTROGEN RESPONSIVE PLASMA PROTEIN BIOMARKERS IN FOUR FISH SPECIES.

C. C. Walker¹, K. A. Salinas¹, P. S. Harris¹, A. D. Benninghoff², K. R. Springman³, D. J. Ostrach⁴ and M. J. Hemmer¹. ¹Gulf Ecology Division, U.S. EPA, Gulf Breeze, FL, ²Department of Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, ³Department of Civil & Environmental Engineering, University of California, Davis, CA and ⁴Department of Pathology, Microbiology & Immunology, University of California, Davis, CA.

We previously reported on the use of mass spectrometry to examine plasma from sheepshead minnows (SHM) exposed to estrogen agonists for changes in estrogen responsive protein biomarkers. In this study male fish of four species representative of three orders were exposed to 17 β -estradiol (E2) and examined for the presence of putative estrogen-responsive plasma protein biomarkers. Species and orders evaluated include: Order Cyprinodontiformes (SHM, *Cyprinodon variegatus*, and Gulf Killifish, *Fundulus grandis*), Order Perciformes (Striped Bass, *Morone saxatilis*) and Order Salmoniformes (Rainbow Trout, *Oncorhynchus mykiss*). Blood plasma was sampled from SHM and killifish after 7 d aqueous exposure, striped bass at 3 d post injection and rainbow trout after 14 d dietary administration. Plasma was diluted with acidified aqueous acetonitrile, combined with a sinapinic acid solution and then analyzed by MALDI-TOF-MS without further cleanup. A number of plasma proteins were upregulated in all four species in response to E2 treatment. However, the specific upregulated proteins varied among the species tested. Proteins in the mass range of 22-31 kDa were upregulated in treated compared to control SHM, killifish and striped bass. In contrast, treated rainbow trout exhibited no increased expression of proteins in the 22-31 kDa range but did show increased expression in the 32-35 kDa range. These results indicate the protein biomarker based estrogen effects screening technique developed for SHM should be readily transferable to other fish species and can be used to understand differences in species sensitivity to estrogen agonists. This approach will also permit the development of a less species-dependent technique than ELISA for environmental monitoring of estrogenic effects in multiple fish species.

534 IMPACT OF IMIDACLOPRID ON THE ACTIVITIES OF SERUM ENZYMES IN FRESH WATER FISH, CHANNA PUNCTATUS.

V. R. Chintalapani and J. C. Prof. Biochemistry, Chaitanya Degree and P.G. College, Warangal, Andhrapradesh, India. Sponsor: C. Chetty.

On the treatment with sublethal concentration of Imidacloprid (organo chloride) the serum enzymes of fish, Channa Punctatus are altered during the toxic exposure periods at different time intervals. The activities of different serum enzymes such as Aldolase, Lactate dehydrogenase (LDH), Iso-citrate dehydrogenase (ICDH), Pyruvate kinase, SGPT, SGOT, Alkaline Phosphatases, Acid Phosphatases and Creatine Kinase (CK) are altered under the impact of imidacloprid. The high activities of Transaminases indicate that Imidacloprid could induce malignance and hepatobiliary disease. Enhancement in Creatine Kinase leads to impairment of central nervous system (CNS) under toxic stress. The activities of enhanced Phosphatases might be due to lysosomal mobilization. The enhanced serum Dehydrogenases reveal the damage of kidney and liver of exposed fishes.

535 CRYOPRESERVED FISH HEPATOCYTES AS A MODEL FOR BIO-ACCUMULATION AND CYTOTOXICITY EVALUATION OF AQUATIC POLLUTANTS.

A. Koganti¹, A. S. Kane¹, J. C. Hardy² and P. M. Silber¹. ¹Celsis In Vitro Technologies, Baltimore, MD and ²Department of Epidemiology and Preventive Medicine, University of Maryland, School of Medicine, Baltimore, MD.

The objective of this study was to develop an in vitro model to examine the bioaccumulation and cytotoxic effects of aquatic and wastewater related pollutants. In support of this objective, we developed a method for the isolation of rainbow trout

(*Oncorhynchus mykiss*) hepatocytes in which viability and metabolic activities are maintained. Using a two-step perfusion technique, we successfully isolated hepatocytes with viabilities ranging from 80-95% as assessed by trypan blue exclusion and flow cytometry. Hepatocytes were cryopreserved in an automated, controlled rate freezer with very little loss in viability. On thawing, these cells were >80% viable as assessed by trypan blue exclusion with vial-to-vial variation of only 6% as assessed by flow cytometry. The biotransforming ability of trout hepatocytes was assessed using the following nine specific substrates: dextromethorphan, tolbutamide, phenacetin, testosterone, mephentoin, chlorzoxazone, coumarin, 7-ethoxycoumarin and 7-hydroxycoumarin. While the specific activities of several CYP enzymes were detected, significant CYP3A-like phase I activity was observed during the conversion of testosterone to 6 β - and 16 β -hydroxytestosterone. Similarly, significant activity of the phase II enzyme, glucuronosyltransferase, was evident by the glucuronidation of 7-hydroxycoumarin. Using the above mentioned panel of substrates we also demonstrated the maintenance of enzyme activities following cryopreservation. For these studies, cryopreserved cells were compared to freshly isolated cell suspensions. Taken together, these results demonstrate that cryopreserved trout hepatocytes are viable and exhibit xenobiotic metabolizing enzyme activities. Hence, they represent a suitable model for screening large numbers of hazardous chemicals for their cytotoxicity and ability to be either metabolized or accumulated.

536 EFFECTS OF ETHYNYLESTRADIOL EXPOSURE DURING LARVAL DEVELOPMENT OF THE AMPHIBIAN, XENOPUS TROPICALIS.

A. W. Olmstead, B. A. Bennett, G. W. Holcombe, P. A. Kosian, K. K. Woodis, J. J. Korte and S. J. Degitz. Mid-Continent Ecology Division, U.S. EPA, NHEERL, Duluth, MN. Sponsor: M. Hornung.

17 α -Ethinylestradiol is a pharmaceutical chemical that primarily enters into the aquatic environment via wastewater from urban centers. This potent estrogen has been reported to impact the endocrine systems of fish species at concentrations in the low ng/l range. In order to evaluate the toxicity of this chemical on an amphibian species, we exposed larval West African clawed frogs, *Xenopus tropicalis*, to ethinylestradiol from 1 day post-fertilization (NF stage 15-20) to metamorphosis (NF stage 66). Exposures were carried out in a continuous flow-through system at concentrations ranging from 10 to 640 ng/l. At metamorphosis, half of the froglets were weighed, blood was collected from the heart, and gonads were excised for quantitative PCR analysis. The froglets not assessed at metamorphosis were placed in clean media and raised until 6 weeks post-metamorphosis at which time they were similarly assessed. Exposure to all concentrations resulted in significantly reduced times to metamorphosis. Ethinylestradiol had no effect on mortality or body mass. The gonads of froglets exposed to ≥ 40 ng/l were all morphologically female based on pigmentation. Additionally levels of vitellogenin, a biomarker of estrogenic exposure, were induced in the plasma at concentrations of ethinylestradiol ≥ 10 ng/l. Quantitative PCR methods for assessing the genes DMRT1 and SOX3 were developed. These genes are expressed predominantly in one sex and are being assessed as biomarkers for intersexuality in amphibians. Results from this study indicate that ethinylestradiol is capable of impacting the endocrine system of amphibians at environmentally relevant concentrations. This abstract does not necessarily reflect EPA policy.

537 HISTOLOGICAL OBSERVATIONS IN NATIVE NEW JERSEY FROGS CAPTURED FROM AGRICULTURAL PONDS CONTAINING ATRAZINE AND OTHER CONTAMINANTS.

M. M. Gutierrez¹, T. Ledoux², K. Cooper¹ and M. Robson³. ¹Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ, ²Division of Science, Research and Technology, New Jersey Department of Environmental Protection, Trenton, NJ and ³School of Environmental and Biological Sciences, Rutgers University, New Brunswick, NJ.

Atrazine is one of the most commonly used herbicides in the United States. This pesticide is routinely found in surface waters where amphibians are non-target species in a unique position for exposure. The literature suggests that low environmentally relevant doses of atrazine have the ability to alter reproductive processes, causing retarded gonadal development (gonadal dysgenesis) and testicular oogenesis (hermaphroditism) in amphibians. To determine whether atrazine poses a risk to frog populations in New Jersey, 391 adult and juvenile green frogs (*Rana clamitans melanota*) and bullfrogs (*Rana catesbeiana*) were collected across nine pond sites during the 2003, 2004 and 2005 breeding seasons in Burlington County, NJ. These sites were evaluated for water levels of atrazine and related compounds. Several pesticide residues were detected in pond waters in addition to atrazine. Resident frogs were assessed histologically and both testicular dysgenesis and oogenesis were observed in captures. The reproductive systems of the two species responded differently to the contaminants in their environment. Retarded gonadal

development was only seen in bullfrogs, while testicular oogenesis was found solely in green frogs. The highest percent incidence of testicular oogenesis was found within the green frog population at the site with the highest atrazine impact. Additionally, parasitic incidence, including brain metacercariae and hepatic protozoan cysts, were compared to the geographic distribution of atrazine use. Further histological observations presented include tissue specific inflammation, tubular degeneration and sperm aggregation within the kidney. This work was supported by the NIEHS training grant in Toxicology ES07148 and NJ DEP contracts SR02-95, SR04-59 and SR05-046.

538 INHIBITION OF TSH-STIMULATED THYROID HORMONE RELEASE FROM THYROID GLAND EXPLANT CULTURES BY THREE CHEMICALS: METHIMAZOLE, PROPYLTHIOURACIL, AND PERCHLORATE.

M. W. Hornung¹, S. J. Degitz¹, L. M. Korte², J. Olson², P. A. Kosian¹, A. L. Linnum³ and J. E. Tietge¹. ¹NHEERL, MED, U.S. EPA, Duluth, MN, ²Student Services Contractor, U.S. EPA, Duluth, MN and ³Senior Service America, U.S. EPA, Duluth, MN.

As part of an ongoing effort to develop a systems model approach for characterization and prediction of thyroid toxicity, we have utilized *Xenopus laevis* thyroid gland explant cultures for investigating the response of the thyroid gland to stimuli independent of the hypothalamic-pituitary-thyroid (HPT) axis. In this study, methimazole and propylthiouracil, both inhibitors of thyroid peroxidase activity, and perchlorate, an inhibitor of iodide uptake, were used to inhibit T4 release by thyroid explant cultures. Thyroid glands from pro-metamorphic tadpoles were cultured at 21°C in L-15 media supplemented with 0.1% BSA and 1 µM KI. Inhibitory potency of methimazole was tested by culturing glands in control media, media with bovine TSH at a concentration to produce maximal T4 release, or media with TSH and graded concentrations of methimazole. Glands were cultured for 6-8d in test media with regular media exchanges. T4 released into media during the last 48h in culture was determined by radioimmunoassay. Inhibition of T4 release was dose related and occurred at 1 or 5 µg methimazole/ml in glands from NF stage 55 or 59 tadpoles, respectively. These methimazole concentrations are slightly lower than the 12 µg/ml previously reported to alter thyroid histology in tadpoles exposed *in vivo*. Histology of the cultured glands after 8d revealed no evidence of necrosis, and glands treated with TSH alone or TSH with methimazole exhibited follicular cell hypertrophy. Perchlorate and propylthiouracil also inhibited T4 production by cultured thyroid glands at d6-8, and as previously shown with methimazole, the extent of inhibition was related to time and concentration of TSH. This *in vitro* assay system is a useful tool to evaluate the potency of chemicals for inhibiting TSH-stimulated T4 release and can help interpret the effects of chemicals on the HPT axis *in vivo*. This abstract does not necessarily reflect EPA policy.

539 DEVELOPMENT OF GENE EXPRESSION MARKERS OF COMPENSATORY AND DIRECT EFFECTS OF TPO AND NIS INHIBITION IN THE AMPHIBIAN THYROID GLAND.

J. J. Korte, M. W. Hornung, G. W. Holcombe, J. E. Tietge and S. J. Degitz. NHEERL, MED, U.S. EPA, Duluth, MN.

An amphibian-based hypothalamic-pituitary-thyroid (HPT) axis model is being developed in a systems biology framework for understanding thyroid toxicity. In developing this model it is important to understand which changes are due to compensatory responses of the animal and which are direct effects of the chemical. Using *Xenopus laevis* as the model organism, responses in the whole organism and thyroid gland culture *in vitro* are being compared to separate compensatory mechanisms from direct effects. The two chemicals used in this study, methimazole and perchlorate, inhibit T4 synthesis by two different mechanisms, TPO inhibition and NIS inhibition, respectively, but each results in decreased circulating T4. The compensatory response of the tadpole to decreasing T4 is to increase circulating TSH to stimulate more T4 production. NF stage 54 tadpoles were treated with methimazole, perchlorate, or dilution water for 6 days. Thyroid glands were removed at 24, 48, 96, or 144 hours. Thyroid glands were processed for histopathology or gene array analysis using Affymetric gene chips. For *in vitro* experiments thyroid glands were dissected from stage 55 tadpoles, cultured in L-15 media with 0.1% BSA at 21°C. Five pairs of glands per treatment were cultured for 24h in media alone (controls) or 500 ng TSH/ml (0.9 mU activity/ml), removed from culture and processed for gene array analysis. Treatment with methimazole and perchlorate resulted in time dependent changes in thyroid gland morphology. Additionally, three patterns of gene expression changes were observed; those characteristic of elevated TSH (based on comparison to the *in vitro* response), those unique to methimazole, and those unique to perchlorate. From these experiments we identified markers within the thyroid gland for thyroid axis inhibition/TSH elevation. We have also established markers for TPO and NIS inhibition, although additional testing with more chemicals is necessary to establish the utility of these markers. This abstract does not necessarily reflect EPA policy.

540 TOXICOLOGICAL EVALUATION OF AN INHALATION EXPOSURE TO BENZENE AND TOLUENE IN A RAPTORIAL BIRD, THE AMERICAN KESTREL (*FALCO SPARVERIUS*).

M. L. Olsard¹ and J. Smits². ¹Toxicology Graduate Program, University of Saskatchewan, Saskatoon, SK, Canada and ²Vet. Pathology, WCVN, University of Saskatchewan, Saskatoon, SK, Canada. Sponsor: D. Bechtel.

Volatile organic carbon (VOC) compounds are by-products from oil and gas production. The two most common VOCs, benzene and toluene have shown numerous toxic effects in rodents after inhalation exposure. Research here is focused on the exposure of a small raptor, the American kestrel (*Falco sparverius*) to benzene and toluene in a lab atmosphere. The exposure situation is comparable to environmental releases as well as rodent derived LOAELs.

The first year of this project included design and construction of the inhalation chamber and the capturing and dosing of wild American kestrels. The second season utilized a well established American kestrel breeding colony for dosing purposes. In year one a high dose situation was tested (benzene 10 ppm, toluene 80 ppm). In year 2 a low group (benzene 0.1 ppm, toluene 0.8 ppm) was added and high was repeated.

The same endpoints were analyzed in years 1 and 2. *In vivo* and laboratory assays were conducted on collected plasma and tissue samples to evaluate the following toxic responses; immunological (Delayed type hypersensitivity (DTH), Enzyme linked immunoassay (ELISA), bone marrow smear differentials), endocrinological (retinol, retinol palmitate, thyroxine (T4), and triiodothyronine (T3) levels), enzyme activities, and behavioural.

Year 1 concluded that DTH was decreased in exposed birds ($p = 0.01$) as was total leukocyte count ($p = 0.002$). Behavioural variations between exposed and control groups include; activity ($p = 0.013$), ability to focus ($p = 0.007$), and defensive behaviours ($p = 0.037$). Year 2 has shown the same decreased DTH response ($p = 0.001$).

Preliminary results show toxicity in American kestrels exposed to benzene and toluene. The end result of years 1 and 2 will identify any toxicological effect environmental levels of benzene and toluene will have on wild raptors. These data and techniques can then be used for *in vivo* testing of wild birds for biological health monitoring purposes.

541 MECHANISTIC EVALUATION OF THE DEVELOPMENTAL TOXICITY OF NITROGEN OXIDES.

B. Reeves, Y. H. Wang and G. A. LeBlanc. Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.

Nitrates have become global contaminants of most aquatic systems due to their extensive use as fertilizers in agriculture. Recent studies have raised concern that nitrates and nitrites (NO_x) might be reduced to nitric oxide (NO) in the body during mitochondrial respiration. NO is a potent cellular signaling molecule that regulates various processes including steroid synthesis and reproduction. We used *Daphnia magna* as a model to mechanistically investigate the effects of NO_x on reproduction and development. The hypothesis was tested that excess NO, derived from NO_x , can cause abnormal embryo development by interfering with ecdysteroid signaling. We further hypothesized that this effect could be elicited by either NO-dependent suppression of ecdysteroid synthesis or through NO binding to NR1D3 (also called E75), a putative NO sensitive regulator of ecdysteroid signaling. Female daphnids were exposed to concentrations of sodium nitroprusside (SNP, an NO donor), sodium nitrite, and sodium nitrate. Effects on ecdysteroid-dependent development parameters associated with embryos were evaluated. All compounds elicited developmental toxicity consistent with anti-ecdysteroid activity with relative potencies of $\text{SNP} > \text{NO}_2 > \text{NO}_3$. These results were consistent with the hypothesis that NO_x elicits toxicity through its conversion to NO. We have ruled out direct reduction in ecdysteroid levels as a mechanism for this toxicity, based on RIA measurements indicating no decrease in levels from embryos obtained from SNP or NO_x treated maternal daphnids. NR1D3 has been identified and cloned in *D. magna*. The NR1D3 recombinant protein is being expressed and evaluated with respect to sensitivity to NO. Results from this study will advance our understanding of the potential threat posed by NO_x pollution to reproductive success.

542 HAZARD REDUCTION OF THE INCINERATED ASH BY USING WASTE WASHING SYSTEM.

E. Cho¹, K. Tameda¹, M. Hanashima², S. Mori³ and S. Higuchi¹. ¹Engineering, Fukuoka University, Kitakyushu, Japan, ²Fukuoka Research Center for Recycling Systems, Fukuoka, Japan and ³Division of Water Quality, North Carolina Department of Environment and Natural Resources, Raleigh, NC. Sponsor: E. Hodgson.

Since securing new landfill sites has been still demanding in Japan, recycling, renewals, and stabilization of the existing landfills by various treatments are necessary. Ash incinerated from municipal solid wastes (MSW) can contain hazardous contaminants such as heavy metals, organic contaminants, etc. Thus, the leachate from

the landfills filled with the incinerated ash might pose its hazard to the surrounding environments. Semi-full scale model facility (capacity: 1 tons/hr) - Waste Washing System (WWS)- was installed at the Eco-town in Kitakyushu, Japan, and the incinerated ash from MSW was fractionated and washed by this system. Four lysimeters were prepared and each lysimeters were filled with A) the ash before washing (< 25 mm), B) ash after washing (0.065 mm – 10 mm), C) 35% to 65% of mixed ash, and D) 65% to 35% of mixed ash with the ratio of the ashes before washing to after washing. The lysimeters were sprayed with de-chlorinated water every week and the toxicities of the leachate from the lysimeters were monitored every two weeks using Microtox™, ToxScreen-II, and DaphTox tests. It was found that the toxicities of the leachate from the lysimeters B and C were reduced faster than those from A and D and TOC, COD, BOD, T-N, NH₄-N, Cl, Cu, Pb, and As concentrations in the leachate from B and C were also lower than those in the leachate from A and D. Therefore, it was concluded that landfilling with the incinerated ash after passing through the WWS or with the mixed ash with higher contents of washed ash can reduce the toxicity of the leachate from the landfill, suggesting that WWS can be used as a pre-treatment method for hazard reduction.

543 IMPACT OF SODIUM TUNGSTATE ON THE VIABILITY OF SELECTED MICROORGANISMS WITH DIFFERING CAPACITIES FOR BIOREMEDIATION.

T. L. Doyle, S. M. Lohrke, E. R. Wilfong and G. D. Chapman. *Naval Health Research Center Detachment, Environmental Health Effect Laboratory, Wright-Patterson AFB, Dayton, OH.*

The use of tungsten munitions has the potential to introduce a new contaminant to sites already contaminated with materials such as perchlorate, heavy metals and other organic contaminants and may impact naturally occurring microbial processes such as bioremediation. To address this possibility, microorganisms with different capacities for bioremediation were evaluated for growth inhibition in response to sodium tungstate. The strains included *Shewanella oneidensis*, *Dechlorosoma suillum* and *Pseudomonas putida*. *S. oneidensis* can remediate metals such as chromium and uranium, while *D. suillum* can convert perchlorate to chloride and *P. putida* can degrade a wide range of aromatic hydrocarbons. The initial phase of the study was designed to evaluate different concentrations of tungsten for toxicity prior to evaluating for effects on bioremediation processes. The strains were cultured in 250 ml flasks containing 50 ml nutrient broth and increasing concentrations of sodium tungstate at 30°C for *P. putida* and *S. oneidensis* and 35°C for *D. suillum*. Growth was determined by measuring optical density of the cultures at hourly intervals. Cultures of *D. suillum* and *P. putida* were significantly inhibited by 50 mM sodium tungstate and completely inhibited by 100 mM sodium tungstate. Conversely, *S. oneidensis* exhibited greater resistance, with complete inhibition occurring at 250 mM. Initially *S. oneidensis* was completely inhibited at all concentrations of sodium tungstate at 7 hours post inoculation, but at 24 hours significant growth had occurred, suggesting an inducible resistance mechanism. Taken together, these results indicate that the presence of tungsten in contaminated environments may have detrimental effects on certain bioremediation processes occurring within that environment.

544 ENVIRONMENTAL FATE AND EFFECTS OF NICOTINE RELEASED DURING CIGARETTE PRODUCTION.

M. S. Stavanja¹, J. A. Seckar¹, P. R. Harp¹, Y. Yi¹, C. D. Garner¹ and J. Doi². ¹Research & Development, RJ Reynolds, Winston-Salem, NC and ²Aqua Survey, Inc., Flemington, NJ.

A variety of test methods were utilized to study the biodegradation, bioaccumulation and toxicity of nicotine including determination of the octanol/water partition coefficient, conversion of nicotine to CO₂ in soil and activated sludge; and evaluation of the effects of nicotine on microbiological inhibition, algal toxicity, plant germination and root elongation. The partitioning of nicotine between octanol and water indicated that nicotine will not bioaccumulate regardless of the pH of the medium. The aqueous and soil-based biodegradation studies indicated that nicotine is readily biodegradable in both types of media. The aquatic and terrestrial toxicity tests indicated nicotine has low toxicity to typical environmental microflora. The EPA Persistence, Bioaccumulation and Toxicity Profiler model, based on the structure of nicotine and predictive rates of hydroxyl radical and ozone reactions, estimated an atmospheric half-life of less than 5.0 hours. Using this value in the Canadian Environmental Modeling Centre Level III Model, it was estimated that the half-life of nicotine in water is 3.0 days and the half-life in soil is 0.5 days. This model also estimated that after equilibration of nicotine into the environment, nicotine would be expected to be found predominantly in water at 93% with 4% in the soil, 3% in air, and 0.4% in sediment. Evaluation of all ecological fate and effects test data suggest that nicotine is readily biodegradable in the environment and non-toxic to the aquatic and terrestrial species evaluated under the conditions of these studies.

545 POLYCYCLIC AROMATIC HYDROCARBONS CONTAMINATION IN SOIL AND AIR FROM THE MEXICAN CARBONIFEROUS REGION OF COAHUILA.

F. Castorena¹, R. Reyes-Mejía¹, P. Vazquez-Vazquez¹, J. Salinas² and A. Albores¹. ¹Centro de Investigación y de Estudios Avanzados, Mexico, Mexico and ²Hospital General de Subzona con Unidad de Medicina Familiar 24, IMSS, Nueva Rosita Coahuila, Mexico.

The release of Polycyclic Aromatic Hydrocarbons (PAHs) into the environment during coal pyrolysis to produce coke represents a risk for the populations living in the industry's neighborhood. The level of PAHs contamination is thus a necessary prerequisite to perform environmental quality and risk assessments. Therefore, we measured PAHs concentrations in soil and air particulates from the vicinity of coke oven factories located in the Carboniferous Region in Coahuila, Mexico. We compared PAHs concentrations in soil and air particulate samples collected from Nueva Rosita and Barroterán, these communities have functional coke ovens, and Juárez, a community with no coal industry. PAHs were determined by CG/MS, using the EPA standard recommendations. The results showed that PAHs levels in soil were as follows: Nueva Rosita > Barroterán > Juárez (1708, 1690 and 2.06. mg/kg of soil dry weight, respectively). Soil PAHs content in Nueva Rosita samples exceeds the level considered as major risk health by EPA (1140 mg/ kg dry weight). The most abundant compounds identified in these soils were chrysene, methyl phenanthrene and methyl naphthalene. Based on the soil results, high volume air samples were placed close to the coke chimneys in Nueva Rosita and Barroterán. The air particles contained the following carcinogenic PAHs: benzo(a)pyrene, benzo(a)anthracene, dibenzo(a,h)anthracene and benzo(b)fluoranthene. These results indicate that PAHs are present in the area and should be considered for remediation (Supported by Conacyt-Semarnat project 2004-01-293).

546 TOXICITY OF CHLORINATED POLYCYCLIC AROMATIC HYDROCARBONES.

T. Nishimura¹, M. Tahara¹, R. Kubota¹, K. Shimizu¹, M. Ema² and H. Tokunaga¹. ¹Environmental Chemistry, National Institute of Health Sciences, Tokyo, Japan and ²Risk Assessment, Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.

Polycyclic aromatic hydrocarbons (PAHs) are discharged from various emission source in aqueous environment. In the case of raw water for drinking water source, these compounds are exposed chlorine in the process for the disinfection in drinking water treatment plant and then are reacted oxidation and/or chlorine displacement. However, there is not much information on the reaction products by chlorination. Additionally, it is afraid the reaction products effect on human health. After Fluoranthene (FL), benzo[b]fluoranthene (B[b]F), benzo[k]fluoranthene (B[k]F), benzo[a] pyrene (B[a]P), benzo[ghi]perylene (B[ghi]P), indeno[1,2,3-cd]pyrene (IP), were exposed with 1mg/L free chlorine in the pure water fortified with 10 mM phosphate buffer (pH 7.0), PAHs and their chlorinated compounds were concentrated by solid phase extraction (SPE) method at the reaction time of 1, 2, 4, 6 and 24 hours, respectively. Under this condition, non-chlorinated PAHs dissolved in water were recovered from 80 % to 120 %. The GC/MS system in selected ion monitoring mode was used for the analysis of PAHs and chlorinated PAHs. PAHs decreased with time-dependent in the case of all six kinds of PAH. The reactivity for the chlorine was sensitive in order of B[a]P > B[k]F > B[b]F = IP > B[ghi]P > FL. Mono-chlorinated PAHs were formed in the case of all six kinds of PAHs. Di-chlorinated PAHs were detected in the case of B[k]F and B[a]P. However, tri-chlorinated forms were not detected in this condition. The extracted compounds from the chlorine solution dissolved PAHs were exposed in HepG2 cells for 24hrs. Mono- and di-chlorinated B[a]Ps showed significant cytotoxicity by lactose-dehydrogenase activity assay, but the chlorinated compounds derived from the other five PAHs hardly showed the cytotoxicity comparing the original compounds. These results indicate B[a]P should be considered most in the chlorination treatment process among six kinds of PAHs.

547 INDOOR AIR QUALITY STUDY-VAPOR INTRUSION OF VOLATILE ORGANIC COMPOUNDS.

F. Ogero¹, D. Skeete¹ and J. Heiser². ¹Biology, Medgar Evers College, Brooklyn, NY and ²Brookhaven National Laboratory, Brookhaven, NY. Sponsor: A. Villobos.

Growing response to residential exposure to Volatile Organic Compounds (VOCs) and Semi-Volatile Organic Compounds (SVOCs) have prompted concern by the EPA to promulgate regulatory limits for VOCs in residential homes. A major source of these fugitive VOCs are dry cleaners, service stations and leaking underground storage tanks. An immediate threat can be realized from the vapors that migrate into residences. This threat can pose chronic health risk for residents if the de-

tectability level is low. The objective of this project is to validate the Johnson-Ettinger (JEM) model and other 2-dimensional and 3-dimensional models using the Brookhaven National Laboratory Air Infiltration Measurement System (BNL/AIMS) technique to determine the subsurface contribution of VOCs intrusion in buildings. Four per fluorocarbon tracers (PFTs) sources were deployed in building 830. Sources were left for approximately 48 hours in six zones. Passive samplers were used to trace the infiltration and exfiltration of PFT sources. Analysis of the samplers in the laboratory showed that the flow rate in three of the six zones were quite comparable. The hallway (Zone 5) had a relatively high concentration rate upwards of 6m³/h. However, the crawl space had low source rates hence there was little detection of PFT sources. This miniature source and sampling tracer kit can measure infiltration rates on the order of 0.2 to 5 changes per hour over time-averaged periods of 1 day to several months or years.

548 UPTAKE OF MERCURY FROM CONTAMINATED SOIL BY DECIDUOUS TREES.

A. C. Nichols¹, D. A. Steffy¹ and E. Muth². ¹Physical and Earth Sciences, Jacksonville State University, Jacksonville, AL and ²Biology, Jacksonville State University, Jacksonville, AL.

Mercury (Hg) contaminated landfill material has been used to landscape a city park in Oxford, AL. An ongoing investigation of Hg occurrence in this watershed has found that Hg from the fill material has been redistributing across the fluvial deposition system. The Hg has also been bioaccumulating in various trophic levels of the freshwater ecosystem. This investigation extends the study to include the measurement of Hg in green ash (*Fraxinus pennsylvanica*), a deciduous tree growing in the contaminated flood plain. Soil samples from this plain had an average Hg concentration of 1.195 mg/kg. Root tissue collected from three trees growing in this flood plain had an average Hg concentration of 0.007 mg/kg (dry wt). Root tissue collected from a green ash growing in an area with the local background level of Hg in the soil (0.066 mg/kg) had no detectable Hg. Samples were analyzed using a CETAC Quick Trace Mercury Analyzer M-1600 cold vapor atomic absorption Hg analyzer with an ASX-400 Autosampler. To determine if the trees were degassing Hg through the leaves, contiguous branches with leaves were sequestered in a 1 gal plastic bag along with a passive Hg sampler (SKC passive sampler for Hg, 520 series). After a 24 h sampling period, the sampler contained 0.040 ug of Hg. A second sampler similarly positioned on the same tree for 24 h and open to the atmosphere had no detectable Hg. This would indicate that Hg from the soil is being released into the atmosphere of the park through tree leaves.

549 GENE EXPRESSION PROFILES IN RAINBOW TROUT, ONORHYNCHUS MYKISS, EXPOSED TO A CHEMICAL MIXTURE.

S. Hook¹, A. D. Skillman¹, J. A. Small² and I. R. Schultz¹. ¹Ecotoxicology and biotechnology, Battelle Marine Sciences Laboratory, Sequim, WA and ²Pacific Northwest National Laboratory, Richland, WA.

One of the proposed uses for microarrays in environmental toxicology is the identification of key contributors to toxicity within a complex mixture. The transcriptomic profile of a complex mixture has not been established, and whether the gene expression profiles resulting from exposure to a complex mixture have patterns of altered gene expression with identifiable contributions from each toxicant component of the mixture remains uncertain. We exposed isogenic (cloned) rainbow trout *Onorhynchus mykiss*, to sublethal levels of individual ethynylestradiol (xeno-estrogen), 2,2,4,4 tetrabromodiphenyl ether (BDE-47, thyroid active), and chromium VI or to a mixture of all three toxicants. Following exposure, fish were euthanized, livers harvested and RNA extracted. Fluorescently labeled cDNA were generated and hybridized against a commercially available Salmonid array (GRASP, University of Victoria) spotted with 16,000 cDNAs. Microarrays were scanned to measure abundance of a given transcript in each sample relative to controls. Data were analyzed via Genespring (Silicon Genetics) to identify a list of up and down regulated genes, and to determine gene clustering patterns that can be used as "expression signatures". The gene ontology terms associated with significantly altered genes were also used to identify functional groups that were associated with toxicant exposure. Our analysis indicates that the gene expression profiles resulting from the mixture exposure resemble those of the individual contaminant exposures, but are not a simple additive list. However, patterns of altered genes representative of each component of the mixture are clearly discernible, and the functional classes of genes altered represent the individual components of the mixture. These findings indicate that the use of microarrays to identify gene expression profiles may aid in the identification of key stressors within a complex mixture, ultimately improving environmental assessment.

FUMONISIN PRODUCTION IS NECESSARY FOR DEVELOPMENT OF THE FULL SPECTRUM OF SYMPTOMS INDICATIVE OF *FUSARIUM VERTICILLIOIDES* MAIZE-SEEDLING DISEASE AND EVIDENCE FOR DISRUPTION OF SPHINGOLIPID METABOLISM AS THE PROXIMATE CAUSE.

L. D. Williams^{1,2,3}, A. E. Glenn², C. W. Bacon², M. A. Smith¹ and R. T. Riley². ¹College of Public Health, University of Georgia, Athens, GA, ²Toxicology and Mycotoxin Research Unit, Athens, GA and ³Burdock Group, Vero Beach, FL.

The fungus *Fusarium verticillioides* infects maize and produces fumonisins, inhibitors of ceramide synthase. To determine the role of fumonisins in maize seedling disease, seeds were inoculated with fumonisin producing or non-producing strains of *F. verticillioides*. Seedlings grown from seeds inoculated with the producing strains had detectable fumonisins in roots and soils, and sphingoid bases and sphingoid base 1-phosphates were elevated in roots. Leaf lesions and abnormal leaf developmental were only observed with producing strains and while non-producing strains of *F. verticillioides* caused reduced root and stalk growth the effect on growth was greatest with producing strains. Leaf lesion incidence and severity of effects on root and stalk growth were significantly correlated with fumonisin in roots and the extent of disruption of sphingolipid metabolism in roots. In a subsequent study with the fumonisin producing strain MRC826, seedlings grown from inoculated seeds were harvested on days 7, 14 and 21. Reduced growth of aerial plant parts and roots were seen in seedling as early as day 7, however, leaf lesions were not apparent until day 14. Fumonisins were detected in the roots of seedlings and was maximal on day 14. There were significant increases in free sphingoid bases on day 7 which were maximal on day 14. There were also significant increases in free sphingoid base 1-phosphates on day 7. However, the level of free sphinganine 1-phosphate decreased significantly after day 7. These results suggest a time-dependent adaptive response to disrupted sphingolipid metabolism after prolonged fumonisin exposure, and also support the hypothesis that fumonisin is necessary and sufficient to produce the full spectrum of symptoms indicative of *F. verticillioides*-induced maize seedling disease.

551

TCDD DECREASES RETINOID SIGNALING AND VENTRAL PROSTATIC BUD FORMATION IN THE MOUSE UROGENITAL SINUS.

C. M. Vezina¹, S. M. Hicks², W. Bushman³ and R. E. Peterson^{1,2}. ¹School of Pharmacy, University of Wisconsin, Madison, WI, ²Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI and ³Department of Surgery, University of Wisconsin, Madison, WI.

2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) interferes with mouse ventral prostate development by blocking initiation of ventral buds from the fetal urogenital sinus (UGS). Retinoic acid (RA) is implicated in many aspects of development but its role in prostate development is unclear. This study tested the hypothesis that decreased RA signaling is partially responsible for inhibiting ventral prostatic bud formation following TCDD exposure of C57BL/6J mouse dams (5 µg/kg, po) on embryonic day (E)15. On E16, TCDD activated the aryl hydrocarbon receptor (AHR), reduced expression of the RA synthesis gene *Raldh2*, and elevated expression of RA metabolizing genes (*Cyp1b1* and *Cyp2c39*) in UGS mesenchyme. These changes resulted in a net decrease of retinoid signaling in the fetal UGS mesenchyme, evidenced by diminished expression of β-galactosidase activity in RARE-*LacZ* retinoid-responsive transgenic mice and diminished expression of the RA target gene *Hoxa13*. TCDD also decreased androgen receptor (AR) protein expression and partially caused a nuclear-to-cytoplasmic redistribution of AR in the peri-urethral layer of UGS mesenchyme cells that also displayed activated AHR. The *Hoxa13* knockout mouse was used to show that loss of *Hoxa13* partially phenocopied TCDD by decreasing expression of AR protein in the UGS mesenchyme and preventing ventral prostatic budding. Together, these results indicate that interference with retinoid signaling in the ventral UGS region of the male mouse fetus may contribute to the UGS region-specific prostatic budding inhibition by TCDD. (Supported by NIH grants F32 ES014284 and R37 ES01332).

552

STUDIES ON WHY VENTRAL PROSTATIC BUDDING IN MOUSE UROGENITAL SINUS (UGS) IS FAR MORE VULNERABLE TO 2, 3, 7, 8-TETRACHLORODIBENZO-*p*-DIOXIN (TCDD) THAN DORSAL, LATERAL, OR ANTERIOR BUDDING.

R. W. Moore^{1,2}, C. M. Vezina¹, S. M. Hicks², T. Lin¹ and R. E. Peterson^{1,2}. ¹School of Pharmacy, University Wisconsin, Madison, WI and ²Mol. Environment Toxicol. Ctr, University Wisconsin, Madison, WI.

Experiments were conducted to investigate why *in utero* TCDD exposure can prevent the UGS from forming any ventral prostatic buds while having far less effect on dorsal, lateral, and anterior budding. Pregnant C57BL/6J mice were given 0 or

5 µg TCDD/kg on gestation day (GD) 15 and UGSs were examined on GDs 15, 16 and 17, the critical window for TCDD-induced ventral bud agenesis. Previous results from mice with an aryl hydrocarbon receptor (AHR)-driven *LacZ* reporter gene indicated that the AHR signaling pathway through which TCDD acts is located almost exclusively (in the UGS) in the periurethral mesenchyme. Similar results have now been obtained for the distribution of EROD activity, a reaction catalyzed predominantly by the TCDD-inducible enzyme CYP1A1. In contrast, distribution of mRNA for another TCDD-inducible enzyme, CYP1B1, was far more widespread, and substantial *Cyp1b1* mRNA was seen in vehicle-exposed UGSs. Regional specificity of AHR signaling in the UGS is due largely to localization of the AHR, whose mRNA distribution pattern closely matched results from the *LacZ* reporter mice and the EROD assays, but not to distribution of the AHR dimerization partner ARNT, which was nearly ubiquitous. Smooth muscle is a barrier to the inductive signals by which UGS mesenchyme stimulates prostatic epithelial budding, but smooth muscle actin distribution was not detectably altered by TCDD. Preliminary evidence suggests that TCDD may inhibit ventral budding, in part, by reducing the size of the ventral mesenchymal pad and/or reducing its expression of fibroblast growth factor 10. In summary, the region-specific inhibition of prostatic budding by TCDD does not appear to result from regional differences in the AHR signaling pathway or from enhanced smooth muscle development. Instead, region specificity appears to be due to intrinsic differences in the regulation of prostatic budding by the different UGS regions. (Supported by NIH ES 01332)

553 SENSITIVITY OF FETAL RAT TESTICULAR STEROIDOGENESIS TO MATERNAL PROCHLORAZ EXPOSURE AND THE UNDERLYING MECHANISM OF INHIBITION.

C. Blystone^{1,2}, C. S. Lambricht², K. L. Howdeshell², J. Furr², R. M. Sternberg¹, B. C. Butterworth³, E. J. Durhan³, E. A. Mayknen³, G. T. Ankley³, V. S. Wilson², G. A. LeBlanc² and L. E. Gray². ¹*Environmental and Molecular Toxicology, NC State University, Raleigh, NC*, ²*Reproductive Toxicology Division, U.S. EPA, ORD, NHEERL, Research Triangle Park, NC* and ³*Mid-Continent Ecology Division, U.S. EPA, ORD, NHEERL, Duluth, MN*.

The sensitivity of fetal testicular steroidogenesis to the fungicide prochloraz (PCZ) was investigated to test the hypothesis that the reported morphological effects from maternal exposure were due to reduced testosterone (T). Pregnant Sprague Dawley rats were dosed by gavage with 0, 7.8, 15.6, 31.3, 62.5, 125 mg/kg/day (n = 8) of PCZ from gestational day (GD) 14 to 18. On GD 18 the effects of PCZ on fetal steroidogenesis were assessed by measuring hormone production from *ex vivo* fetal testes after three hour incubation. PCZ levels in amniotic fluid and maternal serum were measured by HPLC/MS and correlated to the inhibition of steroidogenesis. Fetal progesterone and 17 α -hydroxyprogesterone production levels were increased significantly at every PCZ dose, whereas T levels were significantly decreased only at the two high doses. These results suggest that PCZ inhibits the conversion of progesterone to T through the inhibition of CYP17. To test this hypothesis, the effects of PCZ on CYP17 gene expression and CYP17 hydroxylase activity were evaluated. PCZ had no effect on testicular CYP17 mRNA levels as measured by qRT-PCR. However, microsomal CYP17 hydroxylase activity was significantly inhibited by the fungicide (K_i = 865 nM). Fetal T production was reduced when PCZ levels in amniotic fluid reached ~500 ppb which compares favorably with the K_i for PCZ towards CYP17 hydroxylase activity. These results demonstrate that PCZ lowers testicular T synthesis by inhibiting CYP17 activity which likely contributes to the PCZ induced malformations in androgen-dependant tissues. *This abstract does not necessarily reflect US EPA views or policy.*

554 THE LACK OF A TRANSGENERATIONAL EFFECT OF VINCLOZOLIN FOLLOWING ORAL PRENATAL EXPOSURE TO 100 MG/KG BW.

S. Schneider, J. Hellwig, W. Kaufmann and B. van Ravenzwaay. *Product Safety, BASF AG, Ludwigshafen, Germany*. Sponsor: C. Hastings.

This study was performed to investigate a reported transgenerational effect of Vinclozolin on the integrity and performance of the male reproductive system. Pregnant Wistar rats (F0 generation) were treated with doses of 0, 4 and 100 mg/kg bw/day by oral gavage from days 6-15 p.c. All subsequent generations (F1 – F3) were not exposed to the test compound. 50 male pups per group were selected to become F1 parental male animals to generate F2 pups with untreated female rats. Subsequent breeding was continued in the same manner for 2 generations. F1 and F2 generation male rats were observed for mating behavior and success as well as ability to generate healthy offspring. F1, F2 and F3 generation male gonads were examined on postnatal day 130 (sperm evaluation, detailed histopathology of testes, epididymides and accessory sexual glands, as well as quantification of apoptotic cells in testes). Administration of 4 or 100 mg/kg bw to F0 gestating mothers did not result in any anti-androgenic effects. This is considered due to the fact that

the administration period was only until day 15 p.c. Thus, the findings reported by other authors^{1,2} following intraperitoneal application of Vinclozolin at 100 mg/kg bw were not confirmed in this oral study. F1 and F2 generations of male offspring, derived from Vinclozolin-exposed dams, developed normally to sexual maturity and were able to mate and to generate healthy progeny. Neither histopathology nor quantification of apoptotic cells, examined in the testes of F1 generation males, revealed any adverse effect of the test compound. Spermatid/Sperm count, sperm morphology and sperm motility were not affected in F1 and F2 generation male offspring. At present, after the investigation of F1 and F2 pups, the study gives no indication of a transgenerational effect of Vinclozolin on the integrity and performance of the male reproductive system, in particular spermatogenic capacity and sperm viability.

555 THE GESTATIONAL EXPOSURE TO THE PESTICIDE METHOXYCHLOR (M) INHIBITS TESTOSTERONE (T) FORMATION BY NEONATAL RAT LEYDIG CELLS (LC).

R. C. Derk¹, Y. Akgul^{2,1} and E. P. Muroño^{1,2}. ¹*Pathology and Physiology Research Branch, NIOSH, Morgantown, WV* and ²*Physiology, West Virginia University School of Medicine, Morgantown, WV*. Sponsor: V. Castranova.

M is a pesticide that has been used as a replacement for DDT because it is more rapidly cleared from the body and does not bioaccumulate. M has been reported to exhibit both weak estrogenic and antiandrogenic activities. Recent animal studies suggest that M or its dihydroxylated metabolite, HPTE, inhibits the ability of immature or adult rats to synthesize T. It is not known whether fetal LC present during the last third of pregnancy and for 1-2 weeks after birth in rodents, also are sensitive to M following in vivo exposure. The current studies evaluated whether the daily exposure by gavage of 0, 40, 100 or 200 mg/kg body weight of M dissolved in corn oil to pregnant Sprague-Dawley rats during days 14-22 of gestation, altered the capacity of neonatal (fetal) LC to produce T. Male pups were sacrificed on day 1 after birth, and the serum or testes from all male pups of each litter were pooled into a single sample. The pooled testes were digested with collagenase, and the dispersed LC were cultured in DMEM/F12 medium. Both basal and 10 mIU/ml hCG-stimulated T released into the medium was determined after culture for 4 h. There was a minimum of 11 determinations for each treatment group. Serum T level of animals exposed to 40 or 100 mg/kg M was no different than control; however, the T level declined to ~ 56 % of control in animals exposed to 200 mg/kg M. The basal T level of LC exposed in vivo to 40, 100 or 200 mg/kg M was no different than control. The hCG-stimulated T of LC from control animals was ~ 10.6 fold higher than the basal T from control animals, and the hCG-stimulated T of LC exposed to 200 mg/kg M declined to ~ 37 % of LC from control animals. These studies demonstrate that fetal LC exposed to a higher dose on M during the later third of gestation have reduced capacity to synthesize T.

The findings and conclusions in this abstract have not been formally disseminated by NIOSH and should not be construed to represent any agency determination or policy.

556 A HIGH DOSE OF GENISTEIN INDUCES SIGNIFICANT APOPTOTIC CELL DEATH IN NORMAL HUMAN MYOMETRIAL CELLS (UTSMC), BUT NOT IN HUMAN UTERINE LEIOMYOMA (UTLM) CELLS.

L. Castro, A. B. Moore, L. Yu, X. Zheng, M. Sifre, C. D. Bortner, G. E. Kissling and D. Dixon. *NIEHS, Research Triangle Park, NC*.

Uterine leiomyomas (fibroids) are benign tumors of smooth muscle origin and the primary cause of hysterectomy in reproductive-aged women in the United States. Although the etiology of these tumors remains unknown, the overall lifetime exposure of women to estrogen is a known risk factor. The phytoestrogen, genistein, an isoflavone found in soy products, shares structural similarities to the potent estrogen, 17 β -estradiol. In previous studies, using estrogen-responsive UtLM cells and UtSMC, we found that low doses of genistein stimulate proliferation of UtLM cells, but not in UtSMC, and high doses of genistein results in inhibition of cell proliferation and death in both cell types. In this study we were interested in determining if apoptosis was a mechanism of genistein-induced cell death in UtLM cells and UtSMC. A fluorometric assay for caspase-3 and western blot analysis for bcl-2, bax and bak proteins were done in both cell lines after treatment with a high dose of genistein (50 µg/ml) at 24, 72 and 168 h. We found that genistein caused significant increases in caspase-3 activity at all time points in the UtSMC, but only at 168 h in UtLM cells. Furthermore, caspase-3 activity in the UtSMC was 1.8 fold that observed in UtLM cells at 168 h. Bcl-2:bak and bcl-2:bax ratios were analyzed and the bcl-2:bax ratio was increased by approximately 1.6 fold in the UtLM cells at 72 and 168 h; however, no fold changes in proteins were observed in the UtSMC. Using a Hoechst stain, we found that after treatment of both cell types

with genistein at 168 h, apoptotic bodies were more evident in the UtSMC compared to UtLM cells. In conclusion, both cell types are susceptible to the inhibitory/death effects of a high dose of genistein, however, it appears that inhibition/death in the UtSMC is through increased apoptosis, but not in the UtLM cells. Additionally, protection of the UtLM cells from undergoing apoptosis may occur as a result of increased bcl-2 protein expression.

557 DOWN-REGULATION OF TGF- β PATHWAY GENES, ACTIVIN A AND SMAD3, IN HUMAN UTERINE LEIOMYOMA CELLS TREATED WITH A HIGH DOSE OF GENISTEIN.

X. Di, D. M. Ducharme, C. J. Tucker, L. Yu, X. Zheng, L. Castro, A. B. Moore, T. Hermon and D. Dixon. *NIEHS, Research Triangle Park, NC.*

Previously, we found that genistein at high doses has an inhibitory effect on uterine leiomyoma (UtLM) cell proliferation. In an attempt to identify the molecular mechanisms of this inhibitory effect microarray studies were performed. Five-hundred and forty-one genes in UtLM cells treated with 50 μ g/ml of genistein with average differences of $> \text{or} = 1.5$ -fold were significantly expressed and regulated ($p < \text{or} = 0.001$). Ingenuity Pathways Analysis (Ingenuity® Systems, www.ingenuity.com) revealed that significant alterations in gene expression occurred in several functions including cell cycle, cell death, cellular growth and proliferation and in a number of signaling pathways involving integrin, VEGF, purine metabolism, TGF- β and fatty acid biosynthesis (Path 2). Activin A, activin B, Smad3 and TGF- β 2 gene expression levels were all down-regulated in the TGF- β signaling pathway. In addition, there was downregulation of genes related to cell cycle regulation, such as CDK6, A-myb, and Cyclin B2, while P15, a CDK inhibitor was upregulated. Expression data for the above genes were identified and validated by real-time reverse transcriptase-polymerase chain reaction studies. Gene and mRNA expression data for activin A and Smad3 were further confirmed by western blot analysis of lysates of genistein treated UtLM cells. In agreement with decreased gene, mRNA and protein expression of activin A in genistein treated UtLM cells, we found that the growth of UtLM cells was stimulated under activin A treatment and the inhibitory effect of genistein was partially abrogated. The elevated expression of activin A and Smad3 in human uterine leiomyoma tissue samples in comparison with autologous myometrium further supported the contribution of activin A and Smad3 in promoting the growth of UtLM cells. Thus, the inhibitory effect of genistein on UtLM cells may be through cell cycle dysregulation and partially via down-regulation of activin A and Smad3 through the TGF- β signaling pathway.

558 DISRUPTION OF THE FEMALE REPRODUCTIVE SYSTEM BY THE PHYTOESTROGEN GENISTEIN: SUBCUTANEOUS INJECTION VERSUS ORAL EXPOSURE.

E. Padilla-Banks, W. Jefferson and R. R. Newbold. *NIEHS, Research Triangle Park, NC.*

We have previously shown that neonatal exposure to the phytoestrogen genistein (0.5 – 50 mg/kg) by subcutaneous injection (sc) caused adverse effects on the developing female reproductive system including altered ovarian differentiation. Further, ovarian function was disrupted later in life with increased ovulatory capacity in lower genistein doses and reduced ovulatory capacity at higher doses. Prolonged estrous cycles were seen in genistein treated mice with increased severity over time. Reduced fertility was seen in the 0.5, 5, or 25 mg/kg dose groups and infertility was observed at 50 mg/kg. In addition, females generated from the genistein 25 mg/kg group bred to control males have altered ovarian differentiation suggesting that genistein effects can be transmitted to subsequent generations. Thus, neonatal treatment with genistein at environmentally relevant doses caused adverse consequences later in life. Since infants are primarily exposed in the diet to the glycosylated form of genistein, genistin, we directly compared the estrogenic activity of orally administered genistin with genistein administered sc. Female CD-1 mice were treated on days 1-5 with genistein sc in corn oil (0, 12.5, 20 and 25 mg/kg) or by feeding genistin (0, 6.5, 12.5, 25 and 37.5 mg/kg). Body weights and uterine wet weights were determined at 5 days of age. A significant increase in uterine wet weight followed genistein sc at 20 and 25 mg/kg and oral exposure to genistin at 25 mg/kg; the response of oral exposure to genistin 25 mg/kg was comparable to genistein 20 mg/kg sc. Since the majority of the sc genistein enters the circulation, our data suggests that approximately 80% of the oral dose is absorbed into the circulation causing a similar biological response. Further, oral genistin caused similar developmental alterations as those observed with genistein sc. This study demonstrates that data obtained from a genistein exposure by sc route can be extrapolated to oral exposures to genistin and that both can have long term consequences.

559 EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) DECREASES MAMMARY EPITHELIAL CELL PROLIFERATION IN PREGNANT C57BL/6 MICE.

B. J. Lew¹, B. A. Vorderstrasse² and B. Lawrence¹. ¹*Environmental Medicine, University of Rochester, Rochester, NY* and ²*Pharmaceutical Science, Washington State University, Pullman, WA.*

Development of the mammary gland during pregnancy is a dynamic, orchestrated process involving the proliferation of mammary epithelial cells and their differentiation into cells capable of synthesizing milk components. Alteration in proliferation, differentiation or an early apoptosis of the epithelial cells can lead to a failed lactogenesis. Exposing mice to the aryl hydrocarbon receptor (AhR) agonist TCDD during pregnancy caused the death of pups within 24 hours of birth, but pups that were nursed by control animals survived. Furthermore, pregnant females exposed to TCDD had a poor lobulo-alveolar differentiation and suppressed expression of milk proteins. The present study was conducted to test the hypothesis that exposure to TCDD impairs glandular differentiation by decreasing the proliferation of mammary epithelial cells. Impregnated C57BL/6 mice were treated with vehicle or 5 μ g TCDD/kg on day 0 of pregnancy for animals sacrificed on day 6 of pregnancy, or on days 0 and 7 for animals sacrificed on days 9 or 12 of pregnancy. Three hours before euthanasia, mice were treated with 50 mg/kg bromo-deoxyuridine (BrdU). Left abdominal glands were fixed and stained in carmine-alum to monitor morphological development while the right abdominal glands were paraffin-embedded, sliced and stained with anti-BrdU antibodies to assess cell proliferation. At all points in time examined, mammary glands from TCDD-treated animals had 50% fewer BrdU+ cells than control animals ($p < 0.01$). The effect of TCDD in the number of BrdU+ cells was noted as early as day 6 of pregnancy, when the analysis of the glands showed a 59% decrease when compared with control animals. The results suggest that one of the mechanisms by which AhR activation impairs lactogenesis is through a decrease in epithelial cell proliferation.

560 A BROMINATED FLAME RETARDANT MIXTURE, DE-71, AFFECTS MAMMARY TISSUE OF RAT OFFSPRING FOLLOWING DEVELOPMENTAL EXPOSURE.

C. Coburn^{1,2}, J. L. Rayner³, P. Kodavanti² and S. E. Fenton³. ¹*University of California, Riverside, CA*, ²*Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC* and ³*Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC.*

The brominated flame retardant mixture, DE-71, is made up of multiple congeners, primarily penta- and tetra-brominated diphenyl ethers. These compounds are known to be lipophilic and have been detected in house dust, human milk, and are reported to be on the rise in North American residents. To determine whether or not the commercial mixture acts on the developing mammary tissue of the neonate, time pregnant Long Evans rats (N=8-15 dams/group) were dosed by oral gavage with 0, 1.7, 10.2, or 30.6 mg DE-71/kg body weight (BW) on gestation day 6 through postnatal day (PND) 21. BW of the pups was observed on PND 4, 7, 11, 14, 18, and 21. There was no significant difference in BW across dose at any time examined. Mammary glands were removed from female pups on PNDs 4 and 21, fixed and stained with carmine, and evaluated for age-dependent development on a scale of 1-4. There was no significant treatment effect on PND4 gland development. However, there was a dose-dependent decrease in mammary developmental scores at PND21 ($P < 0.001$). The mammary effects of DE-71 are similar to those previously seen following developmental exposure to dioxin. The epithelial portion of glands of female pups exposed to 10.2 and 30.6 mg DE-71/kg/d exhibited a lack of outgrowth, fewer lateral branches and limited terminal end bud development. These data suggest that lactational transfer may be required for this mixture of brominated flame retardants to affect the developing mammary gland early in life. Further studies designed to examine specific exposure parameters necessary for these effects and to determine the long-term effects of these notable changes in mammary gland development will be helpful in evaluating the health risk of these compounds. (This abstract does not necessarily reflect EPA policy).

561 RESPECTIVE CONTRIBUTIONS OF PRENATAL AND LACTATIONAL PFOA EXPOSURES TO ALTERED MOUSE MAMMARY GLAND DEVELOPMENT.

S. S. White^{1,2}, B. D. Abbott², E. P. Hines², C. J. Wolf², A. M. Calafat³, Z. Kuklennyik³ and S. E. Fenton². ¹*UNC, Curriculum in Toxicology, Chapel Hill, NC*, ²*U.S. EPA, ORD, NHEERL, Reproductive Toxicology Division, Research Triangle Park, NC* and ³*CDC, NCEH, Division of Laboratory Sciences, Atlanta, GA.*

Perfluorooctanoic acid (PFOA) is a ubiquitous and persistent synthetic compound, which has been detected in human and wildlife sera. Previous studies in mice linked prenatal PFOA exposure to decreased neonatal weight gain and survival, as well as altered mammary gland (MG) development, independent of body weight. To determine the respective contributions of prenatal and lactational PFOA-exposures to

altered MG development in offspring, timed pregnant CD-1 mice (N=28-48 dams/group) received 3 or 5 mg/kg PFOA or control vehicle via oral gavage on gestation days (GD) 1-17. On GD18-19 dams were monitored at intervals until parturition, and litters of similar ages were cross-fostered to yield seven exposure groups: control (CC), lactational exposure from a 3 or 5 mg/kg PFOA-treated dam (3L or 5L), intrauterine exposure from a 3 or 5 mg/kg PFOA-treated dam (3U or 5U), or both lactational and intrauterine exposure from a 3 or 5 mg/kg PFOA-treated dam (3U+L or 5U+L). MG were removed from necropsied female offspring at 3, 6, and 9 weeks of age and scored for age-appropriate development on a 1-4 scale. Excepting 3L at 3 weeks and 3U+L at 6 weeks, MG development was significantly diminished ($p<0.05$; body weight-independent) among all PFOA-exposed offspring, compared to CC at respective time points. MG scores did not differ between prenatal and lactational exposures, within respective doses and time points, except at 3 weeks, when 3L displayed better development than 3U ($p<0.05$). Offspring serum PFOA concentrations at necropsy were dependent on exposure conditions and time, and inversely associated with MG development. Taken together, these findings suggest that serum PFOA concentration is more highly associated with altered MG development than are exposure conditions alone. (This abstract does not necessarily reflect EPA policy; S.S.W. funded by EPA T829472, EPA CR833237, NIH T32 ES007126.)

562 DETECTION OF ATRAZINE AND ITS METABOLITES IN BODY FLUIDS OF PREGNANT AND LACTATING LONG EVANS RATS FOLLOWING A LATE GESTATIONAL EXPOSURE.

J. L. Rayner^{1,3}, E. P. Hines³, J. V. Nguyen², P. Panuwet², R. D. Whitehead², D. B. Barr² and S. E. Fenton³. ¹DESE, UNC-CH, Chapel Hill, NC, ²Division of Laboratory Sciences, NCEH, CDC, Atlanta, GA and ³U.S. EPA/ORD/NHEERL/Reproductive Toxicology Division, Research Triangle Park, NC.

Atrazine (ATR) administration to pregnant Long-Evans rats results in abnormal mammary gland development and delayed vaginal opening in their female offspring and in control neonates that nurse from ATR-treated dams. We hypothesized that residual ATR metabolites are transferred to pups both transplacentally and via milk days after exposure ceases (ATR half-life is 5-17 hr in adult non-pregnant rats). Timed-pregnant dams were gavaged dosed on gestation days (GD)13-19 with vehicle (1% methylcellulose), 100 mg ATR/kg, or 8.7 mg/kg of an ATR metabolite mixture (AMM) containing ATR and 4 common metabolites. Maternal urine, serum, amniotic fluid, mammary tissue, and milk samples were collected on GD19, 20, 21, postnatal day (PND)1, 4, and/or 11, when possible. Isotope dilution high performance liquid chromatography tandem mass spectrometry was used to analyze the samples for the presence of ATR and 10 different forms of its hydroxylated, chlorinated, or mercapturic metabolites. Following ATR exposure, metabolites were detected at high levels in maternal urine at least 6 days post-exposure. Exposure to ATR vs. AMM resulted in differing profiles of free metabolites detected in serum on PND4 (hydroxylated in ATR dams and chlorinated in AMM dams). Diaminochlorotriazine was detected in amniotic fluid on GD20 and 21, following either ATR or AMM exposures. Metabolites were detected in mammary tissue extracts from GD20 to PND4, and ATR itself was present in expressed milk as late as PND4. ATR and its metabolites were below the level of detection in control samples. These results suggest that ATR and its metabolites are available to the developing offspring several days following late gestational oral exposure and that the half-life of these compounds is longer in pregnant and lactating dams than that previously reported in adult non-pregnant rats. This abstract does not necessarily reflect EPA or CDC policy.

563 GESTATIONAL EXPOSURE TO THE ATRAZINE METABOLITES DIAMINOCHLOROTRIAZINE AND HYDROXYATRAZINE ALTERS MAMMARY GLAND DEVELOPMENT IN LONG EVANS RAT.

J. P. Stanko and S. E. Fenton. U.S. EPA, ORD NHEERL RTD, Research Triangle Park, NC.

Prenatal exposure to a mixture of atrazine (ATR) and its metabolites hydroxyatrazine (HA), diaminochlorotriazine (DACT), deethylatrazine (DEA), and deisopropylatrazine (DIA) has been associated with persistent alterations in postnatal female offspring mammary gland (MG) development in rats. ATR, DEA, and DIA are catabolized to form DACT, an end product of ATR metabolism, while HA, found in ground and surface water, is formed by the hydroxylation of ATR. Both DACT and HA have been detected in the urine and milk of lactating dams six days after gestational exposure to AMM had ended. We examined whether these metabolites, either alone or together, could mimic the effects of the atrazine metabolite mixture (AMM). Using concentrations derived from a previous study involving an 8.7 mg AMM/kg body weight (BW)/d oral exposure, pregnant Long Evans rats (N≥10/treatment) were gavaged with 7.4 mg DACT/kg BW/d, 1.4 mg

HA/kg BW/d, both DACT and HA at those doses, or 8.7 mg AMM/kg BW/d as a positive control on gestation days (GD) 14-18. Mammary glands collected from female offspring on postnatal day (PND) 4 and 40 exhibited delayed development in all prenatally-exposed pups ($P<0.05$). No significant differences were observed in offspring body weight between groups regardless of age. Serum LH levels in PND4 offspring and the day of and weight at vaginal opening were similar across treatment groups. These results are in agreement with previous findings using AMM alone. Mammary glands of DACT, HA, and DACT and HA treated animals exhibited more marked alterations than did AMM treated animals when compared to controls, suggesting that these metabolites, which are presumed to be transfer to the pup, are actively involved in abnormal mammary gland development. (This abstract does not necessarily reflect EPA policy).

564 A NON-INVASIVE MODEL TO EVALUATE THE EFFECTS OF XENOESTROGENS ON PRE-PUBERTAL FEMALE SWINE.

T. Evans, D. R. Ledoux, T. L. Veum, G. E. Rottinghaus, A. J. Bermudez and M. R. Ellersieck. University of Missouri, Columbia, MO.

There is increased interest in both the effects of xenoestrogens, especially those of fungal and plant origin, in non-rodent mammalian species and the ability to detect those xenoestrogenic effects in a non-invasive manner. Prepubertal female swine were used to develop a non-invasive model to quantitatively evaluate the effects of a known xenoestrogenic mycotoxin, zearalenone (ZEA), in this species, and it was hypothesized that antemortem vulvar measurements in ZEA-treated gilts would correlate well with traditional postmortem biomarkers for xenoestrogenic exposure. Twelve weanling gilts (6 per treatment) were kept in individual pens and fed for three weeks with either a nutritionally balanced control diet or the same diet containing 2 mg of ZEA per kg of feed. On days 0, 4, 7, 14 and 21, the width and length of each gilt's vulva were measured by a single individual blinded with respect to animal treatment group assignment. Animals were euthanized on day 21, and their reproductive tracts were removed and weighed, with selected portions fixed in formalin for histopathologic evaluation. Vulvar width was greater ($P<0.05$) in gilts fed ZEA than in controls from day 4 through day 21, and the length of the vulva was similarly greater ($P<0.05$) in the ZEA-treated gilts from day 7 through day 21. As expected with pre-pubertal xenoestrogenic exposure, reproductive tract weights (total reproductive tract, tubular genitalia and vagina alone) were significantly greater ($P<0.01$) in the gilts fed ZEA, as compared to the gilts fed the control diet, and epithelial hyperplasia and squamous metaplasia were consistently observed in the uterus and vagina, respectively, of Zea-treated gilts. Vulvar width correlated significantly ($P<0.01$), with total reproductive tract weight ($r = 0.91$), the weight of the tubular genitalia ($r = 0.84$) and vaginal weight alone ($r = 0.93$). Data indicate that vulvar measurements can be used as quantitative, non-invasive response variables to evaluate the effects of xenoestrogens on pre-pubertal female swine.

565 EFFECT OF ARSENIC AND DIELDRIN MIXTURES IN PREGNANT AND LACTATING RATS.

T. Graham², L. Ogden^{1,2}, M. Mansour¹ and T. Datiri¹. ¹Veterinary Medicine; Biomedical Sciences, Tuskegee University, Tuskegee, AL and ²Veterinary Medicine; Pathobiology, Tuskegee University, Tuskegee, AL. Sponsor: M. Mumtaz.

The objective of this study is to identify potential toxic effects of sodium arsenite (As) and dieldrin (Ded) mixtures in pregnant rats. After acclimation, plug positive rats were randomly assigned to groups (Gp) (16/each) and orally gavaged on (gestation day) GD4 with As-Ded-mixtures as follows: Gp 1 [0-0], Gp 2 [0.50-0.34], Gp 3 [1.0-0.69], Gp 4 [2.0-1.38], Gp 5 [4.0-2.75] mg/kg/day throughout 21 days of lactation. Biweekly body weights, weekly feed consumption, clinical observations, hematology, clinical chemistry, absolute and relative organ weights and hormones were documented. Randomly selected liver samples were evaluated for biochemical endpoints. Mortalities (2/16) occurred only in Gp 5 (GD 10 & 16). Hyperactivity (10/16) and abnormal behavior (2/16) were noted in Gp 5. Food consumption was lower in Gp5 after the 3rd week (wk) of gestation and the 2nd & 3rd week of lactation. Also the food consumption was lower in Gp 3 during the 2nd wk. There was a trend toward lower body weight throughout the exposure period. Body weight was lower in Gp 5 (from GD10-21, Lactation day (LD) 3, and LD10-21. Body weight was significantly lower in Gp 4 on GD14 and LD10. Increased relative brain to body weight ratio and liver to body weight in Gp 5. Fertility index was 87.5, 87.5, 75, 75, and 75 for Gps 1-5, respectively. The total number of pups were 154, 167, 147, 142, and 139 respectively. These findings suggest that As-Ded may adversely affect body weight (4-2.75), clinical behavior, mortality, relative brain and liver weights of pregnant and lactating dams. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU473408-01).

IN UTERO AND LACTATIONAL EXPOSURE TO 3, 3', 4, 4', 5-PENRACHLOROBIPHENYL MODULATES OVARIAN FOLLICLE DEVELOPMENT AND STEROIDOGENESIS IN IMMATURE RATS.

Y. Sakurada¹, M. Shirota^{1,2}, N. Uchida¹, G. Watanabe³, K. Taya³ and K. Shirota¹. ¹Research Institute of Biosciences and High-Tech Research Center, Azabu university, Sagami-hara, Kanagawa, Japan, ²Hatano Research Institute of Food and Drug Safety Center, Hadano, Kanagawa, Japan and ³Tokyo University of Agriculture and Technology, Fuchu, Tokyo, Japan.

To investigate effects of *in utero* and lactational (IUL) exposure to 3,3',4,4',5-penrachlorobiphenyl (PCB126) on follicle development and steroidogenesis during the immature period of the Sprague-Dawley rats, the ovaries and sera were collected on postnatal days (PNDs) 10, 15, 21 and 24 from the offspring of dams, which were orally administered PCB126 at dose levels of 0 (corn oil), 30, or 100 µg/kg on gestational day (GD) 15. When the number of follicles in the 100 µg/kg-exposed group was compared with that in age-matched control on PNDs 15 and 24, those of secondary and graafian follicles were decreased on PNDs 15 and 24, and on PND 24, respectively. While serum estradiol-17β (E2) and immunoreactive inhibin levels on PND15 were reduced in the PCB126-exposed groups, their serum FSH levels were rather higher than control. Reduction of E2 synthesis in the ovaries of exposed groups was confirmed by quantification of P450 aromatase mRNA level by real-time RT-PCR. Furthermore, expression of mRNAs encoding P450scc, 3βHSD and 17βHSD, which were enzymes synthesizing progesterone and testosterone, was reduced on PNDs 10 and/or 15. Additionally performed experiment, in which 50 µg/kg PCB126 was given to the same strain of dams on GD 15, revealed increased and decreased serum levels of progesterone and testosterone in the female offspring on PND15, respectively. From these results, it is indicated that IUL exposure to PCB126 affected follicle development during the immature period without reducing the circulating FSH level, and ovarian synthesis of testosterone and E2 is likely a one of toxicological target of IUL exposure to PCB126 in rats.

MEASUREMENT OF ENVIRONMENTAL PHENOL LEVELS IN THE URINE OF LACTATING WOMEN.

E. P. Hines¹, J. L. Rayner², J. S. Schmid¹, X. Ye³, A. M. Calafat³ and S. E. Fenton¹. ¹ORD, NHEERL, RTD, U.S. EPA, Research Triangle Park, NC, ²DESE, UNC, Chapel Hill, NC and ³DLS, NCEH, CDC, Atlanta, GA.

This study provides data on urinary levels and types of environmental phenolic compounds to which a cohort of North Carolina mothers were naturally exposed. The US EPA conducted a study entitled Methods Advancement in Milk Analysis (MAMA) in which 34 North Carolina lactating mothers age 18-38 donated urine at 2-7 weeks post-partum and 3-4 months post-partum. HPLC-tandem mass spectrometry was used to determine levels of six halogenated phenols including 2,4-dichlorophenol (2,4-DCP), 2,5-dichlorophenol (2,5-DCP), 2,4,5-trichlorophenol (2,4,6-TCP), 2,4,6-trichlorophenol (2,4,6-TCP), triclosan (TRCS) and ortho-phenylphenol (o-PP) found in pesticides, two alkyl phenols including bisphenol A (BPA) and 4-tert-octylphenol (4-t-OP) with estrogenic capacity, and benzophenone-3 (BP-3), a UV blocking agent, also having estrogenic activity. All of these compounds were detected in greater than 50% of donors except for 2,4,6-TCP, o-PP and 4-t-OP, which were found in 21, 18, and 10% of samples, respectively. Visit one and visit two mean concentrations were not significantly different for any of the measured phenols. Mean $\pm$ SEM levels (ppb) of these compounds were 260.9 $\pm$ 80.9 BP-3, 34.43 $\pm$ 13.8 TRCS, 19.5 $\pm$ 12.4 2,5-DCP, 3.4 $\pm$ 0.8 BPA, 1.1 $\pm$ 0.3 2,4-DCP, 0.5 $\pm$ 0.06 2,4,6-TCP, 0.1 $\pm$ 0.02 o-PP, 0.2 $\pm$ 0.02 2,4,5-TCP, and 0.5 $\pm$ 0.4 4-t-OP. BPA levels in this study were similar to the 90th percentile BPA levels in females age 20-59 in the NHANES III call back cohort. The genesis of exposure to these compounds is unknown for this cohort. However, these chemicals are widespread in the environment and are found in drinking water or sewage, in antibacterial products, in sunscreen and light diffracting plastics, in polycarbonate plastics and epoxy resins used in the manufacture of baby bottles, in dental sealants and food can linings, and in pesticide formulations. (This abstract does not necessarily reflect EPA or CDC policy.)

EXPRESSION OF TRANSPORTER PROTEINS IN RAT PLACENTA.

R. Stratton, P. Bennett, C. Sadler, A. Hargreaves, J. Noakes, T. Aldridge, J. Odum, G. Moffatt, J. A. Wright and I. Kimber. *Reg Toxicology, Syngenta, Macclesfield, United Kingdom.*

ATP-binding cassette (ABC) transporters are a large super family of transmembrane proteins, which mediate trafficking of a wide variety of substrates in an ATP dependent manner across membranes and are fundamental to protecting the foetus from xenobiotic exposure. We investigated the expression profiles of 3 ABC transporters; p-Glycoprotein (p-Gp), Multidrug resistance associated protein 2 (MRP2) and Breast cancer resistance protein (BCRP) in rat placenta using immunohistochemistry, immunoblotting and genomics. Placental tissue from time mated

Han Wistar rats of foetal gestational days 6 -21 were investigated. p-Gp protein and mRNA were found to be expressed in the rat placenta from day 13. MRP2 and BCRP proteins were found to be expressed from day 14 and day 12 respectively. For all proteins examined expression levels increased up to day 20. In contrast, human placental expression of p-Gp is reported to be greatest during the first trimester (the sensitive period of organogenesis) and BCRP is reported to remain constant throughout pregnancy. These temporal differences in expression may lead to differences in foetal sensitivity in the rat, when compared to man, to xenobiotics transported by this superfamily of transporters.

GENDER SUSCEPTIBILITY IS A FACTOR INFLUENCING OFFSPRING TUMOR RISK AND RESPONSE TO PRENATAL CIGARETTE SMOKE EXPOSURE: A ROLE FOR TESTOSTERONE.

S. P. Ng, B. G. Steinetz and J. T. Zelikoff. *Environmental Medicine, New York University School of Medicine, Tuxedo, NY.*

Gender susceptibility is a poorly studied risk factor. Previous data from this laboratory have shown that 5-wk-old male offspring of pregnant B6C3F1 mice exposed prenatally to mainstream cigarette smoke (MCS) (5 d/wk, 4 hr/d from gestational day 4 to parturition) had a significantly higher tumor incidence in response to EL4 tumor cell injection than age-/exposure-matched female counterparts (64% vs 36%). As males appeared more vulnerable to the tumor-modulating effects of prenatal MCS exposure, we hypothesized that testosterone (T) played a significant role in the observed gender differences. Thus, young adult female mice (prenatally exposed to either MCS [CO=25ppm, TSP=16mg/m³] or filtered air) were injected sc with either T-cypionate (1 mg in 0.1 ml sesame oil) or vehicle 48 h prior to tumor cell injection; serum T levels, determined 7 and 14 d following T injection, were similar to those reported for "normal" male mice (~5 ng/ml). EL4-induced tumor incidence in the T-treated females of both exposure groups (i.e., air and MCS) was significantly greater than the vehicle-injected female counterparts with values approaching those observed previously in exposure-matched males. Air-exposed, T-treated females were more vulnerable to tumor cell challenge than vehicle-injected females, suggesting a role for T in overall tumor susceptibility. Prenatal MCS exposure significantly enhanced tumor susceptibility in the T-injected females compared to their air-exposed counterparts. Results of this study demonstrate that T-induced masculinization of female mice diminishes gender differences in transplanted tumor cell susceptibility, and CS-induced effects on offspring tumor resistance. These findings suggest that sex hormones may be an important contributing factor, that acts synergistically with *in utero* CS exposure, to increase tumor risk in male offspring. 570

NON-CLASSICAL MECHANISMS OF RECEPTOR-MEDIATED TRANSCRIPTION.

G. Perdew. *Veterinary and Biomedical Sciences, Penn State University, University Park, PA.*

Transcription factors/nuclear receptors (TF/NR) are generally thought to mediate changes in transcription through binding to their cognate response elements. Additionally, TF/NR can also influence gene transcription through the sequestration of factor(s) from promoter regions or by tethering to another TF on a promoter. Perhaps the best example of the latter mechanism is the ability of the glucocorticoid receptor (GR) to bind to AP-1 and NFκB resulting in attenuation of inflammatory signaling. Studies in mice that express a DNA binding/dimerization mutant of GR exhibit many of the therapeutic properties observed through GR activation. In a similar vein, the estrogen receptor (ER) can also attenuate AP-1 activity, however until recently this mechanism could not be used for therapeutic purposes due to other physiological effects of ER activation. These examples underscore the importance of TF/NR tethering in modulating inflammatory signaling, and thus reveals many possibilities in drug design yielding unique physiological outputs. The goal of this symposium will be to explore various mechanisms utilized by NR (e.g. GR, ER, AhR, PXR) to modulate transcription and explore how non-response element driven responses can be selectively modulated by receptor ligands.

571

PHYSIOLOGIC ROLES OF THE NONCLASSICAL ESTROGEN RECEPTOR ALPHA SIGNALING PATHWAY.

L. Jameson¹, C. Glidewell-Kenney¹, J. E. O'Brien¹, S. C. Hewitt³, M. Tong¹, E. Lee¹, L. E. Pfaff², J. E. Levine², J. Weiss¹ and K. S. Korach³. ¹Medicine, Northwestern, Chicago, IL, ²Neurobiology Physiology, Northwestern, Evanston, IL and ³Laboratory of Reproductive and Developmental Toxicology, NIEHS, Research Triangle Park, NC. Sponsor: G. Perdew.

Estrogen receptor alpha (ERα) can affect gene transcription by classical and non-classical pathways. Classical signaling occurs through ERα binding to estrogen response element (ERE) in DNA, whereas in nonclassical signaling, ERα participates

in protein-protein interactions to alter the activity of transcription factors at non-ERE sites (ie. NF- κ B, AP-1, or Sp1). Previously, our lab generated a Nonclassical Estrogen Receptor Knock In (NERKI) mouse model using a mutant ER α that is unable to bind to ERE but retains intact nonclassical ER α activity. Adding the NERKI allele in the context of the ER α KO genetic background, it is possible to selectively restore nonclassical aspects of ER α signaling. In this report, we describe nonclassical estrogen actions in 2 different physiologic models: 1) Estrogen negative feedback regulation of luteinizing hormone (LH); 2) Estrogen stimulation of uterine responses. We find that selectively restoring nonclassical ER α signaling to the ER α KO significantly decreased LH (0.70 ± 0.18 ng/ml), indicating that the nonclassical pathway mediates the estrogen negative feedback regulation of LH. In the uterine model, the nonclassical pathway was not sufficient to mediate an acute uterotrophic response, characterized by water imbibition after a single injection of E2. However, the uterine epithelial proliferative response to estradiol (E2) and 4-hydroxytamoxifen (4HT) was retained in mice expressing only the nonclassical allele. These results indicate that nonclassical ER α signaling is sufficient to restore luminal epithelial proliferation but not other estrogen-responsive events such as fluid accumulation. We conclude that nonclassical pathway signaling via ER α plays a critical physiologic role in estrogen mediated negative feedback of the hypothalamic pituitary axis and in the uterine response to estrogen.

572 COMBINATORIAL CONTROL OF GENE EXPRESSION BY DIVERSE CLASSES OF AROMATIC HYDROCARBONS AND ESTROGENIC COMPOUNDS.

T. Beischlag¹, J. Lin², B. D. Hollingshead¹, S. Amin² and G. H. Perdew¹.

²Milton S. Hershey Medical Center, The Pennsylvania State University, Hershey, PA.

Tethering of agonist activated estrogen receptor (ER) to the aryl hydrocarbon receptor (AHR) at the latter's cognate DNA response element results in profound repression of dioxin-inducible AHR target gene transcription. More recently we have obtained evidence that estradiol (E2) and the selective estrogen receptor modulator (SERM), tamoxifen (TAM) dose dependently repress halogenated aromatic hydrocarbon (HAH)-responsive CYP1A1 and CYP1B1 transcription. Paradoxically, E2 has no effect on polycyclic aromatic hydrocarbon (PAH) induction of either CYP1A1 or 1B1, but TAM significantly enhances their transcription in the human breast cancer cell line MCF-7 and the human endometrial cancer cell line, ECC-1. These ER-dependent alterations in AHR-mediated CYP1A1 transcription result in concomitantly altered levels of CYP1A1 protein. Therefore, there is a ligand selective switch from co-repressor to co-activator function in response to ER tethering. This response is dictated by conformational changes induced by AHR ligand activation in response to different classes of activators. To our knowledge, this is the first demonstration of combinatorial control of transcription in response to exposure to different classes of ligands. Furthermore, TAM-mediated co-activation of CYP1A1 transcription and increased CYP1A1 protein levels in response to exposure to the PAH, benzo[a]pyrene, results in significantly higher levels of stable 8-deoxy-guanosine-benzo[a]pyrene-diol-epoxide adduct formation in MCF-7 cells. Therefore, estrogens play an important role in an organism's response to environmental toxicants. These results highlight the importance of the non-canonical role played by activated ER and represent a paradigm shift in our understanding of transcription factor function in general. This work was supported by the National Institutes of Health Grant RO1 ES04869 and ES11834 (to G.H.P.)

573 THE GLUCOCORTICOID RECEPTOR: ONE GENE, MANY PROTEINS, EXTENSIVE POST TRANSLATIONAL MODIFICATIONS: PROVIDE NEW MECHANISMS FOR TISSUE SPECIFIC ANTI-INFLAMMATORY ACTIONS OF GLUCOCORTICOIDS IN HEALTH AND DISEASE.

J. A. Cidlowski, N. Z. Lu, C. M. Jewell, L. J. Lewis-Tuffin, K. Smoak, J. Zhou and P. Housley. *Laboratory of Signal Transduction, NIH/NIEHS, Research Triangle Park, NC. Sponsor: J. Cidlowski.*

Glucocorticoids are an important class of steroid hormones that regulate numerous homeostatic functions in mammals and lower species. Examples of the processes influenced by glucocorticoids include: glucose homeostasis, protein catabolism, skeletal growth, respiratory function, inflammation, development, behavior and apoptosis. Our understanding of how one hormone regulates all of these diverse processes is limited although most of these actions are thought to be mediated via the glucocorticoid receptor, which is a product of a single gene. However, recent studies in our laboratory have shown that multiple glucocorticoid receptor isoforms are produced from combinations of alternative mRNA splicing and alternative translation initiation. In addition these glucocorticoid receptor isoforms are subject to several

post-translational modifications including ubiquitination, phosphorylation and sumoylation. In this lecture, I will show that the receptor isoforms regulate specific subsets of genes and that post translational modification of the glucocorticoid receptor alters the ability of the receptor to select and use specific hormone response elements. We also will show that the behavior (mobility, degradation, nuclear targeting) of glucocorticoid receptors in living cells is controlled by the chemical nature of the ligand to which they bind. Finally, we will describe new studies on the human glucocorticoid receptor β protein whose expression is associated with various states of glucocorticoid resistance in human disease. Specifically we show for the first time that hGR β is a ligand independent transcription factor.

574 AHR TRANSCRIPTIONAL REGULATION AND ITS IMPACT ON MAMMARY TUMOR BEHAVIOR.

D. H. Sherr. *Environmental Health, Boston University School of Public Health, Boston, MA.*

The aryl hydrocarbon receptor (AhR) has been studied primarily for its control of biologic responses to toxic and/or carcinogenic environmental ligands. However, it is becoming clear that the AhR influences a number of important biologic functions including cell growth, cell death, and possibly cell migration in the absence of exogenous ligands. Ironically, much of the research revealing the role for the AhR in normal cell physiology involves AhR activity in neoplastic cells in which the AhR is frequently hyper-expressed and constitutively active. Constitutively active AhR in tumors often behaves differently than environmental chemical-activated AhR, particularly with regard to transcriptional regulation of target genes. These results suggest context-specific interaction of the AhR with co-regulators and/or with other transcription factors. To begin to address this issue, we have evaluated differential AhR regulation of four genes important in mammary gland tumorigenesis: c-myc, Bax, CYP1B1, and AhRR (AhR repressor). While all of these genes have multiple AhR binding sites in their regulatory regions, only CYP1B1 is up-regulated by constitutively active AhR while transcription of the other three genes is constitutively repressed. AhR activation with environmental ligands yields a different set of outcomes. Some possible transcriptional mechanisms responsible for these differential gene effects and for the differences observed between constitutively active AhR and environmental chemical-activated AhR are presented. Particular emphasis is placed on possible interactions between the AhR, other transcription factors, and transcriptional co-regulators. Finally, the influence of the AhR and the cofactors it recruits on mammary tumor cell growth and progression will be discussed.

575 ROLE OF NF- κ B IN REGULATION OF PXR AND AHR-MEDIATED GENE EXPRESSIONS: MECHANISMS FOR THE SUPPRESSION OF CYTOCHROMES P450 BY PROINFLAMMATORY AGENTS.

Y. Tian¹, X. Gu¹, S. Ke¹, D. Liu¹, W. Xie³, M. A. Gallo², A. B. Rabson² and Y. Xie¹. ¹VTPP, Texas A&M University, College Station, TX, ²UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ and ³Center for Pharmacogenetics and Department of Pharmaceutical Sciences, University of Pittsburgh, Pittsburgh, PA.

The metabolism and disposition of the xenobiotics and/or endobiotics are regulated at transcriptional level by pregnane X receptor, constitutive androstane receptor (CAR) and aryl hydrocarbon receptor (AhR) which are ligand-dependent transcription factors regulating enormous phase I, II enzymes as well as transporters. It has been known that inflammatory responses and infections decrease metabolisms of xenobiotics and endobiotics in human and experimental animals, resulting in pathological conditions such as the cholestatic diseases. NF- κ B is pleiotropic transcriptional factor that regulates the immune and inflammatory processes. We and others have found that there are interactions between the pathways regulated by PXR, AhR and NF- κ B. These interactions converge at the levels of transcription and affecting several critical stages of the transcriptional processes such as the initiation and elongation. We have found that NF- κ B RelA interacts directly with the receptors and these direct interactions could result in transrepression of the receptor-regulated gene expressions. There are several possible modes of action for the NF- κ B regulated transrepressions: (1) squelching mechanism where NF- κ B activation competes for common transcriptional co-regulators; (2) tethering of the NF- κ B to the regulatory regions by receptor-NF- κ B interactions which may result in further recruitment of repressor complex; and (3) direct disruption of receptor binding to the regulatory regions. The interactions between NF- κ B and nuclear receptors is part of the molecular basis for pathway "cross-talk" and also may be the therapeutic target for treatment of diseases such as the cholestasis/fueled in part by NIEHS, National Institutes of Health Grants ES 09859 and ES 09106 and American Heart Association Grant 0355131Y).

576 UNDERSTANDING THE LINKAGES BETWEEN ENVIRONMENTAL TOXICITY AND HUMAN DISEASE: FROM OBSERVATION TO MECHANISTIC INSIGHT AND FROM INSIGHT TO THERAPEUTICS.

K. Ramos and I. N. Rodriguez. *Department of Biochemistry and Molecular Biology, University of Louisville, Louisville, KY.*

Chemical, physical and biological agents in the environment are believed to play a role in the onset and progression of acute and chronic human illness. Such linkages have been established with some degree of certainty in clinical cases of Parkinsonism caused by recreational exposures to 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine, the occurrence of vaginal cancers in women exposed in utero to diethylstilbestrol, or the rise in sudden cardiac death and emergency room admissions in areas of the world with considerable air pollution, to name a few. In general, however, little progress has been realized in translating basic observations from the research laboratory to the clinical or regulatory setting. Significant impediments to progress are arguably complex and range from the inherent challenges associated with experimental studies in human populations, to deficiencies in coordinated efforts to "bridge the gap" between scientists interested in the study of fundamental mechanisms of toxicity and clinicians interested in the management and prevention of disease. This symposium will highlight recent advances in our understanding of the role of environmental factors in cardiovascular, neurological and oncological health outcomes with the potential for clinical translation. Examples will be presented that identify ways in which cells compensate for toxicant-induced biological deficits, describe potential therapies born out of efforts to elucidate pathogenesis, and the emerging links between therapy and diagnostics. Another goal will be to provide a forum for discussion of novel research paradigms that bridge the gap between mechanistic insight and clinical applications and that exemplify the strength of trans-disciplinary approaches to study of environmental toxicity in human disease.

577 EXAMPLES OF GENE-ENVIRONMENT INTERACTIONS IN PARKINSON'S DISEASE.

D. M. Maraganore. *Neurology, Mayo Clinic College of Medicine, Rochester, MN.*
Sponsor: K. Ramos.

The heritability of Parkinson's disease (PD) is low and it does not segregate in families in a simple Mendelian fashion [Ann Neurol 2004;56:495-502; Ann Neurol 2006;59:788-795]. Therefore, it is widely considered that PD is a complex disease and that the environment plays a major role in its cause. While there is epidemiological evidence that pesticide exposures may confer susceptibility, and while there is experimental evidence that toxins can model PD, there is little evidence that specific pesticide exposures cause PD [Environ Health Perspect 2006;114:156-164; Mov Disord, DOI: 10.1002/mds.21009]. Furthermore, there are only rare examples of specific gene-environment interactions in PD [Ann Neurol 2004;55:430-434]. The most convincing evidence that genetic factors also contribute to PD has been derived from linkage analyses of multiplex kindreds. While causal mutations are rare, common variants in some of these genes may confer risk to PD across populations worldwide [Ann Neurol 2004;55:512-521; JAMA 2006;296:661-670]. For one of these linkage-derived susceptibility genes, alpha-synuclein, there is experimental evidence of interactions with pesticides [Neurotoxicology 2002;23:527-536]. In this presentation, we will present preliminary data from a study of the molecular epidemiology of Parkinson's disease (ES10751) regarding possible interactions between the alpha-synuclein gene and pesticides and also provide an overview of similar epidemiological studies of gene-environment interactions in PD. The demonstration of specific gene-environment interactions in PD may provide mechanistic insights that will guide the development of primary and secondary prevention strategies.

578 CHRONIC EXPOSURE TO ACROLEIN, A UBIQUITOUS POLLUTANT, INDUCES DILATED CARDIOMYOPATHY.

S. D. Prabhu, A. Bhatnagar, J. Luo, Y. Gu, R. Ortines, S. Srivastava and B. Chandrasekar. *Molecular Cardiology, University of Louisville, Louisville, KY.*
Sponsor: K. Ramos.

Although the volatile α,β -unsaturated aldehyde acrolein (ACR) is classified as a high priority air and water toxic, the cardiac effects of ACR exposure are unknown. As ACR is a potent electrophile, we hypothesized that chronic ACR exposure would induce oxidative stress and inflammation in the heart that contributes to cardiomyopathy. Adult C57BL/6 mice ($n = 15$ -18/group) were gavaged either 1 mg/kg/d ACR, a dose approximating human daily oral aldehyde consumption, or water (Control) for 48 d. Oxidative stress was increased in ACR vs. Control hearts, evidenced by a 4-fold increase in membrane bound protein-hydroxy-2-nonenal adducts by immunoblotting ($p < 0.05$). Echocardiography revealed left ventricular

(LV) dilatation and systolic dysfunction in ACR mice ($p < 0.05$). Myocyte cross-sectional area (CSA) on tissue sections was increased 2.5-fold in ACR hearts over Control ($p < 0.001$), indicating myofiber hypertrophy. Pressure-volume analysis revealed significant ($p < 0.05$) depression of both systolic function (30% decrease in dP/dtmax) and relaxation (30% increase in tau). ACR hearts further demonstrated a 6-fold increased ($p < 0.001$) activation of the redox sensitive transcription factor and inflammatory mediator nuclear factor (NF- κ B), evaluated by both DNA binding studies and immunostaining for the activated p65 subunit of NF- κ B. Gene expression of tumor necrosis factor- α , an NF- κ B responsive inflammatory cytokine considered to have an important role in pathologic remodeling, was increased 4-fold in ACR hearts ($p < 0.001$). ACR withdrawal studies after chronic exposure revealed only mild reversibility of the LV functional and structural changes. We conclude that chronic environmental exposure to ACR induces myocardial inflammation and oxidative stress, together with myocyte hypertrophy, LV dilatation and dysfunction that is only partially reversible upon removal of exposure. Similar environmental exposures in humans may contribute to the pathogenesis of dilated cardiomyopathy of unclear etiology.

579 CHILDHOOD CANCER AS MODEL FOR DEVELOPMENTAL DISORDERS.

A. F. Olshan. *Department of Epidemiology, University of North Carolina, Chapel Hill, NC.* Sponsor: K. Ramos.

The investigation of childhood cancer has provided some valuable knowledge on the mechanisms of carcinogenesis. Moreover, there is significant potential for childhood cancers to provide unique insight into the role of preconceptional and *in utero* exposures on developmental dysregulation and disease occurrence not only in childhood, but also into adulthood. Early studies of molecular genetic alterations in retinoblastoma, Wilms tumor and neuroblastoma have provided critical data for the delineation of the two-stage model of cancer initiation and progression. Advances in molecular biology have permitted the development of new tools and models, including animal systems, to investigate the etiology of childhood cancer. In parallel, more than a decade of epidemiologic studies on the etiology of childhood cancer has been conducted. Both the experimental animal and epidemiologic studies have provided valuable clues on relevant etiologic agents and mechanisms. Further, the work has identified important challenges in this line of research that apply more broadly to the study of developmental disorders. This presentation will provide an overview and perspective on the rationale, current evidence, and future of research on the etiology of childhood cancer. This presentation will emphasize the continuing need for closer collaboration between toxicological and epidemiologic investigators.

580 HORMONES, THE ENVIRONMENT AND CANCER.

C. Walker. *University of Texas, Smithville, TX.*

The development of hormone-dependent cancers of the breast and female reproductive tract can be modulated by environmental exposures. Both the man-made and natural environment contain compounds such as pesticides and phytoestrogens that can mimic normal ovarian hormones. Exposure to these "environmental estrogens" or xenoestrogens can increase or decrease cancer risk, depending on the exposure and the target tissue. It is now appreciated that the timing of exposure is also a critical determinant of the toxic response to environmental estrogens. The human experience with DES is the best appreciated example of how an environmental exposure to a xenoestrogen during a critical developmental period can cause an adverse health outcome. Women exposed *in utero* to DES during development of the reproductive tract have congenital reproductive tract abnormalities, and are at greatly increased risk for development of otherwise rare cancers such as vaginal clear cell carcinoma. In the breast, xenoestrogen exposure can have opposing effects on breast cancer risk depending on the timing of exposure. Exposures that occur prenatally can increase susceptibility to the induction of breast cancer, while later post-natal exposures can be protective, due in part to the induction of a more differentiated phenotype in the developing mammary gland. Recently, environmental estrogens have been shown to signal via non-genomic mechanisms, and these rapid responses mediated by cell signaling pathways such as MAPK and PI3K may also contribute to toxic response(s) that occur following exposure to these compounds. Finally, we and others have shown that early life exposures to xenoestrogens during critical developmental windows can cause epigenetic alterations that "reprogram" the genome in such a way as to alter patterns of gene expression in the adult and increase the risk of developing hormone-dependent cancer. In some cases these early life exposures have been shown to alter patterns of promoter DNA methylation, but other epigenetic alterations, such as histone modifications, are also candidate mediators for the reprogramming that occurs following developmental exposure to environmental estrogens.

581 ADVANCES AND CHALLENGES REGARDING MODE-OF-ACTION IN HUMAN HEALTH RISK ASSESSMENT.

N. Keshava² and R. Sams¹. ¹Office of Research & Development, National Center for Environmental Assessment, U.S. EPA, Research Triangle Park, NC and ²Office of Research & Development, National Center for Environmental Assessment, U.S. EPA, Washington, DC.

Mode of action (MOA) analysis is one of the key processes utilized to assess acceptable levels of risk for humans. Central to MOA analysis is the identification of empirically measured key events (i.e. necessary or rate limiting steps) in the development of chemical-induced toxicity. Several recently published guidance documents (USEPA Cancer Guidelines, 2005; IPCS Framework for Analyzing the Relevance of a Cancer MOA for Humans, 2005 Draft for Public Comment) represent a general scientific consensus on the preferred approach for MOA analysis. As the use of MOA information advances, several types of risk assessment issues are emerging. These issues include the weight of evidence (WOE) necessary to establish a MOA for a given compound, harmonization of cancer and non-cancer endpoints through MOA analysis, determining the approach for MOA that supports low dose extrapolation, and how these frameworks should be used for chemical mixtures risk assessment. An effective avenue to overcome these identified issues is to consider risk assessment case studies; since no two chemicals have the same amount or type of MOA information. These case studies should be evaluated based upon the supporting WOE, consistency, and generally through agreement within the scientific community. Additionally, the framework for MOA analysis can be revised based upon recurring issues that are identified through the use of case studies. Throughout this evolving process, approaches that are determined adequate for individual chemicals should be considered by the scientific community as to how the methodology can be applied to "real-world" or comprehensive risk assessments (i.e. chemical mixtures). (Disclaimer: The views expressed in this abstract are those of the authors and do not represent the policy of the U.S. Environmental Protection Agency).

582 INTERPRETATION OF CONFLICTING GENOTOXICITY DATA TO IDENTIFY AN INDIRECTLY MUTAGENIC MODE OF ACTION: A CASE STUDY INVOLVING CARBON TETRACHLORIDE.

D. A. Eastmond. *Environmental Toxicology Program, University of California, Riverside, CA.*

In the new EPA cancer risk assessment guidelines, the classification of whether a chemical is mutagenic or not plays an important role in determining whether a linear or non-linear approach should be used to extrapolate into the low dose region. However, frequently both positive and negative results are seen in genotoxicity studies. In this presentation, discrepant genotoxicity data on carbon tetrachloride will be discussed and shown to be consistent with an indirect mode of action involving lipid peroxidation and cellular toxicity. Carbon tetrachloride is quite unique in that it is essentially negative in inducing gene mutations in *Salmonella* bacteria but is consistently positive in inducing deletion mutations and aneuploidy in fungi. Studies in mammalian cells in vitro have been largely negative. However, positive results have occasionally been seen. Similarly, a large number of in vivo studies have been performed following treatment of rodents with carbon tetrachloride with mixed, largely negative, results. However, DNA adducts, primarily those derived from oxidation and lipid-peroxidation-derived products, have been repeatedly seen in the liver as have DNA double-strand breaks and micronucleated cells. Mechanistic studies are consistent with a role for lipid peroxidation and toxicity as DNA double-strand breaks can be formed from lipid peroxidation products or during nuclease activation during cell toxicity. Consistent with this proposed mode of action, the positive genotoxicity/mutagenicity results that have been seen in fungi and mammalian systems almost always occur concurrent with or during recovery from extensive cellular toxicity. The implications of this mode of action for extrapolation into the low dose region will also be discussed.

583 EPIGENETIC PROCESSES AS KEY EVENTS IN THE MODE OF ACTION FOR TUMOR FORMATION.

R. J. Preston. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*
Sponsor: N. Keshava.

The U.S. EPA's Guidelines for Carcinogen Risk Assessment provides a framework for the development of a cancer risk assessment for exposures to environmental chemicals. A major component of this framework for any particular chemical is the assignment of a mode of action for the induction of tumors and a description of the key events that define this mode of action. The concentration for key events has been on the induction of mutations in critical genes for tumor formation and the role of these mutations on enhanced cell proliferation or in parallel the role of cell proliferation in enhancing the production of mutations in critical genes. It is be-

coming increasingly apparent that there is an additional class of cellular alterations that can have a significant impact upon tumor development and susceptibility to tumor induction. These alterations are considered under the general term of epigenetic effects. Epigenetic effects can be heritable changes to DNA or protein codes. These effects include DNA methylation changes that can in turn lead to changes in gene imprinting, chromatin remodeling that can have an impact on all cell house-keeping processes, and the formation of genomic instability. In addition, it has been proposed that there can be developmental reprogramming at early life stages that can change developmental patterns throughout life and indeed appear also to be heritable. The induction of such reprogramming by chemical exposures of individuals during early life stages could potentially lead to an enhanced tumor production at much later life stages. It is necessary to consider these epigenetic changes along with other key events in the tumor process and also what might be their impact upon overall cancer risk assessment. (This abstract does not necessarily reflect EPA policy)

584 DISRUPTION OF BRAIN CELL REPLICATION AND NEUROTRANSMITTER SYSTEMS DURING DEVELOPMENT LEADING TO COGNITIVE DYSFUNCTION: DEVELOPMENTAL NEUROTOXICITY OF NICOTINE.

W. Slikker¹, Z. Xu², E. D. Levin³ and T. A. Slotkin³. ¹National Center for Toxicological Research, Jefferson, AR, ²Genelogic, Washington, DC and ³Duke University Medical Center, Durham, NC.

Developmental exposure to nicotine in rats results in neurobehavioral effects such as reduced locomotor and cognitive function. Key events in the animal MOA include binding to the nicotinic cholinergic receptor during prenatal and/or early postnatal development. This leads to premature onset of cell differentiation at the expense of cell replication, which leads to brain cell death or structural alterations in regional brain areas. Other events include an initial increase followed by a decrease in adenylyl cyclase activity, as well as effects on the noradrenergic, dopaminergic and serotonergic neurotransmitter systems. Because the nicotine receptor is also present in the developing human brain and the underlying biology for DNA synthesis and cell signaling is comparable, this MOA is likely to be relevant for humans. Although the effects of nicotine exposure in developing humans is not well documented, nicotine exposure as a result of cigarette smoking during pregnancy is associated with several physiological and behavioral outcomes that are reminiscent of the effects of nicotine alone in animal models. As data come available with the advent of the use of the nicotine patch in pregnant humans, the question as to the relative importance of smoking per se vs. nicotine alone may be determined.

585 APPLICATION OF MODE OF ACTION DATA IN A RISK ASSESSMENT FOR METHYL IODIDE.

M. Gargas¹ and J. H. Kinzell². ¹The Sapphire Group, Dayton, OH and ²Arysta LifeScience North America Corporation, San Francisco, CA.

Recent studies have indicated that acute exposures to methyl iodide (MeI) produce a number of effects in laboratory animals, including fetal toxicity, neurotoxicity, and degeneration of the nasal epithelium. An understanding of the mode of action (MOA) by which these effects are produced by MeI is necessary in guiding critical decisions used in the risk assessment. These include the selection of the appropriate internal dose measure(s) calculated using physiologically based pharmacokinetic (PBPK) modeling, and evaluating the relevance of the observations in animals to human health. Several potential MOAs were evaluated and compared for each endpoint using the modified Hill Criteria. These evaluations and comparisons indicated that: 1) fetal toxicity in rabbits is most likely a result of modulation of thyroid hormones due to elevated iodide concentrations in the fetus resulting from metabolism of MeI; 2) neurotoxicity observed in rats is most likely the result of a generalized inhibition of ion currents in the membranes of nerve cells due to high concentrations of parent chemical; and 3) degeneration of the nasal epithelium of rats is dependent on the sustained depletion of GSH below critical levels due to the metabolism of MeI in the nasal tissues.

586 APPLICATION OF MODE OF ACTION AND DOSE-RESPONSE INFORMATION IN A CHEMICAL MIXTURES RISK ASSESSMENT.

J. C. Lipscomb. *National Center for Environmental Assessment, U.S. EPA, Office of Research and Development, Cincinnati, OH.*

Humans are virtually continuously exposed to multiple chemicals through dietary, occupational, recreational and interaction with the indoor and outdoor environment. Chemical mixture risk assessment differs from single chemical mixture risk

assessment in several ways, perhaps most importantly in the amount of toxicity data available upon which to base predictions. Absent data on the mixture, or a toxicologically similar (surrogate) mixture, a component-based approach should be undertaken; approaches of this type require decisions about similarity of mode of action to properly group chemicals. Unless data are available to indicate an interaction of the risks from component chemicals, the approach will be based on the assumption of additivity of risks. In that case, similarity or independence of mode of action will determine whether dose addition (i.e., relative potency factor approach) or response addition should be employed, respectively. Most toxicity data are from single-chemical studies conducted at moderate to high dose. In these cases, uncertainty is introduced at two points; 1) whether information on the mode of action warrants application of dose or response addition, and 2) extrapolation of the dose response relationship to lower levels of exposure (those to which humans may be exposed). The success and acceptance of a mixtures risk assessment depends heavily on interpretation of mode of action and dose-response data. This presentation will synopsise mixtures risk assessment approaches and highlight the application of mode of action information.

587 ALTERNATIVE AND INTEGRATED APPROACHES TO SKIN SENSITIZATION TESTINGS.

I. Kimber² and G. Gerberick¹. ¹Procter & Gamble, Cincinnati, OH and ²Central Toxicology Laboratory, Syngenta, Macclesfield, United Kingdom.

Skin sensitization resulting in allergic contact dermatitis is an important occupational and environmental health issue, and there is a continuing need for effective hazard identification and risk assessment. In the past two decades there has been considerable progress in the toxicological evaluation of skin sensitizing chemicals, but there remains a need to identify alternative approaches that will reduce, refine, and eventually eliminate, the need for experimental animals in safety assessment. To address this need, and in response to new and emerging legislation, there has been a substantial and increasing investment in the design and development of alternative approaches to evaluation of skin sensitization. Among the new initiatives are: the further exploitation of structure-activity relationships, measurement of the ability of sensitizing chemicals to form stable associations with proteins and peptides, examination of the stimulation by chemical allergens of changes in the phenotype and function of dendritic cells (DC) and DC-like cells, and the use of integrated testing systems. Progress in each of these areas, and their likely future contributions to hazard identification, determination of relative potency and risk assessment will be discussed.

588 SKIN SENSITIZATION HAZARD IDENTIFICATION AND HAZARD CHARACTERIZATION: WHAT ARE THE ISSUES?

I. Kimber. Central Toxicology Laboratory, Syngenta, Cheshire, United Kingdom.

Skin sensitization resulting in allergic contact dermatitis is an important occupational health issue. Many hundreds of chemicals have been implicated as skin sensitizers, and allergic contact dermatitis is the commonest manifestation of immunotoxicity in humans. There are currently available guinea pig tests and the mouse local lymph node assay for the identification of skin sensitizing chemicals. There is, however, an increasing requirement to design and develop alternative approaches that refine or reduce the use of animals in skin sensitization safety assessment, or that eliminate altogether the requirement for animals. Both in vitro approaches and prediction models based on structure-activity relationships (SAR) are being explored. However, there are difficult challenges to be addressed in developing alternative methods that reflect sufficiently the complexities of immune responses to chemical allergens, and that will provide the required levels of sensitivity and specificity. Moreover, effective risk assessment requires information on relative skin sensitization potency and such data will not normally be available from in vitro assays or SAR analyses. It may prove necessary to consider the application of testing platforms that integrate information from a variety of independent sources to inform judgements on skin sensitization hazards. Progress is being made in each of these approaches and will be described here.

589 THE BENEFITS AND LIMITATIONS OF (QUANTITATIVE) STRUCTURE-ACTIVITY RELATIONSHIPS ((Q)SARS).

G. Patlewicz¹, A. O. Aptula² and D. W. Roberts³. ¹European Chemicals Bureau (ECB), European Commission, Ispra, VA, Italy, ²SEAC, Unilever Research, Sharnbrook, Beds, United Kingdom and ³School of Pharmacy and Chemistry, Liverpool John Moores University, Liverpool, United Kingdom. Sponsor: E. Gerberick.

There is currently considerable interest in exploiting the information derived from (quantitative) structure-activity relationships ((Q)SARS) and expert systems for use in hazard identification and risk assessment. Much momentum has arisen from

preparations for the forthcoming EU Legislation REACH (Registration Evaluation Authorisation of Chemicals), which calls for more widespread use of (Q)SARS to assess existing chemicals. The 7th Amendment to the Cosmetic Directive has also prompted interest in (Q)SARS since a ban on animal testing for cosmetic ingredients will come into effect from 2009 onwards.

QSARS are statistically established correlations relating a quantitative parameter(s) derived from chemical structure to a quantitative measure of biological activity. SARs are (qualitative) associations between a chemical substructure and the potential of a chemical containing that substructure to exhibit a certain biological effect. SARs and QSARS have been developed for skin sensitization. Both these types of models can be found in expert systems, usually commercial programs which comprise a collection of SARs encoding existing knowledge (e.g. DEREK, Hazard Expert), statistically derived QSARS (e.g. TOPKAT, MCASE) or a hybrid of both (e.g. TIMES). Many of the (Q)SARS to date have been developed on the basis of reaction chemistry where the chemical behaves as an electrophile and the skin protein as a nucleophile. Some of the most common electrophile-nucleophile reactions include Michael-type, SN2, SNAr, acylation and Schiff-base formation.

Current work at the ECB is aiming to characterize a number of available (Q)SARS and expert systems for skin sensitization to determine their scope (by using reaction chemistry), benefits and limitations. We will illustrate some examples and discuss the realistic prospects for their use in future safety assessments.

590 PROTEIN AND PEPTIDE BINDING: AN EMERGING STRATEGY.

G. Gerberick. Procter & Gamble, Cincinnati, OH.

Allergic contact dermatitis resulting from skin sensitization is a common occupational and environmental health problem. In order for a chemical to function as a sensitizer it must penetrate the skin, react with protein and be recognized as antigenic by immune cells. Protein reactivity correlates with skin sensitization potential and this relationship is attributed to the fact that chemical allergens, either directly or following biotransformation have electrophilic properties that enable them to form covalent bonds with nucleophilic amino acids, like cysteine and lysine. This relationship was used as the premise for the development of an in vitro assay to measure the reactivity of chemical allergens with peptides containing nucleophilic amino acids (e.g. cysteine). Specifically, in vitro assays using peptides containing cysteine or lysine, or glutathione as surrogate nucleophiles have been evaluated. Findings to date suggest that a strong correlation exists between sensitization potency and the ability of a chemical to react with protein. Analysis of more than 80 chemicals, including sensitizers and non-sensitizers, confirmed the correlation between reactivity and sensitization potential and has supported further evaluation of peptide reactivity testing in interlaboratory studies as a screening approach for skin sensitization testing. These peptide reactivity data were used to develop prediction models based on classification tree methodology. Collectively, data generated support the use of a peptide reactivity assay a potential method to screen the sensitization potential of new chemicals. This approach along with other approaches may lead to a reduction or replacement of animal use in skin sensitization testing.

591 CELLULAR ASSAY SYSTEMS: DENDRITIC CELLS AND BEYOND.

C. Ryan. Procter & Gamble Company, Cincinnati, OH.

The mechanistic understanding of allergic contact dermatitis (ACD) has increased substantially in recent years; the challenge is to apply this knowledge to the design of a predictive cell-based in vitro alternative test. Langerhans cells (LC), considered the principal antigen presenting cell (APC) in the skin, play a key role in the development of allergic contact sensitization. A number of changes are known to occur in LC as a result of exposure to chemical allergens including the internalization of surface Major Histocompatibility Complex (MHC) class II molecules via endocytosis, the induction of tyrosine phosphorylation, the modulation of cell surface markers and cytokine expression. Given the importance of LC in the initiation of skin sensitization, it seems appropriate to explore whether there are opportunities to develop alternative approaches to hazard identification based upon chemical-induced changes in phenotype or function of these cells. While the availability of sufficient numbers of LC isolated from human or murine sources has been a limiting factor, some investigators have focused on events which occur in epidermal LC following their exposure to chemical haptens as the basis for predictive in vitro methods for skin sensitization. However, more work has been conducted using LC-like dendritic cells (DC) derived from bone marrow or cord blood CD34+ precursors or peripheral blood mononuclear cells as greater quantities of these LC-like APCs can be obtained which allow for the characterization of the effects of allergen exposure and permit investigation of their utility as an in vitro model system for the development of predictive tests. More recently, commercially-available human cell lines

such as the KG-1, U-937, THP-1, and MUTZ-3 cell lines are being explored as potential surrogates for DC. Conceptually, a cell-based in vitro test would be integrated into a battery of test methods that together address the key steps involved in the initiation of ACD and could be used in a weight-of-evidence approach for the identification of skin sensitization hazard.

592 INTEGRATED SYSTEMS AND A MODIFIED LOCAL LYMPH NODE ASSAY.

D. Basketter. *Unilever, Sharnbrook, United Kingdom.*

The existing (in vivo) approaches to the predictive identification and characterisation of skin sensitisation hazard have proven very successful. With care, virtually all chemicals which possess intrinsic skin sensitisation hazard for man can be predicted; risk assessment and management can then be applied, particularly through use of relative potency estimation in the local lymph node assay (LLNA). However, the need to reduce, and ultimately replace, animal testing conflicts with the pressure to conduct retrospective assessment of thousands of existing chemicals. A modified LLNA, which uses only the single high dose group, offers the chance to significantly reduce animal use whilst maintaining an accurate identification of skin sensitisation hazard. Unfortunately, it also brings the consequence that data on relative potency are not generated, so compromising risk assessment/management. Strategies for total animal replacement focus on the main elements of the induction of skin sensitisation: bioavailability, electrophilicity, stimulation of cytokine release from keratinocytes and the activation of dendritic cells. Here, the challenge is not only how to use the output from assays based on these elements to determine the presence of skin sensitisation hazard, but also how to integrate them into a holistic view of the relative potency of an identified skin sensitising chemical. One potential paradigm for this will be discussed, particularly in relation to the now extensive published LLNA potency database.

593 ALTERNATIVE AND INTEGRATED APPROACHES TO SKIN SENSITIZATION: RECENT PROGRESS AND THE WAY FORWARD.

W. S. Stokes. *NICEATM, NIEHS, Research Triangle Park, NC.*

Recent significant progress has been made in reducing and refining the use of animals for assessing skin sensitization potential of chemicals. Progress is also being made in developing methods and strategies that may eventually provide for partial or full replacement of animal use. The validation and international regulatory acceptance of the murine local lymph node assay (LLNA) now allows it to be used in place of standard guinea pig based assays in most testing situations and fully eliminates the potential pain and distress that could previously occur with this testing. New approaches such as use of a LLNA limit dose test will further reduce the numbers of animals needed for this procedure. New models and approaches are also being developed that may eventually allow for decisions about skin sensitization potential of a substance to be made without animals. These include advances in structure-activity relationship models, assessment of protein and peptide bonding potential, and the evaluation of responses in mechanism based cellular systems. Integration of the responses from a battery of test models such as these is also expected to provide improved predictions of sensitization potential. Adding knowledge about physical and chemical attributes of substances associated with sensitivity or non-sensitivity may further strengthen such predictions. Evaluation of these integrated approaches will require adequate validation of each individual model as well as the entire test battery with the same set of reference substances for which there is high quality data from the accepted reference test method. High quality data from human studies for the same reference substances are also desirable, where this can be ethically accomplished. Regulatory acceptance of a proposed integrated testing approach will require demonstration that the approach will provide for equivalent or improved prediction of sensitization potential. Further development, validation, and integrated use of mechanism-based sensitization testing models can be expected to further reduce animal use while providing for continued protection of human health.

594 THYROID HORMONE DISRUPTION: FROM KINETICS TO DYNAMICS.

K. M. Crofton¹ and J. W. Fisher². ¹*Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC* and ²*Department Environ Health Sciences, University Georgia, Athens, GA.*

A wide range of chemicals with diverse structures act as thyroid disrupting chemicals (TDCs). Broadly defined, TDCs are chemicals that alter the structure or function of the thyroid gland, alter regulatory enzymes associated with thyroid hor-

mones (THs), or change circulating or tissue concentrations of THs. TDCs represent a group of structurally diverse chemicals that act through a variety of mechanisms. While serum concentrations of THs are useful bio-indicators of TDCs, the relationship between alterations in serum concentration of THs and developmental toxicities is uncertain, particularly at low doses. This symposium will focus on recent collaborative research aimed at reducing the uncertainties by delineating the relationship between developmental neurotoxicity of the brain and perturbation in the maternal/fetal and neonatal hypothalamic-pituitary-thyroid (HPT) axis. A brief introduction of this session will be given explaining how the speakers presentations will fit together and what we expect to accomplish in this workshop.

595 A PRIMER OF COMPARATIVE THYROIDOLOGY: RELEVANCE TO METHODS AND MODELS.

D. C. Ferguson. *Department Physiol Pharmacology University Georgia, Athens, GA.*
Sponsor: K. Crofton.

While the basic principles of thyroid physiology are common in most vertebrate species, there are key regulatory differences between species such as serum thyroid hormone binding proteins, and hormone and iodide turnover rates. Extrapolating results from one species to another (e.g. rat to man), requires careful consideration of the similarities and differences not only circulating hormones, but also differences in tissue responses of deiodinase and conjugative enzymes involved with hormone clearance. Accurate measurement of free T4 by dialysis is a technique which, if applied appropriately, provides an accurate measurement in serum from all species. Free T4, under most circumstances, predicts the steady-state biological response to thyroid hormone including the feedback response of serum TSH concentrations. However, it is now well accepted that changes in thyroid status or development of non-thyroidal disease exert tissue- or cell type-specific effects. To investigate these tissue changes, it is critical to evaluate tissue concentrations of T3 and T4 and the responses of proteins whose expression and/or activity is regulated by thyroid hormone: Type 1 and Type 2 5'-deiodinase enzymes (D1 and D2), membrane thyroid hormone transport proteins such as organic acid transport proteins (e.g. OATP1C1) and monocarboxylate transport proteins (e.g. MCT8). Accurate measurement of serum thyroid hormone and TSH concentrations in model species, while using assay principles applicable to all species, requires recognition of differences in serum binding protein types and quantity, and differences in TSH structure. Beyond this, it is critical to recognize the species-specific developmental stages of hypothalamic-pituitary-thyroid axis regulation. Examination of in vivo and in vitro studies in model species allows the recognition of conserved regulatory motifs, as well as key differences relevant to the interpretation of perturbations induced by environmental xenobiotics.

596 DEVELOPMENTAL TARGETS AND MECHANISMS OF XENOBIOTICS THAT ALTER THYROID HORMONE HOMEOSTASIS.

M. J. DeVito. *U.S. EPA, Research Triangle Park, NC.*

There are multiple targets for environmental chemicals that disrupt thyroid hormone homeostasis in rats. This includes chemicals that affect iodine uptake, hormone synthesis, transport and catabolism. A number of species differences in mechanisms of thyroid disruption create uncertainties and difficulties in extrapolating rodent data to man. In particular, there are species differences in the role of nuclear receptors in thyroid hormone homeostasis and the importance of the different thyroid hormone transport proteins. A more complete understanding of species differences in these processes will improve species extrapolation of thyroid hormone disruptors.

597 LOW-DOSE THYROID INSUFFICIENCY: IMPACT ON NEURODEVELOPMENT.

M. E. Gilbert. *U.S. EPA, Research Triangle Park, NC.*

Thyroid hormones are critical for normal growth and development of the brain. It is well established that severe reductions in thyroid hormone lead to mental retardation in children. Recent evidence indicates that modest hormone reductions in pregnant women result in subtle changes in cognition and IQ deficits in children. Similarly, environmental insults produce modest perturbations in the thyroid axis, and little is known of their potential hazards to normal brain development. Traditional rodent models of hypothyroidism have been limited to severe depletions, with little information available on potential adverse outcomes of milder forms of developmental thyroid insult. New research using rodent models is exploring sensitive biochemical, physiological and morphological biomarkers of adverse neurological outcomes.

**598** PBPK AND BIOLOGICALLY BASED COMPUTATIONAL MODELS FOR THYROID ACTIVE CHEMICALS AND THE HYPOTHALAMIC-PITUITARY-THYROID AXIS TO EVALUATE DEVELOPMENTAL NEUROTOXICITY.

J. W. Fisher. *Department Environ Health Sciences, University Georgia, Athens, IL.*

Computational models of developmental thyroid disruption require an understanding of the kinetics of thyroid active chemicals in laboratory animals of various reproductive states. These models require unique reproductive state-specific biological determinants that control dosimetry and mode-of-action. New research is using state-of-the-science computational models to address indirect acting agents that exert their effects on the developing brain via the hypothalamic-pituitary-thyroid axis. Future research is needed to develop computational models of the adverse outcomes on neurodevelopment caused by thyroid disruption.

**599** LOW-DOSE THYROID TOXICANTS AND NEURODEVELOPMENT IN RAT: IS IT RELEVANT TO HUMANS?

R. Zoeller. *Department Biology, University Massachusetts, Amherst, MA.*

The original concept of the critical period of thyroid hormone (TH) action on brain development was proposed to identify the postnatal period during which TH supplement must be provided to a child with congenital hypothyroidism to prevent mental retardation. As neuropsychological tools have become more sensitive, it has become apparent that even mild TH insufficiency in humans can produce measurable deficits in very specific neuropsychological functions, and that the specific consequences of TH deficiency depends on the precise developmental timing of the deficiency. Models of maternal hypothyroidism, hypothyroxinaemia and congenital hyperthyroidism have provided these insights. Experimental literature lags behind clinical studies in providing a mechanistic explanation for each of these observations. Recent studies confirm that the specific action of TH depends upon developmental timing. Molecular studies of TH action in the developing brain are generating hypotheses concerning possible mechanisms to account for these pleiotropic actions. New research with rodent models of TH insufficiency is improving our understanding of effects of environmental xenobiotics in humans. Finally, new research directions are required to advance the state of the science for assessing human health and thyroid active chemicals.

**600** ANIMAL RIGHTS EXTREMISM AND THE RESPONSIBLE USE OF ANIMALS IN RESEARCH: THE PAST, PRESENT, AND FUTURE.

J. Oberdoerster¹ and T. Bunton². ¹*Toxicology, Bristol-Myers Squibb, E. Syracuse, NY and* ²*Sratocox LLC, Lancaster, PA.*

The necessary use of animals in biomedical and toxicological research and to fulfill regulatory safety requirements must be acknowledged, with recognition of and respect for the important contribution of animals in the scientific progress. Animals must be humanely treated in accordance with applicable animal welfare laws/regulations and full consideration of the 3Rs - replacement, reduction, and refinement. The Session will call attention to the distinction between animal welfare and animal rights extremism and will explore ways to think about the development of replacement alternatives. How different stakeholders (e.g., the scientific community vs. the animal rights community) look at the 3Rs will be presented. Examples of the actions of animal rights extremists and a new brand of internet-based extremism will be presented and effective and appropriate responses addressed. Measures taken by the scientific community and others in coordinating an effective response to this extremism will be discussed and several "next steps" required to consolidate recent gains highlighted. The processes and practices presented here will help us move forward as humane scientists without sacrificing scientific quality due to illegal tactics and intimidation.

**601** WHAT TO DO WHEN YOUR RESEARCH IS UNDER ATTACK.

R. Phalen². ¹*Toxicology, Bristol-Myers Squibb, E. Syracuse, NY and* ²*Department of Community & Env. Med., University of California Irvine, Irvine, CA.*

When 13 beagle dogs were stolen from the Air Pollution Health Effects Laboratory, replacing the animals was not the most serious problem. The media rushed in, threats were received, staff and their families became fearful, the author's home was picketed, speaking requests arrived, and security systems had to be put in place. Yet, in the midst of the turmoil, opportunities to educate local and national communities were presented. Initially, our efforts were directed by local and national newspaper, magazine, and radio and television reporters. We had the opportunity to explain how and why we did our studies, and why the charges against us were false. As a result, we were usu-

ally given equal, or greater, weight in the media than those who were making inaccurate charges. Good preparation and honest communications helped win the hearts of reporters and the public, and the respect of many of the activists.

If an investigator's home is going to be picketed, they must deal with the family's fears, and let the neighbors know what to expect. During the picketing, it is good to leave your home, leaving your pets in a safe location. Try to arrange with your institution to have security present, and spokespeople to meet the press. Also, inform the local police.

We had numerous interactions with law enforcement. Institutional security focused on improving surveillance and security. Anti-terrorist agencies were interested in finding the animals and the abductors. We were told that the stolen dogs were photographed for fundraising purposes, and then killed. Sadly, we had to identify their charred skeletal remains.

The major lesson that we learned was that it is important to earn the respect and support of the press and the public. That is achieved by open and honest communication.

**602** THE SCIENCE OF ALTERNATIVES.

A. Goldberg. *Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

The word alternatives, often thought of as only replacement, has a deeper and more profound implication when used in its proper context of the 3Rs - replacement, reduction and refinement. There are those in both the scientific community and in the animal rights community that purposefully only focus on replacement. It provides for a more self serving perspective. The 3Rs as used by Bill Russell and Rex Burch in their book "The Principles of Humane Experimental Technique" did not use the word alternative. It was Smyth, several years later, that equated the 3Rs with Alternatives. In meeting after meeting of stakeholders and in the reaffirmation of the 3Rs in a publication in the mid 90's it was decided that the best way to approach this issues was to always use the word alternative with one of the Rs, thus refinement alternative. Practicing the 3Rs is the way to achieve the most humane science. Bill Russell and Rex Burch hypothesized that humane science is the best science. It has taken almost 40 years to be able to prove that this hypothesis is correct. The Science of Alternatives will explore a way to think about the development of replacement alternatives and examine how different stakeholders look at the 3Rs.

**603** FACE-OFF AGAINST 21ST CENTURY EXTREMISM.

M. Caulfield². ¹*Toxicology, Bristol-Myers Squibb, E. Syracuse, NY and* ²*Huntingdon Life Sciences, East Millstone, NJ.* Sponsor: J. Oberdoerster.

Huntingdon Life Sciences, a contract research organization with laboratories located in the US and UK has been the focus of a concerted effort by animal rights extremists to put it out of business by targeting its employees, business associates, financial backers and suppliers. By proactively engaging industry, law enforcement, the courts, and governments on both sides of the Atlantic, HLS has been a successful participant in engineering an outcome that has resulted in high-profile convictions, significantly stronger laws in the UK, similar positive legislative momentum in Washington DC and greatly improved integration of efforts among the various stakeholders in mitigating the threat to research posed by animal rights extremists. This presentation will review measures taken by HLS and others in coordinating an effective response to this new brand of internet-based extremism. It will assess the current environment, and will propose several "next steps" required to consolidate recent gains.

**604** THE PHARMACEUTICAL INDUSTRY AND ANIMAL EXTREMISM: ACTION, REACTION OR INACTION?

T. Morris². ¹*Toxicology, Bristol-Myers Squibb, E. Syracuse, NY and* ²*GlaxoSmithKline, Brentford, Middlesex, United Kingdom.* Sponsor: J. Oberdoerster.

The words and activities of animal rights extremists can be truly shocking. However it is the response that those targeted make that actually determines their impact. What is an effective and appropriate response, and how is it implemented?

**605** PROTECTIVE MEASURES.

M. Moll². ¹*Toxicology, Bristol-Myers Squibb, E. Syracuse, NY and* ²*Office of Infrastructure Protection, Risk Management Division, U.S. Department of Homeland Security, Western Michigan District, MI.* Sponsor: J. Oberdoerster.

This presentation will provide proven protective measures that can be implemented to mitigate potential animal extremists from causing harm. While not intended as an "all-inclusive" checklist, these strategies can keep a person out of harms way, take them out of harms way, and effectively deal with extremists tactics using legally

sound, crime prevention-type principles. Areas to be covered include: demonstrations, harassing of neighbors, protection of family and friends, as well as precautions to take at home, the office, and in your vehicle.

606 MODULATION OF DIBENZO[A, L]PYRENE TRANSPLENTAL CARCINOGENESIS BY GREEN TEA.

D. J. Castro^{1,2,3} and D. E. Williams^{1,2,3}. ¹Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR, ²Linus Pauling Institute, Oregon State University, Corvallis, OR and ³Environmental Health Sciences Center, Oregon State University, Corvallis, OR.

The fetus is a sensitive target for chemically induced toxicity including carcinogenesis. However, few studies have examined the efficacy of chemopreventative agents in the maternal diet. Previous studies showed that a single dose of 15 mg/Kg b.w. of dibenzo[a,l]pyrene (DBP) on gestation day 17 significantly increased mortality in offspring beginning at 12 weeks of age due to an aggressive T-cell lymphoma. All mice surviving to 10 months, exposed *in utero* to DBP, exhibited lung tumors with high multiplicity. In that study, maternal aryl hydrocarbon receptor (AhR) responsiveness was found to decrease offspring mortality ($p = 0.006$). However, AhR-responsive offspring born to these dams had increased mortality compared to their non-responsive litter mates ($p < 0.05$). Interestingly, administration of indole-3-carbinol at gestation day 9 through weaning significantly decreased mortality independent of AhR genotype. Therefore, the goal of the current study was to examine the dietary impact of green tea polyphenols on DBP transplacental carcinogenesis. Pregnant mice were administered DBP as previously described and some were also given caffeinated green tea or decaffeinated green tea from gestation day 0 through weaning at levels reaching 1.5% w/v. Caffeine and epigallocatechin-3-gallate (EGCG) equivalents were also included as separate groups to examine the role of these major constituents found in green teas. The modulation of lymphoma-dependent mortality caused by maternal DBP exposure was significant only in dams receiving caffeinated green tea or caffeine equivalents, suggesting a potential chemoprotective role of caffeine. Current efforts are examining the roles of the AhR and its downstream transcriptional target cytochrome P450 1B1 in mediating DBP-initiated carcinogenesis. Supported by PHS grants CA90890, ES07060, ES03850, and ES00210

607 INHIBITORY EFFECTS OF THE SAPONINS DERIVED FROM ROOTS OF PLATYCODON GRANDIFLORUM ON TUMOR INVASION AND METASTASIS.

E. Kim⁴, J. Choi^{1,2}, S. Roh⁴, Y. Chung³ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea, ³Division of Food Science, Chonju International University, Chonju, South Korea and ⁴Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Chonju, South Korea.

Platycodon grandiflorum is a traditional oriental herbal medicine that is known for its anticancer effects. This study examined the antimetastatic activities of the saponins that were isolated from the roots of Platycodon grandiflorum A. DC (Campanulaceae). Changkil saponins (CKS) were examined using *in vitro* and *in vivo* invasion and metastasis assay. CKS inhibited the invasion of B16-F10 melanoma cells through a reconstituted basement membrane (Matrigel)-coated filter. Zymographic analysis showed that CKS suppressed TPA-induced MMP-9 activity and expression in a dose-dependent manner. We further demonstrated that CKS reduced the transcriptional activity of NF- κ B, an important nuclear transcription factors involved in MMP-9 expression. CKS also inhibited an experimentally-induced lung cancer and increased the survival time *in vivo*. Taken together, these results suggest that CKS can reduce the extent of a lung metastasis of B16-F10 melanoma cells by inhibiting the tumor invasion of the basement membrane possibly by preventing the suppression of MMP-9 expression through inhibiting NF- κ B signaling pathways.

608 EUGENOL PROTECTS AGAINST 7, 12-DIMETHYLBENZ[A]ANTHRACENE-INDUCED DNA DAMAGE IN MCF-7 CELL THROUGH ACTIVATION OF PHASE II ENZYMES.

Y. Hwang^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

Phytochemicals derived from such fruits and vegetables, referred to as chemopreventive agents. Eugenol (2-methoxy-4-allylphenol) is the basic constituent of the clover oil, to which are attributed the chemopreventive and antioxidant properties. Chemopreventive agents induce phase II detoxifying enzymes. NF-E2 re-

lated factor2 (Nrf2) is a transcription factor involved in the cellular protection against oxidative stress through antioxidant response element (ARE)-directed induction of several phase II detoxifying and antioxidant enzymes. This study, examined the chemopreventive effect of eugenol on 7,12-dimethylbenz[a]anthracene (DMBA)-induced DNA damage in MCF-7 cells. Eugenol inhibited the formation of the DMBA-DNA adduct in a dose dependent manner. Furthermore, eugenol increased the expression and enzymatic activity of the phase II enzymes, such as glutathione-S-transferase (GST) and NAD(P)H:quinone oxidoreductase (QR), which detoxify carcinogenic metabolites. In addition, eugenol stimulated the nuclear translocation of Nrf2 as well as the subsequent induction of ARE-mediated GST and QR activities. Therefore, eugenol has a potent protective effect against DMBA-induced genotoxicity, presumably by induction of DMBA detoxification. These results suggest that eugenol has potential as a chemopreventive.

609 CHEMOPREVENTION IN MICE BY 2-ARYL/ALKYL SELENAZOLIDINE-4(R)-CARBOXYLIC ACIDS.

M. R. Franklin, J. C. Roberts, W. M. El-Sayed, T. Aboul-Fadl, T. H. Schofield, J. E. Constance and J. G. Lamb. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

In epidemiology and human supplementation studies, as well as many animal models, selenium has shown chemopreventive activity. The efficacy of a series of 2-aryl/alkyl selenazolidine-4(R)-carboxylic acids (SCAs), compounds designed as selenocysteine pro-drugs, in reducing NNK [4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone] -induced lung adenomas in mice, a model for tobacco-related lung tumorigenesis, has been investigated. Prior studies have shown 2-oxoSCA but not 2-methylSCA or SCA itself to be chemopreventive. In the present study, mice received AIN-76A diet supplemented with the selenazolidines at 15 ppm Se for one month prior to carcinogen administration and during the subsequent four months of tumor development. 2-ButylSCA, 2-cyclohexylSCA and 2-phenylSCA reduced mean lung tumor numbers from the 10.9 ± 0.9 seen in unsupplemented controls to 4.7 ± 0.9 , 5.3 ± 1.0 and 2.8 ± 0.5 respectively. 2-(2-Hydroxyphenyl)SCA was not active in reducing tumor numbers. Repeating the study but with selenazolidine supplementation beginning 3 days after carcinogen administration, only the 2-butylSCA and 2-cyclohexylSCA were chemopreventive. In a third study in which selenazolidine supplementation was only for the period one month prior until 3 days after carcinogen administration, only 2-butylSCA and 2-phenylSCA were chemopreventive. Both retained chemopreventive activity when the supplementation period was shortened further to 9 days prior until 2 days prior to carcinogen administration. The reductions in tumor numbers were 40% for 2-phenylSCA and 44% for 2-butylSCA. With a 2 days prior until 3 days after supplementation regimen, the reductions in tumor numbers, 26% for 2-phenylSCA and 17% for 2-butylSCA, were not statistically significant. Thus dietary supplementation with selenazolidines shows promise as a chemoprevention strategy. For at least two 2-substituted SCAs, short-term rather than continuous supplementation is sufficient to demonstrate chemopreventive activity.

610 A NOVEL NUTRIENT MIXTURE INHIBITS CELL PROLIFERATION, MMP SECRETION AND INVASION IN HEP G2 HEPATOMA CELL LINE.

M. Roomi, V. Ivanov, A. Niedzwiecki and M. Rath. *Dr. Rath Research Institute, Santa Clara, CA.*

Introduction:

A novel nutrient mixture (NM) containing lysine, proline, ascorbic acid and green tea extract has exhibited anti-tumor activity *in vivo* and *in vitro*. In this study we investigated the effect of NM on Hep G2, human hepatoma cell line.

Objective:

NM has been shown to possess a wide range of pharmacological properties, and is one of the most promising chemo preventive agents for cancer. To provide a better understanding of the preventive effect of NM on liver cancer, we examined NM for its effect on proliferation, MMP secretion, invasion and morphology.

Methods:

Hep G2 cells (ATCC) were cultured in MEM medium supplemented with 10% FBS and antibiotics. The cells were then challenged with NM at 0, 10, 50, 100, 500 and 1000 μ g/ml concentration in triplicate at each concentration. Cell proliferation was assessed by MTT assay, MMP activity by gelatinase zymography, invasion through Matrigel and morphology by H&E staining. Cells were also treated with PMA for MMP-9 induction.

Results:

NM was slightly toxic at 100- μ g/ml concentration and significant at 500 and 1000 μ g/ml concentration. NM showed a dose dependent inhibition of MMP-9 in PMA-induced cells, with virtual total inhibition at 500- μ g/ml concentration. Invasion through Matrigel was inhibited by 30%, 80% and 100% at 50, 100 and 500 μ g/ml. H&E staining showed no morphological changes below 500 μ g/ml. Conclusions:

These results suggest that NM has therapeutic potential as a new anti-tumor agent.

611 CALCIUM-INDEPENDENT PHOSPHOLIPASE A₂ AS A NOVEL TARGET FOR THE INHIBITION OF CANCER CELL GROWTH.

S. Talathi, K. Coveney, G. Saavedra, B. Peterson and B. S. Cummings. *Pharmacology and Biomed. Sciences., University of Georgia, Athens, GA.*

We recently demonstrated that inhibition of Ca²⁺-independent phospholipase A₂ (iPLA₂) decreased cellular proliferation in correlation with decreased expression of phosphatidylcholines (PtdCho). However, the mechanisms involved in these processes, and the effect of iPLA₂ inhibition on chemotherapeutic-induced alterations of cell growth were not studied. Thus, this study determined the ability of iPLA₂ inhibitors to alter the effect of chemotherapeutics on cell growth and death in multiple cancer cell lines. Inhibition of total iPLA₂ activity using bromoenol lactone (BEL, 0-5 μ M) decreased cell growth by 20%, decreased 14:0-16:0 and 16:0-16:0 PtdCho, and increased chemotherapeutic-induced cell death in lung, neural, and prostate cancer cells exposed to cisplatin and vincristine (1-50 μ M). Interestingly, the effect of BEL was only evident in cells undergoing log phase growth, and was not evident when confluent cultures were treated. Transfection of cells with siRNA against iPLA₂ β or γ demonstrated that inhibition of iPLA₂ β , but not iPLA₂ γ , decreased cell growth 30-40%. These data were verified using the pharmacological inhibitors R-BEL (microsomal iPLA₂ γ inhibitor) and S-BEL (cytosolic iPLA₂ β inhibitor). To investigate the mechanisms involved in these processes the effect of BEL (5.0 μ M) on the progression of prostate cells through the cell cycle was studied. Exposure of cells to BEL increased the amount of cells in G1 while decreasing the amount of cells in S-Phase. Incubation with cisplatin or vincristine induced a G2-M arrest. However, pretreatment with BEL inhibited this arrest and increased the amount of cells in G1 and sub-G1. These data suggest that iPLA₂ inhibition decreases cell growth by decreasing the progression of cells from the G1 to the S-phase of the cell cycle, that the effect of iPLA₂ inhibitors and chemotherapeutics on cancer cell growth are additive, and that iPLA₂ may be a novel target for the inhibition of cancer cell growth.

612 GENE EXPRESSION PROFILING IN CHEMOPROTECTING ACTION OF CAFFEIC ACID PHENETHYL ESTER (CAPE) ON THE INITIATION IN A RAT HEPATOCARCINOGENESIS MODEL.

O. Beltran-Ramirez¹, A. Sierra-Santoyo², J. Hernandez-Martinez³, J. M. Francois⁴, V. Le Berre⁴, S. Sokol⁴ and S. Villa-Treviño¹. ¹*Cell Biology, CINVESTAV-IPN, Mexico City, D.F., Mexico*, ²*Toxicology, CINVESTAV-IPN, Mexico City, D.F., Mexico*, ³*Dirección de Tecnología de Alimentos de Origen Animal, CIAD, Hermosillo, Sonora, Mexico* and ⁴*Biochips Platform of Genopole Toulouse Midi-Pyrenees, INSA, Toulouse, France.*

CAPE is a natural honeybee hive product that has shown anti-carcinogenic properties in the modified resistant hepatocyte model when is administered on initiation stage. The information about its action mechanism is limited. The aim was to characterize the effect of CAPE on gene expression profile on initiation stage of hepatocarcinogenesis by microarrays analysis. Three groups of male adult Fisher-344 rats were administered with one ip dose of CAPE (20 mg/kg), diethylnitrosamine (DEN) (200 mg/kg) and DEN plus CAPE 12 h before DEN administration. Animals were sacrificed 12 h after CAPE dosing, 24 h after DEN and 12 and 24 h after DEN+CAPE. Liver was removed and processed to obtain microsomes and for microarrays analysis using a cDNA slide with 28800 genes (Transcriptome-Biochips Platform of Genopole Toulouse Midi-Pyrenees). CAPE alone did not produce any alteration in gene expression. At 24 h DEN treatment altered 160 genes, 91 over-expressed and 69 down-expressed including the diminution of several cytochrome-P450 (CYP) isoforms such as CYP2C11 and 3A1. DEN+CAPE treatment at 24 h altered 352 genes, 100 over-expressed and 252 down-expressed including the diminution of CYPs involved in DEN metabolism such as CYP1A1, 2B1 and 2E1. These isoforms were validated by enzymatic activities. In CAPE group CYP1A1, 1A2 and 2B enzymatic activities were reduced. In DEN+CAPE group CYP1A1 and 1A2 were decreased at 12 h and at 24 hr CYP1A1 diminished and CYP1A2 was incremented. These results suggest that CAPE produces a general down-expression in the gene expression profile including CYP isoforms involved in DEN bioactivation. In addition, support the proposal that chemoprotective effect of CAPE may be by hepatic CYP regulation in chemical hepatocarcinogenesis.

613 MRP-MEDIATED GLUTATHIONE DEPLETION AS A POTENTIAL NEW STRATEGY OF CANCER CELL SENSITIZATION.

H. Leitner^{2,1}, R. Kachadourian¹, J. Huang¹ and B. Day¹. ¹*Medicine, National Jewish Research and Medical Center, Denver, CO* and ²*Toxicology, University of Colorado Health Sciences Center, Denver, CO.*

New approaches in cancer therapy focus on better tumor cell targeting strategies. Compounds such as L-S,R-buthionine sulfoximine (BSO) have been developed to deplete cancer cells of their antioxidant stores thereby sensitizing them to pro-oxidant agents. The major draw-back to this type of therapy is an inherent lack of specificity. Since multi-drug resistance proteins (MRPs) are known to be over expressed in tumor cells and can co-transport glutathione (GSH), we have chosen to target this pathway as a selectivity solution. We previously reported that two prototypic flavonoids, i.e. 2',5'-DHC and chrysin, are efficient inducers of GSH depletion in A549 cells. Herein, we report that, in these cells, cisplatin induces a differential expression of mitochondrial respiratory chain proteins and that the potentiation effect of cisplatin's toxicity induced by these flavonoids is associated with intracellular GSH depletion and mitochondrial dysfunction. Compared to BSO, the effects of the two flavonoids were greater. Our data suggests that the efficacy of the cisplatin/flavonoid combination results, in part, from a synergy of pro-oxidant effects, the first by disrupting the formation of the mitochondrial respiratory chain and the second by decreasing the antioxidant defenses of the cell. MRP-mediated GSH depletion may reveal an adjunctive and specific approach to sensitize cancer cells to pro-oxidant treatment. Whereas chrysin induced GSH depletion is known to be mediated by MRP1, MRPs triggered by 2',5'-DHC remain to be identified.

614 SINGLE AND COMBINED EFFECTS OF BENZENE AND DIABETES ON TOXIC AND CARCINOGENIC ACTIVITY OF NDMA IN RABBIT LIVER- PROTECTIVE EFFECT OF DIALLYL SULFIDE.

E. Arinc, S. Arslan and O. Adali. *Department of Biological Sciences, Middle East Technical University, Ankara, Turkey.* Sponsor: A. Karakaya.

Benzene is an occupational and environmental toxicant. Benzene causes acute myelogenous leukemia. Metabolism of benzene by CYP2E1 is required for its hemopoietic toxicity. Nitrosodimethylamine (NDMA) is a procarcinogen. NDMA is converted to its carcinogenic form after it is activated by CYP2E1 dependent NDMA N-demethylase. Induction of CYP2E1 by diabetes was identified in rabbit liver (Arinc, E., Arslan, S., Adali, O., 2005). The goal of this study was to assess interactive effect of benzene and diabetes status on CYP2E1 expression and its associated NDMA N-demethylase activity. We also investigated whether diallyl sulfide (DAS), protected bioactivation thus, carcinogenicity of NDMA by decreasing CYP2E1 protein amount and its associated activity. NDMA activity was found to be increased significantly (p<0.001) in diabetic or benzene-treated rabbits. The combined effects of benzene and diabetes were found to be additive. Similar trend was elicited when CYP2E1 expression was quantitated. CYP2E1 protein immunostaining intensity was increased upto 7.5-fold in the combined case. Results of regression analysis indicated that there was a significant correlation (r = 0.98, p<0.001) between NDMA N-demethylation and relative CYP2E1 staining intensity in all four cases. DAS, a constituent of garlic has been shown to be anticarcinogenic. However, no data is available concerning the influence of DAS on rabbit cytochrome P450 dependent enzymes. A single dose of DAS in corn oil (250 mg/kg body weight) was given intragastrically to rabbits. When DAS was given after benzene treatment, NDMA N-demethylase activity was decreased to its basal level. Similarly, CYP2E1 contents of the microsomes obtained from DAS treated rabbits were also decreased. Thus, DAS reversed hazardous action of benzene, possible carcinogenicity of NDMA by decreasing CYP2E1 protein amount and its associated enzyme activity.

615 A FAR ENHANCER IN THE CYTOCHROME P450 3A4 GENE FUNCTIONS AS A HIGH DENSITY-REGULATORY MODULE IN RESPONSE TO THE PREGNANE X RECEPTOR AND FUNCTIONALLY RELATED PROTEINS.

F. Liu, D. Yang, X. Song, R. Deng and B. Yan. *Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.*

Cytochrome P-450 3A4 (CYP3A4) is the most abundant P450 enzyme and metabolizes more than half of drugs and other xenobiotics. The expression of CYP3A4 is markedly induced by a variety of structurally dissimilar chemicals. The pregnane X receptor (PXR) is recognized as a major regulator for the induction. It has been established that PXR transactivates the CYP3A4 gene by physically binding two elements (DR3 and ER6) in the distal and proximal promoter regions, respectively. Very recently, a farther upstream region (FUR) was found to support constitutive

expression of CYP3A4. Motif analysis revealed that this region contains multiple elements recognized by PXR or functionally related proteins such as hepatocyte nuclear receptor-4 (HNF-4). It was, therefore, hypothesized that FUR represents a high density-regulatory module that supports transactivation activity of multiple nuclear receptors. In order to test this hypothesis, reporter and electrophoretic mobility shift assays were conducted. Consistent with the hypothesis, fusion of FUR to the CYP3A4 proximal promoter markedly increased the reporter activity by PXR activator rifampicin. The increase, however, was significantly abolished when the putative PXR element (F-ER6) was selectively disrupted. Electrophoretic mobility shift assay detected a shifted band toward biotinylated F-ER6 probe, and the shifted band was super-shifted by an antibody against PXR. In addition, selective disruption of individual HNF-1 and -4 elements in FUR resulted in decreased reporter activity, although the magnitude of the decrease was less than that with the F-ER6 disrupted reporter. These findings functionally define FUR as a regulatory module that supports coordinate activity of multiple transcription factors.

616 FUNCTIONAL ANALYSIS OF THE CYP1A1 PROMOTER/ENHANCER REGION FROM DANIO RERIO (ZEBRAFISH).

G. ZeRuth and R. S. Pollenz. *Cell Biology, Microbiology and Molecular Biology, University of South Florida, Tampa, FL.*

The induction of CYP1A1 by the Ah receptor (AHR) is used as an indicator of environmental exposure to halogenated aromatic hydrocarbons, typified by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). The upstream flanking region of a CYP1A1 gene from zebrafish contains 8 putative core xenobiotic response elements (XREs) organized in two distinct clusters. The region between -580 to -187 contains XRE 1-3 while the region between -2608 to -2100 contains XRE 4-8. Only XRE 1, 3, 4, 7, and 8 exhibit TCDD-dependant association of AHR-ARNT complexes when evaluated by gel shift assays. To evaluate this finding in more detail, luciferase constructs were generated that contained both regions (-2608/-2100Ur construct). Mutagenesis of individual XREs confirmed that TCDD-mediated induction could occur when a single XRE was mutated, but maximal induction required XRE 4, 7, and 8 although each did not function in an additive manner. To determine whether non-functional XREs could be made functional, in vitro mutagenesis was used to change nucleotides within the core XRE or in the flanking regions to mirror those of 4, 7 and 8. Interestingly, there were no changes in the level TCDD-induced luciferase activity with any of the changes made. To investigate the role of other transcription factors in CYP1A1 induction, in silico analysis was used to identify Sp1, HNF-3, and CREB binding sites and in vitro mutagenesis was utilized to knock them out within the -2608/-2100Ur construct. The results show that the absence of the Sp1 and HNF-3 binding sites cause a significant reduction of both basal and induced levels of CYP1A1 while the mutation of the putative CREB binding site had no effect. Collectively, these results show that the inability of certain XREs to confer TCDD-mediated gene induction is likely not sequence specific but may involve the inaccessibility of the region containing the binding site. Furthermore, maximal induction of CYP1A1 may require factors other than AHR/ARNT binding at the enhancer region. Supported by ES10991 (RSP).

617 COMPREHENSIVE GENE EXPRESSION ANALYSIS IN MALE NRF2KO MICE TREATED WITH 2, 3, 7, 8-TETRACHLORO DIBENZO-P-DIOXIN (TCDD).

H. Sato^{1,2}, M. Matsumoto², K. Itoh³, M. Yamamoto³ and Y. Aoki². ¹Institute of Medicinal Molecular Design, Inc. (IMMD), Tokyo, Japan, ²National Institute for Environmental Studies, Tsukuba, Japan and ³TARA Center, University of Tsukuba, Tsukuba, Japan.

Nrf2 (nuclear factor erythroid 2-related factor 2) is an essential transcription factor for inducible and/or constitutive expression of a group of Phase II detoxification and antioxidant enzymes. On the other hand, TCDD has been known as an environmental contaminant and a potent agonist of AhR (aryl hydrocarbon receptor) that regulates Phase I enzymes such as CYP1A1 and CYP1A2. Here, we analyze comprehensive gene expression induced by TCDD in livers of male Nrf2 knockout mice to clarify Nrf2-dependent transcriptional regulation. Forty micrograms of TCDD per kg body weight were administered orally to five Nrf2(-/-) mice and five Nrf2(+/+) mice, which were produced by intercrossing Nrf2(+/-) mice. Total RNA was extracted from the livers 24 hrs after the administration. DNA microarray analysis was performed using the CodeLink mouse 20K array. Fold change values with the p-value of less than 0.01 were adopted as statistically significant data in each group of the Nrf2(-/-) and Nrf2(+/+) mice for network analysis using KeyMolnet afterwards. CYP1A1 and CYP1B1 were significantly up-regulated over 2-fold in both Nrf2(-/-) and Nrf2(+/+) mice treated with TCDD, while Nrf2, NAD(P)H quinone dehydrogenase (NQO1), glutathione S-transferases (GSTs) were up-regulated by TCDD in the Nrf2(+/+) mice, but not in the Nrf2(-/-) mice. Keap1, the negative regulator of Nrf2, was significantly down-regulated by TCDD

only in the Nrf2(-/-) mice. Furthermore, the network analysis implies that transcriptional regulation of E2F(Transcription factor E2F) and TCF(T cell specific transcription factor) is involved in the TCDD-treated Nrf2(-/-) mice. Taken together, our observations suggest that the up-regulation of gene expression of NQO1 and GSTs is induced by TCDD depending on Nrf2 regulation and that E2F and TCF transcription factors are activated by TCDD in the absence of Nrf2.

618 REGULATION OF VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR1 (VEGFR1) EXPRESSION BY SPECIFICITY PROTEINS 1, 3 AND 4 IN PANCREATIC CANCER CELLS.

M. Abdelrahim^{1,2,4}, C. Baker^{1,2}, J. Abbruzzese³, D. Sheikh-Hamad⁵, S. Liu⁴, S. Cho⁴, K. Yoon⁴ and S. Safe⁴. ¹Cancer Research Institute, MD Anderson Cancer Center Orlando, Orlando, FL, ²College of Biomedical Sciences, University of Central Florida, Orlando, FL, ³Department of Gastrointestinal Medical Oncology, University of Texas M.D. Anderson Cancer Center, Houston, TX, ⁴Institute of Biosciences and Technology, Texas A&M University, Houston, TX and ⁵Division of Nephrology - Department of Medicine, Baylor College of Medicine, Houston, TX.

Vascular endothelial growth factor receptor 1 (VEGFR1) is expressed in cancer cell lines and tumors and, in pancreatic and colon cancer cells activation of VEGFR1 is linked to increased tumor migration and invasiveness. Tolfenamic acid, a non-steroidal anti-inflammatory drug, decreases Sp protein expression on Panc-1 and L3.6pl pancreatic cancer cells, and this was accompanied by decreased VEGFR1 protein and mRNA and decreased luciferase activity on cells transfected with constructs (pVEGFR1) containing VEGFR1 promoter inserts. Comparable results were obtained in pancreatic cancer cells transfected with small inhibitory RNAs for Sp1, Sp3 and Sp4, and all three proteins bound to GC-rich elements in the VEGFR1 promoter. These results demonstrate that VEGFR1 is regulated by Sp proteins and that treatment with tolfenamic acid decreases expression of this critical angiogenic factor. Moreover, in vitro studies in Panc-1 cells demonstrate that activation of VEGFR1 by VEGF-B to increase mitogen-activated protein kinase 1/2 phosphorylation and cell migration on collagen-coated plates is also inhibited by tolfenamic acid. Thus, targeted degradation of Sp proteins is a highly effective for inhibiting VEGFR1 and associated angiogenic responses in pancreatic cancer.

619 TGF-B1 SUPPRESSES IL-2 PRODUCTION DURING PRIMING OF NAIVE, BUT NOT DURING RE-CHALLENGE OF PREVIOUSLY ACTIVATED CD4⁺ T CELLS: A ROLE FOR CHROMATIN STRUCTURE.

S. C. McKarns and R. H. Schwartz. *NIH, Bethesda, MD.*

When naive CD4⁺ T cells are activated they secrete interleukin (IL)-2 and proliferate. During a secondary immune challenge, IL-2 production is faster and greater in magnitude. This is a consequence of an increased frequency of responding cells, a lower threshold for their activation, less dependence on accessory co-stimulation, and an increased ability to respond to a wider range of antigen presenting cells. We now demonstrate stable chromatin remodeling of the IL-2 locus during priming and resistance to suppression by TGF-b1 during re-challenge. We also demonstrate that TGF-b1 targets the -300 bp minimal essential regulatory region of the IL-2 promoter and suppresses IL-2 transcription in naive CD4⁺ T cells in a Smad3-dependent manner. This effect is abrogated in effector and memory CD4⁺ T cells. We correlate non-responsiveness to inhibition by TGF-b1 with decreased Smad3 binding to the proximal IL-2 locus, despite the presence of functional Smad3 signaling in previously activated CD4⁺ T cells. The differential response to suppression by TGF-b1 reported here provides a mechanism by which TGF-b1 may function in a T cell intrinsic manner to facilitate anergy induction in self-reactive T cells while concomitantly sustaining a source of IL-2 for active suppression of immune responses by T regulatory cells to control inflammation and maintain peripheral self-tolerance.

620 THE NON-PSYCHOACTIVE CANNABINOID, CANNABIDIOL, SUPPRESSES T CELL FUNCTION THROUGH INHIBITION OF NUCLEAR FACTOR OF ACTIVATED T CELLS (NFAT).

B. L. Kaplan^{1,2} and N. E. Kaminski^{1,2}. ¹Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ²Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Marijuana is derived from the Cannabis Sativa plant. Although there are over 60 cannabinoid compounds in the plant, Δ⁹-tetrahydrocannabinol (THC) is the primary psychoactive congener of marijuana and binds to the two known cannabinoid receptors, CB1 and CB2. THC has exhibited immunosuppressive actions both in vivo and in vitro. Interestingly, another predominant cannabinoid from the plant,

cannabidiol (CBD), possesses low affinity for both cannabinoid receptors, yet also exhibits immunosuppressive actions. A major target of immune suppression by CBD is interleukin-2 (IL-2) as demonstrated in PMA/Io-stimulated mouse splenocytes. The focus of these studies was to determine the mechanism by which CBD suppressed IL-2. Using purified T cells from mouse splenocytes, CBD suppressed PMA/Io-stimulated IL-2 production, similar to the transplant drug cyclosporin A. Consistent with the observation that CBD does not possess high affinity for CB1 or CB2, CBD also suppressed PMA/Io-stimulated IL-2 from purified T cells derived from CB1/CB2 null mice. IL-2 transcription is regulated by several transcription factors, including NFAT, activator protein-1 (AP-1), and nuclear factor κ B (NF- κ B). Using the human Jurkat T cell line, in which CBD suppressed PMA/Io-stimulated IL-2 production, NFAT- and AP-1-luciferase reporter constructs were transiently transfected and induced with PMA/Io in order to examine the effect of CBD on transcriptional activation. CBD suppressed both PMA/Io-induced NFAT- and AP-1-luciferase in a concentration-dependent manner. These results are consistent with the mechanism by which other plant-derived, synthetic and endogenous cannabinoids suppress IL-2 and other functional immune endpoints. (Supported in part by NIH DA007908).

621 INVOLVEMENT OF MITOCHONDRIAL AND DEATH RECEPTOR PATHWAYS IN CHOLESTEROL SECOALDEHYDE-INDUCED APOPTOSIS IN MURINE H9C2 CARDIOMYOCYTES.

K. Sathishkumar¹, K. Ganeshkumar², X. Gao¹ and R. M. Uppu¹.

¹Environmental Toxicology, Southern University and A&M College, Baton Rouge, LA and ²Experimental Obesity laboratory, Pennington Biomedical Research Center, Baton Rouge, LA.

Cholesterol secoaldehyde (3 β -hydroxy-5-oxo-5,6-secocholestan-6-al or ChSeco) is known to occur *in vivo* in humans and is associated with atherosclerosis, Alzheimer's disease and Lewy body dementia. Previous studies from our laboratory have shown that ChSeco induces apoptosis in H9c2 cardiomyocytes. In this study, we investigated the downstream signaling mechanisms that culminate in apoptosis. Quantitative RT-PCR analysis revealed that ChSeco activates mitochondrial (intrinsic) and death receptor (extrinsic) pathways. The mitochondrial pathway was shown to be of rapid onset and it involved disruption of transmembrane potential ($\Delta\psi_m$), generation of reactive oxygen species (ROS), increased Bax/Bcl-2 ratio, and decreased oxygen consumption. The loss of $\Delta\psi_m$ was followed by formation of permeability transition pore (release of cytochrome *c*), activation of caspase 9, and up-regulation of Apaf1. The extrinsic pathway involved up-regulation of Fas and FasL. The significance of this pathway was also evident based on activation of procaspase 8. Thus, it appears that a combined activation of intrinsic and extrinsic pathways resulted in activation of effector caspases 3 and 7 and cleavage of poly(ADP-ribose)polymerase. Inhibitors of caspases 8 and 9 decreased the activity of caspase 3, and the cell death was partially prevented by a pancaspase inhibitor, Z-Val-Ala-Asp-fluoromethyl ketone. Antioxidants such as N-acetyl-L-cysteine and Trolox significantly inhibited the ChSeco-induced cell death. In summary, we conclude that ChSeco induces apoptosis by pathways involving both mitochondria and death receptor. The enhanced ROS production and a 'cross-talk' between the two pathways are thought to play a role in ChSeco-induced apoptosis in H9c2 cardiomyocytes. [Funding support from NIEHS ES 10018 and NIH BRIN program of NCRR (grant number P20 RR6456) to RU is acknowledged. Corresponding author: rao_uppu@subr.edu]

622 DEVELOPMENT OF A LIMITED TRANSCRIPT PANEL FOR THE DETECTION OF STRIATED MUSCLE TOXICITY.

C. E. Thomas, R. A. Jolly, M. K. Huffman and G. H. Searfoss. *Toxicology and Drug Disposition, Lilly Research Labs, A Division of Eli Lilly & Co., Greenfield, IN.*

Striated muscle (skeletal and cardiac) toxicity has been an issue for a number of marketed drugs such as the statins and fibrates, and thus represents a target organ toxicity for which new predictive screening tools would be desirable. Traditional clinical chemistry markers for muscle injury, including creatine kinase (CK) and AST, although useful, have limitations. For example, they can be relatively insensitive owing to limited half life in the circulation, they enter the circulation only after tissue injury and are thus not premonitory, and are nonspecific in terms of their ability to distinguish the muscle fiber type affected. Herein, we describe the identification and development of a limited panel of gene transcripts that correlates well, on a sample by sample basis, with skeletal muscle injury detected using histopathology. Importantly, the selected transcripts can identify muscle injury in muscles of differing fiber types that are mediated by compounds directed against differing biological targets. The transcript panel, comprised of transcripts representing several muscle injury mechanistic domains, increases the likelihood of correctly identifying muscle injury induced by compounds with differing mechanisms of action. We also demonstrate: 1) the predictive potential of the transcript panel by showing significant transcriptional modulation of panel members at muscle toxicant doses where no associated pathology was described and, 2) the potential utility of the transcript

panel in an early *in vitro* compound screening paradigm, using a myotube cell line model. Collectively, the data demonstrate that transcript profiling can be used to study myotoxicity in a rapid, facile manner and with improved biological insight, as compared to current methods.

623 CROSS-SPECIES ASSOCIATION MAPPING IDENTIFIES GENETIC RISK FACTORS FOR LIVER TOXICITY.

A major challenge to defining human sensitivity to pharmaceutical agents is a lack of validated rodent models that reflect the genetic diversity of a population. We hypothesized that a panel of inbred mouse strains can be successfully used to define genetic factors that contribute to differential sensitivity to toxicity. In this work, a bedside-to-bench-to-bedside paradigm was explored using acetaminophen (APAP)-induced liver injury as a model exposure. Recent human studies show that the maximum recommended daily dose of APAP may cause liver injury (Watkins et al, JAMA, 2006). This phenomenon was confirmed in an independent cohort of 60 healthy volunteers who received placebo (n=13) or APAP (1,000 mg every 6 hrs for 7 days; n=47) in a randomized clinical trial. Marked differences in individual sensitivity to liver injury due to APAP, as evidenced by elevations in serum ALT greater than 3-fold from the baseline, were detected in 17% of subjects. To identify genetic susceptibility factors, we utilized a panel of 36 inbred mouse strains. Following an acute dose of APAP (300 mg/kg, i.g., n=4/strain), we observed a large degree of strain-specific sensitivity to liver damage. Whole genome association analysis of sensitivity to APAP-induced liver injury identified significant phenotypic correlation within six genomic intervals. Targeted sequencing of candidate regions revealed that polymorphisms in *Ly86*, *CD44*, *CD59a*, and *Capn8* genes correlate strongly with the degree of liver injury in the mouse. The potential importance of these genes in controlling the severity of APAP-induced liver injury was validated in the human cohort. We demonstrate that by using a genetically diverse panel of inbred mice and genetic association analysis, disease-relevant markers of toxicity can be identified and used to predict risk or identify novel therapies in people. Supported by: U19-ES11391, STAR-RD832720, T32-ES07126, N01-ES-35513, N01-ES-25497, N01-ES-65406.

624 CO-EXPOSURE OF MICE TO TROVAFLOXACIN AND LIPOPOLYSACCHARIDE LEADS TO AN ALTERED INFLAMMATORY RESPONSE IN A MOUSE MODEL OF IDIOSYNCRATIC LIVER INJURY.

P. J. Shaw, P. E. Ganey and R. A. Roth. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

Concurrent inflammation caused by lipopolysaccharide (LPS) renders rats susceptible to hepatotoxicity from several drugs known to cause idiosyncratic adverse drug reactions (IADRs) in humans. Among these is trovafloxacin (TVX), a fluoroquinolone antibiotic. We explored whether this hepatotoxic TVX/LPS interaction occurs in mice and characterized the interaction by measuring inflammatory cytokines in plasma. Treatment with TVX alone up to 200 mg/kg did not increase plasma alanine aminotransferase (ALT) activity, a biomarker of liver injury. When mice were exposed to a nontoxic dose of LPS (2×10^6 EU/kg) 3 hours after TVX, a dose-dependent increase in ALT activity was observed with significant liver injury occurring at 150 mg/kg TVX. Examination of histology corroborated hepatocellular necrosis in the TVX/LPS-treated mice. Levofloxacin, a fluoroquinolone antibiotic that does not cause human IADRs, did not interact with LPS to cause liver injury. A detailed examination of the time-course of injury revealed significant increases in ALT activity by 4.5 and peak activity by 15 hours after LPS treatment in TVX/LPS-treated mice. TVX/LPS-treated mice had an accentuated plasma TNF α peak compared to LPS-treated mice. Increases in IL-10, interferon γ , monocyte chemoattractant protein 1 (MCP-1), and IL-6 were also greater in TVX/LPS-treated mice compared to LPS-treated mice. In summary, TVX/LPS cotreatment caused pronounced hepatotoxicity in mice, and the cytokine profiles in LPS-treated mice were significantly enhanced by TVX cotreatment at times near the onset of liver injury. (Supported by NIH grant DK061315.)

625 ANALYSIS OF HEPATIC AND RENAL MULTIDRUG-RESISTANCE ASSOCIATED PROTEIN EXPRESSION IN TYPE 1 DIABETIC MICE.

J. E. Manautou¹, M. Blake-Kinnin¹, A. Dnyanmote², L. M. Aleksunes¹, S. Barnes¹ and H. M. Mehendale². ¹Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT and ²Department of Toxicology, University of Louisiana at Monroe, Monroe, LA.

Insulin-deficient type 1 diabetic (DB) mice are resistant to hepatic and renal toxicity by acetaminophen and S-1,2-dichlorovinyl-L-cysteine, respectively. This resistance is associated with increased hepatic and renal cellular proliferation. Recent

studies suggest that altered expression of hepatobiliary transporters influences susceptibility of liver to chemical injury. Transporters such as the multidrug resistance-associated proteins (Mrp) are critical for the hepatic and renal elimination of chemicals and metabolites. In this study, we examined the hepatic and renal expression of Mrp1-6 in DB mice and investigated whether treatment with the antimetabolic drug, colchicine (CLC), alters Mrp expression patterns in DB mice. Type 1 diabetes was induced in male Swiss-Webster mice with a single dose of streptozotocin (STZ, 200 mg/kg ip). Of these, one group of mice received 2 mg/kg CLC on day 8 and 1.5 mg/kg on day 10 after STZ or vehicle treatment. Livers and kidneys were collected on day 11 for western blot analysis. Hepatic expression of Mrp1 (2-fold), Mrp3 (3-fold), Mrp4 (3.6-fold) and Mrp5 (2-fold) proteins was higher in DB mice compared to controls. Similarly, DB mice showed increased renal Mrp1 (2.5-fold), Mrp4 (1.8-fold) and Mrp5 (5.5-fold) proteins. No change in Mrp2 or Mrp6 expression was observed in either tissue, while Mrp3 was undetectable in kidneys of any treatment group. Expression of Mrp1, Mrp3 (liver), Mrp4 and Mrp5 in livers and kidneys from DB mice receiving CLC was similar to control non-diabetic mice. Blockade of hepatic and renal cell division prevented over-expression of Mrp proteins in DB mice suggesting an association between cell proliferation and transporter expression. Up-regulation of Mrps along with enhanced cell proliferation in DB livers and kidneys may influence pharmacokinetics of drugs and endogenous compounds as well as susceptibility to chemical toxicity.

626 INDUCTION OF HEPATIC MRP3 AND MRP4 TRANSPORTERS BY ACETAMINOPHEN TREATMENT: ROLE OF THE TRANSCRIPTION FACTOR NRF2.

L. M. Aleksunes¹, A. L. Slitt², J. M. Maher², L. M. Augustine³, M. Goedken¹, J. Y. Chan⁴, N. J. Cherrington², C. D. Klaassen² and J. E. Manautou¹.
¹Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT, ²Department of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS, ³Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ and ⁴Department of Pathology, University of California, Irvine, CA.

Transcription factor nuclear factor E2-related factor 2 (Nrf2) regulates detoxification and antioxidant genes following electrophile exposure and oxidative stress. Mice deficient in Nrf2 exhibit lower expression of detoxification and stress genes along with higher susceptibility to acetaminophen (APAP) hepatotoxicity. Toxic doses of APAP significantly induce the basolateral efflux transporter multidrug resistance-associated proteins 3 and 4 (Mrp3 and 4) in mouse liver. The purpose of this study was to determine if Nrf2 participates in Mrp3 and Mrp4 induction by APAP. APAP (200-400mg/kg i.p.) was administered to wild-type (WT) and Nrf2-null (Nrf2^{-/-}) mice. Hepatic gene and protein expression of Mrp3 and Mrp4, and toxicity (serum ALT activity and histopathology) were assessed 24 and 48 hrs later. As expected, hepatotoxicity was greater in Nrf2^{-/-} compared to WT mice. APAP treatment increased hepatic Mrp3 mRNA (5-fold) and protein (1.3-fold) in WT mice. Constitutive Mrp3 protein expression was reduced in Nrf2^{-/-} mice to 20% of WT controls and was not induced with APAP. Similarly, APAP treatment induced Mrp4 mRNA (3.6-fold) and protein (4.5-fold) in WT mice. Mrp4 induction was significantly less in APAP-treated Nrf2^{-/-} mice. Mrp1 mRNA and protein were increased 2-fold in both genotypes suggesting that transcription and translation are functional in Nrf2^{-/-} livers despite greater toxicity. These results show that Nrf2 activation by APAP regulates Mrp3 and Mrp4 expression. Coordinated expression of detoxification and transporter genes by Nrf2 during APAP hepatotoxicity is a mechanism by which hepatocytes limit intracellular accumulation of potentially toxic chemicals.

627 THE ROLE OF DIFFERENCES IN EXPRESSION OF PPAR α BETWEEN MOUSE STRAINS IN PLEOTROPIC RESPONSE TO PEROXISOME PROLIFERATORS.

C. G. Woods¹, A. M. Burns¹, B. U. Bradford¹, D. W. Threadgill², M. L. Cunningham³ and I. Rusyn¹. ¹Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC, ²Department of Genetics, University of North Carolina, Chapel Hill, NC and ³National Center for Toxicogenomics and National Toxicology Program, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Peroxisome proliferators are non-genotoxic rodent liver carcinogens. Studies in peroxisome proliferator activated receptor (PPAR) α -null mice show that this receptor is required for PP-induced liver tumor formation. Inter-species (rodent to human) variability in liver carcinogenesis response to PPs is thought to be, at least in part, a result of differential expression of PPAR α in liver. Thus, we hypothesized that the magnitude of PP-induced response should correlate with expression of PPAR α in liver. A panel of inbred mouse strains that have widely varying levels of basal PPAR α expression in liver was selected for this study. Mice were fed either control or WY-14,643 containing (0.1% w/w) diets for up to 5 wks. Changes in liver and

body weight, cell proliferation, clinical chemistry and a number of molecular endpoints were assessed. No significant inter-strain differences in WY-induced cell proliferation, or liver-to-body weight ratio were observed. However, we observed marked differences in PP-induced alterations in serum triglycerides, glucose, and creatinine, and time-dependent weight loss which suggests that a wide variation in stimulation of fatty acid and energy metabolism in response to PPs exists between strains. We conclude that despite varying receptor expression and inter-strain differences in responses to PPs, the uniform increase in liver cell proliferation in all strains of mice suggests that differences in PPAR α expression alone are not indicative of the potential long-term effects of these compounds (Supported by ES11391, ES11660).

628 HEPATIC MRP4 INDUCTION FOLLOWING ACETAMINOPHEN EXPOSURE IS DEPENDENT ON KUPFFER CELL FUNCTION.

S. Barnes¹, R. Johnson¹, L. M. Aleksunes¹, L. M. Augustine², N. van Rooijen³, G. L. Scheffer⁴, N. J. Cherrington² and J. E. Manautou¹. ¹Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT, ²Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ, ³Department of Molecular Cell Biology, VU Medical Center, Amsterdam, Netherlands and ⁴Department of Pathology, VU Medical Center, Amsterdam, Netherlands.

Increased expression of efflux transporters has been documented with hepatic damage of varying etiologies. The multidrug resistance-associated protein 4 (Mrp4) is the most significantly up-regulated transporter in mouse liver after toxic administration of acetaminophen (APAP). Mrp4 levels are also increased in human liver following APAP overdose. While expression profiles of transporters following APAP hepatotoxicity are well-characterized, the signaling pathways contributing to these changes remain unknown. We hypothesize that Kupffer cell (KC)-derived mediators participate in the regulation of hepatic transporters. To investigate this, C57BL/6 mice were pretreated with liposomal clodronate (0.1 ml i.v.) to deplete KCs and then challenged with APAP (500mg/kg i.p.). Hepatic Mrp4 protein expression was determined by western blot and immunohistochemistry. At 72 hrs after APAP dosing Mrp4 levels were increased by 33-fold in mice receiving empty liposomes. Immunohistochemistry showed that Mrp4 staining was confined to centrilobular hepatocytes. Depletion of KCs by liposomal clodronate increased susceptibility to APAP hepatotoxicity. Remarkably, KC depletion completely prevented Mrp4 induction by APAP. These findings show that KCs protect the liver from APAP toxicity and that KC mediators released in response to APAP are responsible for Mrp4 induction. Enhanced Mrp4 expression may represent a compensatory response to enhance the elimination of mediators of tissue injury and bile constituents from an injured liver. Alternatively, Mrp4 induction might augment the secretion of signaling molecules for tissue repair from injured hepatocytes.

629 LIPOPOLYSACCHARIDE INDUCED CYTOKINE, CHEMOKINE AND ACUTE-PHASE PROTEIN RESPONSE IN KUPFFER CELL DEPLETED RAT LIVER SLICES.

N. Bhandari, C. DeMaula, D. T. Thudium, W. Shao and J. W. Lawrence. Merck & Co., Inc., West Point, PA.

Kupffer cells play an important role in the hepatotoxicity induction of a number of xenobiotics and are the main cellular mediators of the effects of lipopolysaccharide (LPS) in the liver. To elucidate the role of Kupffer cells in the pathogenesis of liver injury, specific Kupffer cell inactivating or depleting agents such as gadolinium chloride (GdCl₃) or liposome-encapsulated dichloromethylene diphosphonate (Cl₂MDP) have been used. To identify the appropriate treatment and dose that will deplete the Kupffer cells from rat liver, rats were intravenously injected with 10mg/Kg of GdCl₃, or 0.2 mL or 1 mL of Cl₂MDP liposomes. Histological examination of the liver after iv administration of India ink (2mL/Kg) showed that Cl₂MDP liposomes (1 mL) caused the maximum decrease in the number and function of Kupffer cells in liver tissue. To investigate the role of Kupffer cells in LPS-induced cytokine, chemokine and acute-phase protein production in the liver slice model, Sprague-Dawley rats were intravenously treated with either 3mL/Kg phosphate buffered saline (PBS), PBS liposomes or Cl₂MDP liposomes. Precision-cut liver slices were prepared and cultured for 4h or 24h in medium containing 0, 1, 10, and 100 μ g/mL LPS. LDH, NO, various cytokines and chemokines and the acute-phase proteins AGP, A2M, ceruloplasmin, haptoglobin, hemopexin and thio-statin were analyzed in the medium. In control liver slices, LPS treatment caused a dose dependent increase in NO, IL-1 α , IL-1 β , IL-6, IL-10, IFN- γ , TNF- α , CINC-1 and MIP-2 at both 4 and 24 h and caused a dose dependent increase in GM-CSF only at 24 h. The acute phase proteins increased with time in the culture medium and no further increase was observed with the LPS treatment. LPS treatment of Kupffer cell depleted liver slices showed a significantly reduced induction of chemokines and cytokines compared to control liver slices. Thus, depletion of Kupffer cells prior to liver slice preparation may provide a tool to assess the role of inflammatory mediators on xenobiotic toxicity in vitro.

630 TROGLITAZONE-INDUCED HEPATIC NECROSIS IN AN ANIMAL MODEL OF SILENT GENETIC MITOCHONDRIAL ABNORMALITIES.

U. A. Boelsterli^{1,2}, M. M. Ong¹ and C. Latchoumycandane¹. ¹Department Pharmacology, National University of Singapore, Singapore, Singapore and ²Department Pharmacy, NUS, Singapore, Singapore.

Troglitazone, a first-generation thiazolidinedione antidiabetic drug, was withdrawn from the market due to an unacceptable risk of idiosyncratic hepatotoxicity. The underlying mechanisms are unclear; normal healthy rodents tolerate high doses of troglitazone without developing liver injury, but in vitro models suggest a mitochondrial hazard at high concentrations. Therefore, we explored whether genetic mitochondrial abnormalities might sensitize mice to the hepatic adverse effects of troglitazone. We used heterozygous superoxide dismutase 2 (*Sod2*^{+/−}) knockout mice as a model, as these mice develop clinically silent mitochondrial stress. Troglitazone was administered daily for 4 weeks at doses comparable to human exposure (0, 10, or 30 mg/kg/d, ip). We found that troglitazone caused overt liver injury in the high-dose group, manifested by increased serum ALT activity and mid-zonal foci of hepatic necrosis which were congruent with TUNEL-positive cells, in *Sod2*^{+/−}, but not wild-type, mice. Hepatic mitochondria isolated from troglitazone-treated mice exhibited decreased activities of aconitase (by 45%) and complex I (by 46%) and increased (by 58%) protein carbonyls, indicative of enhanced mitochondrial oxidant stress. Furthermore, mitochondrial glutathione levels were increased by troglitazone as a compensatory response. Finally, in cultured hepatocytes isolated from untreated *Sod2*^{+/−} (but not wild-type) mice, troglitazone caused a concentration-dependent increase in superoxide anion production as demonstrated with the mitochondria-targeting fluorescent probe MitoSOX Red. In conclusion, prolonged administration of therapeutic doses of troglitazone can superimpose oxidant stress, potentiate mitochondrial damage, and induce hepatic necrosis in mice with genetically compromised mitochondrial function. These data are consistent with our hypothesis that inherited or acquired mitochondrial abnormalities may be one of the contributing determinants of susceptibility to troglitazone-induced idiosyncratic liver injury.

631 ARSENIC-INDUCED TRANSFORMATION OF HUMAN UROGENITAL PROGENITOR CELLS.

E. Tokar¹, M. Webber² and M. Waalkes¹. ¹LCC, NCI at NIEHS, Research Triangle Park, NC and ²Michigan State University, East Lansing, MI.

Inorganic arsenic is a known human carcinogen and is associated with various cancers of the urogenital system (UGS) including the prostate, urinary bladder, and kidney. Our recent data indicate that transplacental arsenic exposure induces tumors and proliferative lesions throughout the UGS of the progeny mice. This suggests that during fetal exposure arsenic may target an undifferentiated, stem/progenitor cell population to induce malignant transformation. Here, we examined the effects of long-term arsenic exposure on the human progenitor cell line, WPE-stem. The WPE-stem cells were isolated from the immortalized, non-tumorigenic, normal human prostate-derived heterogeneous epithelial cell line, RWPE-1. Both cell lines were continuously exposed to a non-toxic concentration (5 μ M) of arsenic for 18 or more weeks. The WPE-stem cells became transformed after only 18 weeks of exposure, as determined by a 470% increase in MMP-9 activity. In comparison, transformation of the RWPE-1 cells took almost twice as long (30 weeks), and they showed only a 220% increase in MMP-9 activity. Additionally, compared to untreated controls, the transformed WPE-stem cells exhibited significant increases in invasion and colony forming efficiency, both markers of malignant transformation. Transformed RWPE-1 cells were not invasive and did not form colonies. An examination of differentiation markers suggests that arsenic may cause aberrant differentiation as a prelude to malignant transformation. These data suggest that: 1) arsenic may indeed target a stem/progenitor population during transplacental carcinogenesis; 2) arsenic-induced cell transformation appears to occur by altering various differentiation pathways of normal UGS cells; and 3) arsenic transformation of progenitor cells occurs much faster and results in a more aggressive malignant phenotype compared to the transformed "mature" cells. Experiments to determine in vivo tumorigenicity of arsenic-transformed progenitor cells are in progress.

632 THE ROLE OF MEMBRANE TRANSPORTERS IN THE CELLULAR METABOLISM OF ARSENIC.

Z. Drobna¹, A. Hernandez-Zavala², V. Devesa², D. J. Thomas³ and M. Styblo^{1,2}. ¹Nutrition, University of North Carolina, Chapel Hill, NC, ²CEMLB, University of North Carolina, Chapel Hill, NC and ³Experimental Toxicology Division, U.S. EPA, Research Triangle Park, NC.

Arsenic (+3 oxidation state) methyltransferase (AS3MT) catalyzes methylation of inorganic arsenic (iAs) in humans. In this pathway iAs is converted to mono-(MAs) and dimethylated (DMAs) metabolites containing either As(III) or As(V).

Because toxicities and metabolic fates of these metabolites differ, the overall toxicity associated with exposure to iAs depends on the pattern and extent of its conversion to metabolites. In a clonal human urothelial cell line expressing rat AS3MT (UROtsa/F35) iAs(III) is more cytotoxic than in parental UROtsa cells that neither express AS3MT nor methylate iAs. Increased cytotoxicity of iAs(III) in UROtsa/F35 cells has been associated with production and retention of MAs. Here, we examined the roles of membrane transporters, multidrug resistance associated proteins (MRPs), and P-glycoprotein (P-gp), in production and retention of iAs metabolites in UROtsa and UROtsa/F35 cells. Retention and methylation of arsenicals were examined in cells in which MRPs or P-gp were inhibited or in untreated cells after exposure to 1 μ M iAs(III), MAs(III), or DMAs(III) for 2 or 24 h. After 2-h exposure, inhibition of MRP or P-gp significantly increased MAs(III) accumulation in either cell line and slightly increased DMAs production in MAs(III)-treated UROtsa/F35 cells. MRP and P-gp inhibition also increased MAs(III) accumulation in UROtsa cells after 24-h exposure. Neither cellular retention nor methylation rate was affected in UROtsa/F35 cells which converted MAs(III) to DMAs. Retention and methylation rates were unaffected in UROtsa or UROtsa/F35 cells exposed to iAs(III) or DMAs(III) for 2 or 24 h. Hence, MRPs or P-gp may play a key role in efflux of MAs(III), a toxic intermediate in iAs metabolism, in cells with limited capacity to convert MAs(III) to DMAs. (This abstract does not reflect EPA policy.)

633 THE INHIBITORY EFFECTS OF LEAD ON BONE FORMATION ARE MEDIATED BY AN INDUCTION OF SCLEROSTIN IN OSTEOBLASTS.

D. Dao, T. Sheu, R. Ubayawardena and J. Puzas. Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY.

Sclerostin is a newly identified regulatory factor that controls bone formation. It has been shown to be a potent repressor of osteoblast activity and may be responsible for mediating the mechano-transduction signals of osteocytes. Sclerostin is known to be produced by both osteocytes and osteoblasts. A number of laboratories have demonstrated that lead exposure in bone leads to a decrease in osteoblast function and a depression in bone formation. Our recent results indicate that the mechanism for this effect is due to a rapid and large upregulation of sclerostin in osteoblasts. Immunohistochemical evaluation of sclerostin expression was performed in mouse long bones and in fracture callus using a commercially available antibody with good specificity. Gene expression of sclerostin was measured in osteoblasts with RT-PCR. Osteoblasts were treated with lead at concentrations ranging from 16 nM to 20 μ M for periods of 24 hours.

We were able to show sclerostin expression in both osteocytes and osteoblasts in normal long bones as well as fracture callus. As would be predicted where bone formation was required to heal the fracture, sclerostin levels were low. They returned to normal after 15-20 days of healing. Osteoblasts that were exposed to lead dramatically upregulated sclerostin expression (by as much as 8 fold) with statistically significant effects occurring at concentrations of 2-4 micromolar and above. The effects were most pronounced in progenitor osteoblasts. Osteoblasts that were allowed to differentiate in culture or were treated with differentiating were not as sensitive to the effects of lead.

Lead exposure has been proposed as a risk factor for osteoporosis and as an inhibitor in fracture healing. The data in this report show that these effects may be mediated by upregulation of the bone-formation-repressor, sclerostin. Moreover, the effect of lead appears to be more pronounced in the less differentiated osteoblasts, implying that committed bone stem cells may be a key target for this heavy metal toxin.

634 LEAD INDUCES OXIDATIVE STRESS IN ARTICULAR CHONDROCYTES: A MOLECULAR MECHANISM FOR THE GENESIS OF OSTEOARTHRITIS.

J. D. Holz^{2,1}, T. Sheu¹, R. Eliseev¹ and J. Puzas^{1,2}. ¹Department of Orthopaedics, University of Rochester School of Medicine, Rochester, NY and ²Department of Environmental Medicine, University of Rochester School of Medicine, Rochester, NY.

Osteoarthritis (OA) is the single most widely distributed musculoskeletal affliction in humans. As a number of reports in the literature have documented the effect of lead exposure on cartilage degeneration in animals and joint pain in humans, we believe lead may be key risk factor for OA. From the data in this study we hypothesize that the effect of this toxin may be mediated by altering the oxidative stress to articular chondrocytes.

Articular chondrocytes were propagated in culture and exposed to lead (80 nM to 2.0 μ M). Generation of oxidizing free radicals was quantified with the dye, DCFDA. Phenotype changes in the chondrocytes were monitored by measuring the expression of type X collagen, caspase 3 and 8. Free radical production, glutathione peroxidase (GPX), superoxide dismutase (SOD-1) and catalase activity were used to assess the balance of oxidative stress on the cells.

Chondrocytes show a statistically significant increase in the production of reactive oxygen species after exposure to lead. Singlet oxygen and superoxide radicals as well as hydrogen peroxide levels were all increased in a time and dose dependent fashion. This was accompanied by an increase in DCFDA conversion. These effects happened within minutes of lead addition. GPX and catalase were inhibited by lead at low concentrations (0.4 micromolar). The resultant increase in oxidative stress induces a phenotypic change in the articular chondrocytes characterized by large increases in type X collagen and the caspases. Interestingly, prolonged exposure of the chondrocytes to lead (24 hours) induced a six fold increase in SOD-1 expression. We interpret this observation as an attempt by the cells to resist the change in the oxidative milieu.

Articular chondrocytes that are exposed to lead alter their redox environment, tipping the balance toward oxidative stress. This induces specific phenotypic changes characteristic of cartilage breakdown that will progress to OA.

635 PARTICULATE CR(VI)-INDUCED DNA DOUBLE STRAND BREAK MISREPAIR LEADS TO NEOPLASTIC TRANSFORMATION.

H. Xie¹, S. Wise¹ and J. P. Wise^{1,2}. ¹Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and ²Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.

DNA double strand breaks (DSBs) are one of the most dangerous types of DNA damage. Defects in DSB repair can cause the loss or amplification of chromosomal material and tumorigenesis. Hexavalent chromium (Cr(VI)) is a potent respiratory toxicant and carcinogen with widespread human exposure. The most toxic and carcinogenic form of Cr(VI) is the particulate such as lead chromate (LC), which deposits and persists in the respiratory tract after inhalation. LC particles induce DSBs in human lung cells. The hMRE11-RAD50-NBS1 protein complex has emerged as a central player in the human cellular DNA-damage response, and recent observations suggest that these proteins are at least partially responsible for linking DSB damage detection to DSB-repair and cell cycle-checkpoint functions. Using the comet assay, we found that LC induced concentration-dependent increases in DSBs in cultured human lung cells with 0.1, 0.5, 1, and 5 µg/cm² LC inducing 1.5, 2, 4.9 and 10.2 percent increase in tail DNA relative to control, respectively. The repair of LC-induced DSBs occurred within 24 h. This repair required MRE11 as reducing Mre11 expression by siRNA inhibited repair. We confirmed these observations by treating MRE11 deficient skin cells with LC and found that the repair of these lesions was greatly reduced in these cells as well. To link the DSB to carcinogenesis, we developed a model of neoplastic transformation using MRE11 deficient cells. A 5 day exposure to LC induced loss of cell contact inhibition in a concentration-dependent manner with 0, 0.1, 0.5 and 1 µg/cm² lead chromate inducing 1, 78, 44, 103 growth foci in 20 dishes, respectively. The transformed cells developed through a series of sequential steps, including altered cell morphology and anchorage-independent growth. These data indicate that MRE11 protects cells from LC-induced DNA DSBs and neoplastic transformation. This work was supported by NIEHS grant ES10838 (J.P.W.)

636 MANGANESE INDUCES RAPID AND SELECTIVE LYSOSOME TRAFFICKING AND DEGRADATION OF THE GOLGI MEMBRANE PROTEIN GPP130.

M. Braun¹, C. Bachert², D. Crooks¹, A. Linstedt² and D. Smith¹. ¹Environmental Toxicology, University of California, Santa Cruz, CA and ²Biological Sciences, Carnegie Mellon University, Pittsburgh, PA.

We used rat neuronally derived GABAergic (AF5) cell and HeLa cell models to investigate the effect of Mn exposure on intracellular trafficking. Cross-reactivity in an immunoblot analysis of AF5 cells revealed that Mn exposure (100 – 150µM) caused the rapid (within 4 hr) depletion of an initially unknown protein with an apparent MW of ~95kDa. Mass spectroscopy identified this protein as Golgi Phosphoprotein 4 (GPP130). GPP130 is a Golgi-localized integral membrane protein that cycles to endosomes where it may mediate endosome-to-Golgi retrieval of other cycling Golgi proteins (Natarajan and Linstedt, 2004). Mn-induced GPP130 degradation was neither recapitulated by the protein synthesis inhibitor cyclohexamide nor blocked by the proteasome inhibitor PSI suggesting a post-translational and proteasome-independent mechanism. After exposure to Mn, GPP130 underwent a dramatic redistribution from its normal Golgi localization to endosomal and lysosomal structures and then, by 2-4 h, was significantly depleted from all cellular structures. In support of the model that Mn had induced trafficking of GPP130 to lysosomes where GPP130 was then degraded the degradation was blocked by the lysosome hydrolase inhibitor chloroquine. Importantly, the normal localization and abundance of endosome and Golgi markers, including the GPP130-related protein GP73 whose Golgi localization depends on endosome-to-Golgi retrieval, indicated that Mn specifically affected GPP130 and did not generally disrupt membrane trafficking. Thus, cellular toxicity resulting from Mn exposure involves, in part, induced trafficking and degradation of the Golgi protein GPP130.

637 CADMIUM INDUCES STAT3 ACTIVATION BY A MECHANISM DEPENDENT ON NADPH OXIDASE ACTIVITY.

V. Souza, L. Bucio, E. Hernandez, L. Gómez-Quiroz, C. Escobar and C. Gutierrez-Ruiz. *Ciencias de la Salud, Universidad Autónoma Metropolitana, MNE-(c)xico, D.F., Mexico.*

Oxidative stress elicited by Cd is a likely contributor to hepatotoxicity. Cd can activate some oxidative stress-sensitive transcription factors that are responsible for regulating gene expression such as AP-1 or Nrf2, however STAT3 is not fully characterized. The aims of this study were to determine the activation of STAT3 pathway induced by Cd-oxidative stress and to address the participation of STAT3 in Hsp70 production in HepG2 cells. Cells were treated with 5 µM CdCl₂ for 0.25, 0.5, 1, 2, 3, 4 or 5 h. Cadmium induced 4-fold Stat3 activation after 1 h treatment, determined by nuclear protein Western blot. To explore the ROS source for Cd-induced STAT3 activation, inhibitors for different ROS generating systems were used. Only DPI, an inhibitor of NADPH oxidase, decreased STAT3 activation. NADPH oxidase activity, was then determined. Cd induced 3-fold the activity of this enzyme. To confirm if NADPH oxidase-derived ROS were involved in STAT3 activation, SOD-peg and Catalase-peg were added as antioxidants. Treatment with Catalase-peg reduced significantly STAT3 activation. MAPK pathway is activated by oxidative stress. In order to explore if MAPK pathway is involved in STAT3 activation, we pretreated HepG2 cells with 20µM of PD98059 (Erk inhibitor), SB203580 (p38 inhibitor) or SP600125 (JNK inhibitor). Only Erk and JNK inhibitors abrogated Cd-induced STAT3 activation. Finally, in order to figure out some physiologic relevance in Cd-induced STAT3 activation, we explored Hsp70 expression, a Cd-induced protein. Pretreatment with a specific STAT3 peptide inhibitor, abrogated Cd-induced Hsp70 expression. Our data suggest that Cd activates NADPH oxidase activity which induces ROS production leading Erk and JNK activation, these MAPK promote STAT3 phosphorylation that can induce a protective mechanism against Cd toxicity.

CONACYT P 39618-M.

638 GENE EXPRESSION PROFILE IN RESPONSE TO POTASSIUM DICHROMATE-INDUCED TOXICITY IN HUMAN DERMAL FIBROBLASTS.

P. Joseph, C. Umbright and Q. He. *National Institute for Occupational Safety and Health, Morgantown, WV.*

Several adverse health effects including irritant and allergic contact dermatitis have been reported among workers following occupational exposure to chromium containing compounds. To understand the molecular mechanisms responsible for the dermal toxicity of chromium, a differential gene expression profile of human skin fibroblasts exposed to a cytotoxic concentration of hexavalent potassium dichromate [Cr(VI)] was studied. Skin fibroblasts were exposed to 5 micromolar Cr(VI) for time intervals up to 24-hours and a differential gene expression profile was studied using the human Toxicology and Drug Resistance Microarray (Super Array Inc.). Of the 280 genes represented on the array, 32 were found differentially expressed in the fibroblasts exposed to Cr(VI). In general, genes involved in stress response, cell cycle control, drug metabolism, apoptosis and growth were found differentially expressed in the Cr(VI) exposed fibroblasts. The molecular mechanisms responsible for the Cr(VI)-induced differential gene expression were investigated using heme oxygenase 1 (HO-1) as the model gene. HO-1 gene expression was significantly higher in the Cr(VI) exposed cells compared with the control cells. Pre-exposure of dermal fibroblasts to actinomycin D (inhibitor of transcription) and N-acetyl cysteine (scavenger of reactive oxygen species) blocked the Cr(VI)-induced overexpression of the HO-1 gene. Similarly, modulating the intracellular glutathione level by pre-treating cells with either BSO or glutathione significantly influenced the potential of Cr(VI) to induce the expression of the HO-1 gene. Similar results were obtained when experiments were conducted using a luciferase reporter gene expression system containing the HO-1 gene promoter. In conclusion, our results demonstrate that the cellular glutathione level may be an important determining factor in the dermal toxicity induced by hexavalent chromium.

639 DEVELOPMENT OF A BASE SET OF TOXICITY TESTS AS A COMPONENT OF A NANOPARTICLE RISK MANAGEMENT FRAMEWORK.

D. B. Warheit, R. Hoke, C. Finlay, M. Donner, K. L. Reed and C. M. Sayes. *DuPont Haskell Laboratory, Newark, DE.*

The development of a risk management framework for nano or ultrafine particle-types requires a base set of hazard data. Previously, we have suggested "parallel tracks" as a strategy for conducting nanoparticle research. Mechanistic studies on "representative" nanoparticles could be supported by governmental agencies. Alternatively, for commercial nanoparticles, the EHS framework would include a minimum base set of toxicity studies, supported by the companies that are develop-

ing that nano-based product. The minimum base set could include: substantial particle characterization, pulmonary toxicity studies, acute dermal toxicity and sensitization studies, acute oral and ocular toxicity studies, along with screening type genotoxicity, and aquatic studies.

We report here the toxicity results of a base set of tests on a newly developed, well-characterized, ultrafine rutile TiO₂ (uf-TiO₂) particle-type. In vivo pulmonary toxicity studies demonstrated low inflammatory potential and lung tissue toxicity. Acute dermal irritation studies in rabbits and local lymph node assay results in mice indicated that uf-TiO₂ was not a skin irritant or dermal sensitizer. Acute oral toxicity studies demonstrated very low toxicity and uf-TiO₂ produced short-term ocular conjunctival redness in 1 of 3 rabbits. Genotoxicity tests demonstrated that uf-TiO₂ was negative in both the Bacterial Reverse Mutation Test and In Vitro Mammalian Chromosome Aberration Test in Chinese Hamster Ovary Cells. The results of aquatic toxicity screening studies demonstrated that uf-TiO₂ exhibited low concern for aquatic hazard in un aerated, 48-hour, static acute tests using the water flea, *Daphnia magna*; exhibited low concern for aquatic hazard in un aerated, 96-hour, static acute tests using the rainbow trout, *Oncorhynchus mykiss*; and exhibited medium concern in a 72-hour, acute test using the green algae *Pseudokirchneriella subcapitata*.

In the aggregate, most of the tests demonstrated low hazard potential in mammals or aquatic species following acute exposures to ultrafine rutile TiO₂ particles.

640 TOXIC EFFECTS OF NANOCOPPER ON ZEBRAFISH, DANIO RERIO.

J. Griffitt¹, R. Weil¹, N. D. Denslow¹, K. Powers² and D. S. Barber¹. ¹Center for Environmental Health and Toxicology, University of Florida, Gainesville, FL and ²Particle Engineering Research Center, University of Florida, Gainesville, FL.

With increasing utilization of metallic nanomaterials there is the potential for environmental release of these materials. Despite this, little is known about potential adverse effects of these nanomaterials on ecologically important species. Because many of the metals being used as particles are toxic in soluble forms, it is important to determine if nanomaterials elicit responses that differ from soluble metals. To investigate this question, adult female zebrafish were exposed to 50nm copper particles at concentrations up to 1.5 mg/L for 48 hours. When added to water, copper particles aggregated and mean particle volume was 20 microns, although large numbers of smaller particles (less than 1 micron) remained in the water column. Copper nanoparticles were less acutely toxic to adult female zebrafish than copper sulfate (the 48-hr LC50 for nanocopper = 1.5 mg/L, vs. 0.25 mg/L for copper sulfate). The observed lethal effects of particle exposure appear to be primarily mediated by the particles, not dissolution. In tanks treated with 1.5 mg/L copper particles, only 0.1 mg/L of dissolved copper was present at 48 hours, equivalent to a concentration of copper sulfate producing 15% mortality. This conclusion was supported by differences in biochemical and molecular changes following exposure to the two forms of copper. While BUN/ALT levels, gene expression patterns in liver, and liver histopathology showed similar responses to both forms of copper, the observed gene expression responses were markedly different in gill samples, indicating that the particles induced a different transcriptome level response than did copper sulfate. Specifically, HIF-1 and HSP 70 were upregulated 10-fold by nanocopper, but not soluble copper. We therefore conclude that copper nanoparticles exert a toxic effect on zebrafish gill that is not solely due to dissolution of the particles. This work is supported by NSF grant BES-0540920.

641 BI-VALVE MOLLUSKS AS VALUABLE MODELS FOR CHARACTERIZING NANOPARTICLE TOXICITY.

A. H. Ringwood¹, K. Gonsalves², S. Khambhammettu², D. Carroll³ and N. Levi³. ¹Biology, UNC-Charlotte, Charlotte, NC, ²Chemistry, UNC-Charlotte, Charlotte, NC and ³Physics, Wake Forest University, Winston-Salem, NC. Sponsor: R. Di Giulio.

There are numerous potential environmental risks of engineered nanoparticles that are not yet well-characterized or understood. Nanoparticles may be introduced into aquatic environments during production processes and also as a result of release following their use in electronic and biological applications. Filter-feeding bivalve mollusks spend their lives removing particles so they are potentially very valuable as model species for characterizing nanoparticle bioavailability and interactions with basic cellular processes. The purpose of these studies was to characterize the toxicity of various nanoparticle preparations (e.g. quantum dots and fullerenes) using various exposure regimes with whole animal exposure, isolated hepatopancreas cells, and embryos of oysters, *Crassostrea virginica*. Nonfunctionalized QDs composed of a Cd/Se core surrounded by layers of Zn (Evident Technologies) were used to evaluate potential hepatotoxicity using a lysosomal destabilization following whole animal and isolated cell exposures. Significant increases in toxicity were observed, similar to levels observed with cadmium chloride concentrations ranging from 10 to 1000 µg/l. Similar toxicity studies were also conducted using fullerene preparations, solubilized using either toluene or THF. Significant toxicity was observed with both preparations, and the toluene extracts were more toxic than the THF extracts with both hepatopancreas assays and embryo development assays.

Fluorescent confocal microscopy and electron microscopy were used to verify the accumulation of the nanoparticles inside hepatopancreas cells and embryos. These kinds of basic studies are essential for addressing the potential impacts of nanoengineered particles on fundamental cellular processes as well as aquatic organisms.

642 IN VIVO TOXICITY EVALUATIONS OF GOLD NANOPARTICLES: PROACTIVELY DESIGNING SAFER NANOMATERIALS.

S. L. Harper^{1,3,5}, R. L. Tanguay^{1,2,3} and J. E. Hutchison^{4,5}. ¹Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, ²Marine and Freshwater Biomedical Sciences Center, Oregon State University, Corvallis, OR, ³Environmental Health Sciences Center, Oregon State University, Corvallis, OR, ⁴Materials Science Institute, University of Oregon, Eugene, OR and ⁵Safer Nanomaterials and Nanomanufacturing Initiative, Oregon Nanoscience and Microtechnologies Institute, Corvallis, OR.

Gold nanoparticles varying in composition, core size and surface functionalization have been proposed for many applications in nanoscience. It has largely been assumed that gold nanoparticles would be biologically inactive given that both the molecular and bulk forms of gold are benign; however, this assumption has not been formally tested. Embryonic zebrafish were chosen as a dynamic whole animal assay to reveal whether gold nanoparticles perturb developing systems. To investigate the importance of size and shape on the toxic potential of nanomaterials, we chose two core sizes (0.8 and 1.5nm) with one of three surface groups (neutral, positive and negative). Embryonic zebrafish were exposed for five days and were evaluated for mortality, morphological malformations and developmental progression. Core size and surface functionalization both influenced toxicity. Gold nanoparticles functionalized with TMAT caused a significant increase in mortality at 10 parts per million (ppm) for 1.5 nm particles and 400 parts per billion (ppb) for 0.8 nm particles. Embryos exposed to 1.5 nm TMAT functionalized nanoparticles also displayed increased incidences of malformations at 50ppm. Exposure to MES functionalized particles did not result in increased mortality at concentrations up to 250 ppm; however, concentrations of 10 and 50 ppm did result in increased incidences of malformation for 1.5 and 0.8nm particles, respectively. MEE surface functionalization was benign for both size particles. Results obtained from these studies demonstrate that integrating the biological assessment of nanomaterials with their development can be used to direct the rational development of safer, less hazardous nanomaterials.

643 IN VITRO STUDIES OF SINGLE-WALLED CARBON NANOTUBES: A TOXICOGENOMICS APPROACH.

M. Shah, C. Lema and M. Cunningham. Houston Advanced Research Center, The Woodlands, TX.

Engineered nanomaterials are characterized as having at least one dimension of 1 – 100 nm. Early reports show contradicting results as to the toxicity of unmodified single-walled carbon nanotubes (SWNT). Here, an *in vitro* toxicogenomics approach is used to assess the toxicity of these nanomaterials. Human epidermal keratinocytes (HEK) and normal human bronchial epithelial (NHBE) cells were cultured for 24 hours with cytotoxic doses of SWNT, silica (SiO₂) and carbonyl iron (CI). Cells from individual treatments were harvested at each timepoint and snap frozen to -80 °C. Total RNA was isolated from these cell pellets and cRNA probes were synthesized and hybridized against gene expression microarrays. All microarray experiments were done in triplicate. To compare expression profiles from the two cell systems, only the 3,464 common unique genes were considered in this work. Gene expression profiles of significantly expressed genes (2-fold change or greater) from HEK cells were nearly 1 – 2 orders of magnitude greater than that of the NHBE cells. Using hierarchical clustering and principal components analysis, the largest variation in the gene expression values were between the skin and lung cells, regardless of nanomaterial treatment. However, at cytotoxic doses, treatment with CI gave the highest gene activity in the HEK cells while treatment with SiO₂ gave the highest activity in the NHBE cells. HEK cells treated with SWNT showed a 4-fold increase in expression for the genes that encode for human IL-8 and cytokine subfamily B (Cys-X-Cys) agreeing with previous citations of particulate exposure. Potential biomarkers of other annotated and unannotated genes were also found.

644 SIZE AND SURFACE PROPERTIES DETERMINE THE INTERNALIZATION PATHWAY OF NANOPARTICLES BY TYPE II ALVEOLAR EPITHELIAL CELLS.

G. Orr, D. J. Panther, J. L. Newell, T. J. Barbara, J. G. Teeguarden and J. G. Pounds. Chemical, Materials & Biological Divisions, Pacific Northwest National Laboratory, Richland, WA.

Accumulating observations suggest that inhaled nanoparticles (NPs) exert harmful effects on human health to a greater extent than larger particles. The effects have been attributed, in part, to NPs large surface-area-to-mass ratio, leading to increased reactivity and oxidative stress. However, it is not yet clear what role specific

physical and chemical surface properties have in modulating the interaction of NPs with the living cell. Although large agglomerates of NPs are found within cells, it is thought that they are formed as NPs accumulate within specific cellular compartments, or as the result of experimental conditions. The initial interaction of NPs with the cell in vivo must occur at the level of individual or small NP aggregates, if the increase in surface-area plays a role in NP reactivity and toxicity. Little is known, however, about the mechanisms that underlie the internalization process of individual NPs. Here we applied time-lapse single-molecule fluorescence imaging techniques to investigate the properties that govern the initial interactions of individual NPs with cultured type II alveolar epithelial cells (C10). Using amorphous silica particles that were tagged with a small number of fluorescent molecules, we compared 500 nm particles with 100 nm or smaller particles, and naked particles with surface-modified particles. We found that 500 nm and 100 nm particles could enter the cells through completely different pathways, and that their route was dependent on specific surface modifications. Our findings support the idea that the size and surface properties of particles determine their initial interactions with alveolar epithelial cells, and suggest that the differential effects of particles with different sizes might originate from their different internalization pathways. Supported by the U.S. DOE under Contract DE-AC05-76RL01830, and conducted in EMSL, DOE User's Facility.

645 TARGETING NANOMATERIALS TO CELL SURFACE RECEPTORS: IMPLICATIONS FOR DEFINING RELEVANT MODES OF ACTION AND CHRONIC TOXICITY.

T. Weber¹, B. Riley¹, S. Addleman¹, L. Fifield¹, D. Dutta², B. Moudgil² and S. K. Sundaram¹. ¹*Pacific Northwest National Laboratory, Richland, WA and* ²*University of Florida, Gainesville, FL. Sponsor: J. Teeguarden.*

Nanomaterials delivered via intravenous administration are cleared by phagocytes located in the liver and spleen with evidence for persistent retention in hepatic tissues. Here we investigated the uptake of SWCNTs by scavenger receptors in RAW 264.7 macrophage cells and associated effects on the inflammatory response to endotoxin (LPS). LPS (1 ng/ml, 24 hr) increased cyclooxygenase-2 (Cox-2) expression, a key mediator of inflammatory responses, in RAW 264.7 cells. Cotreatment of RAW cells with LPS and SWCNTs solubilized by sonication in normal growth medium resulted in the inhibition of LPS-mediated Cox-2 expression, while sonication in an emulsifying agent (Pluronic F-127) was without effect. Fucoidan blocked the ability of SWCNTs to inhibit LPS-mediated Cox-2 expression, implicating scavenger receptors in this process. Expression of class A and B scavenger receptors in RAW cells was confirmed by Western Blot. Alexa 647-labeled SWCNTs were internalized by RAW cells and observed to colocalize with lysosomes, as determined using a lysotracker green dye. Lysosomal localization of Alexa 647-labeled SWCNTs was dramatically reduced by fucoidan and polyinosinic acid, consistent with a role for scavenger receptors in this process. Albumin was identified as the major serum protein binding to SWCNTs. These observations indicate that SWCNTs bind to scavenger receptors in a manner that is dependent upon interaction with serum components indicating that the method of nanomaterial resuspension can dramatically effect their molecular targeting. We hypothesize that nanomaterials that reach systemic circulation have the potential to form nanomaterial-albumin complexes that will be recognized as damaged albumin by scavenger receptors. This hypothesis has plausible implications for the persistent retention of nanomaterials in scavenger receptor rich tissues and chronic toxicity. This research was supported by U.S. DOE funding (Contract DE-AC05-76RL01830).

646 NANOPARTICLES STIMULATE INTRACELLULAR AND EXTRACELLULAR RADICAL SPECIES.

E. Rushton¹, S. Notter¹, L. Opanashuk¹, G. Oberdörster¹ and J. N. Finkelstein^{1,2,3}. ¹*Environmental Medicine, University of Rochester, Rochester, NY,* ²*Pediatrics, Strong Children's Research Center, University of Rochester, Rochester, NY and* ³*Radiation Oncology, University of Rochester, Rochester, NY.*

Nanomaterials are being identified for a number of applications ranging from cosmetics to circuitry. With the increase in production and use comes an increase for potential human and environmental exposures which when combined with nanoparticle hazard presents a potential increase in risk. However, the mechanism of action is not clearly understood. There has been some research suggesting that nanoparticles are capable of eliciting their damage via oxidative damage. This research addresses the questions concerning how much of the oxidative damage is due to the intrinsic activity of the particle, how much is due to stimulation of in vitro models, and how these effects might be additive or synergistic. Rat derived pulmonary or neuronal cell lines were cultured and exposed to copper, titanium dioxide, and aluminum nanoparticles in the presence of fluorescent dyes to detect reactive oxygen species (ROS). Additionally, cell endocytosis was blocked to determine the importance of uptake in ROS generation. Results from the studies reveal that

nanoparticles are capable of producing both intracellular and extracellular ROS; soluble ions did not elicit the same response as the particle. These particle effects are sustained and can be measured even after free particles were removed. Active uptake of particles produces a greater intracellular response compared to particles that are only able to act at the cell surface. We can conclude that nanoparticles do possess intrinsic radical producing activity; which appears to be supplemented by cellular ROS eventually triggering an antioxidant response. These effects varied with both particle and cell type with neuronal cells exhibiting the greatest response to the most benign particles. Those particles that possess the greatest ROS activity were generally the most cytotoxic to the cells; providing evidence that ROS production may be a mechanism of action by which nanoparticles exert toxicity.

647 APPROACHES TO MANAGE ETHICAL CONFLICTS IN RESEARCH.

J. Maurissen⁵, T. McHugh¹, D. Eaton², M. Ehrlich³, A. Hoberman⁴ and L. Reid⁶. ¹*Groundwater Services, Inc., Houston, TX,* ²*University of Washington, Seattle, WA,* ³*Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA,* ⁴*Charles River Laboratories, Horsham, PA,* ⁵*Dow Chemical Company, Midland, MI and* ⁶*Food and Drug Administration, Washington, DC.*

Researchers have identified funding and non-financial factors as potential sources of conflicts for research conducted in or funded by academia, industry, governmental and non-governmental organizations. For example, different organizations may introduce conflicts by retaining control over publication rights for research findings, or by increasing the probability of renewing grants for those researchers who obtain "positive" results. Disclosure and transparency are important tools for the management of conflicts associated with sources of research funding. Current guidelines on conflict of interest from the National Institutes of Health and others most commonly focus on disclosure requirements for financial conflicts of interest and less frequently cover other tools for management of conflicts, such as control of publication rights or comprehensive documentation of research protocols and results. If adopted, these tools may serve to increase the reliability and credibility of research results. Four speakers with research experience in a broad range of setting will address ethical conflicts and potential management tools. University researchers will discuss management of financial and non-financial conflicts and important considerations for conducting privately-funded research in a university setting. A private sector researcher will discuss potential conflict of interest at contract research laboratories and a government regulator will discuss agency procedures to verify research integrity. The presentations will be followed by an open discussion of methods to manage ethical conflicts in research.

648 BEYOND THE SINGLE POINT: THE USE OF DOSE AND TIME IN GENOMIC DATA FOR MECHANISTIC-BASED RISK ASSESSMENT.

C. Corton² and W. Mattes¹. ¹*The Critical Path Institute, Tucson, AZ and* ²*NHEERL, U.S.-EPA, Research Triangle Park, NC.*

As gene expression profiling becomes more common, a growing number of studies have examined gene expression responses over a wide dose range and/or an extended time course. Such data beg two questions. Can gene expression give insight into the adverse events that occur as a result of chronic and/or lower exposures? Can this data identify environmentally relevant effects and distinguish those not associated with toxicity (e.g., adaptive responses) vs those that are associated with toxicity (i.e., mal-adaptive effects)? The discussants will first describe several exemplar studies where multiple dose and/or time points were collected for genomic analysis, covering agents of environmental concern (furans, estrogen and fungicide conazoles) as well as of pharmaceutical interest (acetaminophen). The roundtable will then address questions posed, in the context of gene expression responses that are both continuous and discontinuous over time and dose, and mechanisms that come into play at different stages of the exposure continuum.

649 DOSE-RELATED CHANGES IN THE TRANSCRIPTOMIC RESPONSE OF CELLS AND TISSUES TO GENOTOXIC STRESS.

B. Gollapudi. *Dow Chemical Company, Midland, MI.*

Exposure of cells and tissues is expected to set into motion a series of events, including gene expression changes, to cope with the stress. A number of variables, such as the dose, sampling time, and cell and tissue source have been shown to influence the transcriptomic response in experimental models. This presentation will discuss data from in vitro and in vivo studies that examines the utility (or lack thereof) of transcriptomic responses as indicators of exposure to genotoxic/carcinogenic materials at environmentally relevant dose levels.

650 GENOMIC ASSESSMENT OF DOSE RESPONSES TO CONAZOLE FUNGICIDES.

S. Hester. *NHEERL, U.S.-EPA, Research Triangle Park, NC.* Sponsor: C. Corton.

Acute responses to chemical exposure that are below a toxic threshold can provide data on genes and pathways involved in the action of a chemical or drug. We will present dose response analysis of an Affymetrix dataset with low, non-tumorigenic and tumorigenic doses for a class of triazole-containing fungicides containing 3 conazoles with varied toxicities. Distinct dose-dependent transcriptional profiles were associated with each chemical and these dose profiles could be correlated with other toxicologic endpoints. Tumorigenic doses were associated with defined transcriptional profiles which could differentiate these conazoles. The analyses will highlight an approach to examine the effects of dose and how to interpret these findings in a biological context.

651 MICROARRAY ANALYSIS OF THERAPEUTIC AND TOXIC DOSES OF ACETAMINOPHEN IN RAT LIVERS.

M. Orr. *CDER, FDA, Silver Spring, MD.*

A global snapshot of the molecular changes induced by either therapeutic or toxic doses of acetaminophen allows one to determine if the gene expression responses are unique between an efficacious or a toxic dose of acetaminophen (APAP). This study provides molecular evidence that the low (0.1g/kg) dose of APAP is not inducing toxicity in rats. In addition, this study provides evidence that more cell cycle regulatory genes were dysregulated at earlier time points (3 and 6 hr) while the majority of the phase II genes were dysregulated at 24 hrs following exposure to the high dose of APAP (2g/kg). Based upon microarray generated gene expression information: Can therapeutic index be determined using toxicogenomic data? Preliminary evidence indicates it is possible at the mechanistic level since gene expression profiles are distinct between non-toxic and toxic doses of APAP. Clearly, we would need to collect more toxicogenomic data from dose-ranging studies for multiple compounds to shed further light on this topic.

652 DOSE AND TIME RESPONSE OF ESTROGEN-INDUCED GENE EXPRESSION CHANGES IN THE DEVELOPING REPRODUCTIVE SYSTEM.

G. Daston. *Procter & Gamble Company, Cincinnati, OH.*

Early development is likely to be the life stage that is most susceptible to endocrine-mediated toxicity, but the functional and structural effects of early exposures tend to be latent. We have used dose-response data to confirm that the transcript profile is robust across dose levels, and to shed light on the controversy about the existence of non-monotonic low-dose effects of estrogens on male reproductive development. Our results, using three model estrogens and a 4-6 orders of magnitude spread of dosages, indicates a monotonic dose-response curve for estrogens, with a clear non-observable transcriptional effect level.

653 GRANTSMANSHIP FORUM: FUNDING OPPORTUNITIES AT NIH.

V. S. Vaidya¹ and E. M. Faustman². ¹*Medicine-Renal, Harvard Medical School, Boston, MA* and ²*Env & Occup Hlth Sciences, Institute for Risk Analysis & Risk Communication, Seattle, WA.*

Extramural funding has always been a backbone of academic research and NIH is the leading federal institute to fund extramural research grants with a first year (FY) 2006 budget of \$ 28,740 million. Although traditionally toxicology researchers have received funding from a wide spectrum of the 20 NIH institutes, the NIEHS and NIGMS have been of particular interest in terms of funding chemical toxicology and environmental health related research projects. Similarly, a number of toxicology researchers are also actively pursuing research related to use of genomics and bioinformatics for mechanistic identification of genes, proteins and molecular pathways to identify mechanisms of toxicity. This makes National Human Genome Research Institute (NHGRI) very attractive for potential grant opportunities.

The objective of this forum is to present funding opportunities to toxicology researchers specifically focused on NIH grant opportunities by NIEHS, NIGMS, and NHGRI and will indicate recent announcements for request of applications, novel research directions, and new funding mechanisms for e.g.: NIH Pathway to Independence (PI) Award (K99/R00), the NIEHS Outstanding New Environmental Scientist (ONES) Award, etc.

This session will be chaired by Dr. Elaine Faustman and co-chaired by Dr. Vishal Vaidya. The session will highlight grant opportunities at NIEHS, NIGMS and NHGRI. Dr. Anne Sassaman is the Director of extramural research and training at NIEHS and will discuss the new funding initiatives by the NIEHS

including a discussion of the recent ONES awards. Dr. Richard Okita is the Program Director at the NIGMS and will highlight the novel funding opportunities from the NIGMS for young and established investigators. Dr. Mark Guyer is the Director of the division of extramural research at NHGRI and is responsible for overseeing the NHGRI extramural program. Dr. Guyer will share the new funding opportunities by NHGRI with an emphasis on scientific activities to advance genomics research in environmental health and medicine.

654 UNDERGRADUATE RESEARCH AS A SPRINGBOARD INTO RESEARCH CAREERS.

J. B. Tarloff. *Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

In recent years, SOT has begun to develop and sponsor educational programs targeted at recruiting undergraduate students who may be interested in pursuing toxicology as a career. We believe that one of the best ways to recruit undergraduate students into graduate education is to expose them to well-designed and productive research programs. Undergraduate research benefits the students involved by fostering the development of problem solving and critical thinking skills. Also, when undergraduate students successfully participate in laboratory discussions or scientific presentations, they develop confidence and raise their self-esteem levels. Undergraduate research programs benefit the laboratories involved, providing a pipeline for capable undergraduate research assistants, mentoring opportunities for graduate students, desirable learning outcomes for accreditation agencies, and ultimately a pool of graduates who are highly qualified for graduate study or employment in research laboratories. Programs and initiatives for undergraduate research in toxicology are scattered throughout the country and information about these opportunities is not readily available. Through this workshop, we will highlight several different programs using undergraduate students in research settings, discussing the key components for successful undergraduate research experiences: (1) a well-designed project that yields unambiguous data, (2) time and patience of the principal investigator, and (3) financial remuneration, particularly for summer experiences. For anyone with access to undergraduate students, whether or not they are currently involved in these types of educational research experiences, this workshop will provide the basics for development of a program that will serve as first steps for qualified undergraduate students interested in research careers.

655 UNDERGRADUATE RESEARCH: OPENING THE DOOR TO A CAREER.

K. E. Stine. *Department of Biology/Toxicology, Ashland University, Ashland, OH.*

The value of integrating research into undergraduate science education has been recognized, and has long been promoted by groups such as the Council on Undergraduate Research, Sigma Xi, and Project Kaleidoscope. Over the past fifteen years, the Department of Biology/Toxicology at Ashland University has undergone a significant transition, moving from considering undergraduate research as a peripheral component of undergraduate education to considering it as a focal point of the department. The results of this change have been widely perceived as beneficial, both for the students and for the department. Over the past five years, more than 60 students within the department have participated in research, most of whom had no prior experience in the laboratory, and little or no idea that a research career was desirable or even possible for them. However, given the opportunity to participate in a research project (designing and carrying out experiments, analyzing data and even presenting findings at national meetings or in publications), many of these students became highly motivated to seek out careers in research. Furthermore, even students not directly involved in a laboratory or field project at Ashland have been influenced by the experience of their peers into also pursuing research careers. This presentation will describe the undergraduate research experience at Ashland University, and how this experience is integrated into the university's undergraduate toxicology, biology, and environmental science programs. The focus will be on the impact of research opportunities on undergraduate students in toxicology, including influence on career choice, graduate school acceptance, and job searches. The benefits to faculty of involving undergraduates in their toxicology research will also be discussed, as well as the practical considerations that are necessary in setting up an appropriate niche for undergraduates in a research program. Finally, options for funding undergraduate research in toxicology will be addressed.

656 TURNING STUDENTS INTO SCIENTISTS: SUMMER RESEARCH EXPERIENCES AT THE UNIVERSITY OF THE SCIENCES IN PHILADELPHIA.

J. B. Tarloff. *Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

The Academic Research Enhancement Award (AREA grant, R15) is designed to stimulate investigator-initiated research at colleges and universities that lack significant NIH funding. In addition, the awards are intended to stimulate participation

by both undergraduate and graduate students in research projects. We have supported undergraduate students in research programs funded through the AREA mechanism for the past three summers. The experiences have been invaluable for both students and mentors. Previously, student participated in research during the academic year. Time constraints for students and faculty members significantly impacted the quantity and quality of the research. The AREA program allows concentrated effort for students at a time when faculty members are unencumbered by teaching and service requirements. As part of their curriculum, undergraduate students at USP do simple laboratory experiments and learn basic calculations. Summer research helps bring these experiences in to perspective and reinforces students' skills. Participation of undergraduate students in research projects also gives graduate students opportunities to serve as mentors and advisors. We have found several key points that are critical in designing a meaningful summer research experience for undergraduate students. Intensive participation in the training process by the faculty member is important, as is helping the students understand the hypothesis underlying the specific research project on which the student is working. Laboratory meetings help all the participants see how the separate pieces fit into a whole picture. As undergraduate students gain confidence in their research and problem-solving skills, they develop positive attitudes toward their entire educational experience. Students who complete summer research experiences are extremely successful in securing graduate school admission or full-time research employment following graduation.

i 657 UNDERGRADUATE RESEARCH PROGRAMS AT THE CIIT CENTERS FOR HEALTH RESEARCH (CIIT).

D. C. Dorman. *CIIT Centers for Health Research, Research Triangle Park, NC.*

In 1989, CIIT developed a Summer Intern Program to complement its already broad-based post-doctoral and pre-doctoral training missions. CIIT's cooperative education program was subsequently developed to give undergraduate students the opportunity to integrate their academic studies with related job experience at CIIT. These programs are designed to acquaint promising undergraduates with biomedical research in one of CIIT's research focus areas (respiratory biology, inhalation toxicology, endocrine biology, reproductive toxicology, molecular biology, computational biology, and risk assessment). Students are exposed to many aspects of modern research including literature review, hypothesis formulation, conduct of laboratory experiments, data analysis and interpretation. Professional students (e.g., students enrolled in veterinary medicine) have also participated in the training program. Program participants are supervised by CIIT staff scientist, postdoctoral fellow, or senior staff member. All students also receive orientation in the use of animals in biomedical research as well as health and safety and quality assurance and control training. At the conclusion of the summer, Interns generally present their findings at a seminar attended by CIIT scientists and staff. Research conducted by CIIT undergraduate researchers is critical to the overall research mission of the Institute and often forms the basis of many presentations at national scientific meetings and ultimately publications. Participating students often go on to complete advanced training upon completion of their undergraduate degree. A locally competitive hourly salary is provided to all program participants. Funding for this program is primarily provided through the prospective mentors research grants or contracts. Advertisement of these positions occurs through the institute's website (www.ciit.org) and several internship guides (e.g., Peterson's Guide to Internships). The application deadline is March 1st of the year prior to the summer program and on-line application through CIIT's website is strongly encouraged.

i 658 STUDENT INTERNSHIPS: AN IMPORTANT ELEMENT IN SCIENTIFIC DEVELOPMENT.

M. D. Aleo. *Drug Safety R&D, Pfizer Global R&D, Groton, CT.*

Undergraduate internships in academia and industry can be difficult to obtain, but are extremely beneficial to students, faculty sponsors, and academic/industrial sponsors. Laboratory-based experiences in the undergraduate environment are typically confined to cookbook experiments using basic laboratory procedures, instruments and concepts that are designed to produce a successful outcome within a short period of time. Internships, like independent research experiences, challenge students to learn and be successful, even through failure, in the real world of scientific research. Students are exposed to scientific projects, concepts, techniques, and equipment that expands their experience base. This presentation will focus on the following core elements of helping students obtain internships in an academic research or corporate toxicology setting: understanding the three major types of internship experiences, finding internship opportunities, the application process (timing, application and interview), along with general information regarding eligibility requirements for employment, stipends, housing and travel expenses. The

benefits of internship opportunities will be discussed from the perspective of the student, sponsoring faculty member and academic/industrial sponsor. Information regarding internship opportunities directly targeting minority applicants will also be presented.

659 NOVEL COMPUTATIONAL STRATEGIES FOR REDUCING CHEMICAL RESIDUES IN FOOD OF ANIMAL ORIGIN.

R. E. Baynes¹, J. E. Riviere¹ and A. L. Craigmill². ¹PHP, North Carolina State University, Raleigh, NC and ²Environmental Toxicology, University of California, Davis, CA.

Animal-derived foods can be contaminated with drugs or toxicants at some stage prior to slaughter. One strategy to prevent the entry of contaminated food products from entering the food chain is to allow the clearance of these harmful chemicals from the animal's body to safe levels prior to slaughter. These safe levels refer to concentrations of chemical in the food item that will not cause adverse effects in humans.

Regulatory methods require utilization of classical pharmacokinetic and statistical analyses of drug residue data from target tissues. When the drug concentration has reached the safe level, this is deemed the withdrawal time. If the withdrawal time is adhered to, residue levels in the food item should be safe for human consumption. These computational methods are however limited to the use of approved drugs in approved livestock species at the approved dose, and approved route of administration. Departure from any of these approved conditions will very likely result in violative drug residues. The farmer or veterinarian may be forced to use the drug in an unapproved manner to adequately treat the animal. Animals are also accidentally exposed to environmental contaminants as evidenced by the accidental PBB contamination of livestock feed in Michigan in 1974. This is believed to have resulted in adverse health effects in humans who had consumed dairy or meat products from similarly exposed livestock animals.

The purpose of this workshop is to not only review these cases and the regulatory framework, but to share with participants past, current, and future computational strategies that will significantly limit the presence of harmful chemical residues in meat and dairy products. This workshop will focus computational methods that are based on sound pharmacokinetic and human health risk assessment principles. These approaches also closely examine pharmacokinetics of the drugs/toxicant in livestock within a deterministic and probabilistic context, while limiting exposure to the most sensitive human population.

660 FLUORIDATION: SCIENCE MEETS POLICY: AN HISTORICAL PERSPECTIVE.

S. G. Gilbert¹, D. R. Taves² and J. Doull³. ¹INND, Seattle, WA, ²Self, Redmond, WA and ³Department of Pharmacology Toxicology & Therapeutic, University of Kansas Medical Center, Kansas City, KS.

Fluoridation of drinking water is a controversial topic that highlights the intersection of science and policy in a struggle to balance the benefits and hazards of fluoride exposure. Historically, water fluoridation demonstrates that these controversies can be so intense that it is difficult to get impartial scientific debate on the issues involved. In 2002 the National Academy of Science (NAS) was asked to assess the adequacy of current EPA maximum contaminant level goals (MCLG) of 4 ppm to protect children and adults from adverse effects of fluoride exposure. The March 2006 Report of NAS Committee about fluoride is historic for two reasons. It included scientists who are opposed to fluoridation of the water supplies and it was unanimous in concluding that the EPA maximum contaminant level goal (MCLG) of 4-ppm fluoride is too high. This re-evaluation did not address the issue of benefit or risk of fluoridation.

The history of fluoride is rich and fascinating. It started with dental fluorosis studies that led to the idea of adding fluoride to the drinking water to decrease caries just prior to WWII. Fluoride, toxic and highly reactive, was critical in manufacturing uranium and plutonium for the first atomic weapons during WWII. Early research on the hazards and possible benefits of fluoride exposure was started at the University of Rochester in the 1930s by Harold Hodge, a founder and first president of the Society of Toxicology. It was during this period that the Public Health Service (and later the CDC) switched from a role of requiring a demonstration of safety to one of promoting fluoridation of drinking water. The story of fluoridation demonstrates the complexity of the interaction of science and government policy. This symposium will place the current controversy surrounding fluoride in an historical context and examine critical issues in science and policy making in order to develop a better scientific basis for re-assessing the risks and benefits of fluoridation.

i 661 NEW FRONTIERS IN ENVIRONMENTAL SCIENCES AND HUMAN HEALTH: IMPLEMENTATION UPDATE ON THE NIEHS STRATEGIC PLAN.

D. A. Schwartz, S. A. Newton, W. J. Martin, J. R. Bucher and A. Sassaman. *NIEHS/NIH, Research Triangle Park, NC.*

The NIEHS has begun work to implement its new Strategic Plan, "New Frontiers in Environmental Sciences and Human Health." With the Plan, the NIEHS is changing the way it approaches research, increasing the integration of clinical sciences into environmental health and the translation of basic and clinical research in environmental health into disease prevention strategies, therapeutics, and public health practice. NIEHS is emphasizing a dual approach balancing the work of interdisciplinary teams of scientists along with the very best individual investigator-initiated research. The vision of the NIEHS, supported by the Plan's goals, is to prevent disease and improve human health by focusing our research efforts on using environmental sciences to understand human biology and human disease. The Plan identifies seven major goals for the NIEHS: promoting clinical research in environmental health; using environmental sciences to understand human biology; fostering integrative approaches; promoting community-linked research, both domestically and globally; developing new approaches for studying the biology and measurement of exposure; creating new models for training the next generation of environmental health scientists; and fostering more widespread and effective partnerships to improve both the quality of the Institute's research and its ultimate public health impact. In this informational session, NIEHS and NTP leadership will discuss the Plan, describe recent accomplishments, present new program initiatives to advance the Plan's goals, and invite discussion from participants.

i 662 AIR POLLUTION AND ATHEROSCLEROSIS: IMPACT ON VASCULAR OXIDATIVE STRESS, DYSLIPIDEMIA, AND REMODELING.

M. J. Campen¹ and L. Chen². ¹*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM* and ²*Environmental Medicine, New York University, Tuxedo Park, NY.*

Cardiovascular disease remains a major health concern in the Western World, representing greater than 25% of all-cause mortality. Atherosclerosis, an inflammatory disease of the vasculature that causes or complicates many forms of cardiovascular disease, is greatly influenced by genetics and lifestyle, but environmental factors such as air pollution may cause or promote ongoing disease. Recent animal studies have begun to shed light on epidemiological findings of air pollution-related morbidity and mortality due to ischemic heart disease. Atherosclerosis is a complex disease, characterized by dyslipidemia, oxidative stress, inflammation, and vascular remodeling. Dysregulation of vascular cells can lead to remodeling and the development of vascular lesions or plaques that can obstruct flow in vital organs and erode or rupture to reveal procoagulant factors and induce intravascular clotting. This symposium will explore mechanisms by which air pollutants, mainly particulate matter, can contribute to the vascular lesion progression via each of these various facets of atherogenesis. Studies presented will explore both biological pathways as well as components of air pollution that drive the vascular pathology. A more thorough understanding of the interactions between inhaled toxins and systemic vascular dysfunction may help identify susceptible individuals, highlight potential therapeutic targets, and determine contributing components of the complex pollutant mixture.

i 663 COMPARATIVE PROGRESSION OF ATHEROSCLEROSIS IN APOE^{-/-} MICE EXPOSED TO ETS AND CAPS.

L. Chen¹, Q. Sun^{2,4} and S. Rajagopalan^{2,3}. ¹*Environmental Medicine, NYU School of Medicine, Tuxedo, NY.* ²*Zena and Michael A. Wiener Cardiovascular Institute, Mt Sinai School of Medicine, New York, NY.* ³*Medicine, Ohio State University, Columbus, OH* and ⁴*Environmental Health, Ohio State University, Columbus, OH.*

There are many similarities in the nature and extent of the risks that have been associated with the inhalation of environmental tobacco smoke (ETS) and ambient air fine particulate matter (PM_{2.5}). Population-based risk estimates for chronic exposures are significantly elevated for both of these complex mixtures for lung growth in children, and for cardiovascular disease and lung cancer in adults. For both complex mixtures, the effects seen in population studies have been questioned on the basis of the paucity of toxicological evidence establishing biological plausibility at the relatively low levels of ETS and PM at which humans have been exposed. In this study, we exposed ApoE knockout mice susceptible to atherosclerosis development to ETS at a nominal concentration of 500 ug/m³ for 6 hr/day, 5 day/wk, for 6 months. Atheroma progression and plaque characteristics (lesion cellularity, lipid core formation, and extent of macrophage and T-cell infiltration) were

evaluated using non-invasive ultrasound biomicroscopy (UBM) and immunohistopathology and morphometric analysis. The results were compared to our previous subchronic CAPs inhalation study to evaluate whether ETS and CAPs caused comparable levels of alterations in atherogenesis.

i 664 CARBON NANOTUBE RESPIRATORY EXPOSURE AND RISK FROM SYSTEMIC EFFECTS.

P. P. Simeonova, Z. Li and A. Erdely. *TMBB, HELD, NIOSH, CDC, Morgantown, WV.*

The most attractive features of nanomaterials including their small size, large surface area, and reactivity might also be the main factors for their toxicity. In this regard, nanoparticles may induce not only higher damage at the penetration site but also can lead to unexpected distant responses as a result of their translocation and reactivity through the body. Our research efforts are currently directed to evaluate the cardiovascular effects, including vascular inflammation, blood cell coagulation status, atherosclerosis, as well as the related molecular mechanisms associated with respiratory exposure to different forms of carbon nanotubes (CNT) using animal models. We demonstrated that pulmonary exposure to multiple doses of single wall-CNT induces severe lung toxicity and accelerates the progression of atherosclerosis in ApoE^{-/-} mice. This response is accompanied by oxidative modification in the vascular wall and induction of markers which facilitate blood coagulation. The atherogenic effects might be a result of a systemic effects related to the lung toxicity and/or translocation of nanotubes into the systemic circulation. The accumulation of toxicological data on engineered nanomaterials will allow for development of adequate risk assessment and regulations.

i 665 IN VIVO ENDOTHELIAL RESPONSE OF TIE2-GFP/APOE DEFICIENT MICE TO WHOLE DIESEL EXHAUST.

J. Maresh¹, M. J. Campen², M. D. Reed² and R. V. Shohet¹. ¹*John A. Burns School of Medicine, University of Hawaii, Honolulu, HI* and ²*Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Air pollution accelerates atherogenesis and cardiovascular disease. We examined the effect of diesel exhaust on endothelial gene expression in vivo, utilizing hypercholesteremic transgenic mice. Tie2-GFP mice expressing green fluorescent protein regulated by the endothelial-specific promoter Tie2 were crossed with apolipoprotein E knockout mice to generate Tie2-GFP/ApoE null mice. Tie2-GFP and Tie2-GFP/ApoE mice were exposed to diesel exhaust for 6 hours/day for 3 or 30 days at measured levels of diesel engine particulates from a Yanmar engine (0.3 and 1.0 mg/m³). Within 24 hours of exposure, aortae (pooled from 4 animals) were dissected from the valve to the iliac bifurcation and rapidly processed by proteolytic dissociation followed by fluorescence activated cell sorting to yield > 50,000 cells of > 95% purity. Changes in abundance of endothelial transcripts were then examined comprehensively by microarray techniques. RNA representing > 10,000 cells was subjected to amplification by the Ovation system (Nugen, CA), prior to labeling and hybridization to arrays created from the Operon V3 long oligo set. Following each exposure level, several genes detected by microarray and confirmed by real-time PCR were consistently dysregulated by > 2-fold. After 3 days of exposure at 1.0 mg/m³, increased expression of aryl sulfotransferase 1a and epoxide hydrolase 1 may reflect in vivo response to conditions of oxidative stress, and increased abundance of metal response element transcription factor-2 likely reflects the delivery of particulate-derived metals into the circulation. After 30 days of exposure at either 0.3 or 1.0 mg/m³, dysregulation of gene expression of type 2 angiotensin II receptor, sulfotransferase-related protein 3, and beta-carotene-9',10'-dioxygenase was potentiated in the ApoE deficient mice. The gene regulation identified in these experiments implicates pathways important in enhancement of atherosclerosis by diesel exhaust.

i 666 ENVIRONMENTAL OXIDANT EXPOSURE CAUSES MITOCHONDRIAL DAMAGE ASSOCIATED WITH INCREASED ATHEROGENESIS.

S. W. Ballinger. *Pathology, University Alabama at Birmingham, Birmingham, AL.* Sponsor: M. Campen.

The etiology of atherosclerosis is understood as an inflammatory process of the artery wall involving oxidative stress exacerbated by metabolic defects in cholesterol or glucose metabolism. Stress factors such as diet, diabetes and smoking are well recognized as environmental or metabolic factors that play roles in atherogenesis. More recently, it has become clear that environmental oxidant exposure increases the risk for cardiovascular disease development. One potential mechanism by which environmental oxidant exposure acts to increase cardiovascular disease risk is

by increasing damage to cellular organelles. Mitochondria are important cellular organelles with critical functions related to energy production, programmed cell death, growth, and redox signaling. In this regard, our laboratory has studied the impact of two forms of environmental oxidant exposure (cigarette smoke and ozone) on atherogenesis, mitochondrial damage and function. These studies reveal that neonatal and childhood exposure to cigarette smoke significantly increases the level of adult mitochondrial damage and furthermore, decreases vascular endothelial function in exposed animals (mice and primates). Additionally, our studies have shown that decreased mitochondrial antioxidant capacity increases the impact of environmental oxidant exposure (cigarette smoke) on atherogenesis. Finally, studies investigating the impact of ozone exposure on the cardiovascular have shown that both acute and chronic ozone exposure induces significant mitochondrial DNA damage, and significantly increases atherogenesis. Consequently, these studies support the hypothesis that environmental oxidants increase cardiovascular disease risk by causing mitochondrial damage that manifests in "mitochondrial dysregulation". Mitochondrial dysregulation will ultimately impair vascular cell function via energetic and cell signaling mechanisms. Current and future studies investigating the impact of environmental oxidant exposure on "mitochondrial dysregulation" are underway.

667 EXPOSURE TO WHOLE GASOLINE ENGINE EMISSIONS RESULTS IN ALTERATIONS OF MOLECULAR PATHWAYS INVOLVED IN PROGRESSION OF ATHEROSCLEROSIS.

A. K. Lund, T. Knuckles, J. Seagrave, C. Obot Akata, J. McDonald and M. J. Campen. *Department of Toxicology, Lovelace Respiratory Research Institute, Albuquerque, NM.*

Cardiovascular disease is currently the leading cause of death in the US, with atherosclerosis being responsible for approximately half of all CVD-related deaths. Epidemiological studies have reported an association between environmental air pollution and increased rates of cardiovascular morbidity and mortality. Remodeling of arterial extracellular matrix is a crucial step in the progression of atherosclerosis; therefore we investigated markers of vascular remodeling and inflammation in a model of atherosclerosis-prone ApoE^{-/-} mice, exposed to gasoline exhaust emissions. The aortic biomarkers examined included members of the matrix metalloproteinase (MMP) family and endogenous inhibitors of MMPs, TIMPs. Additionally, reactive oxygen species (ROS) and vascular peptides, endothelin-1 (ET-1) and heme-oxygenase (HO-1), levels were assessed. 10-wk old male ApoE^{-/-} mice (n=8 per conc.), on a high fat diet, were exposed via inhalation for 6 h/d, 7 d/wk, for a period of 1, 3, 7 days (acute: only control and 50 µg PM/m³ exposures) or 7 wks (chronic), to either filtered air, 8, 40, or 60 µg PM/m³, or a particle-filtered exposure (matched by NO_x and CO levels of 60 µg PM/m³). Exposure to gasoline emissions resulted in an increase in aorta MMP-2 and -9 mRNA by d7 in acute studies; chronic studies showed an exposure-related increase in aortic expression of MMP-3, -7, and -9. Aortic TIMP2 mRNA expression was significantly elevated by d1 of exposure, with dose-related increases in chronic exposures. Aorta ET-1 mRNA was significantly elevated by exposure d3, with further increases observed in chronic exposures; whereas HO-1 mRNA was found elevated in all chronic exposure levels. TBARs and nitrotyrosine histochemistry of exposed aortas were indicative of a chronic oxidative stress. Such findings suggest that exposure to gasoline emissions can alter molecular pathways involved in vascular remodeling, inflammation, and the progression of atherosclerosis.

668 EFFECTS OF ACROLEIN EXPOSURE ON ATHEROSCLEROSIS IN MICE: ROLE OF DYSLIPIDEMIA.

D. J. Conklin, S. Srivastava and A. Bhatnagar. *Institute of Molecular Cardiology, University of Louisville, Louisville, KY.*

Environmental pollutant exposure represents an important but understudied cardiovascular disease risk factor. Acrolein is a highly reactive and ubiquitous aldehyde pollutant present in industrial and automobile exhaust, environmental tobacco smoke, drinking water, and several foods. Thus, we asked if acrolein exposure modifies or contributes to classical cardiovascular disease risk factors. Using C57Bl/6 and apoE^{-/-} male mice (8-14 weeks old) as models of normal and at-risk human populations, we determined whether acrolein exposure affects plasma lipids and lipoproteins. Acrolein exposure within the range of expected human exposure (0.1-5 mg/kg; oral dose) in C57Bl/6 mice induced significant dose- and time-dependent changes in plasma lipids (cholesterol: mg/dl, control = 64.4±2.1; treated = 115.3±9.0, n=10,9, respectively; phospholipids: mg/dl, control = 132.5±5.9; treated = 230.7±30.4, n=10,7, respectively; and triglycerides: mg/dl, control = 67.5±6.3; treated = 382.1±114.3, n=10,9, respectively). These changes were positively correlated with the degree of alteration in lipoprotein electrophoretic mobil-

ity on Agarose gels. Additionally, chronic exposure of apoE^{-/-} mice fed high-fat diet to acrolein (0.1-2 mg/kg; 7-8 weeks) also elevated plasma cholesterol and enhanced atherosclerosis lesion area in thoracic aorta. These results suggest that acute and chronic acrolein exposures promote dyslipidemia and exacerbate atherogenesis, possibly due to direct lipoprotein modification. Acrolein exposures are likely to contribute to the increased cardiovascular disease risk associated with exposure to environmental pollutants.

669 INTRODUCTION.

N. I. Kerkvliet² and S. B. Pruett¹. ¹*Cellular Biology & Anatomy, LSU Health Sciences Center, Shreveport, LA and* ²*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR.*

As immunology advances, immunotoxicologists often find that new concepts or methodologies are invaluable in identification and characterization of mechanisms of immunotoxicity. Results presented here provide examples of recent investigations that illustrate this principle. The identification of T regulatory cells and the identification of toll-like receptors and their signaling pathways are new findings in basic immunology that have been exploited to better understand mechanisms of action of immunotoxicants that have been the subject of investigation for many years. The role of T regulatory cells is further considered (along with the role of co-receptors on antigen presenting cells) in xenobiotic-mediated modification of the types of immune response (Type 1 vs. Type 2) induced by a particular antigen. Finally, a completely new concept involving the role of physical interactions between intracellular kinases and ribosomes will be discussed as a mechanism of action for immunotoxic biological toxins on macrophages. These presentations all involve the use of new immunological concepts in understanding the mechanisms of action of immunotoxicants. The results also serve to illustrate that immunotoxicology studies complement basic immunology studies by determining the practical relevance of new basic mechanisms of immunology or new methodologies.

670 TOLL-LIKE RECEPTOR SIGNALING AS A TARGET OF DISPARATE IMMUNOTOXICANTS.

S. B. Pruett. *Cellular Biology & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Toll-like receptors (TLR) have been characterized within the last 8 years as major receptors for recognition of "danger" signals in the form of pathogen associated molecular patterns (PAMPs). They play critical roles in innate immunity, in the guidance of acquired immunity toward Th1 or Th2 (by dendritic cells), in hematopoietic responses associated with infection, and possibly in some harmful manifestations of inflammation such as cardiovascular disease. However, they have only recently begun to be evaluated as potential targets for immunotoxicants. Two compounds with disparate structural and functional characteristics produce similar alterations in cytokine production mediated through TLR3 and TLR4. The effects of ethanol and sodium methylthiocarbamate on cellular signaling events leading to cytokine production and on downstream events in innate immunity illustrate that differing alterations in signaling can yield similar outcomes. These results suggest a need for a comprehensive, systems biology approach to fully explain and predict the effects of altered signaling on downstream outcomes.

671 INDUCTION OF T REGULATORY CELLS AS A MECHANISM OF AHR-MEDIATED IMMUNOSUPPRESSION.

N. I. Kerkvliet, C. J. Funatake and N. B. Marshall. *Env. Molec. Toxicology, Oregon State University, Corvallis, OR.*

TCDD, acting through the Ah receptor, is one of the most potent immunosuppressive chemicals known. However, despite extensive research, the immunological mechanisms underlying the immunosuppression have remained elusive. Recent studies have shown that AhR activation in T lymphocytes induces their differentiation to a regulatory (Treg) cell phenotype, providing a new perspective on the mechanism of AhR-mediated immune suppression. Current data suggest that AhR activation in T cells enhances some known pathways for Treg generation/function (TGFB, IL-10 and IL-2) as well as unique changes not previously described in Treg populations. Since Treg are involved in the control of autoimmune diseases, transplantation tolerance, and anti-tumor immunity, and also inhibit both Th1 and Th2 dependent immune responses, elucidation of the signaling pathways that are activated by the AhR in Treg holds the promise of pharmacologic exploitation of this novel immunosuppressive pathway for clinical use.

**672 MODIFIED IMMUNE RESPONSES THROUGH EFFECTS ON CO-STIMULATION.**

R. Pieters, S. Nierkens, F. van Wijk and C. de Haar. *Institute for Risk Assessment Sciences, Immunotoxicology, and Immunology Division, Utrecht University, Utrecht, Netherlands.*

Cell-bound costimulatory molecules are crucial in naive T cell activation, in particular CD40, CD80 and CD86 on the antigen-presenting cell (APC) side, and CD40L, CD28 and CTLA-4 on the T cell side of the immunological synapse. Importantly, CD28 is a stimulatory molecule, whereas CTLA-4 is regulatory and also constitutively expressed on regulatory T cells. Recently, the role of these costimulatory molecules became the focus of immunotoxicological research, particularly because these molecules may not only have a role in stimulation of immune responses to xenobiotics but also in immune regulation. Food allergy responses, airway responses to particulate matter, as well as local lymph node responses (LLNA and PLNA) all appear to be controlled by costimulatory molecules. Simultaneous blockade (using monoclonal antibodies) of CD80 and CD86 or CD40-CD40L interaction was most effective in inhibition of these responses, whereas CD80 by itself and CTLA-4 (with high binding affinity to CD80) had clear regulatory effects. In particular, blockade of CTLA-4 led to enhanced IgE response, suggesting a potential role of regulatory T cells in dampening immune responses induced by xenobiotics. Expression of costimulation may eventually provide early parameters for hazard assessment. However, knowledge of the role of costimulation and the cells involved (such as regulatory T cells) may also be included in methods to prevent adverse immune reactions.

**673 RIBOSOME-MEDIATED STRESS RESPONSE TO BIOLOGICAL TOXINS IN THE MACROPHAGE.**

J. J. Pestka, H. B. Bae and M. Li. *Microbiology and Molecular Genetics, Food Science and Human Nutrition, Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Major advances in understanding how the immune system is regulated have been derived from increased understanding of intracellular signaling pathways within distinct leukocyte populations. These signaling cascades are directed by protein kinases and impact proteome expression by modulating transcription, mRNA stability and transcript selection for translation. Macrophages are known to play a critical role in innate immune function and regulation of the acquired immune response. Aberrant activation or apoptosis of macrophages can contribute to chronic inflammatory disease and immune suppression, respectively. Biological toxins which interfere with protein synthesis including the trichothecene mycotoxins (Fusarium, Stachybotrys), Shiga toxins (E. coli, Shigella) and ricin (castor bean) have been demonstrated to induce proinflammatory cytokine and chemokine expression as well as apoptosis in cultured macrophages and rodent models. Using molecular and bioinformatic strategies developed for studying intracellular signaling cascades, it has been learned that, in the macrophage, the ribosome functions as a toxin sensor as well as a scaffolding site for phosphorylation and activation of several protein kinases upstream of the mitogen-activated protein kinases (MAPKs). These events drive several intracellular signaling cascades that selectively mediate transcription, mRNA stability and translation of genes associated with innate immune function and apoptosis. Research on this ribosome-mediated stress response indicates the immune system is a primary target of ribotoxic chemicals that might be encountered via natural food or airborne contamination or as a result of chemical terrorism. Such studies inform risk assessment/management efforts and will yield strategies for preventing and/or treating toxic effects in persons exposed to these chemical agents.

**674 MECHANISTIC BIOMARKERS AND INNOVATIVE METHODOLOGIES TO DETECT ACUTE KIDNEY INJURY.**

V. S. Vaidya¹ and D. P. Jones². ¹*Medicine-Renal, Harvard Medical School, Boston, MA* and ²*Medicine-Pulmonary Division, Emory University, Atlanta, GA.*

Acute kidney injury is a common disease and is associated with a high mortality rate. Although there has been a significant progress in understanding the mechanisms of ischemic or toxic forms of acute kidney injury (AKI) in animal models, translation of these findings to therapeutics useful in clinical practice remains challenging. One of the predominant reasons for the slow translation of the results from bench to bedside, especially in the treatment of existing AKI, is the absence of reliable and sensitive biomarkers of injury in animal and human studies. The FDA's critical path initiative has reinforced the need for additional biomarkers to predict drug toxicity in preclinical studies which can act as surrogate endpoints, and/or aid in making efficacious and cost-saving decisions or terminating drug development more quickly.

The objective of this symposium is 3-fold: First to give a mechanistic insight of metabolomic and genomic approaches adopted to discover new biomarkers and discuss the validation of both technologies with respect to various animal models of renal injury. Second aim is to describe the use of novel high throughput technologies such as a multiplexing tool kit based on microbead technology, which is capable of quantitating multiple biomarkers in the same biological sample at one time. Finally, this symposium will also discuss the use of zebrafish as a highly novel tool for mechanistic toxicology and the evaluation of kidney injury in predictive toxicology that may improve our ability to identify effective therapeutic agents for kidney injury and eliminate nephrotoxic compounds early in the drug development process.

This session will be Chaired and Co-Chaired by Drs. Jones and Vaidya respectively. Dr. Vishal Vaidya will give a brief introduction of the session and the first presenter will be Dr. Dean Jones followed by Dr. Donna Mendrick. The third presenter will be Dr. Vaidya followed by Dr. Joseph Bonventre. All the speakers are confirmed.

**675 METABOLOMIC APPROACHES TO DISCOVER PREDICTIVE AND MECHANISTIC BIOMARKERS OF TOXICITY.**

D. P. Jones. *Medicine-Pulmonary Division, Emory University, Atlanta, GA.*

During drug development, unprecedented and novel toxicities arise, and even after introduction of effective drugs into use, other toxicities can become apparent due to drug-genome, drug-environment and drug-drug interactions. Such toxicities can be difficult to detect and monitor, and the mechanisms of toxicity can be obscure, further complicating biomarker discovery and development. Metabolomics is a discipline/method that is well suited to understand environmental, especially toxicologic, influences on living systems. This presentation will focus on human metabolomics research with chemically defined diets to simplify discovery of sensitive metabolic pathways and metabolic response patterns. Two strategies will be discussed, use of 1H-NMR spectroscopy, which provides means to rapidly screen for changes affecting macronutrient metabolism as well as renal function, and liquid chromatography-Fourier-transform mass spectrometry (LC-FT/MS) which provides a similarly rapid and more sensitive detection, but has not yet been standardized for routine use. Both approaches can be applied to a range of biofluids and tissue extracts. Data from different biostatistical and bioinformatics approaches will be used to illustrate extraction of useful toxicologic information from these information-rich technologies.

**676 PHARMACOGENOMIC TECHNOLOGY: A HIGH THROUGHPUT APPROACH FOR PRE-CLINICAL AND CLINICAL RENAL BIOMARKER DISCOVERY.**

D. L. Mendrick. *Gene Logic Inc., Gaithersburg, MD.*

New biomarkers are needed to provide insight into a drug's potential to induce toxicity prior to irreversible damage (the so-called leading or predictive biomarkers). Clearly, better biomarkers of organ toxicity are needed in both preclinical and clinical arenas to protect human safety. Pharmacogenomics opens the door to new discoveries because one can measure the response of thousands of genes at once. However, the measurement of thousands of events at one time adds noise to any system, making false discovery a real problem. This presentation will focus on in silico approaches that can be used to discover and qualify potential biomarkers that bridge preclinical and clinical testing to provide better tools to identify safety risks to patients. Various issues with respect to data-mining, cross platform comparison and validation of the genomic results will also be discussed.

**677 NOVEL METHODS TO QUANTITATE URINARY BIOMARKERS FOR EARLY DETECTION OF NEPHROTOXICITY.**

V. S. Vaidya. *Medicine-Renal, Harvard Medical School, Boston, MA.*

As much as sensitive and specific biomarkers are needed to detect kidney injury, highly sensitive and high throughput methodologies are also needed to quantitate these biomarkers. We have cloned a potential biomarker for AKI named Kidney Injury Molecule-1 (Kim-1) which is upregulated more than any other known protein after renal injury. Kim-1 is a type 1 transmembrane protein that is not detectable in normal kidney tissue but is expressed and shed in the urine at very high levels in dedifferentiated proximal tubule epithelial cells in human and rodent kidneys after ischemic or toxic injury. The challenge now is to design innovative methods to quantitate Kim-1 in the urine which can be used as a sensitive, specific, high

throughput and noninvasive technique in preclinical and clinical detection of kidney injury. This presentation will focus on the development, evaluation and validation of ELISA's and microbead based assay to quantitate urinary Kim-1 in various preclinical and clinical models of acute kidney injury.

678 ZEBRAFISH AS A NOVEL TOOL FOR MECHANISTIC TOXICOLOGY AND HIGH THROUGHPUT SCREENING OF KIDNEY INJURY.

J. V. Bonventre. *Medicine-Renal, Harvard Medical School, Boston, MA.* Sponsor: V. Vaidya.

Zebrafish is a well established model in the study of developmental biology. More recently, zebrafish have been used in models of disease, such as myocardial injury and gastrointestinal lipid metabolism. Taking advantage of the ease of husbandry and wealth of established molecular biology methodology adds versatility to the model. Based on the translucency of zebrafish larvae we developed a fluorescent compound based method to determine changes in larval zebrafish glomerular filtration. We validated this method in a model of nephrotoxicity in larval zebrafish using gentamicin or cisplatin. The small size of larval zebrafish in combination with fluorescent markers make 96-well based high-throughput assays possible. This presentation will be about use of zebrafish as a novel tool for early detection of acute kidney injury and mechanistic toxicology.

679 PIGS AND THE PUBLIC'S HEALTH: AN ASSESSMENT OF HOG FARMING IN NORTH CAROLINA.

D. J. Crawford-Brown¹, C. Williams² and A. M. Jarabek³. ¹*Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.* ²*Department of Animal Science, North Carolina State University, Charlotte, NC* and ³*National Health and Environmental Effects Research Laboratory, Research Triangle Park, NC.*

Hog production in North Carolina has recently transformed from a system dominated by small independent farmers to a large-scale agribusiness, and is one example of an expanding class of confined animal feeding operations (CAFOs) which produce high concentrations of chemical and biological waste. Exposure scenarios include two categories: routine releases and releases during extreme climatic events. The hog CAFOs in NC are concentrated in the coastal plain region that is sensitive due to low-lying flood plains and high water tables. Officials in the state are attempting to understand the benefits that such operations might bring in the face of a declining tobacco and manufacturing base relative to the costs from ecosystem impacts and the reduction of human health and quality of life for those working or living nearby hog CAFOs. Ecological epidemiological and occupational studies suggest a variety of respiratory, gastrointestinal, and neurological health effects due to exposures from CAFOs. These results have spurred an effort to locate more environmentally-sustainable technologies that will reduce these risks. As part of that effort, NC and other states have attempted to apply risk assessment approaches to develop health-based quantitative limits that the technologies must reach with respect to the various contaminants. This symposium will describe the public health problems posed by CAFOs and then consider how toxicological sciences can contribute to the risk assessment effort by translating mechanistic data from in vitro and animal test systems to inform inferences made from observations at the population level in humans. Both chemical and microbial contaminants will be considered by a panel of experts from relevant toxicological disciplines.

680 AN OVERVIEW OF COMMUNITY HEALTH CONCERNS RELATIVE TO CONCENTRATED ANIMAL FEEDING OPERATIONS.

K. J. Donham. *Occupational and Environmental Health, University Of Iowa College Of Public Health, Iowa City, IA.* Sponsor: A. Jarabek.

The proliferation of animal feeding operations (AFO's) has been a phenomenon influenced by economic policy forces associated with our global economy. The observed increased intensity, concentration, specialization and consolidation in livestock and poultry production has been occurring over the past three decades. The US EPA has a specific definition of AFO's that includes the confinement of animals for at least 45 days in a 12 months period, and in a structure or lot where vegetation or crops will not grow. The term: Confined Animal Feeding Operation (CAFO) is used to describe AFO's over a specified size that are a risk as a point source for water pollution, and therefore require regulation (U.S. EPA 2002). In regard to water, air, and solid waste pollution, CAFO's have many of the same concerns as described for other agricultural operations. However, there are special concerns in regards to CAFO's because of the sheer size, the concentration of animals, feed, manure (usu-

ally handled in liquid form), dead animals, flies, and associated gases, particulates, odors and odorants, and infectious diseases all concentrated on a small land area. There are concerns that the manure cannot be recycled without pollution on such a small area, and that local and regional air and water quality suffers. Public concerns relative to adverse consequences of livestock production have been increasingly voiced since the late 1960s (Thu 1998). Numerous regional, national and international conferences have been held on the subject since 1994 (Merchant 2002; Thu 1995). An in-depth review of the literature has been recently published (Donham 2000). One reason large scale livestock production has raised concern is that it has separated from family farming and has developed like other industries in management, structure, and concentration. The magnitude of the problem is highlighted by the following facts relative to the U.S.

681 PUBLIC HEALTH IMPACTS OF INDUSTRIAL SWINE PRODUCTION.

S. Wing. *Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC.* Sponsor: A. Jarabek.

Industrialization of animal agriculture and development of confined animal feeding operations (CAFOs) have resulted in complex ecological impacts at local, regional and global scales. Swine CAFO confinement buildings, waste lagoons, and spray fields contribute to global greenhouse gases and affect local levels of respirable particulate matter, ammonia, hydrogen sulfide, and volatile organic compounds. Chemical and biological contamination of ground and surface waters also occur. Swine CAFOs may threaten public health conditions of host communities through occupational exposures, local air and water pollution, malodor, and threats to healthy community development. In North Carolina swine CAFOs have been located disproportionately in poor communities of color where they may contribute to existing health disparities. Although adverse impacts of confinement building exposures on respiratory health of CAFO workers have been well documented, fewer studies have evaluated impacts on neighbors, including susceptible populations such as children and the elderly. Several epidemiological studies link swine CAFOs to respiratory and gastrointestinal symptoms, immune function, asthma, and impaired quality of life in neighboring communities. Future studies could provide better exposure and outcome assessment using longitudinal study designs.

682 POTENTIAL HEALTH EFFECTS OF ODOROUS AERIAL EMISSIONS FROM SWINE PRODUCTION WASTE: ROLE OF VOCs AND PARTICULATES.

S. S. Schiffman. *Department of Psychiatry, Duke University Medical Center, Durham, NC.* Sponsor: A. Jarabek.

Complaints of health symptoms from ambient odors have become more frequent in communities with confined swine facilities. Health complaints include eye, nose, and throat irritation, headache, nausea, diarrhea, hoarseness, sore throat, cough, chest tightness, nasal congestion, palpitations, shortness of breath, stress, drowsiness, and alterations in mood. While these symptoms usually occur at the time of exposure and typically remit after a short period of time, health symptoms in sensitive individuals such as asthmatic patients may persist for longer periods. This presentation will cover two projects dealing with potential health effects of odorous emissions from swine operations. First, the conclusions of a workshop to assess the current state of knowledge regarding the health effects of ambient odors will be presented; this workshop was cosponsored by the Environmental Protection Agency (EPA) and National Institute on Deafness and Other Communication Disorders (NIDCD). Second, the results of an exposure study will be described in which 48 healthy adult volunteers were exposed for one hour to diluted swine air at a level that could occur at varying distances downwind from a confined swine operation both within and beyond the property line. This study was performed in an exposure chamber located at North Carolina State University's Field Laboratory. Objective measures of blood pressure, temperature, heart rate, respiratory rate, lung function, nasal inflammation, secretory immunity, mood, attention, and memory were correlated with objective measures of air quality. Ratings of perceived (self-reported) health symptoms were also obtained.

683 HOGS AS SOURCES OF ENTERIC AND OCCUPATIONAL ILLNESSES IN HUMANS.

R. Holley. *Food Science, University of Manitoba, Winnipeg, MB, Canada.* Sponsor: A. Jarabek.

In contrast with the US, there is a relationship between pork consumption and pork-associated foodborne illnesses in several European countries including Holland and Denmark where hog densities are high (1500 & 500 animals/km², re-

spectively). In the latter two countries pork is the meat species consumed in the greatest amount and it is a major source of human enteric illness. All human *Yersinia* and most *Salmonella* Typhimurium infections in these two countries are attributed to pork consumption. In Belgium and Norway raw or undercooked pork are the main sources of yersiniosis in man. The two organisms are highly prevalent in Dutch and Danish swine, but more recently improved slaughterhouse hygiene in these countries and in Norway has resulted in declines of pathogen occurrence in hog carcasses. In Holland and Norway decline in the frequency of *Yersinia* contamination has been coincident with the reductions in human clinical cases of yersiniosis. In the US and Canada high pig density and pork production have not increased known numbers of cases of pork-associated illnesses. In both countries pork consumption ranks third after poultry and beef. Cases of human illness attributed to pork fluctuate yearly at about 15% of the total in the US despite relatively high frequencies of pathogens in pigs and retail pork (7.4 to 31.5% and 1.3 to 15.6% respectively). While hog density in North Carolina at 465 animals/km² is close to that of Denmark, the difference in pathogen effects are probably explained by the consumption of well-cooked pork in North America. Improper manure handling can lead to direct contamination of produce, water supplies, animals or even humans. Outbreaks of illness associated with fresh produce and water supplies have risen in recent decades and evidence suggests there may be a connection with improper manure handling in some instances. Increased produce consumption and better reporting of foodborne illness cases have also contributed to this change. Occupational hazards (aerosols, antibiotic resistant bacteria) faced by agricultural laborers and those employed in waste treatment operations are largely uncharacterized.

684 ECOLOGICAL IMPACTS AND RAMIFICATIONS OF ATMOSPHERIC NITROGEN DEPOSITION TO ESTUARINE AND COASTAL WATERS: THE CONCERN ABOUT AGRICULTURAL AMMONIA EMISSIONS.

H. W. Paerl¹, D. R. Whittall², B. L. Peierls¹ and R. L. Dennis³. ¹University of North Carolina Chapel Hill, Morehead City, NC, ²NOAA, Silver Spring, MD and ³U.S. EPA, Research Triangle Park, NC. Sponsor: A. Jarabek.

Atmospheric deposition of nitrogen (AD-N) is a major source of externally-supplied or new nitrogen (N) to N-sensitive estuarine and coastal waters. In European and North American coastal waters downwind of anthropogenic emission sources, AD-N contributes from 10 to over 40 percent of new N loading, and can be the single largest source of new N impacting these waters. In developing regions of the world, AD-N is one of the most rapidly expanding sources of new N. In North Carolina, AD-N deposition has at least doubled since the 1970's, initially as a result of urbanization (chiefly NO_x), but more recently due agricultural growth (NH_x and organic N). Recent growth and intensification of animal operations in coastal regions (e.g., Mid-Atlantic coastal plain) have been linked to increasing amounts of NH_x deposition, according to a 3 decadal analysis of the National Atmospheric Deposition Program (NADP) wet deposition network. Ammonia emitted from these operations accounts for approximately half the AD-N in nearby Atlantic estuarine and coastal waters. The ecological ramifications of this growing N source in these N-sensitive waters include eutrophication, water quality, habitat and food web alterations. The role of AD-N in eutrophication dynamics depends on sources, chemical forms and amounts of N and interactions with other atmospheric nutrient sources (Fe). Ecological effects of AD-N are dependent on physical conditions, including stratification, residence time, and optical properties of receiving waters. AD-N and other atmospheric nutrient sources may promote major biotic changes now apparent in these waters, including the proliferation of harmful algal blooms, declines in water quality (hypoxia) and loss of fisheries habitat.

685 ADVANCES IN THE EFFICACY OF CHELATION TREATMENT TO ALLEVIATE NEUROCOGNITIVE EFFECTS OF LEAD AND AUTISTIC SPECTRUM DISORDERS.

D. Smith. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Clinical and animal model studies showing adverse neurological effects of low level exposures to metals such as lead and mercury underscore the need to devise efficacious intervention strategies to augment primary prevention efforts. Chelation therapy is one such intervention strategy that has been used in the treatment of metal poisoning in children, and it is now being advocated by some for the treatment of neurological disorders, most notably autism spectrum disorders (ASD). However, few clinical or animal model studies have thoroughly investigated the efficacy of chelation to alleviate the adverse neurological effects of lower level metal exposure. Further, the practice of using chelation therapy to treat ASD is becoming more common, though the overall benefits and risks of this therapy are not well known. This workshop will highlight recent clinical and animal model studies to

address the relative benefits and risks associated with chelation treatment for metal poisoning, and the efficacy of chelation in general and succimer treatment in particular in the treatment of ASD.

686 INTRODUCTION; THE EFFICACY OF SUCCIMER CHELATION FOR REDUCING TARGET TISSUE METAL LEVELS.

D. Smith. *Environmental Toxicology, University of California, Santa Cruz, CA.*

Chelation therapy has been used to treat metal poisoning in children for over 50 years. Chelation treatment is also now being advocated by some for the treatment of neurological disorders, most notably autism spectrum disorders (ASD). This presentation will provide an introduction of the workshop speakers, and a presentation of data on the pharmacokinetics of succimer, and its efficacy to reduce target tissue metal levels. Particular emphasis will be placed on the relationship between treatment regimen duration, blood and brain lead reductions, and the extent to which decreases in blood lead levels predicts reductions in brain lead in rodent and non-human primates. A number of studies in rodents and non-human primates have indicated that succimer-mediated reductions in blood lead levels greatly overestimate reductions in brain lead levels, suggesting that treatment regimens designed to bring about an acceptable reduction in blood lead may not achieve sufficient reductions in brain lead levels to achieve the desired efficacy.

687 CHELATION THERAPY, CEREBRAL DEVELOPMENT AND NEUROPSYCHOLOGICAL FUNCTIONS IN LEAD POISONED CHILDREN.

K. Dietrich, PhD. *Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH.* Sponsor: D. Smith.

It is unclear whether chelation therapy can prevent or reverse the neurodevelopmental sequelae of lead toxicity. Our objective is to determine whether chelation therapy with succimer in children with referral blood lead levels between 20 and 44 ug/dL at 12 to 33 months of age confers neurodevelopmental benefits. The Treatment of Lead Poisoned Children (TLC) study is a randomized, double-blind, placebo-controlled trial that was conducted between September 1994 and June 2003 in Philadelphia, PA; Newark, NJ; Cincinnati, OH; and Baltimore, MD. 780 children between the ages of 12 to 33 months were randomized to the active drug and placebo groups stratified by clinical center, body surface area, blood lead level, and language spoken at home. At 7 years of age, 647 subjects remained in the study. Up to 3 26-day courses of succimer or placebo therapy were administered depending on response to treatment in those who were given active drug. Scores on standardized neuropsychological measures that tap cognition, behavior, learning and memory, attention, and neuromotor skills were measured. Chelation with succimer lowered average blood lead levels for approximately six to 12 months but resulted in no benefits with respect to cognitive, behavioral or neuromotor endpoints. These follow-up data confirm our previous finding that the TLC regimen of chelation therapy is not associated with neurodevelopmental benefits in children with blood lead levels between 20 and 44 ug/dL (0.96-2.17 umol/L). In conjunction with new data from the Cincinnati Lead Study cohort that demonstrate cortical gray matter loss and dysfunctional cerebral organization in response to blood lead levels in this range, these TLC results emphasize the importance of taking primary environmental measures to prevent exposure to lead.

688 SUCCIMER CHELATION IMPROVES LEARNING, ATTENTION AND AROUSAL REGULATION IN LEAD-EXPOSED RATS BUT PRODUCES LASTING COGNITIVE IMPAIRMENT IN THE ABSENCE OF LEAD EXPOSURE.

B. Strupp, PhD. *Nutritional Sciences, Cornell University, Ithaca, NY.*

There is growing pressure for clinicians to prescribe chelation therapy at only slightly elevated blood lead levels. However, very few studies have evaluated whether chelation improves cognitive outcomes in lead-exposed children, or whether these agents have adverse effects that may affect brain development in the absence of lead exposure. The present study was designed to answer these questions, using a rodent model of early childhood lead exposure and treatment with succimer. Results indicate that lead exposure produced lasting impairments in learning, attention, inhibitory control, and arousal regulation, paralleling the areas of dysfunction seen in lead-exposed children. Succimer treatment of the lead-exposed rats significantly ameliorated learning, attention, and arousal regulation, although the efficacy of the treatment varied as a function of the lead exposure level and the specific functional deficit. In contrast, succimer treatment of rats not previously exposed to lead produced lasting and pervasive cognitive and affective dysfunction

comparable in magnitude to that produced by the higher lead exposure regimen. These findings suggest that it may be possible to identify a succimer treatment protocol that improves cognitive outcomes in lead-exposed children. However, they also suggest that succimer treatment should be strongly discouraged for children who do not have elevated tissue lead levels.

689 THE CLINICAL USE OF DETOXIFICATION AND CHELATION THERAPY IN CHILDREN WITH AUTISM SPECTRUM DISORDERS.

K. Bock. *Rhinebeck Health Center, Rhinebeck, NY*. Sponsor: D. Smith.

We are in the midst of an epidemic of autism spectrum disorders, with an incidence that has increased from 1 in 2,500 to 1 in 166. Numerous theories exist as to why this has occurred, ranging from better diagnosis to thimerosal induced neurotoxicity. I believe we are looking at an underlying genetic predisposition/vulnerability, in concert with environmental insults, including multiple toxicants. These toxicants include, but are not limited to, mercury, lead, and arsenic; as well as multiple chemicals, including persistent organic pollutants. Recent research has pointed to the synergistic toxicity of combinations of chemicals, and this is known to be true for heavy metals as well. Adverse effects of these toxicants in children with autism spectrum disorders include neurotoxicity, immunotoxicity, and metabolic imbalances. These metabolic imbalances include abnormalities in the methylation and transsulfuration pathways, most likely exacerbated by genetic polymorphisms coding for various enzymes in these pathways, including MTHFR, and glutathione-S-transferase. Clinical detoxification strategies, including methylcobalamin, n-acetyl-cysteine, reduced glutathione; and chelating agents such as DMSA and calcium EDTA, will be discussed in terms of their roles in a comprehensive biomedical treatment program which addresses these toxicities and imbalances, and coupled with intensive therapeutic interventions, may help these children on their road to recovery.

690 USE OF THIOL CHELATORS IN CHILDREN WITH AUTISM SPECTRUM DISORDERS: CLINICAL AND THEORETICAL IMPLICATIONS.

J. Bradstreet. *International Child Development Resource Center, Melbourne, FL*. Sponsor: D. Smith.

In the late 90's, the FDA asked all agencies to report the potential sources of mercury present in various commercially available medical and cosmetic products. This resulted in the observation that the Thimerosal present in many vaccines regularly exceeded the ATSDR and EPA guidelines. Methylmercury is a well described neurodevelopmental intoxicant, however less was known concerning the toxicology of ethylmercury. Further, emerging data indicated fetal exposure patterns were placing one in six children at risk of mercury toxicity at the time of birth. Thus, as this information became disseminated to physicians, some clinicians attempted to quantify relative body burdens of mercury in children with autism spectrum (ASD) using oral succimer (DMSA or Chemet®). One published study demonstrated significantly more mercury excretion during a provocation challenge of autistic children than age matched neurotypical children. Subsequently, Thimerosal has been reduced or eliminated in many vaccines – effectively changing the toxic exposure pattern. However, mercury likely represents a useful and effective model of studying environmental factors interacting with genomic vulnerability. This presentation will review the common practice of using thiol chelators in ASD, and discuss the ongoing controlled studies as well the results of provocation urine studies. This will be integrated into a discussion of observed and published abnormalities of the methylation and transsulfuration pathways in the ASD population.

691 ENVIRONMENTAL INFLUENCES ON THE OVARY AND HYPOTHALAMIC PITUITARY GONADAL AXIS.

W. N. Jefferson¹ and J. Flaws². ¹*Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC* and ²*Department of Veterinary Biosciences, University of Illinois, Urbana, IL*.

A functional ovary is critical to successful conception, regular menses, regulation of circulating steroid hormones and can potentially help regulate risk of serious female reproductive diseases. A variety of environmental components have been implicated in alteration of ovarian function and such events as early menopause, polycystic ovarian syndrome, and infertility/subfertility. In addition, transgenic mouse models lacking estrogen receptor α or β illustrate the ovary as both an endocrine organ and endocrine target for estrogens. Consequently, ovarian function is especially vulnerable to insult by endocrine disrupting chemicals. Developmental exposure to estrogenic chemicals such as genistein causes altered ovarian differentiation and function

contributing to reduced fertility later in life. Exposure to environmental aryl hydrocarbon receptor (AhR) ligands such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) can accelerate reproductive senescence in female primates involving changes in neuroendocrine and ovarian function. The pesticide methoxychlor (MXC) causes antral follicle-specific toxicity, characterized by a decreased number of healthy antral follicles, and an increased percentage of antral follicles undergoing atresia. Exposure to the occupational chemical 4-vinylcyclohexene diepoxide (VCD) is used as a chemical-induced mouse model for menopause characterized by ovarian failure. This symposium will highlight the roles that environmental effectors can have on the ovary and the impact that these effects can have on human health and reproduction.

692 CHRONIC ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR PATHWAY AND REPRODUCTIVE SENESCENCE.

B. Petroff. *Center for Reproductive Sciences, University of Kansas Medical Center, Kansas City, KS*.

The aryl hydrocarbon receptor (AhR) pathway is an evolutionarily conserved, widely expressed orphan receptor pathway that is activated by many environmental and experimental toxicants and carcinogens. The transition to reproductive senescence (i.e. the menopause in primates) in females involves changes in neuroendocrine and ovarian function and can be accelerated by exposure to environmental AhR ligands such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). We will discuss studies addressing the possible mechanisms behind the impact of acute vs. chronic exposure to AhR ligands on the loss of reproductive function with age. Through endocrinological and molecular study, we have attempted to determine when developmentally and where anatomically females are particularly susceptible to endocrine disruption by TCDD during chronic exposures in rats. This work may help characterize and eventually prevent premature loss of reproductive function in smokers and residents of polluted regions. (Supported by Kansas City Area Life Sciences Institute and NIH RO1 ES12916)

693 DEVELOPMENTAL EXPOSURE TO ESTROGENS AND EFFECTS ON OVARIAN MATURATION.

W. Jefferson. *Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC*.

It has been previously shown that developmental exposure to estrogenic chemicals during critical stages of reproductive tract differentiation causes adverse consequences on female reproductive system. The naturally occurring phytoestrogen genistein found in soy-derived products is an example of an environmental estrogen that has been shown to cause altered murine ovarian differentiation and function as well as subfertility/infertility. Mice treated neonatally on days 1-5 with genistein (0.5 – 50 mg/kg/day) by subcutaneous injection exhibit altered ovarian differentiation characterized by inhibition of oocyte nest breakdown leading to the formation of multi-oocyte follicles (MOFs). This malformation is mediated by estrogen receptor β (ER β) since mice lacking ER β do not develop MOFs following neonatal genistein treatment. We have also observed limited ovulatory function in adult mice treated with the highest dose of genistein as evidenced by reduced numbers of corpora lutea. This effect is rescued with exogenous gonadotropin treatment suggesting altered hypothalamic/pituitary/gonadal signaling in genistein treated mice. Reproductive function is also altered with early reproductive senescence in the lower genistein groups and infertility in the highest group. To further characterize female infertility following neonatal genistein, we examined the effects on oocyte quality in culture. Female mice were treated with exogenous gonadotropins (PMS & HCG) and bred to proven control males. Oocytes were collected, counted, and placed in culture. Fertilized oocytes were determined by the appearance of the second polar body and followed to determine progression to 2-cell, 4-cell and blastocyst stages of development. Oocytes from genistein treated mice exhibited lower fertilization rates and reduced ability to develop to the blastocyst stage suggesting poor oocyte quality. These data suggest that exposure to estrogenic chemicals like genistein during critical stages of differentiation can cause long term consequences on ovary differentiation and subsequent reproduction.

694 ENDOCRINE, PARACRINE & AUTOCRINE ACTIONS OF ESTRADIOL IN OVARIAN FUNCTION.

J. F. Couse. *Laboratory of Reproductive and Developmental Toxicology, National Institute of Environmental Health Sciences, Research Triangle Park, NC*. Sponsor: W. Jefferson.

The ovaries produce the bulk of circulating estradiol in females of reproductive age. The endocrine actions of estradiol in the hypothalamic-pituitary axis are well known to be necessary for determining the appropriate pattern of gonadotropin secretion, and are therefore obligatory to ovarian function. In contrast, putative paracrine and autocrine actions of estrogen signaling in the ovary are less understood, largely because in vivo studies of intra-ovarian estrogen action are impeded

by the inability of pharmacological reagents to overcome the immense level of endogenous estrogens within growing follicles. Hence, the advent of gene-targeted mice that lack estradiol synthesis (CYP19-null) or the nuclear estrogen receptors (ER α or ER β) has introduced renewed opportunities in this area of study. The divergence of ovarian phenotypes in each model has expanded our appreciation of the multiple sites at which estrogen signaling impinges upon ovarian function. For example, ER α -null females are anovulatory due to their inability to produce a gonadotropin surge, reflecting the loss of endocrine estradiol actions in the hypothalamic-pituitary axis; but also exhibit constitutively elevated ovarian steroidogenesis due to the loss of ER α -mediated paracrine actions in thecal cells. In contrast, ER β -null females are oligovulatory due to the lack of ER β -mediated autocrine functions that enhance the granulosa cell response to follicle stimulating hormone. CYP19-null ovaries more closely mimic those of ER α -null females but also exhibit features seen only in mice lacking both ER forms. These models nicely illustrate the ovary as both an endocrine organ and endocrine target for estradiol. Consequently, ovarian function must be considered especially vulnerable to insult by endocrine disrupting chemicals. A better understanding of the endocrine, paracrine and autocrine roles of estradiol in ovarian function will improve our abilities to predict the mechanisms by which the ovary is most susceptible to toxic insult and the manifestations that may result.

695 TOXICANT INDUCED FOLLICULAR ATRESIA.

J. A. Flaws. *Department of Veterinary Biosciences, University of Illinois, Urbana, IL.*

Females are born with a finite number of primordial follicles. Although some primordial follicles mature to the antral stage and release eggs for fertilization, greater than 95% undergo atresia. Atresia is an apoptotic process that is regulated by conserved factors, including members of the Bcl-2 family of proteins and oxidative stress pathway. Over time, the ovary becomes devoid of follicles because they are depleted through the processes of atresia or ovulation. Once the ovary is devoid of follicles, the female becomes infertile and is said to have entered reproductive senescence. Any chemical that increases atresia of follicles could increase the rate at which follicles are depleted from the ovary and result in premature ovarian failure. This talk will review chemicals that cause atresia of ovarian follicles. Particular emphasis will be placed on the pesticide methoxychlor (MXC) because it causes antral follicle-specific toxicity, characterized by an increased percentage of antral follicles undergoing atresia versus controls. While previous work indicates that MXC increases atresia of antral follicles, it is important to know whether the increased atresia is due to a direct effect of MXC on antral follicles, or an indirect effect caused by toxicity to other components of the ovary or other tissues that contribute to ovarian function (i.e., the hypothalamus or pituitary). Further, it is important to know the mechanisms by which MXC induces atresia. This talk will present information on the direct effects of MXC on the ovary as well as information on the role of the Bcl-2 family and oxidative stress pathway in MXC-induced atresia. Such information may improve our understanding of toxicant-induced atresia and help in the development of treatments for toxicant-induced atresia. Supported by NIH R21 ES1306, RO1 ES 012893, and Colgate Palmolive.

696 OOCYTE DEPLETION AND EARLY MENOPAUSE.

P. B. Hoyer. *Department of Physiology, University of Arizona, Tucson, AZ.*

A variety of types of health risks are associated with menopause in women. Therefore, it is important to identify environmental influences that damage ovarian follicles and might be capable of causing early menopause. This talk will review classes of environmental chemicals that have been shown to damage ovarian follicles in laboratory animals. It is also important to develop animal-based studies aimed at better understanding menopause-associated disorders. Therefore, this talk will review available animal models for menopause, focusing on ovariectomized and genetically altered animals. Particular attention will be paid to a chemical-induced mouse model for menopause. In this model, ovarian failure induced by the occupational chemical 4-vinylcyclohexene diepoxide (VCD) is gradual, and the animal retains residual ovarian tissue. Thus, the VCD-treated animal model is highly relevant to women undergoing a natural progression through the peri-menopausal transition and into post-menopause. Finally, physiological end points seen in this model that mimic menopause-associated disorders will be presented. (Supported by AG021948)

697 HOW CAN BIOLOGICALLY-BASED MODELING OF ARSENIC KINETICS AND DYNAMICS INFORM THE RISK ASSESSMENT PROCESS?

E. M. Kenyon and H. El Mastri. *ORD/NHEERL/ETD/PKB, U.S. EPA, Research Triangle Park, NC.*

Quantitative biologically-based models describing key events in the continuum from arsenic exposure to the development of adverse health effects provide a framework to integrate information obtained across diverse research areas. For example,

genetic polymorphisms in arsenic metabolizing enzymes can lead to differences in target tissue dosimetry for key metabolites causative in toxic and carcinogenic response. This type of variation can be quantitatively incorporated into pharmacokinetic (PK) models and used together with population based modeling approaches to evaluate the impact of genetic variation in methylation capacity on dose of key metabolites to target tissue. The PK model is an essential bridge to the pharmacodynamic (PD) models. A particular benefit of PD modeling for arsenic is that alternative models can be constructed for multiple proposed modes of action for arsenicals. Genomics data will prove useful for identifying the key pathways involved in particular responses and aid in determining other types of data needed for quantitative modeling. These models, when linked with PK models, can be used to better understand and explain dose- and time-response behaviors. This in turn assists in prioritizing modes of action with respect to their risk assessment relevance and future research. This type of integrated modeling approach can form the basis for a highly informative mode-of-action directed risk assessment for inorganic arsenic. This workshop will address both practical and theoretical aspects of integrating PK and PD data in a modeling framework, including practical barriers to its application.

698 HUMAN GENETIC POLYMORPHISMS: BIOMARKERS OF VARIABILITY IN ARSENIC METABOLISM.

W. T. Klimecki^{1,3}, M. M. Meza², Y. Y. Rodriguez³ and A. Gandolfi¹.

¹Pharmacology and Toxicology, University of Arizona, Tucson, AZ, ²Natural Resources, ITSON, Cd. Obregon, Sonora, Mexico and ³Arizona Respiratory Center, University of Arizona, Tucson, AZ.

Variability in the metabolism of xenobiotics between humans is well established as a determinant of variability in toxicity resulting from the xenobiotic exposure. The presence of variant DNA sequences in genes involved in the relevant biochemical pathways is capable of contributing to this inter-individual variability in metabolism by potentially altering the intrinsic enzyme activity, the quantity, the localization, or the timing of the appearance/disappearance of the gene's protein product. By reducing unexplained variation in the data, the use of DNA polymorphisms as biomarkers can inform both the underlying biological model, as well as pharmacokinetic and pharmacodynamic models. We recently performed a comprehensive screen for DNA biomarkers of arsenic metabolism in 135 human subjects from Sonora, Mexico, exposed to drinking water arsenic concentrations ranging from 5.5 ppb – 43.3 ppb. The screening study focused on three genes with literature-validated functionality in arsenic metabolism, glutathione-S-transferase omega-1, purine nucleoside phosphorylase and arsenic (III) methyltransferase (AS3MT). Within the entire human population a cluster of tightly linked polymorphic sites in AS3MT was strongly associated with urinary dimethylarsenic : monomethylarsenic (D/M) ratio. Closer inspection of the data revealed that this association was only present in the children (7-11 years), and not in the adults (> 18 years). Interpretation of the genetic data required consideration of the number and location of all polymorphisms within AS3MT, the number and location of co-occurring polymorphisms in the cluster with statistical association to urinary D/M ratios, the ethnic ancestry of the subjects, and the relevant covariates within the subjects. This study provides an illustrative example of the complexities surrounding the successful application of DNA biomarkers to inform quantitative biologically-based models.

699 DEVELOPMENT OF A HUMAN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR INORGANIC ARSENIC AND ITS MONO- AND DIMETHYLATED METABOLITES.

H. A. El-Mastri¹ and E. Kenyon². ¹NHEERL, U.S. EPA, Research Triangle Park, NC and ²NHEERL, U.S. EPA, Research Triangle Park, NC.

A physiologically-based pharmacokinetic (PBPK) model was developed to estimate levels of arsenic and its metabolites in human tissues and urine after oral exposure to either arsenate (AsV) or arsenite (AsIII). The model consists of interconnected individual PBPK models for AsV, AsIII, monomethylarsenic acid (MMAV), and dimethylarsenic acid (DMAV). Reductions of MMAV and DMAV to their respective trivalent forms are also described in the overall model. Each PBPK model was constructed using flow limited compartments describing the mass balance of the chemicals in GI tract (lumen and tissue), lung, liver, kidney, muscle, skin, heart, and brain. The choice of tissues was based on physiochemical properties of the chemicals (solubility), exposure routes, and target and metabolic sites of inorganic arsenic and its metabolites. Metabolism of inorganic arsenic in liver was described as a series of reduction and oxidative methylation steps, in addition to the inhibitory influence of the metabolites on methylation. The inhibitory effects of AsIII on the methylation of MMAIII to DMA, and MMAIII on the methylation of AsIII to MMA were assumed to follow a noncompetitive mechanism. Most of the parameters used in the model were estimated from literature. The remaining parameters

were calibrated and evaluated using cumulative levels of inorganic arsenic and its metabolites in urine of exposed people. The calibrated and evaluated human PBPK model can be used, when combined with Monte-Carlo simulations, in identifying population-based distributions for some sensitive parameters (such as metabolic rate parameters differing due to genetic polymorphisms) and address the impact of these distributions on the human risks to arsenic exposure. This abstract does not necessarily

700 COMPUTATIONAL MODELING TO EVALUATE CANDIDATE MODES OF ACTION FOR THE CARCINOGENICITY OF ARSENIC.

R. Conolly, M. Breen and M. Zhao. *U.S. EPA, Research Triangle Park, NC.*

Several modes of action, including cytotoxicity, direct genotoxicity, and oxidative stress, have been proposed to explain carcinogenic effects of arsenic. The goals of our work are to (1) develop biologically-based computational models of candidate modes of action to better understand dose- and time-response behaviors and (2) prioritize the modes for relevance to risk assessment. The value of computational modeling lies in its ability to provide non-intuitive insights into dynamic behaviors. This value can only be realized if the model accurately reflects knowledge about the modes of action. Close consultation between computational modelers and arsenic experimentalists is required to ensure that the model incorporates this knowledge. Identification of the appropriate level of biological detail is also important. There is little point in incorporating large amounts of molecular-level information if corresponding data for parameterization and comparison with model predictions are lacking. Thus, to a large extent, the availability of data determines the level of biological detail. These considerations guide development of a qualitative map of key events for each mode. The quantitative version of the model is then developed by specifying the appropriate functional relationships between the components of the qualitative model and the associated parameter values. Ideally, parameters are set to measured values, though some values may be inferred by optimization. Lack of sufficient, relevant data, however, hinders successful translation of the qualitative model into its quantitative counterpart. Once the quantitative models for candidate modes are available, they will be ranked according to their relative abilities to reproduce time-course and dose-response data for endpoints of regulatory interest such as bladder cancer. Use of the preferred model for risk assessment will first require analysis of uncertainty, as the uncertainty of the biologically-motivated model should be less than that of its default-based counterpart. This presentation may not reflect the official policies of the U.S. EPA.

701 INTEGRATION OF GENOMIC DOSE-RESPONSE INFORMATION IN A MODE OF ACTION DIRECTED RISK ASSESSMENT FOR INORGANIC ARSENIC.

H. Clewell. *CIIT Centers for Health Research, Research Triangle Park, NC.*

It has been suggested that the dose-response for the carcinogenicity of inorganic arsenic (AsI) is highly nonlinear, with an effective threshold, due to an apparent mode of action involving inhibition of DNA repair. In the absence of a fully developed biologically based dose-response model for AsI carcinogenicity, it would be of value to be able to use a margin-of-exposure approach as an alternative to the default linear option. This presentation will describe a proposed approach for conducting a margin of exposure risk assessment for AsI using *in vitro* dose-response information on the expression of genes associated with the obligatory precursor events for tumorigenesis. The cellular effects of AsI can be understood as the superposition of highly-specific direct interactions of AsI with critical proteins containing vicinal dithiols, such as those involved in DNA repair, overlaid against a background of chemical stress, including proteotoxicity and depletion of non-protein sulphydryls, that induces an array of cellular responses common to many types of chemical and non-chemical stressors. The enhanced impact of DNA repair inhibition under conditions of oxidative stress, inflammation, and proliferative pressure leads to a situation in which the cell is no longer able to maintain the integrity of its DNA prior to division. Genomic dose-response data on AsI is consistent with data on other chemical stressors, in that there appears to be a transition from an adaptive state at low concentrations to an impaired state at higher concentrations. In the proposed risk assessment approach, the concentration at which this transition occurs in the human target cells (e.g., bladder epithelium) would be used as the point of departure for the margin-of-exposure determination. The margin of exposure would be selected to consider both variability in the human population (e.g., polymorphic variation) and uncertainty in the mode of action. A key aspect of this approach is the use of *in vivo* biomarker data from populations with known exposure to AsI to anchor the *in vitro* dose-response.

702 USING MODELING TO INFORM THE RISK ASSESSMENT PROCESS FOR ARSENIC.

B. D. Beck and A. S. Lewis. *Gradient Corporation, Cambridge, MA.*

This presentation will discuss how pharmacokinetic (PK) and pharmacodynamic (PD) models for inorganic arsenic (As_i) and organoarsenicals can inform the risk assessment process from an applied perspective. Present risk assessment methods for As_i rely primarily on data from highly exposed non-US populations, with limited consideration given to population variability and potential non-linearities in dose-response. Use of PBPK models to estimate dose to target should reduce uncertainty in extrapolating across populations, particularly with respect to addressing the role of nutritional deficiencies. However, uncertainties in identifying relevant metabolite(s) as a function of tumor type and in interpreting whether impairments in the first methylation step are causal or a result of disease are some of the obstacles to the application of PBPK models. Ongoing PD models for As_i, such as the genomic approach being developed between CIIT, EPRI, and EPA, may provide an elegant way to incorporate biological understanding into the dose-response process and should enhance the epidemiologically-based models. Challenges include the lack of a well-validated animal model for As_i, particularly for bladder and lung cancer, adding uncertainty to the interpretation of genomic changes with respect to tumor development (e.g., what changes are on the causal pathway, how much change is required for tumor development?). In contrast to As_i, dimethylarsinic acid (DMA), an organic arsenic compound, is a recognized animal carcinogen, causing bladder tumors in rats with a relatively well-understood mode of action (cytotoxicity, likely due to DMAV metabolites including DMAIII, followed by regenerative hyperplasia). PBPK and PD modeling for DMA carcinogenesis may have more near-term applicability. In fact, benchmark dose (BMD) modeling has been applied to the critical step in DMA carcinogenesis (increased DNA synthesis) to develop BMD parameters for use in risk assessment. PBPK modeling, particularly to the extent that it incorporates hemoglobin binding of DMA in the rat and its impact on dose, should add precision to cross-species extrapolations for this compound.

703

COMPARISON OF CORROSITEX AND EPIDERM™ IN VITRO SKIN CORROSION SCREENING ASSAYS TO IN VIVO CORROSIVITY RESULTS.

D. M. Wilson, T. T. McMullin, H. L. Kan, R. M. Golden and W. T. Stott. *Dow Chemical, Midland, MI.*

A battery of chemicals was objectively compared in the EpiDerm™ (MatTek Corp., Ashland, OH) and Corrositex (InVitro International, Irvine, CA) *in vitro* corrosivity screens to existing *in vivo* data. EpiDerm™ consists of cultured, normal human epidermal keratinocytes in a differentiated epidermal model with organized basal, spinous and granular layers, and a stratum corneum containing intercellular lamellar lipid layers analogous to those found *in vivo*. Corrosivity is assessed as relative cytotoxicity at 3-min and 1-hr as the mitochondrial reduction of a tetrazolium salt. Corrositex uses a bio-barrier membrane comprised of a hydrated collagen matrix and supporting filter membrane on top of a vial filled with a chemical indicator dye, with corrosivity assessed according to breakthrough time. A panel of 12 reference chemicals recommended in OECD Guideline 431 for laboratory validation procedures was used [six corrosive: 1,2-diaminopropane; acrylic acid; 2-tert-butylphenol; potassium hydroxide; sulfuric acid; octanoic acid; and six non-corrosive: 4-amino-1,2,4-triazole; eugenol; phenethyl bromide; tetrachloroethylene; isostearic acid; and 4-methylthio-benzaldehyde], as well as 15 proprietary chemicals [nine corrosives and six non-corrosives *in vivo*, comprised of one alcohol, three organic acids, seven amines, two acrylic acid derivatives, and two halogenated herbicides]. EpiDerm™ exhibited 96% *in vivo* concordance (26 of 27), with 1 of 27 giving a borderline false negative for an organic acid. Corrositex exhibited 70% (19 of 27) *in vivo* concordance; with 3 of 27 false negatives (two organic acids and one halogenated herbicide), 2 of 27 false positives (both were amines), and 3 of 27 that didn't qualify due to lack of reactivity with the indicator dye. Erroneous results weren't restricted to false negatives, positives or by chemical class. One organic acid was a false negative for both *in vitro* assays, with the borderline EpiDerm™ result suggesting potential corrosivity *in vivo*. In conclusion, EpiDerm™ gave near-perfect concordance with *in vivo* corrosivity data.

704

IN VITRO PREDICTION OF OXAZOLIDINONE-MEDIATED BONE MARROW TOXICITY.

M. Otieno¹, N. Bavuso¹, P. Ciaccio¹, M. Gravestock², R. Illingworth² and E. Pognan³. ¹AstraZeneca Pharmaceuticals, Wilmington, DE, ²AstraZeneca Pharmaceuticals, Boston, MA and ³AstraZeneca Pharmaceuticals, Alderley Park, United Kingdom.

Oxazolidinones are antibiotics that inhibit bacterial protein synthesis. Daily dosing in rats is associated with selective depletion of immature erythroids and reticulocytes by day 5, followed by a 60-80% rebound on day 14. Binding of erythropoi-

etin (Epo) to its receptor EpoR plays a role in erythropoiesis, a multi-stage process requiring proliferation and differentiation of erythroblasts into reticulocytes. The purpose of this study was: (1) to develop an *in vitro* model that predicts *in vivo* reticulocyte reduction and subsequent tolerance by oxazolidinones and (2) to investigate the mechanism of toxicity. Treatment with the Epo-responsive erythroid cell line HCD57 with Epo resulted in a dose-dependent increase in proliferation (EC50=22pM). Addition of oxazolidinones did not affect Epo potency, but reduced proliferative efficacy from 100% to 40% in the absence of cytotoxicity. Oxazolidinones mediated a dose-dependent decrease in proliferation (IC50s: 200nM to 10µM) and were 100-fold less potent in the myeloid cell line FDCP-1 compared to HCD57 cells thus confirming *in vivo* erythroid-specific toxicity. Comparison of *in vitro* IC50s and *in vivo* reduction of reticulocytes (20-90%) in mice for 17 compounds established a linear correlation ($r^2=0.83$), indicating that the *in vitro* assay is predictive of *in vivo* findings. Treatment of cells for 21 days resulted in a dose-dependent suppression of growth for 7 days, followed by a rebound that mimicked *in vivo* effects. Mechanistic studies targeting EpoR find that the compounds have no effect on EpoR protein as determined by western blot analysis nor on EpoR synthesis measured by *in vitro* transcription and translation of the receptor. Binding of the ^{125} I-Epo to its receptor in transfected Cos cells or HCD57 cells was also not modulated by the compounds. In conclusion, HCD57 cells can be used to screen oxazolidinone compounds for bone marrow toxicity, but the mechanism by which the compounds mediate their effects is yet to be determined.

705 POST-IMPLANTATION RAT WHOLE-EMBRYO CULTURE ASSAY: *IN VITRO* – *IN VIVO* EXTRAPOLATION.

J. Bessems¹, W. Slob¹, A. Piersma², B. Hakkert³ and A. Sips¹. ¹Centre for Substances and Integrated Risk Assessment, RIVM (National Institute for Public Health and the Environment), Bilthoven, Netherlands, ²Laboratory for Toxicology, Pathology and Genetics, RIVM, Bilthoven, Netherlands and ³Expertise Centre for Substances, RIVM, Bilthoven, Netherlands.

The postimplantation rat Whole-Embryo Culture (WEC) assay is intended to assess embryotoxicity and was agreed by the ECVAM (European Centre for the Validation of Alternative Methods) Scientific Advisory Committee (ESAC) as a scientifically validated test. The protocol uses parameters such as IC50 values for malformations in purely statistically derived prediction models for classification as *non*, *weak*, or *strong* embryotoxic. However, its biological relevance and validity is under discussion. Further, *in vitro* – *in vivo* extrapolation remains a critical issue in quantitative risk assessment.

Therefore, in the present study, the feasibility of extrapolation of *in vitro* to *in vivo* dose-response relationships was explored. For each of 20 compounds the available *in vivo* studies were reviewed using the Benchmark Dose (BMD) approach by estimating the dose at which 10% foetal reduction and/or 10% prenatal deaths were observed (defined as BMD10). Similarly, for the *in vitro* studies the Benchmark Concentration was assessed for a 5% effect (BMC05). The results indicate that predicting the *in vivo* BMD from the *in vitro* BMC was not possible within one to two orders of magnitude. The large uncertainty in the *in vivo* BMD values is due to large variations in study design (prenatal exposure window, route of exposure, developmental effects at all dose-levels) and limits the possibility to assess extrapolation of the *in vitro* BMC values. Estimated (in *in vivo*) AUC and Cmax values were nearly linearly related to the external dose, indicating that in these cases including toxicokinetics would not improve the correlation. Conclusively, *in vitro* – *in vivo* extrapolations should be further evaluated for application in testing strategies by gathering developmental toxicity studies based on identical protocols.

Keywords: Whole-Embryo Culture, Quantitative *in vitro* – *in vivo* extrapolation

706 *IN VITRO* TOXICITY ASSESSMENT OF PHOTOPOLYMERIZABLE EMBOLIC RESINS.

P. Balbuena¹, K. McKeon², M. Ehrich¹ and B. Love³. ¹Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA, ²School of Biomedical Engineering and Sciences, Virginia Tech - Wake Forest, Blacksburg, VA and ³Materials Science and Engineering, Virginia Tech, Blacksburg, VA.

The present research is part of a multidisciplinary study to achieve a more controlled embolization of vascular defects utilizing photopolymerized acrylates that might be both safer and easier to deploy than current fluids. A mixture of photopolymerized Bisphenol-A-Glycidyl dimethacrylate (BisGMA) and CD582, an alkoxyated cyclohexane dimethanol diacrylate monomer, were assessed for cytotoxicity *in vitro* utilizing trypan blue cell viability assay. Compounds alone, together, and with the photoinitiators were tested to compare toxicity of the different combinations. Rat brain endothelial cells (RBE4) passages 10 to 15 were utilized in the study. Concentrations of approximately 1.6 million cells per well, plated in six-well plates were used. Configuration of design included four different concentrations of the mixtures, and two controls. Assessments were performed for three and six hour

periods. Repetitions of the process were performed to attain statistical relevance. At its highest concentration on the three hours period, CD582 alone exhibited a 73% viability compared to 93% for the controls. However, at six hours cell death with CD582 increased dramatically (to 100%). The presence of the photopolymerizing agent decreased cell death caused by CD582 at both three and six hours for the highest concentration (to 75% & 62% viability, respectively), but had no statistical effect on cell viability or cell toxicity for the BisGMA+photopolymerizing agent mixture, nor for the BisGMA+CD582+ photopolymerizing agent mixture. Overall, toxicity of the mixtures was less than the toxicity of the compounds alone. Different dilutions followed a pattern of decreased toxicity, presumably due to dilution factors of the mixtures, but the decreases were not significant over the concentration ranges tested.

707 TRANSFER OF LEAD ACETATE THROUGH AN *IN VITRO* BLOOD-BRAIN BARRIER SYSTEM.

B. Meldrum, P. Balbuena, K. Fuhrman, B. Wise, A. Hirani, Y. Lee and M. Ehrich. Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA.

Lead-induced neurotoxicity remains a problem for humans and animals. Effects of this heavy metal are dependent on its ability to reach the brain. Transport of lead acetate was examined in an *in vitro* blood-brain barrier (BBB) system consisting of rat endothelial (RBE4) cells and astrocytes. These cells were cultured in Minimal Essential Medium (MEM) with 10% fetal bovine serum and in MEM with 10% heat-inactivated horse serum and placed on the upper and lower sides, respectively, of 0.45 micron inserts coated with collagen type I and placed in 6-well plates. Lead acetate in concentrations of 0.1, 1, 10 and 100 micromolar were placed inside the insert, on the endothelial cells. After 14 hours of exposure, electrical resistance of the BBB and lead concentration in cell culture medium under the barrier was determined. A concentration-related decrease in resistance from the control value of 210-390 ohm.cm² was seen, with 118-130 ohm.cm² measured at the highest lead concentration. Lead (215 ppb) was detected in the medium under the insert of cells exposed to 100 micromolar lead. Separate experiments indicated that RBE4 cells exposed to concentrations as high as 100 micromolar lead still had greater than 90% viability, as indicated by lack of uptake of trypan blue dye. Microscopic visualization of the co-cultures suggested that endothelial cells directly exposed to the lead sustained more damage (indicated by morphological change) as the concentration of lead increased. These experiments indicate that this *in vitro* system has potential value in studies examining lead transport into the nervous system.

708 DETERMINATION OF LC50 AND VISUAL ASSESSMENT OF COMPOUND INDUCED DEVELOPMENTAL TOXICITY ON ZEBRAFISH BODY, LIVER, INTESTINE AND HEART.

W. L. Seng¹, C. Parng¹, K. A. Augustine² and P. McGrath¹. ¹Phylonix Pharmaceuticals, Inc., Cambridge, MA and ²Reproductive Toxicology, Bristol-Myers Squibb Pharmaceutical Research Institute, Hopewell, NJ. Sponsor: C. Zhang.

Twelve blinded compounds provided by BMS were evaluated for developmental toxicity in zebrafish embryos by a LC50/Visual Assessment protocol designed by Phylonix. The goals of this study were to use zebrafish embryos as a model to assess median lethal dose concentration (LC50) and to assess body morphology and liver, intestine, and heart abnormalities after compound treatment.

Embryos were exposed continuously to compounds for 4 days from 24 hours post-fertilization (hpf) to 120 hpf. Total mortality for each compound was assessed every 24 hours. To determine the range for the effective concentration, embryos were initially treated with 5 concentrations one log apart: 0.01, 0.1, 1.0, 10 and 100 µM. If the LC50 was not within the initial test concentration range, additional concentrations were tested. Morphology of the body, heart, liver and intestine were assessed by microscopic examination.

The data from the assay was evaluated for strength in predictivity and accuracy based on their respective *in vivo* teratogenicity properties. Results from the evaluated test set suggested that the assay was good (>70% <80%) for specificity and excellent (>80%) for sensitivity. In this regard, there was a 75% success rate in positively identifying *in vivo* non teratogenic compounds and a 100% success rate in positively identifying *in vivo* teratogens, respectively. The accuracy for predicting relative teratogenic potency of the compounds was excellent with a 92% success rate. This study demonstrates an approach for simple and direct primary assessment of developmental toxicity in zebrafish. In summary, the results of the LC50/Visual Assessment Pilot study demonstrate that the zebrafish embryo assay format (ZE-TAXTM) is a valuable model for conducting predictive teratogenicity studies, presenting excellent concordance with a 92% success rate in positively identifying teratogenic and non teratogenic compounds from the evaluated test set.

709 ZEBRAFISH AS A MODEL VERTEBRATE FOR CARDIOTOXICITY.

A. J. Hill, S. Albert, B. Richards and J. Tinsley. *VASTox Plc, Abingdon, Oxfordshire, United Kingdom.*

Drug discovery is an increasingly expensive and risky process with high rates of safety related attrition often at late stages of R&D. Withdrawals of drugs from the market, especially those affecting the cardiovascular system, demonstrate the difficulties of predicting safety pharmacology at pre-clinical stages.

The zebrafish is a valuable in vivo model for expediting prioritisation of candidate drugs for development and flagging toxicity very early in the R&D process. Strong conservation of genetic pathways, increasing availability of disease models, its small size and ease of administration of compounds (micrograms) to the developing embryo, make zebrafish a very attractive, cost-saving vertebrate model for toxicity testing.

VASTox plc has undertaken validation of a cardiotoxicity assay using a set of thirty compounds targeting mechanisms known to affect the human heart (e.g. various ion channel blockers; HERG blockers; adreno- and muscarinic receptor agonists and antagonists). Larval zebrafish were exposed at a range of doses via the water in 24-well plates for 0-3 h and assessed using a CCD digital camera. Rates of atrial (A) and ventricular (V) contraction were determined; thereby revealing any tachycardia, bradycardia and changes in the A:V ratio.

The effects on zebrafish of known cardioactive compounds showed complete concordance to other higher order vertebrates. This included a specific phenotype indicative for the detection of HERG blockers. These data suggest the zebrafish is a suitable model for assessing drugs for toxicity at early stages of development.

710 DETERMINATION OF XENOBIOTIC INTRINSIC CLEARANCE IN FRESHLY ISOLATED HEPATOCYTES FROM RAINBOW TROUT (ONCORHYNCHUS MYKISS) AND RAT AND ITS APPLICATION IN BIO-ACCUMULATION ASSESSMENT.

X. Han, D. L. Nabb, R. T. Mingoia and C. Yang. *DuPont Haskell Laboratory, Newark, PA.*

Bioaccumulation in fish is a dynamic equilibrium of various processes that involve fish uptake, storage, and elimination of xenobiotics. Elimination via fish biotransformation of xenobiotics is one of the key processes that could be evaluated in an in vitro system to improve the performance of the prediction of xenobiotic bioaccumulation potentials. In this study, values of intrinsic clearance (CL_{int}) of seven reference compounds [atrazine, molinate, 4,4-bis(dimethylamino)benzophenone, 4-nonylphenol, 2,4-di-tert-butylphenol, trifluralin, benzo(a)pyrene] in hepatocytes freshly isolated from rainbow trout and rat were determined using a substrate depletion approach. Atrazine was metabolized in rat hepatocytes with an CL_{int} value of 3.81 (+/-) 1.96 mL/h/106 cells, whereas in trout hepatocytes, no apparent metabolism was observed within the incubation period (4 h). Intrinsic clearance values for all other compounds were 5.5- to 78.5-fold lower in trout hepatocytes than those in rat hepatocytes. Trout hepatic clearance (CL_H) values were extrapolated from the CL_{int} values using scaling factors and a well-stirred liver model. Biotransformation rate constants (k_M) of the compounds in trout were subsequently estimated and used as inputs to a kinetic model for the prediction of bioconcentration factors (BCF) in fish. Compared to the predicted BCF values that were obtained without consideration of fish biotransformation, the inclusion of estimated k_M values significantly improved fish BCF prediction for the reference compounds. Our work provided a framework for future bioaccumulation assessment of xenobiotics using combined information of the physical-chemical properties of the compounds and the biotransformation potentials of the compounds in fish.

711 PBDE AND HEXABROMODODECANE LEVELS IN THE U.S. POPULATION AND THE ENVIRONMENT AND PRELIMINARY PBDE ESTIMATES OF INTAKE FROM FOOD, DUST AND AIR.

A. J. Schecter¹, O. Paepke², R. Harris¹, A. Musumba¹, V. Ramakrishnan¹ and N. Shah¹. ¹Environmental Sciences, University of Texas School of Public Health, Dallas, TX and ²Eurofins -ERGO, Hamburg, Germany.

PBDE brominated flame retardants have been rapidly increasing the past few decades in US human milk and blood at the same time dioxin and PCB levels have been declining. Current US blood and milk levels vary from 4-400 ppb, lipid adjusted, in our studies. In household dust we find levels from 705 to 69,283 ppb with a median of 2,507. These are the highest levels reported worldwide. Food levels are highest in fish, median 616, range 11-3726 pg/g ww/day, then meat, median 190, range 39-1378 pg/g ww, and dairy, median 32, range 8-683 pg/g ww/day. However, dietary intake in the USA is highest from meat because of its predominance in the US diet. US adult dietary intake is approximately 1.0 ng/kg/day. Indoor air levels

are higher than outdoor levels. In our study, the indoor air level mean is 590, outdoors 125 and car 283 pg/cubic meters. We calculate 307 ng/kg/day dietary intake for nursing infant and 1.0 for adults. Air PBDE intake is about 0.109 ng/kg/day for adults. Median dust PBDE intake for adults is 7 ng/day with a range from 0.265 to 346. Under different intakes estimates within the range of levels measured, either diet or dust could contribute more towards PBDE body burden. This is unlike dioxins where food of animal origin is the route of almost all exposure. Hexabromocyclododecane was found at much lower levels in over 20 individually analyzed human milk samples than PBDEs and the alpha congener only was detected, unlike the commercial mixture where the gamma congener predominates.

712 LEAD EXPOSURE IN CHILDREN LIVING IN A SMELTER COMMUNITY FROM NORTHERN MEXICO: A FIVE YEARS FOLLOW-UP AFTER ENVIRONMENTAL INTERVENTION.

J. Duarte¹, M. L. Guerrero-Almeida¹, M. E. Cebrián², M. Rubio-Andrade¹, M. Rosales¹, G. García-Arenas¹, H. Villanueva¹, J. L. Rosado³, R. Meza¹, J. Candelas¹, R. Goytia-Acevedo¹, J. C. Acosta¹, B. E. Vazquez¹ and G. G. García-Vargas¹. ¹Faculty of Medicine, Universidad Juárez Estado de Durango, GNE-ZmeZ Palacio, Durango, Mexico, ²Toxicology Section, CINVESTAV-IPN, Mexico, D.F., Mexico and ³Universidad Autónoma de Querétaro, Querétaro, Mexico.

In 1997 we described the largest environmental problem due to lead exposure in children in Latino America associated with a smelter complex in Torreon City, northern Mexico. In 2001, our studies and other performed by the CDC estimated that more than 32,000 children were at risk to have ≥ 10.0 µg/dL of Pb in Blood (PbB). As a consequence the Smelter Company began an environmental intervention program which consisted in abatement of lead emissions and cleaning up the neighbourhoods around the smelter from contaminated dusts. In 2001 we began a follow up study in 569 children and measuring PbB concentrations at 0, 6, 18 and 60 months. Median (range) for PbB concentrations in each sampling time were: 0 months: 9.40 (2.3 - 43.82) µg/dL; 6 months: 8.65 (2.90 - 41.45) µg/dL; 18 months: 8.37 (2.4 - 35.8) µg/dL; 60 months: 4.51 (1.43 - 30.27) µg/dL. The decrease of PbB with respect to time fitted a linear regression model with a slope of 1.116 (µg/dL)/year ($p < 0.00001$). Equation: $y = -1.116(x) + 10.73$. Also, the significance of the relationship between lead and Zinc-protoporphyrin was gradually reduced, suggesting a relieve in this biomarker of biochemical effect. Although the tendencies of PbB values are encouraging, still there are neighbourhoods with prevalences of lead poisoning in children (PbB > 10.0 µg/dL) higher than 25 %, which means that more aggressive environmental interventions are needed to protect children from the well known adverse effects of lead.

713 POULTRY PRODUCTION AND ARSENIC IN DRINKING WATER FROM GROUNDWATER IN THE EASTERN AND SOUTHERN SHORE COUNTIES OF MARYLAND.

O. Nweke¹, E. Silbergeld², K. Bandeen-Roche², P. Lees², V. Aposhian³, L. Gallicchio², E. Guallar² and A. Alberg². ¹U.S. Environmental Protection Agency, Washington, DC, ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and ³University of Arizona, Tucson, AZ.

Arsenicals are utilized in poultry feeds for both prophylactic and growth promoting purposes. As a consequence, arsenic is excreted in waste and arsenic-containing broiler waste is applied to cropland in broiler producing areas as manure. This practice results in the environmental release of inorganic arsenic species into soils, and possibly groundwater. No previous studies have examined the association between land-applied arsenic-containing broiler waste and arsenic in drinking water from groundwater. This study utilized geographic analysis and multivariate modeling to examine this issue. Total arsenic levels were measured in tap water samples from private wells in the Eastern Shore of Maryland, a site of intensive poultry production and waste disposal, and the Southern Shore of Maryland, an area devoid of commercial broiler farms. Concentrations of arsenic in drinking water samples (Range: below DL-42 ppb) were evaluated in terms of two land use variables - percent cropland and the density of broiler operations. These variables were summarized within 1 Km radius of each drinking water sample. Results show that log arsenic concentration is significantly associated with percent cropland, after adjusting for other predictors ($p < 0.005$). No association was observed with broiler operation density. As further evidence for the role of broiler waste disposal, this association was observed in the region of the Eastern shore characterized by extensive crop production rather than broiler farms. These results are not unexpected, since poultry houses do not accumulate as much waste as land where wastes are frequently disposed. These data suggest that the use of arsenicals in broiler feed and the land application of arsenic-containing broiler waste may introduce arsenic into groundwater/drinking water in poultry producing areas. Research supported by a grant from the Cigarette Restitution Fund, Maryland.

714 DIETARY INTAKE OF PBDES BASED ON CONSUMPTION OF CATFISH IN SOUTHERN MISSISSIPPI.

L. Nguyen¹, D. Staskal², E. S. Williams¹, W. Luksemburg³, L. Haws², L. Birnbaum⁴, D. Paustenbach⁵ and M. Harris¹. ¹ChemRisk, Houston, TX, ²ChemRisk, Austin, TX, ³Alta Analytical Laboratory, El Dorado Hills, CA, ⁴U.S. EPA, ORD, ETD, Research Triangle Park, NC and ⁵ChemRisk, San Francisco, CA.

Polybrominated diphenyl ethers (PBDEs) are used as flame retardants in a wide variety of consumer products. Concerns surrounding these compounds are primarily due to their ubiquitous presence in the environment as well as human tissues, coupled with evidence indicating the potential for adverse effects. Despite these concerns, relatively few studies are available in the literature which characterize and quantify intake by humans. In this study, PBDE concentrations in Southern Mississippi catfish were measured in an effort to determine background levels and daily intake of these compounds from a primary food source for residents in this region of the United States. Sixty-one wild catfish samples were collected from local fisherman in March 2006 from five locations in Southern Mississippi and 28 farm-raised catfish samples were purchased from seven grocery markets. All samples were analyzed by Alta Analytical for 43 PBDEs (mono- through deca- congeners) using high resolution gas chromatography-mass spectrometry. PBDE concentrations and congener profiles varied by fish type and location. The average ΣPBDE concentration in all samples was 3.3 ng/g (wet weight); wild-caught catfish fillets had an average concentration of 3.85 ng/g whereas farm-raised catfish fillets had an average PBDE concentration of 0.45 ng/g. Using a range of consumption rates for catfish only, average PBDE concentrations, and an average body weight of 70 kg, intake values ranged from approximately 14-66 pg/kg bw for all fish types measured, 16-76 pg/kg bw for wild catfish fillets and 2-9 pg/kg bw for farm fillets. These results provide a reasonable data set describing the current background levels and daily intake of PBDEs from consumption of catfish representative of the Southeastern region of the United States. This abstract does not represent EPA policy.

715 OCCUPATIONAL EXPOSURES ASSOCIATED WITH PETROLEUM-DERIVED SOLVENTS CONTAINING TRACE LEVELS OF BENZENE.

P. R. Williams¹, J. Panko², K. Unice², J. Brown² and D. Paustenbach³. ¹ChemRisk, Boulder, CO, ²ChemRisk, Pittsburgh, PA and ³ChemRisk, San Francisco, CA.

Benzene may be present as a trace impurity or residual component of mixed petroleum solvents due to refining processes. In this presentation, we review the physical and chemical properties of various petroleum solvents and characterize the typical airborne concentrations of benzene associated with the handling or use of low-level benzene-containing products in the United States. Our assessment was based on (1) a review of the benzene content and flammability hazard of various petroleum solvents, (2) a review and synthesis of the publicly available literature on measured airborne concentrations of benzene associated with products that have typically contained <0.1% benzene since the late 1970s or early 1980s, and (3) indoor exposure modeling to predict breathing zone 8-hr TWA airborne concentrations of benzene under several hypothetical scenarios involving the use of benzene-containing mineral spirits. Our analysis showed that petroleum-derived products that may have historically contained trace levels of benzene, such as paints and paint solvents, printing solvents and inks, cutting and honing oils, adhesives, mineral spirits and degreasers, and jet fuel could have produced average TWA airborne concentrations of benzene that ranged from 0.002 to 0.2 ppm under standard use scenarios. Higher air concentrations (up to 1 or 2 ppm benzene) have occasionally been reported for specific products, particularly if the bulk content of the product was unknown (or suspected of being greater than 1%) or the sampling was performed under "worst case" solvent use patterns or workplace conditions. The overall weight-of-evidence indicates that only certain low volatility solvents (such as mineral spirits) can be safely used in spray applications or unventilated workplace conditions, and that petroleum-based products containing <0.1% benzene are not expected to produce 8-hr TWA airborne concentrations that exceed current occupational exposure limits under nearly all anticipated product use scenarios.

716 AIRBORNE DUST EXPOSURE ASSESSMENT FOR AUTOMOTIVE BODY SHOP WORK INVOLVING RESIN FILLERS AND ABRASIVES.

M. J. Fedoruk^{1,3}, B. D. Kerger², R. Bronstein¹ and R. O. Richter¹. ¹Exponent, Irvine, CA, ²Health Science Resource Integration, Tallahassee, FL and ³Center for Occupational and Environmental Health, University of California, Irvine, CA.

Airborne dust exposures were assessed for two body shop workers who performed routine body repair work using two different resin filler products and similar abrasive products (sandpapers and powered grinders). This pilot study compared the

composition of total and respirable atmospheric dusts associated with use of the resins and abrasive products with the composition of the original products. Observers documented the timing and nature of tasks performed, and general air flow characteristics. Personal and area samples were collected for total dust, respirable dust, total aluminum oxide and titanium dioxide, and both total and respirable talc. Scanning electron microscopy (SEM) was used to identify the physical characteristics of atmospheric dusts. A continuous dust monitor measured peak exposures from grinding, sanding, or compressed air blowing. Personal total dust concentrations ranged from 0.44 to 18 mg/m³ (background 0.1), while respirable dust ranged from 0.04 to 0.53 mg/m³. Airborne talc levels averaged 0.4% of total dust and < 1.6% of respirable dust, but comprised 10-45% by weight of the resin fillers. Titanium dioxide averaged < 0.9% of atmospheric total dust, but comprised 1-10% of the resin fillers. Airborne aluminum oxide (from abrasives) was not detected. SEM samples indicated most of the atmospheric total dust was comprised of irregular particles > 5 microns in diameter. Despite large differences in talc content between the two resin products, there was no significant difference in airborne respirable dust or talc levels during use. These findings suggest that airborne dusts generated during auto body work are largely comprised of larger particles > 5 microns, and that composition of these airborne dusts differs from the composition of the resin mixtures before curing.

717 AIRBORNE ASBESTOS MEASUREMENTS AND RISK ASSESSMENT FOR AGRICULTURAL ACTIVITIES ON AN EASEMENT WITH INSULATION DEBRIS FROM A PETROLEUM PIPELINE.

M. Roberts¹, M. Meschke², C. Woessner¹ and B. D. Kerger³. ¹Landmark Environmental, Denver, CO, ²ARCADIS G&M, Highlands Ranch, CO and ³Health Science Resource Integration, Tallahassee, FL.

The Arapahoe Pipeline Corridor is a 150 mile easement that contained a former petroleum pipeline spanning through agricultural and ranch lands in northeast Colorado and southwest Nebraska. The pipeline was removed for recycling but debris from the pipeline insulation comprised of chrysotile coated with tar was left in place. After the larger surface debris was removed, a study was undertaken to determine whether upper bound exposures during relevant agricultural land uses on the easement would pose appreciable cancer risk to local farmers or ranchers. A public record survey and numerous personal interviews were conducted to identify land use characteristics and activity patterns relevant to the easement. An airborne asbestos measurement study was carried out to assess potential upper bound exposures from activities that disturbed easement soils: tractor tilling of soils; harvesting with a combine; tractor mowing of grass; and driving a pick-up truck on the easement. NIOSH Method 7400 and the TEM asbestos structure counting rules of AHERA were applied for 49 air samples including personal samples of vehicle drivers and high volume area samples for each soil disturbance activity. The TEM results showed only 1 of 43 valid samples with detectable asbestos (1 chrysotile fiber, 1.4 x 0.11 microns, 0.0017 TEM f/ml). The data were validated and statistically analyzed assuming asbestos to be present at one half the detection limit for non-detects. Three upper bound agricultural exposure scenarios were formulated to simulate local farmer impacts from the easement, and the USEPA cancer potency factor of 0.23 per PCM f/ml was applied. Each 40 year exposure scenario showed upper bound cancer risks below 1 per 10 million from easement-related asbestos exposures. These findings suggest that small amounts of asbestos pipe wrap debris are unlikely to pose an appreciable inhalation cancer risk for common agricultural activities that disturb the impacted soils.

718 AIRBORNE ASBESTOS MEASUREMENTS AND RISK ASSESSMENT FOR AN ATHLETIC FIELD WITH TRANSITE BOARD DEBRIS FROM BARRICKS DEMOLITION.

B. D. Kerger¹, M. Roberts², G. Zellmer³, C. Cramer³ and E. Carman³. ¹Health Science Resource Integration, Tallahassee, FL, ²Landmark Environmental, Denver, CO and ³ARCADIS, Southfield, MI.

Barricks with chrysotile-containing transite board siding at a U.S. Coast Guard facility in Michigan were demolished and most of the debris removed several years before the land was donated to a city government for use as an athletic field. After the larger surface debris (> 2 sq. in.) was removed, a study was undertaken to determine whether upper bound exposures during relevant athletic field uses of this property would pose appreciable cancer risk to the athletic field users and maintenance personnel. An airborne asbestos measurement study was carried out to assess potential upper bound exposures from activities that disturbed the impacted soils: annual soil aeration, grass mowing, and use as a soccer field. NIOSH Method 7400 and the TEM asbestos structure counting rules of AHERA were applied for 56 air samples including personal samples of equipment operators/players and high volume area samples for each soil disturbance activity. The TEM results showed that

none of the 53 valid samples had detectable asbestos (detection limits 0.0017-0.043 TEM f/ml). The data were validated and statistically analyzed assuming asbestos to be present at one half the detection limit for non-detects. Three upper bound exposure scenarios were formulated to simulate field use and maintenance activities that disturb the impacted soils, and the USEPA cancer potency factor of 0.23 per PCM f/ml was applied. Upper bound cancer risk estimates were well below 1 per million for asbestos exposures related to field user or maintenance worker scenarios. These findings suggest that small amounts of transit board debris are unlikely to pose an appreciable inhalation cancer risk for common activities that disturb impacted soils at an athletic field.

719 RIBEPEIX: A COMPUTER PROGRAM TO OPTIMIZE SOME HEALTH RISKS AND BENEFITS RELATED TO FISH CONSUMPTION.

J. L. Domingo¹, A. Bocio¹, J. M. Llobet¹, A. Teixidó² and E. Mata². ¹Toxicology & Environment Health, "Rovira i Virgili" University, Reus, Spain and ²Health, Generalitat de Catalunya, Barcelona, Spain.

In recent years, and based on the importance of fish as a part of a healthy diet, there has been a notable promotion of fish and seafood consumption. For cardiovascular risk reduction in the general population, prestigious institutions such as the American Heart Association has suggested (among other dietary recommendations) to consume fish, especially oily fish, at least twice a week. Oily fish are rich in the omega-3 polyunsaturated acids EPA (eicosapentaenoic) and DHA (docosahexaenoic), which have shown to have protective effects in preventing coronary heart disease among other important health benefits. However, a number of recent studies performed in different regions and countries have shown that fish consumption may be also a potential source of exposure to chemical pollutants, some of them with well known adverse effects on human health. Recently, we determined in 14 edible marine species (the most consumed in Catalonia, Spain) the concentrations of EPA and DHA, as well as those of a number of chemical contaminants: Cd, Hg, Pb, polychlorinated dibenzo-p-dioxins and furans, PCBs, hexachlorobenzene, polycyclic aromatic hydrocarbons, polychlorinated naphthalenes, polybrominated diphenylethers and polychlorinated diphenylethers. To quantitatively establish the intake of these pollutants (risks) versus that of EPA + DHA (benefits), we designed a simple computer program, RIBEPEIX. The concentrations of EPA, DHA, and the chemical pollutants have been used as database of the program. The goal of this presentation is to show to the audience how RIBEPEIX may be used as an easy tool to optimize fish consumption: most suitable species, frequency of consumption, and size of meals. RIBEPEIX can be useful not only for professionals (cardiologists, general physicians, nutritionists, etc.), but also for the general population, as it will be available (free) in Internet.

720 DOCOSAHEXAENOIC ACID CONSUMPTION SUPPRESSES MULTIPLE CREB PHOSPHORYLATION PATHWAYS IN MURINE PERITONEAL MACROPHAGES.

Y. Shi^{1,2} and J. J. Pestka^{1,2,3}. ¹Food Science and Human Nutrition, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.

Fish oil ingestion has been reported to have value in suppressing several chronic inflammatory diseases. Consumption of docosahexaenoic acid (DHA), a major component of fish oil, inhibits induction of interleukin-6 (IL-6) expression by the trichothecene deoxynivalenol (DON) in peritoneal macrophages by decreasing binding activities of transcription factors, most notably cAMP regulated element binding protein (CREB). The purpose of this study was to test the hypothesis that the activities of CREB kinases are impaired in macrophages from DHA-fed mice. Peritoneal macrophages were collected from B6C3F1 mice that were fed for 4 to 6 wk with AIN-93G diet supplemented with 6% high oleic acid safflower oil (control diet) or 6% fish oil (DHA diet). Isolated peritoneal macrophages were treated with DON (250 ng/ml), forskolin (50 μ M) or ionomycin (5 μ M) to activate CREB through protein kinase B (PKB or Akt), mitogen and stress activated protein kinase (MSK) and ribosomal S6 kinase (RSK) (by DON), protein kinase A (PKA) (by forskolin) and calcium/calmodulin-activated protein kinase (CaMK) (by ionomycin) pathways respectively. Proteins were extracted at different time points (0, 15 and 30 min after treatment) and analyzed by Western analysis. Induction of CREB phosphorylation by DON, forskolin or ionomycin at 15 and 30 min was suppressed in macrophages from DHA-fed mice. DON-induced phosphorylation of Akt, MSK and RSK as well as Akt kinase activity were also inhibited in macrophages from mice consuming DHA. Taken together, the data suggest that DHA consumption alters macrophage programming rendering them less capable of CREB activation through multiple pathways induced by chemical stressors. DHA suppression of CREB-activated IL-6 expression might be a critical mechanism for the prevention of inflammatory and autoimmune diseases (Supported by Public Health Service Grants DK58833).

721 CARDIOMYOPATHIC CHANGES INDUCED BY 2-DEOXYGLUCOSE, A POTENTIAL MIMETIC OF CALORIE RESTRICTION.

S. Poosala, R. Minor, R. DeCabo and D. Ingram. NIH, Baltimore, MD. Sponsor: J. Vodela.

This study was designed to test whether the glucose analogue, 2-deoxy-D-glucose (2-DG), which may mimic some of the effects of caloric restriction is safe and effective with chronic use. Caloric restriction (CR) has been proven to extend life span, delay the incidence of several age-related diseases, thereby leading to healthy aging. To effectively obtain the desired beneficial effects of CR, 30% to 40% reduction in food intake is necessary. If a compound such as 2-DG can mimic this effect, then the unlikely paradigm of consuming 30% to 40% less (30-40% CR) can be negated. We used three different concentrations of 2-DG (0.04%, 0.2% and 0.6% w/w in the chow) from two different sources (Sigma and Regent). Two different rat strains (Fisher-344 and Brown Norway) were administered 2-DG in their ad libitum diets for six weeks at the concentrations mentioned. A control group for each strain was included as well. Cardiac muscle was assessed for several parameters by histopathology on hematoxylin and eosin (H&E) and scored on a scale of 0 to 4. A score of 0, which is typical of normal cardiac muscle and a score of 4 which is typical of cardiomyopathic changes was attributed to the sections. The cardiomyopathic changes in the 4+ category included observations such as very thin fibers, loss of fibers, distinct vacuolations dispersed in several fibers, distinct loss of striations and general architecture, expanded interstitial space, or infiltration of inflammatory cells and fibroblasts. Substantial cardiomyopathic changes were seen in both strains at 0.6% 2-DG. However, the changes were more pronounced in Fisher-344 rats. Both 0.2% and 0.04% groups in both strains showed cardiomyopathic changes with score ranges from 0 to 1.33. The control groups showed no observable cardiomyopathic changes on histopathology. We conclude that 2-DG is toxic at the 0.6% and 0.2% doses and we need to see longer exposure with more animals to determine if the low dose would be toxic as well.

722 DERIVATION OF AN ACCEPTABLE DAILY INTAKE (ADI) USING A BENCHMARK DOSE (BMD) APPROACH FOR A VETERINARY PHARMACEUTICAL RESIDUE IN FOOD-PRODUCING ANIMALS.

J. Lamb¹, B. Ryan², D. Gaylor³, K. Hentz¹ and J. Gerhart⁴. ¹THE WEINBERG GROUP INC, Washington, VA, ²Experimur LLC, Chicago, IL, ³Gaylor and Associates LLC, Eureka Springs, AR and ⁴Meril Limited, Duluth, GA.

The Committee for Veterinary Medicinal Products (CVMP) in the European Agency for the Evaluation of Medicinal Products (EMA) has traditionally relied on NO(A)ELs to establish ADIs for residues of veterinary pharmaceuticals found in the edible tissues of food-producing animals. Recently, an ADI was proposed based on the BMD approach for firocoxib use in horses. Horses are considered a food-producing animal in the EU. Firocoxib is an orally administered non-steroidal COX-2 anti-inflammatory drug used for the control of pain, inflammation, and lameness. Based on the comprehensive set of laboratory animal safety studies conducted in support of EU registration, developmental toxicity in rabbits and reproductive toxicity in rats were considered the most appropriate for establishing a point-of-departure for the ADI. Given dose-responses for the most sensitive endpoints and effects at or near the lowest dose levels tested, the BMD approach was considered to be an appropriate and precise method for assessing potential human health risk. Several measures of fetal viability (rabbit developmental toxicity study) and pup mortality (one-generation rat reproductive toxicity study) were modeled to calculate BMDs and benchmark dose limits (BMDLs). The NLogistic Model provided the best goodness-of-fit for both data sets. The most conservative BMDL was 0.34 mg/kg/day from the rabbit developmental toxicity study based on a 1% Extra Risk Level. Use of a 200-fold uncertainty factor (UF) was recommended, resulting in a proposed ADI of 1.7 μ g/kg/day. An independent assessment of the reproductive and developmental data was conducted in the EU and an alternative BMD proposed. An unconstrained Weibull model resulted in a more conservative BMDL of 0.043 mg/kg/day based on the rat reproductive toxicity data. The CVMP applied a UF of 200 to this BMDL and proposed an ADI of 0.215 μ g/kg/day, which is pending final European Commission approval.

723 PHARMACOKINETIC AND DEVELOPMENTAL SAFETY EVALUATION STUDIES OF METHYLSULFONYLMETHANE IN RATS.

R. A. Marulka¹ and B. Magnuson². ¹Burdock Group, Vero Beach, FL and ²Burdock Group, Washington, DC.

Methylsulfonylmethane (MSM) is sold as a dietary supplement to promote joint health. Studies were undertaken to determine the pharmacokinetics of acute MSM in male rats, and its effect in rats when administered orally to pregnant rats during the period of major organogenesis (days 6 through 20).

Male Sprague-Dawley rats were administered a single oral dose of [35S]-MSM (500 mg/kg) and blood levels of radioactivity were determined at different time points for up to 48 hours, and tissue, urine, and fecal radioactivity levels were measured at different time points for up to 120 hours. Oral [35S]-MSM was rapidly and efficiently absorbed with a mean T_{max} of 2.1 hours, and a $t_{1/2}$ of 12.2 hours. Approximately 86% of the dose was recovered in the urine after 120 hours. No quantifiable levels of radioactivity were found in any tissues after 120 hours, indicating complete elimination of [35S]-MSM. Radioactivity concentrations seen in the soft tissues were similar to that seen in the central blood compartment, with a mean MSM blood concentration of 63.7 $\mu\text{g eq/ml}$. In the subsequent developmental study, four groups of 24-25 timed-bred primiparous female rats were administered 0, 50, 500, or 1000 mg MSM/kg/day via gavage on gestation days 6 through 20. Maternal feed consumption, body weight, body weight gain, uterus weight and corrected body weight/body weight gain were unaffected by treatment. No evidence of maternal toxicity or litter differences was detected. No evidence of fetal mortality, toxicity, or growth and structural alterations was observed at any dose level. The results of this study suggest that [35S]-MSM is rapidly absorbed, well distributed, and completely excreted from the body, and has a no-observed-adverse-effect level (NOAEL) for maternal and developmental toxicity of at least 1000 mg/kg/day.

724 ASSESSING TCDD WASTING SYNDROME IN AN *IN VIVO* OBESITY MODEL.

M. La Merrill^{1,2,3}, L. S. Birnbaum^{1,4} and D. W. Threadgill^{1,2,3}. ¹Curriculum in Toxicology, UNC-CH, Chapel Hill, NC, ²Curriculum in Genetics, UNC-CH, Chapel Hill, NC, ³Center for Environmental and Health Susceptibility, UNC-CH, Chapel Hill, NC and ⁴NHEERL, U. S. EPA, Research Triangle Park, NC.

TCDD is a by-product of incineration commonly found as a microcontaminant in the food supply. The TCDD wasting syndrome, characterized by prolonged weight loss, has been examined for decades. Much of this work has focused on high dose *in vivo* and *in vitro* studies. This body of work suggests that TCDD inhibits adipogenesis and that these effects are not rescued by high fat diet. We hypothesized that a low dose of TCDD during a developmentally sensitive window would induce the TCDD wasting syndrome in mice on high and low fat diets. FVB/NJ females were dosed with 1 $\mu\text{g/kg}$ TCDD or vehicle on gestational day 12.5. At birth, cages were placed on standardized low or high fat diets. Body weights were measured weekly through weaning and monthly thereafter. Percent body fat was measured at 5 weeks, 3 and 6 months of age. Fasting blood glucose was measured at 5 weeks, 4 and 6 months of age. Body weights were higher in mice on high fat diet compared to low fat diet throughout the lifespan evaluated. However, TCDD exposure did not alter their body weights. High fat diet increased percent body fat at 3 months and blood glucose at 4 months. Again TCDD had no effect on these measures. In summary developmental low dose TCDD has no overall impact on classic wasting syndrome phenotypes, both during the time period in which TCDD is expected to be in the tissue and long after it is expected to be cleared. This longitudinal study of the affect of low dose TCDD on the wasting syndrome suggests that the wasting syndrome is a high dose phenomenon. (THIS ABSTRACT DOES NOT REFLECT AGENCY POLICY.)

725 CHEMICAL AND TOXICOLOGICAL EVALUATION OF FUMONISIN B₁ IN EXTRUDED CORN GRITS.

K. A. Voss¹, L. S. Jackson², A. Bianchini³, L. B. Bullerman³, M. A. Hanna³ and D. Ryu⁴. ¹Toxicology & Mycotoxin Research Unit, USDA Agricultural Research Service, Athens, GA, ²FDA National Center for Food Safety & Technology, Summit-Argo, IL, ³Food Science & Technology, University of Nebraska, Lincoln, NE and ⁴Department of Nutrition & Food Sciences, Texas Women's University, Denton, TX.

Extrusion cooking reduces fumonisin concentrations in corn but its effect on fumonisin toxicity is unknown. Batches of corn grits were contaminated by spiking with fumonisin B₁ (FB₁) (SG, 43 ppm) or by fermentation (FG1, 46 ppm FB₁; FG2 48 ppm FB₁) and then extruded with and without the addition of glucose (10% w/w). FB₁ concentrations of extruded SG (E-SG), extruded FG1 (E-FG1) and extruded FG2 (E-FG2) were 34 (31% reduction), 29 (37%), and 51 ppm (no reduction). Glucose increased reductions: FB₁ concentrations in E-SG plus glucose (E-SG+), E-FG1 plus glucose (E-FG1+) and E-FG2 plus glucose (E-FG2+) products were 9.8 (77% reduction), 5.9 (87%), and 11.7 ppm (76%), respectively. Significant amounts (20-38 ppm) of the FB₁-glucose reaction product, *N*-(deoxy-D-fructosyl-1-yl) FB₁ were found only in the glucose-supplemented products. SG, FG1 or FG2 (50% w/w in rodent chow) and equivalent weights of each extruded material were fed to male Sprague-Dawley rats for 4 weeks to assess toxicity. Control groups were fed (50% w/w) uncontaminated grits or extruded uncontaminated grits. Relative kidney weights of rats fed E-FG2+ (0.83% BWt) and control diets (0.79-0.82% BWt) were similar and greater than those of the other groups (0.72-0.76% BWt). Microscopic kidney lesions were typical of those caused by

FB₁. Those found in rats fed E-FG1+ were scored as less severe (mean score = 1.2) than those from groups fed FG1 or E-FG1 (3.0). Comparison of kidney lesions from the SG, E-SG, and E-SG+ or the FG2, E-FG2 and E-FG2+ groups revealed no differences; their histopathology scores averaged 2.6-3.0. In summary, extrusion with glucose significantly reduced FB₁ in the grits (>75%) but had an inconsistent effect on *in vivo* toxicity. Extrusion must be further evaluated to determine if it is a suitable method for reducing fumonisins in foods.

726 TOXICOLOGICAL EVALUATION OF *FUSARIUM VERTICILLIOIDES* CULTURE MATERIAL NIXTAMALIZED IN THE PRESENCE AND ABSENCE OF CORN MATRIX.

T. D. Burns¹, M. E. Snook², R. T. Riley^{1,2}, T. R. Mitchell² and K. A. Voss^{1,2}. ¹Interdisciplinary Toxicology Program, University of Georgia, Athens, GA and ²Toxicology & Mycotoxin Research Unit, ARS-USDA, Athens, GA.

Cooking-steeping corn in alkaline water (nixtamalization) reduces the amount of detectable fumonisin B₁ (FB₁) in masa and tortilla products. However, reductions might be overestimated if FB₁ reacts with the corn matrix to form undetectable reaction products. The purpose of this study was to investigate if corn matrix facilitates the reduction of measurable FB₁ during nixtamalization and reduces toxicity of the cooked material. *Fusarium verticillioides* culture material (CM) was nixtamalized in the absence (NCM) and presence (NCMC) of ground uncontaminated corn. Sham nixtamalization (cooking-steeping in water) of the CM without (SCM) and with corn (SCMC) was also done. Equivalent weights of each material were added to rodent chow and fed to male SD rats for 1 (n=3/group) or 3 weeks (n=5/group) to evaluate toxicity. Control groups were fed chow plus uncontaminated corn (UC), chow plus nixtamalized uncontaminated corn (NUC), or uncooked CM. FB₁ concentrations of the diets were: UC = 0.15, NUC = 0.16, CM = 9.08, NCM = 2.08, NCMC = 0.49, SCM = 1.19 and SCMC = 0.95 ppm. Hydrolyzed FB₁ concentrations were: UC = 0.07, NUC = 0.09, CM = 0.25, NCM = 1.27, NCMC = 1.60, SCM = 0.55 and SCMC = 0.37 ppm. No differences in body weights, food consumption or relative kidney weights were found during the feeding study. Apoptotic kidney lesions typical of fumonisins were found in all groups except UC and NUC. Compared to the CM group (mean apoptotic cell counts at week 3 = 207 $\pm$ 105 (SD)), fewer apoptotic renal epithelial cells were found in rats from all other groups. Furthermore, apoptosis counts in the NCMC group (22 $\pm$ 8) were less than those of the NCM group (44 $\pm$ 12). Apoptosis counts of the SCM and SCMC groups were similar, averaging 17 $\pm$ 5 and 19 $\pm$ 6. These findings suggest that the corn matrix facilitated reduction of measurable FB₁, possibly through matrix binding, and further reduced toxicity of nixtamalized CM.

727 GENE EXPRESSION PROFILING AND DIFFERENTIATION ASSESSMENT IN PRIMARY HEPATOCYTE CULTURES, ESTABLISHED HEPATOMA CELL LINES, AND LIVER TISSUES.

K. M. Olsavsky¹, J. Page¹, M. Johnson¹, S. Strom² and C. Omiecinski¹. ¹Department of Veterinary and Biomedical Sciences, Penn State University, University Park, PA and ²Department of Pathology, University of Pittsburgh, Pittsburgh, PA.

Primary hepatocytes are frequently used as a viable *in vitro* model for the liver *in vivo*. However, the culture conditions reported vary considerably, with associated variability in performance. In this study, we used microarray gene expression profiling to evaluate the differentiation character of a highly defined serum-free two-dimensional sandwich culture model for primary human hepatocytes, one that configures hepatocytes with collagen I as the substratum together with a dilute extracellular matrix (Matrigel) overlay and nanomolar levels of dexamethasone. Expression profiles were compared to those exhibited by human liver tissues and by cultures of the hepatoma-derived cell lines HepG2 and Huh7. Analyses using the PANTHER database (ABI) identified biological processes significantly overrepresented among probe sets differentially expressed in the *in vitro* systems vs. those in human liver. Categories relevant to liver function, such as 'detoxification' and 'steroid metabolism,' exhibited altered function in the *in vitro* models. Within each category, hepatocytes maintained expression unchanged from the liver for more than 77% of the probe sets, representing such genes as *CYP2B6*, *CYP3A4*, *ABCB11*, and *SLC22A1*. In contrast, HepG2 and Huh7 cells were unchanged from the liver tissues for fewer than 48% and 55% of these probe sets, respectively. Further, hierarchical clustering of the hepatocytes, but not the cell line samples, changed from donor-specific to treatment-specific when the probe sets were filtered to focus on the phenobarbital (PB)-inducible genes, indicating that only the hepatocytes exhibited responsiveness to PB. These data support the use of a highly defined 2-D primary hepatocyte culture system that establishes gene expression endpoints closely resembling that of liver, including maintenance of responses to inducer challenge. Supported by NIEHS ES11387 and NIGMS GM66411.

728 PREDICTING IN VIVO OUTCOMES FROM IN VITRO mRNA PROFILING.

K. M. Goldstein¹, R. A. Jolly², G. H. Searfoss², T. P. Ryan¹, C. E. Thomas² and S. T. Estrem¹. ¹Department of Integrative Biology, Lilly Research Laboratories, Greenfield, IN and ²Department of Investigative Toxicology, Lilly Research Laboratories, Greenfield, IN.

In vivo rodent studies are used during the lead optimization phase of drug development to evaluate the toxicity of new candidate drugs. These studies require a significant amount of test article and live phase resources, making them impractical for screening large numbers of compounds earlier in development. Alternatively, *in vitro* assays employing rat primary hepatocytes have been evaluated as surrogates for short term *in vivo* toxicity studies using biochemical, morphological, and genomic endpoints. Although mechanistic data obtained *in vitro* has proven useful in resolving issues with individual molecules, the application of genomics to the rat primary hepatocytes model in compound screening has been more elusive. Here, we demonstrate that although mRNA profiles from *in vitro* studies did not correlate well with *in vivo* profiles, similar signaling and response pathways were modulated based on functional grouping of altered transcripts. For example, treatment with a PPAR coagonist, resulted in 1027 transcriptional changes *in vivo* and 813 changes *in vitro*, with only 33 transcripts in common. When evaluated from a mechanistic view, we observed a significantly higher concordance in GO Biological Process terms, which is one method for functional grouping of array data. These changes indicate that both *in vivo* and *in vitro*, hepatocytes undergo similar physiological responses to xenobiotics despite minimal overlap in the individual genes modulated by compound treatment. From these studies, we have demonstrated that gene expression in primary rat hepatocytes can be used to identify compound associated hepatic liabilities, thus enabling prioritization of molecules to bring forward for *in vivo* evaluation in drug development.

729 GENE PROFILING IN WILD TYPE AND PPAR α NULL MICE EXPOSED TO PFOA.

M. Rosen, B. D. Abbott, J. R. Schmid, R. D. Zehr, K. P. Das, C. J. Wolf and C. S. Lau. RTD/NHEERL/ORD, U.S. EPA, Research Triangle Park, NC.

Perfluorooctanoic acid (PFOA) is a perfluoroalkyl acid used in a variety of commercial applications. Concerns have been raised because PFOA is ubiquitous in the environment and can be detected in human tissues. PFOA is a rodent carcinogen and a developmental toxicant in mice. While the mode of action (MOA) of PFOA toxicity is not clear, this compound is a PPAR α agonist and a peroxisome proliferator. For this reason, liver tumors in rodents are thought to be related to PPAR α signaling. However, PFOA also increases liver weight in the PPAR α null mouse. To further study the MOA of PFOA, wild type and PPAR α null mice were orally dosed with either PFOA (1 or 3 mg/kg), Wy14,643 (50 mg/kg), or vehicle for 7 days. Wy14,643 was included as a known PPAR α agonist. Animals were euthanized, livers weighed, and liver samples collected for preparation of total RNA. Gene profiling analysis was conducted using Applied Biosystems microarrays on 4 animals per group. In wild type mice, Wy14,643 induced many of the predicted PPAR α related changes in genes associated with lipid metabolism, sterol biosynthesis, bile acid biosynthesis, retinol metabolism, and inflammation. Wy14,643 had little effect on the PPAR α null mouse. On the other hand, while it was clear from the response of the wild type mice that the majority of PFOA related changes were mediated through PPAR α , changes in gene expression were nonetheless observed in the knockout animal. These included 177 genes that were similarly altered in both wild type and knockout mice. Among the up-regulated genes were several Cyp2 and Cyp3 genes, Acyl CoA dehydrogenase (long chain), Cyclin D1, Aox1, Dbi, Aldh1a7, and Cyp4a10. Included in the group of down-regulated genes were Complement components 4A and B, Complement factors B and H, Cathepsin C, and Baat. These results indicate that while PFOA influences certain biological processes such as lipid homeostasis, inflammation, and cell cycle progression via a PPAR α mediated MOA, there also appears to be a non-PPAR α related component to this response. This abstract does not necessarily reflect EPA policy.

730 PREDICTIVE PROFILING OF HEPATOTOXICITY USING GENOMIC CLUSTER AND NETWORK ANALYSIS.

T. Fukushima, R. Kikkawa, Y. Hamada and I. Horii. Pfizer Global & Research Development, Taketoyo, Japan. Sponsor: M. Kurata.

In the present study, in order to estimate the usability of genomic approaches to predict hepatotoxicity with short-term treatment, we treated male rats with acetaminophen (APAP), carbon tetrachloride (CL), amiodarone (AD) or tetracycline at toxic doses. At 6 or 24 hours post dosing, their livers were removed and used for pathological examination and genomic analysis. Histopathologically, no noteworthy changes were observed at 6 hr, but some were detected at 24 hr except in the AD group. Regarding the genomic analysis, to confirm the reliability of the

GeneChip data, we performed hierarchical cluster analysis by using S-plus. The individual microarray data were classified clearly into 5 treatment-related clusters at 24 hr as well as at 6 hr when no remarkable morphological changes were detectable. In the gene expression analysis using GeneSpring, transcription factor genes, as well as oxidative stress- and lipid metabolism-related genes, were markedly affected in all treatment groups at both time points when compared with their expression in the control group. Finally, we investigated gene networks involving the above affected genes by using Ingenuity Pathway Analysis. Down-regulation of lipid metabolism-related genes regulated by SREBP1 was observed in all groups at both time points, whereas up-regulation of oxidative stress-related genes regulated by Nrf2 was found in the APAP and CL treatment groups. From the above findings, for the application of genomic approaches to predict hepatotoxicity, we considered that cluster analysis for classification and early prediction of hepatotoxicity and network analysis for investigation of toxicological biomarkers would be useful. Currently, we investigate the protein expression of above two transcription factors in order to support our consideration.

731 THE SEARCH FOR TOXICOGENOMICS BIOMARKERS BRIDGING BETWEEN *IN VIVO* AND *IN VITRO*: ANALYSIS OF THE HEPATOTOXICITY OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS.

D. Kakiuchi¹, A. Ono¹, T. Miyagishima¹, T. Urushidani¹ and T. Nagao². ¹Toxicogenomics Project, National Institute of Biomedical Innovation (NIBIO), Ibaraki, Osaka, Japan and ²National Institute of Health Science (NIHS), Tokyo, Japan.

Gene expression analysis opens new perspectives in toxicology to identify mechanisms of toxicity and biological response and to improve toxicity assessment. Toxicogenomics project (TGP), a 5-year project started in 2002, is a collaborative project by NIBIO, NIHS and 15 pharmaceutical companies in Japan. The goal of our project is to construct a large-scale database of over 150 drugs exposed to rats (in vivo, in vitro) and to human (in vitro), to develop a system that will forecast the toxicity of new chemical in the early stage of drug development, hopefully by in vitro experiments. TGP database integrates gene expression data analyzed by Affymetrix GeneChip with traditional toxicological endpoints including blood biochemical, hematological, and pathological data.

In the present study, to search for genes, which consistently changed in vivo and in vitro, gene expression data of rat livers and hepatocytes treated with non-steroidal anti-inflammatory drugs (NSAIDs; aspirin, diclofenac, ibuprofen, indomethacin, naproxen, and sulindac) were selected. By multivariable analysis of these expression data, 45 probe sets that showed dose-dependent expression changes by the exposure to NSAIDs were extracted. These 45 probe sets contained endoplasmic reticulum (ER) stress markers (erp70, grp94, etc.). Our results are in accordance with previous reports, that long-term treatment of NSAIDs causes apoptosis through ER stress in various types of cells, and this is independent of their cyclooxygenase activity. We suggest that the in vitro expression profile of these 45 probe sets could be used to predict in vivo phenotypes caused by long-term treatment of NSAIDs, and that they would be practical biomarkers in drug research and development. At present, pathological examination by electron microscopy is in progress confirming the occurrence of ER stress in rat livers treated with single administration of NSAIDs.

732 HEPATOCELLULAR INJURY AND GENE EXPRESSION ANALYSIS IN LIVERS OF RATS CO-TREATED WITH LIPOPOLYSACCHARIDE AND CHLORPROMAZINE.

W. Zou¹, S. S. Devi², L. Lecureux³, L. Lehman-McKeeman³, D. Nelson³, R. A. Roth² and P. E. Ganey². ¹Departments of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, ²Departments of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and ³Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.

Idiosyncratic drug reactions are adverse responses that typically occur in a small fraction of the population taking therapeutic drugs. Chlorpromazine (CPZ) is a phenothiazine drug that was associated with idiosyncratic hepatotoxicity during its use as an antipsychotic drug. Previously, we demonstrated that cotreatment of rats with small doses of lipopolysaccharide (LPS) and CPZ produces liver injury that mimics human idiosyncratic responses to this drug. In this study we tested the hypothesis that unique gene expression changes occur in livers near the time of onset of injury in rats treated with LPS plus CPZ. Rats were treated with a nonhepatotoxic dose of LPS (1.1X 10⁶ EU/kg, iv) or its saline vehicle. Two hours thereafter they were given either CPZ (70mg/kg, ip) or its saline vehicle. They were killed 2 or 6 h after drug treatment, and serum and liver samples were collected. Alanine aminotransferase (ALT) activity, an indicator of hepatic parenchymal cell injury, increased significantly in sera of LPS/CPZ-cotreated rats compared to rats receiving

LPS or CPZ alone. Microarray analysis was performed on RNA isolated from livers. Principal component analysis and hierarchical clustering of gene expression distinguished rats treated with LPS/CPZ or CPZ from those treated with LPS alone. Expression of a large number (>7,000) of genes was changed by CPZ, irrespective of LPS cotreatment. Expression of many inflammatory genes, including NF-kappa B, several chemokines, Kruppel-like factor 4 and MMP9, were changed by LPS/CPZ treatment. These results suggest that gene expression changes after cotreatment with LPS and CPZ are driven largely by CPZ, but LPS cotreatment affects expression of several genes potentially related to the hepatotoxic response. (Supported in part by GM075865.)

733 GENE EXPRESSION ANALYSIS OF LIVERS FROM RATS CO-TREATED WITH LIPOPOLYSACCHARIDE AND AFLATOXIN B1.

S. S. Devi¹, J. P. Luyendyk¹, M. J. Liguori², E. A. Blomme², J. F. Waring², P. E. Ganey¹ and R. A. Roth¹. *Pharmacology and Toxicology, Michigan State University, East Lansing, MI and ²Abbott Laboratories, Abbott Park, IL.*

Aflatoxin B1 (AFB1), causes both acute hepatotoxicity and hepatic neoplasia in exposed humans and rats. Previous studies in rats demonstrated that a small, noninjurious dose of lipopolysaccharide (LPS) augments the hepatotoxicity of AFB1 through activation of inflammatory cells and production of soluble inflammatory mediators. We tested the hypothesis that hepatic gene expression changes could be distinguished among vehicle-, LPS-, AFB1- and AFB1/LPS-treated rats before the onset of liver injury in the AFB1/LPS-treated rats. Male, Sprague-Dawley rats (250-350 g) were treated with 1 mg AFB1/kg, ip or its vehicle (0.5% DMSO/saline) and 4 h later with either E. coli LPS (7.4 x 10⁶ EU/kg, iv) or its saline vehicle. Animals were sacrificed at 6 h and 12 h after AFB1 treatment, and liver samples were collected for evaluation of liver injury and isolation of RNA. Hepatic parenchymal cell injury, as estimated from increases in serum alanine aminotransferase (ALT) activity, was observed only in rats cotreated with AFB1/LPS and only at 12 h. Hierarchical clustering of gene expression data from the 6-h (i.e. before the elevation of ALT) grouped animals distinctly according to treatment. Less distinct clustering was observed at the 12-h. Relative to treatment with AFB1 or LPS alone, AFB1/LPS cotreatment altered hepatic expression of numerous genes, including those encoding products involved in inflammation and cell death, such as early growth response gene-1, monocyte chemoattractant protein-1, Cxcl2, and interleukin-6. These data suggest that enhanced expression of inflammatory genes by cotreatment with AFB1 and LPS contributes to liver injury (Supported in part by GM075865).

734 TOXICOGENOMICS AND PROTEOMICS ANALYSES FOR HEPATOCARCINOGENICITY OF THE STRUCTURAL ISOMERS, 2, 4- AND 2, 6-DIAMINOTOLUENE IN RATS.

N. Moriwaki, Y. Kawakami, Y. Kawano, K. Nakayama, M. Tsuchitani and M. Sekijima. *Kashima Laboratory, Mitsubishi Chemical Safety Institute, Kamisu, Ibaraki, Japan.*

The aromatic amines, 2,4-diaminotoluene (2,4-DAT) and 2,6-diaminotoluene (2,6-DAT) are structural isomers that are mutagenic in Ames test (+S9) but have different results in rat carcinogenicity bioassays. In the rat liver UDS and RDS tests, only 2,4-DAT was reported to be positive. To elucidate the difference, rat hepatocarcinogenicity using both DATs, toxicogenomics with GeneChip, and proteomics with 2D-DIGE analyses were performed. Male Sprague-Dawley rats (5 wk) were administered by oral gavage with 2,4-DAT (2, 10, 50 and 250 mg/kg) or 2,6-DAT (1.6, 8, 40 and 200 mg/kg) and sacrificed 3, 6, 9, 24 and 48 hrs after the dose to obtain the liver and serum samples. According to serological and liver histological examinations, no toxicity was observed except for 2,4-DAT-administered group at the maximum dosage (250 mg/kg). In gene and protein expression profiling, both DATs affected aromatic compound-inducible P450 (CYP1A1), steroid metabolism, and cytosolic fatty acid beta-oxidation. However, ATM-p53 (DNA damage/repair), Keap1/Nrf2 (oxidative stress response) signaling pathways, and liver regeneration (cell proliferation, cytoskeleton, ribosome biogenesis, protein folding etc.) were activated at 2,4-DAT in the 50 and 250 mg/kg groups as compared to the 2,6-DAT groups. Activation of these pathways may be reflected in the results of the rat liver UDS and RDS by 2,4-DAT. In addition, 2,4-DAT caused a decrease of Sult1c1/2, which is known to be involved in carcinogenesis of the aryl amine compound, 2-AAF. We hypothesized that Sult1c1/2 may play an important role for DAT-induced rat hepatocarcinogenicity, that is, 2,4-DAT was activated to an electrophilic metabolite that react with DNA and/or protein by sulfate conjugation, whereas 2,6-DAT lacks metabolic activation.

735 DETECTION OF POSSIBLE TOXIC RESPONSE AT DOSE LEVELS BELOW NOAEL FROM DOSE-DEPENDENT CHANGES IN GENE EXPRESSION PROFILE.

R. Ise¹, M. Narahara², T. Nakamura¹, Y. Fukuya¹, T. Obara², T. Saito², H. Tsusaki¹, S. Kanazashi¹, Y. Harada² and R. Nagata¹. *¹Shin Nippon Biomedical Laboratories, Ltd., (SNBL), Tokyo, Japan and ²Hitachi, Ltd., Life Science Group, Saitama, Japan.*

The use of toxicogenomic approaches in the evaluation of candidates for the drug discovery decision-making process and in the prediction of toxicity at an early stage of drug development is widely accepted. However, there are few reports that describe any relationship between dose-dependent gene expression and toxicological findings, including histopathological changes. In the present study, we examined dose-dependent effects on gene expression of various hepatotoxic drugs including fibrates (clofibrate and gemfibrozil). The gene expression profile was then compared with changes in the conventional toxicological parameters. Each drug was administered in three oral doses (low, middle and high) by single dosing or by repeated dosing for 4 days to male SD rats, aged 7 weeks. At necropsy 6 hours after the final administration, blood samples were drawn for hematology and biochemistry examinations, and the livers were collected for gene expression analysis and histopathology. DNA microarray analysis revealed that genes related to beta-oxidation of fatty acid metabolism were up-regulated dose dependently from the low dose to high dose level in the single and repeated dose studies of fibrates and benzobromarone, which is reported to have adverse effects similar to those of fibrates. These genes are considered to be important for peroxisome proliferation through PPARalpha-mediated signaling. After clofibrate and benzobromarone treatment, changes in the gene expression profile were associated with histopathological findings in the liver (eosinophilic and other proliferative changes) at the high dose level in the repeated dose study, but not at the low dose level. It was concluded from these results that dose-dependent changes in gene expression profile could allow detection of possible toxic response even in the absence of conventional toxicological findings such as histopathological changes.

736 MULTIFACTOR CLUSTER ANALYSIS OF GENDER, CHEMICAL, AND DOSE EFFECTS UPON GENE EXPRESSION IN TCDD AND AROCLOR 1254 EXPOSED RATS.

J. Silkworth¹, E. Carlson¹, K. Illouz¹, A. Possolo¹, K. Holtzclaw², S. Goodwin³ and T. R. Sutter³. *¹GE, Global Research, Niskayuna, NY, ²GE, Corporate Environmental Programs, Fairfield, CT and ³Feinstein Center for Genomic Research, University of Memphis, Memphis, TN.*

The toxic equivalency quotient (TEQ) methodology is used to estimate human health risks from exposure to dioxins and PCBs. Since mixtures comprise varying quantities of full agonists, partial agonists, and antagonists of the aryl hydrocarbon receptor (AHR), the integrated biological activity of such mixtures may show dependencies on more complex factors than just the presence of the AHR. Thus, the TEQ approach likely provides an over simplistic and imprecise estimation of the true potency of TEQ mixtures that would be better determined by testing the actual mixture. The current study evaluates the relative importance of chemical, dose, and gender on gene expression response to Aroclor 1254 and TCDD. Rats (n=4) were administered corn oil or 0.3 or 3.0 ug/kg TCDD or 0.6, 6.0, or 60 mg/kg Aroclor 1254 mg/kg po for 3 consecutive days. Day 4 hepatic RNA was screened using Affymetrix RG U34 arrays. An in-house (GE) linear model was used to generate a discovery gene set fulfilling both a 2-fold change and 0.005 q-value cutoff requirements in at least 2 exposure groups. The discovery dataset, representing a total of 107 probe sets or ~73 rat genes, was dominated by enzymes involved in xenobiotic/steroid/lipid metabolism. Distinct clusters displayed significant gender (i.e., Cyp3a13), chemical (i.e., Comt, Cyp2b), dose effects (i.e., Nqo1, Cyp1b1), and various interactions among these 3 variables (i.e., Igfbp1, Hgf). This approach may have utility for characterizing sets of responsive genes and in identifying which of multiple experimental factors are most important in determining the profile of both AHR-dependent and AHR-independent responses.

737 ASSESSING AHR-MEDIATED GENE EXPRESSION EFFECTS IN A NOVEL HUMAN LIVER ADULT STEM CELL LINE.

S. Kim^{1,2}, E. Dere^{1,2}, L. D. Burgoon^{1,2}, C. C. Chang^{2,4} and T. R. Zacharewski^{1,2,3}. *¹Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI, ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ⁴Department of Pediatrics & Human Development, Michigan State University, East Lansing, MI.*

Primary and continuous cell lines are valuable in vitro models that have been widely used to provide insights into mechanisms of toxicity. The recent availability of human hepatic adult stem cells provides an innovative in vitro model that may

more accurately predict in vivo toxicity. The human liver adult stem cell line, HL1-1, was used to assess gene expression effects elicited by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Expression of the aryl hydrocarbon receptor (AhR) in HL1-1 cells was verified by quantitative real-time PCR (QRT-PCR) and Western blot analysis. For temporal studies, cells were treated with 10 nM TCDD or vehicle (DMSO) for 1, 2, 4, 8, 12, 24 or 48 hrs. Cyp1a1 was induced >100-fold between 2 to 48 hrs, with an EC50 value of 8.30 nM, in dose response studies using QRT-PCR. Global gene expression responses of cells treated with TCDD in the absence and presence of cycloheximide (CHX) were conducted using custom human cDNA microarrays representing 7,844 unique genes to identify primary responses. Empirical Bayes analysis identified 78 and 200 active genes that were differentially regulated by TCDD at 4 and 12 hr, respectively, with 77 potential primary based on CHX co-treatment studies. Comparison to CHX studies in murine Hepa1c1c7 cells identified 4 differentially regulated orthologous genes that are putative conserved primary responses. Species-dependent and cell line differences likely contribute to the low overlap, but also provides further evidence of species-specific AhR regulons. Supported by NIGMS grant R21 GM075838.

738 METABOLOMIC ANALYSES OF LIPID AND AQUEOUS LIVER EXTRACTS IN TCDD-TREATED MICE.

M. Kent¹, N. V. Reo¹, J. L. Gary², N. DelRaso³, D. Boverhof⁴, L. Burgoon⁴, D. Jump⁴ and T. Zacharewski⁴. ¹Biochemistry & Molecular Biology, Wright State University, Dayton, OH, ²BAE System, San Diego, CA, ³AFRL/HEPB, Wright-Patterson AFB, Dayton, OH and ⁴Biochemistry & Molecular Biology, National Food Safety & Toxicol Ctr, Ctr Integrative Toxicol, Michigan State University, East Lansing, MI.

The hepatic metabolomic response of immature ovariectomized C57BL/6 mice to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) was examined using thin layer chromatography (TLC), 13C, 31P, and 1H NMR (14.1 T), and high-pressure liquid chromatography (HPLC). Mice received either sesame oil or 30 ug/kg TCDD by gavage and were sacrificed at 168 hr post dose. TCDD induced a significant increase in liver weight with marked cytoplasmic vacuolization accompanied by individual cell apoptosis and foci of mixed populations of inflammatory cells consisting mainly of mononuclear cells and some neutrophils. Oil Red O staining indicated vacuolization was due to lipid accumulation and TLC of lipid extracts revealed a 2.5-fold increase in triacylglycerides (TAG). The 13C lipid spectra were subdivided into 1024 integral regions (bins) for Principal Component Analysis (PCA), which yielded two distinct data clusters (treated and control) in the PCA scores plot (PC1 vs. PC2). Spectral examination showed: (1) cholesterol levels were unaffected, (2) TAG were increased 3.5-fold (20.8 ± 1.9 vs. 6.0 ± 0.3 umol/g liver), and (3) omega-3 fatty acids were decreased by 22% (treated vs. controls, $p < 0.005$). 31P NMR phospholipid analyses showed that TCDD increased phosphatidylcholine 24%, while phosphatidylethanolamine and cardiolipin each decreased 16% ($p < 0.05$). HPLC of lipid extracts identified >3-fold increases in 16:0, 18:1n9, 18:2n6, 18:3n3, 20:2n, 20:3n6, 20:3n9 and 22:5n3 fatty acids. 1H and 31P NMR of aqueous extracts also displayed a clear separation in the PCA scores plots. Thus in addition to eliciting changes in transcription (Boverhof, et al. Toxicol Sci 85, 1048 (2005)), TCDD also induces alterations in hepatic aqueous molecules and lipids. Relationships among changes in genes transcripts and metabolites are being sought. Funded by RO1 ES013927.

739 COMPARATIVE TOXICOGENOMICS OF AH RECEPTOR MEDIATED HEPATOTOXICITY IN C57BL/6 MICE.

A. N'jai^{1,2}, D. Boverhof^{4,2}, L. Burgoon^{1,2}, E. Dere^{1,2}, Y. Tan^{1,2}, J. C. Rowlands³, R. Budinsky³, K. Stebbins³ and T. Zacharewski^{1,2}. ¹Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²Center for Integrative & National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and ³The DOW Chemical Company, Midland, MI.

Temporal microarray analyses were performed on hepatic tissue from orally gavaged immature female C57BL/6 mice in order to evaluate similarities and difference in gene expression profiles between 2,3,7,8-TCDD (TCDD) and 2,3,7,8-TCDF (TCDF). Time course studies out to 168 h were conducted with 300 µg/kg TCDF, 30 µg/kg TCDD or sesame oil. Gene expression was monitored using cDNA microarrays containing 13,362 features, representing 8,516 genes. Empirical Bayes analysis identified 342 differentially expressed genes following treatment with TCDF. Comparison of TCDF and TCDD differential gene expression identified 192 genes which exhibited common responses; 140 common responses exhibited comparable profiles (correlation coefficients > 0.3). In general, TCDF was less potent when compared to TCDD at later time points, with maximal efficacy occurring primarily at 12 h. QRT-PCR verification of Cyp1a1 and Ngq1 induction were consistent with differences in efficacy observed in microarray results. TCDF elicited hepatocytes cytoplasmic vacuolization consistent with lipid accumulation at 24 h, was more severe at 72 h, but significantly subsided by 120 and 168 h compared to

TCDD. Hepatic TCDF levels were significantly lower than TCDD after 24 h, with maximal levels attained at 12 h. This was followed by a gradual decrease between 18 and 168 h, suggesting pharmacokinetic differences may account for the lower accumulation of hepatic lipids and gene expression activity elicited by TCDF at later time points. The declining TCDF responses observed after 24 h relative to TCDD, due to metabolism and/or excretion, suggests that TCDF's TEF of 0.1 may overestimate its hepatic toxicity. Funds provided by The DOW Chemical Company.

740 COMPARATIVE TOXICOGENOMIC ANALYSIS OF THE HEPATOTOXIC EFFECTS OF TCDD IN SPRAGUE DAWLEY RATS AND C57BL/6 MICE.

C. Tashiro⁴, D. Boverhof^{4,3}, L. D. Burgoon^{1,3}, B. Sharratt⁴, B. Chittim⁴, J. Harkema^{2,3}, D. Mendrick⁵ and T. R. Zacharewski^{1,3}. ¹Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI, ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI, ⁴Wellington Laboratories, Guelph, ON, Canada and ⁵Gene Logic, Gaithersburg, MD.

Comparative temporal and dose-response microarray analyses were performed on hepatic tissue from immature, ovariectomized Sprague Dawley rats and C57BL/6 mice to further characterize conserved and species-specific mechanisms of TCDD-mediated toxicity. For temporal studies, rats and mice were gavaged with 10 or 30 µg/kg of TCDD, respectively, and sacrificed after 2, 4, 8, 12, 18, 24, 72 or 168 hrs while dose-response studies were performed at 24 hrs. Hepatic gene expression was monitored using custom cDNA microarrays containing 8,567 (rat) or 13,361 (mouse) cDNA clones. Affymetrix data from male rats treated with 40 µg/kg TCDD were also included to expand the species comparison. In total, 3,087 orthologous genes were represented in the cross-species comparison. Comparative analysis identified 33 orthologous genes that were commonly regulated by TCDD as well as 185 rat-specific and 225 mouse-specific responses. Functional annotation identified conserved gene responses associated with xenobiotic/chemical stress and amino acid and lipid metabolism. Rat-specific gene expression responses were associated with cellular growth and lipid metabolism while mouse-specific responses were associated with lipid uptake/metabolism and immune responses. The common and species-specific gene expression responses were also consistent with complementary histopathology, clinical chemistry, hepatic lipid analyses and reports in the literature. These data expand our understanding of TCDD-mediated gene expression responses and indicate that species-specific toxicity may be mediated by differences in gene expression. This may explain the wide range of species sensitivities and will have important implications in risk assessment. Funded by NIH R21 GM75838.

741 COMPARATIVE TOXICOGENOMIC EXAMINATION OF THE HEPATOTOXIC EFFECTS OF 3, 3', 4, 4', 5-PENTACHLOROBIPHENYL (PCB126) AND 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) IN C57BL/6 MICE.

A. K. Kopec¹, D. R. Boverhof^{4,2}, L. D. Burgoon^{1,2}, C. Tashiro³, B. Chittim³ and T. R. Zacharewski^{1,2}. ¹Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³Wellington Laboratories, Guelph, ON, Canada.

Polychlorinated biphenyls (PCBs) are persistent environmental pollutants with potent dioxin-like properties that elicit a wide range of effects in humans and wildlife. The most toxic congener, 3,3',4,4',5-pentachlorobiphenyl (PCB126), was chosen to characterize hepatic temporal gene expression responses in immature ovariectomized C57BL/6 mice to further elucidate its mechanisms of toxicity. Mice were gavaged with 300 µg/kg PCB126, or vehicle (sesame oil) and sacrificed after 2, 4, 8, 12, 18, 24, 72 or 168 hrs. Comparisons were also made to mice treated with 30 µg/kg 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) to identify conserved responses and assess the appropriateness of the PCB126 Toxic Equivalence Factor (TEF) of 0.1. Hepatic gene expression was monitored using a 13361 feature cDNA microarray representing 8516 unique genes. PCB126 induced the differential expression of 285 features (243 unique genes) at one or more time points, as determined by an empirical Bayes approach. Functional gene annotation from public databases with complementary histopathology, clinical chemistry and hepatic triglyceride analysis identified gene expression responses consistent with the observed physiological effects including responses involving oxidative stress, differentiation, gluconeogenesis and fatty acid uptake and metabolism. Hepatic PCB126 levels were also determined in order to associate differential gene expression to tissue levels. Despite comparable hepatic TEQ levels and early gene expression responses, collectively the data indicate significant differences in efficacy between PCB126 and TCDD suggesting that the PCB126 TEF of 0.1 is an over estimate of its potency. This work was funded by Superfund P42ES04911.

742 COMPARATIVE ONTOLOGICAL ANALYSIS OF HEPATIC GENE EXPRESSION PROFILES FOLLOWING 52 WEEKS OF CHRONIC EXPOSURE TO PCB126, PCB153 AND A BINARY MIXTURE OF PCB126 AND PCB153.

B. J. Ovando, K. Kransler and J. Olson. *Pharmacology & Toxicology, University at Buffalo, Buffalo, NY.*

Our laboratory conducted a series of gene array experiments to evaluate toxicogenic effects in the liver of female Sprague Dawley rats exposed for 52 weeks to PCBs in recently completed NTP studies (2004, 2006). Our studies were conducted in an effort to understand the relationship between the toxicogenic responses of the liver to PCBs and the pathological endpoints seen with chronic exposure to these toxins; which include non-neoplastic lesions, hepatocellular adenoma and cholangiocarcinoma in rats exposed to the AHR ligand PCB126, but not to the non-AHR ligand PCB153. Interestingly, co-administration of PCB126 and PCB153 potentiated the effects of PCB126. This is not explained by the pharmacokinetics of PCB126, which exhibits decreased hepatic retention when co-administered with PCB153 (NTP, 2004). In an effort to identify the genes which may be responsible for the potentiation of hepatotoxicity seen with co-exposure to PCB126 and PCB153, we have conducted ontological analysis on genes differentially expressed following exposure to PCB126 and PCB153, alone and in combination. Utilizing Ingenuity Pathway Analysis software we identified gene clusters that may be contributing to the lesions seen in the liver. The following list of biological functions significantly associated with differentially expressed genes will read as follows; biological function followed in parenthesis by the number of genes associated with said function differentially expressed by PCB126, the binary mixture and PCB153, respectively. A few of the biological functions that are relevant to genes differentially expressed by these compounds include cancer (108, 136, 18), cell death (100, 127, 15), inflammatory disease (27, 46, 4), endocrine system disorder (4, 25, 7), cell cycle (7, 24, 8) and lipid metabolism (42, 56, 29). These analyses will help in efforts to evaluate the mechanisms and risks associated with real world exposure to mixtures of PCBs.

743 PHENOTYPIC TRANS-DIFFERENTIATION OF HEPATOCYTES TO BILIARY CELLS AFTER BILE DUCT INJURY INDUCED BY METHYLENE DIANILINE.

P. Limaye, W. C. Bowen and G. K. Michalopoulos. *Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Cholestatic liver diseases (CLD) are life threatening liver complications with suppression of biliary epithelium (BE). Recent studies from our laboratory demonstrate that hepatocytes transdifferentiate to BE cells in case of impaired biliary regeneration following bile duct ligation and subsequent administration of biliary toxicant methylene dianiline (DAPM). Present study is aimed at determining if hepatocytes transdifferentiate into BE after structural destruction of bile ducts induced by DAPM alone. Immunohistochemistry of biliary specific cytokeratins such as AE1/AE3 and CK19 conducted on liver sections of male F344 rats treated with DAPM (50 mg/kg) revealed that periportal hepatocytes acquire biliary markers during bile duct repair indicating hepatocyte transdifferentiation. When Chimeric rats carrying dipeptidyl peptidase IV (DPPIV)-positive hepatocytes (DPPIV) were treated with DAPM (50 mg/kg, every 2 days, 3 times), bile ductules bearing the donor hepatocyte marker DPPIV were evident within 30 days after the DAPM treatment indicating hepatocyte transdifferentiation. To investigate the mechanisms of transdifferentiation, an in vitro organoid culture of rat hepatocytes was utilized where hepatocytes to BE transdifferentiation has been previously demonstrated. Growth factors known to be involved in differentiation including HGF, EGF, VEGF, PDGF, SCF, MSP, FGF-a, FGF-b, and FGF-8b were tested for their ability to promote hepatocyte transdifferentiation. None of the growth factors except HGF and EGF induced formation of BE despite the presence of cognate receptors. Microarray analysis of the organoid cultures indicated upregulation of various HGF and EGF targets such as osteopontin, CXC chemokine LIX, CXC receptor LCR1, chemokine orphan receptor 1, cyclin D1, and CD44. These data suggest that HGF and EGF signaling is responsible for transdifferentiation of hepatocytes to biliary cells. Moreover, this study has revealed hepatocyte transdifferentiation as a novel therapy against CLD.

744 HEPATIC GENE EXPRESSION PROFILE AND LIPID HOMEOSTASIS IN MICE EXPOSED TO ETHANOL.

H. Yin¹, Y. Kim¹, J. Kim², G. Kong³, J. Chung¹ and B. Lee¹. ¹College of Pharmacy, Seoul National University, Seoul, South Korea, ²College of Medicine, Seoul National University, Seoul, South Korea and ³College of Medicine, Hanyang University, Seoul, South Korea.

Ethanol is a well-known hepatotoxicant that induces cumulative liver damage, which includes steatosis, steatohepatitis, and cirrhosis. In the present study, we investigated the effects of acute and chronic ethanol exposure on gene expression in

the mouse liver using the Applied Biosystems Mouse Genome Survey Microarray. For acute exposure, A single oral dose of 0.5 or 5 g/kg ethanol was administered to male ICR mice, and liver samples were obtained after 6, 24, and 72 h. For chronic exposure, mice were fed regular Lieber-Decarli ethanol diet ad libitum and liver samples were obtained after 1, 2 and 4 weeks. Histopathological evaluation showed typical fatty livers in the high-dose group at 24 h (acute) as well as in 2 and 4 weeks (chronic). In these groups serum AST, ALT and triglyceride levels were slightly elevated. Microarray analysis identified 28 genes as being ethanol-responsive, in that their expression levels differed significantly from the controls (two-way ANOVA; $p < 0.05$), after adjustment by the Benjamini-Hochberg multiple testing correction; these genes displayed more than 2-fold induction or repression. The expression of genes that are known to be involved in fatty acid synthesis was examined. The transcript for lipogenic transcription factor, sterol regulatory element (SRE)-binding factor 1 (SREBF1), was upregulated by ethanol exposure. Of the genes known to contain SRE or SRE-like sequences and to be regulated by SRE-binding protein 1, those encoding malic enzyme (Mod1), ATP-citrate lyase (Acl), and fatty acid synthase (Fasn) in the cytosol, and stearoyl-CoA desaturase (Scd1) in the endoplasmic reticulum, were induced by ethanol. Quantitative real-time PCR confirmed the changes in the expression levels of the selected genes. Overall, our results suggest that the global changes in hepatic gene expressions that follow acute and chronic ethanol exposure can be used as biomarkers for ethanol induced hepatotoxicity.

745 TOXICOGENOMICS STUDY OF FLUTAMIDE USING CHIMERIC MICE WITH HUMANIZED LIVER.

S. Yokokawa¹, D. Mulhern¹, M. Kakuni², H. Oshita², T. Shimada², S. Ninomiya¹ and Y. Yamazoe³. ¹ADME/TOX Research Institute, Daiichi Pure Chemicals Co., Ltd., Ibaraki, Japan, ²PhoenixBio Co., Ltd., Hiroshima, Japan and ³Division of Drug Metabolism and Molecular Toxicology, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan. Sponsor: T. Miyaoka.

Flutamide, a non-steroidal antiandrogen, is widely used in the treatment of prostate cancer. However, flutamide occasionally causes severe liver dysfunction resulting in hepatitis, liver necrosis or cholestasis. Although rats treated with flutamide show liver enlargement, no serious liver injury has been reported in rats in pre-clinical studies. To investigate the cause of human-specific adverse effects, we studied the effect of flutamide on chimeric mice with near-completely humanized liver. Chimeric mice were generated by transplanting human hepatocytes into urokinase-type plasminogen activator-transgenic SCID mice (uPA/SCID mice). Both rat and chimeric mice were dosed with flutamide (30 & 300 mg/kg daily) and their liver gene expression profiles compared after 6h, 24h and 8 days. Rats treated with flutamide for 8 days showed an 80% increase in liver mass. However, no other significant changes in histopathology were observed in either species at earlier time points. After 24 h, flutamide strongly induced Cyp1a1 in rat liver and by 8 days induced other aryl hydrocarbon receptor (AhR) regulated genes including Cyp1a2 and NADPH quinone oxidoreductase (Nqo-1). AhR regulated genes remained largely unchanged after flutamide treatment in chimeric mice liver. Reports that reduced expression levels of AhR regulated genes are involved in the onset of flutamide-induced human specific hepatic injury and our microarray data suggests that induction of these genes protects rats from flutamide-induced hepatotoxicity. In addition, we found several differences in the expression levels of ADME related genes which may further explain the human-specific hepatic injury induced by flutamide. This study demonstrates that chimeric mice with humanized liver are useful models for the investigation of mechanisms involved in human drug-induced hepatotoxicity.

746 INVESTIGATION OF HEPATOCELLULAR CARCINOMA IN MALE RATS USING EARLY GENE EXPRESSION PROFILING.

M. Cooper, S. Hu, K. Dolim, J. Allard, S. Platz and K. Kolaja. *Investigative Toxicology, Roche, Palo Alto, CA.*

The carcinogenic potential of RO-XXX was investigated in vivo using a 2-year oral gavage carcinogenicity study in Sprague-Dawley rats. RO-XXX treatment induced hepatocellular adenomas in males and females ($p \leq 0.001$) and hepatocellular carcinoma in male rats ($p \leq 0.008$); a no-effect level for hepatocellular neoplastic changes was not achieved in male rats. Despite these findings, no previous in vivo studies in rats raised hepatocarcinogenic concerns. In addition, all genotoxicity testing results for RO-XXX were negative, including: Ames assay, in vitro mouse micronucleus test, human lymphocyte chromosome aberration test, in vivo mouse and rat bone marrow micronucleus test, in vivo kidney and liver rat comet assays, and SHE cell assay. Further development of RO-XXX was halted and subsequent work has focused on identifying the molecular mechanism of hepatocellular neoplastic transformation. In an attempt to gain further insight into the mechanism of carcinogenesis for RO-XXX, we examined gene expression in rat liver samples from animals treated with RO-XXX in a 4-day repeat dose study. Samples were profiled

using Affymetrix RG230v2 microarrays and the Iconix ToxFx data analysis service. The significantly perturbed genes from RO-XXX treated rats were enriched for genes associated with lipid and fatty acid metabolism, and electron transport. The aryl hydrocarbon receptor and RXR signaling pathways were also significantly affected. An apparent absence of DNA damage and a lack of changes in DNA repair genes suggest an epigenetic mechanism of carcinogenicity.

747 GENDER DIFFERENCES IN THE CANINE LIVER IN RESPONSE TO PHENOBARBITAL.

K. K. Daniels¹, M. Summan², P. G. Rossi¹ and D. L. Mendrick¹. ¹Toxicogenomics, Gene Logic Inc., Gaithersburg, MD and ²Gene Logic Labs, Gene Logic Inc., Gaithersburg, MD.

The antiepileptic drug phenobarbital (PB) has a long history of use in preclinical investigations as a prototypical inducer of drug metabolizing enzymes (DMEs) and is known to increase total serum cholesterol levels in rodents, canines and humans. The present investigation evaluated the effect of gender on liver gene expression in beagle dogs using Affymetrix GeneChip® Canine Genome 2.0 Arrays following treatment with PB. Animals in the PB-treated group (n=3 per gender) received via oral gavage (p.o.) 10mg/kg/day on treatment Days 1 and 2 and 30 mg/kg/day on treatment Days 3-7. Vehicle control animals (n=3 per gender) received deionized water via oral gavage (p.o.). Animals were sacrificed, and livers were removed for histopathological examination and gene expression analysis at 7 days post-study initiation. Histopathological examination showed mild centrilobular hypertrophy in the PB-treated animals from both genders. Likewise, up-regulation in mRNA levels of various DMEs was observed in both genders following treatment. However, there were significant differences in expression perturbations between genders in the effect of PB exposure on cholesterol biosynthesis pathway constituents. Specifically, the expressions of HMG-CoA reductase and squalene monooxygenase, the rate-limiting enzyme genes in cholesterol biosynthesis, were up-regulated in male dogs but not in females. These findings suggest that while both genders respond to PB treatment with increased mRNA levels of various DMEs, gender differences arise at the gene expression level in the effect of PB treatment on cholesterol biosynthesis pathways, implying that male dogs have a greater potential for cholesterol accumulation than female dogs. While it is unknown as to whether these differences between genders in the canine response to PB treatment translates to humans, it does serve to illustrate the importance of addressing potential gender differences in preclinical animal models and to prioritize understanding how such information may be impactful in the clinical setting.

748 IDENTIFICATION OF LIVER GENE EXPRESSION CHANGES ASSOCIATED WITH HIV PROTEASE INHIBITOR-INDUCED HYPERLIPIDEMIA IN SENSITIVE AND RESISTANT STRAINS OF RATS.

Y. Yang¹, E. A. Blomme¹, D. J. Kempf¹, L. Klein¹, K. C. Marsh¹, A. J. Dahly-Vernon², Y. A. Harrington², J. A. O'Connor², D. L. Evans², R. J. Roman^{2,3}, H. J. Jacob^{2,3} and J. E. Waring¹. ¹Global Pharmaceutical Research and Development, Abbott Laboratories, Abbott Park, IL, ²PhysoGenix, Inc., Milwaukee, WI and ³Medical College of Wisconsin, Milwaukee, WI.

A number of HIV protease inhibitors (PI) have been associated with elevations in serum triglycerides and cholesterol in patients. The standard preclinical animal species, such as Sprague-Dawley (SD) rats, are not sensitive to HIV PI-induced hyperlipidemia, making mechanistic studies and the identification of new PIs not associated with dyslipidemia a challenge. The purpose of this study was to employ a panel of rat strains with controlled genetic diversities in order to identify rat strains that reflect the hyperlipidemia associated with PIs in humans. Ritonavir was administered to Fischer 344 (F344), SD, and 12 PharmGenixTM panel (PG1-PG12) rats for 5 days. Following drug treatment, blood samples were evaluated for changes in serum lipids. Increases in triglyceride and cholesterol levels were observed in the PG2 strain with ritonavir treatment, while the lipid levels in the other strains remained near baseline. Livers from the sensitive rats and the Sprague-Dawley rats were then evaluated for differences in gene expression profiles. CYP7A1, a key enzyme for cholesterol metabolism, was down regulated in the sensitive strain and up regulated in the resistant strain. A number of genes involved in the lipid synthesis and metabolism were also regulated differently between the two rat strains. Collectively, these results suggest novel potential mechanisms for this clinically relevant HIV PI-induced hyperlipidemia.

749 EFFECTS OF AFLATOXIN ON HEPATIC GENE EXPRESSION IN A POULTRY MODEL.

L. P. Yarru¹, R. S. Settivari¹, C. S. Reddy², E. Antoniou¹ and D. R. Ledoux¹. ¹Animal Science, University of Missouri, Columbia, MO and ²Biomedical Sciences, University of Missouri, Columbia, MO.

Aflatoxin is a toxic secondary metabolite produced by the fungi *Aspergillus flavus* and *A. parasiticus*. Ingredients of livestock and poultry feed are often contaminated with aflatoxin. Aflatoxin affects many species including humans, dogs, cats, pigs,

cattle, and poultry, with liver being the major organ affected. A chicken model was used to evaluate the effect of aflatoxin on hepatic gene expression. Seventy five day-old male broiler chicks were assigned to three dietary treatments (5 replicates of 5 chicks each) from hatch to day 21. The diets contained 0, 1 and 2 mg/kg aflatoxin/kg of feed. Feed intake, body weight gain, liver weights and serum chemistry were evaluated at the end of the study and liver samples were collected in RNase free tubes and stored at -80°C. Aflatoxin reduced ($P \leq 0.05$) feed intake, body weight, serum total proteins, serum calcium and phosphorus but increased ($P < 0.01$) liver weights in a dose dependent manner. Microarray experiments were conducted using chicken long oligo arrays, to identify the changes in hepatic gene expression in chicks fed 0 (control) and 2mg/kg aflatoxin/kg of feed. A loop design was followed for microarray experiments with four technical and four biological replicates per treatment group. RNA was extracted from liver tissue and its quality was determined using gel electrophoresis. High quality RNA was purified from DNA contamination, reverse transcribed to cDNA and was used for microarray hybridizations. Microarray data will be analyzed using a 2-step ANOVA model using GenePix and MAANOVA softwares, and the differentially expressed genes will be identified using SAM, TIGR, and Cluster softwares. The microarray data will be validated using real time PCR. It is hypothesized that genes associated with antioxidant, detoxification and immune systems will be affected along with many unidentified pathways in birds fed aflatoxin compared to controls.

750 TRANSCRIPTOME CHANGES IN HEPG2 CELLS EXPOSED TO COPPER: GO ANALYSIS AND HIERARCHICAL CLUSTERING.

M. Song and J. H. Freedman. LMT/DIR, NIEHS, Research Triangle Park, NC.

Copper is an essential trace element that serves as an important catalytic cofactor for cuproenzymes. It has been shown that copper has the potential to generate free radicals and oxidize cellular components through its redox activity. We have previously shown that copper activates transcription through both metal- and oxidative stress-responsive signal transduction pathways. Our hypothesis is that copper modulates the activity of multiple intracellular signal transduction pathways to affect transcription, which ultimately disrupt normal development. HepG2 cell transcriptomes were analyzed using Agilent human microarrays, and differentially expressed genes identified for cells exposed to copper (100, 200, 400 and 600 μ M) for 4, 8, 12 and 24-h. We mapped differentially up-regulated genes onto Gene Ontology categories using GenMAPP, and then performed hierarchical clustering (average linkage) with Cluster. Hierarchical clustering shows that as toxicity increases, the number of significantly enriched ($p \leq 0.01$) GO categories increase and that there is a change in the types of categories across the 16 conditions. Metal ion binding and homeostasis, TGF- β receptor signaling, anti-apoptosis, IL 1 receptor binding and glutathione synthesis were significantly enriched all across 16 conditions with higher z values at lower concentrations (100 and 200 μ M). Regulation of transcription, insulin-like growth factor binding, LDL receptor binding and immune cell activation were enriched only at higher concentrations (400 and 600 μ M) for all exposure time points. Morphogenesis and immune response are GO categories enriched at most conditions except at lower concentrations after 8 h exposure. Significantly enriched GO categories for down-regulated genes were cellular lipid metabolism, mRNA processing, regulation of DNA replication, phosphoinositide-mediated signaling, oligosaccharide metabolism and DNA packaging. We will perform investigation of potential signal transduction pathways based on mapped biological and molecular pathways.

751 LABORATORY DIET ALTERS GENE EXPRESSION IN MICE.

C. D. Kozul¹, A. P. Nomikos^{1,2}, T. H. Hampton^{1,2}, J. C. Davey^{1,2}, J. A. Gosse^{1,2}, L. A. Warnke³, M. A. Ihnat³, B. P. Jackson² and J. W. Hamilton^{1,2}. ¹Pharmacology/Toxicology, Dartmouth Medical School, Hanover, NH, ²Center for Environmental Health Sciences, Dartmouth College, Hanover, NH and ³Department of Cell Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Nutritional studies in laboratory animals have long shown that various dietary components can contribute to health consequences, but the effects of diet alone have not been carefully considered in toxicogenomic whole animal studies. In this study, C57BL/6J mice (n=5 per group) were raised for five weeks on either a standard lab chow diet LRD-5001 or a purified, low-arsenic AIN-76A diet as part of a larger study examining the effects of arsenic (As) in diet or drinking water on gene expression. Affymetrix Mouse Whole Genome 430 2.0 microarrays were used to assess gene expression changes in the liver. Using a robust analysis and a two-fold change cutoff, 360 genes were found to be differentially expressed. Many of these genes are involved in Phase I and Phase II metabolism, cholesterol metabolism, immune response, electron transport, ubiquitination, nitric oxide biosynthesis, glutathione metabolism, estrogen signaling, G-protein coupled receptor signaling, and transcriptional regulation. We found, using ICP-MS, that the AIN-76A diet con-

tained 5 ppb total As, while the LRD-5001 diet contained a mixture of inorganic and organic As at a total concentration of 290 ppb. Chronic human exposure to As has been known to cause a variety of health problems, and many of the genes found to be differentially expressed in this study are known to have roles in As metabolism and toxicity. Thus, the substantial gene expression differences between these diets may confound or contribute to investigations of effects of As or other toxicants. Previous published studies on As toxicogenomics in mice have used standard lab chows, containing fish meal (a probable source of As) as the primary protein source and have not considered the amount of As naturally found in the chow. These results indicate that diet must be carefully controlled in whole animal toxicogenomic studies. (NIH-NIEHS P42 ES07373)

752 GENE EXPRESSION CHANGES IN RAT PANCREATIC ACINAR CELLS ISOLATED FROM RATS ADMINISTERED WYETH 14, 643 OR AMMONIUM PERFLUOROCTANOATE.

D. G. Farrar¹, S. M. Plummer² and C. R. Elcombe². ¹Ineoschlur Ltd., Runcorn, United Kingdom and ²CXR Biosciences Ltd., Dundee, United Kingdom.

The nongenotoxin ammonium perfluorooctanoate (APFO, 300ppm in the diet) has been shown previously to induce pancreatic acinar cell tumours in rats. The aim of this study was to assess whether procarcinogenic gene expression changes that were identified previously in whole pancreas tissue in response to APFO and Wyeth 14,643 (Wy) treatments were taking place in acinar 'target' cells. Male Sprague Dawley rats (6-7 weeks old) were fed either the potent pancreatic carcinogen Wy in the diet at 50ppm (a carcinogenic dose) or APFO at 300 ppm for up to 4 weeks. Pancreatic acinar cells were isolated and purified using collagenase digestion and centrifugation. Transcription profiling analysis was performed on acinar cells after 1, 7 and 28 days of dosing using a rat whole genome 60mer oligonucleotide array containing about 44,000 genes. 'Signature' gene lists of significantly ($p < 0.01$) regulated genes for each treatment were compared using LuminatorR software. Time course analysis of the previously identified carcinogenesis-associated genes Early Growth Response 1 (EGR1), Growth Arrest and DNA Damage 45 alpha (GADD45alpha), Thymine Glycosylase and TPA-associated Sequence II (TISII) indicated that the gene expression changes observed in whole pancreas did not occur in purified acinar cells. By contrast, the metabolic genes Phosphoenolpyruvate Carboxykinase (PEPCK) and Dual Specificity Phosphatase 6 (DUSP6), both markedly regulated by Wy and APFO in whole pancreas, were changed also in the acinar cells by both treatments in a similar fashion across time. These results suggest that either procarcinogenic gene expression changes that were observed with these treatments in whole pancreas were selectively negated by the work-up procedure for purification of the acinar cells, or that the initial procarcinogenic changes are taking place in a different (non-acinar) cell population. This work was funded by Plastics Europe

753 COMPARISON OF ENDOTHELIAL CELL PROLIFERATION IN LIVER AND ADIPOSE TISSUE IN B6C3F1 MICE, F344 RATS, AND HUMANS.

T. Ohnishi, L. L. Arnold, N. M. Clark and S. M. Cohen. University of Nebraska Medical Center, Omaha, NE.

A new class of drugs called peroxisome proliferator-activated receptor gamma (PPAR- γ) agonists has been developed for use in the treatment of diabetes. Vascular tumors were increased in animals treated with some of these drugs. In a 2-year bioassay, troglitazone, a member of this class of drugs, caused an increased incidence of hemangiosarcomas in male and female mice but not in rats. Rodents treated with these drugs also had increased interscapular brown fat with an increased rate of endothelial cell proliferation. Hemangiosarcomas, arising from the endothelial cells are rare in rats and humans with a generally poor prognosis. However, the B6C3F1 mouse has a high rate of spontaneous hemangiosarcoma formation in all tissues. The mechanism of hemangiosarcoma induction is not well understood. The objective of this study was to determine the endothelial cell proliferation rate in normal liver and adipose tissue of B6C3F1 mice, F344 rats, and humans to aid in the investigation of the genesis and development of hemangiosarcomas, and to help determine the relevance of the increased vascular proliferation rate of endothelial cells in drug-treated rodents in assessing the risk of these drugs in humans. We determined the proliferative index (PI) in untreated mice, rats, and humans, of endothelial cells in normal liver, brown fat (rats and mice only) and white fat by dual immunohistochemical staining for CD-31 (endothelial cell marker) and Ki-67 (proliferation marker). The PI was highest in mice and lowest in humans. The difference in the PI was statistically significant when the mouse was compared to the human and rat (except for female rat white fat) and when the rat was compared to the human. The male PI was significantly increased when compared to the female PI in the liver tissue in mice and rats and in the white fat tissue in mice. The

increased rate of spontaneous or PPAR- γ agonist-induced hemangiosarcoma formation may be related to the increased normal proliferation rate of endothelial cells in this strain of mouse compared to rats and humans.

754 MODULATION OF AHR-DEPENDENT SIGNALING BY PPARB/D.

M. G. Borland¹, M. T. Bility¹, J. Lin², D. Desai², S. Amin², G. H. Perdew¹ and J. M. Peters¹. ¹Department of Veterinary and Biomedical Sciences, Pennsylvania State University, University Park, PA and ²Department of Pharmacology, Pennsylvania State University, Hershey, PA.

Peroxisome proliferator-activated receptors (PPARs) are ligand activated transcription factors, and each PPAR isoform (α , β (also referred to as δ), and γ) regulates specific target genes involved in a multitude of biological processes. Previous evidence has shown PPAR β can attenuate skin tumorigenesis, and this could be due to differences in the metabolism of the carcinogen. While treating primary keratinocytes with 7,12-dimethylbenz[a]anthracene (DMBA) induces expression of cytochrome P450 1A1 (CYP1A1) or CYP1B1 mRNA or protein in wild-type cells; surprisingly, this effect is not found in similarly treated PPAR β -null cells. This expression profile was confirmed upon treatment with other polycyclic aromatic hydrocarbons (PAHs), and this effect does not appear to be due to differences in the relative level of the AhR, which is known to mediate changes in CYP expression. Interestingly, PAHs also cause an increase in the expression of mRNA encoding heme oxygenase I in wild-type keratinocytes, and this effect does not occur in similarly treated PPAR β -null keratinocytes. This demonstrates that the relative ability of PAH to induce CYPs in the presence (wild-type) or absence (null) of PPAR β also correlates well with the induction of heme oxygenase; a phase II enzyme that is not known to be regulated by the aryl hydrocarbon receptor (AhR). The accumulation or ineffective clearance of chemical carcinogens can also lead to altered formation of protein or DNA adducts. Consistent with this idea, preliminary data suggest that DNA adduct formation is significantly lower in PPAR β -null primary keratinocytes treated with benzo[a]pyrene (B[a]P). These findings suggest a novel mechanism where PPAR β modulates AhR-dependent signaling and alters the carcinogenic effect induced by PAH, likely through modifying the balance between bioactivation and clearance of PAH. 755 EPIGENETIC EFFECTS OF THE PEROXISOME PROLIFERATOR WY-14, 643 IN MOUSE LIVER.

I. P. Pogribny², V. P. Tryndyak², C. G. Woods¹, S. E. Witt² and I. Rusyn¹. ¹Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC and ²Division of Biochemical Toxicology, National Center for Toxicological Research, Jefferson, AR.

Peroxisome proliferators are potent rodent liver non-genotoxic carcinogens. The mode of action of these agents in rodents includes increased cell proliferation, decreased apoptosis, secondary oxidative stress and other events; however, it is not well understood how peroxisome proliferators trigger the plethora of the molecular signals leading to cancer. Epigenetic changes have been implicated in the mechanism of liver carcinogenesis by a number of environmental agents. Short-term treatment with peroxisome proliferators induced hypomethylation of DNA and proto-oncogenes in mouse liver, events that were suggested to correlate with a burst of cell proliferation. In the current study, we investigated whether or not long-term exposure to peroxisome proliferators is accompanied by a sustained epigenetic change. Male SV129 mice were fed a control, or WY-14,643-containing (1000 ppm) diet for 1 wk, 5 wks or 5 mo. Treatment with WY-14,643 lead to progressive global hypomethylation of liver DNA as determined by an HpaII-based cytosine extension assay with the maximum effect reaching ~200% at 5 mo. Likewise, trimethylation of histone H4 lysine 20 and H3 lysine 9 was significantly decreased at all time points. Since the majority of cytosine methylation in mammals resides in repetitive DNA sequences, we measured the effect of WY-14,643 on the methylation status of major and minor satellites, as well as in IAP, LINE L1 and LINE L2 elements. Exposure to WY-14,643 resulted in gradual loss of cytosine methylation in major and minor satellites, IAP, LINE L1 and LINE L2 elements. Interestingly, the majority of the epigenetic changes were not correlated with the temporal effects of WY-14,643 on cell proliferation, especially at the 5 mo time point, and no effect on c-myc promoter methylation was observed. These data indicate the importance of epigenetic alterations in the mechanism of action of peroxisome proliferators.

756 PPARALPHA-DEPENDENT GENE EXPRESSION CHANGES IN THE MOUSE LIVER AFTER EXPOSURE TO PEROXISOME PROLIFERATORS.

H. Ren¹, B. Vallanat¹, W. Bao², R. Wolfinger² and C. Corton¹. ¹NHEERL, U.S.-EPA, Research Triangle Park, NC and ²SAS, Cary, NC.

Peroxisome proliferators (PP) are a large class of structurally diverse chemicals that mediate their effects in the liver mainly through the PP-activated receptor α (PPAR α). Development of PP induced hepatocarcinogenesis in mouse liver is

known to be dependent on PPAR α but downstream events related to the alteration in cell proliferation and apoptosis are not well defined and are needed for mode of action analysis. Using BrdU labeling of replicating hepatocytes, we first characterized cell proliferation effects in wild-type and PPAR α -null mice at 12, 24, 48, and 96 hrs after initial exposure. Cell proliferation peaked at 48 hrs in wild-type mice. PPAR α -null mice did not exhibit changes at any of the time points measured. Gene expression changes after the 12 hr treatment were assessed using Affymetrix U74Av2 gene chips. Significance Analysis of Microarray data showed that ~500 genes were significantly different between the treated and untreated groups at a 0.05 False Discovery Rate and almost all of the genes were dependent on PPAR α for regulation. To further understand the biological significance of these alterations, we compared the gene expression profiles to those from historical experiments assembled in a PP Compendium containing Affymetrix gene chip data from rats and mice exposed to different PP. Sets of genes commonly regulated by PP were identified at different time points and after exposure to different PP. These genes fell into a number of categories known to be regulated by PPAR α strengthening the argument that many PP cause effects in the liver through PPAR α . This abstract does not necessarily reflect EPA policy.

757 IDENTIFICATION OF COMMON GENES AND PATHWAYS REGULATED BY PPARALPHA ACTIVATORS.

S. Lloyd, B. Vallanat, M. Rosen, B. D. Abbott, K. P. Das, R. D. Zehr, C. Lau and C. Corton. NHEERL, U.S.-EPA, Research Triangle Park, NC.

Exposure to peroxisome proliferators (PPC) leads to alterations in hepatocyte growth and apoptosis, increases in liver to body weights (LW/BW) and liver tumors. There is strong evidence that PPC cause many of these effects through the nuclear receptor peroxisome proliferator-activated receptor alpha (PPAR α). The molecular events that occur after PPAR α activation and alteration in liver growth are not well characterized. To help identify common genes and pathways that may be mechanistically linked to PPC-induced carcinogenesis, we have compared the transcript profiles of the livers of wild-type or PPAR α -null mice exposed to a number of PPC using Affymetrix chip data. A number of PPC which all induce liver cancer were compared in this study including WY-14,643 (WY) and di(2-ethylhexyl) phthalate (DEHP) which require PPAR α for increases in LW/BW and perfluorooctanoic acid (PFOA) which causes increases in LW/BW in both wild-type and PPAR α -null mice. Transcript profiling was performed using either mouse U74Av2 or 430_2 Affymetrix chips. Significantly altered genes were identified using Rosetta Resolver. Under similar exposure conditions (7 consecutive daily gavages) a number of common functional categories of genes were identified including those involved in fatty acid oxidation and transport, peroxisome biogenesis, proteome maintenance, coagulation, complement cascade and oxidative stress as well as those linked to cell growth control. Almost all of these common genes were dependent on PPAR α for changes in transcript levels as the changes were not observed in PPAR α -null mice. Each chemical also altered a unique set of genes. For WY all of these genes were dependent on PPAR α . These results indicate that the model PPC WY, does not alter gene expression in the mouse liver independently of PPAR α , and that all PPC examined alter a smaller unique set of genes. Future work will be directed toward characterizing the functional significance of the changes in the cell growth genes commonly regulated by many PPC. This abstract does not necessarily reflect EPA policy.

758 THE ROLE OF KUPFFER CELLS IN HEPATOCARCINOGENESIS.

S. M. Corthals, J. E. Klaunig and L. M. Kamendulis. Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN.

The induction of chemically induced hepatic neoplasia is a multi-step process involving DNA damage and cell proliferation. Recent research has suggested a role for nonparenchymal cells, specifically Kupffer cells, as mediators of cell proliferation by tumor promoters. Kupffer cells, the resident macrophage of the liver, upon activation, secrete bioactive products including cytokines and reactive oxygen species that may participate in hepatocarcinogenesis through inducing oxidative stress and damage, and altering signaling cascades; events that may ultimately lead to hepatocellular proliferation. Our group has examined the role of the Kupffer cell on hepatocellular growth using both in vitro and in vivo models. In vitro, basal levels of DNA synthesis in purified hepatocyte cultures (lacking Kupffer cells) were reduced compared to standard (non-purified) hepatocyte cultures in both the mouse and rat. In addition, the hepatic tumor promoter Wyeth 14,643 failed to induce DNA synthesis in pure hepatocytes. Together, these results suggest that Kupffer cells act as mediators of DNA synthesis in hepatocytes. Activation of p38 MAP kinase has been shown to participate in cellular responses to external stress signals, and invokes signaling cascades that lead to altered cell growth. Wyeth 14,643 induced phosphorylation of p38 in standard hepatocyte cultures, but not in pure he-

patocyte cultures. In vivo, male B6C3F1 mice treated with LPS (0.25mg/kg; 1 or 2x/week) increased the number of Kupffer cells (~150 – 170%) and increased DNA synthesis in hepatocytes (~147%) over control levels. Conversely, Kupffer cell depletion via liposomal delivery of clodronate reduced the number of Kupffer cells (~80%) and both basal and LPS-induced DNA synthesis in the liver (57% and ~67% decreases, respectively). These data demonstrate that Kupffer cell activation stimulates hepatocellular growth while depletion of Kupffer cells inhibits hepatocellular growth, results that provide further support for the involvement of Kupffer cell in hepatocarcinogenesis.

759 DIET ACIDIFICATION HAS NO EFFECT ON PEROXISOME PROLIFERATOR ACTIVATED RECEPTOR (PPAR) OR EPIDERMAL GROWTH FACTOR (EGF) SIGNALING IN RAT URINARY BLADDER UROTHELIUM.

We previously reported prevention of urolithiasis and associated rat urinary bladder tumors by urine acidification (via diet acidification) in male rats treated with the dual PPAR α / γ agonist muraglitazar. Because the potential for urine acidification to alter urothelial PPAR or EGF signaling was not examined, we evaluated urothelial PPAR expression and signaling, cell proliferation, and/or epidermal growth factor receptor (EGFR) expression and signaling in rats fed either a normal or an acidified diet for 5, 18, or 33 days. A subset of rats in the 18-day study also received 63 mg/kg of the PPAR γ agonist pioglitazone daily for the final 3 days to directly assess the effects of diet acidification on responsiveness to PPAR γ agonism. Urothelial PPAR expression and signaling were evaluated in the 18- and 33-day studies by immunohistochemical assessment of PPAR protein levels (33-day study only) and quantitative real-time polymerase chain reaction (qRT-PCR) measurement of PPAR-regulated gene expression. In the 5 day study, EGFR expression and signaling were evaluated by immunohistochemical staining of total and phosphorylated EGFR protein and qRT-PCR measurement of egfr and akt2 mRNA levels. Diet acidification did not alter urothelial PPAR α or γ receptor levels, expression of PPAR α - or γ -regulated genes, EGFR protein levels or phosphorylation, egfr or akt2 expression, or urothelial cell proliferation. Moreover, diet acidification had no effect on pioglitazone-induced changes in urothelial PPAR γ -regulated gene expression. From this work, we conclude that urine acidification does not prevent PPAR γ -induced bladder tumors by altering PPAR or EGFR expression or signaling in rat bladder urothelium.

760 UROTHELIAL CARCINOGENESIS IN THE URINARY BLADDER OF MALE RATS TREATED WITH MURAGLITAZAR, A PPAR α/γ AGONIST: EVIDENCE FOR UROLITHIASIS AS THE INCITING EVENT IN THE MODE OF ACTION.

Muraglitazar, a PPAR α / γ agonist, dose dependently increased urinary bladder tumors in male HSD rats administered 5, 30, or 50 mg/kg/day for up to 2 years. To determine the mode of tumor development, rats were treated daily for up to 21 months at doses of 0, 1, or 50 mg/kg while being fed either a normal or 1% NH₄Cl-acidified diet. Muraglitazar-associated, time-dependent changes in urine composition, urothelial mitogenesis and apoptosis, and urothelial morphology were assessed. In control and treated rats fed a normal diet, urine pH was generally ≥ 6.5 , which facilitates formation of calcium- and magnesium-containing solids, particularly in the presence of other prolithogenic changes in rat urine. Urinary citrate, an inhibitor of lithogenesis, and soluble calcium concentrations were dose dependently decreased in association with increased calcium phosphate precipitate, crystals and/or microcalculi; magnesium ammonium phosphate crystals and aggregates; and calcium oxalate-containing thin, rod-like crystals. Morphologically, sustained urothelial cytotoxicity and proliferation with a ventral bladder predilection were noted in treated rats by month 1 and urinary carcinomas with a similar distri-

bution occurred by month 9. Urothelial apoptotic rates were unaffected by muraglitazar treatment or diet. In muraglitazar-treated rats fed an acidified diet, urine pH was invariably <6.5, which inhibited formation of calcium- and magnesium-containing solids. Moreover, dietary acidification prevented the urothelial cytotoxic, proliferative, and tumorigenic responses. Collectively, these data support an indirect pharmacologic mode of urinary bladder tumor development involving alterations in urine composition that predispose to urolithiasis and associated decreases in urine soluble calcium concentrations.

761 THE EFFECTS OF CIGARETTE SMOKE INHALATION ON THE BLADDER UROTHELIUM OF FEMALE C57BL/6 MICE.

N. M. Clark¹, T. Ohnishi¹, J. He¹, L. L. Arnold¹, C. Boyer², S. Kawasaki³, X. Liu³, S. Rennard³ and S. M. Cohen¹. ¹Path/Micro, University of Nebraska Med. Ctr, Omaha, NE, ²Genetics Cell Bio & Anat, University of Nebraska Med. Ctr, Omaha, NE and ³Int Med. Pulm, University of Nebraska Med. Ctr, Omaha, NE.

Cigarette smoking is the major environmental risk factor for bladder cancer in humans. The exact mechanism is unknown but the potent bladder carcinogens, aromatic amines, are present in cigarette smoke and are believed to be involved. Increased cell proliferation, caused by a direct mitogenic effect or in response to cytotoxicity, is a well-accepted mode of action for tumor formation, and may play a role in cigarette smoke-induced bladder cancer. Hyperplasia of the bladder epithelium has been found in human cigarette smokers. We examined the effects of inhalation exposure to smoke in a whole body exposure (Teague) system, 2 hours/day, 5 days/week, on the urothelium of female C57BL/6 mice. In study 1, the effects of smoking were determined at 1 week and 1 and 3 months by light microscopy and by Ki-67 labeling index (LI). Reversibility was examined by treating for 1 week or 1 month followed by 3 weeks or 2 months, respectively, of no treatment. In study 2, the effects of treatment were determined at 1 and 5 days by light microscopy, and bromodeoxyuridine (BrdU) LI. Reversibility was examined by treating for 5 days followed by no treatment for 2 days. In both studies, there was no increase in urothelial hyperplasia by light microscopy. However, in study 1, the Ki-67 LI of the urothelium was significantly increased in the smoking group compared to the control group at all time points. The Ki-67 LI in the reversibility group was similar to control at 1 month and significantly lower than the control at 3 months. In study 2, the BrdU LI in the smoking group was similar to control on day 1 but was significantly increased compared to the control at 5 days. The LI in the reversibility group was increased compared to control but the increase was not statistically significant. Exposure of female C57BL/6 mice to cigarette smoke by inhalation induced an increase in urothelial cell proliferation which was reversible upon cessation of exposure.

762 EFFECT OF TREATMENT WITH SODIUM ARSENATE (ASV) OR SODIUM ARSENITE (ASIII) IN THE DRINKING WATER ON THE BLADDER UROTHELIUM OF MALE AND FEMALE F344 RATS AND C57BL/6 MICE.

L. L. Arnold, N. M. Clark, J. He, T. Ohnishi and S. M. Cohen. *Pathology & Microbiology, University of Nebraska Med. Ctr, Omaha, NE.*

Based on epidemiological data, inorganic arsenic (arsenate and arsenite) in the drinking water is carcinogenic to the urinary bladder in humans. The lack of a good animal model has made studies of the mechanism of inorganic arsenic carcinogenesis in humans difficult. Previous long-term studies in rats and mice with inorganic arsenic were negative although these studies were done prior to the development of today's standards for 2-year bioassays. We evaluated the effect of treatment with 100 ug/g AsV or AsIII in the drinking water for 2 weeks on the urothelium of male and female rats and mice using light microscopy. There was a significant decrease in body weight gain in AsV-treated rats and the female mice and in AsIII-treated rats and mice. This may indicate that the arsenic doses used were toxic, or the decreased body weight gain may be related to an aversion to drinking the arsenic-containing water. By light microscopy, there was a significant increase in the incidence of hyperplasia in the urothelium of AsV-treated rats, with the female more sensitive than the male. There were no changes in the urothelium of AsV-treated mice. In the AsIII-treated animals, there was a significant increase in urothelial hyperplasia in the treated rat and mouse groups, with the females more sensitive than the males of each species. The urothelial changes in the AsV-treated rats confirm a previous report from our laboratory of increased urothelial hyperplasia in AsV-treated female rats and indicate that the rat may be useful in studies evaluating the mode of action of arsenic-induced urinary bladder cancer in humans. However, significant differences in the metabolism of arsenic in the rat compared to humans should be taken into account. Based on the changes in the bladder urothelium of AsIII-treated mice

and the similarity in arsenic metabolism in mice compared to humans, the mouse may provide a more appropriate animal model for mechanistic studies of AsIII-induced urinary bladder cancer.

763 INDUCTION OF URINARY BLADDER PATHOLOGY IN MALE AND FEMALE C3H MICE EXPOSED TO SODIUM ARSENITE FROM GESTATION THROUGH YOUNG ADULTHOOD.

G. Ahlborn¹, R. Grindstaff¹, J. Allen¹, G. Nelson¹, K. Kitchin¹, J. Preston¹, M. Waalkes², B. Diwan³ and D. Delker¹. ¹Environmental Carcinogenesis Division, U.S. EPA, Research Triangle Park, NC, ²Laboratory of Comparative Carcinogenesis, NCI at NIEHS, Research Triangle Park, NC and ³Basic Research Program, NCI, Frederick, MD.

Epidemiology studies suggest that chronic exposure to inorganic arsenic is associated with cancer of the skin, urinary bladder and lung as well as the kidney and liver. Recently, an in utero animal model was developed to characterize the carcinogenic properties of inorganic arsenic (Waalkes et al., 2003). A brief exposure to sodium arsenite in utero (gestation day 8 to 18, GD8-18) increased liver, lung, adrenal, ovarian and uterine tumors in C3H and/or CD-1 mice. In the study described here, C3H mice were exposed to 85 ppm inorganic arsenic in their drinking water in utero (GD8-18) or a similar brief exposure post-pubescent (postnatal day 57 to 67, PD57-67) or a prolonged continuous exposure through both stages of development (GD8-PD67). At PD67, groups (n=5) of male and female mice from control and all treatment groups were examined pathologically. A treatment-related increase in eosinophilic granules of the urinary bladder transitional epithelium was observed in all male and female mice of the continuous (GD8-PD67) and post-pubescent groups (PD57-67). These eosinophilic granules are representative of degradative products in response to injury. The severity of bladder lesions was greatest in the GD8-PD67 group followed by the PD57-67 group. One female mouse in the in utero only exposure group also demonstrated minimal eosinophilic granule accumulation in the bladder epithelium. Uterine hyperplasia was observed in two female mice in the GD8-PD67 group and one female mouse in the PD57-67 treatment group. These results demonstrate that a brief exposure, in utero or post-pubescent, to sodium arsenite is sufficient in inducing aberrant changes in urinary bladder and/or uterine pathology in mice and that prolonged exposure from gestation through young adulthood increases the severity/incidence of these lesions. This abstract does not necessarily reflect EPA policy.

764 ARL HYDROCARBON RECEPTOR (AHR): DUAL FUNCTIONS, ONE FOR TUMOR PROMOTION THROUGH DRUG METABOLISM AND THE OTHER FOR TUMOR SUPPRESSION.

Y. Hirabayashi¹, B. Yoon¹, G. Li¹, Y. Fujii-Kuriyama², T. Kaneko¹, J. Kanno¹ and T. Inoue³. ¹Division of Cell & Mol Toxicol, Center for Biol Safety & Res, Nat'l Inst. of Health Sciences, Tokyo, Japan, ²Tsukuba Adv Res Alliance, University of Tsukuba, Tsukuba, Japan and ³Center for Biol Safety & Res, Nat'l Inst. of Health Sciences, Tokyo, Japan.

Ahr plays a role of tumor promoting function via xenobiotic activation of cytochrome p4501A1. However, accumulated current data contrarily suggest its tumor suppressive function, such as an activation of p27, association with Rb gene for cell-cycle arrest, etc., although direct evidence has never yet been reported by lifetime observation studying the tumorigenicity. Aim of the present study is to establish a CYP1A1-independent, Ahr-mediated tumor suppressive function using Ahr knockout (KO) mice. **Materials and methods:** The generation of homozygous Ahr KO (Ahr^{-/-}) mice, 129/SvJ, is described elsewhere (Mimura, 1997). Twenty-four mice of Ahr^{+/-}, 23 of Ahr^{+/-}, and 18 of Ahr^{-/-} male mice used in this study were monitored their spontaneous tumor development throughout the lifetime. Survival curves were applied to Gompertzian law of mortality to examine life spans and mortality rates. Cell kinetic study of hemopoietic stem-cell compartment was also conducted. **Results and Discussions:** The mean life span of the Ahr^{-/-} group was 756 days, which was significantly shorter than those of Ahr^{+/-} (855 days) and wild type mice (890 days) (Kaplan-Meier/logrank test: P<0.002 and p<0.0001, respectively). The shortened life span in Ahr^{-/-} mice was based on an early onset of hemopoietic neoplasms, and an early and high incidence of hepatoma development in the Ahr^{-/-} group. The histological spectrum of hepatomas observed among the groups was essentially identical. Because of the early onsets of lymphomas and hepatomas observed in Ahr^{-/-} mice, and the faster cell cycle in the hemopoietic progenitor cells, the biological function of Ahr is implied to be a tumor suppression, and the function of aryl hydrocarbon receptor in the hemopoietic progenitor cell is to keep the stem cell compartment be quiescent and stabilized from risky stem-cell cycling and perturbation.

765 FORMATION OF REACTIVE OXYGEN SPECIES (ROS) IN TCDD- AND ESTRADIOL-TREATED LIVER CELLS.

M. Goettel¹, M. Fusser², B. Epe², A. Mally³, W. Dekant³ and D. Schrenk¹.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) was classified as a human carcinogen. TCDD acts as a liver carcinogen in female but not in male Sprague-Dawley rats. Its effects are mediated by the aryl hydrocarbon receptor (AhR). The activated AhR enhances the transcription of a wide spectrum of genes including cytochromes P450 (CYP) 1A1, 1A2, and 1B1. There is good evidence for a role of estrogens in the mechanism of TCDD-induced hepatocarcinogenesis in the rat showing estrogen-dependent formation of 8-oxo-2'-deoxyguanosine (8-oxo-dG) in female rat liver DNA. It was postulated that estrogens can act as genotoxic procarcinogens. In particular, the catechol estradiol metabolite 4-hydroxyestradiol, formed by CYPs, can generate DNA damaging ROS via redox cycling and the corresponding quinone may cause DNA damage.

We examined the formation of ROS using the 2',7'-dihydrodichlorodifluorescein diacetate (H2DCFDA) fluorescence assay after incubation of hepatoma cells or rat primary hepatocytes with TCDD and/or estradiol (E2). The amount of 8-oxo-dG in DNA of hepatoma cells was measured by HPLC-MS/MS. In addition, we analysed the amount of 8-oxo-dG in hepatic DNA from mice deficient in 7,8-dihydro-8-oxoguanine-DNA glycosylase (Ogg1 protein) and Cockayne syn-drome B (Csb) using a modified alkaline elution technique.

Induction of CYPs by TCDD was able to increase ROS formation in rodent but not in human HepG2 hepatoma cells. Co-incubation of TCDD with 100 nM E2 did not markedly enhance TCDD-induced ROS formation. 8-oxo-dG levels in the DNA of H4IIE cells, HepG2 cells and rat hepatocytes after TCDD treatment were in good agreement with ROS formation and induction of CYP1A activity. However, in vivo treatment with TCDD (96 h) had no effect on steady-state levels of fpg-sensitive base modifications neither in wild-type nor in mice deficient in the repair of 8-oxo-dG.

766 ARYL HYDROCARBON RECEPTOR (AHR) MODULATES VANADATE INDUCTION OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF) IN CULTURED TRAMP MOUSE PROSTATE.

W. A. Fritz, R. E. Peterson and T. Lin. School of Pharmacy, University of Wisconsin, Madison, WI.

AhR, hypoxia inducible factor-1 α (HIF-1 α) and aryl hydrocarbon receptor nuclear translocator (ARNT also named HIF-1 β) are PAS family transcription factors. AhR and HIF-1 α dimerize with ARNT to alter gene expression. The impetus for the present study was the finding that AhR null (*Ahr*^{-/-}) transgenic adenocarcinoma of the mouse prostate (TRAMP) mice develop prostate tumors with greater frequency than AhR wild-type (*Ahr*^{+/+}) TRAMP mice. This suggests that *Ahr* inhibits prostate carcinogenesis. Induction of prostate epithelial hyperplasia is not altered by *Ahr* genotype, but macroscopic tumor development is inhibited in AhR wild-type (*Ahr*^{+/+}) TRAMP mice. In TRAMP mice, prostatic hypoxia stabilizes HIF-1 α which induces expression of VEGF facilitating blood vessel migration into prostatic ducts, a prerequisite for tumor growth. Since ARNT is a common dimerization partner of AhR and HIF-1 α , we tested the hypothesis that AhR in wild-type (*Ahr*^{+/+}) TRAMP mice inhibits prostate tumor formation by competing with HIF-1 α for ARNT, thereby inhibiting VEGF production. At 140 days of age, prostates from *Ahr*^{+/+}, *Ahr*^{-/-} and *Ahr*^{-/-} C57BL/6J TRAMP mice were minced and incubated in culture media containing graded concentrations of vanadate, an inducer of phosphatidylinositol 3-kinase and the HIF-1 α /ARNT pathway and subsequent VEGF expression. Vanadate induced VEGF protein in a dose-dependent fashion in *Ahr*^{+/+} and *Ahr*^{-/-} TRAMP prostate cultures, but not in *Ahr*^{+/+} cultures. Western blot analysis demonstrated that vanadate induced upstream proteins in the signaling cascade to a similar extent in TRAMP prostates of each *Ahr* genotype, evidenced by Akt phosphorylation. These findings suggest that inhibition of prostate carcinogenesis in *Ahr*^{+/+} TRAMP mice may result from increased AhR-ARNT dimerization reducing the amount of ARNT available to interact with HIF-1 α , thereby reducing VEGF production and tumor growth. (Supported by NIH grants CA095751, ES01332 and ES12352).

767 ASSESSMENT OF 4-CHLOROBIPHENYL *IN VIVO* USING THE BIG BLUE RAT MODEL: MUTAGENICITY, GENE EXPRESSION, AND HISTOLOGY.

J. Jacobus¹, L. Lehmann², H. Esch¹, L. Robertson¹ and G. Ludewig¹. ¹OEH, University of Iowa, Iowa City, IA and ²Section of Food Chemistry and Toxicology, University of Karlsruhe, Karlsruhe, Germany.

Toxicological studies of polychlorinated biphenyls (PCB) have traditionally focused on receptor-mediated effects. However, the toxicity of lower-chlorinated PCB congeners via metabolic pathways should not be ignored. PCB3 (4-chlorobiphenyl) is

detected in urban air when careful analysis is undertaken to measure this semi-volatile congener. We hypothesize that PCB3 causes DNA mutations directly via metabolic transformation to an electrophilic species, or indirectly by increasing cellular oxidative stress. To investigate the *in vivo* mutagenicity of PCB3, male and female Fischer 344 BigBlue® rats, transgenic for the lacI gene, were injected intraperitoneally with PCB3 (600 μ mol/kg), 4-hydroxy-PCB3 (4-HO-PCB3, 400 μ mol/kg), 3-methylcholanthrene (3-MC, 300 μ mol/kg, positive control), or corn oil (negative control) once per week, for 4 weeks. Animals were killed 17 days after the last injection and the mutant frequency (MF) of the liver lacI gene was determined using E. coli plated in agar containing X-Gal. In male rats 3-MC induced a 4-fold increase of the MF of the lacI gene in the liver. The MF in male PCB3-treated animals was also significantly elevated. In contrast, 4-HO-PCB3 induced a non-significant doubling of the MF. Examination of the livers showed no morphological or histological toxicity in PCB-treated animals, excluding general toxicity as cause for the increased MF with PCB3. Microarray analysis of gene expression in the livers revealed changes in 3-MC, but not in PCB-treated animals. LacI mutations were sequenced and examined to determine the type of mutational event. Transversions and frameshift mutations dominated in 3-MC and PCB-mutants compared to controls. In female rats 3-MC induced just over a 2-fold increase in MF and PCB3-treatment resulted in only a slight increase in MF. This study demonstrates for the first time the mutagenicity of a PCB *in vivo*. (Supported by ES013661, DAMD17-02-1-0241, R-82902102-0 and CHEEC)

768 ALTERATION OF GROWTH REGULATION DURING THE PROMOTION OF HEPATOCARCINOGENESIS BY PCBs IN MICE LACKING THE P50 SUBUNIT OF NF- κ B.

S. Banerjee¹, L. Chan¹, J. C. Tharappel¹, B. T. Spear¹, H. J. Lehmler², L. W. Robertson² and H. P. Glauert¹. ¹University of Kentucky, Lexington, KY and ²University of Iowa, Iowa City, IA.

Polychlorinated biphenyls (PCBs) are persistent ubiquitous chemical compounds which bioaccumulate and act as liver tumor promoters in rodents. Previous studies have shown that the promotion of hepatocarcinogenesis by PCB-153 was diminished when NF- κ B activation is impaired by the absence of p50. The present study examined the effect on growth regulation in mice that lack the NF- κ B p50 subunit. Wild type and p50^{-/-} male mice were injected with DEN (90 mg/kg) and then subsequently injected biweekly with 27 injections with corn oil or 300 μ mol/kg of 3,3',4,4'-tetrachlorobiphenyl (PCB-77) or 20 biweekly injections of 2,2',4,4',5,5'-hexachlorobiphenyl (PCB-153). Mice were administered bromodeoxyuridine in the drinking water for 6 days before euthanasia for the measurement of cell proliferation. Controls not receiving DEN were also studied. In DEN-treated mice, cell proliferation in normal hepatocytes was significantly increased in mice receiving PCB-153; this increase was inhibited in p50^{-/-} mice. PCB-77 did not affect cell proliferation in normal hepatocytes. In hepatic tumors, the rate of cell proliferation was much higher than in normal hepatocytes, but was not affected by PCB treatment or p50 deletion. The rate of apoptosis, as measured by the TUNEL assay, was significantly higher in normal hepatocytes from p50^{-/-} mice receiving PCB-77 compared to wild-type mice receiving PCB-77. The apoptotic index was slightly lower in wild-type mice receiving PCB-153 than in control wild-type mice or p50^{-/-} mice administered PCB-153. In hepatic tumors, the rate of apoptosis was lower than in normal hepatocytes, but was not affected by PCB treatment or p50 deletion. Taken together, these data indicate that the absence of the NF- κ B p50 subunit alters the proliferative and apoptotic changes in mouse liver in the response to PCBs. (Supported by ES013661, ES07380, and the Kentucky Agricultural Experiment Station.)

769 MODULATION OF EXPRESSION OF MDM2 AND MATRIX METALLO PROTEINASES (MMPs -9, -10, -12) DURING DIMETHYLNITROSAMINE (DMN)-INDUCED PROGRAMMED AND UNPROGRAMMED LIVER CELL DEATH.

S. Ismail, J. Rathod, M. Parmar and S. D. Ray. Mol. Toxicology Labs, Division of Pharmacology Scs., Arnold & Marie Schwartz College of Pharmacy and Health Scs., Long Island University, Brooklyn, NY.

The rapid multiplication of cells in the early phase of a tumor usually does not cause serious disease as long as the tissue growth remains confined to its original loci. In contrast, malignant cells migrate from their original location, invade surrounding normal tissue areas, and ultimately disseminate throughout the body. Remodeling of the surrounding extracellular matrix (ECM) proteins facilitates this process. It appears that proteolytic enzymes, such as Plasmin and MMPs play an instrumental role in degrading the surrounding ECM, thereby "clearing a path" for tumor cell migration. Although the precise role of high-level expression of distinct MMPs during malignant tumor invasion appears to be more or less settled, *in vivo* modulation of MMPs during hepatocarcinogen-induced programmed and unpro-

grammed cell death remains unknown to date. Therefore, in order to investigate the role of MDM2 and MMPs in the liver, toxic doses of DMN (0, 25, 50 and 100 mg/kg, ip) were administered to male C3H mice for 24 hours. Liver samples were subjected to biochemical analysis. Besides classic cell death parameters (determination of serum ALT activity, oxidative stress, genomic fragmentation, expression of bcl-XL, p53), expression of MDM2, MMPs-9, -10 and -12 (Gelatinase-B, Stromelysin-2, Metalloelastase) were also analyzed by western blot in the liver homogenates. Results show that DMN induced dose-dependent increases in the expression of MDM2 and MMPs, and expression of these genes strongly correlated with the elevated levels of the toxic markers (ALT in U/L: Con-75 and 100 mg DMN-3830; malondialdehyde nmol/g.liv: Con-22 and 100 mg/Kg DMN-102; DNA fragmentation: Con-100% and 100 mg/Kg DMN-375%). In conclusion, this study for the first time, has shown involvement of MDM2 and MMPs during DMN-induced acute liver injury suggesting a possible contributory role for these proteins in the propagation of drug and chemical-induced organ toxicities.

770 GLOBAL GENE-EXPRESSION PROFILING OF TAMOXIFEN-INDUCED RAT HEPATOCARCINOGENESIS.

T. V. Bagnyukova, I. Pogribny, T. Han, C. Moland, F. A. Beland and J. C. Fuscoe. *National Center for Toxicological Research, Jefferson, AR*. Sponsor: B. Delclos.

Tamoxifen is a non-steroidal anti-estrogen used for the treatment of breast cancer and, more recently, as a chemopreventive agent in healthy women at high risk of developing breast cancer. On the other hand, tamoxifen is a potent hepatocarcinogen in rats, with both tumor initiating and promoting properties. Recently it has been demonstrated that, in addition to the genotoxic components, tamoxifen-induced hepatocarcinogenesis in rat is characterized by substantial epigenetic changes. Considering the crucial role of epigenetics in regulation of gene expression, the present study was undertaken to investigate whether or not epigenetic changes induced by long-term exposure of rats to genotoxic hepatocarcinogen tamoxifen are accompanied by a sustained alteration in gene expression profile. Female F344 rats were fed a control or tamoxifen-containing diet (420 ppm) for 24 weeks. The global gene expression profile was determined in liver tissues after 12 and 24 weeks of exposure to tamoxifen. Differentially expressed genes involved distinct cellular pathways for lipid biosynthesis and metabolism, hormone metabolism, cell signaling, oxidative-stress response genes, cell proliferation and apoptosis. In addition, we identified three different patterns of gene expression associated with temporal changes in progression of the carcinogenic process: 1 - differentially expressed genes specific to 12 week time-point only; 2 - differentially expressed genes specific to 24 week time-point only; 3 - common genes differentially expressed after 12 and 24 weeks of exposure. Importantly, differentially expressed genes include those playing an important role in cancer development, such as *ABCC3*, *BRCA2*, *PPAR α* , *RBP*, *ETS-1*, *PDGFC*, *GDF15*, *pFKB1*, *GAS6*, and *LIFR*. These data indicate the importance of global gene expression profiling for elucidating the molecular mechanisms of tamoxifen-induced changes related to carcinogenesis with the potential to be used as early biomarkers for carcinogenicity.

771 LASOFOXIFENE AND OTHER SERMS INDUCE GENE TRANSCRIPTION PROFILES CONSISTENT WITH ESTROGEN RECEPTOR AGONISM IN THE MALE RAT KIDNEY.

G. D. Cappon¹, P. H. Koza-Taylor¹, J. C. Cook¹, S. Deng² and M. P. Lawton¹. ¹DSRD, Pfizer Global Research, Groton, CT and ²Non-Clinical Statistics, Pfizer Global Research and Development, Groton, CT.

Lasofloxifen is a selective estrogen receptor modulator (SERM), having receptor affinity comparable to that of the endogenous hormone 17 β -estradiol (E2). In a two-year carcinogenicity study, an increased incidence of renal tumors was observed in lasofloxifen-treated male rats, but not in female rats or mice of either sex. Examination of the metabolism and genotoxicity of lasofloxifen suggests that tumor formation does not result from either direct DNA damage or a sex or species selective difference in exposure. Small numbers of renal tumors have also been detected in male rats following long-term administration of other estrogenic compounds (raloxifen, droloxifen, tamoxifen and chlorotrianisene). In order to test the hypothesis that a hormone-mediated mechanism leads to renal tumors, SERMs were evaluated for estrogen receptor (ER) agonist activity in the male rat kidney using transcriptomics. Renal expression profiles were generated utilizing Affymetrix rat genomic arrays and tissues from male rats dosed daily for 15 days with E2, or E2 plus ICI-182,780 (ICI), an ER antagonist. From this experiment, 190 Estrogen Responsive Fingerprint (ERF) genes were identified and incorporated into a custom Affymetrix FlexArray that also included 1,420 control genes for normalization. A study was undertaken that included E2 and 17 α -ethinylestradiol (EE) as positive controls, haloperidol as a negative control, and the SERMs lasofloxifen, ta-

moxifen and raloxifen. Detailed statistical analysis of the data from the ERF array revealed that lasofloxifen did indeed regulate ERF gene expression, and that the lasofloxifen profile was most similar to that of raloxifen, closely followed by tamoxifen. The results from this experiment demonstrate that SERMs have ER agonism activity in the male rat kidney and therefore that a hormone-mediated mechanism could explain the renal tumors observed in the two-year carcinogenicity study with lasofloxifen.

772 ESTROGENIC STATUS MODULATES DMBA-MEDIATED HEPATIC GENE EXPRESSION AND CARCINOGENICITY: MICROARRAY-BASED ANALYSIS.

R. Singhal¹, K. Shankar^{1,3}, T. M. Badger^{2,3} and M. J. Ronis^{1,3}. ¹Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR, ²Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR and ³Arkansas Children's Nutrition Center, Little Rock, AR.

Estrogenic status in women influences the metabolism and toxicity of polycyclic aromatic hydrocarbons (PAH). The objective of this study was to examine the influence of estradiol (E2) on 7,12 dimethylbenz(a)anthracene (DMBA), a PAH and ligand for aryl hydrocarbon receptor, mediated changes on hepatic gene expression. Sprague-Dawley rats were ovariectomized at post natal day 50 and infused with E2 using osmotic pumps for 14d at 5 μ g/kg/day. Changes in hepatic gene expression were examined 24h following gavage with 50mg/kg DMBA. To understand the mechanism of DMBA-mediated hepato-carcinogenicity in the presence of E2, microarray analysis (Affymetrix Rat 230 2.0 GeneChip) was performed. 225 genes were down-regulated while 54 genes were up-regulated significantly (± 2 fold, $P < 0.05$) by DMBA treatment. Expression of 520 genes was altered by the combination of E2 and DMBA. Hierarchical clustering revealed that expression of 24 genes (including *egf*, *gh receptor*, *leptin receptor*, *igfbp1*) was reversed by the co-treatment of E2 and DMBA compared to DMBA alone. Gene ontology associated regulation of 303 genes involved, for example, in transcriptional regulation (including *ahr*, *hepatic nuclear factor4*, *sp1*, *igfbp3*), protein modification, xenobiotic and stress response, uniquely with the interaction of E2 and DMBA, but not by the either treatment alone. Results from *real-time* RT-PCR confirmed a significantly ($P < 0.05$) higher hepatic *cyp1a1* and *cyp1b1*, pro-carcinogen metabolizing enzymes, mRNA expression in the groups co-treated with E2 and DMBA as compared to DMBA alone, suggesting increased DMBA-mediated mutagen activation, and hence carcinogenesis, in the presence of E2. These data expand our understanding of the synergistic, additive and interactive effects of E2 on PAHs-mediated carcinogenicity. Supported by USDA #6251-51000-005-02S.

773 IDENTIFICATION OF GENES THAT MAY PLAY A KEY ROLE IN PHENOBARBITAL (PB)-INDUCED MOUSE LIVER TUMORIGENESIS DUE TO ALTERED DNA METHYLATION.

J. M. Phillips¹ and J. I. Goodman². ¹Biochem. & Mol. Biol., Mich. State U., East Lansing, MI and ²Pharmacology & Toxicology, Mich. State U., East Lansing, MI.

The epigenetic DNA modification 5-methylcytosine regulates tissue-specific gene expression. Abnormal patterns of DNA methylation facilitate altered gene expression underlying tumorigenesis. PB, a nongenotoxic rodent hepatocarcinogen, alters DNA methylation during tumor promotion. Our laboratory devised a method, involving methylation-sensitive restriction digestion, arbitrarily-primed PCR, and capillary electrophoretic separation of the PCR products, that detects treatment-related regions of altered DNA methylation (RAMs), i.e., hyper-, hypo-, and "new" methylations in multiple portions of the genome, simultaneously. Male B6C3F1 mice, sensitive to PB-induced liver tumorigenesis, and the relatively resistant C57BL/6 strain were treated with PB, 0.05% (w/w) in drinking water for 2 or 4 wk prior to analysis of methylation status. RAMs that were unique to the B6C3F1, especially those that carried forward from 2 to 4 wk, are deemed possible key RAMs involved in tumorigenesis (Bachman et al., 2006). The goal of the current study is to annotate the key RAMs. PCR products representing key RAMs were cloned, sequenced, and annotated via the UCSC BLAT sequence alignment tool. A third of the 138 unique PB-induced RAMs have been annotated. Genes that may play key roles during mouse liver tumorigenesis include: Ephrin-B2 (EfnB2) encodes a ligand that activates a signaling pathway which plays an essential role in angiogenesis and vessel maturation and is hypomethylated at 2 wk; tyrosine kinase non-receptor 2 (Tnk2) whose overexpression in human cancer cells causes an increase in cell motility, invasiveness, and metastasis, is hypomethylated at 4 wk; and protein tyrosine phosphatase, receptor type O (Ptpro), a potential tumor suppressor gene whose overexpression delayed re-entry of human cells into the cell cycle and increased susceptibility of the cells to apoptosis, is hypermethylated at 4 wk. In this fashion we are striving to discern novel genes that may play a role in tumorigenesis due to altered methylation.

774 EFFECT OF DIET AND *HELICOBACTER HEPATICUS* INFECTION ON THE DETECTION OF LIVER CARCINOGENICITY IN B6C3F₁ MICE FOLLOWING TWO-YEAR DERMAL EXPOSURE TO TRIETHANOLAMINE.

M. D. Stout, F. A. Suarez and J. R. Bucher. *NTP/NIEHS, Research Triangle Park, NC.*

Nomination for NTP characterization of the carcinogenicity of triethanolamine (TEA) was based on the likelihood of human exposure and the potential for metabolism to the carcinogen, *N*-nitrosodiethanolamine. An initial two-year study in mice was repeated due to the detection of *Helicobacter hepaticus* (*H. hepaticus*), which was associated with hepatitis in males. Male (0, 200, 630, or 2000 mg/kg) and female (0, 100, 300, or 1000 mg/kg) B6C3F₁ mice were topically administered TEA in both studies, but the diets differed between the first (NIH-07 diet) and second (NTP-2000 diet) studies. A PCR-based method was used to evaluate tissues for the presence of *H. hepaticus*. In the initial study, significant increases in hepatocellular adenomas (HAD) and multiple hepatocellular adenomas (MHAD) were found at the high dose in both sexes, and in hepatocellular carcinomas at 300 mg/kg in females. In the second study, a significant increase in hepatic hemangiosarcomas was found in males exposed to 630 mg/kg. The incidence of HAD, although lower in controls when compared to the first study, was not affected by TEA exposure. Significant increases in HAD at all dose levels and in MHAD at 300 and 1,000 mg/kg were found in females. The incidence of liver tumors in controls was decreased two-fold when compared to the initial study. Observed control liver tumor incidences in females were similar to those predicted by a statistical model for each diet. The first study was considered *inadequate to evaluate carcinogenicity* due to uncertainty over the role of *H. hepaticus* infection in the observed liver tumor incidences. In the second study, liver tumor data provided *equivocal* (males) and *some* (females) *evidence of carcinogenic activity*. While the presence of *H. hepaticus* did not markedly affect the overall conclusions of the study, the lack of a HAD response in males was likely due to the absence of *H. hepaticus* infection and hepatitis. The decrease in control liver tumor formation, which was attributed to improved diet, enhanced the sensitivity of the assay in females.

775 CHILD-SPECIFIC REFERENCE VALUES FOR SCHOOL SITE RISK ASSESSMENT ARE BASED ON PHARMACODYNAMIC AND PHARMACOKINETIC DIFFERENCES BETWEEN CHILDREN AND ADULTS.

S. A. Knadle, D. W. Chan, D. Qiao, S. A. Camacho and D. M. Siegel. *Integrated Risk Assessment Branch, Cal/EPA, OEHHA, Sacramento, CA, CA.*

California Health and Safety Code 901(g) requires the Office of Environmental Health Hazard Assessment (OEHHA) in the California Environmental Protection Agency (Cal/EPA) to identify chemical contaminants at school sites that may be of concern because of child-specific exposure and child-specific physiological sensitivities. These chemicals are found in soil and indoor dust of new schools constructed in urban or agricultural settings. The lack of guideline toxicity studies in juvenile animals has required a choice between trying to identify and apply a child-specific safety factor appropriate for all chemicals to an existing guideline study or to search for peer-reviewed experimental studies in immature animals to develop child-specific reference doses (chRDs). The Integrated Risk Assessment Branch (IRAB) found that data are more available on pharmacokinetic (PK) age-related comparisons than for pharmacodynamic (PD) comparisons. Mechanism of action research usually provides the only PD data for chemicals that alter maturation in developing organs compared to causing overt toxicity to a mature organ. IRAB will present three neurotoxins - chlorpyrifos, dieldrin and toluene - to exemplify different effects on developing brain compared to mature brain. They also illustrate the attributes of toxicity in juvenile animals: 1) toxicity is chemical specific and the mechanism of toxicity in young animals may differ from that in adults, 2) adverse effects during development alter mature function but produce no visible pathology, and 3) effects on developing animals are usually irreversible, whereas the same exposures to adult animals cause transient effects. IRAB will also show the PD or PK aspect of each finalized chRD (cadmium, chlordane, heptachlor, heptachlor epoxide, manganese, and nickel) and "public review" chRDs (atrazine, chlorpyrifos, DDT, deltamethrin, dieldrin, endosulfan, lead, methoxychlor, and toluene) and compare juvenile and mature organ endpoints.

776 MICROARRAY ANALYSIS OF OFLOXACIN-INDUCED CHONDROTOXICITY IN MALE JUVENILE RATS.

K. Goto, T. Suzuki, Y. Yamamoto, K. Yabe, Y. Tsuchiya, K. Takasuna and K. Furuhashi. *Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., Ltd., Tokyo, Japan.*

To investigate the molecular details of chondrotoxicity due to the quinolone antibacterial agent ofloxacin (OFLX), this agent was orally administered once at 900 mg/kg to male juvenile (3 weeks old) Sprague-Dawley rats, and then gene expres-

sion profiles in the articular cartilage of the distal femur were measured at 2, 4, 8 and 24 h post-dose with Affymetrix GeneChip Rat Genome 230 2.0 Array. Some of genes were confirmed by a quantitative real-time reverse transcription-polymerase chain reaction (qRT-PCR) analysis. As a result, 134 probes showed a statistical difference in expression and an up- or down-regulation at least 1.5-fold in the OFLX-treated group as compared with the vehicle group. Based on hierarchical clustering, these probes were classified into the following 6 groups: group 1, inflammatory and cell death-related genes (22 probes, up-regulated at 4 and 8 h post-dose); group 2, stress response genes (22 probes, up-regulated at 8 and 24 h post-dose); group 3, matrix-degrading protease and protease inhibitor genes (46 probes, up-regulated at 24 h post-dose); group 4, endoplasmic reticulum-related genes (4 probes, down-regulated at 4 and 8 h post-dose); group 5, interleukin-related genes (15 probes, up-regulated at 2 h post-dose); group 6, matrix synthesis and protection-related genes (25 probes, down-regulated throughout the study period). Among these genes, significant increases in tumor necrosis factor receptor superfamily, member 12a (Tnfrsf12a, group 1), prostaglandin-endoperoxide synthase 2 (Pgs2, group 1), matrix metalloproteinase 3 (MMP3, group 3) and interleukin 6 receptor (Il6r, group 5), and decreases in gremlin 1 homolog, cysteine knot superfamily (Grem1, group 6) and hyaluronan synthase 2 (Has2, group 6) were observed in the qRT-PCR analysis. In conclusion, the initial event of OFLX-induced chondrotoxicity was considered to be increases in cytokines and prostaglandins in the cartilage, followed by the activation of cartilage disruption and disturbance of cartilage protection.

777 GENDER BASED PRELIMINARY PEDIATRIC STUDIES FOR SERUM AMYLOID A (SAA) AND C-REACTIVE PROTEIN (CRP).

I. Hauge^{1,2}, S. M. Golden^{2,1}, J. Y. Richardson^{2,1}, M. Niemotka^{2,1}, R. Pabros^{2,1}, G. L. Gildengorin^{2,1} and S. Stassen^{2,1}. ¹AFRL/HEPB, Wright-Patterson AFB, OH, Fairborn, OH and ²CIF, Travis AFB, CA, Fairfield, CA. Sponsor: D. Mattie.

Proinflammatory response is a key to many toxicological exposures. Knowing the acute phase reactants baseline levels are critical to defining the initial response state in risk groups, such as children. Serum Amyloid A (SAA) and C-Reactive protein (CRP) increase in inflammatory, infectious and neoplastic disorders. Pediatric SAA data are limited. Our study objectives were to measure the SAA and CRP levels in non-infected male and female children and to compare them to children with acute viral or bacterial infections. We found significant gender differences in SAA values within the non-infected group (males median = 4.81 µg/mL, females median = 9.77 µg/mL; p<0.05). Despite the finding, these differences are not considered clinically relevant. We examined SAA values separately in males and females. For males, SAA values were significantly elevated in the bacterial infection group (151 µg/mL; p<0.0001) compared to non-infected controls. Significantly elevated SAA levels were also found in males with viral infection (27.6 µg/mL; p = 0.005). In males, SAA levels, therefore, appear to be of value in the diagnosis of infection, and may also be of value in differentiating between viral and bacterial infections. In contrast, females had no differences in SAA levels between the three groups examined. By comparison, there were no gender differences in the CRP non-infected group concentrations. CRP levels were found significantly higher in the bacterial group (0.42 mg/dl) as compared to the non-infected group (0.09 mg/dl, p<0.001), as well as in the viral infection group compared to the non-infected group (0.34 mg/dl, p=0.004). In summary, for males, SAA and CRP levels can be indicative of generalized infection, and comparison between the two may be useful in the early differentiation between viral and bacterial infections. Further studies are needed to verify these preliminary findings. In females, pre- and post-menstrual studies are required to further evaluate our current data.

778 ARSENIC AND DIELDRIN MIXTURES CAUSE A DELAY OF MATURATIONAL INDICES IN NEONATAL AND JUVENILE RATS.

L. Ogden^{1,2}, T. Graham², M. Mansour¹ and T. Datiri¹. ¹Veterinary Medicine; Biomedical Sciences, Tuskegee University, Tuskegee, AL and ²Veterinary Medicine; Pathobiology, Tuskegee University, Tuskegee, AL. Sponsor: M. Mumtaz.

The objective of this study is to identify potential toxic effects of sodium arsenite (As) and dieldrin (Ded) mixtures in neonatal and juvenile rats using in-life data and hormone levels as end points. After acclimation, plug positive rats were randomly assigned to 1 of 6 Groups (Gp) (16/Gp) and orally gavaged from Gestation day (GD)7 through lactation with As-Ded-mixtures as follows: Gp 1 [0-0], Gp 2 [0.5-0.34], Gp 3 [1.0-0.69], Gp 4 [2.0-1.38], Gp 5 [4.0-2.75] mg/kg/day. After weaning, neonates were gavaged from postnatal day (PND) 22 through PND80 with the same dose that their respective dams received. Litter weights were determined at PND 0, 7, 14, and 21. Biweekly body weights, weekly feed consumption, daily clinical observations, hormones, and maturational indices were documented in the F1 male and female offspring.

Neonatal mortalities were greatest in the higher doses (Gp 4 & 5). On PND0 there was a trend toward shortening of the anogenital distance (AGD) in all male pups exposed to the mixtures; the difference was significant in Gps 3, 4, and 5. Female pups showed a similar effect in Gps 3 & 5 (PND 0 & 4). There was a delay in preputial separation in males and vaginal opening in females. Incisor eruption and eye opening were delayed in both males (Gps 3 & 5) and females (Gps 4 & 5). These data suggest a general delay in maturation of both sexes but a specific increased tendency toward femaleness following exposure to As-Ded mixtures. (Supported by MHPF/ATSDR Cooperative Agreement # U50/ATU473408-01).

779 ENHANCED IMMUNOSUPPRESSION OF THE PLAQUE FORMING CELL (PFC) ASSAY IN JUVENILE B6C3F1 MICE EXPOSED TO 1, 2,5, 6 DIBENZANTHRACENE (DBA) AS COMPARED TO ADULT MICE.

D. Hernandez, W. Auttachoat, T. L. Guo, J. K. Ritter and K. L. White. *Virginia Commonwealth University, Richmond, VA.*

Numerous findings have suggested that the increased prevalence of childhood illnesses such as cancer, infection, and allergy may be due to environmental exposures. One such cause may be maternal smoking or passive smoke exposure. Known immunotoxicants in cigarette smoke and environmental pollution include polycyclic aromatic hydrocarbons such as DBA. The objective of these studies was to evaluate the immunosuppressive effects of DBA on various stages of immune system development. Adult mice were administered DBA in corn oil at dose levels of 158, 500, 1580, and 5000 µg/kg sc for 28 days. Immunosuppression was not observed at levels less than 5000 µg/kg in the following immune parameters: NK cell activity, anti-CD3 antibody-mediated proliferation and mixed-leukocyte response. In contrast, holistic assays such as the PFC assay and the delayed type hypersensitivity response were significantly suppressed at dose levels of 500 µg/kg and greater. Mice exposed to DBA in utero and through lactation showed neither immunosuppressive nor sex differences among the immune parameters tested when evaluated at weaning, postnatal day (PND) 21. Transference of DBA metabolites from mother to pup is suggested by HPLC analysis of milk extracted from PND 8 pups. In contrast, juvenile mice administered DBA beginning on PND 21 at dose levels from 0.25 to 2500 µg/kg for 28 days demonstrated a dose-dependent suppression (43-79%) of the PFC assay, statistically significant at or above the 2.5 µg/kg dose level. Neither immunosuppressive nor sex differences were observed among the various other immune parameters evaluated. Collectively, these studies indicate that the juvenile life stage in B6C3F1 mice is the most vulnerable to DBA-induced immunotoxicity with a 200-fold enhancement in immunosuppression of the PFC response as compared to adult mice. These studies provide insight into how environmental contaminants, such as DBA, may impact children's health. Sponsored by NIEHS F31 ES-014111 and in part by NIEHS N01 ES-05454.

780 TOXICITY STUDY OF ULTRA-VIOLET LIGHT ABSORBER 2-(3', 5'-DI-TERT-BUTYL-2'-HYDROXYPHENYL)-5-CHLOROBENZOTRIAZOLE (DBHCB) IN RATS DURING THE PRE-WEANING PERIOD.

M. Ema¹, T. Matsuyama², M. Matsumoto¹, A. Hirose¹, M. Hirata-Koizumi¹ and E. Kamata¹. ¹Risk Assessment, National Institute of Health Sciences, Tokyo, Japan and ²Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.

DBHCB is an ultraviolet light absorber widely used in polyolefines, polyvinyl chloride, polycarbonates, polyurethane, plexiglass and many kinds of paint. We also showed that toxicological changes in the liver, including increase in weight, were noted in male rats, but not in female rats, given DBHCB at 250 mg/kg and higher for 14 days by gavage, from the age of six weeks (SOT, 2007). In the present study, the toxicity of DBHCB was investigated in pre-weaning rats. Crj:CD(SD) rats were given DBHCB by gavage at a daily dose of 0, 250 or 500 mg/kg during the pre-weaning period, postnatal days (PNDs) 4-21. Four litters per group were used in this study. All littermates (4 males and 4 females) were assigned to the same dosage group. On PND 22, rats were necropsied. In dams, no effects of DBHCB were observed on general condition, body weight, food consumption, or in necropsy findings. In pre-weaning rats, decrease in body weight was observed in both sexes of the DBHCB-treated groups. In pre-weaning rats of both sexes in the DBHCB-treated groups, increases in absolute and relative weights of the liver, increases in the levels of aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase and total bilirubin in plasma, and histopathological changes in the liver, were noted. These data indicate that there were no sex differences in liver toxicity between males and females when DBHCB was given to rats during the pre-weaning period. Supported by the grant from the Japanese Ministry of Health, Labour and Welfare.

781 INTERPRETATION OF BIOMONITORING DATA FOR TOLUENE: USE OF PBPK MODELING.

L. Aylward¹ and S. M. Hays². ¹Summit Toxicology, LLP, Falls Church, VA and ²Summit Toxicology, LLP, Lyons, CO.

Previously published rat and human physiologically-based pharmacokinetic (PBPK) models for toluene inhalation from the literature were modified to incorporate an oral route of exposure. The models were used to simulate blood level profiles in rats and adult humans for a) exposure regimens that serve as the basis for the derivation of the current US EPA IRIS RfD and RfC values (0.08 mg/kg-d and 5 mg/m³, respectively), and b) chronic exposures at the RfD and RfC. The impact of differing levels of uncertainty factors used in the derivation of the IRIS benchmarks was assessed. The models were also used to evaluate maximal metabolic rate achieved under various exposure scenarios as surrogates for maximal metabolite concentrations, which may be relevant to kidney toxicity observed in rodent bioassays. Simulated human exposures at the RfC and the RfD resulted in blood level profiles that differed substantially, both in toluene blood levels achieved and in temporal profiles. The influence of differences in children's metabolic capability compared to adults was also evaluated based on the published literature. Infants and young children develop CYP2E1 capability gradually, resulting in higher predicted blood toluene levels in infants and young children than adults for the same external exposures. Based on the modeling and evaluation of underlying data, the blood level associated with chronic exposure at the RfC in a typical adult (approximately 17.5 µg/L) appears to provide a reliable benchmark as a safe blood level of toluene. This benchmark can be used to assess measured levels of toluene in blood collected during biomonitoring studies in children and adults by calculating a hazard index as a ratio of measured blood levels to the RfC-associated benchmark blood level. Blood levels of toluene measured in a previous study of school-aged children in an urban community corresponded to hazard indices of less than 0.02 using this approach, suggesting that ambient exposures to toluene are well below levels of health concern.

782 COMBINED REPEATED DOSE TOXICITY STUDY WITH THE REPRODUCTIVE/DEVELOPMENTAL TOXICITY SCREENING TEST OF ULTRAVIOLET ABSORBER 2-(3', 5'-DI-TERT-BUTYL-2'-HYDROXYPHENYL)-5-CHLOROBENZOTRIAZOLE (DBHCB) IN RATS.

K. Fukunishi², A. Hirose¹, M. Matsumoto¹, M. Hirata-Koizumi¹, E. Kamata¹ and M. Ema¹. ¹Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan and ²Shin Nippon Biomedical Laboratories, Osaka, Japan.

DBHCB is widely used as a UV absorber within many kinds of polymer products. The possibility of these chemicals entering the biological system has aroused great concern about their toxic potential. However, very little information is available for the toxicity. It is important to gain the toxicological information for investigating the possible influences on human health. In this study, the repeated dose toxicity and reproductive toxicity of DBHCB was evaluated in rats. Crj:CD(SD)IGS rats were given DBHCB by gavage at dose of 0, 2.5, 25 or 250 mg/kg/day. Male and female rats were dosed beginning 28 days before mating and each female rat was mated with a male rat of the same dosage group. Males were dosed for total of 56-57 days, and females were dosed to day 3 of lactation throughout the mating and pregnancy period. The remaining control and high dose groups of rats were kept without treatment for 14 days. No effects on general condition, body weight, food consumption or reproductive/developmental parameters were observed. Significant decrease in the number of red blood cells and increase in the number of neutrophilic leukocytes at 250 mg/kg/day, and increases in the albumin levels, albumin/globulin ratio and alkaline aminotransferase levels at 25 mg/kg/day and higher were noted in males. Significantly increased levels of albumin levels were also found in males at 250 mg/kg/day after recovery period. The absolute and relative weight of the liver was noted in males at 25 mg/kg/day and higher. No change in the parameters of hematology and blood chemistry and liver weight was observed in females of any group. No significant changes in histopathological examination of the organs, including the liver, were found. This study was supported by the grant from the Japanese Ministry of Health, Labour and Welfare.

783 AN INTRA-NASAL IRRITATION ASSESSMENT OF ANTI-BACTERIAL OINTMENT ALONE OR IN COMBINATION WITH MUPIROICIN VERSUS BACTROBAN NASAL IN RABBITS.

A. S. Faqi¹, D. Colagiovanni², S. Bell² and S. Gill². ¹MPI Research, Inc., Mattawan, MI and ²Replidyne, Inc., Louisville, CO.

The purpose of this study was to evaluate the potential irritating effects of an anti-bacterial (REP8839) ointment alone or in combination with Mupirocin versus Bactroban Nasal in rabbits and to assess reversibility of any changes following a 14-day recovery period. Five treatment groups of six/sex received dose levels of 1, 2, or

4% REP8839, 2% Bactroban Nasal, and 2% REP8839/2% Mupirocin combination. One additional group served as the vehicle control. The test articles or vehicle was administered to the external nares, twice a day at approx. 8 hr intervals between the doses for 21 consecutive days, at a dose volume of 100 µL per naris/dose. The external nares were reflected back and the mucosal lining was evaluated and scored for erythema and edema within 30 to 60 minutes following the first dose each day. Blood samples were collected from all animals at designated time points on Day 21 of the study to assess exposure levels. Cross sections of the nasal tract were performed in all the groups for microscopic evaluation; these were labeled as nose level A-D, which consisted of cross sections trimmed from just posterior to the upper incisors, anterior to the incisive papilla up to the first upper molar to the second upper molar.

Mucosal scoring of the narice did not reveal any edema or erythema in any of the dose groups of REP8839 alone or the combination product and as well as with Bactroban Nasal. Minimal plasma exposure was observed in the rabbits (<5 ng/mL). The REP8839 groups did appear to have dose-responsive exposure (from below the limit of quantitation to 5 ng/mL with 1%, 2%, and 4% REP8839, respectively). Microscopic changes on the nasal sectioning noted in these animals were infrequent and considered incidental findings unrelated to administration of the test articles. Doses of up to 4% of REP8839 or 2% of the combination product as well as 2% Bactroban Nasal were not found to induce mucosal irritation. Additionally, no delayed effects were observed in the recovery animals.

784 DEVELOPMENT OF A MURINE PNEUMONIA MODEL FOR VACCINE TESTING.

P. Beaumier¹, H. Wardell¹ and G. Mahairis². ¹*Safety Assessment, SNBL USA, Everett, WA* and ²*VieVax, Seattle, WA*. Sponsor: *M. Osier*.

Streptococcus pneumoniae is a common respiratory pathogen and a major cause of morbidity and mortality in humans, especially infants under 2 and people over 60 years of age. Current conjugate vaccines (eg. PREVNAR, Wyeth) have limited serotype coverage (4, 6B, 9V, 14, 18C, 19F and 23F). The purpose of this study was to develop a mouse pneumonia model suitable for testing novel vaccine test articles. Two pneumococcal strains, TIGR4 (serotype 4) and D39 (serotype 2) were passaged intraperitoneally through mice and stored at -80°C. Bacteria for infection were thawed rapidly, cultured in Todd Hewitt Broth to an O.D. of 0.6, harvested by centrifugation and resuspended in PBS, pH 7.4. The in vivo portion of the study was performed in an AAALAC accredited barrier facility applying Laboratory Biosafety Level 2 (BSL 2) precautions in compliance with applicable laws and regulations under IACUC oversight. One hundred µL of log phase bacteria was administered intranasally to isofluorane anesthetized mice. In Phase A, mice (n=5/group) were administered saline, TIGR4 or D39 strains at 7X10E7, 3.5X10E8, 7X10E8 CFU/mL on day 1. In Phases B and C, mice (n=10/group) were dosed subcutaneously with saline or PREVNAR (3.2 µg/mouse) on days 1 and 15 and then infected with D39 or TIGR4 intranasally on day 22. Body weight and time to death in hours (including moribund sacrificed animals) were monitored. All groups showed a continued increase in body weight during the study. In Phase A, mean time to mortality averaged 60 hr (TIGR4) and 46 hr (D39) and was similar at all three inoculum levels. In Phases B and C, PREVNAR was protective against TIGR4 (time to death 382 hr compared to saline control 79 hr) but only partially against D39 (mean time to death 144 hr compared to saline control 106 hr) as expected. The difference in time to death among saline controls between Phase A and Phase B and C was attributed to mice being 3 weeks older and heavier body weight. In conclusion, a viable murine *S. pneumonia* model suitable for novel vaccine screening studies was developed.

785 COMPARISON OF THE IN-VIVO PRIMARY DERMAL IRRITATION STUDY IN RABBITS WITH THE IN-VITRO TECHNIQUE OF THE CORROSITEX SYSTEM: CORROSIVE NATURE OF FOURTEEN TEST ARTICLES.

V. Mallory¹, G. P. Thomas¹, C. Spainhour¹ and R. Papciak². ¹*Pharmacology, Calvert Laboratories, Inc., Olyphant, PA* and ²*Huntsman Corporation, The Woodlands, TX*.

Assessment of the irritation and corrosive nature of test materials have been historically required by regulatory agencies. Rabbit Primary Dermal Irritation assay is performed routinely for this purpose. Recently progress in in-vitro testing methods and the wide commercial availability of certain in vitro models have enabled refinement, reduction and replacement of animal models. The purpose of this study was to determine the potential irritant and/or corrosive effects of several test articles on the skin of rabbits and correlate these data with the in-vitro assay (Corrositex System) which is presently accepted by regulatory agencies like Department of Transportation (DOT).

Fourteen test articles, (classified as Packing Group I, II or III) were subjected to the in vitro technique of the Corrositex System and were subsequently tested for dermal irritation in New Zealand White rabbits (applied to three sites on the clipped dorsal trunk for a period of 3 and 60 minutes and 4 hours).

The results were as follows;

- 1) Both assays predicted two test materials to be non-corrosive.
 - 2) The Corrositex System could not be utilized in 2 of 14 instances since the test articles did not qualify for the assay. The in-vivo assay indicated 1 as a severe irritant and 1 as a corrosive.
 - 3) The in-vitro results indicated 10 test articles to be non-corrosive. The in-vivo assays indicated those 10 test articles to be corrosive.
- Based on the results of this comparison, the correlation of the in-vitro to the in-vivo was very low (2/14). Since in 10 of 14 instances, false negative responses were obtained in the in vitro system, further evaluation of the system is necessary before the in-vivo assay can be ruled out as the benchmark standard for actual dermal exposure.

786 ELUCIDATING SIGNALING NETWORKS IN THE PERI-PUBERTAL TESTIS FOLLOWING SERTOLI CELL TOXICANT-INDUCED INJURY.

M. Hixon, G. Ouellet, T. Rasoulpour and M. Harmon. *Pathology and Laboratory Medicine, Brown University, Providence, RI*.

Children born small for gestational age (SGA) have a significantly elevated risk of cardiovascular and metabolic diseases in adulthood; however, data is limited on how SGA may impact reproductive development. Studies indicate that altered intrauterine growth increases the risk of congenital hypospadias, cryptorchidism, and testicular cancer approximately 2- to 3- fold. Evidence for these outcomes points towards alterations in the normal function of both the Sertoli and Leydig cells. Animal and human studies suggest that impaired peri-pubertal growth can affect testis size and function into adulthood. Therefore, elucidating signaling networks which modulate testis growth and identifying environmental toxicants which impinge upon these pathways will significantly impact environmental health. The Akt gene family effects testis growth. Akt1-deficient mice are born small for gestational age and have significantly smaller testes throughout their lifetime, and the germ cells of these mice are more sensitive to ionizing radiation. Our preliminary data indicate that the Akt1 signaling pathway plays a significant role in maintaining peri-pubertal testicular homeostasis. We found a striking sensitivity to germ cell apoptosis in vivo in the testis of Akt1-deficient mice exposed to Mono-2-ethylhexyl-phthalate, MEHP, a peri-pubertal Sertoli cell toxicant; and a reduction in testis size and reproductive potential in mice exposed to 6-N-propylthiouracil (PTU), a thyroid toxicant which targets Sertoli cell proliferation and differentiation. Based on these findings, we hypothesize that the Akt gene family plays a critical role in peri-pubertal testis homeostasis and that toxicants which target the Sertoli cell at this developmental window provide a crucial link between the environment and the etiology of male reproductive disease.

787 104-WEEK SAFETY EVALUATION ON IC TAG (MICROCHIP) IMPLANTED SUBCUTANEOUSLY IN RAS H2 MICE.

M. Wada¹, T. Kurebayashi¹, K. Fukazawa¹, K. Urano² and T. Usui². ¹*CLEA Japan Inc., Shizuoka, Japan* and ²*Central Institute for Experimental Animals, Kawasaki, Japan*.

We have reported that IC Tags, an animal identification tool, had no effect on a 26-week carcinogenicity test of rasH2 mice (Urano et al. in press). In this study, we investigated the chronic effect on IC Tags on growth, survival rate, and pathological findings in rasH2 mice with IC Tags implanted subcutaneously for a longer period. A 104-week observation was performed on a total of 600 mice including 150 male and female rasH2 mice (Tg mice) each, and 150 male and female non-Tg mice from the same litter as the rasH2 mice divided into a IC Tag implanted group (implanted group) and non-IC tag implanted group (non-implanted group). In the implanted group, all mice were implanted with IC Tags with an exterior finish of polypropylene subcutaneously at 7 weeks of age with a special needle, and no implantation was performed in animals in the non-implanted group. All mice were housed in plastic cages at up to five animals per cage until 104 weeks of age. Clinical observation and body weight measurement were performed every day and once every other week, respectively. A pathological examination was performed on all mice. Body weight in the implanted group was significantly higher than that in the non-implanted group in females of both Tg and non-Tg mice. The survival rate showed no difference between the implanted group and non-implanted group in Tg and non-Tg mice at 52 weeks of age. However, a slight increase in the survival rate in males in the implanted group was shown compared with the non-implanted group at 104 weeks of age. In the pathological examination, there were no specific changes induced by the IC Tag except for a subcutaneous mass observed in a female in the implanted group of Tg mice. From these data, we conclude that strong effects were not shown in rasH2 mice with IC Tags implanted for long periods.

788 INDUCED ATRIAL FIBRILLATION IN THE ISOLATED RABBIT HEART.

E. Tanhehco, M. D. Veits and P. B. Senese. *CorDynamics, Chicago, IL.*

Atrial fibrillation (AF) is common cardiac arrhythmia that can precipitate potentially lethal events such as ventricular arrhythmias and stroke. Currently, most AF models involve whole animals. We have developed a method to induce sustained AF ex vivo. Isolated hearts from New Zealand White rabbits of either sex were perfused with low potassium Krebs-Henseleit buffer (2.5 mM K⁺; normally 5.9 mM K⁺). After a period of equilibration, 300 μ M acetylcholine chloride (ACh), followed by 50 μ M epinephrine, was introduced into the perfusate solution. Following approximately 5 minutes of ACh/epinephrine exposure, AF was triggered with bursts of pacing consisting of 6000 beats per minute, through the right atrium, lasting approximately 15 seconds. These bursts of pacing were repeated until AF did not spontaneously revert. In 8 hearts, 7 developed sustained AF. The average number of episodes of burst pacing needed to generate persistent AF was 2.9. One heart did not develop AF after 20 attempts and was deemed not inducible. Left ventricular function appeared independent of atrial function in this model. A subset of hearts (n=3) were exposed to 10 μ M flecainide (a known treatment for AF) after AF was established. Within 6 minutes after exposure to flecainide, AF subsided in these hearts indicating that this model is responsive to pharmacologic intervention. Our model provides a promising method that may be used to determine the efficacy of therapies directed against AF.

789 SUPPRESSION OF HEPATIC FIBROSIS BY THE RADIX OF PLATYCODON GRANDIFLORUM.

H. Jeong and K. Lee. *Pharmacy, Chosun University, Kwangju, Kwangju, South Korea.*

Herbal medicines are increasingly being utilized to treat a wide variety of hepatic disease processes. We previously reported that aqueous extract from the roots of *Platycodon grandiflorum* A. DC (Campanulaceae), Changkil (CK), had hepatoprotective effects against acetaminophen induced liver injury. In the present study, we assayed the preventive and therapeutic effects of CK on experimental hepatic fibrosis induced by dimethylnitrosamine or carbon tetrachloride in rats. Rats were given a single intraperitoneal injection of 20 mg/kg dimethylnitrosamine or 0.5 ml/kg carbon tetrachloride twice weekly for 4 weeks. In each model, CK was given orally at 10-200 mg/kg daily for 4 weeks. CK reduced the hepatic levels of malondialdehyde, a production of lipid peroxidation and partially prevented the marked decrease in body weight and reduced the mortality rate. The degree of fibrosis was evaluated by image analysis and also by measurements of collagen and hydroxyproline content in the liver. CK treatment significantly decreased the dimethylnitrosamine- or carbon tetrachloride-induced collagen and hydroxyproline contents. Immunohistochemical examination showed that CK reduced the deposition of type I and III collagen and the expression of α -smooth muscle actin in the liver in a dose-dependent manner. These findings indicate that CK suppress the induction of hepatic fibrosis and suggest that CK might be useful therapeutically in hepatic fibrosis/cirrhosis.

790 FEASIBILITY OF MULTI-FOCAL ELECTRO-RETINOGRAPHY IN THE CYNOMOLGUS MONKEY.

B. Niggemann¹, F. M. Barker² and G. Weinbauer¹. ¹*Covance Laboratories GmbH, Muenster, Germany* and ²*Pennsylvania College of Optometry, Philadelphia, PA.*

Introduction: Humans and primates are unique in sharing a central point of best visual acuity that is a result of their macula lutea. The macula is an area of the retina that is specifically susceptible to degenerations, toxicities and photo-toxicities that can cause legal blindness. The multifocal ERG (mERG) is an important new development that enables objective topographic evaluation of the visual function of the outer layer of the posterior retina, thus highlighting the vision of the macula. The mERG is non-invasive and can be performed on repeated occasions within the in-life phase of any toxicology study. Method: Cynomolgus monkeys were tested using a combined mERG-SLO system (Roland Retiscan version 3.1; Rodenstock SLO). They were anesthetized using ketamine and xylazine injection and were placed in the prone position within a stereotaxic device (Crist Instruments, Hagerstown, MD, USA). Pupils were dilated using 1% tropicamide and 1 % atropine topical drops. The cornea of the eye being tested was anesthetized with 0.5% proparacaine drops. A wire speculum to maintain the ocular aperture and then the specially designed wide aperture monopolar platinum mERG electrode with a scleral flange was inserted. Macula position was maintained by direct control of eye position in relation to the mERG stimulus field as viewed on the SLO video screen. Results: First order P1 amplitude and latency data were recorded. The primary outcome measures of this study were taken from the mERG "ring" printout of 19 hexagonal field positions arrayed with a central peak and surrounded by two concentric rings of successively lower amplitude. Conclusion: The data demonstrate good centration of the macula and proof of concept for the mERG as a first order toxicology testing procedure in the cynomolgus monkey.

791 ASSAY DEVELOPMENT FOR INSULIN AND GROWTH HORMONE ASSESSMENT IN CYNOMOLGUS MONKEYS.

B. Lee¹, N. Makori¹, M. Gronka¹, R. Grant¹, J. Klaassen¹, S. Meyer¹ and R. Nagata¹. ¹*SNBL USA, Ltd., Everett, WA*, ²*SNBL USA, Ltd., Everett, WA*, ³*SNBL USA, Ltd., Everett, WA*, ⁴*SNBL USA, Ltd., Everett, WA*, ⁵*SNBL USA, Ltd., Everett, WA* and ⁶*SNBL USA, Ltd., Everett, WA.*

The purpose of this study was to establish analytical methods using an enzyme-linked immunoassay (ELISA) for serum insulin and growth hormone (GH) in non-human primates commonly used in toxicity testing. To determine the induction of these markers, including glucose, cynomolgus monkeys were overfed on the first day (20 biscuits at 09:00, and 20 biscuits at 16:00). On the second day, animals were fed a normal meal of 20 biscuits/day (15 biscuits at 07:00, and 5 biscuits at 16:00). On the third day, no food was provided (fasting condition) until completion of the oral glucose tolerance test (OGT). Blood samples were processed and the serum analyzed for insulin, growth hormone and glucose on Days 2 and 3 at defined intervals for a total of 7 time-points on each day. After the 7th blood draw on the third day, glucose was administered to all animals by oral gavage (at 2g/kg body weight as 34% aqueous solution). Blood samples for serum were taken at approximately 30 minute intervals for another 3 hours (for a total of 6 time-points). Constant serum glucose levels were observed on Day 2 and Day 3 before the OGT. Following administration of the glucose, there was a sharp transient serum glucose increase which lasted for approximately 1 hr. Serum insulin levels on day 3 were constant before the OGT test, and increased thereafter, correlating with glucose level increases within the same transitory period. Growth hormone increased after OGT with minimum time lag to glucose/insulin increase. The increase in growth hormone was unexpected and was attributed to handling stress. These data suggest that the analytical methods following the OGT are efficient tools to assess insulin and glucose level changes in cynomolgus monkeys.

792 APPLICATION OF OBJECT BASED IMAGE ANALYSIS AND VIRTUAL MICROSCOPY TO QUANTIFY PANCREATIC ISLET MASS IN A MOUSE GENETIC MODEL OF DIABETES.

A. Opsahl¹, R. Korn², G. Tassopoulos², J. Schreiber², S. Carvajal-Gonzalez³, A. Shen¹, D. Brees¹, W. Soeller⁴, R. Dunstan⁵ and D. Stephenson¹. ¹*Drug Safety and Research Development, Pfizer, Groton, CT*, ²*Definiens, Munich, Germany*, ³*Preclinical Statistics, Pfizer, Groton, CT*, ⁴*CVMD Biology, Pfizer, Groton, CT* and ⁵*Drug Safety and Research Development, Pfizer, Ann Arbor, MI.* Sponsor: J. Cook.

Evaluation of drug effects on pancreatic islet mass can be measured biochemically by measurement of insulin content, or morphometrically using unbiased stereology or semiquantitative image analysis of immunohistochemically-stained tissue sections. However, these methods are often very labor intensive and demonstrate high inter-animal variability, thus limiting their practical use in drug discovery. Two recently developed imaging technologies, virtual microscopy and automated image analysis, offer the potential of overcoming these problems. Combined, they allow for capturing of an area of interest at one magnification and its analysis in greater detail at a higher magnification. These two technologies were used to quantify insulin expression in the Wolframin mouse model which has been shown to have progressive islet degeneration and loss of insulin staining (Ishihara et al). Insulin area and insulin staining intensity were determined in wild type and Wolframin Knock-out mice. As previously reported for this model, islet area and insulin staining were decreased in KO mice (0.75X wild type values). In addition, this object-based image analysis approach allows easy partitioning and segmentation within the islet based upon intensity of cell staining (not easily done with standard pixel-based image analysis systems), leading to additional information to assess preclinical efficacy with islet sparing therapies. Furthermore, the effects of potential therapies on islet integrity may be an important toxicologic endpoint for assessing pancreatic toxicity in preclinical safety studies. Finally, these methods have broad applicability to other tissue-based image analysis questions.

Ishihara et al, Human Molecular Genetics, 2004, Vol. 13, No. 11

793 THE RELATIONSHIP BETWEEN BLOOD GLUCOSE LEVELS AND AMPHETAMINE-INDUCED DOPAMINE DEPLETION.

M. L. Jobes¹ and G. C. Wagner². ¹*Toxicology, Rutgers University, New Brunswick, NJ* and ²*Psychology, Rutgers University, New Brunswick, NJ.*

The mechanism through which amphetamine causes a long-lasting dopamine depletion remains unknown. In rodents, amphetamine has also been shown to cause an immediate increase in blood glucose levels followed by a marked period of hypoglycemia. As glucose is the main energy source for the brain, the hypoglycemia

caused by amphetamine may play an important role in amphetamine's dopaminergic toxicity. In a preliminary study, we found that pretreatment with dextrose counteracted the marked period of amphetamine-induced hypoglycemia and afforded some protection against dopamine depletion. In the present study, we demonstrated a significant decrease in blood glucose levels in mice that then shows a slow recovery over a 72 hour period though they are still significantly lower at 72 hours post-amphetamine. Correspondingly, dopamine levels were depleted by 80% at the 72 hour time point. We conclude that amphetamine's effects on glucose levels may play an important role in determining its toxicity in the brain.

794 REDUCED VESICULAR STORAGE OF DOPAMINE CAUSES PROGRESSIVE NIGROSTRIATAL NEURODEGENERATION.

M. Caudle^{1,2}, J. R. Richardson^{1,2,3}, K. R. Shepherd^{1,2}, M. Z. Wang^{1,2}, T. S. Guillot^{1,2}, A. L. McCormack⁴, R. E. Colebrooke⁵, D. A. Di Monte⁴, P. C. Emson⁵ and G. W. Miller^{1,2}. ¹Center for Neurodegenerative Disease, Emory University, Atlanta, GA, ²Department of Environmental and Occupational Health, Emory University, Atlanta, GA, ³Department of Environmental and Occupational Medicine, University of Medicine and Dentistry-New Jersey/Robert Wood Johnson Medical School and Environmental and Occupational Health Sciences Institute, Piscataway, NJ, ⁴The Parkinson's Institute, Sunnyvale, CA and ⁵Neurobiology Programme, Babraham Institute, Cambridge, United Kingdom.

The vesicular monoamine transporter 2 (VMAT2) is responsible for packaging dopamine into vesicles for subsequent release. VMAT2 has been suggested to serve a neuroprotective role in the dopamine system. Here we show that mice that express approximately 5% of normal VMAT2 (VMAT2 LO) display age-dependent nigrostriatal dopamine dysfunction. Over the course of 22 months, VMAT2 LO mice display elevated cysteinyl adducts to DOPA and DOPAC, and increased striatal protein carbonyl and 3-nitrotyrosine formation. These changes were associated with decreased striatal dopamine, decreased expression of the dopamine transporter (DAT) and tyrosine hydroxylase (TH). Furthermore, we observed an increase in alpha-synuclein immunoreactivity and aggregation, as well as evidence of neurodegeneration and cell loss in the substantia nigra pars compacta in aged VMAT2 LO mice. These data suggest that mishandling of dopamine via reduced VMAT2 expression is, in and of itself, sufficient to cause dopamine-mediated toxicity and neurodegeneration in the nigrostriatal dopamine system.

795 A MODEL FOR THE ANALYSIS OF NEUROTOXIC ACTION ON EMBRYONIC DEVELOPMENT BY THE ESTIMATION OF THE SOMATOSENSORY MATURATION IN MICE.

A. N. Murashev, A. V. Lobanov and M. M. Suvorova. *Biological Testing Laboratory, Branch of the Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Science, Pushchino, Russian Federation.* Sponsor: K. Khamidullina.

The standard substance, cytosine arabinoside (Ara-C), was used for the creation of abnormality mice embryonic development model. This substance is an inhibitor of DNA synthesis. It has a potent cytotoxic property concerning the divisible cells. The dates of dosing were chosen in compliance with the critical periods of mice cortex development. The consequences of Ara-C administration at prenatal days 12,5-13,5 and 13,5-14,5 were studied with respect to mice soma-tosensory development in the postnatal period. For the testing of offspring, modified Fox battery was used. It was shown that such difference in substance administration date led to various neu-rotoxic damages of the posterity, which were detected in the range of tests (cliff avoidance response, geotropism response, grasping hind limb, hind limb placing response, fore limb coordination, hind limb coordination). The present model allows us to carry out a fine analysis of the neurotoxic action of new pharmacological substances on mice embryonic development.

796 DEVELOPMENT OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODEL FOR PARAQUAT (PQ) IN C57BL/6 MICE AND ESTIMATION OF HUMAN BRAIN EXPOSURE TO PQ UNDER FIELD CONDITIONS.

L. McIntosh¹ and G. L. Kedderis². ¹Exponent, Inc., Menlo Park, CA and ²Independent Consultant, Chapel Hill, NC.

PQ and the combination of PQ and maneb (MB) have been investigated as possible risk factors for the development of Parkinson's Disease in humans (see Li et al., JOEM 47:1059-87, 2005). The first step toward determining whether laboratory

results obtained using i.p. injection of PQ in C57BL/6 mice are useful for human risk assessment is to compare i.p. exposure with the penetration of PQ into the body and brain using routes of exposure applicable to humans under realistic conditions. Adult mice were dosed by typical human routes of exposure: oral (10 mg/kg PQ $\pm$ 30 mg/kg MB), dermal (40 mg/kg PQ $\pm$ 120 mg/kg MB), and intranasal (to mimic inhalation of pesticide droplets) (3 mg/kg PQ $\pm$ 10 mg/kg MB), and 14C-PQ was quantified in blood, brain, carcass, and excreta over 24 hrs. Postnatal day 5 mice were dosed orally (0.3 mg/kg PQ $\pm$ 1 mg/kg MB) and similarly tracked for 24 hrs. Adult (10 mg/kg PQ $\pm$ 30 mg/kg MB) and juvenile (0.3 mg/kg PQ $\pm$ 1 mg/kg MB) mice were also dosed i.p. for comparison of time course and distribution of PQ. The doses were chosen to be high but below known toxicity to the lung and kidney in each route of exposure. Using separately determined tissue partition coefficients and the data from this study, the parameters for PQ entry into and exit from blood and brain were estimated from a PBPK model for PQ distribution in mice. Using literature-derived human absorption parameters for each route of exposure, and published descriptions of PQ exposure to humans during actual field conditions, a human PBPK model can be used to predict the human brain dose of PQ during field exposure conditions or through the general food and water supply. This information will allow calculation of human internal doses of PQ detected in food surveys like the Total Diet Study, PQ levels in pesticide applicator populations, and in research studies using doses applicable for risk assessment based on realistic human exposure conditions.

797 IMPROVED HUMANISED PXR AND CAR MOUSE MODELS.

J. Ross¹, N. Schneer², A. Rode², C. R. Wolf¹ and C. R. Elcombe¹. ¹CXR Biosciences Ltd., Dundee, United Kingdom and ²Artemis Pharmaceuticals GmbH, Koln, Germany.

Nuclear receptors such as the pregnane X receptor (PXR) and the constitutive X receptor (CAR) regulate hepatomegaly and drug metabolising enzymes. To investigate the roles of PXR and CAR we have created improved mouse models in which the murine genes have been exchanged for their human counterparts in the same locus (huPXR, huCAR). Existing models require two independent genetic alterations (knockout of murine genes and insertion of the human transgenes) and encode unphysiological expression levels that are liver specific, due to constitutive expression from the albumin promoter. In our huPXR and huCAR mice, the expression of human CAR and PXR are under the control of their respective mouse promoters. This strategy ensured recapitulation of endogenous tissue expression patterns and levels of PXR and CAR. P450 inducers exhibiting differing affinities for the human and mouse receptors can differentially activate the human and murine receptors in Wild Type (WT) and humanised mouse liver. Treatment with the selective "human" CAR activator, CITCO (6-(4-chlorophenyl)imidazo[2,1-b][1,3]thiazole-5-carbaldehyde O-(3,4-dichlorobenzyl)oxime 50 mg/Kg bwt., i.p.), resulted in the induction of the CAR-dependent gene, Cyp2b10, by 33- and 15-fold in the huCAR mice and WT mice respectively (pentoxifyresorufin-O-depentylation (PROD) activity). In contrast, PROD activity was increased 10-fold in WT mice and unchanged in huCAR mice following treatment with TCPOBOP (1,4-Bis[2-(3,5-dichloropyridyloxy)]benzene, 1mg/Kg bwt., i.p.), a selective "murine" CAR activator. Debenzylation of 7-benzoyloxyquinoline was used as an indicator of Cyp3a expression, which is predominantly controlled by PXR. The "human" PXR activator, rifampicin (20 mg/Kg, i.p.) increased Cyp3a activity 5-fold in the huPXR mice and only 1.5-fold in the WT mice. Cyp protein expression (immunoblots) always correlated with enzyme activity data. Preliminary studies with the cross of the huPXR and huCAR mice suggest that chemical-selective induction is maintained in the double "humanised" mouse. Programme supported by ITI Life Sciences.

798 APPLICATION OF THE HEPATIC REDUCTASE NULL (HRN) MOUSE MODEL TO A LOW CLEARANCE COMPOUND.

J. Verbeeck¹, M. Rouan¹, M. Geldof² and K. Anciaux². ¹Tibotec, Mechelen, Belgium and ²JéPRD, Beersse, Belgium. Sponsor: W. Coussement.

A diarylquinoline compound under development in our laboratories is extensively distributed and slowly cleared from the body. It is metabolized by the cytochrome P450 (CYP) system, mainly by CYP3A to the N-desmethyl derivative (M2) which is further metabolized via oxidative pathways. The effect of hepatic metabolism on the pharmacokinetics of both the parent and M2 was investigated using the Hepatic Reductase Null (HRN) mouse model (at CXR Biosciences Ltd, where it was developed). This HRN model has almost no liver CYP activity due to postnatal conditional deletion of hepatic cytochrome P450 reductase. Two single oral doses (10 and 60 mg/kg) of the drug substance were given to female HRN mice and one single oral dose (60 mg/kg) was given to female wild-type C57BL/6 mice. Blood samples were taken over 2 weeks after administration and the plasma concentrations of the parent compound and M2 were determined by LC/MS/MS. The

area under the plasma concentration-time curve of M2 calculated over two weeks ($AUC_{0-2weeks}$) was 2.4 times higher than that of the parent compound in the wild-type mice, whereas the $AUC_{0-2weeks}$ of M2 was similar to parent in the HRN mice. These results suggest that M2 may be partly formed by extrahepatic metabolism since the amount of circulating M2 was reduced in the HRN mice but still significant. These results demonstrate that the HRN model has the potential to elucidate certain *in vivo* metabolism characteristics of a compound or examine metabolite-associated toxicity. However, deletion of hepatic and extrahepatic CYP activity, eg in the gut, may be required to further decrease the systemic exposure to the M2 so that it becomes possible to understand the relative contribution of the parent compound and M2 to the toxicological profile of the diarylquinoline compound.

799 CYTOCHROME P450 ACTIVITY OF HUMAN HEPATOCYTES PROPAGATED IN UPA/SCID MICE.

C. Yamasaki¹, C. Tateno^{1,2}, M. Kataoka¹, S. Matsuda³, Y. Adachi³, S. Ninomiya³ and K. Yoshizato^{1,2,4}. ¹*Yoshizato Project, CLUSTER, Hiroshima Prefectural Institute of Industrial Science and Technology, Hiroshima, Japan*, ²*Hiroshima University Liver Project Research Center, Hiroshima, Japan*, ³*ADME/TOX Research Institute, Daiichi Pure Chemicals Co., Ltd., Ibaraki, Japan* and ⁴*Developmental Biology Laboratory, Department of Biological Science, Graduate School of Science, Hiroshima University, Hiroshima, Japan*. Sponsor: T. Miyaoka.

The metabolism of chemicals for medicines has been examined using rodents in laboratories. However, there are differences in drug metabolisms among animal species, indicating that fresh human hepatocytes are an ideal source for the test cell in investigations with such purposes. Thus, cryopreserved human hepatocytes have been used, but they are compromised upon thawing, resulting in decline and changes in their normal functions. We made "chimeric mice" by transplanting human hepatocytes into albumin enhancer/promoter-driven urokinase-type plasminogen activator transgenic/SCID mice whose liver showed normal expression patterns of human specific cytochrome P450 (CYP) genes and proteins as in the human body. Thus, these chimeric mice are utilized to predict metabolisms of drugs in human liver *per se*. In addition, when the mice were administered with ketoprofen, glucuronide conjugates were detected in their sera and bile. In the present study, we measured CYP activity of human hepatocytes isolated from the chimeric mice by the collagenase perfusion method. CYP activities of human hepatocytes from chimeric mice were higher/similar than/to cryopreserved donor cells. Importantly, ketoprofen was metabolized through glucuronide conjugates in these hepatocytes. Cryopreserved donor hepatocytes did not show such activities, demonstrating that frozen and thawed human hepatocytes regain their innate functions of drug metabolisms when propagated in mice liver. In conclusion, fresh human hepatocytes isolated from uPA/SCID mice humanized with cryopreserved hepatocytes are suitable for *in vitro* metabolic studies on drugs.

800 CHARACTERIZATION OF KNOCK-IN MICE EXPRESSING CYP1A1 PROTEIN ONLY IN MICROSOMES VERSUS ONLY IN MITOCHONDRIA.

H. Dong, T. P. Dalton and D. W. Nebert. *Environmental Health and Center for Environmental Genetics, University of Cincinnati, Cincinnati, OH.*

CYP1A1 participates in both the detoxication and metabolic activation of numerous polycyclic aromatic hydrocarbons. Although the CYP1A1 protein historically is known to localize to the endoplasmic reticulum (ER; microsomes), it is now clear that CYP1A1 is one of at least six members of the microsomal CYP1, CYP2 and CYP3 families that can also be targeted to the inner mitochondrial membrane. Mitochondrial import of CYP1A1 occurs after N-terminal processing exposes a cryptic targeting signal; mitochondrial (mt1A1) and microsomal (mc1A1) CYP1A1 exhibit both different substrate specificities and inducer profiles. To understand the physiological and toxicological variations between mt1A1 and mc1A1, we have generated three knock-in mouse lines, starting with the *Cyp1a1(-/-)* knockout genotype: *Cyp1a1(mtt/mtt)* mice encode a Truncated CYP1A1 protein that begins at residue 33, deleting the ER-targeting signal and exposing the cryptic mitochondrial-targeting signal; *Cyp1a1(mtp/mtp)* mice encode a CYP1A1 protein having Leu7Asn and Leu17Asn mutations so that it lacks the signal recognition particle (SRP)-binding and subsequent ER-targeting, but requires Proteolysis for mitochondrial import; *Cyp1a1(mc/mc)* mice encode a microsomes-only CYP1A1 protein having Arg34Asp and Lys39Ile mutations that abolish the mitochondrial targeting signal. Using different inducers, CYP1A1 has now been confirmed to target exclusively to mitochondria in the *Cyp1a1(mtt/mtt)* and *Cyp1a1(mtp/mtp)* mice and exclusively to the ER in *Cyp1a1(mc/mc)* mice. Preliminary data with oral benzo[a]pyrene (BaP; 125 mg/kg/day) for 30 days suggest that mc1A1, but not mt1A1, is required for protection against BaP that is seen in wild-type mice but not in *Cyp1a1(-/-)* knockout mice. Additional previous CYP1A1-mediated toxicity studies are being revisited, comparing these three knock-in lines with the wild-type mouse.—Supported in part by NIH grants R01 ES08147, R01 ES014403, and P30 ES06096.

801 OVARIAN MICROSOMAL METABOLISM OF BENZO(A)PYRENE IN VARIOUS MAMMALS.

D. L. Harris¹, A. Huderson¹, A. E. Archibong² and A. Ramesh¹. ¹*Biomedical Sciences, Meharry Medical College, Nashville, TN* and ²*Obstetrics & Gynecology, Meharry Medical College, Nashville, TN.*

Knowledge of the ability of female reproductive system to metabolize polycyclic aromatic hydrocarbons (PAHs) is critical to the management of female infertility and for risk assessment purposes. The PAHs are a family of widespread pollutants that are released into the environment from automobile exhausts, cigarette smoke, burning of refuse, industrial emissions, and hazardous waste sites. In exposed animals, PAHs becomes activated to reactive metabolites that interfere with target organ function and as a consequence cause toxicity. The extent of susceptibility to PAH exposure may depend on the ability of animals to metabolize these chemicals. The present study has been undertaken to see whether any differences exist among mammals in the metabolism of benzo(a)pyrene (BaP), a prototypical PAH compound. Microsomes isolated from the liver and ovaries of rat, mouse, goat, sheep, boar, and cow were incubated with 5 μ M BaP. Post incubation, samples were extracted with ethyl acetate and analyzed for BaP/metabolites by reverse-phase HPLC with fluorescence detection. The metabolism of BaP in both liver and ovaries were in the order: cow > goat > sheep > boar > rat > mouse under conditions of the test system used. The rate of metabolism (pmol of metabolite/min/mg protein) was found to be more in liver than in ovary in all the species studied. The BaP metabolites identified were 4, 5-diol; 7,8-diol; 9,10-diol; 3-hydroxy BaP; 8-hydroxy BaP; and 9-hydroxy BaP. The rodent microsomes produced considerably higher proportion of BaP 4,5-diol and 9, 10-diol than did cow, boar, goat, and sheep. On the other hand, microsomes from higher mammals converted a greater proportion of BaP to 3-hydroxy and 9-hydroxy BaP, the detoxification products of BaP. Overall, our results revealed a great variation among species to metabolize BaP (supported by the NIH grants G12 RR03032, 1S11ES014156-01A1, 5T32HL007735-12, GM08037, 1U54HD0431501-09 and RO1 HD020419-19S1).

802 PRE-CLINICAL PHARMACOKINETICS: THE IMPORTANCE OF CHOOSING THE CORRECT ANIMAL MODEL.

E. Koo¹, C. Ciubotaru¹, C. Godin¹ and C. Tuthill². ¹*Toxicology, Gene Logic Inc., Gaithersburg, MD* and ²*SciClone Pharmaceuticals, Inc., San Mateo, CA.*

SCV-07 (D-glutamyl-L-tryptophan) is an immune-stimulating dipeptide being developed as a potential treatment for infectious diseases. The pharmacokinetic (PK) and bioequivalence (BE) profiles of SCV-07 were performed following subcutaneous (SC), oral, intraperitoneal (IP), or intravenous (IV) administration in rats and mice. In rats, a BE study following single oral, SC, and IV dosing of SCV-07 at 0.01, 1, or 100mg/kg produced both dose- and route of administration-dependent PK profiles. Mean plasma SCV-07 concentrations were below the limit of quantitation at all sampling times following all routes of administration of SCV-07 at 0.01mg/kg and following oral dosing at 1mg/kg. After oral administration at 100mg/kg, SCV-07 mean concentrations attained C_{max} (3.1ug/mL) at 4-hour postdose (T_{max}). C_{max} following SC administration of SCV 07 at 100mg/kg (176ug/mL) was observed at the first sampling time postdose (0.25h; T_{max}), indicating rapid absorption. C_{max} after IV dosing at 100mg/kg was 389ug/mL. The estimated bioavailability of SCV-07 after SC dosing was 82% at 1mg/kg and 94% at 100mg/kg. The estimated bioavailability following oral dosing at 100mg/kg was 7.5%. In contrast, a BE study following single oral, IP, and IV administration of SCV-07 at 10mg/kg in mice generated PK profiles that were significantly different from those of rats. In short, the PK data from the mouse study yielded an estimated bioavailability of SCV-07 after oral and IP dosing of 52% (vs. 7.5% in rats) and 66%, respectively. In conclusion, since it was unclear what the bioavailability of this dipeptide would be following oral administration in humans, a clinical development program for an oral formulation of SCV-07 based on the PK data obtained from either the mouse or the rat model would have led to widely different conclusions. This series of preclinical studies in comparative dosing of SCV-07 in rats and mice highlight the importance of using the appropriate animal model as a basis for a clinical drug development program.

803 SEMIQUANTITATIVE HISTOCHEMICAL ANALYSIS OF OLFACTORY EPITHELIAL CYTOCHROME OXIDASE ACTIVITY FOLLOWING ACUTE HYDROGEN SULFIDE EXPOSURE.

M. F. Struve, S. A. Bumgardner and D. C. Dorman. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Our laboratory has previously shown that hydrogen sulfide (H₂S)-induced inhibition of cytochrome oxidase may be associated with olfactory neuronal loss in rats. A positive correlation between H₂S flux to the exposed epithelium and olfactory neuronal loss has also been demonstrated using an anatomically correct computational

fluid dynamics model of the rat nose. The purpose of this pilot study was to develop enzyme histochemical methods to assess cytochrome oxidase activity in situ in the nasal epithelium and to evaluate whether cytochrome oxidase inhibition is correlated with the location and severity of H₂S-induced lesions. Male CD rats (n=3-4/exposure group) were exposed by nose-only inhalation for 2 hours at inspired concentrations of 0 or 200 ppm H₂S, an exposure level associated with olfactory neuronal loss in rats. Immediately following the exposure, animals were euthanized by pentobarbital overdose, perfused with paraformaldehyde, and the nose and brain were removed and placed in sucrose for cryoprotection. Frozen sections of brain (positive control) and three transverse levels of the nose containing olfactory epithelium were collected and processed for semiquantitative (densitometric) cytochrome oxidase enzyme histochemistry. The level of cytochrome oxidase activity in control nasal epithelium varied depending on location and exceeded the normal levels seen in some brain regions. Olfactory epithelial cytochrome oxidase activity was reduced in the dorsal meatus, septum, and certain turbinates of H₂S-exposed rats vs. air-exposed controls, sites that also exhibited olfactory neuronal loss. Ongoing efforts will complete production of epithelial mapping of cytochrome oxidase activity in treated and control animals with subsequent evaluation of site-specific flux to these sites.

804 REPEATED INTRANASAL EXPOSURES TO THE MACROCYCLIC TRICHOHECENE RORIDIN A EVOKES OLFACTORY SENSORY NEURON LOSS AND INFLAMMATION IN THE MURINE NOSE AND BRAIN.

J. R. Harkema¹, K. N. Corps¹, Z. Islam² and J. J. Pestka². ¹Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI and ²Food Science and Human Nutrition, Michigan State University, East Lansing, MI.

Macrocyclic trichothecene mycotoxins (MTMs) are produced by molds that may contaminate water-damaged buildings, like those along the Gulf Coast of the United States after Hurricanes Katrina and Rita. The purpose of the present study was to determine the adverse effects of repeated exposures to a representative MTM, roridin A (RA), on the nasal airways of laboratory mice. Female C57Bl/6 mice were exposed to a single daily, intranasal, instillation of RA (0.4, 2.0, 10.0, or 50.0 µg/kg bw) in saline (50 µl) or saline alone (controls), 5 days/wk, for 3 consecutive wks. Other mice were intranasally instilled with 250.0 µg/kg RA, once a day, 5 or 4 days/wk (9 days total), for 2 wks. All mice were sacrificed 24h after the last instillation and nasal airways were processed for histopathologic, immunohistochemical and morphometric analyses. Dose-response analyses revealed that the no-effect and lowest-effect levels were 10 and 50 µg/kg bw, respectively. RA exposure induced a dose-dependent neutrophilic inflammation and loss of olfactory sensory neurons (OSNs) in both the nose and olfactory lobe of the brain. Mice exposed to 50 and 250 µg/kg bw had approximately 70% and 90% less OSNs in their olfactory epithelium, respectively, compared to that in control mice. These results suggest that nasal inflammation and olfactory neural toxicity may be important adverse health effects associated with long-term inhalation exposures to RA or similar mycotoxins found in the indoor air of severely water-damaged buildings.

805 UPTAKE AND INTERNAL DOSIMETRY OF CHLORINE IN THE UPPER RESPIRATORY TRACT (URT) OF F344 RATS.

K. C. Roberts¹, O. R. Moss¹, M. A. Sochaski¹, R. A. James¹, E. A. Gross¹, M. E. Andersen¹ and A. M. Jarabek². ¹CIIT CHR, Research Triangle Park, NC and ²NHEERL ETD, U.S. EPA, Research Triangle Park, NC.

Due to large-volume commercial use, chlorine (Cl₂) is an important hazardous air pollutant. Inhaled Cl₂ causes irritant effects in the respiratory tract. We conducted studies to characterize determinants of its mass transfer and tissue extraction in the URT. Extraction efficiency in the URT was determined as the percentage of inhaled Cl₂ retained in the surgically isolated URT of anesthetized F344 rats (both sexes) exposed by unidirectional delivery. Cl₂ analysis was done using a thermoionic analyzer previously used in human studies (Nodelman et al., 1998, Rev. Sci. Instrum. 69, 3978), modified to accommodate the lower flow rates and volumes in rodents. Exposure sets consisted of 5 animals exposed to a single concentration and flow rate. The flow rates (100, 200, or 400 ml/min) used correspond to the minute ventilation for rats of the size used, and one half and double that flow rate. The 3 concentrations (0.5, 1.0, or 2.5 ppm) correspond to a 2-year bioassay of Cl₂. The experimental design also compared uptake in live animals versus in animals killed 2 hours prior to exposure to evaluate the role of blood flow and mucus production. Internal tissue dose of Cl₂, specifically its hydrolysis product, hypochlorous acid (HOCl), that reacts with various tissue constituents, was measured by an assay of chlorotyrosines (3-chlorotyrosine and 3,5-dichlorotyrosine; Cl-Tyr). Cl-Tyr were measured in samples from 4 locations in the URT representing respiratory and olfactory tissues in the septal and lateral airstreams. High levels of extraction (>90%) were seen in all exposure sets, consistent with mice (Morris et al., 2005, Toxicol. Sci. 83, 380) and humans (Nodelman et al., 1998, J. Appl. Physiol. 87, 2073).

Flow- and concentration-dependencies were also apparent, but the responses as percent conversion to the biomarkers were complex. These data will be used to verify mass transfer coefficients and aid development of dosimetry models for Cl₂ for use in risk assessment. (This abstract does not reflect Agency policy).

806 RESPIRATORY RESPONSE AND INTERNAL TISSUE DOSE OF INHALED CHLORINE IN THE RESPIRATORY TRACT OF B6C3F1 MICE: SEX AND STRAIN COMPARISONS.

E. W. Tewksbury¹, O. R. Moss¹, M. A. Sochaski¹, C. U. Parkinson¹, E. A. Gross¹, R. A. James¹, M. E. Andersen¹ and A. M. Jarabek². ¹CIIT CHR, Research Triangle Park, NC and ²NHEERL ETD, U.S. EPA, Research Triangle Park, NC.

Chlorine (Cl₂), a high-production volume air pollutant, is an irritant. Reactive airways disease or hyper-reactivity is reported after high-concentration occupational exposures. We studied sensory apnic responses and the respiratory dose associated with a 50% reduction in ventilation frequency (RD50) in both sexes of B6C3F1 mice, the strain used in a 2-year bioassay of Cl₂. Respiratory frequency and tidal volume were determined by whole-body and double-chamber plethysmography using a Buxco system (Buxco, Inc., Stamford, CT). The American Society for Testing and Materials protocol E981-84 (ASTM, 2000) was modified to extend the exposure to 120 minutes to ensure a maximal plateau in the response. Eight mice were exposed per concentration across a range from 0 to 15 ppm. Mice were sacrificed 1 hr after exposure to harvest tissues for use in biochemical assays to measure indicators of internal Cl₂ dose, including 3-chlorotyrosine and 3,5-dichlorotyrosine (Cl-Tyr), resulting from reactions of its hydrolysis product, hypochlorous acid (HOCl), with proteins. Soluble antioxidants and Cl-Tyr were measured from samples in 4 locations in the nose and 1 in the lower left lung lobe. The RD50 in these mice was lower than previously reported, which may be due to the longer exposure or differences in the plethysmography system employed. The differences between this strain and others tested (Morris et al., 2005, Toxicol. Sci. 83, 380; Gagnaire et al., 1994, J. Appl. Toxicol. 14 (6), 405) confirm differences postulated to be due to airway architecture (Moss and Oldham, 2006, J. Aerosol Med., In Press). Female mice have a slightly higher RD50 (~2-fold) than males, which may result in a greater internal delivery, providing insight on their increased response in various toxicological studies. The biochemical data on tissue biomarkers aid in verifying dosimetry model predictions of tissue reactions for use in dose-response assessment. (This abstract does not reflect Agency policy).

807 RESPIRATORY RESPONSE AND INTERNAL TISSUE DOSE OF INHALED CHLORINE IN THE RESPIRATORY TRACT OF F344 RATS: SEX AND SPECIES COMPARISONS.

C. U. Parkinson¹, O. R. Moss¹, M. A. Sochaski¹, E. W. Tewksbury¹, E. A. Gross¹, R. A. James¹, M. E. Andersen¹ and A. M. Jarabek². ¹CIIT CHR, Research Triangle Park, NC and ²NHEERL ETD, U.S. EPA, Research Triangle Park, NC.

Inhaled chlorine (Cl₂) causes respiratory effects. Females show more severe effects than males in various toxicological studies. Females rats had decreased survival in a 2-year bioassay, requiring their exposure be reduced to 3 d / wk. We conducted a study to characterize the sensory apnic response and respiratory dose associated with a 50% decrease in ventilatory frequency (RD50) in both sexes of F344 rats, the strain used in the bioassay. Respiratory frequency and tidal volume were determined by whole-body and double-chamber plethysmography using a Buxco system (Buxco, Inc., Stamford, CT). The American Society for Testing and Materials protocol E981-84 (ASTM, 2000) was modified to extend the exposure to 120 minutes to ensure a maximal plateau in the ventilatory response. Eight rats were exposed per concentration across a range from 0 to 60 ppm. Rats were sacrificed 1 hr after exposure to harvest tissues for use in biochemical assays to measure indicators of internal Cl₂ dose, including 3-chlorotyrosine and 3,5-dichlorotyrosine (Cl-Tyr), resulting from reactions of its hydrolysis product, hypochlorous acid (HOCl), with proteins. Soluble antioxidants and Cl-Tyr were measured from samples in 4 locations in the nose and 1 in the lower left lung lobe. The internal dose measures will allow comparison of internal dose after in vivo cyclical breathing versus unidirectional steady-state exposures. Results show the RD50 is lower than previously reported and may be due to the longer period of exposure or differences in the plethysmography system employed. F344 rats have a higher RD50 (~20 ppm) than mice (~3 to 12 ppm, depending on the strain). Female rats have a higher RD50 than males which may result in an increased internal delivery, providing insight into their more severe effects. The biochemical data will help verify dosimetry model predictions of these reaction products for use in risk assessment. (This abstract does not reflect Agency policy).

808 SENSORY IRRITANT RESPONSIVENESS IN LPS-INDUCED LUNG INFLAMMATION.

M. S. Collins, R. P. Vaughan, M. J. Lanosa, C. R. DeSesa and J. B. Morris. *Toxicology Program, University of Connecticut, Storrs, CT.*

Our previous studies have shown that responsiveness to sensory irritants is enhanced in ovalbumin-induced eosinophil-rich allergic airway disease. The current study was performed to determine if a similar phenomenon occurred in neutrophil-rich airway inflammation. Toward this end, sensory irritant responsiveness was measured in female C57Bl/6J mice 1, 3 or 8 days after intranasal instillation of 20 µg lipopolysaccharide (LPS, Sigma 011:B4) or vehicle. Non-invasive plethysmography was used to assess irritant sensitivity using the induction of sensory irritation, characterized as a decreased breathing frequency due to a braking in the early phase of expiration, as a biomarker for respiratory tract sensory nerve activation. Acetic acid (80 ppm) and environmental tobacco smoke (1.7 mg/m³) were used as prototypical irritants. As assessed by lavage cellularity, neutrophilic airway inflammation was present 1 and 3 days post LPS, but had resolved by day 8. Tidal volume and peak expiratory flow to tidal volume ratio were significantly decreased from control levels on days 1 and 3 post LPS as would be expected with lung inflammation; both of these parameters had returned to control levels by day 8. At the concentrations used, both acetic acid and environmental tobacco smoke induced a mild sensory irritation response; similar irritant responsiveness was observed in both control and LPS treated mice at all time points. Thus, in contrast to ovalbumin-induced allergic airway disease, LPS-induced neutrophilic airway inflammation did not enhance irritant responsiveness, suggesting that sensory irritant hyperresponsiveness may be related to the presence of eosinophils in allergic airway disease.

809 DEPOSITION EFFICIENCY OF INHALED PARTICLES FROM 30 NM TO 10 µM IN DIFFERENT INDIVIDUAL HUMAN NASAL REPLICAS.

B. A. Wong, E. W. Tewksbury, G. M. Garcia and J. S. Kimbell. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Inhaled air that is filtered by the nose may prevent toxic particles from reaching the lungs. The deposition efficiency of the nose may be studied by using anatomically accurate nasal replicas. Nasal replicas were produced from magnetic resonance imaging (MRI) scans from four healthy individual humans, using a stereolithography process. In another individual with atrophic rhinitis, computed tomography (CT) scans were made pre- and post-reconstructive surgery that narrowed the nasal passages. Deposition efficiency measurements were made by producing a monodisperse aerosol and measuring particle concentration at the inlet and outlet to the nasal replica. A vibrating orifice aerosol generator was used to produce monodisperse particles from 1 to 10 µm in aerodynamic diameter. Nano-sized particles were produced using a nebulizer and differential mobility analyzer to select sizes from 30 to 100 nm. An aerodynamic particle sizer and scanning mobility particle sizer were used to count micrometer- and nanometer-sized particles, respectively. Airflow through the nasal replicas was in the inspiratory direction at a constant rate. Experimental results showed that nanoparticles around 100 nm were deposited with < 10% deposition efficiency that increased slightly as particle size decreased to 30 nm. Nanoparticle deposition efficiency did not differ significantly between the various replicas. At a particle size of 8 µm and flow rate of 20 L/min, deposition efficiency ranged from about 60% to 90% in the healthy nasal replicas. Particle deposition efficiency in the nasal replicas of pre- and post-surgical treatment for atrophic rhinitis differed significantly. Deposition in the pre-surgery nasal passages, which had a more open cross section, was much lower (about 20%) than in the narrowed post-surgery nasal passages. These studies suggest that nasal deposition efficiency and hence lung exposure may be less affected by variability in nasal passage geometry and airflow for nanoparticles than for larger-sized particles.

810 METHOD FOR EVALUATING PULMONARY DEPOSITION AND CLEARANCE OF DIFFERENT SIZED FINE-MODE PARTICLES IN A SINGLE ANIMAL.

A. K. Madl and K. E. Pinkerton. *Center for Health and the Environment, University of California, Davis, CA.*

Over the last decade, great attention has been given to particles that are 2.5 µm in diameter or less (e.g., PM_{2.5}). While it is not uncommon for inhalation studies to involve the delivery of multiple sized particles, to trace the deposition and clearance pattern of particles of a specific size range, airborne particles generally have to be delivered in separate monodisperse aerosol applications. As a result, the deposition and clearance of different sized particles are evaluated in separate animal groups. This study describes a unique approach in which particles of varying sizes are delivered as a monodisperse aerosol and the deposition and clearance of these particles are evaluated within a single animal. Sprague Dawley rats were exposed to aerosolized 0.5, 1, and 3 µm microspheres (3hr/day, 3 consecutive days). Animals

were examined following the end of each exposure period, as well 24 and 48 hr following the last day of aerosolization. The mass concentrations of aerosolized 0.5, 1 and 3 µm microspheres were 0.3, 1.7 and 2.1 mg/m³, respectively. The deposition pattern for the different sized microspheres varied with airway pathlength, with the larger sized microspheres (3 µm) primarily depositing in the cranial lobe and the large airways. The deposition of 0.5 and 1 µm particles increased from the bronchus to the terminal bronchioles. Total particle burden (number) of 0.5 µm microspheres in the lung was observed to be 2- and 240-fold greater than the deposition of 1 and 3 µm microspheres, respectively. Significant clearance of 3 µm microspheres was noted (50% after 48 hr), whereas little clearance was found for 0.5 and 1 µm particles up to 4 days post-exposure. The retention pattern of the different sized microspheres corresponded well with known mechanisms of particle clearance. This study design could be used to assess how other air pollutants, which target different regions of the lung, may influence the total and regional pulmonary deposition and clearance patterns of different sized particles. USEPA R831714 and R832414

811 MURINE MODEL OF SO₂ EXPOSURE EFFECTS ON AIRWAY INFLAMMATORY PROCESSES.

D. Hochman^{1,2} and E. Brooks². ¹Experimental Pathology, UTMB, Galveston, TX and ²Division of Infectious Disease and Immunology Department of Pediatrics, UTMB, Galveston, TX.

Oxidant air pollutants (ozone, oxides of sulfur and nitrogen, fine particulates, and aldehydes) are among the known risk factors contributing to the development of asthma and allergies. Sulfur dioxide (SO₂) is a known respiratory irritant and a major component of most PM 2.5 that induces bronchoconstriction in asthmatics, but its role as a modifier of allergic sensitization is less well understood. The generation of reactive oxygen species (ROS) may be responsible for the formation of an inflammatory profile leading to airway hypersensitivity and immunomodulation. C57/B6 mice and knock-out mice for the mast cell NADPH Oxidase (gp/91phox) gene and the epithelial NADPH oxidase gene (Duox1), were chamber exposed to both low (ambient exposure; 1 ppm) and high (accidental exposure: 50 ppm) dose SO₂. Mice were additionally sensitized to ovalbumin (Ova) by either IP injection or by nebulization. After Ova challenge, bronchoalveolar lavage (BAL) was collected for cell differentiation and cytokine profiling. Homogenized lungs were used for Bioplex cytokine measures and sulfite residue measures by fluorescent HPLC. Alternate lungs were removed and utilized for histopathology. Spleen T-cell proliferation was measured with H3-thymidine. Measurement of hypersensitivity to methacholine challenge was determined by the tracheal ring assay. High dose SO₂ induced an immunosuppressive effect, with evident damage to the epithelium, while exposure to ambient levels of SO₂ caused a Th2-type allergic response. Both exposures were dependent upon ROS production. ROS induced degranulation of mast cells appeared to be central to ambient level exposure responses, while signaling in epithelium appeared to be responsible for inflammation in the high level exposures. Ambient exposure via PM 2.5 may lead to asthma exacerbations through enhancement of allergic hypersensitivity. High concentration occupational exposure could lead to the syndrome known as occupational asthma via a chronic inflammatory state induced by ROS damage in the epithelium.

812 DIESEL PARTICLE INSTILLATION ENHANCES INFLAMMATORY AND NEUROTROPHIN RESPONSES IN THE LUNGS OF ALLERGIC BALB/C MICE.

A. K. Farraj, N. Haykal-Coates, B. J. Sutherland and S. H. Gavett. *Experimental Toxicology Division, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Neurotrophins, including nerve growth factor (NGF) mediate many features of allergic airways disease. Antibody blockade of NGF attenuates airways resistance associated with the allergen-specific airways responses in mice. Exposure to diesel exhaust particles (DEP) associated with the combustion of diesel fuel exacerbates allergic airways responses. We hypothesized that the intranasal instillation of DEP in allergic mice will increase the hallmark features of allergic airways disease including increased neurotrophin production. Ovalbumin (OVA)-sensitized and non-sensitized BALB/C mice were intranasally instilled six times over two weeks with 10 (DEP1) or 50 (DEP2) µg of the PM_{2.5} fraction of NIST SRM-2975 DEP or saline alone. The mice were then challenged with an OVA aerosol. Non-allergic mice instilled with DEP1 had a 2.7-fold increase in macrophages in the lung lining fluid one day after challenge, while those instilled with DEP2 had a 3-fold increase in macrophages and a 19-fold increase in eosinophils relative to saline instilled mice. OVA-allergic mice instilled with saline had increases in macrophages (2-fold) and eosinophils (7.1-fold) relative to non-allergic mice. DEP1 did not enhance OVA-induced responses. DEP2-exposed OVA-allergic mice had increases in macrophages (1.61-fold), eosinophils (1.45-fold), and neutrophils (1.78-fold) in the lung lining fluid one day after challenge relative to saline-instilled mice. DEP2 instillation also increased levels of the neurotrophin NT-3 (2-fold) in the lung lining fluid and serum IgE (1.4-fold) relative to saline-instilled mice. Three days after

OVA challenge, DEP2-exposed OVA-allergic mice had increased macrophages (1.4-fold), eosinophils (4.4-fold) and neutrophils (1.53-fold) in the lung lining fluid, but no change in NT-3 or IgE levels relative to saline-instilled mice. Neutrophin upregulation may trigger DEP-induced enhancement in serum IgE and pulmonary inflammation in allergic mice (This abstract does not reflect EPA policy).

813 RELEASE OF IL-8 AND IL-6 BY BEAS-2B CELLS FOLLOWING *IN VITRO* EXPOSURE TO BIODIESEL PM EXTRACTS.

K. J. Swanson¹, M. C. Madden², A. J. Ghio² and N. Y. Kado^{3,4}. ¹*Env. Sciences Engineer., U. North Carolina, Chapel Hill, NC*, ²*ORD, NHEERL, HSD, Clinical Research Branch, U.S. EPA, Chapel Hill, NC*, ³*ARB, Cal EPA, Sacramento, CA* and ⁴*U. California, Davis, CA*.

Biodiesel, an alkyl ester of plant oils that can be used in an unmodified diesel engine, is a renewable fuel alternative which show signs of becoming a commercially accepted part of our nation's energy infrastructure. Biodiesel exhaust has been physicochemically characterized, but little evaluation of the inflammatory potential of biodiesel emission Soluble Organic Fraction (SOF) has been performed. BEAS-2B cells, a transformed airway epithelial cell line, were exposed *in vitro* for 24 hr to the SOF emissions extracts from 2 petroleum diesel particulate matter (PM) samples [Standard Reference Material (SRM) 1975 and Phillips D2], hydrogenated soy ethyl ester (HySEE) PM, and soy methyl ester (SME) PM. Our data suggest HySEE and SME extracts are more potent inflammatory stimulants than SRM 1975 and D2 SOF on a mass PM equivalent per ml media ($\mu\text{g PM eq/ml}$) basis, an extracted material unit. The SOF extracts of biodiesel PM in an aqueous solution increased the release of pro-inflammatory cytokines IL-8 and IL-6 by BEAS cells relative to control (vehicle exposed) cells. The SOF of HySEE and SME biodiesel begins to elicit a cytokine response in BEAS cells at approximately 40 $\mu\text{g PM eq/ml}$, whereas SRM 1975 increased IL-8 and IL-6 at 922 $\mu\text{g PM eq/ml}$ (about 25 $\mu\text{g SOF extractable material/ml}$). The exposure range tested for all SOF was not cytotoxic. It was also noted that the solvent exchange method utilized may not be appropriate for the investigation of biodiesel extracts, though it has been used extensively in petroleum diesel PM research. More research is required to characterize the potency of the SOF of biodiesel PM from different sources (e.g., vegetation type) and run conditions (e.g., engine load) compared to petroleum diesel PM. This research was supported in part by the NHEERL-DESE Cooperative Training in Environmental Sciences Research, EPA CT826513. This abstract of a proposed presentation and does not necessarily reflect EPA policy.

814 *IN VITRO* RESPONSES OF AIRWAY CELLS EXPOSED TO ENVIRONMENTAL PARTICLES: SIGNALING PATHWAYS AND ARTIFACTS.

J. M. Veranth, N. Cutler and G. S. Yost. *University of Utah, Salt Lake City, UT.*

Studying effects of inhalable particles by *in vitro* toxicology assays aids understanding of biochemical mechanisms and offers the potential to efficiently study complex mixtures found in ambient particulate matter. We have used these assays to assess soil-derived dusts, combustion ash, metal oxide nanoparticles, and laboratory surrogates. We have focused on transcription and secretion of the proinflammatory interleukins IL-6 and IL-8 in airway epithelial cells exposed to particles alone and in combination with pathway-specific inhibitors. Cell responses depend on the particle source and chemical composition in a complex manner suggesting that chemical speciation by elements, carbon fractions, and soluble ions is not measuring the toxicologically important parameters. Different cell types and cell culture conditions produce altered response to the same particle. Manufactured nanoparticles induce IL-6 and IL-8 secretion in human airway epithelial cells, but are not consistently more potent than an equal mass of micron-sized particles of the same nominal composition and the pure oxides are less potent than natural particles derived from soil dust. Different cell signaling pathways have been proposed to explain how dust components such as endotoxin, transition metals, and reactive oxygen species-generators induce release of cytokines by lung cells. We find that inflammatory soil dusts stimulate the p38 MAP kinase pathway. Use of specific inhibitors, however, indicate that Jnk and Erk1/2 as well as p38 MAP kinase pathway pathways are needed for full IL-6 response. Further work with specific signaling inhibitors indicates that the pro-inflammatory response of bronchial epithelial cells is mediated by several receptors located at the plasma membrane, including EGFR and IL-1R. In conclusion, bronchial epithelial response to soil dust is complex, involving many interacting molecules, and reliance on a single readout such as IL-6 release gives only a partial picture. Supported by the Southwest Consortium for Environmental Research & Policy, grant A-05-06 & NIEHS K25 ES11281.

815 DIFFERENTIAL GENE EXPRESSION BY SEX IN AIRWAYS OF MICE EXPOSED TO SIDESTREAM TOBACCO SMOKE (TS).

L. S. Van Winkle¹, M. Shultz¹, K. Sutherland¹, P. Edwards¹, G. Baker² and D. Nguyen¹. ¹*Center for Health & Environment, VM:APC, VM: Mol Biosci, Med.: PHS, UC Davis, Davis, CA* and ²*Battelle Toxicology Northwest, Richland, WA*.

Following birth, the lung continues to both grow and differentiate while interacting with the environment. Exposure to TS pre- and postnatally alters the conducting airways and has been correlated with airway diseases in both children and adults. Many of these airway diseases have sex-differences in prevalence and severity. We studied the effect of prenatal vs. pre+postnatal TS exposure on airway specific gene expression in adult male and female mice. Mice were exposed to 1 mg/m³ total suspended particulate tobacco smoke (TS) or filtered air (FA) for 5 days per week, 6 hrs per day from d6 of gestation to adulthood. Exposure groups were: pre and postnatal FA (FA/FA), prenatal TS + postnatal FA (TS/FA), pre and postnatal TS (TS/TS). At 8 wks of age, lungs were removed and inflated with RNA laterTM. Airways were microdissected. Custom spotted glass slide 50 mer oligo microarrays containing 20,000 mouse genes were used. FA/FA RNA samples from males were combined; FA/FA females were combined in one estrus cycle stage. In males, the TS/FA group contained more unique upregulated (727) and down regulated genes (501) than the TS/TS (295; 172) male group. 1134 genes were up or down regulated in common. In females, the TS/FA group contained more unique up regulated (86) and down regulated genes (291) than the TS/TS (5; 30) female group. 126 genes were up or down regulated in common. In general the number of altered genes was less in females but was greater for mice exposed to TS solely during the prenatal period. In females, the tendency was for genes to be downregulated by TS but in males more genes were upregulated by smoke. This may be due to sex-differences in basal gene expression. We conclude that 1) there are sex-based differences in airway responses to tobacco smoke exposure, 2) exposure regime changes gene response patterns and 3) prenatal exposure to ETS is sufficient to cause persistent changes in gene expression in adult airways. Support: NIH ES013066 & ES05707

816 AIRWAY INFLAMMATION AND INJURY FOLLOWING IN-UTERO EXPOSURE OF RATS TO CIGARETTE SMOKE AND POSTNATAL EXPOSURE TO OZONE.

Z. Hamdan¹, T. Akinbiyi¹, J. Hatfield³, A. K. Rishi^{3,4}, E. Levi^{3,2} and D. K. Bhalla¹. ¹*Fundl/Appl. Sciences., Wayne State University, Detroit, MI*, ²*Pathology, Wayne State University, Detroit, MI*, ³*V.A. Med. Cntr., Detroit, MI* and ⁴*Medicine, Karmanos Cancer Institute, Detroit, MI*.

An exposure to environmental pollutants during pregnancy raises the possibility of development related changes and increased sensitivity to subsequent pollutant exposures. In this study rats were exposed *in-utero* to environmental tobacco smoke (ETS), followed by exposure of the newborn to O₃. ETS was generated from research cigarettes (1R4F; Univ of Kentucky) in a Walton cigarette machine by mixing mainstream with side stream smoke. Timed pregnant S/D rats were exposed 3hr/day for 15 days to ETS (100 mg/m³ TPM) or air, and the offspring received either a single 3 hrs exposure or 3 wks of repeated exposures to air or 0.6 ppm O₃ starting on day 13 after birth. The exposure groups were Air/Air (Control), Air/O₃, ETS/Air and ETS/O₃. The bronchoalveolar lavage (BAL) was analyzed for total protein, the cellular fraction for PMNs and tissues for cytokine gene expression using an inflammatory gene microarray (GEArray). A single postnatal exposure to O₃ resulted in a significant increase in total BAL protein and PMNs compared to controls. The results also showed an upregulation of genes for IL-1 α , IL-1 β , IL-8r β , IL-9 α , IL-13, IL-24, TGF β 1 and TNF α ; the increase was greatest for the ETS/O₃ group. Cellular expression of cytokines to detect the exposure-associated changes is currently in progress to complement the gene expression data. The differences in BAL protein and PMNs seen after a single postnatal exposure were not observed after repeated exposures. Tissue sections were also processed for immunocytochemical staining with an antibody against Podoplanin, a mucin-type glycoprotein expressed by lymphatic endothelial cells which appears to play a role in tumor progression. A lack of differential staining among exposure groups did not permit its utility as an early marker of injury. The results overall show a greater response after one day postnatal O₃ than after three weeks of postnatal exposure.

817 ASSESSING RESPIRATORY HEALTH IMPACTS OF GENERAL PURPOSE CLEANING PRODUCTS CONTAINING SOLVENTS WITH DIFFERENT REACTIVITIES.

E. P. Naess, S. M. Ebersviller, K. G. Sexton, K. M. de Bruijne, M. L. Doyle and H. E. Jeffries. *Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC*.

There is growing interest in switching from petroleum to biogenic-based cleaning products. States are bringing forth regulation to control product compositions based on reactivity, yet the health impacts from exposure to these cleaning products

cannot be described merely by assessing their reactivity. Several issues should be considered when assessing the impacts of consumer products. While determination of the ozone forming potential is crucial, the possible toxic effects from the components or their reaction products should not be ignored. To look more closely at the chemistry and relative health risks of consumer products, pure d-limonene, glycol ether, and two general purpose cleaning products, one containing d-limonene (GCP1) and one containing glycol ether (GCP2) were examined. Indoor use experiments included techniques that simulated spraying and mixing the cleaning products or the individual solvents with background levels of indoor ozone utilizing clean air found in the chamber. Human respiratory epithelial cells were exposed to both the gas and particle phases of the unreacted and reacted chamber mixtures using a modified *in vitro* exposure system and analyzed for cytotoxicity and inflammation using LDH and IL-8 protein mediators. Detailed chemical and particle composition analyses were performed both before and after oxidative aging. The analysis shows that glycol ether induces greater inflammation and cytotoxicity than d-limonene; GPC2 containing glycol ether also causes a greater response than GPC1 containing d-limonene. There was an increased cytotoxic and inflammatory response from exposure to particles from the glycol ether, GPC1 and GPC2 than from the exposure to gases alone. Assessing the indoor chemistry and the potential health effects of both primary and secondary toxics presents a more balanced approach for evaluating the environmental and health impacts of consumer products and their formulations.

818 MULTIPLE CHALLENGES IN A MOUSE MODEL OF CHEMICAL-INDUCED ASTHMA.

V. De Vooght, J. Vanoirbeek, B. Nemery and P. Hoet. *Occupational, Environmental and Insurance Medicine, KULeuven, Leuven, Belgium.*

To validate a mouse model of chemical-induced asthma we compared a single with a multiple challenge protocol.

On day 1 and 8 BALB/c mice were dermally sensitized with 0.3% TDI (20 µl/ear) or vehicle (acetone/olive oil). From day 15 on the mice received 1 to 6 intranasal instillations (challenges) with 0.1% TDI (10 µl/nostril) or vehicle, with 1 week interval between instillations. The airway responses were measured (Penh and pulmonary resistance) after the last challenge. Mice were sacrificed 24 hours later. Total and differential cell counts were performed in the broncho-alveolar lavage (BAL) fluid and TNF- α and MIP-2 concentrations were measured. Total serum IgE, IgG, and IgG_{2a} levels were measured. Lymphocyte subpopulations (CD4⁺, CD8⁺, CD19⁺) were determined in the auricular (ALN) and cervical (CLN) lymph nodes. IL-4 and IFN- γ release, *in vitro*, after concanavalin A (ConA) stimulation, was assessed.

After 1, 2 or 3 challenges with TDI, a significant increase in airway hyperreactivity was found in TDI sensitized mice. This response diminished with further challenges. An increase in the total cell count and percent neutrophils (15-20 %) was found in BAL fluid, but this decreased with increasing TDI challenges. There was a decrease in the percent of CD4⁺ and CD8⁺ cells and an increase in the percent of CD19⁺ cells in the ALN and CLN, which was restored to control values with increasing TDI challenges. Increased levels of IL-4 were found in CLN cells *in vitro*. The total serum IgE levels in TDI sensitized mice were always significantly increased compared to control mice.

Ventilatory responses and lung inflammation diminish after multiple challenges with 1 week interval between challenges. It is likely that this 'fading out' is due to the acquisition of tolerance. Nevertheless, some immunologic parameters are still increased after 6 challenges with TDI.

819 TIME COURSE OF VENTILATORY, INFLAMMATORY AND IMMUNOLOGIC PARAMETERS IN A MOUSE MODEL OF CHEMICAL INDUCED ASTHMA.

J. Vanoirbeek, V. De Vooght, P. Hoet and B. Nemery. *Occupational, Environmental and Insurance Medicine, KULeuven, Leuven, Belgium.*

To validate our mouse model of chemical-induced asthma we compared different time points of methacholine challenge and autopsy after the last intranasal instillation, in a multiple challenge protocol.

On day 1 and 8, BALB/C mice received 0.3% toluene diisocyanate (TDI; 20 µl/ear) or vehicle (acetone/olive oil) on each ear. On day 15, 16, 17, 22, 23 and 24 they received an intranasal instillation of 0.1% TDI (10 µl/nostril) or vehicle. Airway reactivity to methacholine (AHR) was measured (Penh and pulmonary resistance) 22 h and 46 h later. The autopsy was performed 2h later. Total and differential cell counts were assessed, along with levels of TNF- α and MIP-2, in bronchoalveolar lavage (BAL). Total serum IgE, IgG₁ and IgG_{2a} levels were measured. Relative lymphocyte subpopulations (CD4⁺, CD8⁺ and CD19⁺) in auricular (ALN) and superficial cervical lymph nodes (CLN) and release of IL-4 and IFN- γ by LN cells incubated with concanavalin A, were assessed.

Methacholine reactivity, was lower at 46 h than at 22 h after the last challenge. Pulmonary inflammation was characterized by neutrophils (15-20%) and eosinophils (2-3%), 24 h after the last intranasal instillation. Another 24h later, this proportion changed to 6-8% for neutrophils and eosinophils. MIP-2 in BAL was increased both at 24h and 48h after the last instillation. In both groups (24 and 48 h) an increase in CD19⁺ and a decrease in CD4⁺ and CD8⁺ lymphocytes in ALN and CLN was found. Increased levels of IL-4 in ALN and CLN cells could be detected in all treated groups. Increased levels of total serum IgE and decreased levels of total serum IgG_{2a} were found in TDI sensitized mice.

Ventilatory response decreased and pulmonary inflammation parameters change (less neutrophils, more eosinophils) with increasing time between the last intranasal instillation and the autopsy. Nevertheless, immunological parameters were not influenced by the time point of autopsy.

The time point of evaluation has an important influence on inflammatory parameters, but not on immunological parameters.

820 FETAL EXPOSURE TO ENVIRONMENTAL TOBACCO SMOKE (ETS) EXACERBATES SUBSEQUENT ADULT RESPONSES TO INITIAL ALLERGEN EXPOSURE.

A. Penn¹, R. Rouse¹, D. Horohov³, M. Kearney², D. Paulsen² and L. Lomax². ¹CBS, LSU School Vet. Med., Baton Rouge, LA, ²PBS, LSU School Vet. Med., Baton Rouge, LA and ³Coll. of Agriculture, University KY, Lexington, KY.

Epidemiology studies have associated fetal exposure to maternal smoking and post-natal exposure to environmental tobacco smoke (ETS) with increased asthma risk. We tested the hypothesis, in a mouse model of asthma, that in utero ETS exposure alters airway function and respiratory immune responses in adults. Pregnant Balb/c mice were exposed daily to ETS (10 mg/m³) or filtered air (AIR). Offspring inhaled aerosolized saline in weeks 7-8, and were sensitized to ovalbumin (OVA) via injections in weeks 11 and 13 and challenged with OVA aerosol in weeks 14 and 15. We identified eleven endpoints, including OVA-specific serum immunoglobulins, bronchoalveolar lavage cell and cytokine levels, lung histopathology and airway hyperresponsiveness (AHR), that have a direct relationship to airway inflammation and/or airway Th2 responses (i.e., they increase as inflammation increases), and compared paired group means for these endpoint measures for both sets of mice in tests of trend. The Wilcoxon test on these paired sign data demonstrated that responses in ETS/OVA mice were consistently higher (p = 0.001) than in AIR/OVA mice across all data. This trend was further supported by a Pearson correlation value of 0.99 and a ranked regression yielding an adjusted R² of 0.98. These results support the conclusion that in utero ETS exposure exacerbates subsequent adult responses to initial allergen exposure. In mice, this sensitivity lasts at least 15 weeks after birth. If this heightened sensitivity extends beyond OVA to unrelated antigens, as seems likely mice exposed to ETS in utero and then to other antigens as adults (e.g., Aspergillus, cockroach antigen, bacterial lipopolysaccharide or respiratory viruses) would be expected to display more aggravated responses than mice not exposed in utero to ETS.

821 DEVELOPMENT OF A MURINE MODEL OF ASTHMA USING COCKROACH ALLERGEN AND DIESEL EXHAUST-RELATED AIR POLLUTANTS.

E. M. Vancza¹, J. Reibman², L. Chen¹ and T. Gordon¹. ¹Environmental Medicine, New York University School of Medicine, Tuxedo, NY and ²Bellevue Hospital, New York, NY.

Allergic asthma is a complex respiratory disease and its incidence is on the rise, particularly in children from urban areas. The underlying etiology of this upward trend is unclear, yet mounting evidence suggests that air pollution may play a significant role, specifically ambient urban particles like those found in diesel exhaust. Although ovalbumin (OVA) is the standard for asthmatic mouse models, indoor pollutants, such as cockroach antigen, are highly suspect in real world asthma cases. This study was conducted to develop a novel sensitization protocol using cockroach allergen Bla g 2 and to test the hypothesis that diesel exhaust acts as an immunological adjuvant in Bla g 2-sensitized mice. A model of allergic asthma was first established in adult female Balb/c mice by ip sensitization with 10 µg OVA followed by a 10 µg OVA ip boost and a 10µg OVA aspiration challenge. This model was later optimized for use with 1 µg of Bla g 2. Lavage and serum were recovered 24-48 h post-challenge and eosinophilia along with Th1:Th2 cytokine and antibody profiles were examined to characterize the degree of "asthmatic" response. Mice sensitized to either OVA or Bla g 2 were then co-exposed to increasing concentrations of diesel exhaust particles (DEPs) at the time of their final challenge. It was found that DEPs altered levels eosinophilia and IgE antibody production in a dose-dependent manner for both OVA- and Bla g 2-sensitized mice, suggesting that DEPs do act as an immunological adjuvant for these two allergens. Similar results were generated from a group of Bla g 2-sensitized mice co-exposed to 1 mg/m³ of

whole diesel exhaust (DE) at the time of Bla g 2 challenge. Further research will enable us to examine age-dependent differences in immune response, to delineate the adverse effects of DE inhalation on these responses, and to quantify the relative contribution of biological and environmental factors on the exacerbation of pediatric asthma.

822 SUPPRESSION AND ENHANCEMENT OF ALLERGIC AIRWAY RESPONSES BY PM_{2.5} IS DEPENDENT ON PHYSICOCHEMICAL CHARACTERISTICS.

J. Wagner¹, M. Morishita², G. J. Keeler² and J. R. Harkema¹. ¹Mich State University East Lansing, MI and ²University Mich, Ann Arbor, MI.

Increased concentrations of fine particulate matter (PM_{2.5}) have been associated with increased symptoms in asthmatic patients. Eosinophilic inflammation, excessive airway mucus and mucous cell metaplasia/hyperplasia (MCM) are common histopathologic features of asthmatic airways. We tested the hypothesis that exposure to concentrated fine airborne particles (CAPs) from two urban areas with qualitatively disparate PM atmospheres will exacerbate allergen-induced MCM and inflammation in airways of Brown Norway (BN) rats. Male BN rats were exposed in whole-body exposure chambers, located within a mobile laboratory located in either urban southwest Detroit, MI (DTW) with impact from local and transported PM sources, or Grand Rapids, MI (GRR), with transported and mobile PM sources. Ovalbumin (OVA)-sensitized BN rats were exposed to CAPs or filtered air (FA) for 1 day (7:00 am to 3:00 pm). A Harvard/EPA ambient fine particle concentrator was used to generate the CAPs from the urban air in DTW (542 µg/m³) and GRR (519 µg/m³). One hour before exposure, rats were intranasally challenged with 0.5% OVA in saline or with saline alone (SA). Rats were sacrificed 16h later and bronchoalveolar lavage fluid (BALF) was collected from right lung lobes. Left lung lobes were processed for light microscopy and morphometric analysis of intraepithelial mucosubstances (IM; measure of MCM) in pulmonary axial airways. In both DTW and GRR, SA/CAPs rats (controls) had no airway inflammation or MCM. In contrast, OVA/FA rats had more neutrophils (25-30-fold), eosinophils (8-10x), and total protein (3-4x) in BALF than controls. DTW CAPs enhanced all allergic endpoints by 30-100%, whereas GRR CAPs suppressed all allergic responses by 50%. GRR CAPs was derived primarily from motor vehicle sources. Conversely, DTW CAPs had high sulfate, smaller sized particles and originated from both coal and local combustion sources. These data demonstrate opposing effects of PM on allergic airway disease depending on source and characteristics of particles. (Supported HEI and MEDC)

823 ASSESSING THE RESPIRATORY SENSITIZATION POTENTIAL OF PROTEINS USING THE MOUSE INTRANASAL TEST (MINT).

S. M. Krieger, M. R. Woolhiser, L. K. Anderson, M. J. Filary, D. A. Keeley, S. G. Walker and J. A. Hotchkiss. The Dow Chemical Company, Midland, MI.

A need exists for a simple predictive animal model to identify proteins with the potential to induce respiratory sensitization in humans. The MINT has been successfully used to predict human sensitivity to inhaled industrial enzymes, however, its utility in predicting the allergenicity of other classes of proteins is untested. In this study, BDF1 mice were intranasally instilled on days 1, 3, 10, 17 and 24 with 0, 0.5, 5, or 25 µg Subtilisin Carlsberg (SUB; known respiratory sensitizer), ovalbumin (OVA; potent food allergen), β-lactoglobulin (BLG; moderately potent food allergen), or keyhole limpet hemocyanin (KLH; strong immunogen with no reports of respiratory sensitization). Pulmonary function (PF) data were collected for methacholine (MCh) or specific protein aerosol challenge using whole-body plethysmography (WBP). Bronchoalveolar lavage (BAL) was performed to evaluate cellular inflammation, and serum was collected to determine protein-specific IgG1/IgG2a levels (ELISA) and specific IgE by passive cutaneous anaphylaxis (PCA). All proteins induced significant eosinophilia (70-83%). BLG and KLH had no effect on PF parameters following MCh or protein challenge. Protein challenge using SUB and OVA altered minute volume and tidal volume responses, but only mice exposed to SUB demonstrated airflow restriction. Specific IgE PCA titers were ranked SUB>OVA>KLH>BLG. Based on IgG ELISA titers SUB, OVA and KLH were immunologically more potent than BLG, but only SUB and OVA had high IgG1/IgG2a ratios suggesting a Th2-oriented immune response. Acute phase airway response to inhaled protein in "sensitized" mice was not a better predictor of respiratory sensitization potential than MCh challenge. WBP did not appear to be a sensitive measure in comparison to antibody measurements. Using these endpoints the MINT can be used to identify allergenicity potential of potent protein allergens. These endpoints may not be effective for classification of proteins with weaker potential, and appear to be confounded by proteins with strong immunogenicity.

824 RELATIVE ORAL BIOAVAILABILITY OF POLYCHLORINATED DIBENZO-*P*-DIOXINS/DIBENZOFURANS IN SOIL.

J. M. Warmerdam, E. J. Morinello and B. L. Finley. ChemRisk, San Francisco, CA.

Bioavailability is a key consideration in quantitative assessments of the potential risk posed to humans exposed to polychlorinated dibenzo-*p*-dioxins/dibenzofurans (PCDD/Fs). Because PCDD/Fs are persistent in the environment, ingestion of soil may be an important route of exposure in some circumstances. The oral bioavailability of PCDD/Fs in soil samples collected from five representative locations at an industrial site was evaluated in female Sprague Dawley rats. The PCDD/F content of the soil was dominated by dibenzofurans; dibenzo-*p*-dioxins were responsible for less than 5% of the soil TEQ. Relative bioavailability determinations were based on comparisons of the concentration of PCDD/Fs in the liver of rats treated with an aqueous soil suspension to those in animals treated with a reference formulation. The reference formulations were prepared in corn oil and contained the seventeen 2,3,7,8-substituted PCDD/Fs in proportions similar to those in the soil. Each animal received a single oral gavage dose of a soil suspension or reference formulation, and liver samples were collected 24 hours after dosing. Eight to 16 PCDD/F congeners were detected at sufficient concentrations to be included in the bioavailability determinations for each soil. The bioavailability of individual PCDD/Fs was inversely correlated with the degree of chlorination, and the mean values ranged from 15% for 1,2,3,7,8,9-HxCDF to 90% for 1,2,3,7,8-PeCDD. The overall relative bioavailability of PCDD/Fs in the soil samples (on a TEQ basis using the 2005 WHO toxic equivalency factors) ranged from 17 to 51% with a mean of 38%. There was no correlation between overall bioavailability and the concentration of PCDD/Fs in the soil samples. These data indicate that the oral bioavailability of PCDD/Fs can vary by congener or location and suggest that site-specific evaluations should be utilized in quantitative risk assessments. The results of this study also indicate that reliance on a default assumption of 100% bioavailability may result in substantially overestimated values for the risk posed by PCDD/Fs in soil from this site.

825 ABSOLUTE ORAL BIOAVAILABILITY OF POLYCHLORINATED DIBENZO-*P*-DIOXINS/DIBENZOFURANS IN SOIL.

E. J. Morinello, J. M. Warmerdam and B. L. Finley. ChemRisk, San Francisco, CA.

The absolute oral bioavailability of polychlorinated dibenzo-*p*-dioxins/dibenzofurans (PCDD/Fs) in soil samples collected from five locations at an industrial site in the southwestern United States was evaluated in female Sprague Dawley rats. Bioavailability was calculated by comparing the concentration of PCDD/Fs in the liver of rats treated with an aqueous soil suspension by oral gavage to those treated with a reference formulation by via a 3-hour intravenous infusion. The reference formulations contained the seventeen 2,3,7,8-substituted PCDD/Fs in proportions similar to those present in the soil. Each animal received a single dose of the reference formulation or soil sample, and the liver was collected 24 hours after dosing. The overall absolute bioavailability of PCDD/Fs in the soil samples (on a TEQ basis using the 2005 WHO toxic equivalency factors) ranged from 11% to 38% with a mean of 27%. There was no correlation between the overall bioavailability of PCDD/Fs and the TEQ concentration of the soil samples. The absorption of individual PCDD/Fs in the soil samples was inversely correlated with the degree of chlorination, and the mean absolute bioavailability values ranged from 4% for OCDF to 110% for 2,3,7,8-TCDF. It was believed that the short initial half-life of 2,3,7,8-TCDF, 1,2,3,7,8-PeCDD, and 1,2,3,7,8-PeCDF in liver resulted in the calculation of erroneously high absolute bioavailability values for those congeners. The bioavailability of 2,3,7,8-TCDD could not be determined due to its low concentration in soil at this site. The bioavailability values for the remaining thirteen congeners, which accounted for 89-96% of the TEQ concentration of the soil samples, were considered to be reliable. These data are suitable for use in quantitative risk assessments of PCDD/Fs in soil from this site and may be applicable to other experimental or environmental scenarios in which PCDD/F exposure occurs by the oral route.

826 POLYCHLORINATED DIBENZO-*P*-DIOXINS, POLYCHLORINATED DIBENZOFURANS AND DIOXIN-LIKE PCBs IN HUMAN ADIPOSE TISSUE IN TURKEY.

I. Cok¹, M. K. Donmez¹, H. Satioglu², B. Aydinuraz³, B. Henkelmann⁴, J. Kotalik⁴ and K. Schramm⁴. ¹Toxicology, Gazi University, Faculty of Pharmacology, Ankara, Turkey, ²Obstetrics and Gynecology, Ankara University, School of Medicine, Ankara, Turkey, ³IVF& Reproductive Biotechnology, Gen-Art Women Health, Ankara, Turkey and ⁴Institute of Ecological Chemistry, GSF - National Research Center for Environment and Health, Neuherberg, Germany. Sponsor: A. Karakaya.

During the twentieth century, production and use of toxic chemicals has increased rapidly thousands of chemicals have been introduced into the environment. Persistent organic pollutants (POPs) are very important group of these chemicals.

Polychlorinated dibenzo-p-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs) and polychlorinated biphenyls (PCBs) are 3 of the 12 UNEP internationally recognized POPs and also they are most important, toxic members of POPs. There is no previous report from Turkey on chemically determined polychlorinated dibenzo-para-dioxins (PCDDs), polychlorinated dibenzofurans (PCDFs), and dioxin-like polychlorinated biphenyls (PCBs) in human tissues expressed as World Health Organization (WHO) toxic equivalents (TEQs). The objective of this study was to determine the occurrence of PCDDs/Fs, and dioxin-like PCBs in the general adult Turkish population. For this reason we measured adipose tissue concentrations of PCDDs/Fs and dioxin-like PCBs in 23 Turkish men living in Ankara, Turkey in 2004. PCDD/F concentrations ranged between 3.2 and 19.7 pg WHO-TEQ/g fat (5.34 and 42.7 pg WHO-TEQ/g fat, respectively, including dioxin-like PCBs). The mean concentrations of WHOPCDD/F-TEQ and WHOPCB-TEQ were 9.2 and 6.67 pg/g on a lipid basis, respectively. Samples were analyzed for PCDD/F and twelve dioxin-like PCB congeners using high resolution gas chromatography/high resolution mass spectrometry (HRGC/HRMS). This study is very important since it is the first report on PCDDs/Fs and dioxin-like PCB contamination in human adipose tissue from Turkey.

827 UP-REGULATION OF CYCLOOXYGENASE-2 EXPRESSION BY 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN IN THE HUMAN ENDOTHELIAL-LIKE ECV304 CELL LINE.

J. Kim^{1,2}, H. Kim^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD), a prototype of many halogenated aromatic hydrocarbons, is a ubiquitous, persistent environmental contaminant and the most powerful tumor promoter in rodent bioassays. In the present study, we investigated the effects of TCDD on the cyclooxygenase-2 (COX-2) gene expression in the human endothelial-like ECV304 cell line. TCDD significantly increased the prostaglandin E2 production and the expression of COX-2. To investigate the significant cis-acting regions which COX-2 promoter, transient transfection experiments were carried out using reporter vectors harboring deleted COX-2 promoters. The transcriptional factor binding sites for CRE and C/EBP between -372 and -51 in COX-2 promoter could be important for the induction of COX-2 by TCDD. The results of these studies suggest that induction of transcriptional activation of COX-2 by TCDD might be mediated through the CRE and C/EBP activation.

828 A PUTATIVE ROLE OF BLIMP-1 AND AP-1 IN TCDD-INDUCED SUPPRESSION OF THE IGM RESPONSE IN B CELLS.

D. Shnaider^{1,2}, B. S. Yoo³ and N. E. Kaminski^{1,2}. ¹Center for Integrative Toxicology, Michigan State University, East Lansing, MI, ²Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI and ³Department of Biology, Kyonggi University, Paldal-gu, Suwon-Si, South Korea.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is a potent and persistent environmental pollutant. Many toxic effects of TCDD are mediated through the aryl hydrocarbon receptor (AhR). The primary humoral (IgM) response to bacterial lipopolysaccharide (LPS) in CH12.LX cells, a mouse B cell line, is markedly suppressed by TCDD. Pax5, a major repressor of spontaneous B cell differentiation, is downregulated by LPS. In the presence of TCDD, Pax5 downregulation is attenuated, in correlation with the suppression of the IgM response. Our objective was to identify the upstream factors involved in the attenuation of Pax5 downregulation in activated B cells in the presence of TCDD. Four distinct Pax5 isoforms were shown to be downregulated in CH12.LX cells by LPS and attenuated by TCDD in a similar manner over a 72h culture period, suggesting a common regulatory mechanism for each one of the isoforms. AhR binding to a putative DRE site in Pax5 promoter was weak, suggesting that additional transcriptional factors are involved. Blimp-1, an important regulator of B cell differentiation acts as a transcriptional repressor of Pax5. Blimp-1 mRNA was induced by LPS and suppressed by TCDD during the 72h culture period. By comparison, Blimp-1 DNA binding activity in the Pax5 promoter was induced by LPS and suppressed by TCDD. Similarly to Pax5, two putative DREs in the Blimp-1 promoter showed weak AhR-binding, suggesting that additional transcription factors are involved in the suppression of Blimp-1 by TCDD. Gel shift assays analyzing three putative AP-1 binding sites in the mouse Blimp-1 promoter showed an increase in AP-1 binding in the presence of LPS, which was attenuated in the presence of TCDD during the 72h time course. In summary, these data link AP-1 to the suppression of the IgM response by TCDD through the regulatory axis involving transcription factors Blimp-1 and Pax5. (NIH grants R01 ES02520 and P42 ES04911)

829 QUANTITATIVE MICROARRAY ANALYSIS WITH "PERCELLOME" METHOD IN 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN-TREATED MURINE FETAL PALATE.

A. Takagi¹, N. Nakatsu¹, K. Igarashi¹, K. Aisaki¹, M. Ema² and J. Kanno¹. ¹Division of Cellular and Molecular Toxicol, National Inst. Health Sciences, Setagaya-ku, Tokyo, Japan and ²Division of Risk Assessment, National Inst. Health Sciences, Setagaya-ku, Tokyo, Japan. Sponsor: A. Takagi.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is well known as a potent teratogen, causing cleft palate. The mechanisms of the cleft palate induction by TCDD are not well understood. In this study, we have applied a newly developed quantitative microarray method (designated as "Percellome" method) for identifying genes associated with the teratogenic effect of TCDD. On gestation day (GD) 12.5 (plug day GD 0.5), pregnant mice (C57BL/6) were given single oral administration of TCDD (20µg/kg bw). On GD13.5, 14.5 and 15.5, the fetal palate were dissected and pooled. Grade-dosed spike cocktail (GSC) was added to the sample homogenates in proportion to its DNA concentration and processed by the Affymetrix Standard protocol. The GeneChips used were MG-U74v2A. By using the Percellome method, data was expressed as mRNA copy numbers per cell. We have already demonstrated that Affymetrix GeneChip microarrays using the Percellome method and quantitative PCR showed high concordance (up to 90%). Microarray data obtained from TCDD-treated group was compared to no-treated control group at GD13.5, 14.5 and 15.5. Cyp1a, Cyp1b1, AhRR and Tiparp (TCDD-inducible poly (ADP-ribose) polymerase), which were known to be induced by TCDD, were strongly up-regulated. Cyp1a1 was increased at all time points to a maximum of about 500-fold. Cyp1b1 induction was approximately 70-fold less than for Cyp1a1. AhRR induction was approximately 100-fold. We also detected changes of many other genes in expression associated with apoptosis, cell cycle, metabolism, differentiation etc. These quantitative microarray data will contribute the understanding of the molecular mechanisms of TCDD-induced cleft palate.

830 ALTERED EXPRESSIONS OF ARTHRITIS-ASSOCIATED GENES IN CHONDROCYTES IN CULTURE FOLLOWING DIOXIN EXPOSURE.

J. Yang, H. Lee, S. Kim, E. Choi, K. Park, H. Kim and Y. Choi. School of Medicine, Catholic University of Daegu, Daegu, South Korea. Sponsor: T. Jeong.

While effects of dioxin on bone are relatively well documented, effects on cartilage tissues are rarely understood. Joint disease is common among "Yusho" patients and PAHs in the cigarette smoke has an association with rheumatoid arthritis (RA). RA is a chronic inflammatory condition with cartilage degradation. Cartilage tissue is solely composed of chondrocytes which play an essential role in keeping cartilage integrity. Since the effects of chondrocytes upon the exposure of pathogens are important in the etiology of RA, we attempted to look into possible effects of dioxin in chondrocytes to understand the mechanism of environmental toxicant-derived arthritis. Articular chondrocytes isolated from cartilage slices of 2-week-old New Zealand White rabbits were exposed with TCDD. TCDD exposure for 24hr increased levels of CYP1A1, CYP1A2, CYP1B1 mRNAs and EROD activity. The induction was both dose- and AhR-dependent. A considerable amount of AhR, ARNT and HIF-1a mRNAs were also expressed. Cartilage degradation is preceded by the production of proinflammatory cytokines, reactive oxygen species and angiogenesis. In the present study, dioxin induced increases of IL-1β, iNOS, NF-κB, COX-II and VEGF mRNA levels. Considering roles of these genes in arthritic pathogenesis, our results suggest that dioxin may interfere with the interdependent regulation of arthritis-associated genes in primary chondrocytes and lead to the pathogenesis of arthritis. Levels of PKC-α, -βII, and -ε proteins were altered at 10nM TCDD. TCDD also increased ROS production in a dose-dependent fashion. Altered expressions of PKC isozymes were blocked with NAC (10mM) or Trolox (100uM), indicating that ROS may play a role in activation of certain PKC isozymes. Our results strongly indicate that chondrocyte is a target cell type sensitive to the dioxin exposure and provide a scientific basis to understand the mechanism of joint diseases with respect to environmental exposures. This is the first report on the effects of dioxin in the primary chondrocytes. Supported by RIC, MOICE.

831 ALTERATIONS IN FEEDING BEHAVIOUR IN DIOXIN-EXPOSED RATS.

S. Lensu^{1,2}, J. Lindén³, J. Tuomisto¹ and R. Pohjanvirta^{3,4}. ¹National Public Health Institute, Kuopio, Finland, ²Department Pharmacology & Toxicol., University of Kuopio, Kuopio, Finland, ³Department Food & Environmental Hygiene, University of Helsinki, Helsinki, Finland and ⁴Kuopio Research Unit, Finnish Food Safety Authority, Evira, Kuopio, Finland.

TCDD is the most potent and toxic compound in the group of polychlorinated dioxins and related halogenated aromatic hydrocarbons. Despite numerous studies, mechanisms for the toxic effects of TCDD are still largely unknown.

We have utilized an exceptionally wide sensitivity difference between two rat strains to gain more insight into one of the hallmark effects of TCDD, the wasting syndrome. TCDD-sensitive Long-Evans (L-E, Turku A/B) rats were exposed to either 10 or 100 µg/kg TCDD (UFA-Oil institute, Russia, intragastric administration [ig]), and extremely resistant Han/Wistar (H/W, Kuopio) rats to 1000 µg/kg dose of TCDD. TCDD was dissolved in corn oil (Sigma, MO, USA), which was administered to controls (4 ml/kg [ig]). Only male rats were used. Behavioural changes in feeding (intake of dust-free Bio-Serv® food pellets) and drinking were monitored continuously with Coulbourn Habitest® system and Graphic State 3.02 software, the data-analysis was completed with SPSS 13.0.

Follow-up times varied between 5 and 14 days after the exposure. TCDD decreased dose-dependently feed consumption in L-E rats, and this was accompanied by weight loss. H/W rats decreased their feeding for a few days after exposure, but the suppression leveled off in appr. 10 days. The exposed H/W rats lost about 10 % of their initial body weight during the first week, and then sustained the new weight level throughout the study (14 days). In drinking, no marked dose-related effects were detected. A detailed analysis of feeding behaviour revealed distinct differences between the rat strains. Especially after the high dose of TCDD (100 µg/kg), L-E rats exhibited reduced meal sizes and a decelerated eating rate coupled with a compensatory increase in the number of both feeding and drinking episodes. These findings suggest that TCDD treatment does not abolish the sensation of hunger but rather enhances the satiating properties of feed in rats.

832 DOSE RESPONSE OF TCDD-INDUCED HEPATIC BILIVERDIN ACCUMULATION IN FEMALE RATS.

M. Niittynen^{1,2} and J. T. Tuomisto¹. ¹Department of Environmental Health, National Public Health Institute, Kuopio, Finland and ²University of Kuopio, Kuopio, Finland. Sponsor: M. Viluksela.

We have previously reported a new 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD)-induced liver toxicity syndrome characterized by hepatic accumulation of biliverdin, an intermediate product of heme degradation, and its derivatives. The syndrome displays clear genetic variability as most cases have been recorded in one rat line (line B) originating from the crossbreeding of the TCDD-sensitive and the TCDD-resistant rat strains Long-Evans (Turku/AB) and Han/Wistar (Kuopio; H/W), respectively. Line B rats express normal aryl hydrocarbon receptor but are moderately resistant to acute toxicity of TCDD due to H/W-type alleles of another, yet unidentified gene contributing to TCDD sensitivity ("gene B"). Current studies aim at elucidating the mechanism of biliverdin accumulation as this might have implications for the toxic mechanisms of TCDD. Using HPLC with UV-VIS detection we measured the hepatic concentration (nmol/g) of biliverdin and biliverdin derivatives in line B female rats 28 days after intragastric exposure to 3, 10, 30, 100, 200 or 300 µg/kg of TCDD in order to define a dose-response relationship for the TCDD exposure and biliverdin accumulation. In addition, bilirubin, the end product of heme degradation, and its derivatives were quantified. Mean biliverdin concentration in control group was 1 nmol/g; other analytes were undetectable. 3-30 µg/kg of TCDD did not induce significant increases in any of the analytes. When TCDD dose was 100 µg/kg or more, the concentrations of biliverdin, bilirubin and their derivatives were dose-dependently elevated, except that the maximal response of biliverdin derivatives (49 nmol/g) was reached already when the dose was 200 µg/kg. Biliverdin derivatives were the main accumulating form of biliverdin as their amount was three- to tenfold relative to free biliverdin in groups dosed with 100-300 µg/kg of TCDD. Interestingly, the individual-level correlation between biliverdin and bilirubin concentrations was poor. Further research is needed to reveal the immediate precursor of the accumulating biliverdin.

833 EFFECTS OF TCDD ON DIFFERENTIATION OF BONE CELLS.

M. Korkalainen¹, K. Nelo², E. Kallio², J. Ilvesaro², J. Tuukkanen² and M. Viluksela¹. ¹Department of Environmental Health, National Public Health Institute, Kuopio, Finland and ²Department of Anatomy and Cell Biology, University of Oulu, Oulu, Finland.

Environmental contaminant TCDD has been shown to affect bone growth, modeling and mechanical strength in our earlier experiments *in vivo*. These TCDD-induced effects seem to be mediated by AhR receptor, but the detailed mechanisms are still unknown. Bone remodelling is a constant process involving resorption of bone by osteoclasts and formation of equal package of new bone by osteoblasts. In this study, we utilized differentiation of bone marrow stem cells to osteoblasts and osteoclasts as a model system to study the effects of TCDD on bones. Stem cells isolated from bone marrow of femurs and tibias of Sprague-Dawley rats or C57BL/6 mice were differentiated to both osteoclasts and osteoblasts. Progress of osteoblastic differentiation was monitored by measuring mRNA expression levels of differentiation markers from control and TCDD-treated cells using quantitative RT-PCR. TCDD significantly decreased the mRNA levels of all three measured markers of

osteoblastic differentiation, of which transcription factor RUNX2 is expressed in a period of active proliferation, alkaline phosphatase in matrix maturation and osteocalcin in the onset of mineralization. In addition, TCDD decreased significantly the amount of calcium depositions. Cell proliferation, however, was not affected. In the case of differentiating osteoclasts, the number of tartrate-resistant acid phosphatase (TRAPC) -cells and resorbing activity were used as differentiation markers. TCDD decreased the number of TRAPC-positive multinucleated cells and also the area of bone resorption. Both osteoblastic and osteoclastic effects took place at very low doses of TCDD; even 10 pM TCDD was enough to significantly affect the differentiation markers. Therefore, differentiation of osteoblasts and osteoclasts from bone marrow stem cells seems to be a very sensitive target for TCDD. Disturbed osteoclastogenesis, in addition to disrupting effects in osteoblastic cells, may play a role in the weakening of bone quality in TCDD exposed animals.

834 9-CIS-4-OXO-13, 14-DIHYDRO-RETINOIC ACID (9C-4O-DH-RA) – A NEW SENSITIVE BIOMARKER FOR TCDD TOXICITY.

N. Giese¹, M. Viluksela², H. Hakansson³ and H. Nau¹. ¹Department of Food Toxicology, University Veterinary Medicine, Hannover, Germany, ²Department of Environmental Health, National Public Health Institute, Kuopio, Finland and ³Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Dioxins are known to alter endogenous retinoid contents in various tissues. One toxicological endpoint after TCDD exposure is the decrease of hepatic retinyl-ester content. Here we show that the retinoic acid metabolite – 9c-4o-dh-RA – which was characterized as an endogenous retinoid occurring in the livers of mice, rats and humans, is especially sensitive to TCDD and that this TCDD/retinoid interaction is AhR-receptor (AhR) dependent. We analyzed the retinoid contents in rat and mouse liver from four TCDD exposure studies. These studies include a time-course experiment with adult SD-rats (1), a long-term low-dose study with Long-Evans rats (2), an *in utero*/lactational exposure study with SD-rats (3) and an experiment with AhR-KO mice (4). (1) 3 days after a single oral dose (10 µg/kg) the liver concentration of the metabolite decreased to 10% of the initial concentration, remained at this level until day 28 and recovered to the initial level on day 112. (2) The rats were dosed by sc injection once a week at calculated daily doses ranging from 0 to 100 ng/kg for 20 weeks. The liver concentration of the metabolite decreased to 36% of the control value at the low dose (1 ng/kg) and further under the detection limit at 10 ng/kg. (3) Pregnant SD rats were given a single dose (0.1 µg/kg) on GD 11. A dose dependent decrease in the liver concentration of the metabolite was shown in pups at PND 7 and PND 35 starting from the low dose (0.03 µg/kg). (4) AhR-KO and WT mice were given a total of 0 or 200 µg/kg over a period of 10 weeks. In TCDD exposed WT mice the metabolite's concentration decreased under the detection level whereas in AhR-KO mice it remained at the same level as in non-exposed animals. These results show that 9c-4o-dh-RA is a very sensitive marker of TCDD exposure. The retinoid's decrease correlates with increased TCDD levels. This interrelationship between the novel retinoid and TCDD is AhR dependent.

835 INDUCTION OF EROD ACTIVITY *IN VITRO* BY 2, 3, 7, 8 TETRACHLORINATED N-METHYL AND SULFOXO PHENOTHIAZINES.

K. W. Fried¹, W. Levy Lopez², C. Corsten², K. Schramm² and K. K. Rozman^{1,3}. ¹Department of Pharmacology, Toxicology & Therapeutics, University of Kansas Med. Ctr., Kansas City, KS, ²Institute of Ecological Chemistry, GSF-National Research Center for Environment and Health, Neuherberg, Germany and ³Institute of Toxicology, GSF-National Research Center for Environment and Health, Neuherberg, Germany.

The structural dioxin analogue 2,3,7,8-tetrachlorophenothiazine (TCPT) is a known high affinity AhR ligand and an agonist regarding the induction of CYP1A1 activity *in vitro*. The expected main metabolites of TCPT are its two sulfoxo derivatives and its hydroxylamine derivative. Ring hydroxylation is likely to play only a minor role, if any, since TCPT lacks the required vacant vicinal aryl positions. In order to investigate the role (potency, efficacy) of TCPT-metabolites regarding EROD induction via the AhR-mediated pathway, TCPT and five derivatives were studied *in vitro* in the rat hepatoma cell line H4IIEC/T3. The following phenothiazine derivatives were compared to the effects of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) after induction for 12, 24, 48, and 72 h: TCPT, 5-oxo-TCPT (TCPT-O), 5,5-dioxo-TCPT (TCPT-O2), N-methyl-TCPT (Me-TCPT), N-methyl-5-oxo-TCPT (Me-TCPT-O), and N-methyl-5,5-dioxo-TCPT (Me-TCPT-O2). N-methylated derivatives of TCPT were used as models for inhibited hydroxylation of the heterocyclic amine.

It was discovered that potency decreases with increasing degree of oxidation, which is associated with greater molecular bulk and changed sterics of the respective molecules compared to each parent compound. The only derivative with almost constant, though low, potency was Me-TCPT-O2, which provides very little access to metabolic transformation. The potency of the other TCPT derivatives was deter-

mined to be time-dependent under the experimental conditions used. This reduction in potency over time is most likely the result of a combination of biotransformation and its eventual saturation in this *in vitro* system. Relative to TCDD, all phenothiazine derivatives retained high induction efficacy at high concentrations, and at later time points.

836 GESTATIONAL EXPOSURE TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN ADVERSELY AFFECTS LUNG DEVELOPMENT.

K. M. Kransler¹, B. P. McGarrigle¹, R. J. Russell² and J. R. Olson¹.

¹Pharmacology & Toxicology, University at Buffalo, The State University of New York, Buffalo, NY and ²Harlan Sprague-Dawley, Inc., Indianapolis, IN.

In mature laboratory animals, adverse effects on the lung have been observed after chronic exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and include lesions such as alveolar-bronchiolar metaplasia, hyperplasia of the bronchiolar epithelium, adenomatous hyperplasia and keratinizing squamous cell carcinoma. We hypothesized that the developing lung may also be adversely affected by TCDD which may represent a significant factor contributing to the high rate of perinatal mortality observed after gestational exposure. Pregnant Holtzman rats received a single dose of TCDD (1.5 or 6 µg/kg, po) on gestation day (GD) 10 or a vehicle control with fetal and neonatal analysis occurring on GD20 or post natal day (PND) 7. High rates of mortality were observed on GD20 (18% and 30%) and PND7 (40% and 100%) in the TCDD exposure groups (1.5 and 6 µg/kg TCDD, respectively). Significant decreases were observed in relative lung weight and the normalized lung to body weight ratio in the 6 µg/kg exposure group on GD20 and in the 1.5 µg/kg exposure group on PND7. Real time PCR was used to assess the gene expression of several genes including Ahr, Arnt, Ahrr and Cyp1a1 in the fetal lung on GD20. While the expression levels of Ahr and Arnt were unaltered between the control and treated animals, Cyp1a1 and Ahrr were both dramatically induced by TCDD exposure giving light to a responsive AhR-signaling pathway within the developing lung. Pups that were gestationally exposed to TCDD appeared to have retarded lung development which was manifested as a significant decrease in lung sacular area when compared to age-matched controls when morphology was assessed through histological examination of H&E stained slides. Together, these results identify the developing lung as target for the toxicity of TCDD and support the need for further mechanistic studies.

837 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) REVERSES HYPERGLYCEMIA IN A TYPE II DIABETES RAT MODEL.

K. K. Rozman^{1,2} and K. W. Fried¹. ¹Department of Pharmacology, Toxicology & Therapeutics, The University of Kansas Medical Center, Kansas City, KS and ²Institute of Toxicology, GSF-National Research Center for Environment and Health, Neuherberg, Germany.

Exposure to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) has been linked to increased risk for diabetes in humans. The key clinical sign of human type II diabetes is hyperglycemia resulting from insulin resistance. A suitable animal model for the induction of diabetes by TCDD has not yet been found. An established diabetic rat model was used for the study of the effects of TCDD on this disease as a pre-existing condition. Type II diabetes was induced by a high fat diet and the administration of streptozotocin. After the complete manifestation of diabetes, monitored by measuring serum glucose levels, male Sprague Dawley rats received a loading dose rate of up to 12.8 µg/kg p.o. TCDD followed by weekly maintenance dose rates to replace the AUC lost during the week. Serum parameters measured before the first administration of TCDD (day 0) marked the clinical picture of type II diabetes in rats (412 ± 58.5 mg/dL glucose). Healthy negative controls were fed the same high fat diet as treated animals, without receiving streptozotocin or TCDD, but they were administered the respective vehicles. By day 2 after the loading dose rate of TCDD, serum glucose in streptozotocin treated high-dose animals was already significantly lower (202.6 ± 23.8 mg/dL glucose) than in diabetic rats, but still above control levels (160.1 ± 4.0 mg/dL glucose). By day 8, diabetic rats treated with TCDD had reached serum glucose levels of healthy controls, which they maintained throughout the remainder of the study (32 days after a loading dose rate of TCDD). These results demonstrate that TCDD effectively counteracts hyperglycemia as a result of type II diabetes in this rat model. It is assumed that the mechanism of action is sensitization of the animals to the action of insulin as suggested by earlier work (Gorski et al. 1987).

838 CPLA2 IS AN EARLY COMPONENT OF TCDD'S INFLAMMATORY SIGNALING.

E. M. Sciuillo, C. F. Vogel and F. Matsumura. Environmental Toxicology, UC Davis, Davis, CA.

The main focus of this project has been to understand and characterize 2,3,7,8-tetrachlorodibenzo-p-dioxin's (TCDD's) inflammatory signaling pathway in human macrophage cells. TCDD is a ubiquitous environmental pollutant that ex-

hibits complex signaling and diverse end-point toxicities. This study focuses on the highly potent inflammatory cascade evoked by TCDD following its subsequent AhR activation. Using RT-PCR we have discovered a novel pro-inflammatory gene (cPLA2) that is activated following treatment with TCDD. We then performed inhibitor studies and used RT-PCR to evaluate any possible effects on well-known up-regulated inflammatory genes downstream. Reporter assays were then performed using the enzyme luciferase for cPLA2's promoter region. Inhibitor studies were performed to confirm AhR dependency and to test the specific actions of the inhibitors tested. Radiolabeled arachidonic acid was used to show a functional activation of cPLA2 following treatment by TCDD. TCDD exposure has been shown to result in increased levels of lipid peroxidation in a number of liver models. Using our human macrophage model, we tested for lipid peroxidation following TCDD treatment as well as diagnostic inhibitors specific for cPLA2. Our results indicate that TCDD treatment stimulates the up-regulation of cPLA2 mRNA in human macrophage cells as early as 3 hours. We found that by treating cells with AACOCF3, a specific blocker for cPLA2, a significant decrease was seen on well-known inflammatory genes induced by TCDD. In addition, we could show that TCDD stimulated cPLA2 at the promoter level, and that this effect was AhR-dependent. In addition, we could show that TCDD stimulates the release of arachidonic acid further supporting a functional activation of cPLA2. We could also show an increase in lipid peroxidation in human macrophage cells following TCDD treatment that was cPLA2-dependent. In summary, the data indicate that TCDD treatment results in a rapid activation of cPLA2 that is a necessary component of its inflammatory signaling in human macrophage cells.

839 CYTOCHROME P450 MEDIATED BIOTRANSFORMATION OF 2, 2', 6, 6'-TETRACHLOROBIPHENYL.

P. Edwards and S. M. Bandiera. Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.

The objective of this study was to identify the cytochrome P450 (CYP) enzymes involved in the biotransformation of 2,2',6,6'-tetrachlorobiphenyl (PCB 54). PCB 54 is a tetra-ortho substituted, non-coplanar polychlorinated biphenyl (PCB). Little is known regarding the metabolism of highly ortho-substituted PCBs. PCB 54 was incubated with liver microsomes prepared from Long-Evans rats treated with phenobarbital (PB, 80 mg/kg/day x 3 days), dexamethasone (DEX, 100 mg/kg/day x 3 days), 3-methylcholanthrene (25 mg/kg/day x 3 days) and corn oil. A validated and optimized method to analyze PCB 54 biotransformation was developed using liquid chromatography-negative electrospray mass spectrometry. The sole metabolite produced was a monohydroxyl metabolite. Based upon a difference in retention times, the hydroxylated metabolite was not 2,2',6,6'-tetrachloro-4-biphenylol (4-OH-CB54). Due to a lack of standards, the structure of the metabolite could not be determined. In order to quantify metabolite production, 4-OH-CB54 was used as a surrogate standard. No metabolite was detectable when PCB 54 was incubated with hepatic microsomes from MC- or corn oil-treated rats. The rate of product formation was greater in assays using hepatic microsomes of PB-treated rats (7200 pmol/min/mg protein) than assays using hepatic microsomes of DEX-treated rats (550 pmol/min/mg protein). The involvement of CYP enzymes was investigated further using a panel of recombinant rat CYP enzymes. Only recombinant CYP2B1 (5.9 pmol/min/pmol CYP) and CYP3A1 (0.03 pmol/min/pmol CYP) hydroxylated PCB 54 to the monohydroxyl metabolite. No metabolites were detectable when PCB 54 was incubated SUPERSOMES expressing CYP1A2, CYP2A2, CYP2C6, CYP2C11, CYP2C13, CYP3A2 or CYP2D1. In summary, these results demonstrate the involvement of the CYP2B enzymes and CYP3A enzymes in the biotransformation of PCB 54.

840 CHANGES IN PROTEOMIC PROFILES OF CEREBELLUM AND HIPPOCAMPUS FOLLOWING EXPOSURE TO A DEVELOPMENTAL NEUROTOXICANT.

P. R. Kodavanti¹, J. R. Royland¹, R. Ramabhadran¹ and O. Alzate².

¹Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC and ²Duke Neuroproteomics Lab., Duke University Medical Center, Durham, NC.

The vast literature on polychlorinated biphenyls (PCBs) makes it a unique model to understand major issues related to persistent chemicals. At background exposure levels, PCBs have been shown to affect human health, including learning and memory. Although the molecular basis is still unclear, a series of *in vitro* and *in vivo* studies have revealed that in addition to the effects on thyroid hormones, the disruption of Ca²⁺-mediated signal transduction play significant roles in PCB-induced developmental neurotoxicity. The culminating event in a variety of signal transduction pathways is the regulation of gene and protein expression, which ultimately affect the growth and function of the nervous system. Our previous results showed changes in gene expression profiles related to signal transduction and neuronal growth. In this study, the protein expression profiles in cerebellum and hippocampus following PCB developmental exposure were examined. Pregnant rats (Long

Evans) were dosed perinatally with 0 or 6 mg/kg/day of Aroclor 1254 (AccuStandard Inc., Lot # 124-191) from gestation day 6 through postnatal day (PND) 21, and the cerebellum and the hippocampus from PND14 animals were isolated by two-dimensional differential gel electrophoresis using fluorescent cyanine dyes and identified by mass spectrometry (MS). Two proteins were found to be differentially expressed in the cerebellum following chemical exposure while 18 proteins were differentially expressed in the hippocampus. MS identification revealed that these proteins are related to energy metabolism in mitochondria (creatine kinase and malate dehydrogenase), calcium signaling (endoplasmic reticulum ATPase and Ryanodine receptor type II) or growth of the nervous system (collapsing response mediator protein 3 (CRMP-3)). These results suggest that changes in energy metabolism and intracellular signaling may be involved in the developmental neurotoxicity of persistent chemicals. (This abstract does not necessarily reflect USEPA policy).

841 POLYCHLORINATED BIPHENYLS ALTER TIGHT JUNCTION PROTEIN DISTRIBUTION AND EXPRESSION IN HUMAN BRAIN MICROVESSEL ENDOTHELIAL CELLS.

S. Eum¹, I. E. Andras¹, B. Hennig² and M. Toborek¹. ¹*Surgery/Neurosurgery, University of Kentucky, Lexington, KY* and ²*Animal Sciences, University of Kentucky, Lexington, KY*.

Polychlorinated biphenyl (PCB) congeners and related compounds exhibit a broad range of adverse biological effects from carcinogenesis, tumor-promoting effects to neurotoxicity. The mechanisms by which PCBs cause neurotoxic effects are still not completely understood. The blood-brain barrier (BBB) is a physical and metabolic barrier separating the microenvironment of the central nervous system (CNS) from the peripheral circulation and is mainly composed of endothelial cells connected by tight junctions. Tight junctions consist of the integral membrane proteins such as occludin, claudins, and junction adhesion molecules (JAMs) as well as the cytosolic accessory proteins such as zonula occludens (ZO) or AF6 that form a scaffold to link tight junction proteins to the cytoskeleton. In the present study, we examined the effects of exposure to different PCB congeners on expression of tight junction proteins in human brain endothelial cells. Several highly-chlorinated PCBs, such as 3,3',4,4'-tetrachlorobiphenyl (PCB77), 2,2',4,5,5'-pentachlorobiphenyl (PCB104), 2,3',4,4',5-pentachlorobiphenyl (PCB118), 3,3',4,4',5-pentachlorobiphenyl (PCB126), and 2,2',4,4',5,5'-hexachloro-biphenyl (PCB153) were employed in these experiments. Treatment for 24 h with specific PCB congeners at the concentration of 5 μ M resulted in a disrupted pattern of plasma membrane expression of the tight junction accessory proteins AF6, ZO-1 and ZO-2. In contrast, PCB exposure did not alter JAM-A and claudin-1 expression. These data suggest that PCB-mediated alterations of tight junction protein expression may disrupt the BBB integrity and thus contribute to the development of the neurotoxic effects in the CNS. Supported by NIH/NIEHS (P42 ES 07380).

842 CROSS-TALK BETWEEN GLUCOCORTICOID AND AH RECEPTORS: IMPLICATIONS FOR CALUX/CALFUX DIOXIN BIOASSAY ANALYSIS.

C. Sorrentino and M. S. Denison. *Environmental Toxicology, University of California Davis, Davis, CA*.

Halogenated aromatic hydrocarbons (HAHs), including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD, dioxin) and related dioxin-like chemicals, are highly toxic environmental contaminants. Since at present the instrumental quantitation of HAHs is costly and time consuming, there is the need for validated alternative assay methods that are able to reliably estimate the overall relative TCDD-like activity in samples. For a scientifically sound use of the data generated, it is necessary to identify and characterize factors that can impact the outcome of these assays. Activation of the glucocorticoid receptor (GR) has been shown to alter HAH-induced gene expression, consequently we hypothesized that the presence of the GR activating compounds such as dexamethasone (Dex) in samples could have an impact on our Ah receptor (AhR)-based cell bioassays, CALUX and CALFUX. Co-exposure to Dex significantly increased in a concentration-dependent manner both luciferase activity and green fluorescent protein expression induced by TCDD in rat cells and this enhancement was significantly inhibited by the GR antagonist RU486. In fact, exposure to Dex induced reporter gene activity even in the absence of TCDD. Using different CALUX cell bioassays we found that the Dex induction or enhancement effects were species-specific, occurring in rat and human but not mouse and Guinea pig cells, and dependent upon the dioxin-responsive domain from the upstream region of the mouse CYP1A1. While identity of the specific regulatory element(s) are still unknown, these results clearly demonstrated that the use of rat or human cells for dioxin bioassay analysis could be problematic and produce false positives if GR activating chemicals are present in the sample extract. Our results highlight the importance of using the correct cell line for the screening of dioxin-like compounds in various matrices and of the purification of the sample extracts as an integral part of the bioassays. NIEHS ES04699, ES5707

843 EXPOSURE TO PBDES AND BTBPE IN THE INDOOR ENVIRONMENT.

T. F. Webster¹, J. Allen¹, M. McClean¹ and H. Stapleton². ¹*Department Environmental Health, Boston University School of Public Health, Boston, MA* and ²*Duke University, Durham, NC*.

Polybrominated diphenyl ethers (PBDEs) are used as fire retardants in foam-containing furniture and electronics. 1,2-bis(2,4,6-tribromophenoxy)ethane (BTBPE) is being produced as a replacement for octaBDE. We previously showed a strong association, independent of diet, between penta-like PBDE concentrations in breast milk and dust sampled from participants' homes (collected using a standard protocol), implying exposure from the indoor environment, possibly via dust ingestion. We found no relationship between PBDE levels in breast milk or dust and home characteristics, but dust had been composited from more than one room per home. In the current study, we therefore collected three different dust samples from each of 20 homes: one from the participants' vacuum cleaner bag, and two from the bedroom and living room using our protocol (vacuuming measured areas using a Eureka Mighty-Mite with a cellulose extraction thimble inserted in the crevice tool). Dust samples were sieved, extracted and analyzed by GC/MS. We collected information by room on foam furniture, electronics and carpeting. Concentrations of PBDEs and BTBPE in house dust were lognormally distributed. Geometric mean (GM) concentrations of total PBDEs were highest in the living room (13900 ng/g, 33% BDE 209), followed by the bedroom and vacuum cleaner bag. Correlations between the three types of samples ranged from 0.1 to 0.6. The GM concentrations of BTBPE were much lower, 8.2 ng/g overall, and not correlated with PBDEs. We found no associations between dust concentrations by room and room contents. The BDE 197/BDE 201 ratio of a number samples was consistent with possible breakdown of decaBDE.

Our results suggest: 1) at least for PBDEs, vacuum cleaner bags and the crevice tool method are not particularly good surrogates for each other; 2) PBDE concentrations are not uniform within homes. BTBPE has not been previously found in house dust. Predicting PBDE concentrations in dust based on room characteristics remains an outstanding issue.

844 FREE RADICAL FORMATION POTENTIAL OF DECA-BROMODIPHENYL ETHER (DECA-BDE).

Y. Suh¹, G. R. Buettner², L. W. Robertson¹ and G. Ludwig¹. ¹*Occupational and Environmental Health, University of Iowa, Iowa City, IA* and ²*Free Radical and Radiation Biology & ESR Facility, University of Iowa, Iowa City, IA*.

Recent studies report increasing levels of polybrominated diphenyl ethers (PBDEs) in humans and our environment. A deca-BDE mixture is still widely manufactured and used. Deca-BDE absorbs UV light and is degraded to lower BDEs by solar or artificial irradiation. We hypothesized that this UV degradation is accompanied by free radical formation, which will result in synergistic toxicity of UV plus deca-BDE. As first step to test this hypothesis we examined UV-induced radical formation. For this purpose a commercial deca-BDE mixture (DE-83R, Great Lakes, USA) was dissolved in tetrahydrofuran (THF). Electron spin resonance (ESR) was used to monitor the generation of free radicals using 5,5-dimethyl-1-pyrroline N-oxide (DMPO) as a spin trap. Samples were purged with argon to remove oxygen and irradiated with a xenon lamp. A 307 nm cut-off filter was used to avoid absorption by DMPO at shorter wavelengths. Irradiation of deca-BDE under these conditions resulted in ESR spectra that were distinctly different from pure THF. Radical formation was positively correlated with both, the deca-BDE concentration and irradiation time. The hyperfine splittings suggest that with deca-BDE and light, carbon-centered radicals are dominant, whereas oxygen-centered radicals dominate in pure THF. The spectral pattern from deca-BDE changed and was similar to the pattern of THF alone, if a 400 nm cut-off filter was used with the BDE, indicating that the activating wavelength is between 307 and 400 nm, i.e. in the UVA to high UVB range. The spectrum from non-brominated diphenyl ether was different from that of deca-BDE, but the same as from pure THF, indicating the involvement of bromine. Our findings that UV irradiation of deca-BDE in THF leads to free radical formation indicates that synergism in toxicity between PBDEs and UV light should be examined. (Supported by ES013661 from NIEHS, DAMD17-02-1-0241 from DOD, and R-82902102-0 from EPA)

845 LACK OF ALTERATIONS IN THYROID HORMONES FOLLOWING A SINGLE POSTNATAL EXPOSURE TO POLYBROMINATED DIPHENYL ETHER 47.

J. R. Gee^{1,2}, J. M. Hedge², P. M. Phillips², K. L. McDaniel² and V. C. Moser². ¹*NCSU, Raleigh, NC* and ²*NTD/NHEERL, U.S. EPA, Research Triangle Park, NC*.

Polybrominated diphenyl ethers (PBDEs) are commonly used as commercial flame retardants in a variety of products including plastics and textiles. There has been a rapid accumulation of these chemicals in the environment and high levels of

PBDEs have been found in the adipose tissue, blood, and breast milk of humans. This is especially true for the congener, 2,2',4,4'-tetrabromodiphenyl ether (BDE 47), which has shown an accelerated accumulation in humans in recent years. Concern over BDE 47 exposure has also stemmed from the similarity of its molecular structure with that of polychlorinated biphenyls (PCBs) which are known to disrupt thyroid hormone homeostasis. Furthermore, there are reports of thyroid alterations following perinatal exposure to PBDE mixtures. Disruption of thyroid hormone levels has been shown to be important in development of the brain due to its role in neurite outgrowth, synapse formation, and neuronal guidance. Thus disruptions in thyroid hormone levels may underlie certain behavior deficits observed in animals following PBDE exposure, such as reduced habituation and learning and memory abnormalities. The aim of this study was to determine whether a single exposure to BDE 47 in C57BL/6 mice would alter thyroid hormone levels during a phase of rapid brain development. Male mice were dosed with either 0 (corn oil vehicle), 1, 10, or 30 mg/kg on postnatal day 10, and sacrificed for collection of serum at 1, 5, or 10 days after the dose (n=5-6 litters/dose/time point). Body weight gain was not altered. Total thyroxine (T4) and triiodothyronine (T3) were measured by RIA. No effects of BDE 47 were observed on the T4 levels at any age examined; T3 assays on remaining sera (n=2-5/dose/time point) also showed no changes. This indicates that alterations in thyroid hormone levels may not contribute to the purported behavior abnormalities seen in mice following acute neonatal exposure to BDE 47. This is an abstract of a proposed presentation and does not reflect US EPA policy.

846 EVALUATION OF THE DEVELOPMENTAL TOXICITY OF A POLYBROMINATED DIPHENYL ETHER MIXTURE (DE-71) IN THE ANURAN, *XENOPUS* (SILURANA) TROPICALIS.

D. J. Fort¹, R. L. Rogers¹, P. D. Guiney² and J. A. Weeks². ¹Fort Environmental Laboratories, Stillwater, OK and ²S.C. Johnson & Son, Racine, WI.

The commercial polybrominated diphenyl ether (PBDE) flame retardant, DE-71 was selected for further examination of developmental toxicity because of its ubiquity in the environment and potential to disturb endocrine activity. DE-71 was previously found to inhibit progesterone, and to a lesser extent androgen-induced, in vitro oocyte maturation in *Xenopus*. Therefore, a partial lifecycle study exposing *X. (Silurana) tropicalis* to 0.0, 0.43, 0.9, 2.1, and 3.8 mg/L DE-71 from early embryo through the completion of metamorphosis was conducted. Endpoints measured included the rate of metamorphosis, whole body weight, external malformation, internal abnormalities, gender ratio, and whole body PBDE residue. A concentration-dependent increase in whole body DE-71 residues was measured ranging from 43.4 mg/Kg to 203.3 mg/Kg in the 0.43 mg/L and 3.8 mg/L DE-71 treatments. The rate of metamorphosis decreased slightly with increasing concentration from 39 (37-41) d in control organisms to 44 (42-46) d in 3.8 mg/L DE-71 treatment. However, no marked effect on thyroid gland histology was found in specimens from any of the PBDE treatments. Whole body weight in newly metamorphosed organisms increased with increasing DE-71 exposure concentration. Gender ratios (male:female) were similar to the control in the 0.43 mg/L and 0.90 mg/L DE-71 exposure treatments. However, an increase in the proportion of females was observed in the 2.1 and 3.8 mg/L DE-71 treatments. No evidence of induction of external abnormalities was noted as the result of DE-71 exposure. However, a concentration-related increase in liver necrosis (males and females), and abnormal ovary development characterized by previtellogenic oocyte necrosis and arrested development in pools of vitellogenic oocytes in females were observed. No apparent effect on testis morphology was observed, although further examination of spermatogenesis is warranted. Results suggest that PBDEs are capable of interfering with *X. (Silurana) tropicalis* development.

847 THE POLYBROMINATED BYPHENYL ETHER MIXTURE DE-71 IS MILDLY ESTROGENIC.

M. Mercado Feliciano¹, X. Qiu², R. A. Hites² and R. M. Bigsby^{3,4}. ¹Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, ²School of Public and Environmental Affairs, Indiana University, Bloomington, IN, ³Obstetrics & Gynecology, Indiana University School of Medicine, Indianapolis, IN and ⁴Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN.

Our goal is to determine if the polybrominated diphenyl ether (PBDE) mixture DE-71 has estrogenic activity. METHODS: Ovariectomized BALB/c, C57BL/6, and ER α knockout (ER α KO) mice were treated for 5 weeks with vehicle, DE-71, estradiol benzoate (EB), or both DE-71 and EB. MCF-7 cell proliferation was assessed after 10-day incubation with either estradiol (E2), DE-71, antiestrogen, or combinations of DE-71 and E2 or antiestrogen. To test if metabolic activation occurred, DE-71 was incubated with female rat microsomes in a NADPH regenerating buffer. Extracted incubations and controls were tested for estrogenic activity

using an Estrogen Response Element (ERE) - luciferase reporter gene construct, and 3H-estradiol displacement from recombinant estrogen receptor alpha (ER α). RESULTS: DE-71 increased uterine weight in C57BL/6 mice over control, but not in BALB/c or ER α KO. DE-71 slightly increased uterine epithelial height (UEH) and vaginal epithelial thickness over control, and attenuated the EB-induced increase in UEH in BALB/c mice, but not in C57BL/6 or ER α KO. Both DE-71 and EB increased liver weight in BALB/c mice and their effects were additive. DE-71 but not EB increased liver size in C57BL/6 mice. DE-71 increased MCF-7 cell proliferation after 10-day incubation and this increase was prevented by co-treatment with the antiestrogen fulvestrant. When cells were co-treated with E2 and DE-71, there was a decrease in cell proliferation compared with E2 treatment alone. While DE-71 by itself weakly activates estrogen-responsive luciferase reporter constructs, this activation increased significantly when DE-71 was pre-incubated with liver microsomes. Ongoing experiments are aimed towards determining the effect of metabolic hydroxylation on the estrogenic activity of DE-71. Supported by NIEHS Grant # 1 F31 ES013341

848 DEVELOPMENTAL TOXICITY OF POLYBROMINATED DIPHENYL ETHER 47 IN THE AMPHIBIAN MODEL SPECIES *XENOPUS LAEVIS*.

S. J. Degitz, G. W. Holcombe, P. A. Kosian, B. C. Butterworth and J. E. Tietge. NHEERL, MED, U.S. Environmental Protection Agency, Duluth, MN. Sponsor: M. Hornung.

Polybrominated diphenyl ethers (PBDEs), used as flame retardants, are found ubiquitously in the environment. PBDEs have been shown to affect thyroid axis homeostasis in mammal, avian, and fish species. Effects on the thyroid axis in those species were observed as decreased circulating T4 levels. Recently, we have developed an amphibian screening assay for evaluating the effects of xenobiotics on the thyroid axis. In this study, we used this assay to determine if PBDE-47, the major component of DE-71, a specific flame retardant formulation, has antithyroid effects in *X. laevis* similar to those observed in other species. Stage 51 tadpoles were fed a control sera micron diet or a diet spiked with PBDE-47 concentrations of 1.58, 4.57, 9.29, and 19.6 mg/g. After 21 days of dietary exposure, all tadpoles were weighed and evaluated for developmental stage. Blood was collected from a subset for the analysis of serum T4 concentrations. All remaining animals were frozen for subsequent analysis of whole body PBDE-47 concentrations. Treatment had little or no effect on growth at concentrations of ≤ 9.29 . However, there were obvious signs of toxicity, as determined by a significant decrease in weight at 19.6 mg/g. PBDE-47 treatment also resulted in a dose dependent developmental delay at concentrations of 4.57 mg/g and above. As a result T4 measurements were made only in the 1.58 and 4.57 mg/g treatment groups, where no effects on serum T4 levels were observed. These results indicate that PBDE-47 is developmentally toxic to *X. laevis*, resulting in decreased growth at higher dietary concentrations and retarded development at all but the lowest dietary concentrations. Since these effects were observed in the absence of altered serum T4 concentrations, the mechanism of PBDE-47-mediated developmental toxicity remains unclear for this species. This abstract does not necessarily reflect EPA policy

849 PERINATAL EXPOSURE TO DE-71 ALTERS EXPRESSION OF HEPATIC GENES INVOLVED IN THYROID HORMONE DISRUPTION IN MALE RATS.

D. T. Szabo¹, J. J. Diliberto², V. M. Richardson², P. S. Kodavanti² and L. S. Birnbaum². ¹Toxicology, UNC, Chapel Hill, NC and ²ORD/NHEERL, U.S. EPA, Research Triangle Park, NC.

DE-71, commercial mixture containing mostly tetra- and penta-bromodiphenyl ethers, has been commonly used as a flame retardant in polyurethane foam. These PBDE congeners are of concern because they are ubiquitous in our environment and increasing in human tissue. Developmental studies show exposure to PBDEs may affect thyroid hormone levels by inducing hepatic uridine diphosphate-glucuronosyltransferases (UGTs) and transthyretin (Ttr) binding. This study examines effects of DE-71 on genes related to thyroid hormone disruption at different developmental time points in male rats. Pregnant Long-Evans rats were orally gavaged at 0, 1.7 (low), 10.2 (mid) or 30.6 (high) mg/kg/day of DE-71 in corn oil from gestational day 6 to postnatal day (PND) 21. For pups at PND4 and PND22, serum was collected for thyroid hormone levels and livers were analyzed for mRNA expression by RT-PCR. Serum total T4 concentrations were unchanged at PND4 while they decreased 50% (mid) and 80% (high) at PND22. Ugt1a1 mRNA remained unchanged at PND4 while a 30% decrease was observed in the high dose at PND22. Ugt1a6 increased 2 (low), 8 (mid) and 21 (high)-fold at PND4 while there was no change observed at PND22. At PND4, Ugt1a7 increased 2-fold (mid) and 3-fold (high) while there was a 3-fold increase at PND22 (high). Ugt2b increased 5-fold (high) at PND4 and 58-fold (high) at PND22. At PND4, deiodinase I mRNA was reduced 40% (mid) and 50% (high) while at PND22 decreased 30% (high). Ttr mRNA was unchanged at PND4 and reduced 30% (high) at

PND22. This study demonstrates perinatal exposure to DE-71 alters the expression of genes involved in thyroid hormone homeostasis although total T4 concentration were not significantly decreased at PND4. Thus, the alterations in gene expression are dose- and time-dependent but may not necessarily correlate with significant decreases in circulating thyroid hormone. (This abstract does not necessarily reflect USEPA policy. Supported in part by NIH T32 ES007126)

850 POLYBROMINATED DIPHENYL ETHERS AND THYROID HORMONE METABOLISM IN CARP (CYPRINUS CARPIO).

R. V. Benedict¹, C. L. Mitchelmore¹ and S. V. Brown². ¹UMCES, Chesapeake Biological Lab., Solomons, MD and ²Environment Canada, Burlington, ON, Canada.

The debromination of polybrominated diphenyl ether (BDEs) congeners has been demonstrated in whale, rat, rainbow trout and carp microsomes. This research investigated a potential mechanism of BDE debromination and endocrine associated impacts of BDE exposure in carp. Fish were fed 2,2',4,4',5 pentabromodiphenyl ether (BDE-99) spiked food for 62 days and allowed to depurate for 5 days. Total plasma thyronine (T3) and thyroxine (T4) concentrations were assessed by radioimmunoassay. Liver and intestinal deiodination activity was assessed by radioactive deiodination assays. Iodothyronine products were analyzed by high performance liquid chromatography. Results indicated that total plasma T3 levels were depressed in dosed fish as compared with controls. On day 30, intestinal and hepatic microsomes from exposed fish exhibited lower T4 outer ring deiodination activity than controls. Further, intestinal microsomes from BDE-99 exposed fish exhibited lower T3 inner ring deiodination than controls on day 10 through day 62. Additional in vitro deiodination studies assessed the impacts of BDEs on deiodinase (DI) enzyme activity. Four sets of carp intestinal and hepatic microsomes were incubated with radioactive thyroid hormones, 2,4,4',6-tetrabromodiphenyl ether (BDE-75), BDE-99, or decabromodiphenyl ether (BDE-209), a DI inhibitor (iodoacetic acid), and/or competitor (reverse thyronine). Results indicated that BDE-75 inhibited DI activity whereas BDE-99 and BDE-209 had no effect. Together the carp in vivo and in vitro BDE studies suggest that: 1) BDE-99 and BDE-209 debromination are not likely occurring by deiodinase enzymes, 2) a BDE-99 metabolite may be responsible for the lower plasma thyroid hormone levels and deiodination activities and 3) tetra brominated BDEs may have the ability to interrupt thyroid hormone metabolism at the enzymatic level.

851 EFFECT OF BDE-47 ON HEPATIC DRUG METABOLIZING ENZYMES IN ISOGENIC RAINBOW TROUT.

J. Sahi¹, K. Johanning², J. Wright², J. Stover², L. Easterwood², J. Hill² and I. R. Schultz³. ¹R&D, CellzDirect Inc., Ann Arbor, MI, ²Metabolism, CellzDirect Inc., Austin, TX and ³Marine Research Operations, Battelle, Sequim, WA.

Polybrominated diphenyl ethers have been used extensively as flame retardants over the past two decades. BDE-47 is the dominant congener in water systems and is found in fish from many parts of the world. There are increasing concerns about the effects of this contaminant on aquatic and upstream species, particularly if there is bioaccumulation. BDE-47 alters gene expression in trout, induces activity of the major hepatic drug metabolizing enzyme CYP1A, at low concentrations and inhibits CYP1A activity at higher concentrations, potentially decreasing detoxification capacity and increasing the risk of bioaccumulation. The effect of BDE-47 on the other major drug metabolism pathways has not been reported. In this study, sexually mature male rainbow trout (*Oncorhynchus mykiss*) were orally dosed with BDE-47 (50 µg/Kg/day) for 21 days. Semen from these and control trout was used to fertilize eggs obtained from a single, unexposed female. The resulting offspring were separated as per lineage and treated with BDE-47 for 21 days at 6 months in age. Livers from unexposed and exposed F1 control and F1 BDE treated fish were harvested and S9 fractions were prepared using standard methods. Activities for CYP2E, CYP1A, CYP2B, CYP3A, CYP2C and UGT were measured for each treatment group to evaluate 1) changes in enzyme activity following BDE 47 exposure and 2) transgenerational effects due to exposure. These results will aid in understanding of bioaccumulation of environmental contaminants such as polybrominated diphenyl ethers and potential effects on fish and other aquatic organisms.

852 EFFECTS ON HEPATIC GENE EXPRESSION IN MALE RATS ADMINISTERED PBDES IN HOUSEHOLD DUST.

V. M. Richardson¹, H. Hakk², J. J. Diliberto¹ and L. S. Birnbaum¹. ¹ORD/NHEERL/ETD, U.S. EPA, Research Triangle Park, NC and ²ARS Bioscience Research Laboratory, USDA, Fargo, ND.

Studies show that polybrominated diphenyl ethers (PBDEs) decrease thyroid hormone concentrations via induction of hepatic uridinediphosphate-glucuronosyl-transferase (UGTs) and transthyretin (Ttr) binding. Because PBDEs exhibit en-

docrine disrupting properties and are present in human tissue, sources of human exposure are of increasing interest. Our laboratory has found that PBDEs fed to adult male rats in dust (NIST Standard Reference Material 2585) or an oil vehicle are equally bioavailable. This study examines the effects of PBDEs in household dust through their ability to induce genes involved in thyroid hormone disruption. Adult male Sprague-Dawley rats were fed either household dust at 319 or 1851 ng PBDEs/day or peanut oil containing 20 PBDEs at 181 or 906 ng PBDEs/day for 21 days. On day 22, livers were taken for gene expression analysis using real-time RT-PCR. Hepatic Cyp1a1 mRNA was unchanged in rats fed PBDEs in oil, but was increased 2 and 3-fold in the 319 and 1851 ng PBDEs/day dust treatment groups, respectively. Exposures to 181 ng PBDEs/day in the oil vehicle had no effect on hepatic Cyp2b1 mRNA. Increases in hepatic Cyp2b1 mRNA were seen with 906 ng PBDEs/day in oil, and in both dose levels in dust (319 and 1851 ng PBDEs/day), by 4, 2, and 3-fold, respectively. Hepatic Cyp2b2 mRNA was unchanged in both dust and oil treatment groups of 319 and 181 ng PBDEs/day, respectively; whereas, Cyp2b2 mRNA increased 5 and 3-fold in the 1851 and 906 ng PBDEs/day of the dust and oil treatment groups, respectively. There was no change in hepatic Ugt1a1, Ugt1a7, Ugt2b, or Ttr mRNA. This study shows that household dust is equally as effective as a PBDE oil mixture through its induction of CYP2b2 mRNA, but the administered concentrations may not be sufficient for thyroid hormone disruption. The observed effects on CYP1a1 mRNA are likely due to other polyhalogenated aromatic compounds found in the household dust. (This does not necessarily reflect USEPA policy).

853 PET CATS IN THE U.S. HAVE HIGH POLYBROMINATED DIPHENYL ETHER (PBDE) SERUM LEVELS.

J. Dye¹, M. Venier², C. R. Ward³, R. A. Hites² and L. S. Birnbaum¹. ¹NHEERL, Experimental Toxicology Division, U.S. EPA, Research Triangle Park, NC, ²School of Public and Environmental Affairs, Indiana University, Bloomington, IN and ³College of Veterinary Medicine, University of Georgia, Athens, GA.

Coincident with the introduction of brominated flame-retardants in consumer products nearly 30 years ago, hyperthyroidism in cats has increased substantially. We hypothesize that increasing exposure to PBDEs has, in some manner, contributed to the abrupt increase in and now common occurrence of hyperthyroidism in older pet cats. In this pilot study, we assessed the feasibility of detecting PBDEs in small serum volumes that could be safely collected from geriatric cats. We evaluated 14 cats [4 young, 4 older, non-hyperthyroid (non-HT), and 6 hyperthyroid (HT) cats]. Results demonstrated that even in 1–2 mL of serum, a variety of congeners were readily detected (i.e., BDE-47, -99, -100, -153 and/or -154, -183, -207, -208-, and -209). Other congeners (i.e., BDE-66, -85, -196, -197, and -201) were present in some cats, in lesser quantities. Owing to insensitivity of the gravimetric lipid assay used, we were not able to accurately determine sample lipid content. Hence, results are expressed as the concentration of ΣPBDEs (ng/mL) present. The mean ± SE (and median) ΣPBDE serum concentrations in young, non-HT, and HT cats were 4.4 ± 2.0 (2.7), 7.20 ± 3.4 (4.76), and 15.0 ± 6.7 (5.55) ng/mL, respectively. We conclude that pet cats — with exposures likely paralleling that of their owners — are useful sentinels to assess potential endocrine health outcome related to cumulative, low-level PBDE exposure. (This abstract does not reflect USEPA policy).

854 PROTEOMIC ANALYSIS OF A [¹⁴C]-CHOLESTEROL ENRICHED FRACTION FROM HEPATIC CYTOSOL OF CHLORDEKONE PRETREATED MICE USING AMINE-SPECIFIC ISOTOPIC LABELING.

R. C. Scheri¹, J. Lee¹, D. F. Barofsky² and L. R. Curtis¹. ¹EMT, Oregon State University, Corvallis, OR and ²Chemistry, Oregon State University, Corvallis, OR.

Previous work has shown that the pretreatment of male C57BL/6 mice with low doses of the organochloride insecticide chlordane (CD) stimulated hepatic trafficking of [¹⁴C]-cholesterol. The intracellular transport of cholesterol is complex and both vesicular and non-vesicular transport mechanisms are involved. Their relative roles have not been fully elucidated and the non-vesicular transport mechanisms are not well understood. The present study was undertaken to see if a proteomic approach could be used to identify and monitor relative changes in hepatic cytosolic proteins that were initially isolated using [¹⁴C]-cholesterol challenged mice after pretreatment with CD.

Prospective protein fractions for analysis were isolated from CD (15 mg/kg) pretreated mice that had been challenged three days later with [¹⁴C]-CH. Animals were sacrificed 4 hours after the challenge dose was administered. The labeled protein fraction was isolated from hepatic cytosol with either ammonium sulfate or streptomycin precipitation.

Samples from CD (15 mg/kg) pretreated mice that were sacrificed three days later with no challenge were analyzed on a matrix assisted laser desorption ionization time of flight mass spectrometer. Isolated protein fractions were first di-

gested with trypsin and then the control and treatment groups were labeled with different isobaric mass tags (iTRAQ). Peptides were separated with strong cation exchange followed by C18 reverse phase high performance liquid chromatography. Tandem mass spectra were used for protein identification and iTRAQ mass tag ratios were used for relative quantification.

Initial results indicated that about 70 proteins could be identified with this protocol. Levels of glutathione s-transferase and liver fatty acid-binding protein increased about two fold in the CD pretreated group when compared to controls. The majority of proteins detected appeared to be unaffected by CD pretreatment, including sterol carrier protein 2.

855 A PILOT STUDY ON THE CONCENTRATIONS OF VARIOUS PERFLUORINATED ORGANIC COMPOUNDS IN THE BLOOD OF RESIDENTS IN CATALONIA, SPAIN.

A. Teixidó¹, I. Ericson², A. Vilanova¹, B. van Bavel², G. Lindström² and J. L. Domingo³. ¹Health, Generalitat de Catalunya, Barcelona, Spain, ²MTM research Centre, Örebro University, Örebro, Sweden and ³Toxicology & Environment Health, "Rovira i Virgili" University, Reus, Spain.

Fluorinated organic compounds (FOCs) are a group of chemicals widely used as surfactants, lubricants, polymers, and fire-fighting foams. Until recently, these chemicals were perceived as more biologically inert than chlorinated and brominated organic compounds and therefore, less likely to have an impact on human health or the environment. However, a number of recent studies have shown the ubiquitous distribution of FOCs in the environment, wildlife, and humans. We here report the results of a pilot study conducted to provide preliminary data on the levels of 13 FOCs in the blood of 48 residents in Catalonia, Spain, in relation to gender and age (25±5 and 55±5 years). The highest mean concentration was obtained for perfluorooctane sulfonate (PFOS, 7.64 ng/ml), followed by perfluorohexane sulfonate (PFHxS, 3.57 ng/ml) and perfluorooctanoic acid (PFOA, 1.80 ng/ml). Four other FOCs showed mean levels between 0.30 and 0.44 ng/ml, whereas those of the remaining 6 compounds were below the detection limit. Regarding gender, only the blood levels of PFHxS and PFOA were significantly higher ($p < 0.05$) in men than in women, while differences according to age were only noted for PFHxS ($p < 0.05$) and perfluorooctane sulfonamide (PFOSA) ($p < 0.001$), for which the levels were higher in the younger (25±5 years) group of subjects. A significant correlation between PFOS levels and those of the remaining detected FOCs (except PFDA) was found. In general terms, the current FOC concentrations were lower than those found in recent studies concerning levels of these chemicals in human blood and serum of subjects from different countries.

856 ROLE OF CAVEOLIN-1 AND ENDOTHELIAL NITRIC OXIDE SYNTHASE (eNOS) IN ACETAMINOPHEN-INDUCED HEPATOTOXICITY.

C. R. Gardner^{1,3}, J. P. Gray², J. Dubois¹, J. D. Laskin^{2,3} and D. L. Laskin^{1,3}. ¹Rutgers University, Piscataway, NJ, ²UMDNJ/RWJMS, Piscataway, NJ and ³EOHSI, Piscataway, NJ.

Acetaminophen (APAP) is a mild analgesic and antipyretic agent known to cause centrilobular hepatic necrosis in a CYP2E1-dependent manner. We have previously demonstrated that nitric oxide (NO) generated via inducible nitric oxide synthase (iNOS) is an important mediator of APAP-induced hepatotoxicity. Thus, both wild type (WT) mice treated with an iNOS inhibitor and iNOS^{-/-} mice are protected from APAP-induced hepatotoxicity. Recent studies have demonstrated that NO can be hepatoprotective against CYP2E1-dependent toxicity by preventing oxidative stress. We speculated that this may be mediated by NO generated via eNOS, which is an important regulator of blood flow and of microvascular permeability during inflammation and this was examined. Treatment of WT mice with APAP (300 mg/kg, i.p.) resulted in a rapid (within 3 hr) upregulation of eNOS mRNA in the liver. This was associated with a marked decrease in expression of Cav-1, a 21-24 kDa membrane scaffolding protein that functions to concentrate eNOS and negatively regulate its activation state. Pretreatment of WT mice with N^G-nitro-L-arginine methyl ester (L-NAME, 10 mg/kg), an inhibitor of eNOS, had no major effects on APAP-induced toxicity. In contrast, pretreatment of Cav-1^{-/-} mice, which are resistant to APAP, with L-NAME prior to APAP, resulted in marked increases in serum transaminases levels and centrilobular hepatic necrosis. These data suggest that NO generated via eNOS can contribute to hepatoprotection during APAP-induced inflammation and tissue injury. This is supported by findings that production of mediators important in repair of APAP damaged livers including MCP-1, IL-1, and IL-6 are altered in Cav-1^{-/-} mice, when compared to WT mice and that expression of the anti-inflammatory cytokine, IL-10 is upregulated immediately after APAP administration. These data demonstrate that Cav-1 plays an important role in regulating inflammatory responses and tissue repair initiated by APAP. (NIH GM034310, ES004738, ES005022).

857 ROLE OF β -CATENIN IN LIVER REGENERATION FOLLOWING ACETAMINOPHEN-INDUCED ACUTE LIVER FAILURE.

U. Apte, G. Zeng, P. Muller, B. Cieply and S. Monga. *Department of Pathology, University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Overdose of acetaminophen (APAP) is the leading cause of acute liver failure (ALF). Understanding the mechanisms of liver regeneration following APAP-induced liver injury is thus of high therapeutic relevance. To investigate the role of Wnt/ β -catenin, an important pathway in liver biology, in liver regeneration after APAP-induced ALF, male CD-1 mice were treated with a non-lethal dose of APAP (500 mg/kg), which induced extensive liver injury and subsequent regeneration. Rapid induction in the total and active β -catenin was evident at 1-3 hr after APAP treatment, along with its nuclear translocation at 6 hr. Investigation into the mechanisms of β -catenin activation revealed involvement of canonical (GSK-3 β -dependent) and non-canonical (c-met-dependent) components. Following treatment with a lethal dose of APAP (700 mg/kg) known to inhibit liver regeneration, β -catenin activation was completely suppressed. Furthermore, suppression of β -catenin activation was observed in human APAP-induced ALF liver samples along with suppression of liver regeneration. Taken together, these data indicate that β -catenin activation is among the earliest events related to stimulation of liver regeneration following APAP overdose and might have therapeutic and prognostic implications in APAP ALF. (Supported by RSG-03-141-01-CNE and NIH - 1R01DK62277 to SPSM).

858 LEFLUNOMIDE RESCUES MICE FROM ACETAMINOPHEN-INDUCED LIVER INJURY BY INHIBITING JNK-MEDIATED MITOCHONDRIAL PERMEABILIZATION.

C. Latchoumycandane¹, C. W. Goh¹, M. M. Ong¹, R. C. Tan¹ and U. A. Boelsterli^{1,2}. ¹Department Pharmacology, National University of Singapore, Singapore, Singapore and ²Department Pharmacy, NUS, Singapore, Singapore.

We have recently demonstrated that leflunomide (LEF), a disease-modifying anti-rheumatic pro-drug, and its active metabolite A77 1726 protect from acetaminophen (APAP)-induced cell injury in human hepatocytes by inhibiting the JNK pathway. The aim of this study was to determine whether LEF afforded protection from APAP-induced hepatotoxicity in vivo. Male C57BL/6 mice were given a hepatotoxic dose (750 mg/kg, ip) of APAP, followed by a single dose of LEF (30 mg/kg, ip) 4 h or 8 h after APAP. LEF fully prevented the increase in serum ALT activity and greatly reduced the extent of centrilobular necrosis determined at 8 h or 24 h post-APAP. LEF still protected when given as late as 8 h after APAP. The hepatoprotection was not due to inhibition of APAP bioactivation because LEF was administered after maximal depletion of GSH by the thiol-reactive intermediate. Similarly, hepatoprotection by LEF was not mediated through inhibition of the innate immune system as judged from unchanged transcript levels of key cytokines/chemokines involved in APAP hepatotoxicity. Both the APAP-induced mitochondrial release of cytochrome c and the drop in the ATP-biosynthesizing capacity of ex vivo isolated mitochondria were prevented by LEF, indicating that the protection was upstream of the mitochondrial permeability transition (mPT). Furthermore, APAP-induced nitrotyrosine-positive immunostaining was reduced by LEF, indicating that mitochondrial peroxynitrite formation was inhibited. Because both iNOS and the mPT are regulated by JNK, we determined the effects of LEF on APAP-induced increased JNK activation (phosphorylation). Immunoreactive P-JNK1/2 levels (but not JNK1/2 expression) were increased after APAP but remained low after combined APAP+LEF, thus blocking phosphorylation of downstream regulators of the mPT. In conclusion, LEF protects from APAP-induced hepatotoxicity by preventing mPT and release of death proteins by inhibiting the JNK-signaling pathway in mice.

859 COMPARISON OF PROTECTIVE EFFECTS OF S-ADENOSYL-L-METHIONINE (SAME) AND N-ACETYL-CYSTEINE (NAC) GIVEN AFTER ACETAMINOPHEN (APAP) TREATMENT IN MICE.

M. Valentovic¹, M. V. Terneus¹ and A. Carpenter². ¹Pharmacology, Marshall University School of Medicine, Huntington, WV and ²Pathology, Marshall University School Of Medicine, Huntington, WV.

Acetaminophen (APAP), in excessive doses, is associated with hepatic toxicity. At the present time, one-third of all acute liver failure in the U.S. are attributed to APAP overdose. This study examined the protective effect of SAME when administered after APAP similar to what occurs in a human overdose. Male C57BL/6 (16-25 g) n= 5 animals/group $\pm$ SEM were used in the studies. The mice were randomly divided into 6 groups, vehicle (VEH), APAP, SAME, SAME plus APAP

(SAME+APAP), NAC and NAC plus APAP (NAC+APAP). The animals were injected intraperitoneal (ip) with 250mg/kg APAP or water. One hr later, SAME and SAME+APAP groups were injected (ip) with 1.25 mmol/kg SAME and the NAC and NAC+APAP groups were injected (ip) with 1.25 mmol/kg NAC. Toxicity was assessed 4 h after APAP injection by monitoring hepatic glutathione (GSH) levels, changes in ALT, lipid peroxidation levels, liver weight and histology as parameters of APAP toxicity. SAME protected the liver from APAP-induced damage by decreasing ALT and lipid peroxidation levels as well as preventing depletion of glutathione. NAC also reduced APAP hepatic toxicity. Further studies investigated the protective effects of SAME against APAP-induced hepatotoxicity on 4-hydroxynonenal (4HNE) adducted proteins and protein carbonyls. The results of this study have found that SAME protects the liver from production of protein carbonyls and 4HNE adducts. In summary, APAP hepatic toxicity occurs within 1 h after injection in mice. SAME administered 1 h after APAP was successful at reducing APAP hepatic toxicity. SAME administered 1 h after APAP also reduced the extent of oxidative stress associated with APAP.

860 HEPATOTOXIC SENSITIVITY OF NONALCOHOLIC STEATOHEPATITIC (NASH) MICE TO ACETAMINOPHEN IS DUE TO LOW PPAR α

S. Donthamsetty, V. Bhawe, M. Mitra and H. M. Mehendale. *University of Louisiana, Monroe, LA.*

The objective was to determine if the hepatotoxic sensitivity in NASH mice to acetaminophen (APAP) is due to downregulation of nuclear receptor PPAR α via lower cell division and tissue repair. Male SW mice fed methionine and choline deficient diet for 31 days exhibited NASH. On 32nd day, exposure to a marginally toxic dose of APAP (350 mg/kg, ip) yielded 70% mortality in NASH mice 8 to 24 h later, while all non NASH mice receiving the same dose survived. Covalent binding of ¹⁴C-APAP-derived radiolabel to the liver macromolecules, CYP2E1 protein, and enzyme activity did not differ from the controls, obviating increased APAP bioactivation as the cause of amplified APAP hepatotoxicity. Liver injury as assessed by liver histopathology and plasma ALT progressed only in NASH livers between 6 to 24 h. Cell division and tissue repair assessed by 3H-thymidine incorporation and PCNA were inhibited only in the NASH mice given APAP. These results strongly suggested that higher sensitivity of NASH liver to APAP-induced hepatotoxicity was due to lower tissue repair. Because PPAR α induction is known to promote tissue repair, the hypothesis that impeded liver tissue repair in NASH mice was due to downregulation of PPAR α was tested. PPAR α was downregulated in NASH evidenced by lower expression of CYP4A protein, consistent with the compromised liver tissue repair seen in NASH mice exposed to APAP. To investigate that downregulation of PPAR α in NASH is the critical mechanism of compromised liver tissue repair, PPAR α was induced in NASH mice with clofibrate (250 mg/kg for 3 days, ip) before injecting APAP. All clofibrate pretreated NASH mice receiving APAP exhibited lower injury (ALT and histopathology), which did not progress and the mice survived. The protection was not due to lower bioactivation of APAP as assessed by ¹⁴C-APAP covalent binding, CYP2E1 protein, and enzyme activity, but due to higher liver tissue repair as assessed by an increased DNA synthesis and PCNA. These findings suggest that inadequate PPAR α expression sensitizes NASH mice to APAP hepatotoxicity.

861 ROLE OF THE INNATE IMMUNE SYSTEM IN THE INCREASED SUSCEPTIBILITY OF INTERLEUKIN-13 DEFICIENT MICE TO ACETAMINOPHEN-INDUCED LIVER DISEASE.

S. B. Yee, M. Bourdi, M. Masson and L. R. Pohl. *Molecular and Cellular Toxicology Section, Laboratory of Molecular Immunology, NHLBI, National Institutes of Health, Bethesda, MD.*

Recently, we have shown that endogenous interleukin (IL)-13 protected mice from acetaminophen (APAP)-induced liver disease (AILD). Several proinflammatory cytokines and chemokines downstream of reactive metabolite formation appear to be regulated by IL-13, as their serum expression was found to be higher in APAP-treated IL-13 knockout (KO) than wild-type (WT) mice. In the present study, we evaluated the pathologic role of proinflammatory factors in IL-13 KO mice following challenge with 200 mg APAP/kg. When interferon (IFN)- γ neutralizing antibody (NAb) was administered to APAP-treated IL-13 KO mice, IFN- γ levels decreased significantly and AILD was attenuated. Since natural killer (NK) cells and NK cells with T-cell receptors (NKT cells) are major sources for IFN- γ , the importance of these innate immune cells was investigated. Administration of NK 1.1 NAb to APAP-treated IL-13 KO mice depleted both NK and NKT cells, attenuated liver injury and abrogated IFN- γ levels, suggesting these cells play a critical role by secreting injurious IFN- γ . Additionally, based on observations of elevated neutrophil (polymorphonuclear leukocyte, PMN) chemoattractants, along with immunohistochemically-determined greater hepatic PMN accumulation in APAP-treated IL-13 KO mice compared to WT, the role of PMNs was also investigated.

Administration of PMN NAb to APAP-treated IL-13 KO mice greatly reduced hepatic PMN accumulation and attenuated liver injury, suggesting PMNs contribute to AILD in this susceptibility model. Collectively, these results indicate IL-13 modulates the pathologic role of the innate immune system in AILD and suggests IL-13 is an important hepatoprotective cytokine in drug-induced liver disease. *This research was supported by the Intramural Research Program of the NIH and NHLBI.*

862 HEPATOPROTECTIVE EFFECTS OF THE SAPONINS ISOLATED FROM ROOTS OF PLATYCODON GRANDIFLORUM AGAINST CARBON TETRACHLORIDE-INDUCED TOXICITY.

S. Roh⁴, K. Lee¹, J. Choi^{1,2}, Y. Chung³ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea, ³Division of Food Science, Chonju International University, Chonju, South Korea and ⁴Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Chonju, South Korea.

The protective effects of the saponins isolated from the roots of *Platycodon grandiflorum* A. DC (Campanulaceae), Changkil saponins (CKS), on carbon tetrachloride induced hepatotoxicity and the possible mechanisms involved in this protection were investigated. Pretreatment with CKS prior to the administration of carbon tetrachloride significantly prevented the increased serum enzymatic activities of alanine and aspartate aminotransferase and hepatic lipid peroxidation in a dose-dependent manner. The effects of CKS on the cytochrome P450 (P450) 2E1, the major isozyme involved in carbon tetrachloride bioactivation were also investigated. Treatment of mice with CKS resulted in a significant decrease of P450 2E1-dependent p-nitrophenol and aniline hydroxylation in a dose-dependent manner. CKS showed anti oxidant effects in FeCl₂ ascorbate induced lipid peroxidation in mice liver homogenate and in superoxide radical scavenging activity. Our results suggest that the protective effects of CKS against carbon tetrachloride-induced hepatotoxicity possibly involve mechanisms related to its ability to block P450 mediated carbon tetrachloride bioactivation and free radical scavenging effects.

863 RETROSPECTIVE ANALYSIS OF ALANINE AMINOTRANSFERASE ELEVATIONS WITH THE MAXIMUM RECOMMENDED DOSE OF ACETAMINOPHEN SHOWS ELEVATIONS ARE LOW, TRANSIENT, AND CLINICALLY INSIGNIFICANT.

J. Baggish, A. Temple, K. Cooper, J. Baggish and D. Parenti. *McNeil Consumer Healthcare, Fort Washington, PA.*

In some osteoarthritis (OA) studies where acetaminophen (APAP) was given over multiple days, low-level alanine aminotransferase (ALT) elevations have occasionally been reported. No comparable animal model of this phenomenon is available, so careful evaluation in clinical trials is necessary. We retrospectively analyzed ALT data from McNeil studies to assess the frequency and magnitude of ALT elevations and the patterns of onset and resolution while on the maximum recommended daily dose (MRDD) of APAP. Nine controlled OA trials were identified in which APAP alone was administered in at least 1 treatment group. Baseline and on-treatment ALT values were measured in 7 studies. Patients receiving the MRDD of APAP (3900 or 4000mg/day) for 4 weeks to up to 12 months were included. In the 7 studies, 892 patients had baseline transaminase activity at or below the upper limit of the reference range (ULRR), had an on-treatment ALT measurement, and received the MRDD of APAP. In this analysis, 733 (82.2%) of 892 patients never had an ALT above ULRR. Of the 892 patients, 159 (17.8%) had an ALT >ULRR, but only 42 (4.7%) had an on-treatment ALT >1.5X ULRR. A subsequent ALT value following the elevation was available for 29 of these 42 patients. Documented resolution or a decreasing ALT while continuing APAP treatment was noted for 27 patients (93.1%). No patient had an on-treatment ALT >3 times ULRR in conjunction with hyperbilirubinemia. An ALT above ULRR was not associated with an increased frequency of symptoms potentially related to a hepatic origin. No patient treated with the MRDD of APAP developed hepatotoxicity or hepatic failure. This analysis involving 892 patients treated with 3900–4000mg/day of APAP shows that low-level ALT elevations may occur but usually resolve or decrease with continued APAP treatment, are unaccompanied by signs or symptoms of liver injury, and appear to be clinically insignificant. The maximum recommended daily dose of APAP did not cause liver failure or dysfunction.

864 REGULATION OF THE MEVALONATE PATHWAY INFLUENCES PROLIFERATIVE EFFECTS OF WY-14,643 IN MOUSE LIVER.

A. M. Burns, C. G. Woods and I. Rusyn. *Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.*

Peroxisome proliferators (PP), such as WY-14,643, are a widely studied class of non-genotoxic rodent liver carcinogens. Presence of active peroxisome proliferator activated receptor (PPAR) α is required for the effects of PPs on cell proliferation,

induction of peroxisomes and liver carcinogenesis. In addition, a number of studies have suggested that PPAR α plays a central role in the synergistic effects of statins and PPs. Here, we explored the consequences of blocking the mevalonate pathway with lovastatin (20 mg/kg/day, i.g.) or increasing the availability of isoprenoids by adding exogenous farnesol (250 mg/kg/day, i.g.) on liver effects of WY-14,643 (WY, 0.1% diet for 3 days) in C57BL/6J male mice. Lovastatin alone had no appreciable effect on WY-induced liver enlargement, cell proliferation, induction of acyl CoA oxidase (ACO) activity or other liver-related endpoints with the exception of its anticipated effect on blood cholesterol levels. Interestingly, while farnesol had no effect on WY-induced ACO activity (i.e., peroxisomal proliferation), it blocked the increase in cell proliferation. In animals that received WY, lovastatin and farnesol, relative liver weight and ACO activity were significantly higher than in the WY-only group; however, cell proliferation rates in liver were lower than in the WY-only group, but higher than in the WY+farnesol-treated mice. Collectively, these results indicate that dysregulation of the mevalonate pathway affects the promotional ability of PPs in liver, but not their ability to cause induction of peroxisomes. Thus, the perturbations of lipid metabolism in liver that are caused by PPs may be linked to the ability of these agents to induce cell proliferation.

865 INCREASED ACYL COA OXIDASE ACTIVITY IN RATS AFTER FIVE CONSECUTIVE DAILY DOSES OF PERFLUOROBUTANESULFONATE, PERFLUOROHXANESULFONATE, AND PERFLUOROOCTANESULFONATE.

D. J. Ehresman¹, S. Chang¹, J. A. Bjork², J. A. Hart¹, P. H. Lieder¹, K. B. Wallace² and J. L. Burenhoff¹. ¹3M Company, St. Paul, MN and ²University of Minnesota, Duluth, MN.

Recent scientific and regulatory interest in perfluoroalkyl sulfonates (PFAS) led us to study liver peroxisome proliferation potential with a series of PFAS that included perfluorobutanesulfonate (PFBS), perfluorohexanesulfonate (PFHS), and perfluorooctanesulfonate (PFOS).

Male SD rats (N=6/group) were given 5 consecutive daily doses of either vehicle control (1% carboxymethyl cellulose), or K⁺ salts of PFBS (4.44 mmole/kg-d), PFHS (0.11 mmole/kg-d), or PFOS (0.56 mmole/kg-d). Rats were sacrificed via CO₂ 4 hrs after the final dose, immediately after which liver weight (LW) was obtained and sections of livers were: (1) taken for histology (formalin fixation, paraffin embedding, H&E); and (2) snap frozen for acyl CoA oxidase (ACOX) activity and determination of test material concentrations. Serum was also obtained. Concentrations of test materials in liver and sera were determined by LC/MS/MS. Body weight (BW) was measured daily and at term.

Only PFOS affected BW (mean loss of ~ 13% vs. control). PFBS and PFHS increased mean LW over control by 15 and 43%, respectively. Mean LW/BW % was increased over control with statistical significance with all 3 test compounds, with mean values of 4.2, 4.8, 5.8, and 4.8% for control, PFBS, PFHS, and PFOS, respectively. Compared to control, ACOX activity was also significantly increased by 271, 303, and 207% by PFBS, PFHS, and PFOS, respectively. For PFBS, PFHS, and PFOS, respectively, mean $\pm$ SD liver concentrations were 428 $\pm$ 102, 576 $\pm$ 54, and 563 $\pm$ 62 μ g/g, and mean $\pm$ SD serum concentrations were 268 $\pm$ 38, 409 $\pm$ 65, and 261 $\pm$ 19 μ g/mL. No changes suggestive of toxicity occurred on histomorphologic examination of fixed liver sections. With PFOS, liver cells were more eosinophilic, possibly due to less stored glycogen.

PFBS doses in mmole/kg $\geq$ 50 times higher than either PFOS or PFHS were required to produce similar increases in ACOX activity; however, liver concentrations achieved were similar.

866 PERFLUOROOCTANOIC ACID AND WY 14, 643 TREATMENT INDUCED PEROXISOME PROLIFERATION IN LIVERS OF WILD-TYPE BUT NOT PPAR α -NULL MICE.

C. Lau¹, B. D. Abbott¹ and D. C. Wolf². ¹Reproductive Toxicology Division, U.S. Environmental Protection Agency, Research Triangle Park, NC and ²Environmental Carcinogenesis Division, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Perfluorooctanoic acid (PFOA) is a fluorinated organic chemical widely used in consumer and industrial products. Its persistence in the environment and presence in humans and wildlife have raised considerable concerns. PFOA induces liver tumors in rodents, which is thought to be mediated by PPAR α activation. The extent of PPAR α 's contribution to the PFOA-induced liver tumors became questionable when liver enlargement, a response associated with PPAR α agonists, was detected in PPAR α -null mice exposed to PFOA. The current study evaluated hepatocyte proliferation, light microscopic and ultrastructural liver alterations in CD-1, 129S1 wildtype (WT) or PPAR α knock-out (KO) mice after 7 daily PFOA-NH₄⁺ (1, 3, or 10 mg/kg, p.o.) treatments, and the results were compared to mice treated with the

prototype PPAR α -agonist WY 14,643 (WY, 50 mg/kg). PFOA treatment induced a dose-dependent increase in hepatocyte hypertrophy and hepatocyte labeling index (LI) in WT mice. In these animals, liver alterations were similar between WY and 10 mg/kg PFOA. The ultrastructural alterations were essentially the same between WY- and PFOA-treated WT mice, and consisted of peroxisome proliferation. KO mice had a dose-dependent increase in hepatocyte vacuolation and increased LI only at the high dose of PFOA. In KO mice, only PFOA treatment produced ultrastructural changes, which consisted of accumulation of large clear vacuoles. These data suggest that PPAR α is required for WY- and PFOA-induced cellular alterations in the mouse liver. The origin and pathological significance of the vacuoles seen in the PFOA-treated KO mice are not clear and remain to be determined. This abstract does not necessarily reflect US EPA policy.

867 CHARACTERIZATION OF THE HEPATOMEGALY INDUCED BY AMMONIUM PERFLUOROOCTANOIC ACID (APFO) IN RATS.

C. R. Elcombe¹, B. M. Elcombe¹, J. R. Foster² and D. G. Farrar³. ¹CXR Biosciences Ltd., Dundee, United Kingdom, ²AstraZeneca, Macclesfield, United Kingdom and ³Ineoschlor, Runcorn, United Kingdom.

Ammonium perfluorooctanoic acid is non-genotoxic but has induced liver tumours when administered to rats. The objective of this study was to characterise the APFO-induced hepatomegaly previously reported in rats. APFO (300ppm, equivalent to a mean ingested dose of 19.57 $\pm$ 0.14 mg/Kg body weight) was administered in the diet to male Sprague Dawley rats for 1, 7 and 28 days. Animals were implanted with osmotic pumps containing bromodeoxyuridine (BrdU) 5 days before termination. Animals sacrificed after exposure to diet for 1 day were administered BrdU by subcutaneous injection 2 hours prior to sacrifice. Relative liver weights were increased to 150% of control values after 7 and 28 days. Hepatic peroxisomal β -oxidation (CN-insensitive palmitoyl CoA oxidation) was increased 2-, 6- and 10- fold after 1, 7 and 28 days respectively. Western blotting of liver microsomes demonstrated the marked induction of CYP2B2, CYP3A4 and CYP4A1 by APFO. Histopathology (H and E) of liver sections revealed that APFO caused dose-related hepatocellular glycogen loss, hypertrophy and hyperplasia. The nuclear incorporation of BrdU was determined as a measure of cell proliferation. APFO increased the hepatocellular labelling index (approximately 4-fold) 1 and 7 days after commencement of treatment. After 28 days the hepatocellular labelling index of livers from APFO-treated animals appeared to return to control levels. In conclusion, the administration of APFO to rats leads to hepatomegaly characterised by hypertrophy and hyperplasia. These data clearly demonstrate that APFO exhibits the prototypical properties of a peroxisome proliferator, but in addition possesses the properties of a mixed type of enzyme-inducing agent. The profile of CYP induction suggests that APFO interacts with multiple members of the of the nuclear hormone super family, particularly PPAR α , CAR and PXR.

These studies were funded by Plastics Europe.

868 NEUTROPHIL INTERACTION WITH THE HEMOSTATIC SYSTEM CONTRIBUTES TO LIVER INJURY IN RATS COTREATED WITH LIPOPOLYSACCHARIDE AND RANITIDINE.

X. Deng¹, J. Luyendyk², W. Zou³, E. Tukov², J. Lu¹, E. Malle⁴, P. Ganey² and R. Roth¹. ¹Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, ²Pharmacology and Toxicology, Michigan State University, East Lansing, MI, ³Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI and ⁴Institute of Molecular Biology and Biochemistry, Medical University Graz, Graz, Austria.

Cotreatment of rats with nontoxic doses of ranitidine (RAN) and lipopolysaccharide (LPS) causes liver injury in rats, and this drug-inflammation interaction might be a model for idiosyncratic adverse drug response in humans. Both neutrophils (PMNs) and the hemostatic system have been shown to be important in the liver injury. We tested the hypothesis that PMNs cause liver injury by interacting with the hemostatic system and producing subsequent hypoxia. In rats cotreated with LPS/RAN, PMN depletion by anti-PMN serum reduced fibrin deposition and hypoxia in the liver. PMN depletion also reduced active plasminogen activator inhibitor-1 (PAI-1), an important downregulator of the fibrinolytic system. This suggests that PMNs cause fibrin deposition by increasing PAI-1. PMN activation as measured by HOCl-modified protein staining occurred in the livers of LPS/RAN-cotreated rats. Antiserum against PMN adhesion molecule CD18 protected against LPS/RAN-induced liver injury. Since CD18 is important for PMN transmigration and activation, this suggests that PMN activation is required for the liver injury. The selective upregulation of the chemokine MIP-2 after LPS/RAN treatment raises the possibility that chemokines participate in the PMN response. In summary, PMNs are activated in LPS/RAN-cotreated rats and appear to participate in the liver injury in part by contributing to hemostasis. (Supported by NIH grant DK061315).

869 SIGNIFICANCE OF CARBONYL GROUPS IN 3-(3,5-DICHLOROPHENYL)-2,4-THIAZOLIDINEDIONE (DCPT)-INDUCED HEPATOTOXICITY IN RATS.

N. N. Patel, C. M. Crincoli, R. T. Chao and P. J. Harvison. *Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA.*

DCPT, which contains a 2,4-thiazolidinedione (TZD) ring, is hepatotoxic in Fischer 344 (F344) rats. A TZD ring is also found in the glitazones, which are insulin-sensitizing drugs used in the treatment of type II diabetes. These drugs have been associated with liver damage in some patients. To demonstrate that DCPT may be useful for investigating the role of the TZD ring in hepatotoxicity, we have been conducting studies with TZD ring-modified DCPT analogues. The importance of the carbonyl group in the 4-position of the TZD ring was therefore investigated by synthesizing and testing 3-(3,5-dichlorophenyl)-2-thiazolidinone (2-DCTD) in male F344 rats at 0.2, 0.4, 0.6 and 1.0 mmol/kg doses. 2-DCTD retains the carbonyl group in the 2-position between the sulfur and imide nitrogen atoms. Other rats received DCPT (0.6 mmol/kg) or corn oil (4 ml/kg, vehicle controls). Liver and kidney function and morphology were assessed 24 h post-dosing. Compared to the corn oil controls, serum alanine aminotransferase (ALT) levels were unaltered by 2-DCTD. In contrast, DCPT produced significant ALT elevations. Blood urea nitrogen levels were not altered in any of the treatment groups. Histological results from 2-DCTD-treated rats showed no alterations in hepatic morphology at any of the doses examined, compared to the corn oil controls. However, pockets of liver necrosis were observed in liver sections from the DCPT-treated rats. None of the treatments produced significant changes in kidney morphology. Our results suggest that replacement of the TZD ring of DCPT with the 2-thiazolidinone ring of 2-DCTD abolishes hepatotoxicity. This is consistent with our previous finding that 3-(3,5-dichlorophenyl)-4-thiazolidinone (4-DCTD), an isomer of 2-DCTD, was also non-toxic. We therefore conclude that DCPT-induced hepatotoxicity is critically dependent on the presence of both carbonyl groups in the TZD ring. Furthermore, metabolism of 2-DCTD to DCPT does not occur in rat liver. Supported by PHS grant ES012499.

870 EFFECTS OF LXR AGONIST (TO901317) ON GENE EXPRESSIONS AND LIPID DEPOSITION IN HUMAN HEPATOCYTES OF CHIMERIC MOUSE LIVER.

A. Tachibana^{1,2}, C. Tateno^{1,3}, M. Kataoka¹, R. Utoh¹, C. Yamasaki¹ and K. Yoshizato^{1,3,4}. ¹*Yoshizato Project, Hiroshima Prefectural Institute of Industrial Science and Technology, Higashihiroshima, Japan,* ²*PhoenixBio, Co. Ltd., Higashihiroshima, Japan,* ³*Hiroshima University Liver Project Research Center, Hiroshima, Japan* and ⁴*Department of Biological Science, Graduate School of Science, Hiroshima University, Higashihiroshima, Japan.* Sponsor: T. Miyaoka.

Chimeric mice were produced by transplanting human hepatocytes into immunodeficient and liver-diseased mice [albumin enhancer/promoter-driven urokinase-type plasminogen activator-transgenic/SCID (uPA/SCID) mice]. Because the humanized liver expressed human specific cytochrome P450 genes at levels comparable to human liver, these animals are useful to predict metabolisms of chemicals and drugs in human liver *in vivo*. A variety of drugs targeted for nuclear receptors have been and will be designed. The microarray analysis of human hepatocytes isolated from chimeric liver showed that most of human nuclear receptors were expressed in the chimeric mouse liver at similar levels to human liver.

In this study, the responsiveness of human nuclear receptors in the chimeric mouse liver to TO901317, a well-characterized LXR agonist, was investigated. TO901317 is also known to be a strong liver steatotic inducer in rodents. The chimeric mice were made by transplanting cryopreserved human hepatocytes (7.5×10^5 cells) from a 4-year-old-Caucasian girl into the liver of uPA/SCID mice. These mice were orally administered with TO901317 for 3 days at 50 mg/kg body weight/day and sacrificed at 24 hours after the last injection. Liver cryosections were prepared and treated with Oil red O for lipid staining. mRNA expression levels were determined by real time RT-PCR using total RNAs isolated from the liver tissues as templates. TO901317 induced severe steatosis in human hepatocytes in the mice and elevated the expression of the targeted genes such as ABCG1 and FASN. In conclusion, the chimeric mouse was proved to be a useful animal model to predict effects of chemicals and drugs targeted for nuclear receptors on gene expressions and toxicity in human liver *in vivo*.

871 EFFECT OF SUBCHRONIC EXPOSURE ON TOXICITY OF PERCHLOROETHYLENE IN SWISS WEBSTER MICE.

B. K. Philip¹, J. R. Latendresse², M. Mumtaz³ and H. M. Mehendale¹. ¹*Toxicology, University of Louisiana, Monroe, LA,* ²*Toxicologic Pathology Associates, Jefferson, AR* and ³*ATSDR, Chamblee, GA.*

The aim was to study the subchronic toxicity of perchloroethylene (Perc) by measuring injury and repair in liver and kidney in relation to disposition of Perc and its major metabolites. Male SW mice (25-29 g) were given three dose levels of Perc (150, 500, and 1000 mg/kg/d) via aqueous gavage for 30 days. Tissue injury was

measured during the dosing regimen (0, 1, 7, 14, and 30 d) and over a time course of 24 to 96 h after the last dose (30 d). Perc produced significant liver injury (ALT) after single day exposure to all three doses. Liver injury was mild and regressed following repeated exposures, except after the high dose showing sustained injury until 7 d of exposure. Liver tissue repair peaked on 7 d, with all three doses preventing progression of injury. While hepatic tissue repair was sustained after medium and high doses for 14 d, it regressed to basal levels with low dose exposure. Hepatic CYP2E1 expression and activity were unchanged indicating unaltered bioactivation after subchronic Perc exposure. Hepatic CYP4A expression was transiently higher after d 7 with the high dose, but was unchanged at later time points. Kidney function was unaffected as evidenced by unchanged BUN levels during the entire time course and lack of kidney injury was confirmed by histopathology. Kidney tissue repair, as evidenced by replicative DNA synthesis and PCNA immunohistochemistry, was moderate. TCA was the major metabolite detected in blood, liver, and kidney. Traces of DCA were also detected in blood at initial time points after single day exposure. AUC/dose for Perc was significantly higher and for TCA was lower in liver and kidney, following repeated exposure indicating saturation of Perc metabolism. These data indicate that subchronic Perc exposure via aqueous gavage does not induce nephrotoxicity or persistent hepatotoxicity in SW mice suggesting adaptation (ATSDR U61/ATD 681482).

872 PBDE CONGENERS ARE PXR ACTIVATORS.

E. K. Pacyniak¹, X. Cheng¹, M. Sanders², M. Cunningham², K. Crofton³, K. Kramer⁴, C. D. Klaassen¹ and G. L. Guo¹. ¹*Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS,* ²*Chemical Toxicology Group, National Institute of Environmental Health Sciences, Research Triangle Park, NC,* ³*National Health and Environmental Effects Laboratory, Environmental Protection Agency, Research Triangle Park, NC* and ⁴*Business Development, Puracyp, Inc., Carlsbad, CA.*

Polybrominated diphenyl ether (PBDE) congeners are used as flame retardants and they are universally present in the environment. Researchers have detected an exponential increase of PBDE congeners in the US population over the last two decades, especially with unexpected high levels in breast milk from women. We are most commonly exposed to three PBDE congeners, BDE47 (tetraBDE), 99 (pentaBDE), and 209 (decaBDE). PBDE congeners induce cytochrome P450s (CYPs), disrupt thyroid hormone homeostasis, act as neurotoxins, and are labeled as potential carcinogens. We have little understanding of the mechanism by which PBDE congeners exert their toxicities. Our current research goal is to clarify the mechanism by which PBDE congeners induce P450 enzymes. We hypothesize that PBDEs are activators for xenobiotic nuclear receptor, pregnane X receptor (PXR), a ligand-activated nuclear receptor that mediates the induction of P450 enzymes by many xenobiotics. Treatment with PBDE congeners, BDE47, 99, and 209 induced cyp3a11 and cyp2b10 in a dose-dependent manner in C57BL6 mice, which was not shown in the PXR knockout mice. In addition, BDE47, 99, and 209 activated both mouse and human PXRs as revealed by the luciferase reporter gene assay. These data strongly suggest that PBDE congeners are activators for xenobiotic nuclear receptors, PXR.

873 THE EFFECTS OF T-2 TOXIN ON HEPATIC DRUG METABOLIZING ENZYMES IN PIGLETS.

D. Kesu¹, Y. Konishi², J. Yu³, P. Tulayakul¹ and S. Kumagai¹. ¹*Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan,* ²*Division of Microbiology, National Institute of Health Science, Tokyo, Japan,* ³*Graduate School of Medicine, The University of Tokyo, Tokyo, Japan* and ⁴*The University of Tokyo, Tokyo, Japan.*

T-2 toxin is one of trichothecenes, which are a structurally diverse group of toxic secondary metabolites produced by *Fusarium* and related species of fungi, which usually contaminate cereal grains throughout the world. Although the pig is increasingly being used in pharmacological and toxicological studies, there is not enough information about the effects of T-2 toxin on drug-metabolizing enzymes in pigs. The purpose of this study is to investigate the effects of T-2 toxin on the activities of hepatic Phase I and Phase II metabolizing enzymes in piglet liver. Piglets were administered 0.3 mg T-2 toxin/Kg Bwt dissolved in DMSO by single subcutaneous (s.c.) injection. Control animals received only vehicle (DMSO). The activities of Phase I and Phase II enzymes were determined at 24h and 48h after the last s.c. injection. The activities of cytochrome P450 (CYP) 1A2 and 2E1 increased slightly at 24h and 48h ($P < 0.05$). The CYP3A4 activity increased at 24h ($P < 0.01$), and tended to decrease at 48h, but not significantly ($P > 0.05$). The glutathione S-transferase activity toward cumene hydroperoxide increased slightly at 24h ($P < 0.05$), but decreased slightly at 48h ($P < 0.05$). No significant changes were observed in the glutathione S-transferase activity toward CDNB either at 24h or 48h. Western blot analyses of the liver fractions revealed increased levels of CYP1A2, 2E1, 3A4, GST alpha and GST M1-1 at 24h, and that of CYP2E1 at 48h. RT-PCR showed changes of the mRNA expression of those 5 kinds of enzymes in liver. The results suggest that T-2 toxin causes modulation of Phase I and Phase II drug-metabolizing enzymes in piglets.

874 COX-2 INHIBITION AGGRAVATES sPLA₂-MEDIATED PROGRESSION OF ACUTE LIVER INJURY.

V. S. Bhav¹, S. Donthamsetty¹, J. Latendresse² and H. M. Mehendale¹. ¹ULM, Monroe, LA and ²NCTR, Jefferson, AR.

Previous studies have shown calpain's involvement in CCl₄- and acetaminophen-induced progression of acute liver injury (PLI). Our present work identifies secretory phospholipase A₂ (sPLA₂) as another mediator of PLI. Upon toxicant challenge, perinecrotic cells secrete large amounts of sPLA₂, which along with COX-2 rids the tissue of necrotic cell debris. Action of sPLA₂ releases arachidonic acid, a precursor for protective prostaglandins (PGE₂ and PGF₂). Hence, co-localization of sufficient COX-2 with sPLA₂ is critical in tissue recovery. The objective of the present work was to test the hypothesis that sPLA₂ spreads hepatocyte injury through hydrolysis of plasma membrane phospholipids in the absence of sufficient COX-2. Two groups of male SD rats were administered two different doses of CCl₄ (2 and 3 ml/kg, ip). Liver injury was assessed by plasma ALT and histopathology. Plasma and liver sPLA₂ and COX-2 activities in rats challenged with a non lethal dose of CCl₄ (2 ml/kg) rose with liver injury. Immunohistochemical co-localization of these proteins was noted in the perinecrotic areas, suggesting a protective role of sPLA₂ when co-localized with COX-2. In contrast, the lethal dose (3 ml/kg) treated rats exhibited very high sPLA₂ activity, but minimal COX-2 activity, leading to progression of injury, liver failure, and 70% mortality between 12 to 36 h. Immunohistochemistry showed high staining for sPLA₂, but minimal COX-2 staining throughout the time course suggesting a destructive role of sPLA₂ in the absence of sufficient COX-2. Time- and dose-dependent increase in cell injury and death (LDH and MTT) of freshly isolated hepatocytes when incubated with sPLA₂ suggested sPLA₂'s ability to damage hepatocytes and contribute to PLI when present extracellularly. COX-2 inhibition using NS398 in Fisher rats challenged with CCl₄ (1 ml/kg) led to 50% increase in mortality due to progression of liver injury. These results support sPLA₂'s destructive role in PLI by hydrolysis of plasma membrane phospholipids of perinecrotic hepatocytes unless mitigated by simultaneous presence of sufficient COX-2.

875 DRUG CHALLENGES TO TEST THE FUNCTIONAL INTEGRITY OF NEURAL SYSTEMS INVOLVED WITH MEMORY AFTER EARLY DIAZINON EXPOSURE IN RATS.

O. Timofeeva¹, C. Roegge¹, F. J. Seidler², T. A. Slotkin^{2,1} and E. D. Levin^{1,2}.

¹Department of Psychiatry, Duke University Med. Ctr, Durham, NC and

²Department of Pharmacology, Duke University Med. Ctr, Durham, NC.

Developmental organophosphate pesticide exposure can cause persisting effects on cognitive function. We have found that developmental exposure of rats to chlorpyrifos can cause persisting memory impairment. Drug challenges helped elucidate the neural systems involved in the impairment. Rats with a history of chlorpyrifos exposure were under-responsive to the amnesic effect of scopolamine, suggesting that they were not relying on muscarinic acetylcholine neural systems to perform the memory task. Chlorpyrifos-exposed rats were hyper-responsive to amnesic effects of ketanserin, a serotonin type2 receptor antagonist, suggesting that instead they had increased reliance on these serotonergic systems for memory function. In the current study, rats were exposed to diazinon during early postnatal development (0, 0.5 or 2 mg/kg/day, PND 1-4). When trained in adulthood on the radial-arm maze, the 0.5 mg/kg diazinon group showed a significant ($p < 0.025$) impairment of working memory function. This dose group was hyper-responsive to scopolamine showing a significantly ($p < 0.01$) greater amnesic effect with a low scopolamine dose (0.04 mg/kg), which in unexposed animals was subthreshold for causing impairment. This suggested that these diazinon-exposed rats had less functional reserve in their muscarinic acetylcholine systems than controls. No differential effect of ketanserin was seen. An inverted dose-effect function in response to the GABA-A agonist muscimol was seen in the diazinon 2 mg/kg/day exposure group relative to control, demonstrating differential involvement of GABA systems in memory after early diazinon exposure. Studies with the NMDA glutamate antagonist dizocilpine are being conducted. Using selective ligands for transmitter systems involved in cognitive function can help determine how neural systems are functionally disrupted by toxicant exposure.

(Supported by the Duke University Superfund Basic Research Center ES010356).

876 MINNOW BIOGENIC AMINE TRANSPORTER BINDING AND RESPONSE TO PESTICIDES AND PHARMACEUTICALS.

G. G. Gould¹, B. W. Brooks² and A. Frazer¹. ¹Pharmacology, University of Texas Health Science Center at San Antonio, San Antonio, TX and ²Environmental Studies, Baylor University, Waco, TX.

Model systems are needed to assess neurotoxicological effects of chronic pesticide exposures. Mammalian serotonin (SERT) and norepinephrine transporters (NET) are target sites for antidepressants, and are also affected by pesticide exposure.

Following chronic administration of certain antidepressants to rats, SERT or NET binding sites are reduced. Similarly, exposure to some pesticides causes SERT binding site reductions. Our research goal is to determine if minnow SERT and NET respond to pharmaceuticals and pesticides comparably to mammalian SERT and NET. If fish transporters are sensitive to chronic, low-dose exposures, then their SERT and NET can be used to model and monitor exposures. We examined central SERT and NET binding sites of the golden shiner minnow, and compared their pharmacological profile to those of rats. Homogenate binding with the radioligand [3H] citalopram indicated that the golden shiner SERT has a KD of 7 ± 3 nM and a Bmax of 226 ± 46 fmol/mg protein. These values are similar to those of rat SERT (KD 1.4 ± 0.1 nM and Bmax 240 ± 48 fmol/mg protein). The minnow NET (measured using [3H] nisoxetine) has a KD of 12 ± 5 nM and a Bmax 187 ± 49 fmol/mg protein, comparable to rat NET (KD 5 ± 2 nM and Bmax 93 ± 8 fmol/mg protein). Minnow SERT and NET binding is displaceable by antidepressants. We also examined brain SERT binding properties of fathead minnow and found them to be similar to golden shiner SERT. Finally, we exposed zebrafish to the SSRI sertraline at 1 or 10 ug/meal, or to the organophosphate chlorpyrifos at 10 ug/meal, for 21 days with 2 days of physiological washout. After either treatment, SERT binding in brain homogenates was reduced by 50% ($N=3-6$, $p < 0.05$). In summary, minnow SERT and NET express lower affinity for ligands and antidepressants than rats. However, since magnitudes of affinity are similar, and because SERT binding declines after chronic sertraline or chlorpyrifos administration, minnow biogenic amine transporters may be useful indicators of exposure.

877 ACUTE DELIBERATE ORGANOPHOSPHATE (COUMAPHOS) POISONING WITH INTERMEDIATE SYNDROME IN A ONE YEAR OLD CHILD.

W. A. Kiat. Toxicology, St. Luke's Medical Center, Quezon City, Philippines. Sponsor: I. Makalinao.

Objective: To report a case of acute organophosphate poisoning in a one year old child and development of intermediate syndrome in just eight hours after exposure. Case Report: This is a case of a one year old child who came in the emergency room because of sudden onset of difficulty of breathing, cyanosis, excessive oral secretions, diarrhea and weakness noted three hours earlier after ingesting allegedly contaminated powdered milk formula. Vital signs showed a blood pressure of 90/60, cardiac rate of 112 per minute, respiratory rate of 12 cycles per minute and axillary temperature of 35.4 degrees Celsius. Arterial blood gas analysis showed respiratory acidosis. Endotracheal intubation was immediately done and was hooked on mechanical ventilation. The toxidrome of the patient is compatible with acute cholinergic excess; hence a trial dose of atropine was given. Eight hours later, neurological examination showed absence of deep tendon reflexes, no spontaneous respiration, no response to pain, flaccid muscle tone, no neck rigidity and lateralizing signs but with spontaneous eye opening. Referral to a Pediatric Neurologist ruled out the possibility of CNS infection or trauma. Atropine was given at 0.02 milligrams per kilogram intravenously until full atropinization was achieved. Twenty-four hours later, patient was noted to have response to painful stimuli and spontaneous respiration. Atropine was continued until the patient regained full consciousness and restoration of full motor and sensory function. Test was done on the allegedly contaminated milk using GC-MS, positive for Coumaphos. The patient was extubated on the fourth hospital day. The rest of hospital stay was unremarkable and was discharge after seven days. Atropine was continued for six weeks. Conclusion: Intermediate syndrome usually develops within 48-96 hours after acute cholinergic crisis due to prolonged inhibition of cholinesterases(1). There is probably a difference with regards to time of occurrence of Intermediate Syndrome or maybe a difference in Acetylcholinesterase function between a very young child and adult.

878 ELUCIDATION OF THE ROLE OF ADULT DETOXICATION ENZYMES IN THE AGE-RELATED TOXICITY DIFFERENCES OF ORGANOPHOSPHATE INSECTICIDES.

V. C. Beasley¹, E. C. Meek¹, H. W. Chambers², J. E. Chambers¹ and R. L. Carr¹. ¹Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS and ²Department of Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS.

It is well documented that organophosphate (OP) insecticides are more toxic to juvenile animals than they are to adults. While it is common to refer to the enhanced vulnerability of juveniles to OP insecticides, it is may be more appropriate to refer to the reduced vulnerability of adults which is mediated primarily by the higher mature levels of detoxication enzymes such as the carboxylesterases and non-target cholinesterases. It is thought that if these enzymes were not present in the adult, the toxicity level of an OP would be similar in adults and juveniles. To test this, adult rats and juvenile rats at postnatal day 1 (PND1) and PND12 were treated with similar dosages of the prototypical OP compound paraoxon (P=O) and brain

cholinesterase (ChE) inhibition was determined. Additional adult animals were then pre-treated with specific inhibitors of the carboxylesterases and non-target cholinesterases prior to exposure to the same dosages of P=O and brain ChE inhibition was compared to the inhibition obtained without the pre-treatment. In adult animals, 0.25, 0.3, and 0.75 mg/kg resulted in 18%, 41%, and 89% inhibition, respectively, while at PND12, 0.25 and 0.3 mg/kg resulted in 90% and 92% inhibition respectively. The level of inhibition at PND1 was similar to PND12 with 0.25 yielding 96% inhibition. However, when the activity of the carboxylesterases and non-target cholinesterases was eliminated in adult animals prior to treatment with 0.25 mg/kg, the level of ChE inhibition increased to 86% which is comparable to that observed in the juvenile animals. These data suggest that the greater vulnerability of juvenile animals to OP insecticides is due to, for the most part, the lack of protective esterases which are present in the adult. (Supported by NIH R01 ES011287).

879 *IN VIVO* STRIATAL ACETYLCHOLINE ACCUMULATION IN ADULT AND AGED RATS FOLLOWING PARATHION EXPOSURE.

S. Karanth, J. Liu, A. Ray and C. N. Pope. *Physiological Sciences, Oklahoma State University, Stillwater, OK.*

Aged rats are more sensitive than adults to the acute toxicity of the organophosphorus insecticide parathion. We studied the effects of parathion on striatal cholinesterase activity and acetylcholine accumulation in 3- and 18-month old Sprague-Dawley rats. Adult and aged rats were treated with either vehicle (peanut oil, 2 ml/kg) or equitoxic dosages of parathion (adult, 27 mg/kg, sc; aged, 9 mg/kg, sc). Body weight, functional signs of toxicity, and motor activity were recorded for seven days. On day 3 and 7 after parathion, striatal microdialysates were collected and rats were then sacrificed for biochemical measurements. Both age groups showed severe signs of cholinergic toxicity (involuntary movements and SLUD signs) with peak effect 3-4 days after parathion. In general, there was an increase in diurnal (1000-1900 hrs) motor activity (ambulation and rearing) following parathion while nocturnal (1900-0700 hrs) activity was significantly reduced in both age groups. Similar extensive striatal cholinesterase inhibition (91-95 %) was noted in both age-groups at both time-points. In contrast, age-related differences in acetylcholine accumulation were noted, with aged rats showing about 2-fold lower extracellular acetylcholine levels compared to adult rats. When neostigmine (1 μ M) was subsequently infused to completely block local acetylcholinesterase activity, no age-related differences in acetylcholine accumulation were noted. Comparison of *in vitro* striatal acetylcholine synthesis in synaptosomes from adult and aged rats also suggested no age-related differences in synthetic capacity. The results suggest that equitoxic dosages of parathion can cause differential effects on acetylcholine levels in adult and aged rats and that the higher sensitivity to parathion noted in aged rats is not related to greater acetylcholine accumulation. Supported by NIEHS R01ES009119 and Oklahoma State University Board of Regents.

880 AGE-RELATED DIFFERENCES IN DETOXICATION AND ACUTE TOXICITY LEVELS OF TWO ORGANOPHOSPHATES IN RATS.

E. C. Meek¹, V. Beasley¹, R. L. Carr¹, H. W. Chambers², J. Wagner¹ and J. E. Chambers¹. ¹Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS and ²Department of Entomology, Mississippi State University, Mississippi State, MS.

The organophosphorus (OP) insecticides, chlorpyrifos (CPS) and methyl parathion (MPS), which cause acetylcholinesterase (AChE) inhibition, display greater acute toxicity in juveniles than in adults. The roles of carboxylesterases (CbxE) in stoichiometric detoxication and A-esterases (paraoxonases) in catalytic detoxication were investigated in liver and serum from adult (70 days of age) and juvenile (1 and 12 days of age) rats. The detoxication ability of both compounds by both esterases increased with age. CbxE were extremely sensitive (IC₅₀) to inhibition by chlorpyrifos-oxon (CPO $\leq$ 1nM) and much less sensitive to methyl paraoxon (MPO $\geq$ 300nM). CPO, but not MPO, was readily detoxified by A-esterases. Therefore, detoxication potential for CPO (both CbxE and A-esterases) was much greater than for MPO (neither esterase). To validate *in vitro* results, rats of the same 3 ages were exposed IP to each of the oxons to determine the dosages required to inhibit brain AChE at 3 levels (80-90%, 40-50%, and 10-20%). Subsequently, rats of the same 3 ages were exposed IP to each of the parent OPs to determine the dosages required to inhibit brain AChE at same 3 levels. The dosages that resulted in 40-50% inhibition were much higher for the parent insecticides than the oxons for both compounds. There was a much greater differential between the dosages yielding the same level of brain AChE inhibition between adults and juveniles for CPO than MPO, and for CPS than MPS. For example, the fold-differences in dosages yielding 40-50% inhibition between the ages were: CPO, 6; MPO, 1; CPS, 7; and MPS, 2. These results support the concept that the greater detoxication of OPs in the adult is an important factor in the greater tolerance of OPs by adults, and that

the extent of esterase-mediated detoxication along with differences in P450 metabolism among compounds is a critical determinant in toxicity levels. (Supported by NIH R01 ES11287).

881 SARIN CAUSES DIFFERENTIAL REGULATION OF mRNA EXPRESSION OF MUSCARINIC RECEPTOR SUBTYPES 24 HRS POST TREATMENT IN RATS.

T. V. Damodaran^{1,2}, M. A. Bilski¹ and M. B. Abou-Donia¹. ¹Department of Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC and ²Center for Human Genetics, Duke University Medical Center, Durham, NC.

Sarin, isopropyl methyl phosphonofluoridate, is an organophosphate ester neurotoxin that inhibits acetylcholinesterase (AChE) in the central and peripheral nervous systems, and has been implicated in the Gulf War Syndrome. Recently, our published global gene expression data from sarin treated rats at different time points (both early and late) had shown the important role of muscarinic receptors and their down-stream molecules in exposure related abnormal clinical manifestations. In order to further investigate the role of different members of muscarinic receptor family members, we studied the expression pattern of m1, m2, m3, m4, and m5 muscarinic receptor subtypes in different regions of the rat brain exposed to 50 μ g / kg / ml dose of sarin at 24 hr post treatment. Semi-Quantitative reverse transcriptase polymerase chain reaction (RT-PCR) was used to study the mRNA expression levels. Both β -actin and 18S RNA levels were also estimated. 18S RNA levels were used for normalization, as β -actin levels were induced to 1.60 fold in cerebellum and midbrain, while 18S RNA levels remained unchanged in all regions. Differential regulation of mRNA expression levels was noted for m1, m2, m3, m4, and m5. In cerebellum, transcript levels of m3, m4, and m5 were decreased by 2.03, 1.70, and 1.20 fold respectively. In midbrain, transcript levels of m3, m4 and m5 were increased by 3.53, 1.45 and 2.09 fold respectively. The spatial differences in the expression of different members of the muscarinic receptor family members further support the complexity of the toxicity induced by sarin exposure, which may involve both cholinergic and non-cholinergic pathways in a region-specific manner. This work was supported by DAMD-17-98-8027 grant

882 EFFECTS OF SUBCHRONIC, LOW-LEVEL CHLORPYRIPHOS EXPOSURE ON FAST AXONAL TRANSPORT.

D. W. Sickles, D. Gearhart, M. Middlemore and A. Terry. *Medical College of Georgia, Augusta, GA.*

Exposure to chlorpyrifos (CPF) compromises spatial learning and reduces presynaptic cholinergic markers. One possible mechanism for producing these effects is reduced fast transport of vital macromolecules. To determine if transport compromise is correlated with these changes, adult, male rats were given subcutaneous injections of CPF @ 18 mg/kg/d in peanut oil every other day for 30 days (n=5), or the same treatment plus 14 days of no injections (washout; n=5), or single injections @ 2, 12, 24 or 48 hrs (n=3/group) before sacrifice. Controls received equal volume of peanut oil only. The motor nerve to the quadriceps femoris was removed under anesthesia and dissected down to single fascicles for visualization of vesicle transport in single axons using video-enhanced DIC microscopy. The flux of vesicles in a standard volume of axoplasm over ten minutes of time was determined by an observer blind to experimental group. Thirty days of CPF exposure reduced fast anterograde transport (faAXT) from 428 $\pm$ 15 vesicles to 333 $\pm$ 27 and retrograde transport (rAXT) from 209 $\pm$ 19 to 171 $\pm$ 25, a 22 and 18% reduction, respectively. After 14 days of washout, the faAXT remained reduced by 20% from control while the rAXT was reduced by 28%. Single injections of CPF had no effect at 2 hours but did show a significant and progressive effect with time. At 12 to 24 hours, faAXT was reduced 10 to 20% from control, respectively and rAXT was reduced 7.5 to 32% from control, respectively. Forty-eight hours after a single injection the quantity of faAXT was reduced 14.5% from control while rAXT was still reduced 25.8%. We conclude that low levels of CPF exposure produces a significant reduction in both faAXT and rAXT. The lipid soluble CPF takes longer to produce a reduction compared to other water soluble toxicants observed to inhibit transport. The effect is more prolonged, consistent with continual release of CPF from lipid stores. Inhibition of fast transport may be responsible for altered delivery of presynaptic cholinergic markers and compromised spatial memory. Supported by R01ES012241 and R01ES011223.

883 INHIBITION OF GROWTH OF NEURAL PROCESSES OF PRIMARY RAT DORSAL ROOT GANGLIA (DRG) CULTURES AS A MODEL FOR PROMOTION OF AXONOPATHIES.

A. Moretto, A. Nicolli and M. Lotti. *University of Padova, Padova, Italy.*

Certain esterase inhibitors, such as phenylmethane sulfonyl fluoride (PMSF), cause clinical and morphological exacerbation (promotion) of toxic or traumatic axonal lesions. The hypothesis was made that promotion was due to interference with the

mechanisms of axonal repair/regeneration. Degeneration of neural processes of cultured rat DRGs caused by neuropathic organophosphates (OP) has been already described as possible model for studying promotion. Since the dissection of the DRGs is a traumatic axonal lesion, we tested this lesion as a possible model for studying promotion as defined by inhibition of process outgrowth. Desheathed DRGs from 13-16 day old rats were dissected and plated on poly-L-lysine pre-coated dishes. Since in untreated control DRGs processes appeared at about 48 hours after plating, inhibitors were incubated at 24 hours. PMSF (0.5-1.5 mM) caused a dose dependent impairment of process outgrowth as determined 4 and 6 days after plating. Control inhibitors were the neuropathic non-promoter dibutylchlorovinyl phosphate (DBDCVP; 0.01 or 0.1 mM), and paraoxon (0.01 or 0.1 mM) that is neither neuropathic nor promoter, but is a potent inhibitor of acetylcholinesterase (AChE). DBDCVP caused significant reduction in the number and length of the processes at 0.1 mM, whereas at 0.01 mM the number of processes was comparable to controls. However, their morphological characteristics was different from control because at day 6 a beading-like degeneration was observed as already described with another neuropathic OP. Paraoxon also caused significant inhibition at 0.1 mM, possibly associated with cell death. At 0.01 mM no effect on the number of processes was observed and the processes were morphologically undistinguishable from controls. It should be noted that DBDCVP concentration was more than 2 orders of magnitude higher than that necessary to critically inhibit the target of the neuropathy (i.e. neuropathy target esterase), and that paraoxon concentrations were more than 2 orders of magnitude higher than those required to completely inhibit AChE.

884 LONG-TERM EXPOSURE TO TWO NEUROTOXIC ORGANOPHOSPHATES AND CORTICOSTERONE IN RATS ALTERS SURAL NERVE G RATIO.

B. S. Jortner, S. K. Hancock, J. Hinckley, L. Williams, E. Binder, J. Carter and M. Ehrlich. *Laboratory for Neurotoxicity Studies, Virginia Tech, Blacksburg, VA.*

We conducted an investigation of the effects of long-term, multiple dose exposure to two neurotoxic organophosphates in rats, in the presence of a chronic stress model. Details of the experimental design have been published (Jortner et al., *Toxicol. Pathol.* 33:378). In summary, young adult male Long-Evans rats were administered two 60 mg/kg subcutaneous chlorpyrifos exposures and/or 14 tri-orthotolyl phosphate (TOTP) gavage doses at 75, 150 or 300 mg/kg, over a 63-day period. Corticosterone was given at 400 micrograms/ml in the drinking water (to model chronic stress) for 90 days. Sacrifice was on days 63 and 90. Portions of this study already reported (Jortner et al.) showed organophosphate induced delayed neuropathy manifest by TOTP dose-related diminished activity of brain neurotoxic esterase on day 63, and distal gracile fasciculus and peripheral nerve Wallerian-like myelinated fiber degeneration. The lesions progressed in the 63 to 90 day period, although exposure to the organophosphates had ceased. Because of spinal somatosensory fasciculus gracilis involvement, we extended studies to sural nerve peripheral sensory myelinated fibers. Lesions were most evident on day 90, such as axonopathy progressing to fiber degeneration. Neurons in dorsal root ganglia, a source of gracile and sural fibers, showed chromatolytic changes. Morphometric alterations were seen in residual sural nerve fibers, with the g ratio (axon diameter/fiber diameter) most sensitive in differentiating treatment effects. This was reduced in rats receiving 300 mg/kg TOTP dosages plus chlorpyrifos and/or corticosterone ($p < 0.05$, ANOVA followed by LSD, $n = 3-6/\text{group}$), most marked in rats dosed with all three compounds. G ratios of rats dosed with TOTP alone were not different ($p > 0.05$) from the controls. In our dosing regimens, combining TOTP with chlorpyrifos and/or corticosterone diminished the g ratio in the sural nerve, likely related to axonal atrophy. Supported by USAMRMC DAMD17-99-1-9489.

885 MULTIPLE NEUROTRANSMITTER RECEPTORS ARE INVOLVED IN THE CHANGES IN BDNF GENE EXPRESSION INDUCED IN HIPPOCAMPAL ORGANOTYPIC SLICES EXPOSED TO CHLORPYRIFOS AND CHLORPYRIFOS-OXON.

R. L. Carr and A. M. Betancourt. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

The organophosphate (OP) insecticides exert their toxicity by the inhibition of acetylcholinesterase leading to the accumulation of the acetylcholine which causes overstimulation of the cholinergic receptors. We have reported that both in vivo and in vitro exposure to chlorpyrifos (CPS) leads to increased expression of the brain derived neurotrophic factor (BDNF). To further investigate the basis for this alteration of gene expression, hippocampal organotypic slice cultures were prepared, maintained in culture for 14 days, incubated with either 10 μM CPS or 1 μM chlorpyrifos-oxon (CPO) for 32 hrs, harvested, and mRNA levels were determined. The concentrations of CPS and CPO produced 63% and 73% inhibition of cholinesterase in the slice cultures but did not alter their viability. Similar to pre-

vious studies both CPS and CPO induced BDNF expression. Inclusion of the muscarinic receptor antagonist atropine (5 μM) in the incubation eliminated the induction of BDNF expression. However, inclusion of the NMDA receptor antagonist MK-801 (20 μM) also eliminated the induction of BDNF expression. These data suggest that the observed increased BDNF gene expression involves indirect activation of glutamatergic receptors which occurs as a result of OP-induced muscarinic receptor activation. Direct receptor activation can induce BDNF expression as it displays an immediate early gene nature. However, increased reactive oxygen species (ROS) can also increase BDNF expression and CPS has been shown to induce ROS both in vivo and in vitro in cell culture. In our exposure paradigm, heme oxygenase-1, a marker for ROS, is increased in hippocampal slices by CPS and CPO exposure at levels similar to those obtained by exposure to glutamate alone. Thus, the basis for the increased BDNF expression is not clear but it is possible that the indirect activation of the glutamatergic receptor may be linked to both ROS production as well as the increased expression of BDNF. (Supported by NIH 1P20-RR17661)

886 CHLORPYRIFOS INDUCES REDOX-SENSITIVE GENE EXPRESSION IN OLIGODENDROCYTES.

M. D. Saulsbury, S. O. Heyliger, K. Wang, Q. Chen, J. Morse and D. J. Johnson. *Pharmaceutical Sciences, Hampton University, Hampton, VA.*

There are increasing concerns regarding the relative safety of chlorpyrifos (CPF) to various facets of the environment. Although, literature suggests that CPF is relatively safe in adult animals, recent evidence indicates that juveniles, both animals and humans may be more sensitive to CPF toxicity than adults. In young animals, CPF is neurotoxic and mechanistically interferes with cellular replication and cellular differentiation, which culminates in the alteration of synaptic neurotransmission in neurons. Our laboratory has previously demonstrated that CPF and its metabolites are also toxic to oligodendrocyte progenitors. To further characterize these toxic effects, targeted microarrays were utilized to specifically identify genes which may be involved in CPF-induced toxicity in glial cell progenitors. Results reveal that sustained exposure for eight (8) days to CPF at non-lethal concentrations (10 μM) up-regulated redox-sensitive transcription factors *egr-1* (*krox-24*), *c-jun*, *myc* and *c-fos* and down-regulated the anti-apoptotic gene *Birc3*. Real-time PCR analysis confirmed that CPF produced 3.637 ± 1.250 (SEM) -fold induction of the early response gene-1 (*Egr1* or *krox-24*) and 8.787 ± 3.610 (SEM) -fold induction and 2.320 ± 0.8401 -fold induction of *c-fos* and *c-myc*, respectively. In acute studies, at higher concentrations (30-60 μM), CPF exposure resulted in the up-regulation of *NF-k-B* as well as the heme oxygenase-1 gene. It should be noted the heme oxygenase-1 gene expression is induced under oxidative stress and is tightly controlled by redox sensitive transcription factor *Nrf2* (nuclear factor erythroid-2 related factor). Collectively, this data suggests that CPF induces toxicity by the generation of reactive oxygen/nitrogen species which, in turn, activates cellular responses at the transcriptional level.

887 INCREASE OF NEUROPATHY TARGET ESTERASE ACTIVITY IN BOVINE CHROMAFFIN CELLS IN CULTURE USING AN ADENOVIRAL VECTOR.

E. Vilanova¹, E. Quesada¹, C. José², V. Carrera¹, E. Sabater¹ and M. Sogorb¹. ¹*Toxicología y Seguridad Química, Universidad Miguel Hernandez de Elche, Elche (Alicante), Spain and* ²*Centro de Investigación, Hospital "La Fe", Valencia, Spain.*

Neuropathy target esterase (NTE) is present in many of tissues included the bovine chromaffin cell cultures which show the highest level of NTE of all the studied tissues. It is well known that inhibition and specific modification of NTE by some organophosphorous (OPs) compounds induce a neurodegenerative disorder. It has been suggested that NTE shows a lysophospholipase activity involved in the phosphatidylcholine homeostasis but its role in the neuropathy induction is not completely clear. The cDNA of human NTE (4.4 kb) has been inserted into an adenoviral vector. Bovine chromaffin cells cultured at 50,000 cells/well were incubated with the vector for 2 hours and after that cells were kept in the incubator. NTE activity measured after 24 hours was 6.8 ± 0.5 mU/106 cells in untreated cells and 14.8 ± 1.5 mU/106 cells, 19.3 ± 2.9 mU/106 cells, 24.8 ± 0.9 mU/106 cells and 30.9 ± 1.0 mU/106 cells in cells incubated with 2, 4, 8 and 16 μl of vector, respectively. Kinetic inhibition curves with mipafox of NTE activity were performed in cells treated and untreated with the vector. After 60 minutes of inhibition with the inhibitor the calculated IC_{50} values were 5.5, 6.2 and 6.6 μM for cells incubated with 0, 2 and 10 μl of vector. Results present in this work confirm that the adenoviral vector containing the human NTE gene is active in bovine chromaffin cells in culture and the NTE activity expressed by the vector show the same inhibition pattern by the neuropathic OP mipafox than NTE activity from bovine chromaffin cells.

ACKNOWLEDGMENTS: E. Quesada is granted by Spanish Ministry of Culture. We thank Dr. Paul Glynn for handing over the cDNA of human NTE.

888 MOLECULAR MODELING PREDICTS CONFORMATIONAL CHANGES IN THE NEUROPATHY TARGET ESTERASE (NTE) CATALYTIC DOMAIN (PNTE) AFTER INHIBITION AND AGING.

S. J. Wijeyesakere¹, J. A. Stuckey² and R. J. Richardson¹. ¹Toxicology Program, University of Michigan, Ann Arbor, MI and ²Life Sciences Institute, University of Michigan, Ann Arbor, MI.

Inhibition and aging of NTE by organophosphorus compounds (OPs) triggers axonopathy. Identifying OP-induced structural changes will help illuminate NTE's pathogenic role. Lacking experimental structural data, molecular modeling can be used. We used docking with simulated inhibition (SI) and aging (SA) to test the hypothesis that these chemical alterations produce conformational changes in modeled PNTE. We did docking with Fujitsu CAChe using diisopropylphosphorofluoridate (DFP) as the ligand. We did SI using DFP-inhibited PNTE. We built the structure of diisopropylphosphoryl-serine (DPSer) from that of monoisopropylphosphoro-Ser (MPSer) downloaded from HIC-UP and substituted DPSer for Ser966 in PNTE using 'O' ver 10.1. We used the lego loop procedure in O to fix chain breaks arising from the substitution and subjected the resulting structure to 300 rounds of minimization using the MM3 protocol in CAChe. We did SA of DPSer-PNTE by deleting an isopropyl group from DPSer and minimizing the negatively charged adduct with MM3/CAChe. Docking showed that the P-atom of DFP was 4.7 Å from Ser966 OG and 3.7 Å from Asp1086 OD2, indicating that DFP can be accommodated in the active site of PNTE oriented suitably for inhibition. DFP's binding energy was -36.1 kcal/mol, indicating favorable energetics. SI resulted in a significant conformational change: the Ser966 OG to Asp1086 OD2 distance increased from 2.9 Å in PNTE to 5.2 Å in DPSer-PNTE. SA of DPSer PNTE showed a relaxation of the structure: the Ser966 OG to Asp1086 OD2 distance decreased to 3.7 Å in MPser-PNTE. These results support the hypothesis that inhibition of NTE produces a conformational change in the tertiary structure of PNTE and that aging of the NTE-OP adduct results in another conformational change. These models provide templates to guide research in solving the crystal structures of native, inhibited, and aged NTE (Funded by ARO DAAD19-02-1-0388, MEDC, and NIH ES07062).

889 COMPUTATIONAL DOCKING OF CYCLIC NUCLEOTIDES INTO THE PUTATIVE REGULATORY DOMAINS OF NEUROPATHY TARGET ESTERASE (NTE).

R. J. Richardson¹, S. J. Wijeyesakere¹ and J. A. Stuckey². ¹Toxicology Program, University of Michigan, Ann Arbor, MI and ²Life Sciences Institute, University of Michigan, Ann Arbor, MI.

Specific chemical modification NTE leads to axonopathy. NTE's structure is unknown, but molecular modeling can give structural insight. Although little is known about regulation of NTE, we previously showed that NTE has 3 putative regulatory cyclic nucleotide (CNP) binding domains: CNP1, CNP2, and CNP3. We developed homology models for these structures using TM1171 (PDB ID 1o5l; a homolog of catabolite activator protein (CAP)) as the template. The present study used docking to test the hypothesis that CNPs form suitable regulatory-type complexes with NTE's CNP domains. The CAP-cAMP crystal structure indicated Gly72, Arg83, Ser84 and Thr128 were involved in binding cAMP. Sequence alignments of CAP, TM1171, and NTE's CNP domains showed that these residues correspond to Ser64, Arg80 and Thr81 in CNP1; Gly64, Leu74 and Ile75 in CNP2; and Gly63, Ala74 and Thr75 in CNP3. We docked cAMP and cGMP into each CNP domain using the automated docking algorithm in Fujitsu CAChe. Docking revealed cAMP's binding energies (kcal/mol) to be -33.3 (CNP1), -27.1 (CNP2) and -52.3 (CNP3). Binding energies for cGMP (kcal/mol) were -31.1 (CNP1), -32.4 (CNP2) and -50.2 (CNP3). This shows favorable binding of cAMP and cGMP to NTE's CNP domains. CNP1 and CNP2 had higher binding affinities for cAMP; CNP2 had a higher affinity for cGMP. Analysis of the docked structures showed cAMP and cGMP bind NTE's CNP domains in a hydrophilic pocket on the surface of the proteins. Ser64 and Thr81 of CNP1; Leu74, Phe76 and Ile75 of CNP2; and Thr75 and Gln24 of CNP 3 made ionic contact with cAMP. Similarly, Ser64, Thr81 and Lys54 of CNP1; Leu74 of CNP2; and Leu74 and Glu66 of CNP3 mediated ionic contact with cGMP. These results support the hypothesis that CNPs form regulatory-type complexes with NTE's putative regulatory domains and provide templates to guide research in studying regulation of NTE and solving its crystal structure. (Funded by ARO DAAD19-02-1-0388, MEDC and NIH ES07062).

890 DIFFERENTIALLY EXPRESSED PROTEINS AND CARBONYL CONTENT IN N, N-DIETHYLDITHIOCARBAMATE (DEDC) MYELINOPATHY.

O. M. Viquez¹, H. L. Valentine¹, D. B. Friedman¹, S. J. Olsen¹ and W. M. Valentine^{1,2}. ¹Pathology, Vanderbilt University, Nashville, TN and ²Department of Biochemistry and Center in Molecular Toxicology, Vanderbilt University, Nashville, TN.

The neurotoxicity of dithiocarbamates has been observed in both humans and experimental animals. Previous studies have shown that the neurotoxicity of certain dithiocarbamates can manifest as a primary myelinopathy of peripheral nerve. Because increased levels of copper and lipid peroxidation products in peripheral nerve accompany DEDC induced lesions it has been suggested that disruption of copper homeostasis and increased oxidative stress may contribute to myelin injury. To assess the potential of DEDC to promote oxidative stress in peripheral nerve; changes in protein expression and protein carbonyl content resulting from DEDC exposure were determined in nerve using 2D-DIGE and immunohistochemistry, respectively. Rats were exposed to DEDC by intraperitoneal osmotic pumps for 8 weeks; and sciatic nerve proteins were extracted from DEDC exposed and non-exposed animals. Fifty-six gel plugs with an increase or decrease change greater than 1.3 fold (p<0.05) were picked from the gel, excised for trypsin digestion and identified by MALDI-TOF/MS. Twenty-six spots were up-regulated and 18 down-regulated. Among the up-regulated proteins were immunoglobulins (IgG and IgG-2a), and three isoforms of glutathione transferase important for detoxification of reactive α,β -unsaturated aldehydes generated from lipid peroxidation, including glutathione transferase pi which was localized to the cytoplasm of Schwann cells. Protein carbonyl levels from the DEDC exposed rats were significant higher by approximately 2 fold. These data support the ability of DEDC to promote protein oxidative injury in peripheral nerve and to produce lipid peroxidation in either myelin or another component of the Schwann cell, accompanied by a protective cellular response to oxidative stress. (Supported by NIH grant ES06387)

891 TIME-COURSE OF ACUTE NEUROTOXICITY PRODUCED BY N-METHYL CARBAMATES IN PREWEANLING RATS.

K. L. McDaniel, P. M. Phillips and V. C. Moser. NTD/NHEERL, U.S. EPA, Research Triangle Park, NC.

N-Methyl carbamate insecticides are reversible inhibitors of central and peripheral acetylcholinesterase (ChE). Despite their widespread and long-term use, we could find no studies of a systematic comparison of neurotoxicity in young animals across this group of chemicals. To learn more about potential age-differential responses, we conducted time-course studies of seven carbamates in 17-day old Long-Evans (LE) male rats. Rats receive a single oral dose of either carbaryl (30 mg/kg), carbofuran (1 mg/kg), formetanate (3 mg/kg), methiocarb (12 mg/kg), methomyl (2.5 mg/kg), oxamyl (0.5 mg/kg), or propoxur (10 mg/kg). These doses were chosen based on data from range-finding studies. Treated rats were euthanized and blood and brain were collected 15, 45, 90, 180 min, or 24 hr after dosing; control tissues from rats dosed with the appropriate vehicles were collected at 45, 180 min, or 24 hr. A radiometric assay was used to obtain ChE levels for brain and erythrocytes (RBC). Almost all carbamates showed maximal ChE inhibition encompassing the 45-min time point. Methomyl was the only carbamate tested to show maximal inhibition only at 15 min, and at 45 min the enzyme inhibition was significantly less. At 24 hr, all effects had fully recovered except for carbaryl-inhibited RBC (87% of control) and methomyl-inhibited brain (94% of control). The RBC inhibition was generally 10-30% greater (the least for formetanate, the greatest for carbaryl) than the brain inhibition with all carbamates except for propoxur, which showed similar levels of inhibition. The time-course of recovery of enzyme inhibition was similar for RBC and brain for all carbamates. These data determined the time of maximal effect to be used in dose-response studies for each chemical. Compared to previous work with these carbamates in adult LE male rats, the preweanling rats are somewhat more sensitive and slower to fully recover. This is an abstract of a proposed presentation and does not necessarily reflect US EPA policy.

892 BRAIN CHOLINESTERASE INHIBITION PRODUCED BY PROPOXUR AND DEPRESSION OF THE PHOTIC AFTER DISCHARGE OF FLASH EVOKED POTENTIALS IN LONG EVANS RATS.

J. Mwanza², J. E. Graff¹, C. L. Spivey¹ and D. W. Herr¹. ¹Neurotoxicology, U.S. EPA, Research Triangle Park, NC and ²NRC, Washington, DC.

Propoxur is a widely used N-methyl carbamate pesticide that acts by inhibiting cholinesterases (ChE), which may lead to cholinergic toxicity. Flash evoked potentials (FEPs) are a neurophysiological response following stimulation of the visual

system with flashes of light. They are often used to detect central nervous system (CNS) changes following exposure to neurotoxic compounds. Disruption of CNS function by ChE inhibitors produced decreases in the photic after discharge (PhAD) of the FEP. The PhAD is related to higher cortical processing of visual information. To determine the dose-response for propoxur on the PhAD, FEPs were recorded in adult male Long-Evans rats after oral gavage with propoxur 0, 0.3, 3, 10, 20, 30 or 40 mg/kg (corn oil vehicle). One week before testing, rats were implanted with electrodes over the visual cortex and allowed to recover. FEPs were recorded for 2 consecutive days to familiarize the rats with the test procedure and to develop the PhAD. On the 3rd day, pupils were dilated (40 min) and animals dosed (30 min) before testing. Immediately after testing, rats were sacrificed, and the brains removed and stored at -80°C, until determination of brain ChE levels by a radiometric assay. All doses greater than 0.3 mg/kg of propoxur significantly inhibited brain ChE. Three-40 mg/kg propoxur inhibited 38-63% of brain ChE. The duration of the PhAD was significantly decreased at 30 mg/kg by 54%. A correlation was obtained between brain ChE levels and the PhAD duration. A significant decrease in colonic temperature was observed at 10, 20 and 40 mg/kg propoxur. Treatment with 40 mg/kg propoxur increased the latency of peak N₁₆₆. No effect on the latency and amplitude of early components of the FEP was observed. These results indicate that ChE inhibition produced by propoxur disrupts the cortical processing related to the later portion of the FEP.¹ Supported by a NRC Fellowship. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

893 CHANGES IN ELECTROENCEPHALOGRAMS (EEG) OF LONG-EVANS RATS PRODUCED BY CARBARYL AND PROPOXUR.

J. E. Graff¹, J. Mwanza² and D. W. Herr¹. ¹Neurotoxicology, U.S. EPA, Research Triangle Park, NC and ²NRC, Washington, DC.

N-methyl carbamate (NMC) pesticides are widely used agriculturally and residentially and act by inhibiting cholinesterases (ChE), which may lead to cholinergic toxicity. We investigated the utility of EEG recording to assess changes in central neurophysiology post treatment with NMC pesticides. Long Evans rats were implanted with epidural screw electrodes. Following recovery, restrained animals were tested for 2 days to allow acclimation to the test procedures. On day 3, the rats' pupils were dilated and 10 min later they were dosed (po) with 0, 1, 10, 30, or 50 mg/kg carbaryl or 0, 10 or 30 mg/kg propoxur (corn oil vehicle). EEG recording occurred 5, 15, and 30 min later. Thirty EEG segments (2 s) were collected at each time point. The EEG was transformed using a FFT and the spectra averaged. Immediately after testing rats were sacrificed and the brains removed and stored at -80°C until determination of brain ChE levels by radiometric assay. Carbaryl produced significant reductions in ChE activity at 10, 30 and 50 mg/kg, and propoxur decreased ChE activity at 10 and 30 mg/kg. Fifty mg/kg carbaryl inhibited ChE activity to 42% of control and 30 mg/kg propoxur reduced ChE activity to 27% of control. Thirty mg/kg propoxur increased the peak amplitude in the Theta band when recorded between the visual cortex and the cerebellum. Carbaryl treatment resulted in a similar trend, but did not reach statistical significance. When considering animals with >20% brain ChE inhibition, regression of ChE activity vs. peak Theta amplitude showed a marginally significant (p=0.04) relationship after carbaryl, but not after propoxur (p=0.06; due to the small sample size). These studies show that treatment with NMCs may result in increased activity in the Theta range of the EEG.² Supported by a NRC Fellowship. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

894 NEUROTOXICITY OF CARBARYL IN THE AGING BROWN NORWAY (BN) RAT: EFFECTS ON CORE TEMPERATURE (TC) AND MOTOR ACTIVITY (MA).

C. J. Gordon, C. M. Mack and P. Becker. Neurotoxicology, U.S. Environmental Protection Agency, Res. Tri. Park, NC.

The US EPA is pursuing a variety of research efforts to assess the susceptibility of the aged to neurotoxicants. The BN strain is a popular animal model for aging studies but there is a need for improved methods of monitoring their physiological responses to neurotoxicants over the animal's life span. This study used radiotelemetry to follow longitudinal changes in Tc and MA, and sensitivity to carbaryl in 16 male rats surgically implanted with radiotransmitters (Data Sciences Int.). Tc and MA were recorded at 5 min intervals for 7 days in undisturbed animals. Monitoring was initiated at 90 days of age and was repeated every other month. Following the baseline monitoring, rats were dosed with carbaryl (25 mg/kg; po) or the corn oil vehicle. Tc and MA data in the undisturbed animals were ensemble into a single 24 hr period for statistical analysis. At the time of writing, data have been collected in animals at ages of 90, 150, and 210 days. Aging has quantitative and qualitative effects on the circadian rhythm of Tc and MA and on intra-subject variation. Aging has been associated with a slight reduction in Tc; rats at 90, 150, and 210 days had a mean Tc of 37.23, 37.15, and 37.11 °C. MA

has not paralleled the changes in Tc. Mean MA was 1.88 and 1.57 cts/min in 90 and 150 day old rats but increased to 1.64 cts/min in the 210 day old animals. The thermoregulatory response to carbaryl has also changed with aging. The first dosing with carbaryl led to a prolonged hypothermic response and little effect on MA that recovered within 24 hr. The peak decrease in Tc following carbaryl was -1.9, -1.9, and -0.7 °C at ages of 90, 150, and 210 days of age, respectively. Baseline Tc and MA and their response to carbaryl will be followed at 60 day intervals for at least two years. The data will provide a framework to develop methods for using the BN rat as a model of susceptibility to neurotoxic agents in the aged. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

895 MECHANISM OF SELECTIVE TOXICITY OF ENDOSULFAN IN INSECTS AND MAMMALS.

X. Zhao, J. Z. Yeh and T. Narahashi. Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL.

Endosulfan is a broad spectrum insecticide and acaricide. It exhibits acute oral and inhalation toxicity to mammals, but is neither mutagenic nor carcinogenic. The acute toxicity is known to be due to overstimulation of the CNS, and the GABAergic system is suspected to be a major target site. Since the GABAergic system is found in both mammals and insects, a question arises as to whether there is another target site that confers a selective toxicity in insects over mammals. In vitro experiments were performed by the whole-cell patch clamp technique using the rat dorsal root ganglion (DRG) neurons and cockroach ganglion neurons. α -Endosulfan had a dual effect on the GABA-induced current in rat DRG neurons, the initial fast inhibition followed by a slow recovery in the continuous presence of the drug in a concentration-dependent manner. The IC₅₀ for the initial block was ~10 nM. α -Endosulfan also blocked cockroach GABA currents with an IC₅₀ of 5 nM (n = 3). However, unlike DRG neurons, no recovery was observed during application of α -endosulfan. In addition, the glutamate-activated chloride channels (GluCl_s), which are present in insects but not in mammals, were found to be potentially blocked by α -endosulfan. The GluCl had two components, a desensitizing and a non-desensitizing current. We found easy ways to separately record the two components. Trypsin inhibited the non-desensitizing current, leaving the desensitizing current intact. Soybean Trypsin Inhibitor and polyvinylpyrrolidone (PVP) inhibited the desensitizing current, leaving the non-desensitizing current intact. α -Endosulfan inhibited GluCl_s slowly, reducing the non-desensitizing current more potently and efficaciously than the desensitizing current. In conclusion, the selective toxicity of endosulfan in insects over mammals is due largely to its potent blocking action on GluCl_s and due partly to its higher potency to block the cockroach GABA receptor than the rat DRG GABA receptor. Supported by NIH grant NS014143.

896 β SUBUNITS INCREASE SENSITIVITY OF SODIUM CHANNEL Na_v1.3, BUT NOT Na_v1.2, TO TYPE II PYRETHROIDS.

T. J. Shafer¹, C. A. Meacham¹ and J. A. Watkins². ¹Neurotoxicology Division, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC and ²North Carolina State University, Raleigh, NC.

Voltage-sensitive sodium channels (VSSCs) are targets of pyrethroid insecticides and are comprised of a pore-forming α and auxiliary β subunits. Multiple isoforms of both subunit types exist. The pyrethroid sensitivity of different isoform combinations has not been well characterized, yet differences in VSSC sensitivity to pyrethroids exist in intact neurons. The present experiments examined the influence of the β subunit on pyrethroid sensitivity of Na_v1.2 and Na_v1.3 channels. *X. laevis* oocytes were transfected with rat α (Na_v1.2 or Na_v1.3) with or without co-transfection with β_3 or β_1 subunit mRNA and sodium currents were recorded using two-electrode voltage clamp techniques. Tetrodotoxin (1 μ M) blocked peak inward current, and minimal tail current was present upon repolarization. The %pyrethroid-modified channels was determined based on tail current induced by DLT. In the absence of any β subunit, DLT (10 μ M) modified 1.25 and 3.0% of Na_v1.2 or Na_v1.3 channels, respectively. Upon co-transfection with β_1 , DLT (10 μ M) modified 2.17% and 8.31% of Na_v1.2 and Na_v1.3 channels, respectively; while co-transfection with β_3 did not alter DLT modification of Na_v1.2 channels (1.92%) but increased modification of Na_v1.3 channels (11.71%). Expression of Na_v1.2/ β_3 subunits predominate in adult central neurons, while expression of Na_v1.3/ β_3 subunits predominates in embryonic neurons. Thus, differential sensitivity of these subunit combinations was examined for several pyrethroids (10 μ M each; n=3-21 oocytes/compound). Type II pyrethroids differentially modified Na_v1.3/ β_3 and Na_v1.2/ β_1 respectively: β -cyfluthrin (19.75% vs. 1.54%); esfenvalerate (28.36% vs. 2.67%) and fenvalerate (14.55% vs. 1.89%). These results demonstrate that the β subunit has a significant impact on the sensitivity of Na_v1.3, but not Na_v1.2 channels, and that Na_v1.3/ β_3 channels are more sensitive than Na_v1.2/ β_1 rat sodium channel to Type II pyrethroids. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy).

897 EFFECTS OF ACUTE PYRETHROID EXPOSURE ON THERMOREGULATION IN RATS.

M. J. Wolansky¹, C. M. Mack², P. B. Becker², K. M. Crofton² and C. J. Gordon². ¹U.S. NRC, Durham, NC and ²Neurotoxicology Division, NHEERL, ORD, U.S. EPA, Durham, NC.

Pyrethroid insecticides produce acute neurotoxicity in mammals. According to the FQPA mandate, the USEPA is required to consider the risk of cumulative toxicity posed to humans through exposure to pyrethroid mixtures. Thermoregulatory response (TR) is being used to determine if the dose-additive action for motor function can be generalized to other endpoints in rats. Adult male Long Evans rats were monitored for 48 h for core temperature (T_c) and motor activity (MA) at 5 min intervals by surgically implanted radiotransmitters. Acute oral dose-response studies [n=6-13; 6 doses/compound] were carried out for a Type-I (Permethrin, PER, 5-220 mg/kg) and a Type-II (Deltamethrin, DLT, 0.5-12 mg/kg) pyrethroid. Both pyrethroids produced acute effects, including increased MA and compound-specific changes in TR that recovered within 12 hr after dosing. Area under the curve (AUC) from 1 to 7 hr post-dosing was determined for each pyrethroid dose and used for statistical analysis. PER elicited a hyperthermic response at 75-220 mg/kg. The TR dose-response to DLT was biphasic, with 1.5-3 mg/kg eliciting a significant elevation in T_c and higher doses eliciting a prolonged hypothermic response. In addition, animals dosed with 9-12 mg/kg DLT exhibited a slight elevation in T_c the day after exposure (0.16-0.22 °C above controls). In a preliminary mixture study, the TR response to 220 mg/kg PER and 12 mg/kg DLT resulted in an approximate algebraic summation of the TR responses to the individual compounds: the AUCs for PER, DLT and the mixture were 12.4, -8.8, and 4.65 °C.hr-1, respectively. Future work will include testing other pyrethroids and an environment relevant mixture of them using TR as a sensitive endpoint. This abstract does not necessarily reflect the policy of the US EPA.

898 DOSE-RESPONSE MODELING OF THE TRANSCRIPTIONAL RESPONSE OF RAT CEREBROCORTICAL TISSUE AFTER ACUTE PYRETHROID EXPOSURE IN VIVO.

J. A. Harrill¹, F. A. Wright² and K. M. Crofton³. ¹Curriculum in Toxicology, UNC-CH, Chapel Hill, NC, ²Department of Biostatistics and Carolina Environmental Bioinformatics Research Center, UNC-CH, Chapel Hill, NC and ³NTD, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC.

Pyrethroid insecticides produce neurotoxicity in mammals by disrupting ion channel function in excitable nerve membranes. Pyrethroid use has increased as regulatory guidelines have restricted the use of other pesticide classes. Currently, a sensitive, specific, dose-responsive biomarker of effect that correlates with pyrethroid-induced disruption of nervous system function is not available. This study used a novel combination of statistical methods to identify dose-responsive transcripts from a microarray data set. Our goal was to characterize potential biochemical markers of pyrethroid effects. Long-Evans rats (n = 8-12/group) were orally dosed with permethrin (1, 10, 100 mg/kg), deltamethrin (0.3, 1.0, 3.0 mg/kg) or corn-oil vehicle and cerebrocortical tissue was collected at 6 hours. Affymetrix Rat 230 2.0 GeneChip® microarrays were used to obtain transcriptional profiles. Dose-responsive transcripts were identified using a standard Significance Analysis of Microarrays (SAM) approach and an isotonic regression model that assumes a monotonic dose-response relationship, but otherwise makes no assumptions about the precise form of the dose-response curve (M-score, Hu et al. 2005). Permutation-based calculation of false discovery rates were used to provide multiple comparison error control. These analyses revealed several candidate transcripts commonly regulated by both compounds. qRT-PCR confirms dose-responsive relationships for: increased expression of Camk1γ and decreased expression of Abcb1a, prominin 1 and dopa decarboxylase, for both deltamethrin and permethrin. Future work will validate the use of these transcripts, their corresponding proteins, or components of cellular signaling pathways in which they are involved, as specific biomarkers of effect for pyrethroids. *This abstract does not necessarily reflect the policy of the US EPA.*

899 ROTENONE TOXICITY IN NURR1-NULL HETEROZYGOUS AND WILD-TYPE MICE.

J. B. Eells, S. Hoffman and T. Brown. *Department of Basic Sciences, Mississippi State University, Mississippi State, MS.* Sponsor: M. Ross.

Parkinson's disease is the 2nd most common neurodegenerative disease effecting 1-2% of the population over 65 years of age. The hallmark of Parkinson's disease is selective nigrostriatal dopaminergic degeneration that is believed to be caused by a combination of environmental and genetic factors. One environmental factor implicated in Parkinson's disease is exposure to pesticides. A genetic factor may be the nuclear receptor Nurr1 as mutations in Nurr1 have been implicated in Parkinson's

disease and dopamine neurons in Nurr1-null heterozygous (+/-) mice are more susceptible to certain neurotoxins. The mechanism(s) for this increased susceptibility, however, has not been determined. Chronic exposure to the pesticide rotenone has been found to reproduce many features of Parkinson's disease in rodents. Rotenone is a common organic pesticide and acts as a complex I inhibitor of the mitochondrial respiratory chain. The purpose of the current experiment was to determine if the +/- genotype makes dopamine neurons more susceptible to the neurotoxic effects of rotenone than wild-type mice. In this experiment a subcutaneous osmotic pump was implanted into 26 male mice for 7 days. The subjects were split into two groups according to their genotype. Half of the subjects for each genotype received a pump containing rotenone (6-8 mg/kg/day), and the other half received a vehicle (containing a 1:1 ratio of DMSO and PEG). Rotenone treatment had no effect on the number of tyrosine hydroxylase immunoreactive neurons or on dopamine levels in the striatum. Roto-Rod performance, however, was impaired in +/- rotenone treated mice as compared to rotenone treated +/- mice. Wild-type mice were more sensitive to rotenone toxicity based on survival rates as 62.5% of these mice died from treatment while all +/- mice survived. Based on these data, the +/- mice appear more resistant to systemic rotenone toxicity. Furthermore, the toxic dose appears to be lower than the effective dose at destroying dopamine neurons in these mice.

900 SYNERGISTIC EFFECT ON NEURONAL CELL DEATH OF THE PESTICIDE ROTENONE IN THE PRESENCE OF EXCITOTOXINS ON ORGANOTYPIC RAT HIPPOCAMPAL SLICE CULTURES.

C. C. Matthews^{1,2}, R. A. Schuh¹ and P. S. Fishman^{1,2}. ¹Research Service, Veterans Affairs Health Care System, Baltimore, MD and ²Neurology, School of Medicine, University of Maryland, Baltimore, MD.

Exposure to inhibitors of oxidative phosphorylation or activators of inotropic glutamate receptors is known to cause neuronal death associated with free radical production. We hypothesized that exposure to rotenone, an inhibitor of complex I of the mitochondrial electron transport chain, might exacerbate glutamate excitotoxicity, possibly by oxidative damage due to superoxide production. Using rat organotypic hippocampal cultures, we investigated the effects of rotenone (1 – 300 nM) given alone, or in combination with one of three excitotoxic agents, NMDA (1 – 10 μM), AMPA (1 – 10 μM) or TEA (0.5 – 2 mM). Low doses of rotenone (100 nM), NMDA (1 μM), AMPA (1 μM) or TEA (0.5 mM), caused neuronal death that was comparable to controls as measured by propidium fluorescence after 24 hr. However, exposure to rotenone combined with NMDA, AMPA or TEA, all at concentrations that individually were not neurotoxic, resulted in significant (p < 0.001) neuronal death. Combined exposure to rotenone and excitotoxin produced a synergistic effect on neuronal death at low doses, gradually becoming additive as the doses were increased. Stimulation of hydrogen peroxide production as measured by amplex red was also observed. These results suggest that sub-lethal exposure to rotenone can predispose neurons to excitotoxic injury.

901 BFGF PROTECTS AGAINST ROTENONE-INDUCED DOPAMINERGIC APOPTOSIS THROUGH ACTIVATION OF ERK1/2 AND PI3-KINASE PATHWAYS.

H. M. Klintworth¹, S. Hsuan¹ and Z. Xia^{1,2}. ¹Department of Env. & Occ. Health Sciences, University of Washington, Seattle, WA and ²Graduate Program in Neurobiology & Behavior, University of Washington, Seattle, WA.

Administration of rotenone to rats reproduces many features of Parkinson's disease including dopaminergic neuron degeneration, and provides a useful model to study the pathogenesis of Parkinson's disease. However, the cell death mechanisms induced by rotenone and potential neuroprotective mechanisms against rotenone are not well defined. Here we report that rotenone-induced apoptosis in human dopaminergic SH-SY5Y cells is attenuated by pretreatment with basic fibroblast growth factor (bFGF). bFGF activated both extracellular signal-regulated kinase 1/2 (ERK1/2) and phosphatidylinositol-3 kinase (PI3-kinase) pathways in SH-SY5Y cells. Ectopic activation of ERK1/2 or PI3-kinase protected against rotenone, while inhibition of either pathway attenuated bFGF protection. bFGF induced a long-lasting phosphorylation of the pro-apoptotic protein BAD at serine 112, suggesting BAD inactivation through the ERK1/2 signaling pathway. Reducing the expression of BAD by siRNA rendered SH-SY5Y cells resistant to rotenone, implicating BAD in rotenone-induced apoptosis. Rotenone stimulated AIF release from the mitochondria and subsequent nuclear translocation, a process blocked by bFGF, further implicating mitochondrial dysfunction in rotenone-induced apoptosis. Moreover, the selective loss of dopaminergic neurons from primary mesencephalic cultures was attenuated by bFGF and was dependent on activation of ERK1/2 and PI3-kinase signaling. In addition, bFGF blocked rotenone-induced AIF nuclear translocation in primary dopaminergic neurons. These data suggest that rotenone-induced dopaminergic apoptosis requires BAD, and identify bFGF and its activation of ERK1/2 and PI3-kinase signaling pathways as novel intervention strategies to block cell death in the rotenone model of Parkinson's disease.

902 MECHANISMS OF MPP+, ROTENONE, AND PARAQUAT TOXICITY: THIOREDOXIN OXIDATION, AND ACTIVATION OF CELL DEATH PATHWAYS.

S. Ramachandiran¹, J. M. Hansen², D. P. Jones³, J. R. Richardson⁴ and G. W. Miller¹. ¹Center for Neurodegenerative Disease, Department of Environmental and Occupational Health, Emory University, Atlanta, GA, ²Department of Pediatrics, Emory University, Atlanta, GA, ³Department of Medicine and Clinical Biomarkers Laboratory, Emory University, Atlanta, GA and ⁴Department of Environmental and Occupational Medicine, University of Medicine and Dentistry-New Jersey, Piscataway, NJ.

The parkinsonian-inducing chemicals MPTP, rotenone and paraquat have been shown to reproduce several features of Parkinson's disease (PD) in animal and cell culture models. Although these chemicals are known to disrupt dopamine homeostasis and induce neuronal cell death, their molecular mechanisms of actions are not well delineated. Using human neuroblastoma cells stably expressing dopamine transporter (SK-DAT) as a model system, we have previously shown that paraquat does not require functional dopamine transporter (DAT) and does not inhibit mitochondrial complex I in order to mediate its toxic action (Richardson et al., 2005). In this study we show that paraquat specifically oxidized the cytosolic form of thioredoxin (Trx1) followed by a robust Jun N-terminal kinase (JNK) and mild p38 activation culminating in caspase-3 activation. Cells were almost completely protected from paraquat-induced toxicity by a cell permeable caspase-3 inhibitor. Conversely, MPP+ and rotenone preferentially oxidized the mitochondrial form of thioredoxin (Trx2), but did not activate JNK, p38 MAPK or caspase-3. These data suggest that, oxidative modification of cytosolic proteins is important to paraquat toxicity, while mitochondrial oxidative stress is crucial for MPP+ and rotenone mediated toxicity of SK-DAT cells (NIH U54 ES012068; F32 ES013457).

903 ENVIRONMENTAL NEUROTOXIC AGENTS INFLUENCE LRRK2, DJ-1, PARKIN AND PINK1 EXPRESSION IN DOPAMINERGIC NEURONAL CELLS: RELEVANCE TO GENE-ENVIRONMENT INTERACTION AND PROTEASOMAL DYSFUNCTION IN PATHOGENESIS OF PARKINSON'S DISEASE.

V. Anantharam, C. Song, A. J. Carrel, E. Sun, H. Jin, R. Gordon, A. Kanthasamy and A. G. Kanthasamy. Biomedical Sciences, Iowa State University, Ames, IA.

Environmental exposure to metals and pesticides, genetic defects in LRRK2, PINK1, Parkin, DJ-1 and α -synuclein, proteasomal dysfunction and oxidative insults are implicated in Parkinson's disease (PD). However, interactions of environmental factors with PD genes and subsequent impacts on proteasomal dysfunction and oxidative damage are yet to be clarified. Herein, we examined the effect of environmental neurotoxicant exposure on LRRK2, PINK1, Parkin and DJ-1 levels in various cell models of PD. Acute exposure to 100 μ M dieldrin for 5-60 min induced a time-dependent decrease in protein levels of LRRK2, Parkin, PINK1 and DJ1 in the N27 mesencephalic cell line. LRRK2, Parkin, PINK1, and DJ1 expression was decreased by 35-75% as compared to vehicle-treated cells. In order to further understand dieldrin-induced alterations in PD gene expression and their role in proteasomal function and oxidative damage, we engineered N27 cells to stably express either human α -synuclein, caspase-cleavage resistant PKC δ D327A mutant, wild-type or mutant ubiquitin proteins Ub^{WT}, Ub^{K48R} and Ub^{K63R}. α -Synuclein overexpression attenuated dieldrin-induced decrease in Parkin protein but exacerbated DJ1 levels without any effect on LRRK2 and PINK1 levels. Overexpression of the oxidative stress insensitive kinase mutant PKC δ D327A significantly blocked dieldrin-induced decreases in Parkin and exacerbated PINK1, with no effect on LRRK2 and DJ-1. Furthermore, overexpression of wild-type ubiquitin protein Ub^{WT} exacerbated the dieldrin-induced reduction in LRRK2, Parkin, PINK1, and DJ1 levels. Conversely, overexpression of Ub^{K48R} and Ub^{K63R} mutants significantly attenuated dieldrin-induced reduction in Parkin, LRRK2, DJ-1 and PINK1 levels. Collectively, our data demonstrate a significant interplay between environmental exposure, PD gene expression and proteasomal function in cell culture models of PD. (supported by NIH grant ES10586).

904 EFFECTS OF THE ORGANOCHLORINE PESTICIDE METHOXYCHLOR ON DOPAMINE METABOLITES AND TRANSPORTERS IN THE MOUSE BRAIN.

R. A. Schuh^{1,2}, J. R. Richardson³, R. Gupta², J. A. Flaws² and G. Fiskum^{1,2}. ¹Anesthesiology, University of Maryland Baltimore, Baltimore, MD, ²Epidemiology and Preventive Medicine, Program in Toxicology, University of Maryland Baltimore, Baltimore, MD and ³Environmental and Occupational Medicine, UMDNJ/RWJMS and EOHHSI, Piscataway, NJ.

Organochlorine pesticides are implicated as environmental risk factors for neurodegenerative diseases, e.g., Parkinson's disease (PD). Inhibition of complex I of the mitochondrial electron transport chain has also been indicated as possibly playing a

role in the demise of vulnerable neuronal populations in PD. We previously demonstrated respiratory inhibition in non-synaptosomal mitochondria from rat brain mitochondria exposed to mxc in vitro, and from isolated mouse brain mitochondria following chronic in vivo mxc exposure. Further, stimulation of H₂O₂ production (in response to mitochondrial reactive oxygen species generation) and increased protein carbonylation, a marker of oxidative stress, were observed. In this study, female CD1 mice were chronically treated with mxc (16-64 mg/kg/day i.p. x 20 days) prior to striatal isolation to identify early markers of damage to the nigrostriatal dopamine system. HPLC measurements of dopamine and its metabolite DOPAC were significantly decreased ($p < 0.05$). Dopamine levels decreased ~ 15% at the lower doses and 31% at the highest mxc dose as compared to controls. Western immunoblots demonstrated a 48% decrease in dopamine transporter (DAT; $p < 0.01$) levels at the two higher doses, and a 35% decrease at the lowest dose compared to control. The vesicular monoamine transporter 2 levels were decreased (VMAT2, $p = 0.06$), and tyrosine hydroxylase levels were not affected. These results suggest that perturbation of dopamine metabolism and transport may be early indicators of damage to the dopaminergic system and is consistent with the possibility that mxc can act as an environmental neurotoxicant capable of promoting neurodegeneration.

905 ELEVATED LEVELS OF CHLORINATED PESTICIDES IN THE BRAIN ARE ASSOCIATED WITH PARKINSON'S DISEASE.

J. M. Hatcher¹, M. Gearing¹, A. I. Levey¹, K. D. Pennell^{1,5} and G. W. Miller^{1,6}. ¹Center for Neurodegenerative Disease, Emory University School of Medicine (EUSM), Atlanta, GA, ²Alzheimer's Disease Research Center, EUSM, Atlanta, GA, ³Department of Pathology, EUSM, Atlanta, GA, ⁴Department of Neurology, EUSM, Atlanta, GA, ⁵School of Civil & Environmental Engineering, Georgia Institute of Technology, Atlanta, GA and ⁶Department of Environmental & Occupational Health, Rollins School of Public Health, Emory University Atlanta, GA.

Parkinson's disease (PD) is a chronic, progressive neurological disorder that affects more than one million people in the United States each year. Numerous epidemiological studies have shown that pesticide exposure may be a significant risk factor for PD. Additionally, previous work from our lab has shown that the pesticide dieldrin, as well as polychlorinated biphenyls (PCBs), are capable of causing disruptions in the dopaminergic system that are consistent with PD pathophysiology and thus may be promoters of PD pathogenesis. Here, we report findings of a screen of 17 pesticides and PCB congeners in the brains of PD patients versus age-matched controls. Two, pesticides, dieldrin and DDE, the major metabolite of DDT, were three times higher in the brains of PD patients. In addition, we demonstrate that using occipital cortex tissue (non-precious tissue in PD cases) to analyze pesticide levels in humans is a valid approach by showing that the distribution of a single oral dose of dieldrin (11 mg/kg) in mice is consistent throughout a variety of brain regions over several time points. Furthermore, we show that the same 11 mg/kg cumulative dose of dieldrin given either orally or intraperitoneally to mice results in similar levels of pesticide in the brain at 30 days suggesting that the bulk of the dose is absorbed via both routes. Finally, the ratio of brain to blood levels of dieldrin (approximately 3.5:1, respectively) may be a useful clinical measure to identify patients with a higher brain burden of pesticide. These findings may help provide a strategy to identify other compounds that are associated with PD diagnosis as well as understanding the possible mechanisms involved in the association between pesticide exposure and increased risk of developing PD.

906 THE NEUROLOGICAL ASSESSMENT OF ACUTE AND SUBCHRONIC INHALATION EXPOSURE OF DIMETHYL DISULFIDE (DMDS) IN CRL:CD® RATS.

M. Beck¹, M. D. Nemec¹, D. T. Kirkpatrick¹, E. Tanchevski¹, J. P. Ogg¹, B. J. Varsho¹, C. J. Bowman¹ and C. Farr². ¹WIL Research Laboratories, LLC, Ashland, OH and ²Arkema, Inc., Philadelphia, PA.

Dimethyl disulfide (DMDS) is a naturally occurring methyl bromide replacement candidate. Acute (ANT) and 90-day neurotoxicity studies of DMDS were conducted using 6-hour, whole-body inhalation exposures either once (ANT) or daily for at least 90 days. For both studies, neurotoxicity was evaluated in 12 rats/sex/group using an FOB screening battery, motor activity and neuropathology. Exposure levels were 0, 100, 200 and 750 ppm (ANT) and 0, 5, 20 and 80 ppm (90-day). FOB and activity were evaluated at pretest, peak effect (Tmax) and 7 and 14 days post-exposure (ANT) and at pretest and during study weeks 3, 7 and 12 (90-day). One 750 ppm female died. Salivation was noted during exposure in the 100, 200 and 750 ppm groups. In the FOB at Tmax for 750 ppm animals, there was an increased incidence of drooping eyelids, soiled fur and red deposits around the mouth, increased frequencies of tremors, grooming and urination and decreased body temperatures; none of these differences were sustained. Soiling of the

fur, red deposits around the mouth and tremors were also noted at T_{max} in the 200 ppm group. Drooping eyelids, salivation, increased grooming, red deposits and soiled fur most likely resulted from the slightly irritating properties of DMDS and were not considered indicative of systemic toxicity. Motor activity at T_{max} was reduced at 750 ppm and at week 12 in 80 ppm males, although habituation was unaffected. Brain lengths were reduced in 80 ppm males after 13 weeks of exposure, although there was no evidence of neuropathy. Based on these results, the autonomic, CNS activity, CNS excitability and physiological functional domains described by Moser were affected by a single 6-hour exposure of DMDS while only the CNS activity and physiological functional domains were affected by repeated 6-hour exposures of DMDS. Therefore, the NOAEL for neurotoxicity after a single whole-body inhalation exposure to DMDS was 100 ppm and after repeated exposures to DMDS was 20 ppm.

907 ATRAZINE-INDUCED DISRUPTION OF THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS: CENTRAL MONOAMINES AND BEHAVIOR.

M. M. Taylor¹, V. M. Rodriguez², J. Kochar², M. Thiruchelvam² and D. A. Cory-Slechta². ¹Pharmacology and Toxicology, Rutgers, The State University of New Jersey, Piscataway, NJ and ²Environmental and Occupational Health Sciences Institute, Piscataway, NJ.

Our previous research shows that acute exposure to the widely used herbicide atrazine (ATR) increases levels of dopamine (DA) and its metabolites (DOPAC or HVA) in the striatum (STR), nucleus accumbens (NA), frontal cortex (FC) and midbrain (MB) of male rats and increases corticosterone (CORT) to levels observed in restraint stress in female mice, implicating it as a chemical stressor. This study sought to determine whether ATR concomitantly alters CORT and brain neurochemistry in both genders and the impact of such changes for behavior. Adult male and female mice were exposed to ATR (0, 10, 25 or 50mg/kg i.p.); blood was collected for serum CORT analysis and tissue from hypothalamus (HYPO), MB, STR and FC for monoamine determinations 1, 4 or 8 hrs later. Locomotor activity was measured for 45 min following ATR. In males, all three doses increased CORT at 1 and 4 hrs post-exposure, which returned to control levels at 8 hrs. In females, all doses of ATR produced a robust increase in CORT at all time-points. There was no effect of ATR on HYPO DA or DOPAC levels or DA activity in either gender. However, ATR increased HYPO HVA in both males and females. Similarly, ATR did not impact DA, DOPAC or DA activity in MB, STR or FC in either gender, but HVA was increased in FC of both genders. Interestingly, ATR increased HVA at the 1 hr time-point in male STR and female MB as well. ATR produced the greatest impact on CORT and HVA 1 hr post-exposure. In males, all ATR doses reduced horizontal and vertical activity; in females, reductions in horizontal activity were dose-dependent, while vertical activity was reduced only at 25 and 50 mg/kg. Thus ATR negatively impacts the HPA axis and increases HVA levels in several brain areas of both genders, suggesting that it may contribute to conditions involving abnormal CORT function or altered DA activity, such as depression, schizophrenia or Parkinson's disease. ES012712, ES007148.

908 ACUTE EFFECTS OF ATRAZINE EXPOSURE ON EXTRACELLULAR DOPAMINE LEVELS IN THE STRIATUM OF CONSCIOUS MICE.

M. M. Hossain, S. C. Sistrunk and N. M. Filipov. CEHS, Basic Sciences, Mississippi State University, Mississippi State, MS.

Recently, we demonstrated that 14-day oral exposure to atrazine (ATR), a widely used herbicide in the United States and the world, decreased striatal dopamine (DA) levels, as well as the number of tyrosine hydroxylase (TH)-positive dopaminergic neurons in substantia nigra pars compacta (SNpc) of male juvenile C57BL/6 mice. Similarly, other investigators have observed ATR-caused dopaminergic dysfunction in chronically exposed rats. In order to understand the mechanism of dopaminergic neurotoxicity, the acute effects of ATR exposure on extracellular levels of DA and its metabolites in the striatum of conscious mice were studied by an in vivo microdialysis. The microdialysis probe was implanted into the left striatum of adult male C57BL/6 mice and, following 3 days recovery from surgery, the mice were exposed to atrazine or corn oil (vehicle control), by oral gavage. Vehicle treatment had no pronounced effect on the efflux of DA. On the other hand, 250 mg/kg ATR inhibited the extracellular levels of DA to about 50% of baseline. In addition to the decrease in basal DA release, ATR also decreased the amount of amphetamine-stimulated DA release. The extracellular levels of the DA metabolites, DOPAC, and 3-MT were not affected by ATR, while the level of the other DA metabolite, HVA, was moderately decreased. In previous studies, we and others observed that the loss of TH-positive dopaminergic neurons caused by an exposure to ATR was not confined to the SNpc and it also occurred in the ventral tegmental area (VTA). To determine whether this neuronal loss in the VTA is also associated with DA alterations in a terminal field area, the nucleus accumbens (NA), besides

conducting experiments with lower doses of ATR and various pharmacological manipulations, we are currently investigating the consequences of ATR exposure of extracellular DA levels in the NA. (Supported by P20 RR017661 (NIH) and by the ACC/SOT Early Career in Neurotoxicology Award).

909 EFFECTS OF ACUTE ATRAZINE (ATR) EXPOSURE ON SERUM CORTICOSTERONE LEVELS AND HYPOTHALAMIC MONOAMINE CONTENT IN THE RAT.

D. A. Cory-Slechta, M. J. Thiruchelvam, A. Rossi-George, J. Kochar and V. M. Rodriguez. Environmental and Occupational Medicine, EOHHSI The University of Medicine and Dentistry of New Jersey, Piscataway, NJ.

It has been reported that the herbicide atrazine is a putative neuroendocrine disruptor in the rat due to alterations in the levels of testosterone, luteinizing hormone, estradiol, prolactin, and thyroid hormones, among others. This study sought to further examine relationships between the endocrine and monoamine effects of ATR. Chronic ATR exposure in the rat causes alterations in hypothalamic monoamine content. In this study we acutely co-exposed rats to a dose of 100 mg ATR/kg of b.w. or 1% methyl cellulose (MC 1%) by intraperitoneal injections and 0.01 mg/kg of haloperidol (HAL) or saline (SAL) by subcutaneous injections. Rats were sacrificed 90 minutes or 4 hours later, blood was collected and the hypothalamus was dissected. Serum corticosterone levels were increased by 56 % and 65 % in the groups exposed to ATR-SAL and ATR-HAL respectively 90 minutes after exposure. However, 4 hours after exposure only the ATR-HAL group showed a sustained increase in corticosterone serum levels (96%). Significant alterations in hypothalamic monoamine content were observed 90 minutes after treatment. Dopamine content was decreased in the groups exposed to MC 1%-HAL and ATR-SAL whereas DOPAC was increased in the group exposed to ATR-HAL and HVA was increased in both ATR-SAL and ATR-HAL groups. Noradrenaline levels were decreased in the groups exposed to ATR-SAL and ATR-HAL. Four hours after treatment there was an increase in hypothalamic DOPAC content in the groups exposed to ATR-SAL and ATR-HAL. These increments in the corticosterone levels may be related to the hypothalamic alterations in the monoamine content in the groups exposed to ATR. Further studies to determine the effects of ATR exposure in stress related disorders are necessary. ES05903, 10791 and 012712.

910 ATRAZINE EXPOSURE CAUSES ALTERATIONS IN THE NIGROSTRIATAL AND MESOSTRIATAL SYSTEMS IN THE RAT.

V. M. Rodriguez, M. J. Thiruchelvam, J. Kochar and D. A. Cory-Slechta. Environmental and Occupational Medicine, EOHHSI The University of Medicine and Dentistry of New Jersey, Piscataway, NJ.

The herbicide atrazine (ATR) is widely used to control weeds and grass on a wide variety of crops. It has previously been shown that chronic ATR exposure in rats reduces striatal dopamine (DA) and hypothalamic serotonin levels, and produces a loss of dopaminergic and non-dopaminergic neurons in substantia nigra and ventral tegmental area. Microdialysis studies showed that acute ATR exposure decreases basal and high potassium-evoked striatal DA release in the striatum, an effect reversed by concurrent administration of a D2 receptor antagonist (haloperidol) with ATR. To further evaluate mechanisms of ATR effects on monoamine systems, rats were treated with either 1% methyl cellulose (vehicle) or 100 mg/kg ATR i.p. and sacrificed 90 minutes or 4 hr later. Striatum, ventral midbrain, nucleus accumbens, hypothalamus and prefrontal cortex were dissected and processed for monoamine concentrations and level of phosphorylated tyrosine hydroxylase (pTH) at sites 19 and 40. Acute ATR exposure significantly increased levels of DA and its metabolites (DOPAC and HVA) in the striatum, nucleus accumbens, prefrontal cortex and midbrain, while decreasing hypothalamic DA and NE levels. ATR exposure produced increases in the content of pTH at sites 19 and 40 in the striatum and nucleus accumbens. Taken together these results indicate that acute ATR exposure affects DA systems, decreasing DA release but increasing DA content and levels of pTH-19 and pTH-40. These findings suggest that ATR could act by increasing the activity of tyrosine hydroxylase and affecting vesicular DA dynamics in the dopaminergic systems. The impact of ATR on brain DA systems suggests it could contribute as a risk factor to diseases and dysfunctions that include learning disorders, attention deficit hyperactivity disorder and motor dysfunction, among others. ES05903, 10791 and 05017.

911 DECREASE OF 5-HT LEVELS AFTER GLYPHOSATE HERBICIDE TREATMENT IN RATS.

A. Anadon, J. del Pino, M. A. Martínez, V. Caballero, M. J. Díaz, I. Ares, I. Nieto, M. Martínez and M. R. Martínez-Larrañaga. Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.

Glyphosate (N-phosphonomethyl-glycine) is a synthetic amino acid with an empiric formula of C₃H₈NO₅P. The compound is used worldwide as a broad-spectrum systemic herbicide; it inhibits the shikimic acid pathway that is important for plant

protein synthesis. Glyphosate's mechanisms of action in mammals is still questioned, and it may have several enzymatic effects. Accidental ingestion of glyphosate is generally associated with mild to moderate effects such as spasms, panting, shaking, hind-leg ataxia and muscle spasms. Fatal cases in dogs have been reported and correlated with the agricultural use of glyphosate. Because of toxicological data are needed to further define the use safety of this herbicide, the objective of the present study was to investigate neurochemical effects following the administration of glyphosate (150 and 800 mg/kg/day, orally for 5 days) in male Wistar rats (n = 6/group). Animals were killed 24 hours after the last dose by cervical dislocation and decapitation and the brains removed. The frontal cortex, mid-brain and striatum were dissected and analyzed for content of 5-hydroxytryptamine (5-HT) and its metabolite 5-hydroxy-3-indole acetic acid (5-HIAA) using a HPLC method with electrochemical detection. The frontal cortex, midbrain and striatum were dissected and analyzed for content of 5-hydroxytryptamine (5-HT) and its metabolite 5-hydroxy-3-indole acetic acid (5-HIAA) using a HPLC method with electrochemical detection. A serotonin depleting effect was produced by this herbicide. Glyphosate decreased 5-HT levels in frontal cortex (32%; $P < 0.001$), midbrain (22%; $P < 0.01$) and striatum (49%; $P < 0.001$) and increased 5-HIAA levels in frontal cortex (54%, $P < 0.001$) and midbrain (33%; $P < 0.01$) but not in striatum. The data presented herein suggests that a lower activity of serotonergic system exists in the action of glyphosate. This work has been supported by project No. AGL2005-05320-C02-02 (MEC), Spain.

912 COMPARATIVE MICROARRAY ANALYSIS OF TOXIC AND NON-TOXIC ARYL HYDROCARBON RECEPTOR LIGANDS IN MURINE HEPATOCYTE CELLS.

M. S. Kiewitt^{1,2}, E. Dere^{1,2}, S. S. Lundback^{1,2}, L. D. Burgoon^{1,2} and T. R. Zacharewski^{1,2,3}. ¹Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

The aryl hydrocarbon receptor (AhR) mediates the response of many toxic and non-toxic ligands. In order to characterize and distinguish ligand-specific responses, gene expression effects elicited by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) were compared to indolo[3,2-b]carbazole (ICZ) and β -naphthoflavone (β NF). Murine Hepa1c17 wild-type (WT) and aryl hydrocarbon nuclear translocator (ARNT) defective C4 mutant hepatoma cells were treated with either 10 nM TCDD, 1 μ M ICZ, 10 μ M β NF or vehicle (DMSO) for 1, 2, 4, 8, 12, 24 or 48 hrs. Dose-response studies at 12 hrs with WT cells exhibited EC50 values for Cyp1a1 induction of 19 pM, 21 nM and 1.6 μ M for TCDD, ICZ and β NF with varying levels of induction (293, 86, 53-fold, respectively) when compared to time-matched vehicle controls as determined using quantitative real-time PCR. Global gene expression profiles were monitored using custom cDNA microarrays containing 13,361 cDNA clones representing 8,194 unique genes. Empirical Bayes analysis of the microarray data identified 297 TCDD and 190 ICZ elicited gene expression responses differentially regulated at one or more time points. Further analysis identified 170 genes commonly regulated by both ligands, suggesting a conserved mechanism of action, while 127 gene responses were specific to TCDD and 20 to ICZ. These ligand-specific gene expression responses suggest selective AhR-mediated modulation of gene expression that may be important in the observed ligand-specific differences in toxicity. Supported by NIH T32 ES07255.

913 AN IMAGING-BASED ASSAY FOR ACTIVATION OF THE ARYL HYDROCARBON RECEPTOR: A MECHANISM-DEPENDENT, HIGH THROUGHPUT TOXICITY ASSAY FOR DRUG DISCOVERY.

M. J. Graham¹, H. Garside², N. Brown², M. Sullivan² and E. Cooke². ¹Safety Assessment, AstraZeneca, Leicestershire, Leicestershire, United Kingdom and ²Advanced Science and Technology Laboratory, AstraZeneca, Loughborough, Leicestershire, United Kingdom.

Early assessment of potential toxicity in drug discovery is now accepted as essential to the selection of candidate drugs with reduced risk of late-stage failure attributable to toxicological reasons. An important aspect of this is development of mechanism-based, high-throughput in vitro toxicity assays. Activation of the Aryl hydrocarbon receptor (AhR) can lead to wide array of toxicological responses including tumour promotion and endocrine disruption. We describe the development of a novel imaging assay able to monitor quantitatively ligand-induced receptor translocation in both immortalized cell lines and primary rat hepatocytes using specific antibodies. A confocal imaging plate reader, the IN Cell 3000 was used to image 96 well plates and algorithms were used to analyse both population data and individual cell responses. Endogenous AhR translocation and subsequent upregulation of the downstream target, CYP1A1 was monitored in mouse Hepa-1 cells, human HepG2 cells and rat primary hepatocytes in response to prototypical AhR ligands.

This assay was able to demonstrate the efficacy and potency of agonists and calculated EC50 values agreed closely with Kd values reported in the literature for the different receptor agonists tested. Furthermore, in line with published data, species-specific responses were observed. To conclude, we have established a robust, automated and quantifiable high throughput assay for the identification of AhR receptor activators in both cell lines and primary cells. We estimate this assay is able to screen 2000 compounds per week, allowing screening of compound collections for potential toxicity via activation of the AhR. This is consistent with the aim of front-loading toxicity assessment into drug discovery.

914 NON-CLASSICAL ACTIVATION OF AHR BY OMEPRAZOLE STIMULATES THE EXPRESSION OF HIGFBP-1.

I. A. Murray and G. H. Perdew. CMTC, Pennsylvania State University, University Park, PA.

It has been reported that Omeprazole (OME), a benzimidazole derived gastric proton pump inhibitor clinically used to alleviate gastric reflux disease; can stimulate the expression of CYP1A1 via activation of the Aryl Hydrocarbon Receptor (AhR) in a non-ligand binding fashion. We wished to test the specificity of OME-induced AhR activation with regard to gene expression. Human Insulin-like Growth Factor Binding Protein-1 (hIGFBP-1) is a multifunctional protein involved in regulating the bioavailability of mitogenic IGFs together with modulating integrin and other signaling cascades in its own right. Analysis of the hIGFBP-1 1Kb proximal promoter reveals the presence of a single consensus Dioxin Response Element (DRE). To test the functionality of this DRE with regard to OME induction, HepG2 cells were exposed to 0-300 μ M OME and hIGFBP-1 mRNA expression assessed by RTqPCR. OME treatment resulted in a dose-responsive stimulation of hIGFBP-1 achieving ~30 fold at the highest dose tested. Comparison with classical AhR ligands (10nM TCDD and 1 μ M β -NF) revealed OME to be a more potent inducer of hIGFBP-1 and not additive with TCDD. Antagonism of AhR with α -NF ablated TCDD-mediated hIGFBP-1 expression, however the effect on OME-mediated expression was much less pronounced perhaps suggestive of an AhR-independent effect of OME. To investigate this hypothesis, siRNA-mediated AhR "knockdown" studies were performed. Loss of AhR completely inhibited TCDD-mediated hIGFBP-1 induction, interestingly; OME-mediated induction was similarly ablated thus indicating an absolute requirement for AhR. Furthermore, reporter assays performed using the wild-type (wt) and mutant (Δ DRE) hIGFBP-1 promoter identified the requirement of an intact DRE to mediate both TCDD and OME-mediated stimulation of hIGFBP-1. These data demonstrate that non-classical i.e. non-ligand binding activation of AhR is a global phenomenon and not limited to CYP1A1. Additionally, we demonstrate that OME, acting via AhR is a potent activator of hIGFBP-1 expression and as such may impact IGF-dependent & independent signaling.

915 LIGAND-DEPENDENT INTERACTIONS OF THE AH RECEPTOR WITH COACTIVATORS IN A MAMMALIAN TWO-HYBRID ASSAY.

S. Zhang¹, C. Rowlands² and S. Safe^{3,1}. ¹Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX, ²Toxicology & Environmental Research, Dow Chemical Co., Midland, MI and ³Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX.

Halogenated aromatic hydrocarbons (HAHs), such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and 1,2,3,7,8-pentachlorodibenzo-p-dioxin (PeCDD), bind and activate the aryl hydrocarbon receptor (AhR). HAHs and many other structurally-diverse AhR agonists induce CYP1A1; however, induction of many other responses are ligand structure- and cell context-dependent. We hypothesize that HAHs may also exhibit selective AhR modulator (SAhRM)-like activity, and this was investigated by determining ligand structure-dependent differences in the interaction of AhR with a series of coactivators in mammalian two-hybrid assays. TCDD and PeCDD induced CYP1A1 in several Ah-responsive cancer cell lines including mouse Hepa-1, human Panc1, and human HEK293 cells. However, there was structure-dependent activation of luciferase activity in these same cells transfected with VP-AhR and GAL4-coactivator (SRC-1, SRC-2, SRC-3, CARM-1, PGC-1 and TRAP220) chimeras and a GAL4-response element-luciferase promoter construct. In Panc1 cells, TCDD and PeCDD induced transactivation in cells transfected with GAL4-TRAP220 and VP-AhR constructs, and TCDD, but not PeCDD, also induced activity in cells transfected with GAL4-CARM-1. In contrast, ligand-induced AhR-coactivator interactions were not observed for any other coactivators in a mammalian two-hybrid assay in Panc1 cells. The most striking difference in ligand-induced AhR-coactivator interactions in this assay was observed in HEK293 cells where TCDD induced activity only in cells transfected with the GAL4-CARM-1 chimera. In contrast, the other HAHs did not induce

AhR interactions with any of the coactivators. These results suggest that HAHs selectively interact with coactivators and these interactions are dependent on cell-context. (Supported by a grant from the Dow Chemical Co.)

916 THE ROLE OF COACTIVATORS IN THE DIOXIN-INDUCED DIFFERENTIAL ACTIVATION OF CYP1A1 AND CYP1B1.

R. T. Taylor^{1,3,4}, F. Wang^{2,3,4}, R. Zhang^{2,3,4} and O. Hankinson^{1,2,4}. ¹Molecular Toxicology IDP, University of California, Los Angeles, Los Angeles, CA, ²Pathology and Laboratory Medicine, UCLA, Los Angeles, CA, ³Jonsson Comprehensive Cancer Center, UCLA, Los Angeles, CA and ⁴David Geffen School of Medicine, UCLA, Los Angeles, CA.

2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-induced activation of cytochrome P450 1A1 (CYP1A1) and cytochrome P450 1B1 (CYP1B1) transcription is mediated by the Aryl Hydrocarbon Receptor complex (AHRC). Transcriptional regulation by the AHRC requires the coordinated recruitment of transcriptional coactivator proteins and chromatin remodeling factors. The aim of this study was to further elucidate the role of coactivators in the differential induction of two AHRC target genes CYP1A1 and CYP1B1. We have identified dioxin-dependent recruitment of several coactivator proteins, as well as, histone modifications over the CYP1A1 and CYP1B1 genes. Specifically, by use of the Chromatin Immunoprecipitation (ChIP) assay, we demonstrate a dioxin-dependent recruitment of the p300, Sp1, Brg-1, Brahma (Brm) coactivator proteins, as well as, a dioxin- and time-dependent acetylation of lysine residues on histone H4. We show that dioxin-induced acetylation of histone H4 is very robust at the promoter regions of the genes when compared to the enhancer regions. We are able to inhibit the dioxin-dependent acetylation of histone H4 by knocking down the endogenous levels of the p300 coactivator protein by RNA interference. These data implicate p300 as a regulator of dioxin-induced acetylation of lysine residues on histone H4 on responsive genes. SiRNA has also allowed us to identify the chromatin remodeling factors Brg-1 and Brm as gene specific coactivators of dioxin induction of CYP1A1. Loss of Brg-1 and Brm has a negative effect on CYP1A1 dioxin-induction, while having no significant effect on CYP1B1 induction. This indicates that the Brg-1 and or Brm proteins may play a significant role in the differential regulation of CYP1A1 and CYP1B1 in these MCF-7 human breast cancer cell lines. Our studies have lead to significant insight into these cells transcriptional response to chemical insults.

917 INTERACTION BETWEEN THE ARYL HYDROCARBON RECEPTOR AND AHR REPRESSOR IN REGULATING 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD)-RESPONSIVE GENES.

M. J. Jenny, S. I. Karchner, D. G. Franks, M. Jonsson, J. J. Stegeman and M. E. Hahn. Department of Biology, Woods Hole Oceanographic Institution, Woods Hole, MA.

The aryl hydrocarbon receptor (AHR), a member of the basic helix-loop-helix-Per-ARNT-Sim (bHLH-PAS) protein family, is a ligand-activated transcription factor that mediates transcriptional and toxic responses to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). The AHR repressor (AHRR) is a closely related bHLH-PAS family member that forms a negative feedback loop to repress AHR signaling in vitro, but the function of AHRR in vivo is not well understood. As a result of a teleost-specific genome duplication, zebrafish (*Danio rerio*) have three AHR (*AHR1a*, *AHR1b*, *AHR2*) and two AHRR (*AHRRa*, *AHRRb*) genes. To further characterize the interactive role of zebrafish AHRs and AHRRs in the transcriptional control of endogenous TCDD-responsive genes, morpholino oligonucleotides (MO) were employed in zebrafish embryos and a liver cell line (ZF-L). Zebrafish embryos were exposed to DMSO or TCDD (2 nM and 8 nM) for one hour starting at 4 hours post fertilization (hpf) and quantitative PCR was used to assess gene expression at later time points. *CYP1A1* was significantly upregulated at 24, 48 and 72 hpf in a dose-dependent manner by TCDD, while *AHRRa* and *AHRRb* were significantly upregulated at 48 and 72 hpf. A MO targeted against *AHR2* decreased the TCDD-induced expression of *Cyp1A1*, *AHRRa* and *AHRRb* by 65%, 55% and 35%, respectively, in 48 hpf larvae, demonstrating a role for AHR2 in mediating AHRR transcription. Transfection of ZF-L cells with a MO targeted against *AHRRa* failed to yield any consistent effect on AHR target genes. However, co-transfection of MOs targeting both *AHRRa* and *AHRRb* significantly increased the basal expression of *CYP1A1* by 70% and enhanced induction of *CYP1A1* by TCDD in a dose-dependent manner by an average of 45%. Although additional genes (*AHR1b*, *CYP1B1*, *CYP1C1*, and *CYP1C2*) were induced by TCDD in ZF-L cells, the *AHRRa/AHRRb* knockdown did not enhance the basal or induced expression of these genes, suggesting that regulation by AHRRs is gene-specific. (R01ES006272)

918 CHARACTERIZATION OF AN ARYL HYDROCARBON RECEPTOR REPRESSOR FROM THE FROG *XENOPUS LAEVIS*

A. L. Zimmermann, E. A. King, S. R. Scogin and W. H. Powell. Biology, Kenyon College, Gambier, OH.

Xenopus laevis and other frogs are extremely insensitive to the toxic effects of xenobiotic ligands of the aryl hydrocarbon receptor (AHR), including 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Embryos and premetamorphic life stages are especially insensitive, and they are refractory to induction of *Cytochrome P4501A6* (*CYP1A6*), the most highly induced target gene in older tadpoles. The aryl hydrocarbon receptor repressor (AHRR) is a member of the AHR gene family. AHRR expression is ordinarily induced by TCDD in an AHR- and ARNT-dependent fashion. The AHRR protein then binds ARNT and represses AHR transcriptional activity in an apparent negative feedback loop. In this study, we sought to test the hypothesis that constitutive AHRR expression underlies the lack of *CYP1A6* induction and TCDD toxicity in early frog life stages. Using an RT-PCR approach, we determined the sequence of a single AHRR cDNA encoding a protein of 85.3 kDa sharing 52-55 percent identity with the aligned bHLH/PAS domains of AHRRs from mammals and fish. In transient transfection assays, *X. laevis* AHRR inhibited TCDD-induced reporter gene expression mediated by either *X. laevis* AHR paralog, AHR1alpha or AHR1beta. AHRR mRNA was minimally detectable by quantitative RT-PCR in *X. laevis* embryos (Nieuwkoop-Faber stage 33-38; approximately 52 h.p.f.), even following overnight exposure to ³H-TCDD (59.4 ng/g wet weight). In contrast, AHRR was induced 2- to 4-fold in whole tadpoles at stages 52-55 (prometamorphic; ~4 weeks post-fertilization) and in isolated viscera of stage 62 tadpoles (in the metamorphic climax; ~7 weeks post-fertilization), even at much smaller TCDD body burdens (3-8 ng/g). Although the magnitude of induction was much smaller, the temporal pattern of AHRR expression and inducibility resembled that previously observed for *CYP1A6*. Thus, attenuated transcriptional activation of AHR target genes and low TCDD toxicity in *X. laevis* embryos cannot be explained by constitutive, high-level expression of AHRR. [NIH R15 ES011130]

919 IDENTIFICATION AND FUNCTIONAL ANALYSIS OF A HUMAN AHR REPRESSOR.

S. I. Karchner, B. Evans and M. E. Hahn. Biology Department, Woods Hole Oceanographic Institution, Woods Hole, MA.

The aryl hydrocarbon receptor (AHR) repressor (AHRR) is a bHLH-PAS protein related to AHR, but acts as a transcriptional repressor of AHR function. Additionally, AHRR expression is regulated by the AHR signaling pathway. Previous studies have characterized the repressor function of AHRRs from mice and fish, but a human AHRR homolog identified in a large-scale cDNA screen appeared to be non-functional in vitro. We have identified a novel human AHRR cDNA that lacks an internal exon of the original AHRR clone. This new AHRR is expressed predominantly in the testis, spleen, and small intestine, whereas the original cDNA is not detected in these tissues. In transient transfection assays using COS-7 cells, the new human cDNA effectively repressed the transactivation function of the human AHR expressed from an AHR cDNA. Similarly, experiments in HepG2 cells showed that the AHRR repressed the ability of the endogenous AHR to activate transcription of a luciferase reporter gene. The repression was not relieved by overexpression of any of several nuclear receptor co-activators (SRC-1a, SRC-1e, GRIP1, CoCoA, GAC63, and p300), suggesting that squelching may not be involved in the mechanism of repression. Furthermore, co-transfection of human AHRR did not affect the ability of a mouse AHR-YFP fusion protein to translocate to the nucleus. Our previous studies showed that the mechanism of repression did not involve competition for ARNT or displacement of AHR from dioxin-responsive enhancer elements. Together, these results demonstrate that humans express a functional AHRR and that the mechanism of repression is more complex than previously indicated. [R01ES006272]

920 UP-REGULATION OF THE ARYL HYDROCARBON RECEPTOR AND ITS REPRESSOR (AHRR) DURING MAMMARY TUMORIGENESIS.

S. E. Solomon¹ and D. Sherr². ¹Boston University School of Medicine, Boston, MA and ²Boston University School of Public Health, Boston, MA.

Historically the aryl hydrocarbon receptor (AhR) has been studied in the context of its ability to bind to and be activated by ubiquitous environmental carcinogens such as polycyclic aromatic hydrocarbons (PAHs). DMBA (7,12-dimethylbenz[a]anthracene) is a prototypical PAH known to promote tumors by the indirect activation of AhR. Recently the focus of research has shifted to the endogenous role of the AhR, based on studies showing high levels of constitutive AhR being present in the absence of environmental ligands. The aryl hydrocarbon receptor repressor (AhRR)

has been shown to have profound suppression of AhR activity in mammary tumors suggesting that AhRR might be an effective approach to suppressing AhR-driven tumors growth and progression. Here, the repressive effects of constitutively active and environmental ligand induced AhRR on the AhR were investigated. Female FVB mice were given six weekly doses of 1 mg of DMBA by gavage and tumors arose with 75% of them being mammary tumors. A majority of these tumors showed higher levels of AhR and AhRR protein and mRNA compared to normal mouse mammary tissue. The endogenous expression of AhR and AhRR was studied by transducing an immortalized human mammary cell line, MCF-10F, with a lentivirus construct containing a GFP-expression vector or a construct encoding both GFP and the AhRR derived from *F. heteroclitus*. Cells transduced with the GFP-AhRR construct showed significantly slower growth by ³H-Thymidine incorporation when compared to the GFP control and wild type MCF-10F cells. A reduction of AhR activity was seen in the Fh-AhRR lentivirus transduced cells while the reporter activity and endogenous AhRR mRNA were found to be over expressed in the Fh-AhRR transduced line compared to the GFP controls. Based on this, the Fh-AhRR lentivirus transduced cell line will be a potent tool to understand how AhR is regulated by AhRR in relation to mammary tumorigenesis.

921 COMPARATIVE MICROARRAY ANALYSIS OF GENE EXPRESSION IN MOUSE HEPA-1C1C7 AND B MUTANT CELL LINES - THE EFFECT OF THE AROMATIC HYDROCARBON RECEPTOR ON THE PHENOTYPE OF THE CELLS IN THE ABSENCE OF EXOGENOUS LIGANDS.

F. Wang, S. Shi, R. Zhang and O. Hankinson. UCLA, Los Angeles, CA.

Studies on the Hepa-1c1c7 line, and B mutant derivatives that are deficient for expression of AhR, have helped to elucidate the mechanism of aromatic hydrocarbon receptor (AhR)-mediated gene expression. However, little is known about the other biological processes that may differ between the wild type Hepa-1c1c7 and the B mutant cells. In this study, we elucidated the profile of genes that are differentially expressed in these cells using DNA microarray analysis. We found that a large number of genes are expressed differentially between wild type Hepa-1c1c7 and B mutant cell lines. Further study of the profile of gene expression between c12, a B mutant cell line, and c12 cells containing re-introduced exogenous AhR, using DNA microarray analysis, showed that the gene expression changes between wild type Hepa-1c1c7 and c12 is not ascribed to the deficiency in AhR in c12 cells. Previous data from our laboratory indicated that the primary defect in the B mutants resides in a transcription factor or chromatin remodeling factor. Our current data suggest that the difference in gene expression between the Hepa-1c1c7 and B mutant cells is due to absence of this factor rather than AhR. The AhR has also been demonstrated to modulate the cell cycle, differentiated state, and morphology of Hepa-1c1c7 cells independently of exogenous ligands. In this study, we found that the expression of the albumin gene, previously reported to be upregulated by the unliganded AhR, was undetectable in c19 cells, another B mutant cell line, both before and after introduction of AhR. Consistent with these findings, we also found that in c12 cells, the expression of albumin, morphology, and cell cycle parameters did not undergo any changes in response to over-expression of exogenous AhR, indicating that the expression of albumin and changes in morphology may be dependent on the aforementioned transcription factor or chromatin remodeling factor.

922 COMPARATIVE ANALYSIS OF GLOBAL GENE EXPRESSION RESPONSES ELICITED BY TCDD IN HUMAN HEPG2, MOUSE HEP1C1C7 AND RAT H4IIE CELL LINES.

E. Dere^{1,2}, A. S. Harney^{1,2}, S. S. Proper^{1,2}, L. D. Burgoon^{1,2} and T. R. Zacharewski^{1,2,3}. ¹Department of Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI and ³Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a ubiquitous environmental contaminant that causes physiological and toxic effects in a species-dependent manner. In order to gain further insight into these differences, a comparative genomic approach was utilized to examine species-specific differential gene expression responses elicited by TCDD. Mouse Hepa1c1c7, rat H4IIE and human HepG2 cells were treated with 10 nM TCDD or vehicle control (DMSO) for 1, 2, 4, 8, 12, 24 or 48 hrs. Gene expression profiles were measured using custom cDNA microarrays representing 6,293 human, 8,194 mouse or 4,717 rat genes with cross-species analysis identifying 1,860 orthologous genes. Empirical Bayes analysis identified 308, 184 and 30 differentially expressed orthologs in the HepG2, Hepa1c1c7 and H4IIE cells, respectively. Pair-wise species comparisons identified 4 differentially expressed orthologs between the Hepa1c1c7 and H4IIE cells, while 32 differen-

tially expressed orthologs were identified between HepG2 and Hepa1c1c7 cells. The limited number of differentially expressed orthologs between Hepa1c1c7 and H4IIE cells is consistent with histopathology and *in vivo* microarray results. Furthermore, species-dependent gene expression responses are in agreement with computational dioxin response element searches, which report significant species differences in the promoter and enhancer regions of targeted genes that may also contribute to the differential responses to TCDD. Collectively, these results suggest that there are significant species-specific differences in the aryl hydrocarbon receptor regulon that increases uncertainty in the extrapolation of rodent data for use in human risk assessment. Supported by NIH P42 ES04911 and R21 GM075838.

923 STAGE-SPECIFIC EFFECTS OF TCDD ON GENE EXPRESSION PATTERNS DURING DEVELOPMENT OF THE FROG *XENOPUS LAEVIS*.

D. M. Spahlinger¹, E. A. King¹, B. D. Jones² and W. H. Powell¹. ¹Biology, Kenyon College, Gambier, OH and ²Mathematics, Kenyon College, Gambier, OH.

Xenopus laevis embryos are insensitive to developmental toxicity associated with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). TCDD insensitivity has been ascribed to species-specific properties, including aryl hydrocarbon receptors (AHRs) with low affinity for TCDD. However, stage-specific mechanisms may also limit toxicity during early development, since the primary transcriptional response, CYP1A6 induction, is much smaller in embryos than tadpoles. We sought to determine whether the attenuation of CYP1A6 induction in embryos was gene-specific or indicative of broad repression of AHR-mediated transcriptional regulation in early development by comparing global changes in gene expression in embryos and tadpoles following TCDD exposure. Embryos (stage 36-37; ~50 hpf) and tadpoles (stage 52-55; 4 weeks old) were treated with vehicle or ³H-TCDD for 24 hours (5 replicates/exposure group). Embryos accumulated mean TCDD body burdens of 32 ng/g; tadpoles had 20 ng/g. Total RNA was obtained from whole animals and gene expression patterns analyzed using Affymetrix GeneChips. Using two-way ANOVA, we identified 528 genes exhibiting significantly different expression after TCDD exposure. However, most changes were very small and of questionable biological relevance. In embryos, only 3 genes were induced more than 1.5 fold, including CYP1A7 (9-fold) and CYP1A6 (2.4-fold). 12 genes were repressed more than 1.5-fold, including amino acid synthesis enzymes and extracellular matrix components. In tadpoles only 6 genes were induced more than 1.5-fold, again including CYP1A6 (11.5-fold) and CYP1A7 (10.2-fold), while only five were repressed, most encoding unknown products. Notably, CYP1A6 was more strongly induced in tadpoles, while CYP1A7 was induced to a similar degree in both stages, suggesting a stage-specific regulatory mechanism for CYP1A6. The overall low responsiveness in both stages is consistent with previous observations of low binding affinity of *X. laevis* AHRs for TCDD. [NIH ES11130; HHMI Education Grant to Kenyon College]

924 IN VIVO GENOME-WIDE LOCATION ANALYSIS OF TCDD-MEDIATED PROMOTER BINDING OF THE ARYL HYDROCARBON RECEPTOR IN C57BL/6 HEPATIC TISSUE.

J. W. Burt^{1,2,3} and T. R. Zacharewski^{1,2,3}. ¹Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³National Food Safety and Toxicology, Michigan State University, East Lansing, MI.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) exerts most, if not all of its toxicological effects through the aryl hydrocarbon receptor (AhR), a ligand activated transcription factor which binds to regulatory dioxin response elements (DREs). The *in vivo* genomic binding location of the activated AhR protein was investigated in liver samples from C57BL/6 mice treated with 30 ug/kg TCDD for 1, 2, and 4 hrs using a chromatin immunoprecipitation (chIP) assay for tissue samples. Formaldehyde cross-linked chromatin was isolated from TCDD treated and vehicle treated liver samples, and AhR bound genomic regions were antibody precipitated. PCR with primers designed against various known and putative DRE regions was performed to investigate the kinetics of AhR binding. These results show that activated AhR has a specific interaction with the previously identified DRE region of the Cyp1a1 promoter as well as the DRE-free region proximal to the transcriptional start site but not to other regions of the promoter. In addition, activated AhR interactions were characterized within regions of the Cyp1b1, Nqo1, Aldh3a1 and Por promoters containing high numbers of computationally identified putative DREs. These results complement *in vitro* studies examining AhR binding and correlate with *in vivo* hepatic gene expression studies, thus further elucidating AhR action through the identification of primary responses. Ongoing studies analyzing AhR chIP isolated DNA using microarray technology will allow for a more comprehensive identification of *in vivo* AhR interacting sites and will continue to refine the AhR regulon. Supported by grants NIH R21 GM75838 and T32 ES07255.

COMPARATIVE ANALYSIS OF THE GENOMIC BINDING LOCATIONS OF THE ARL HYDROCARBON RECEPTOR AND THE ARL HYDROCARBON RECEPTOR NUCLEAR TRANSLOCATOR IN TCDD TREATED HEPA-1C1C7 CELLS.

P. Griffin¹, J. W. Burt^{1,2,3} and T. R. Zacharewski^{1,2,3}. ¹Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³National Food Safety and Toxicology, Michigan State University, East Lansing, MI.

The aryl hydrocarbon receptor (AhR) is a ligand activated transcription factor that recognizes and binds a variety of environmental contaminants, including dioxins. Activated AhR heterodimerizes with the aryl hydrocarbon receptor nuclear translocator (ARNT), binds regulatory xenobiotic response elements (XREs) and activates the transcription of proximal genes. Global genomic binding of AhR:ARNT complexes was investigated in Hepa-1c1c7 cells following 2 hr treatment with 10 nM TCDD or DMSO using ARNT antibody chromatin immunoprecipitation (chIP) and mouse promoter tiling microarrays (chIP-chip). The AhR:ARNT-bound, enriched DNA was amplified and hybridized to a mouse promoter array, consisting of fifteen 50mer probes tiled across the regulatory region of 26,275 genes and putative coding regions, and was compared to vehicle (DMSO) treated sample. Genes associated with the regulatory regions putatively bound by AhR:ARNT complexes were identified by filtering for probe sets demonstrating a high density of enrichment. Comparisons to AhR antibody chIP-chip results showed a high degree of overlap, with 65% of the AhR-bound regions also showing an interaction with ARNT. PCR verification of chIP-isolated DNA demonstrated an ARNT interaction with the Cyp1a1, Cyp1b1, Nqo1 and Aldh3a1 promoter regions previously shown to interact with AhR. These results confirm the obligatory nature of the AhR-ARNT interaction in TCDD elicited gene expression and provide further evidence of activated AhR-ARNT binding to previously unknown XREs which warrant further investigation. Supported by grants NIH R21 GM75838 and T32 ES07255.

CHARACTERIZATION OF TCDD INDUCED HISTONE MODIFICATIONS TO STUDY THE DIFFERENTIAL REGULATION OF THE CYP1A1 AND CYP1B1 GENES.

S. B. Reddy, R. Taylor and O. Hankinson. *Molecular Toxicology, UCLA, Los Angeles, CA.*

The Aryl Hydrocarbon Receptor/ARNT heterodimer mediates carcinogenesis by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD or dioxin) and certain polycyclic aromatic hydrocarbons (PAHs) by activating gene transcription. Metabolism of PAHs by CYP1A1 and CYP1B1 plays a major role in carcinogenesis mediated by these compounds. The overall goal of this study is to understand the mechanisms involved in differential regulation of the human CYP1A1 and CYP1B1 genes. We will study the regulation of these genes in three different cell lines (MCF-7, MDA-MB 231, and HepG2) as the endogenous expression and induction levels of these genes upon treatment with TCDD differ significantly between these cell lines. Studying the differential regulation of CYP1A1 and CYP1B1 genes in these cell lines will lend more insight into which specific coactivators and protein complexes are required for expression of each gene. To elucidate the mechanisms involved in the differential regulation of these genes, we characterized the different dioxin-inducible chromatin modifications (i.e. acetylation, methylation, and phosphorylation) that occur across the CYP1A1 and CYP1B1 enhancer and promoter regions using the Chromatin Immunoprecipitation (ChIP) assay. In accordance with our hypothesis, the results from the PCR and quantitative real-time PCR analysis of ChIP samples showed that differential chromatin modifications occur across the CYP1A1 and CYP1B1 enhancer and promoter regions. These modifications, at least in part are contributing to the differential induction of these genes upon treatment with TCDD. The future aim of this study is to characterize the different histone modifying proteins and transcription factors recruited to the regulatory regions. We hypothesize that different transcription factors and cofactors are recruited to the CYP1A1 and CYP1B1 enhancer and promoter regions leading to different covalent histone modifications.

TOXICITY STUDIES OF THE DIPEPTIDE SCV-07 IN RATS AND DOGS.

S. Godin¹, E. Zahalka¹, E. Koo¹, J. Wu¹, J. Price¹ and C. Tuthill². ¹Gene Logic, Inc., Gaithersburg, MD and ²Sciclone Pharmaceuticals, San Mateo, CA.

SCV-07 (D-glutamyl-L-tryptophan) is an immune-stimulating dipeptide that is being developed as a potential treatment for various infectious diseases and other indications. The repeat-dose toxicity of SCV-07 was evaluated in a 26-week study

in rats (20/sex/group) that were administered daily subcutaneous doses of 0, 2, 5, and 10 mg/kg/day and in a 39-week study in dogs (4/sex/group) that were administered daily subcutaneous doses of 0, 0.5, 0.5, and 5 mg/kg/day. There was no evidence of adverse systemic toxicity in either species; clinical pathology results in the rat study indicated minimally lower hepatic protein production and cholesterol metabolism but it was not considered to be adverse. Plasma toxicokinetic data indicated that SCV-07 was rapidly absorbed following administration; C_{max} was reached at 0.25 h in rats and from 0.5 to 1 h in dogs. The AUC indicated that exposure to SCV-07 was dose-dependent in both species with minimal accumulation with repeated dosing. The no-observed-adverse-effect-level for systemic toxicity was 10 and 5 mg/kg/day in rats and dogs, respectively, representing 1000- and 500-fold the anticipated human dose. The potential neurotoxicity of SCV-07 was assessed in rats (10/sex/group) that were administered subcutaneous doses of 0, 25, 50, and 100 mg/kg. The functional observational battery was conducted prior to dosing, and at approximately 0.5 and 24 hours following dosing; there were no test article-related effects. A cardiovascular safety pharmacology study was conducted in a group of 4 dogs at doses of 0, 1, 5, and 10 mg/kg, and respiratory safety was assessed in the same animals following a dose of 10 mg/kg. There were no test article-related effects on heart rate, blood pressure, electrocardiography (including QT interval and QTc), respiratory rate, Sp_{O_2} , or $ETCO_2$. These results, together with those obtained from in vitro safety pharmacology studies and genetic toxicology studies, indicate that SCV-07 has an appropriate toxicological profile in animals to support the conduct of human clinical safety trials.

EVALUATION OF THE TOXICITY OF ALACRAMYN.

L. Garza-Ocanas¹, O. Torres-Alanis¹, E. Tamez de la O¹, R. Reyes-Araiza¹, V. Tamez-Rodriguez¹, J. Gonzalez-Canudas² and W. Garcia U.². ¹Pharmacology and Toxicology, Medicine School, UANL, Garza Garcia, Nuevo Leon, Mexico and ²Investigacion Clinica, Instituto Bioclon, Mexico, Distrito Federal, Mexico.

About 250,000 people are stung by scorpions every year in México. Alacramyn® is an anti-venom that has cut yearly scorpion-related deaths to 100 from 800. In the present study we evaluated the in vitro cytotoxicity of Alacramyn® as well as its safety after topical and intradermic administration in humans. Primary cultures of hepatocytes and kidney cells and Chang liver and MDOK cell lines were used for cytotoxicity studies. Alacramyn® (Lote B-4D-10) was dissolved in 5 mL of diluting agent (isotonic NaCl solution) and further dilutions were done with culture medium. Twelve different concentrations were evaluated. Cells were cultured in 96-well plates (1 x 10⁴ cells/mL). Four wells were used for each concentration tested. Culture plates were incubated for 24 and 72 h. Appropriate controls wells were included in each tray. Cytotoxicity was determined by the MTT test. For clinical studies an experimental protocol was approved by the Human Subjects Ethical Committee of our institution. Written informed consent was obtained from 40 (18-25 years) healthy volunteers. Clinical history, physical examination, laboratory analyses (blood chemistry, hematology and urinalysis) and EKG were carried out in all the cases before the study. Twenty subjects received Alacramyn® by an intradermic injection (100 microliter of 1:1000 dilution) and the other 20 by dermic patches (100 microliter of 1:100 dilution). Physical examination and evaluation of dermic reaction (NOM-033-SSA1-1993) or systemic symptoms were made after 3, 6, 12 and 24-h. Laboratory analyses were made after the evaluation periods. Cytotoxicity: Alacramyn® was no cytotoxic to Chang liver, MDOK cell lines, primary liver and kidney cell cultures in any of the period tested. Clinical evaluation: No clinically significant drug-related symptoms were found in any of the subjects. All clinical laboratory results were normal in all the cases.

THE SAFETY EVALUATION OF ITMN-191, A NOVEL ORALLY AVAILABLE HEPATITIS C SERINE PROTEASE INHIBITOR.

G. E. Dearlove¹, B. Marafino², J. T. Secrest³, E. A. Smith⁴, S. D. Seiwert⁵ and L. M. Blatt⁶. ¹Preclinical R & D, InterMune, Inc., Brisbane, CA, ²Preclinical R & D, InterMune, Inc., Brisbane, CA, ³Research Department, MPI Research, Mattawan, MI, ⁴Research Department, SNBL USA, Everett, WA, ⁵Applied Research, InterMune, Inc., Brisbane, CA and ⁶Research Department, InterMune, Inc., Brisbane, CA.

ITMN-191 is a macrocyclic, orally available HCV serine protease inhibitor with an EC50 of <0.5 nM in biochemical protease assays and an EC50 of ~2 nM in HCV genotype 1 replicon assays. The preclinical toxicity studies described below support initial Phase 1 clinical trials with the molecule.

ITMN-191 passed the acute oral limit test in rats (2000 mg/kg). Neurobehavioral evaluations (FOB and MA) conducted in rats revealed no significant neurological impairment at doses ≤600 mg/kg. The Ames test and mouse lymphoma assays (each with and without rat metabolic activation factor S9) and rat micronucleus were negative at exposure levels of ≤5000 µg/plate, ≤175 µg/mL and ≤2000 mg/kg, respectively.

The hERG channel assay and the canine Purkinje fiber APD assay each suggested no potential for cardiotoxicity. The hERG produced only 18% inhibition at 100 µg/mL and no prolongation of repolarization was noted at ≤500 µg/mL in the APD assay. An acute telemetered-primate cardiopulmonary safety study revealed no changes in cardiac or pulmonary functions at oral doses ≤600 mg/kg. The 28-day repeat-dose oral toxicity studies in rats (≤1200 mg/kg/day) and in cynomolgus monkeys (≤300 mg/kg/day), revealed no significant, prolonged or adverse/life-threatening events associated with administration of ITMN-191. Standard hematology, serum chemistry, coagulation, and histopathologic evaluations revealed no adverse effects at ≤100 mg/kg/day in monkeys and ≤400 mg/kg/day in rats. The occasional recurrent emesis and liquid stool in the high dose group monkeys were readily controlled with standard veterinary supportive therapy (antiemetics and Pepto-Bismol®). ITMN-191 was determined to be safe and well tolerated in rats and monkeys over the dose ranges and durations of exposure examined.

930 SAFETY EVALUATION OF TRASTUZUMAB-DM1, AN ANTIBODY DRUG CONJUGATE TO HER2.

T. Reynolds¹, H. Hiraragi¹, S. Kaur¹, J. Tibbitts¹, J. Yi¹, K. Achilles-Poon¹, J. Miller² and K. Williams¹. ¹Genentech, Inc., South San Francisco, CA and ²Covance, Madison, WI.

Trastuzumab-DM1 (Tmab-DM1) is an antibody drug conjugate (ADC) composed of the humanized monoclonal antibody to HER2 conjugated to the maytansine derivative DM1. Safety studies conducted with Tmab-DM1 prior to initiation of clinical trials consisted of monkey and human tissue cross reactivity, single-dose (SD) toxicity studies in rats and monkeys, SD cardiovascular safety pharmacology and multiple-dose (MD) toxicity studies in monkeys, in vitro hemolytic potential and blood compatibility, and a SD study of DM1 in rats. ADC doses of 6, 20, 60 mg/kg in rats and 3, 10, 30 mg/kg in monkeys resulted in equivalent body surface area-based DM1 doses of 610, 2040, 6120 µg/m² in both species. The Highest-Non-Severely-Toxic-Dose (HNSTD) in SD studies was 20 and 30 mg/kg in rats and monkeys, respectively, and 10 mg/kg in the monkey MD study (dosing every 3 weeks x 4). The SD HNSTD produced increases in liver enzymes, decreases in platelets and an increased number of mitotic epithelial and/or phagocytic cells arrested in metaphase. More pronounced effects on liver enzymes and bone marrow hematopoietic cells occurred in the MD study. Microscopic findings of increased mitotic figures in various epithelial tissues were consistent with the pharmacologic activity of DM1 as a tubulin polymerization inhibitor. Hypertrophy and arrested mitoses in phagocytic cells were attributed to mobilization of scavenging mechanisms secondary to the presence of heterologous protein. Axonal degeneration of the dorsal funiculus of the spinal cord and the sciatic nerve associated with hypertrophy/hyperplasia of the Schwann cells were noted in the MD study at 10 and 30 mg/kg. With the exception of the axonal lesion, all findings were reversible or significantly reduced following the recovery period. Tmab-DM1 produced no evidence of cardiotoxicity, and was compatible with human and cynomolgus blood, serum and plasma. Tmab-DM1-related toxicities were consistent with those described for maytansine.

931 TWENTY-EIGHT-DAY ORAL TOXICITY STUDY OF PERFLUOROBUTYRATE IN RATS.

P. H. Lieder¹, S. Chang¹, D. J. Ehresman¹, R. R. Roy¹, F. M. van Otterdijk² and J. L. Butenhoff¹. ¹3M Company, St. Paul, MN and ²NOTOX, 's-Hertogensbosch, Netherlands.

Perfluorobutyrate (PFBA), has been detected in surface waters and in public and private wells up to low ng/mL levels. A 28-day oral toxicity study was performed with ammonium PFBA to support risk assessment. Ammonium perfluorooctanoate (PFOA, 30 mg/kg) was used as a positive control. PFBA was given to male (M) and female (F) Sprague Dawley rats (20/sex/group) at doses of 0, 6, 30 and 150 mg/kg-d for 28 days. Half of the rats in each group were allowed to recover for 21 days. Endpoints evaluated were: clinical chemistry; hematology; body and organ weights; food consumption; gross and microscopic histology; and functional observations. Primary treatment related effects for PFBA (M only) included increased liver weights and decreases in cholesterol (30 and 150 mg/kg-d), and absence of bilateral pupillary reflex and increased serum K⁺ and inorganic PO₄²⁺ (150 mg/kg-d). Effects in M rats receiving PFOA included absence of bilateral pupillary reflex, reductions in RBC parameters (slight), body weight, weight gain, absolute food consumption (first week), total serum protein, and physical activity and health, and increases in relative feed consumption (2nd week through recovery), albumin, ALT, BUN, ALP, liver weights, and platelets. Females receiving PFOA had increased ALT, albumin, and liver weight, and reduced physical activity and health. During recovery, liver weight and cholesterol effects in PFBA treated Ms resolved as did the liver weight effects for the PFOA treated Ms and Fs, and PFOA treated rats no longer showed signs of reduced health. The slight effects on RBCs in PFOA-treated

males persisted. Major differences between male rats given PFBA and PFOA were that PFBA did not affect body weight and did lower cholesterol; whereas, PFOA caused body-weight reduction, reduced activity and health, and slight reductions in RBC-related parameters (likely not adverse). Preliminary BMDL₁₀ estimates for PFBA-induced liver-weight increase and cholesterol decrease were 10.5 and 3.4 mg/kg-d, respectively.

932 NINETY DAY REPEATED DOSE ORAL (GAVAGE) TOXICITY STUDY WITH ALPHA-ISO-METHYLIONONE IN RATS.

A. Lapczynski¹, V. T. Politano¹ and A. Api¹. ¹RIFM, Woodcliff Lake, NJ and ²RIFM, Woodcliff Lake, NJ.

alpha-iso-Methylionone was evaluated for its toxicity in a ninety day repeated dose oral (gavage) study in rats (OECD #408). The test material or vehicle (corn oil) was administered by gavage to three groups, each of ten male and females Sprague-Dawley Crl:CD® (SD) IGS BR strain rats, for ninety consecutive days, at dose levels of 0, 5, 30 and 500 mg/kg/day. The study evaluation included: clinical observations, body weight, food and water consumption, haematology and blood chemistry, ophthalmoscopic, gross necropsy and histopathological evaluation. There were no unscheduled deaths and no clinical signs of toxicity observed. No adverse effect on bodyweight, dietary intake or food efficiency and treatment-related haematology changes was detected. A statistically significant increase in both absolute and relative liver and kidney weights were observed in animals treated with 500 mg/kg/day. Males treated with 500 mg/kg/day showed a statistically significant increase in spleen weight. A significant increase in plasma creatinine, total protein and cholesterol was observed in animals from 500 mg/kg/day group. Also, males from this group showed a significant increase in plasma albumin. No abnormalities were observed at necropsy examination. Histopathology revealed an enlargement of hepatocytes in the liver (regarded as adaptive in nature) of animals treated with 500 mg/kg/day, and a greater incidence of globular accumulations of eosinophilic material in the kidney's tubular epithelium of males treated with 30 and 500 mg/kg/day, a higher incidence of follicular cell hypertrophy in thyroid and adipose infiltration of the bone marrow (indicative of marrow hyperplasia) in males treated with 500 mg/kg/day. The No Observed Effect Level (NOEL) was considered to be 30 mg/kg/day for females and 5 mg/kg/day for males. Because the kidney changes were consistent with well documented changes that are peculiar to the male rat in response to treatment with some hydrocarbons, the No Observed Adverse Effect Level (NOAEL) for males was established as 30 mg/kg/day.

933 COMPARATIVE 13-WEEK CIGARETTE SMOKE INHALATION STUDY IN SPRAGUE-DAWLEY RATS: EVALUATION OF CIGARETTES WITH TWO BANDED CIGARETTE PAPER TECHNOLOGIES.

E. H. Theophilus, K. W. Shreve, P. H. Ayres, C. D. Garner, D. H. Pence and J. E. Swauger. *Research & Development, RJRT, Winston-Salem, NC.*

This study compared the toxicological responses of Sprague-Dawley rats exposed nose-only to mainstream smoke (MS) from Test cigarettes (1, 2, and 3) with banded cigarette paper technologies (BCPT) to Control cigarettes without BCPT. Test cigarettes 1 and 2 used one technology (two band weights) while Test cigarette 3 used a different technology. Rats were exposed to humidified HEPA filtered air (Sham) or to MS at concentrations of 0.06, 0.20, or 0.80 mg wet total particulate matter/liter air. Each exposure group contained 30 animals/sex (sentinel had 20 animals/sex). The study had 2 phases (13 weeks each): MS exposure (1 hour/day, 5 days/week) and recovery without smoke exposure. Endpoints included clinical observations, respiratory physiology, hematology, serum chemistry, blood carboxyhemoglobin (COHb), serum nicotine, body/organ weights, gross pathology, and histopathology. Comparisons conducted were: Sham exposed vs. all cigarettes, Control cigarette vs. all Test cigarettes and Test 1 vs. Test 2. Control and Test MS had comparable effects on respiratory physiology, COHb, serum nicotine, serum chemistry, and hematology. While a few differences were observed, in general, Control and Test MS had comparable effects on clinical signs, body/organ weights, and gross pathology/histopathology. Consequently, exposure of rats to equivalent MS concentrations from the 4 cigarettes induced similar toxicological responses under the conditions of this study.

934 26-WEEK INHALATION TOXICOLOGY STUDY OF NEBULIZED DENUFOSOL TETRASODIUM IN SPRAGUE DAWLEY RATS.

S. Anderson¹, C. Crean¹, D. Poulin², S. Ching³, W. Peterson¹ and M. S. Cowlen¹. ¹Inspire Pharmaceuticals, Inc., Durham, NC, ²Charles River Laboratories, Montréal, QC, Canada and ³SVC Associates, Inc., Apex, NC.

Denufosol tetrasodium (denufosol) is a P2Y₂ receptor agonist in Phase 3 clinical development as a potential pharmacological therapy for cystic fibrosis (CF). Denufosol was evaluated for local and systemic toxicity following daily inhalation

administration to Sprague Dawley rats for a minimum of 26 weeks at pulmonary-deposited dose levels of 0, 3.74, 11.7 and 17.9 mg/kg body weight/day (0, 0.943, 2.69 and 3.85 mg/g lung weight/day), followed by a 4-week recovery period. Evaluations included clinical observations, body weight, food consumption, ophthalmology, clinical pathology, toxicokinetics, macroscopic observations at necropsy, organ weight and histopathology. There were no treatment related deaths during the course of the study. Group mean body weight, body weight gain, and food consumption were reduced relative to controls in mid and high dose animals. Changes in body weight gain and food consumption were reversible. There were no changes in ophthalmology, hematology, clinical chemistry, organ weight or macroscopic observations attributed to denufosol exposure. Reversible squamous metaplasia of the ventrolateral larynx epithelium was observed in high dose animals. No other microscopic changes were attributed to denufosol exposure. Due to a lack of quantifiable denufosol in plasma, no toxicokinetic analysis was performed. In conclusion, the no observable-effect-level (NOEL) was considered to be the low dose of 3.74 mg/kg/day (0.943 mg/g lung weight) based on decreased body weight, body weight gain and food consumption at higher doses. Based on histopathological findings consistent with local irritation in the larynx at the high dose, and a general lack of systemic exposure and target organ toxicity at any dose, the no observed-adverse effect level (NOAEL) was considered to be the mid-dose of 2.69 mg/g lung weight/day. The NOAEL is at least 6.8- and 14.9-times greater than the highest proposed Phase 3 clinical dose of denufosol in children and adults with CF, respectively.

935 52-WEEK INHALATION TOXICOLOGY STUDY OF NEBULIZED DENUFOSOL TETRASODIUM IN BEAGLE DOGS.

M. S. Cowlen¹, C. Crean¹, D. Poulin², S. Ching³, W. Peterson¹ and S. Anderson¹. ¹Inspire Pharmaceuticals, Inc., Durham, NC, ²Charles River Laboratories, Montréal, QC, Canada and ³SVC Associates, Inc., Apex, NC.

Denufosol tetrasodium (denufosol) is a P2Y₂ receptor agonist in Phase 3 clinical development as a potential pharmacological therapy for cystic fibrosis (CF). The objective of this study was to assess the potential toxicity and toxicokinetics of a nebulized aerosol formulation of denufosol to beagle dogs following daily oronasal administration for 52 weeks at pulmonary-deposited doses of 0 (vehicle), 29.9 and 58.5 mg/kg body weight/day (3.13 and 6.26 mg/g lung weight/day), followed by a 1-month recovery period. Evaluations included clinical observations, body weight, food consumption, ophthalmology, electrocardiography, respiratory minute volume, hematology, clinical chemistry, urinalysis, toxicokinetics, macroscopic observations at necropsy, organ weights, and histopathology of respiratory and over 40 other tissues. There were no deaths during the study. Coughing was observed sporadically during denufosol exposure. There were no changes attributed to denufosol exposure in any other parameter evaluated during the study, including lung histopathology. Toxicokinetic evaluation of plasma denufosol concentration indicated that systemic exposure to denufosol was maximal during or shortly after treatment. In conclusion, daily oronasal administration of nebulized denufosol to beagle dogs for 52 consecutive weeks at pulmonary-deposited doses of 29.9 and 58.5 mg/kg body weight/day (3.13 and 6.26 mg/g lung weight/day) produced no adverse changes in body weight, food consumption, ophthalmology, electrocardiography (including QTc interval), respiratory minute volume, clinical pathology, organ weights, or gross and histological pathology of any tissue examined. Based on a general lack of local or systemic toxicity, the no observed-adverse effect level (NOAEL) for this study was considered to be the high dose of 6.26 mg/g lung weight/day, or at least 15.7- and 34.8-times the highest proposed Phase 3 clinical dose of denufosol in adults and children with CF, respectively.

936 MAXIMUM TOLERATED DOSE AND PHARMACOKINETICS (PK) OF STARCH CONJUGATED DEFEROXAMINE (S-DFO OR 40SD02) FOLLOWING INTRAVENOUS INFUSION FOR 7 DAYS TO ADULT BEAGLE DOGS WITH 14 DAYS RECOVERY.

J. Bakke¹, L. Sharp¹, B. Hedlund², R. Swezey¹, C. Green¹ and K. Steinmetz¹. ¹SRI International, Menlo Park, CA and ²Biomedical Frontiers, Inc., Minneapolis, MN.

Chelation therapy has been shown to reduce iron-related morbidity and improve the quality of life in patients with β -thalassemia (Cooley's anemia). Currently approved therapy utilizes deferoxamine mesylate (DFO) which has a short intravenous (IV) $t_{1/2}$ requiring frequent infusions for 8-10 hr/day. S-DFO, DFO covalently bound to a soluble starch polymer, has been shown to have low toxicity, extended plasma $t_{1/2}$ and stimulate dose-dependent urinary iron excretion in a single dose study with β -thalassemia patients. In the current study, S-DFO was evaluated for PK and toxicity following daily IV administrations (total dose = 7000 mpk), 4/week (4000 mpk), 3/week (3000 mpk), 2/week (2000 mpk) followed by 14 days observation. S-DFO was very well tolerated with few clinical signs and no

clinical pathology findings up to 15 mL/kg daily dosing. S-DFO was present in the plasma up to 120 hr. Dogs receiving two infusions per week had the same plasma levels on Days 1 and 7. All other treatment regimens had higher plasma concentrations on Day 7 suggesting accumulation. The $t_{1/2}$ (~20 hr) and mean residence time (40 hr or more) support a slow clearance of the drug from the circulation ($Cl \approx 5$ mL/hr/kg after daily dose administration). The volume of distribution (0.2 to 0.4 L/kg) indicates distribution only to the extracellular body fluids. S-DFO maintains the DFO moiety in the plasma ready for iron chelation. S-DFO appears to be relatively nontoxic even at high plasma concentrations potentially offering improved chelation therapy for both acute and chronically iron-overloaded patients. This work was supported by NIDDK contract N01-DK-3-2624.

937 COMPARATIVE PHARMACOKINETICS OF PERFLUOROBUTYRATE (PFBA) IN RATS, MICE, AND MONKEYS.

S. Chang¹, J. A. Hart¹, D. J. Ehresman¹, K. Das², C. S. Lau², P. E. Noker³, G. S. Gorman³, Y. Tan⁴ and J. L. Butenhoff¹. ¹3M Company, St. Paul, MN, ²U.S. EPA, Research Triangle Park, NC, ³Southern Research Institute, Birmingham, AL and ⁴CIIT, Research Triangle Park, NC.

Perfluorobutyrate (PFBA) is a 4-carbon fluorochemical acid salt formed by industrial synthesis and the metabolism and hydrolysis of certain chemicals. PFBA has been detected in surface waters and in public and private wells at up to low ng/mL concentrations. In support of dose-setting for toxicological studies in rats and mice, and pharmacokinetic (PK) modeling in primates, we undertook a series of PK studies with ammonium PFBA (SD rats and CD-1 mice) and potassium PFBA (cynomolgus monkeys). These included: (1) elimination studies over a wide range of single oral doses (6-300 mg/kg) in non-fasted male (M) and female (F) rats; (2) IV elimination studies at 30 mg/kg in M & F rats; (3) oral uptake and elimination studies at 30 mg/kg in fasted, jugular-cannulated M & F rats; (4) elimination studies following a wide range of single oral doses in M & F mice (10-100 mg/kg); and, (5) IV elimination in M & F cynomolgus monkeys (10 mg/kg). Group sizes per dose level and sex were 3 in all cases. PK analysis of rat, mouse, and monkey data was conducted using WinNonlin® software. PFBA was determined in sera (all species), liver (rats and mice), urine (rats and monkeys), and feces (rats) using LC/MS/MS techniques. The elimination of PFBA in M & F rats was rapid and almost entirely in urine. Serum half-life ($T_{1/2}$) values in rats were 7.0-9.2 and 1.6-1.8 hrs in M & F rats, respectively. In rats, liver PFBA concentration was 20-25% of serum PFBA concentration. The elimination of PFBA in mice appeared to be biphasic with the first phase occurring at serum PFBA concentrations above 0.1-1.0 μ g/mL and giving $T_{1/2}$ values of ~17 and ~3 hrs in M & F mice, respectively. By comparison, $T_{1/2}$ of PFBA in monkeys was biphasic, with first- and second-phase $T_{1/2}$ s of 1.6-2.4 hrs and 1.7 days, respectively, with the first phase also occurring at serum concentrations above 0.1 μ g/mL. The volumes of distribution suggested that PFBA was distributed primarily in extracellular space.

938 PK/RANGE-FINDING STUDY OF WOLINASE IN RATS.

E. Glaze², W. Johnson¹, E. Majerova², S. Stinson², C. Detrisac³, D. McCormick¹ and J. Tomaszewski². ¹IIT Research Institute, Chicago, IL, ²National Cancer Institute, Bethesda, MD and ³Pathology Associates, Chicago, IL.

Lymphoblastic leukemia and lymphoma cells lack asparagine synthetase, thus they are unable to convert aspartic acid to asparagine (Asn) like normal mammalian cells. As such, these cells depend on the Asn from extracellular sources, making them particularly sensitive to asparaginase (Asp)-induced depletion of Asn in the blood. The Asp from *Wolinella succinogenes* (Wolinase) is currently in preclinical development, and like *E. coli* Asp and *Erwinia* Asp (both being used clinically), it shows strong activity in these disease models. Within 10 min of a single iv or im dose of 10,000, 30,000 or 60,000 U/m² Wolinase, circulating Asn levels in Sprague Dawley rats were depleted and remained so for 12-24 h. Dose dependent increases in Asp activities were achieved, suggesting that high concentrations of this Asp are not necessary for optimal activity. Mean Asp activities were 23 U/mL (10,000 U/m²), 78 U/mL (30,000 U/m²), and 216 U/mL (60,000 U/m²) 10 min after iv dosing, whereas mean peak Asp activities after im dosing (@90-120 min) were 0.45 U/mL, 1.89 U/mL and 2.59 U/mL for the respective doses. The iv doses of Wolinase produced the same undesirable effect on glutamine (Gln) as the other Asp, as Gln levels were completely depleted at 10 min with 30,000 and 60,000 U/m², and partially depleted with 10,000 U/m²; partial or full recovery occurred by 4 h. The im doses had no apparent effect on Gln levels. Modulation of Asn activity occurred without any treatment-related effect on clinical signs, body weight, or clinical pathology measurements. Similarly, microscopic evaluation of tissues from rats dosed with 60,000 U/m² iv and im did not reveal any treatment related effects relative to control rats. Additional studies will be required to determine if Wolinase shares the same adverse effects as the other Asp after repeat dosing, and whether it can be used as a substitute in the event of systemic allergic reactions to one of the other Asp. (N01-CM-42202 and N01-CO-12400)

939 MULTIPLE DOSE TOXICITY STUDY OF WOLINELLA ASPARAGINASE (WOLINASE) IN RATS.

W. D. Johnson¹, D. L. McCormick¹, E. R. Glaze², E. Majerova², S. Stinson², C. J. Detrisac³ and J. E. Tomaszewski¹. ¹ITT Research Institute, Chicago, IL, ²National Cancer Institute, Tucson, AZ and ³Pathology Associates, Chicago, IL.

Due to their lack of asparagine synthetase, lymphoblastic leukemia and lymphoma cells are highly sensitive to depletion of plasma asparagine by asparaginases. To evaluate the biological activity and toxicity of Wolinase, an asparaginase derived from *Wolinella succinogenes*, Sprague-Dawley rats (15/sex + 9 male satellites/group) received iv injections of Wolinase (in saline) at doses of 0, 6,000, 18,000 or 60,000 U/m² three times/week for 3 weeks. Biomarkers were assayed on timed blood samples collected after the first and last doses of Wolinase. 5 rats/sex/group were necropsied for evaluations of toxicity on Day 6 (after dose 3), Day 20 (after dose 9), and after a 28-day recovery period. Wolinase induced dose-dependent increases in asparaginase activity. At five minutes after the first and last doses, mean asparaginase activities were 2, 67, and 153 IU/mL and 14, 11, and 149 IU/mL in the low, mid, and high dose groups, respectively. Plasma asparagine was completely depleted within 5 minutes at all Wolinase dose levels, and remained undetectable for at least 24 hours in the high dose group. The high dose of Wolinase also completely depleted plasma glutamine within 5 minutes, while partial depletion of glutamine was seen at the low and mid doses. Partial or full recovery of plasma glutamine levels was seen in all groups at 4 hours post-dosing. No treatment-related clinical signs or effects on body weight, food consumption or clinical pathology parameters were observed. Several deaths were observed in the mid and high dose groups after the 7th dose, but neither macroscopic nor microscopic evaluations identified a cause of death. No treatment-related microscopic changes were observed in any high-dose animals that were necropsied after the 3rd or 9th doses. Based on lack of histopathologic effects, the NO[A]EL for intravenous administration of Wolinase using a q.o.d. x 3 schedule was 60,000 U/m². (N01-CM-42202 and N01-CO-12400)

940 SAFETY EVALUATION OF A THAI TRADITIONAL ORAL HYPOGLYCEMIC FORMULA ORM1 RECIPE COMBINED WITH A HYPOGLYCEMIC DRUG TOLBUTAMIDE IN TYPE II DIABETES MELLITUS PATIENTS.

N. Bhanidch¹, Y. Tengwattanachoti¹, Y. Pimainok², S. Supalaknaree¹ and S. Wongyai¹. ¹Oriental Medicine, Rangsit university, Mueng, Patumtani, Thailand and ²Medical Technology, Rangsit University, Mueng, Patumtani, Thailand. Sponsor: P. Singhaseni.

At present diabetes mellitus (DM) is one of serious and chronic health diseases among the world population. Hypoglycemic drugs are needed to lower blood glucose concentration. Ignorance of health care and treatment in the DM patients can be leading to complications of many diseases such as cardiovascular diseases including atherosclerosis and hypertension, renal failure, blindness and gangrene. Oral hypoglycemic drugs can be used effectively in Type II DM or non-insulin dependent diabetes mellitus (NIDDM). Drugs resistance, hypoglycemia and renal insufficiency are some examples of adverse effects among other effects frequently observed in patients using hypoglycemic drugs. Therefore, an alternative treatment of DM has been developed as a combination with traditionally used to cure DM like symptoms in Thai medicine for some hundreds years ago. In the study, "ORM1 recipe" was given orally to 100 DM volunteers; 35 male and 65 female, aged 35-55, who have used hypoglycemic drugs both orally and injection administration for a period of 3-10 years. Monitoring of blood sugar was determined as fasting blood sugar (FBS) along the 6 months period of treatment with "ORM1 recipe". Decrease in mean FBS was found related to time and gradually lower after taking the formula for 6 months comparing to mean FBS before taking "ORM1 recipe" with statistically significant difference ($p < 0.05$). For safety evaluation of the recipe, it was found no toxicity to liver, pancreas and kidney as indicated by determining no difference between levels of AST, ALT, ALP, BUN and creatinine of the patients after taking the formula for 6 months comparing to the chemical data before taking the formula.

941 CHRONIC TOXICITY OF MURAGLITAZAR, A NOVEL PPAR ALPHA AND GAMMA DUAL AGONIST.

C. R. Waites, B. E. Schilling, T. P. Sanderson and M. A. Dominick. *Drug Safety Evaluation, Bristol-Myers Squibb Pharmaceutical Research Institute, Evansville, IN.*

Chronic toxicity of muraglitazar, an oxybenzylglycine, non-thiazolidinedione peroxisome proliferator activated receptor (PPAR α and γ) agonist was assessed in rats and monkeys. Rats were given 0.3, 3, 30 or 300 mg/kg for 6 months and monkeys were given 0.4, 2, or 5 mg/kg for 12 months. Comparable groups of 20 rats per sex and 4 monkeys per sex received vehicle alone and served as controls. At the highest

dose in rats, survival was significantly decreased with deaths or moribund sacrifices in greater than 50% of the animals. No additional muraglitazar-related deaths occurred in rats or monkeys. Similar to other PPAR gamma agonists, pharmacologically mediated effects including subcutaneous edema, hematologic and/or hematopoietic and serum chemistry changes and morphologic alterations in heart and adipose tissue were observed in rats and monkeys administered muraglitazar. In rats and monkeys, liver weights were increased but were not accompanied by increased serum transaminases or correlative histopathologic alterations. Mild to moderate elevations in serum thyroxine, unaccompanied by microscopic thyroid findings were noted in monkeys administered ≥ 2 mg/kg. In female monkeys, left ventricular wall thickening (diastole and systole) and increased calculated shortening fraction were observed at the highest dose of 5 mg/kg. No differences in systemic exposure were apparent between sexes in either species. Muraglitazar exposures [AUC (0-24)] at the clinically well tolerated doses of 30 mg/kg in rats and 2 mg/kg in monkeys were 53 to 59 and 9 to 14 times therapeutic exposure, respectively. Collectively these data demonstrate that chronic administration of muraglitazar resulted in predominantly pharmacologically mediated findings at significant systemic exposures in rats and monkeys.

942 EMBRYO-FETAL DEVELOPMENT STUDY OF ALL-TRANS-RETINOIC ACID IN SPRAGUE-DAWLEY RATS.

N. Makori, S. Oneda, T. Hughes, H. Wardell, W. Congdon, B. Baker and S. Meyer. *Safety Assessment, SNBL USA, Ltd., Everett, WA.*

The purpose of this study was to validate the rat model for teratology studies by studying the adverse embryo-fetal outcomes of *All-trans*-retinoic acid in pregnant Sprague-Dawley rats. Rats were single housed in polycarbonate, solid bottom cages under controlled environmental condition. Females were mated with males on a one to one basis, and the day which copulation was designated as gestation Day 0 (GD0). Fifty-nine control animals were dosed sterile water via oral gavage from GD6 to GD17. Twenty mg/kg of *All-trans*-retinoic acid (Sigma, dissolved by DMSO in corn oil) was administered orally to 20 SD rats from GD6 to GD12. All dams were euthanized on GD20, and fetuses were examined. In dams, no treatment related effects in clinical signs were observed. Reduced body weight gain due to high resorption rate was noted in *All-trans*-retinoic acid group (hereafter treated group). Percentage of body weight in treated group to the control group was 101, 98, 96, 87 and 80% on GDs 0, 6, 12, 18 and 20, respectively. Number of implantation (16.3/16.1 in the control/treated group) and implantation rate (83.6%/87.4%) were comparable between both groups. Number of live fetuses (48.9/2.1) and fetal viability rate (98.0%/13.0%) was markedly decreased in the treated group accompanied with increased number of dead embryo-fetus (0.5/14.0) and embryo-fetal death ratio (3.0%/87.0%). Fetal weight in the treated group (male/female = 2.61 g/2.56 g) was clearly lower than that of the control group (3.76 g/3.74 g). All live fetuses in the treated group had at least one malformation, including exencephaly (97.3%), micrognathia (72.9%), anal atresia (23.3%), spina bifida (12.7%), acardate (11.7%), anophthalmia (8.3%), curled tail (8.3%), cleft palate (6.7%), hydrocephalus (1.0%), agnathia (1.0%) and short tail (1.0%). These embryotoxicity and malformations observed in this study were comparable with those reported previously. Based on these results, it was concluded that the methods used in this study are suitable for embryo-fetal development assessment.

943 TOXICOLOGICAL EVALUATION OF DIMETHICONE 350 CST AS AN INACTIVE INGREDIENT IN DRUG PRODUCTS.

V. M. Tai and J. Daniels. *Pharmaceutical & Healthcare Group, CANTOX Health Sciences Intl., Mississauga, ON, Canada.*

The U.S. FDA requires that a safety evaluation be completed for inactive ingredients that are not fully qualified by existing safety data with respect to the currently used level of exposure, duration or route of administration. Dimethicone is a polydimethylsiloxane (PDMS) which is a mixture of fully methylated linear siloxane polymers and is widely used in medical devices as well as an inactive ingredient in drug products. A detailed toxicological evaluation of dimethicone 350 cSt was conducted. Currently, FDA's Inactive Ingredient Database indicates that dimethicone 350 cSt has a maximum use level 3.7 mg administered orally. Recently conducted toxicology studies with dimethicone 350 cSt administered in 28-day and 13-week studies in Fischer rats via dietary administration demonstrated no adverse effects or target organs. The highest doses tested in the 28-day and 13-week studies were 100,000 and 50,000 ppm, respectively, which were also established as NOEL doses in the respective studies. These exposures were equivalent to 10,615 mg/kg/day for males and 11,325 mg/kg/day for females in the 28-day investigation and 3,784 mg/kg/day for males and 4,275 mg/kg/day females in the 13 week study, respectively. PDMS has also been evaluated by the Joint FAO/WHO Expert Committee on Food Additives (JECFA) which established an acceptable daily intake (ADI) for chronic human exposure of 1.5 mg/kg based on a NOEL of 0.1% in

the diet (equivalent to 150 mg/kg body weight/day) in several chronic/carcinogenicity rodent studies. For a 60 kg individual, the total daily dose would be 90 mg/day. The use of the JECFA ADI would provide a conservative estimate of the maximum human level permitted via oral route. On the basis of the conducted 28-day and 13-week studies, together with the JECFA evaluation, the use of dimethicone 350 cSt in drug products is supported at levels greater than those currently employed.

944 TOXICOLOGICAL QUALIFICATION OF HYDRAZINE.

K. L. Bibeau, L. A. Haighton, G. H. Goodfellow and J. M. Daniels.
Pharmaceutical & Healthcare Group, CANTOX Health Sciences Intl, Mississauga, ON, Canada.
