Thresholds for genotoxic impurities have recently been developed by various groups including regulatory agencies (EMEA) and industry. However, if exposures exceed the threshold, possibly due to limitations in reducing the concentration in active ingredients, or if it is an excluded compound on the basis of high potency, it is necessary to characterize the risk of the impurity and develop chemical specific concentration limits. The results for hydrazine, a genotoxic compound, which is a known metabolite and degradant of isoniazid (a treatment for tuberculosis), is presented as a case study.

In determining concentration limits of hydrazine in isoniazid active pharmaceutical ingredient, the risk level considered should be in keeping with the risk benefit ratio as it relates to the intended patient group. Thus, while a risk level of 1-in-100,000 may be recommended for a generally healthy population, a higher risk level might be supported for a more serious indication where the medication is urgently needed, particularly if it is not possible to significantly reduce levels of the impurity in the medication. Based on maximum use levels of isoniazid, to be prescribed for a period of up to one year, hydrazine exposures that correspond to risk levels of 1-in-10,000 and 1-in-100,000 were determined to be 2.3 and 0.23 micrograms/kg/day, respectively. The corresponding concentration limits for hydrazine in isoniazid for the prevention of tuberculosis in adults (assuming 300 mg/day for a period of up to 12 months) that would correspond to exposures at each of the risk levels was calculated to be 460 ppm for 1-in-10,000 and 46 ppm for 1-in-100,000. For use in children (receiving 10 mg isoniazid/kg/day) the concentrations limits for hydrazine in isoniazid corresponding to exposures at each of the risk levels were 230 ppm and 23 ppm for 1-in-10,000 and 1-in-100,000, respectively. Concentration limits for other dosing regimens (other doses or different durations of treatment, etc.) can be determined using this same methodology.

945 COMPARATIVE BIOAVAILABILITY OF SOME XANTHENE DYES AFTER ORAL AND DERMAL EXPOSURE.

H. Rothe and C. Goebel. *Human Safety Assessment, Wella Service GmbH/Procter & Gamble, Darmstadt, Germany.* Sponsor: F. Gerberick.

Xanthene dyes are generally used as color additives in drugs and cosmetics. For the safety assessment of topically applied cosmetics, e.g. hair dyes, mainly NOAELs obtained from repeated dose oral rodent studies are required and the comparison of the systemic bioavailability after oral and dermal exposure is a key consideration. In our present study, we compared the systemic exposure of three Xanthene colors halogenated to different degrees: D&C Red no. 28 > Tetrabromophenol Blue > HC Blue No. 15.

Mass balance analysis of Tetrabromophenol Blue and HC Blue No. 15 demonstrated that the major route of elimination was fecal excretion after single intravenous (> 94%), oral (>95%), and dermal (10% and 2% respectively) exposure. The high rate of fecal elimination after intravenous exposure indicated an important role of biliary excretion for both dyes. The corresponding bioavailability calculated from the plasma levels after oral exposure was 7-16% and 33-35% for Tetrabromophenol Blue and HC Blue No. 15, respectively. These findings correspond to the published data for D&C Red No. 28 (Sweet et al., 2004), demonstrating that following oral and intravenous exposure the major route of elimination is fecal and biliary excretion, and that bioavailability after dermal exposure is moderate or low. A correlation between halogenation and systemic exposure, as suggested by Sweet et al., 2004, was found, since bioavailability after oral exposure of D&C Red no. 28 with 8 halogens was comparatively lower than of Tetrabromophenol Blue (7 halogens). The highest bioavailability after oral dosing was found for HC Blue No. 15 (2 halogens).

Bioavailability after dermal exposure of Tetrabromophenol Blue, HC Blue No. 15, and D&C Red No. 28 was analyzed by in vitro skin penetration studies, indicating a extremely low systemic exposure rate below 0.03 % of the applied dose.

We conclude that the bioavailability of Xanthene dyes after oral dosing is 3-4 decimal orders of magnitude higher than after dermal exposure.

946 SAFETY PHARMACOLOGY: AUTOMATED ASSESSMENTS OF NEUROMUSCULAR DEFICITS USING ACRYLAMIDE IN SPRAGUE-DAWLEY RATS.

E. J. Martinez¹, G. Gagnon², L. Grantham² and T. K. Brabham². ¹*University of New Mexico, Albuquerque, NM* and ²*Pfizer Global Research and Development, Ann Arbor, MI.*

Acrylamide, a classic peripheral neurotoxicant, was used to assess the sensitivity of an automated behavioral test system for neuropathy. Neuromuscular deficits were assessed in the rat following single intraperitoneal doses of acrylamide for 5 days. Thirty-two male Sprague-Dawley rats, assigned to 4 dose groups (N=8) were given acrylamide at 0 (saline), 5, 25 and 50 mg/kg. Evaluations for neurotoxicity were performed on test days-2, 5 and 8. As part of a "functional observational battery" testing regimen, animals were assessed using a 2-tiered approach. Tier I quantified sensorimotor activity in response to exercise procedures. Tests included Cage-side Observations, Open-field Assessments, Locomotor Activity, Body Weight, Forelimb Grip Strength and Hindlimb Footsplay. Tier II procedures measured overt changes in response to forced exercise endurance testing and included Forced Running Wheel and Treadmill. Greatest impact following acrylamide exposure was measured on Test Day 5 or after. Cage-side observations showed clinical signs associated with acrylamide were dose-dependent, increasing in incidence and severity with increases in dose. Changes in open field behavior were only detected at the high dose. Also at the high dose, locomotor activity tests showed a 64% decrease in Vertical Movement and a 35% decrease in Total Distance traveled¹. Body weight decreased 8% in the 50mg/kg dose group, compared to controls. There was no significant difference detected in dose-groups using forelimb grip strength, hindlimb footsplay and treadmill. Forced Running Wheel revealed a 19% decrease in duration on wheel and an increase in incidence of coasting¹. Results from this study indicate that the automated *in vivo* neuromuscular test battery was a sensitive and valid model for detecting drug-induced neuropathy; and that acrylamide is a suitable positive control for defining peripheral nerve loss of function.

¹ Results depict significant 50mg/kg acrylamide value differences as compared to vehicle control (p ≤ 0.05).

947 OCULAR EVALUATION OF POTENTIAL OCULAR TOXICITY IN REGULATORY NON CLINICAL SAFETY STUDIES.

O. M. Logez. *Non-Clinical Safety, Addex Pharmaceuticals SA, Plan-les-Ouates/GenÈve, Switzerland.*

Regulatory non-clinical safety studies are required before EIH (Entry Into Human) in order to predict possible side-effects of administration of new pharmaceuticals. Such studies comprise ophthalmic examinations and are carried out in at least one rodent (generally rats, mice or hamsters) and one non-rodent species (generally dogs, non-human primates or minipigs). Risk assessments regularly identify visual system deficits in chronically exposed individuals.

After some considerations on ocular exposure, toxic mechanisms of action, guidelines and their consequences for regulatory testing visual function are discussed. Regulatory guidelines state that ocular investigations should be performed prior to administration of a test substance and at the termination of the non-clinical safety studies (end of treatment period and eventually end of treatment-free period) using appropriate equipment. The choice of this equipment is the responsibility of ophthalmologists and will be further detailed.

We describe then the normal ocular pattern of different non-rodent species alternative to dog used in ocular toxicology, as well as some ocular findings, in order to define the main variants and to compare them in different species used in toxicology studies.

There will be additional demand in future for less common animal models, notably for species whose metabolic assimilation of the drug under investigation is as close as possible to that of man.

948 N-METHYL-N-NITROSOUREA (MNU): A ROBUST POSITIVE CONTROL AGENT FOR P53+/- MOUSE CARCINOGENICITY STUDIES.

K. L. Bailey¹, C. L. Stout¹, K. A. White¹, D. Morton² and D. J. Ball². ¹*Drug Safety Research & Development, Pfizer, Inc., Kalamazoo, MI* and ²*Drug Safety Research & Development, Pfizer, Inc., Groton, CT.*

The typical positive control agent for p53+/- mouse carcinogenicity studies, p-cremidine, has demonstrated inconsistent results that in some cases could invalidate a study. Treatment of p53+/- mice with a single intraperitoneal dose of N-methyl-N-nitrosourea (MNU), a DNA alkylating agent, produced malignant lymphoma (T-cell lymphoma) of the thymus in 80% of males and 90% of females. These tumors were identified at necropsy as thymic masses or enlargements in all affected animals, excepting 1 male. The high incidence of neoplasms in treated animals, cou-

pled with the close correlation of gross and microscopic findings, suggests that a single intraperitoneal dose of MNU at 75 mg/kg represents a suitable positive control model for 6-month p53+/- carcinogenicity studies. The high incidence of thymic malignant lymphoma in both sexes suggests that it should be possible to examine only the thymus in positive control p53+/- mice treated with MNU.

949 ARE DUAL CONTROL GROUPS NECESSARY FOR CARCINOGENICITY STUDIES? AN EVALUATION USING MOUSE DATA.

P. Baldrick and L. Reeve. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: D. Everett.

Although current regulatory thinking allows for the use of single control groups for rodent carcinogenicity testing, it has been argued that dual control groups are vital in the identification of tumorigenic risk potential in these studies. However, whether this is indeed the case has had little coverage in the published literature? A recent evaluation of dual control carcinogenicity data in the rat (Baldrick, *Tox Path* 2005, 33: 283-291) showed that although no major differences in tumor incidences between the control groups were found, some inter-study variation occurred and in cases were a notable difference was seen, the use of 2 control groups, as well as robust, contemporary background data, allowed an easier interpretation of findings in drug-treated groups. As a follow-up to this investigation, the incidence of tumors from 10 mouse carcinogenicity studies, performed between 1991 and 2004, with 2 control groups, was examined. As in the rat, inter-study variation was seen and in some cases, the use of dual control groups assisted in the tumor risk assessment. Thus, the continued use of 2 control groups can have a vital role in mouse carcinogenicity studies.

950 MORTALITY AND IN-LIFE PATTERNS IN HAN WISTAR RAT TUMORIGENICITY STUDIES, COMPLETED OVER THE PERIOD OF 1994 TO 2006.

W. Hooks, C. J. Groom and M. Lelasseux. *Toxicology, Huntingdon Life Sciences, Huntingdon, Cambridgeshire, United Kingdom.* Sponsor: C. Hardy.

Previous reviews of Han Wistar (HsdBrl:WH) rat tumorigenicity studies, completed over 1994 to 2000, indicated that the strain had a high survival rate, a satisfactory tumour profile not masked by geriatric lesions, and was a suitable strain for use in tumorigenicity studies. The purpose of this review of up to 35 studies, completed up to 2006, was to establish if the strain was still performing as expected in tumorigenicity studies by comparing possible differences over time and also between the dietary and oral gavage routes of administration, by evaluation of mortality, bodyweight and food consumption data. All these studies used low protein diet and the animals were gang-housed. The analyses have shown that the mortality values at termination (104 weeks) were low, with mean and standard deviation values of $24 \pm 6.5\%$ for males and $32 \pm 8.8\%$ for females. Statistical analyses of the terminal mortality against time (1994-2006) did not reveal any significant trends in either sex, for all studies or separately by route of administration. The terminal mortality values for oral gavage studies were slightly, but not statistically significantly, higher for both sexes when compared with dietary studies, with the mortality over 2 years showing a similar pattern for both routes. There were no major differences over time or between the routes of administration for bodyweight growth pattern, bodyweight gain and food consumption data. In conclusion, the results indicate that the Han Wistar rat continues to show a low mortality pattern with no indication of any major differences over time or between the routes of administration for mortality or in-life data, and therefore the strain continues to be suitable for use in tumorigenicity studies.

951 HISTOPATHOLOGY HISTORICAL CONTROL DATA FROM DOGS AND MONKEYS.

S. Goel, X. Mu, L. Carter and V. Laast. *Covance Laboratories Inc., Vienna, VA.*

Histopathology data constitute a critical part of the safety evaluation information submitted to regulatory agencies in support of the safety evaluation of new drugs or chemicals. Historical control pathology data have been shown to be valuable in the interpretation and evaluation of results from safety evaluation studies. The Registry of Industrial Toxicology Animal data (RITA) was developed to collect historical control neoplastic data in rodents. However, similar historical control data for non-neoplastic findings are generally unavailable in a single database for non-rodent species. Histopathology data from control dogs and monkeys were compiled and reviewed from safety evaluation studies conducted at Covance Laboratories, Virginia during the past 10 years (1996-2006). Most commonly occurring microscopic findings in control animals are presented and categorized based upon the length of dosing (4, 13, or 52 weeks) and the route of administration (oral gavage

or IV bolus). Some of the more common microscopic findings in the dog from the database included: renal mineralization characterized by the presence of basophilic concretions within the lumen of the tubules, primarily affecting the renal papilla; inflammation of the liver characterized by randomly distributed focal aggregates of lymphocytes and macrophages; and inflammation of the lung characterized by intra-alveolar macrophages and randomly distributed focal aggregates of mononuclear cells. Common microscopic findings in the monkey from the database included: renal mineralization similar to that observed in the dogs in addition to foci of inflammation characterized by infiltration of the cortical interstitium with lymphocytes and macrophages; inflammation of the liver and lungs similar to that observed in the dog; the presence of pigment (parasite origin) in the lungs; and inflammation of the heart characterized by randomly distributed aggregates of lymphocytes and macrophages. The use of historical control data in supporting interpretation of safety evaluation studies has its benefits. The data does however, have limitations and must be used prudently.

952 THE EFFECT OF PARTICLE SIZE ON THE LOCAL TISSUE CHANGES ASSOCIATED WITH THE INTRAMUSCULAR ADMINISTRATION OF DEPOT FORMULATIONS IN RABBITS.

M. Knickerbocker¹, W. P. Beierschmitt¹, A. M. Ryan¹ and J. C. Shah². ¹*Drug Safety Research and Development, Pfizer Inc., Groton, CT* and ²*Pharmaceutical Sciences, Pfizer Inc., Groton, CT.*

As part of an effort to identify and develop a long duration intramuscular (IM) injection of the atypical antipsychotic ziprasidone, the irritation potential of several proposed IM depot formulations at the injection site was evaluated in an in vivo rabbit model. Two of the formulations investigated were aqueous suspensions containing 210 mg/mL ziprasidone: one consisted of micron-sized particles of drug, while the other consisted of nanoparticles of drug with a mean particle size <500 nm. When administered intramuscularly in rabbits, both formulations were well tolerated; however, the gross and microscopic tissue changes at the injection sites demonstrated that the nanoparticle formulation was considerably less irritating. Microscopic changes, initially characterized by hemorrhage, myofiber degeneration, and mononuclear cell infiltrates with subsequent myofiber regeneration and fibroplasia, were produced with both formulations but were more severe and persisted longer with the micron-sized formulation. With both formulations, injected drug was still visible grossly within the muscle at study termination 4 weeks post-dose. Microscopically, there was a pronounced foreign body inflammatory cell reaction with the micron-sized formulation that was not observed with the nanoparticle formulation. Pharmacokinetic studies in dogs indicated that the nanoparticle formulation additionally increased bioavailability and led to greater and more prolonged depot-phase systemic exposure. These findings suggest that nanoparticle technology may warrant consideration as a formulation tool during the development of parenteral drugs.

953 CYTOKERATIN AND KI-67 EXPRESSION IN THE EPITHELIUM OF THE CANINE LARYNX.

C. M. Bray, C. L. Scudamore, P. A. Long and A. Postoyalko. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: D. Everett.

The larynx is a potential target organ in inhalation studies and is a standard tissue for histological examination on repeat dose toxicity studies (CPMP/SWP/1042/99). There is limited information on the microscopic anatomy of the normal canine larynx therefore a preliminary study was performed to map the epithelium.

Larynges from five, 18 month old, control Beagle dogs were collected at necropsy, fixed in formalin and processed routinely. Five cross sectional samples were cut through each larynx from the epiglottis to the first tracheal rings. Sections were stained with haematoxylin and eosin and by immunohistochemistry for a limited panel of cytokeratins (CK) and the proliferation marker Ki67. Twelve pre-selected areas of epithelium from each larynx were examined microscopically and by image analysis.

The epithelium was uniformly squamous through the main body of the larynx becoming pseudo-stratified abruptly at the cranial trachea. The mean number of layers in the squamous epithelium was generally 2 to 4 but it was significantly thicker (5 to 6 layers) at the ventral epiglottis and ventral floor of the glottis. There was a strong correlation between the number of layers of epithelium and the number of Ki67 positive nuclei/ μm ($r^2 = 0.4$; $P < 0.0001$). All epithelia stained positively with anti-pan-cytokeratin antibody. In addition the squamous epithelium was positive for CK4 and negative for CK18. The pseudo-stratified epithelium was positive for CK4 and CK18 and the submucosal glands were positive for CK18 and negative for CK4.

The results provide a baseline against which potential induced toxicological changes in the laryngeal epithelium can be assessed.

954 THE ROLE OF DOSING REGIMEN IN PPAR-INDUCED PHARMACOLOGIC EFFICACY AND SKELETAL MUSCLE DAMAGE IN RATS.

W. E. Maier. *Toxicology, Pfizer Inc., Ann Arbor, MI.*

Peroxisome proliferator-activated-receptor (PPAR) agonists are soluble nuclear hormone receptor agonists that bind to specific PPAR DNA response elements and activate a number of genes predominantly involved in lipid homeostasis. One untoward effect of PPAR agonism is skeletal muscle damage, which occurs in multiple species. Compound A is a PPAR agonist with dual beta/alpha agonist activity (PPAR β/α) designed to treat hyperlipidemia. Previously, Compound A was shown to produce skeletal muscle damage in male rats following 10 consecutive days of dosing at 50 mg/kg. The present study in rats was undertaken to determine the role of dosing frequency on pharmacologic efficacy and skeletal muscle toxicity. Efficacy was measured by effects on peroxisomal liver oxidation activities, and toxicity was evaluated by histologic changes in skeletal muscle architecture. In this study, animals were given 10 doses of Compound A either daily or every other day and necropsied. At termination, all animals given daily doses of Compound A had minimal to moderate skeletal muscle damage, and elevated creatinine kinase (CK) activities, relative to controls. In animals given Compound A every other day, the incidence and severity of skeletal muscle damage was similar as noted in their respective control group and mean CK activity was not elevated. Liver acyl CoA oxidase and fatty acid beta-oxidation activities were elevated in drug-treated groups above respective controls (up to 7-fold) and were comparable between the treated groups regardless of regimen. These data indicate that intermittent dosing of a PPAR β/α agonist can achieve similar pharmacologic activity as seen with daily dosing yet not produce untoward skeletal muscle injury.

955 COMPARISON OF TWO GASTRIC EMPTYING MODELS (CHARCOAL MEAL AND GLASS BEAD) IN RATS: EFFECTS OF MORPHINE AFTER ORAL AND SUBCUTANEOUS ADMINISTRATIONS.

B. Klatt, G. P. Thomas, W. Allen, L. Varner and C. Spainhour. *Pharmacology, Calvert Laboratories, Inc., Olyphant, PA.*

Gastric emptying studies are routinely used in safety assessment to ascertain the potential effects of new drugs on gastro-intestinal function. Charcoal meal model is very commonly utilized in GI studies, however, charcoal absorbs many substances. The present study compares the efficacy of morphine administered subcutaneously and orally to inhibit the gastric emptying in an effort to compare these models. Two groups of rats were administered with morphine orally or subcutaneously while another two groups were similarly administered with the vehicle. Fifteen minutes after the subcutaneous and 30 minutes after the oral doses of morphine or vehicle, rats were administered with a 10% suspension of activated charcoal at 3 mL/rat. Rats were euthanized 30 minutes after receiving the charcoal. The stomach (with contents) was excised, weighed and the "full weight" was recorded. The contents of the stomach were then removed, the stomach again weighed, and the "empty" weight recorded.

Two other groups of rats were administered with morphine orally or subcutaneously while another two groups were similarly administered with the vehicle. Fifteen minutes after the subcutaneous and 30 minutes after the oral doses of morphine or vehicle, rats were administered 60 glass microspheres (1000-1190 μ m in diameter, suspended in 1.0 mL of saline) by oral gavage. Rats were euthanized 30 minutes after receiving the glass microspheres, and the microspheres remaining inside the stomach counted from each rat.

Morphine (5mg/kg) after subcutaneous administration produced a 33% decrease in gastric emptying in the charcoal meal model, while in the glass bead model the inhibition was 47%. Similarly after oral administration, morphine (30 mg/kg) inhibited gastric emptying by 65% and 63% in charcoal and glass bead models respectively. The present study thus suggests that both charcoal meal and glass bead models are equally effective if the study design provides adequate contact time for the test article.

956 EVALUATION OF ADVERSE EVENT SAMPLING BIAS.

S. Ulloa¹, K. C. Findley^{1,2}, G. Casella³ and C. J. Borgert^{1,4}. ¹*Applied Pharmacology and Toxicology, Inc., Gainesville, FL*, ²*North Florida South Georgia Veterans Health System, Gainesville, FL*, ³*Department of Statistics, University of Florida, Gainesville, FL* and ⁴*C.E.H.T., Department Physiol. Sciences., UF College of Vet. Med., Gainesville, FL.*

As Americans consume increasingly complex combinations of prescription medications and dietary supplements, the concern for adverse events attributable to interactions between these agents increases accordingly. An emerging problem that will likely affect clinicians' perceptions and expert judgments about interactions stems from the use of anecdotal adverse event reports (AERs) to evaluate drug and dietary supplement safety. The only broad-based collection of information concerning

AERs from drugs and supplements is the FDA-sponsored voluntary reporting system, which does not provide a representative sample of adverse events in the population. We have evaluated the literature on AERs with respect to the statistical tests that might be used to estimate adverse event prevalence and incidence, and the inferences that can be drawn from those tests. We found at least two underlying sources of bias inherent in the statistical tests when using non-randomly sampled data: first, adverse event reports for specific outcomes are often recruited through advertising, producing a database that reflects trends in reported associations due to fluctuations in public awareness and worse, is vulnerable to reporting of associations influenced by special interests. A second type of bias results from over-reporting of disease or adverse events. It may seem that a well-studied population is very ill, but in reality, that perception can be created simply from an increased amount of information. The FDA is considering changes to the voluntary reporting system to minimize sampling bias. Until improvements are made, particularly regarding the use of the database in product liability litigation, reporting bias must be recognized and accounted for.

957 PREVENTION OF CROSS-CONTAMINATION IN CANINE NON-CLINICAL SAFETY STUDIES.

J. E. Burnett and S. Turner. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: *D. Everett.*

Rigorous management of non-clinical safety studies to prevent cross contamination of control animals, or the samples from control animals, with test substance is required by the regulatory authorities. This poster describes how cross contamination was successfully prevented during a non-clinical safety study conducted in the dog over a 52 week period.

Areas considered during the planning and in-life phases of the study were:

The pharmacology of the test substance

Formulation procedures

Housing and welfare of the animals

Blood sampling and processing procedures

As a result of the considerations made and subsequent preventative measures taken, interpretation of the toxicokinetic, in-life and histopathological data was straight forward allowing an adequate assessment of the risk to human safety and the submission of valid study to the regulatory authorities.

958 INTERACTIONS BETWEEN CHEMICALS AND DRUGS IN THE WORKPLACE. IS THERE A CAUSE FOR CONCERN?

A. Vyskocil, C. Lapointe and C. Emond. *Environmental and Occupational Health, University of Montréal, Montréal, QC, Canada.*

Workers are frequently exposed to mixtures of chemicals. Additionally, they intentionally use different prescription and over-the-counter drugs to treat various health conditions. Acetylsalicylic acid (AAS), acetaminophen and cimetidine are the most non-prescription drugs used. In respect of worker's life privacy and because of ignorance, the potential interactions between drugs and workplace chemicals are not usually considered. It appears that a better understanding of interactions between drugs and workplace chemicals may contribute to diminish the risk of toxic effects. The objective of this study was to identify binary interactions between drugs and regulated toxic substances found in workplaces (principally solvents and pesticides). Information was drawn from primary references available on TOXLINETM and PubMedTM databases. Human as well as animal studies were evaluated. Since at massive doses most chemicals would cause polysystemic effects, the interactions were evaluated only for realistic exposure concentrations of workplace chemicals up to the short-term exposure limit or ceiling value or five times the 8-h time-weighted-average (TWA) permissible exposure limit (PEL) for human data and up to 100 times the 8-h TWA PEL or ceiling value for animal studies. Only few reasonable human and animal studies were identified involving almost exclusively non-prescription drugs. Thus, 26 pairs of binary co-exposures of drugs and workplace chemicals from 20 studies were identified. From them 7 pairs presented potentiation effects, 7 presented kinetic inhibitions and 12 reported no interactions. For example, AAS potentiates ototoxic and developmental effects of toluene and phenobarbital potentiates hepatotoxic effects of trichloroethylene and carbon tetrachloride. This review highlights a lack of toxicological studies evaluating co-exposure of drugs and workplace chemicals for realistic exposure concentrations. An effort in this field might help scientists to understand changes in the metabolism and toxic effects of workplace chemicals due to co-exposure to drugs.

959 ELECTRORETINOGRAM (ERG) RECORDING IN THE DOGS, RABBITS, MONKEYS AND MINI-PIGS.

A. Patel and M. Vezina. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.*

Assessment of visual response can be evaluated through recording of electroretinograms (ERG) to provide indicators of the health and the physiological function of the retina, specifically rod and cone response. For compounds administered by in-

travertine injection, ERG evaluation is an important parameter, as the compound is in direct contact with the retina, and is especially important if there are prolonged effects on intraocular pressure (IOP) or if the compound is blood-retina barrier permeable. In our Laboratory, ERGs are obtained using an UTAS-E 3000 or UTAS-E 4000 ERG recorder and an automated Ganzfeld Dome. ERG Jet® contact lens electrodes are applied to each eye, along with an intradermal reference electrode and a ground electrode. Dogs, rabbits, monkeys and mini-pigs are anesthetized, a topical anesthetic is applied and for mini-pigs a small suture is used to maintain the eye position. Following at least 30 minutes dark adaptation, eyes are tested using a series of scotopic and photopic flash stimuli. Each ERG occasion consists of a series of 3 scotopic single flash ERG, from dim to bright light (-30 to 0 dB), with variable duration between each flash to assess rod activity alone and rod/cone activity combined. Following the scotopic ERG sequence, animals are adapted for 5 minutes to background light at 25-30 cd/m², followed by an average of 20 sweeps of photopic white flicker at 1 Hz, and 20 sweeps of photopic flicker at 29 Hz, to assess cone function. Parameters typically measured are a-wave and b-wave amplitude and implicit time.

Our studies show ERG data/trends are reproducible, however, individual variation should be considered since inter-eye variability in the same animal can be 30-35%. ERG data should also be evaluated in conjunction with ophthalmology, tonometry and histopathology, to provide perspective on possible changes. ERG can be a valuable parameter for determining early onset of retinal damage and consequently a vital marker in subsequent clinical trials.

960 *IN VITRO* HEPATIC METABOLISM OF N-ALKANES, NONANE, DECANE AND TETRADECANE.

S. S. Anand, J. L. Campbell and J. W. Fisher. *Environmental Health Science, University of Georgia, Athens, GA.*

Exposure to jet propellant 8 (JP-8) jet fuel is a major public health concern. JP-8 is a complex mixture of aromatic and aliphatic hydrocarbons. Semi-volatile n-alkanes of C₉-C₁₄ make up significant proportion of JP-8. While toxicity of these alkanes has been reported, information on metabolism is very limited. The aim of this study was to determine Michaelis-Menten constants for the metabolism of nonane (C₉), decane (C₁₀) and tetradecane (C₁₄) by rat liver cytochrome P450s (CYPs) *in vitro*. The metabolism was assessed by measuring disappearance of parent compound. Various concentrations of n-alkanes were incubated with liver microsomes from adult male F344 rats in presence and absence of NADPH. The incubation conditions varied with compound; nonane - 1 mg microsomal protein and 30 min incubation; decane - 1 mg microsomal protein and 60 min incubation and tetradecane - 1-5 mg microsomal protein and 30-120 min incubation. The parent compounds were measured by gas chromatography. Nonlinear kinetic constants for nonane and decane were: V_{max} (nmol/mg protein/min) - 7.26±0.20 and 2.80±0.35, respectively and K_m (μM) - 294.83±68.67 and 398.70±42.70, respectively. Metabolic capacity of CYPs as assessed by intrinsic clearance (V_{max}/K_m) was 5-fold higher for nonane (0.03±0.005) than that of decane (0.007±0.001). There was no appreciable metabolism of tetradecane even with higher microsomal protein concentration (5 mg protein/ml) and longer incubation time (120 min). The results of the present study show a negative correlation between metabolic clearance and chain length of n-alkanes, suggesting that longer the chain, slower the metabolic clearance and higher the internal exposure. The metabolic rate constants reported in this investigation will be useful in the development of a physiologically-based pharmacokinetic model for JP-8 exposure and toxicity (Supported by AFOSR grant F49620-03-0157).

961 METABOLISM OF 1-FURAN-2-YL-3-PYRIDIN-2-YL-PROPENONE, AN ANTI-INFLAMMATORY PROPENONE, IN RAT BY LIQUID CHROMATOGRAPHY-ELECTROSPRAY IONIZATION TANDEM MASS SPECTROMETRY.

T. Jeong, S. Lee, D. Lee, H. Jeong, S. R. Bista, E. Lee and H. Chang. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, South Korea.*

1-Furan-2-yl-3-pyridin-2-yl-propenone (FPP-3) has been characterized to have an anti-inflammatory activity through the inhibition of the production of nitric oxide and tumor necrosis factor-α. In the present studies, *in vitro* and *in vivo* metabolisms of FPP-3 were investigated in male Sprague-Dawley rats. When FPP-3 was incubated with rat liver microsomes and cytosols in the presence of NADPH, 2 major peaks were detected on LC/ESI-MS. Two metabolites (i.e., M1 and M2) were characterized as reduced forms on propenone: M1 (1-furan-2-yl-3-pyridin-2-yl-propan-1-one) was the initial metabolite and M2 (1-furan-2-yl-3-pyridin-2-yl-propan-1-ol) was a secondary alcohol. Following a single intravenous injection of male Sprague-Dawley rats with 4 mg kg⁻¹ of FPP-3, three different metabolites of FPP-3 were identified as M1, M2 and M3 (a glucuronide conjugate of M2) in rat urine by LC/ESI-MS. Although all metabolites of FPP-3 were identified in rat

urine, M1 and M2 except M3 were observed in the bile and feces. Pharmacokinetic parameters for FPP-3 and its metabolites were determined at the same time by using high-performance liquid chromatography-ultraviolet spectrometry. (Supported by a grant from KOSEF and a BK 21 grant)

962 CHARACTERIZATION OF THE ENZYMES INVOLVED IN THE *IN VITRO* METABOLISM OF 1-FURAN-2-YL-3-PYRIDIN-2-YL-PROPENONE, AN ANTI-INFLAMMATORY PROPENONE COMPOUND.

S. R. Bista, S. Lee, D. Lee, C. Kim, H. Jeong, M. Kang, E. Lee and T. Jeong. *Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, South Korea.*

Carbonyl reduction is a significant step in the phase I biotransformation for a great variety of aromatic, alicyclic and aliphatic carbonyl compounds. 1-Furan-2-yl-3-pyridin-2-yl-propenone (FPP-3) has been characterized to have an anti-inflammatory activity through the inhibition of the production of nitric oxide and tumor necrosis factor-α. In the present studies, the metabolic fate and a possible involvement of 11β-hydroxysteroid dehydrogenase (11β-HSD) and carbonyl reductase (CBR) in the metabolism of FPP-3 were investigated in rat liver subcellular fractions. When FPP-3 was incubated with rat liver subcellular fractions in the presence of NADPH, two major peaks were detected by reduction on the propenone: M1 (1-furan-2-yl-3-pyridin-2-yl-propan-1-one) and M2 (1-furan-2-yl-3-pyridin-2-yl-propan-1-ol). The pH optimum for metabolism of FPP-3 was around 6.5. Selective inhibitors of CBR, such as quercitrin, ethacrynic acid and menadione, significantly increased the formation of M1, but effectively inhibited the formation of M2 in subcellular fractions. Moreover, 18β-glycyrrhetic acid, an 11β-HSD selective inhibitor, significantly inhibited the reduction of FPP-3 in microsomes. In correlation studies, good correlation was observed between the formation of M2 and CBR activity with 4-pyridine carboxaldehyde (r=0.72) and D,L-glyceraldehyde (r=0.63) as substrates in cytosol, respectively. The present results indicated that FPP-3 might be metabolized by microsomal 11β-HSD and cytosolic CBR in rats. (Supported by a grant from KOSEF and a BK 21 grant)

963 CYTOCHROME P450-CATALYZED INDOLINE DEHYDROGENATION IS A NOVEL AROMATIZATION PROCESS.

H. Sun, C. A. Reilly, D. L. Lanza and G. S. Yost. *Pharmacology & Toxicology, University of Utah, Salt Lake City, UT.*

Indoline derivatives possess therapeutic potential in a variety of drug candidates. In this study, we found indoline is aromatized by P450 enzymes to produce indole through a dehydrogenation pathway. Similarly, 3-substituted indoles like 3-methylindole and zafirlukast are dehydrogenated to form 3-methyleneindolenine electrophiles, which react with protein and/or DNA nucleophilic residues to cause toxicities. The aromatization of indolines is likely to change the therapeutic properties of these compounds. Indole was indeed efficiently produced by human liver microsomes (K_m = 194 μM, k_{cat} = 1.5 min⁻¹), and CYP3A4 had the highest "aromatase" activity (K_m = 135 μM, k_{cat} = 2.9 min⁻¹). Additionally, four other indoline metabolites (M1-M4) were characterized. M1-M4 were not metabolites of indole. M1, mainly produced by CYP2D6 and CYP3A4, appeared to be an unstable arene oxide, but its GSH adduct was characterized by LC/MS/MS. M2, M3 and M4 were produced by FMO3. Characterization of these metabolites showed that indoline is oxidized to N-hydroxyindoline (M3) and an unstable intermediate indoline nitron, which tautomerized to form N-hydroxyindole (M2) and then dimerized to produce a novel diindole (M4). UV/vis spectral and tandem mass fragmentation patterns, as well as ¹H NMR spectra, were consistent with the putative sequential indoline oxidation. No evidence was found for the P450-mediated production of an aliphatic alcohol from indoline that might dehydrate to produce indole. Taken together, these results demonstrate that several P450s catalyze the novel "aromatase" metabolism of indoline to produce indole. The mechanism of this process does not appear to occur through N-oxidation or dehydration of an alcohol, but rather through a formal dehydrogenation pathway. Supported by NIH grants HL13645 and GM074249.

964 NOVEL OXIDATIVE *IN VITRO* METABOLITES OF ZEARELENONE.

E. Pfeiffer, A. K. Heyting and M. Metzler. *University of Karlsruhe, Karlsruhe, Germany.*

Zearelenone is a macrocyclic resorcylic acid lactone produced by various fungi of the species *Fusarium* and frequently found in moldy corn. To date, the only known phase I metabolites of this mycotoxin are zearelanone and the alpha- and beta-isomers of zearelanol and zearelanol, which are formed from zearelenone via reductive pathways.

The aim of the present study was to clarify whether zearalenone is prone to oxidative biotransformation. When zearalenone was incubated with liver microsomes from male Sprague-Dawley rats in the presence of a NADPH-generating system, subsequent analysis by HPLC showed the formation of seventeen metabolites. In addition to alpha-zearalenol and small amounts of beta-zearalenol, seven monohydroxylation products of zearalenone and three monohydroxylated zearalenols were detected by gas chromatography-mass spectrometry after trimethylsilylation. Small amounts of three dihydroxylated zearalenones were also found. The two major metabolites of zearalenone were monohydroxylated at the aliphatic macrocycle, as tentatively concluded from the electron impact mass spectra of the trimethylsilyl derivatives. When these major metabolites were isolated by HPLC and again incubated with rat hepatic microsomes, metabolites were obtained that were also observed in the microsomal incubation of zearalenone.

Our study has shown for the first time that zearalenone not only forms reductive metabolites but also a large number of oxidative metabolites with rat hepatic microsomes. Further studies are now needed to unambiguously establish the exact chemical structures of the hydroxylated metabolites and to find out which of them are formed in vivo.

Supported by the State of Baden-Wuerttemberg, Germany (Research Program "Mycotoxins" as part of the State Research Initiative "Food and Health").

965 IN VITRO METABOLISM OF ARYLAMINE HAIR DYES IN HUMAN HEPATIC MICROSOMES AND HUMAN HEPATOCYTES.

J. A. Skare¹, R. Powrie², R. Strife¹ and C. Elcombe². ¹Procter & Gamble Company, Cincinnati, OH and ²CXR Biosciences Ltd., Dundee, United Kingdom.

Metabolism is a key consideration in the safety assessment of primary arylamines used in oxidative hair dyes, especially for the assessment of potential carcinogenicity, since N-hydroxylamine formation by CYPs is regarded as a key step in the activation of certain arylamines that have been identified as human bladder carcinogens (4-aminobiphenyl, 2-naphthylamine, benzidine). Previous studies have shown that *p*-phenylenediamine and 2,5-diaminotoluene, two widely used oxidative hair dye ingredients, do not form mono-oxygenated metabolites in cryopreserved human hepatocytes, hepatic microsomes or recombinant CYPs. Only the mono- and diacetylated metabolites were observed in human hepatocytes. The purpose of the present work was to screen additional arylamine hair dyes for oxidative metabolism in human hepatic microsomes and to conduct more in depth metabolism studies with any compounds exhibiting evidence of oxidative metabolism. Five primary arylamines that are widely used in oxidative hair dyes were screened and showed no evidence of oxidative metabolism. One compound, 4-amino-2-hydroxytoluene (AHT), showed evidence of formation of two hydroxylated metabolites by human, rat, and mouse hepatic microsomes. However, there was no evidence of covalent binding of ¹⁴C-radiolabeled AHT to human microsomal protein, suggesting that the monohydroxylated metabolites formed were not biologically reactive. One of these metabolites was confirmed to be hydroxylated on the methyl group and the other is likely to be ring hydroxylated. Further in vitro studies in human, rat, and mouse hepatocytes indicated that phase II reactions (sulfation, acetylation, glucuronidation) predominate in the intact hepatocyte and that mono-oxygenated metabolites are not detected. Our results indicate that none of the hair dyes tested show evidence of hepatic metabolism to potentially biologically reactive oxidative metabolites. As such, the metabolism of these compounds appears distinct from that exhibited by known human bladder carcinogens.

966 IN VITRO METABOLISM OF 8-2FLUOROTELOMER ALCOHOL IN MULTIPLE SPECIES.

W. J. Fasano¹, D. Nabb¹, B. Szostek¹, S. A. Gannon², R. C. Buck¹, S. H. Korzeniowski¹ and M. Gargas². ¹E.I. DuPont de Nemours & Co., Inc., Wilmington, DE and ²The Sapphire Group, Inc., Beavercreek, OH.

The identification of perfluorinated organic compounds in the environment has generated interest in understanding the biological and environmental fate of these chemicals. 8-2 Fluorotelomer alcohol (8-2 FTOH) is a raw material used in the manufacture of fluorotelomer-based products. This study investigated the in vitro metabolism of 8-2 FTOH and selected metabolites by rat, mouse, trout and human hepatocytes and by rat, mouse and human liver microsomes. Clearance of 8-2 FTOH in hepatocytes was rat > mouse > human > trout. The major metabolic pathway for 8-2 FTOH in hepatocytes was conjugation of parent 8-2 FTOH with glutathione or glucuronic acid with no chemical breakdown. Another metabolic pathway was formation of 8-2 FT aldehyde and saturated acid. These were consistent with previously reported metabolites. Metabolites not previously reported included 7-3 saturated and unsaturated aldehyde, 7-2 α -ketone, 7-3 β -ketoaldehyde, and the taurine conjugate of 7-3 saturated acid. No unique metabolites were observed in human hepatocytes. The relative ranking of perfluorooctanoate (PFO) production in hepatocytes was mouse > rat > human = trout. Incubation of 8-2

FTOH with liver microsomes resulted in formation of many of the same metabolites observed in hepatocytes including PFO with the exception of human microsomal incubations in which no PFO was detected. To further elucidate the metabolic pathways for 8-2FTOH, hepatocytes and microsomes were incubated with various 8-2 and 7-3 acids. Hepatocyte incubations with 8-2 saturated acid metabolized to 8-2 unsaturated acid then 7-3 unsaturated and 7-3 saturated acid which was subsequently conjugated with taurine. In microsomes, no metabolism of the 8-2 or 7-3 acids was observed in any species. Hepatocytes from all species were capable of metabolizing the 8-2 and 7-3 acids but more slowly than 8-2 FTOH. Overall, the results suggest that 8-2 FTOH is rapidly metabolized in rats, mice and humans and to a lesser degree in trout and production of PFO may be mediated by microsomal enzymes.

967 HYDROXYLATED POLYBROMINATED DIPHENYL ETHERS (HO-PBDES) AND BROMOPHENOLS FOUND IN MICE PLASMA AFTER EXPOSURE TO A PENTABROMO DIPHENYL ETHER FLAME RE-TARDANT.

X. Qiu¹, M. Mercado Feliciano², R. M. Bigsby^{3,4} and R. A. Hites¹. ¹School of Public and Environmental Affairs, Indiana University, Bloomington, IN, ²Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, ³Obstetrics & Gynecology, Indiana University School of Medicine, Indianapolis, IN and ⁴Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN.

Previous studies showed that in vitro microsomal metabolites of polybrominated diphenyl ethers might weakly activate estrogen-responsive luciferase reporter constructs. To de-terminine the metabolites, mice plasma samples were collected after continuous oral and subcutaneous exposure to the commercial pentabromo diphenyl ether product (DE-71) for 34 days. Samples were denatured, extracted, separated into neutral and phenolic fraction, and analyzed with GC/MS-ECNI. In the neutral fraction, the concentration of BDE-153 was nearly three times higher than that of BDE-99 for oral exposed samples, while BDE-153 was only 10% of BDE-99 in DE-71. This suggested that BDE-153 was resistant to enzymatic degradation in mice. For the phenolic fraction, two main bromophenols (2,4-dibromophenol and 2,4,5-tribromophenol) and seven HO-PBDEs were detected and quantitated. The presence of 2,4-bromophenol and 2,4,5-tribromophenol suggested cleavage of the ether bond of BDE-47 and BDE-99, which were the two main components of DE-71. The HO-PBDEs might come from hydroxylation or hydroxylation and debromination. For the HO-tetra-BDEs, which might come from the hydroxylation of BDE-47, the concentration of 4-HO-BDE-42, 3-HO-BDE-47, 6-HO-BDE-47, and 4'-HO-BDE-49 were 180, 53, 22, and 42 ng/g wet weight, respectively. The presence of 4-HO-BDE-42 and 4'-HO-BDE-49 suggested that there was a shift of a bromine during the hydroxylation process. The relatively high concentration of 4-HO-BDE-42 and 4'-HO-BDE-49 also suggested that para-HO-PBDE might be the most important hydroxylated metabolites. This was significant because para-HO-PBDE could be the most thyroxine like compounds.

968 CONGENER SPECIFIC PCB METABOLISM IN VITRO BY HUMAN LIVER MICROSOMES.

J. E. McGraw and D. P. Waller. *Biopharmaceutical Science, University of IL at Chicago College of Pharmacy, Chicago, IL.*

Polychlorinated biphenyl congeners (PCBs) such as PCBs 101, 118, 138, 153, and 180 are common, persistent environmental contaminants. Information related to their metabolism in humans is lacking. PCB metabolism was investigated using an in vitro human liver microsome (HLM) system, which represents a mixture of human CYP 450 isoforms and their relative ability to metabolize PCBs. The PCBs were incubated with HLM's and evaluated for the presence of metabolites by GC. No or minimal metabolite peaks were observed for all the PCBs except for PCB 101. The human CYP isoform responsible for PCB 101 metabolism was identified as human CYP2A6 using specific recombinant human CYP isoforms. Study results indicated selective and extensive metabolism of PCB 101 to 4-hydroxy-PCB 101.

969 DEVELOPMENT OF A NEW UPLC/MS/MS METHOD TO STUDY THE METABOLISM OF BENZO[A]PYRENE BY CYP1S.

S. Zhu¹, P. Carvalho², L. Li³, B. Avery³ and K. Willett¹. ¹Pharmacology and Environmental Toxicology Research Program, The University of Mississippi, University, MS, ²Medicinal Chemistry, The University of Mississippi, University, MS and ³Pharmaceutics, The University of Mississippi, University, MS.

Our goal is to compare benzo[a]pyrene (BaP) metabolism and catalytic efficiency of the newly identified CYP1B and CYP1C isoforms that have been identified in fish to mammalian CYP1s. In order to sensitively detect the BaP metabolites we have

developed an UPLC/MS method which is more rapid and sensitive than traditional HPLC methods. Two types of samples were extracted by liquid-liquid separation for BaP metabolite determination. *In vivo* metabolism was assessed using bile from BaP exposed fish, while *in vitro* metabolism was measured using human and fish recombinant CYP1s. UPLC separation was carried on an Acquity UPLC BEH C18 column (1.7 μ m, 2.1 $\times$ 50 mm) at a flow rate of 0.25 mL/min with an analysis time of 10 minutes. BaP and eight metabolites were separated with a gradient mobile phase (0.3% formic acid/acetonitrile). 6-Hydroxychrysene was used as the internal standard. Mass spectrometry detection was carried out with Waters Quattro micro API quadrupole mass spectrometer in selected ion recording (SIR) mode, equipped with an APCI+ interface. BaP and the following BaP metabolites: BaP-1, 6-dione, BaP-3, 6-dione, BaP-6, 12-dione, BaP-9, 10-dihydrodiol, BaP-7, 8-dihydrodiol, BaP-7, 8, 9, 10-tetrol, 9-hydroxyBaP, 3-hydroxyBaP and internal standard 6-hydroxychrysene were base line separated. The calibration curves of all compounds were linear between 0.2 ng/ μ L and 6 ng/ μ L ($r^2 = 0.97$ for BaP-7, 8, 9, 10-tetrol, $r^2 = 0.99$ for all other compounds). The intra- and inter-day assay precision were within $\pm 10\%$ CV and the accuracy were in the range of 85% to 115% for all the analytes. The extraction recoveries of all compounds were between 80%-115%. This method will be useful for further defining species differences of cytochrome P450-mediated BaP metabolism and genotoxicity. Supported by NIEHS R01ES012710 and CDC CA5 U01 CI00021.

970 EXTRA-HEPATIC METABOLISM OF DELTAMETHRIN.

J. V. Bruckner, S. S. Anand and K. B. Kim. *Department of Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA.*

Deltamethrin (DLM) is a relatively potent neurotoxin and a widely used pyrethroid insecticide. DLM is metabolized by carboxylesterases (CaEs) and cytochrome P450s (CYPs). Although these enzymes are present predominantly in liver, they are also found in other tissues and are regulated differently in different tissues. While metabolism in intestine (oral exposure) and lung (inhalation) will contribute to first-pass metabolism, brain metabolism may contribute to target tissue levels and total body burden of the neurotoxic parent compound. Hence, extrahepatic metabolism, if any, may influence the internal dosimetry of DLM and other pyrethroid insecticides. The objective of this study was to evaluate metabolism of DLM in intestine, lung and brain relative to liver. Metabolism was quantified *in vitro* by monitoring the disappearance of DLM from S9 fractions of these tissues obtained from male SD rats. CYP-mediated metabolism was not observed in brain, intestine or lung. While intestinal CaEs did not metabolize DLM, intrinsic clearance (V_{max}/K_m) by CaEs in lung (0.9 ± 0.1) was 2-fold higher than in brain (0.4 ± 0.04). These values were ~25- to 50-fold lower than intrinsic clearance by liver CaEs (24.9 ± 2.1). The present results show that intestinal metabolism is apparently not a factor in the first-pass elimination of oral DLM exposure. Other than plasma CaE-mediated hydrolysis, extra-hepatic metabolism does not seem to contribute significantly to the clearance and toxicity of DLM (Supported by EPA STAR Grant R830800).

971 *IN VIVO* AND *IN VITRO* METABOLISM OF DIISOPROPYL ETHER (DIPE).

E. Stagiola and R. A. Scharz. *Toxicology, Northeastern University, Boston, MA.*

Diisopropyl ether (DIPE) is a volatile solvent that can be added to gasoline to improve combustion efficiency and thus reduce toxic emissions. Due to the volatility of ethers, respiratory toxicity has been assessed using lavage fluid analyses after inhalation exposures. Our lab has shown an increase in toxicity markers after methyl-tert butyl ether (MTBE) and ethyl-tert butyl ether (ETBE) exposures to 250 - 500ppm. DIPE produces minimal respiratory toxicity after inhalation exposures at concentrations as high as 5000ppm. Other branched aliphatic ethers such as MTBE and ETBE are metabolized by the CYP450 system to produce potentially toxic metabolites (tert-butyl alcohol, formaldehyde and acetaldehyde). Currently, no data is available on the metabolism of DIPE although it has been suggested that metabolism produces isopropyl alcohol and acetone. The aim of this study was to determine the major metabolites of DIPE using rat nasal mucosa microsomes. *In vitro*, acetone and isopropyl alcohol were produced in a concentration-dependent manner. Organ specific variations in metabolism of DIPE in Sprague-Dawley rats indicate that nasal mucosa tissue has the highest rate of DIPE metabolism, while lung and the liver tissue produce much lower levels of metabolites, less than 0.01% of the nasal mucosa. To evaluate the role of P450 isoforms in DIPE metabolism, we used 8-methoxypsoralen (8-MOP; CYP2A3/6 inhibitor), 4-methylpyrazole (4-MP; CYP2E1 inhibitor) and ketoconazole (KTZ; CYP3A4 inhibitor). K_i values were 0.56, 7.7 and 32 μ M for 8-MOP, 4-MP and KTZ, respectively, implicating CYP2A3 and 2E1 as the major enzymes involved in DIPE metabolism. *In vivo* studies showed elimination of DIPE, acetone and isopropanol from the blood within 24 hours of inhalation exposures to 5000ppm DIPE (1 day, 6 hours/day). Rapid systemic clearance of DIPE as well as the production of relatively less toxic metabolites may contribute to reduced toxicity compared to MTBE and ETBE.

972 COMPARATIVE METABOLISM AND DISPOSITION OF SINGLE AND MULTIPLE DOSES OF ACRYLAMIDE (AM) USING *CYP2E1*^{-/-} (KO) AND WILD-TYPE (WT) MICE.

R. Bai, U. Hoffler, L. El-Hadri, A. Rahman, L. Ferguson and B. I. Ghanayem. *Laboratory of Pharmacology and Chemistry, NIEHS/NIH, Research Triangle Park, NC.*

AM is a reactive monomer that is used to synthesize polyacrylamide for use in chromatography gels, paper and textile industries, and cosmetics. AM is formed in starchy foods that are prepared at high temperatures including French fries, potato chips, and cereals. Because AM is neurotoxic, carcinogenic, and a reproductive toxicant, there is major concern about the consequences of exposure to AM on human health. AM causes dominant lethal mutations after daily administration to male mice for 5 consecutive days. Cytochrome P450 2E1 (CYP2E1) is a major enzyme involved in AM metabolism. Current studies were undertaken to compare the metabolism and disposition of 2,3-¹⁴C-AM after a single or 5 consecutive daily doses at 12.5 or 50 mg/kg/day using KO and WT mice. Renal excretion of AM-derived radioactivity was dose-dependent and was the major route of elimination in mice of both genotypes. Elimination of unmetabolized AM was less in the urine of WT vs. KO mice. AM-mercapturate was the main urinary metabolite and accounted for ~81-88% in KO vs. 44-57% of the urinary radioactivity in WT mice. In contrast to their levels in WT mice, glycidamide (GA) and GA-mercapturate (GAMA) were barely detectable in KO mice. However, while GA accounted for 3-13% of the AM-derived urinary radioactivity, GAMA constituted 8-14% in WT mice administered at 12.5 or 50 mg AM/kg/day. Elimination of AM-derived radioactivity in the feces and in the expired air as CO₂ and organic volatiles in both KO and WT mice was minimal. Blood and tissue concentrations of AM-derived radioactivity increased as a function of dose and the number of doses administered in mice of both genotypes. In conclusion, this work confirmed that CYP2E1 is the primary enzyme responsible for the formation of the proximate metabolite, GA. Further, retention of AM-derived radioactivity in blood and tissues increased as a function of the number of doses administered and points out to the potential accumulation of this chemical in association with long-term exposure.

973 COMPARATIVE METABOLISM AND DISPOSITION OF SINGLE AND MULTIPLE DOSES OF TRICHLOROETHYLENE (TCE) USING *CYP2E1*^{-/-} (KO) AND WILD-TYPE (WT) MICE.

B. I. Ghanayem and D. Kim. *Laboratory of Pharmacology and Chemistry, NIEHS/NIH, Research Triangle Park, NC.*

TCE is classified as a rodent carcinogen and a "probable human carcinogen." It was reported that Metabolism of TCE occurs via cytochromes P450 (CYPs) and CYP2E1 is thought to play an important role. The objective of the present work is to assess the role of CYP2E1 in TCE metabolism using KO vs. WT mice. Animals were administered a single 250 or 1000 mg/kg dose of 1,2-¹⁴C-TCE or 250 mg/kg/day for 4 consecutive days. Mice were placed in glass metabolism cages that allowed for the collection of expired air, urine, and feces. At 24 hr after a single dose or after the last of the 4 daily doses, animals were euthanized and blood and tissues were collected. Exhalation of TCE-derived ¹⁴CO₂ was time- and dose-dependent. Further, while exhalation of TCE-derived ¹⁴CO₂ gradually increased in WT mice with continued daily dosing, it plateaued after the first dose in similarly treated KO mice. Elimination of organic volatiles, of which TCE is the only detectable chemical, in the expired air was significantly higher in KO vs. WT mice exposed to single or multiple doses of TCE. A significantly greater % of the dose was excreted in the urine of WT vs. KO mice. Three metabolites (trichloroethanol (TCOH)-glucuronide, trichloroacetic acid, and free TCOH) were identified with TCOH-glucuronide being the major metabolite in the urine of mice of both genotypes. Free urinary TCOH was significantly higher in KO vs. WT mice. Further, free TCOH in the urine of KO mice was significantly greater after 4 daily doses vs. a single dose. Levels of TCE-derived radioactivity in tissues were significantly higher after 4 daily doses vs. a single dose in mice of both genotypes with the highest levels found in the liver, forestomach, and kidneys. In conclusion, these data confirmed earlier finding that while CYP2E1 plays an essential role in the metabolism of TCE, other CYPs are also important. However, it remains to be established if CYP2E1 or other CYPs are involved in the metabolism of TCE metabolites such as trichloroacetic and dichloroacetic acids.

974 STUDY OF THE EFFECTS OF DICHLOROACETIC ACID ON THE METABOLISM AND DISPOSITION OF TRICHLOROETHYLENE IN *CYP2E1*^{-/-} (KO) AND WILD-TYPE (WT) MICE.

D. Kim and B. I. Ghanayem. *Laboratory of Pharmacology and Chemistry, NIEHS/NIH, Research Triangle Park, NC.*

Dichloroacetic acid (DCA) is a chlorination by-product formed during water disinfection and it is one of the most abundant haloacetic acids in water supplies. Several studies showed that DCA causes peroxisome proliferation and is a liver carcinogen

in mice. DCA is a metabolite of trichloroethylene (TCE), which is also a water contaminant and liver carcinogen in mice. DCA was reported to be an inducer of hepatic cytochrome P450 2E1 (CYP2E1) and a suicidal substrate inhibitor of glutathione-S-transferase zeta (GSTz). Because these enzymes are involved in TCE metabolism, we hypothesized that DCA may influence TCE metabolism via its effects on CYP2E1 and GSTz. In order to test this hypothesis, KO and WT mice were administered by gavage a single dose of DCA at 500 mg/kg or at 50 mg/kg/day for 5 consecutive days followed 24 hr later by the administration of 1,2-¹⁴C-TCE at 250 mg/kg by gavage. Mice were immediately placed in glass metabolism cages that allowed for the collection of expired air, urine, and feces. Twenty-four hours after TCE administration, animals were euthanized and blood and tissues were collected and frozen for analysis. Pretreatment of mice with DCA resulted in a significant inhibition of the exhalation of TCE-derived CO₂ and significantly increased the exhalation of organic volatiles (primarily parent TCE) in mice of both genotypes. Further, DCA pretreatment caused a significant decrease in the elimination of TCE-derived radioactivity in the urine of mice of both genotypes. These results confirmed that DCA pretreatment causes inhibition of TCE metabolism. Subsequent studies using real time PCR showed that DCA pretreatment, similar to those used in the current metabolism studies, decreased the expression of CYP2E1 in WT mice and significantly inhibited the activity of GSTz in mice of both genotypes. In conclusion, inhibition of TCE metabolism by DCA may be mediated by its inhibitory effects on GSTz and CYP2E1.

975 DISPOSITION OF 1-BUTYL-3-METHYLIMIDAZOLIUM CHLORIDE (BMIM-CL) FOLLOWING IV, ORAL OR DERMAL ADMINISTRATION IN MALE F-344 RATS.

R. Kuester, G. A. Knudsen, L. M. Jacobs and I. G. Sipes. *The University of Arizona, Tucson, AZ.*

These studies characterized the effect of dose and route of administration on the disposition and metabolism of the ionic liquid, 1-butyl-3-methylimidazolium chloride (Bmim-Cl). [14C] Bmim-Cl was administered intravenously (IV), dermally or orally to male Fischer-344 rats. Following IV administration of [14C] Bmim-Cl (5 mg/kg), it decreased rapidly from blood in a biphasic manner. The key calculated kinetic parameters were: $t_{1/2\beta} = 960$ min; $AUC = 150 \mu\text{g} \cdot \text{min}/\text{mL}$; $CL_b = 5.8$ mL/min. The major route of elimination was urinary (84±10% of dose in 12 h). Urine was also the major route of elimination (60-70% in 12 h) following a single oral administration of Bmim-Cl (50, 5 or 0.5 mg/kg). Systemic bioavailability was >70% at 48 h. Bmim-Cl (50 mg/kg) was absorbed following dermal application in an methanol vehicle (25-35%), but resulted in apparent irritation at the site of administration. At a 10X lower dose (5 mg/kg) irritation was not observed. It exhibited poor to moderate absorption following application in an aqueous, ethanol or dimethylformamide vehicle (approx. 1, 3, or 13%). Regardless of route of exposure, analysis of urine by UV/Vis-radio HPLC showed a single radiolabeled peak that co-eluted with the Bmim-Cl standard, indicating that Bmim-Cl is excreted unchanged. While metabolism of Bmim-Cl following oral administration is negligible, and systemic bioavailability is high, that which is absorbed is extensively extracted by the kidney and eliminated in the urine as parent compound. (This research was supported by the NIEHS NTP Grant No. N01-ES-45529 and NIEHS-sponsored Southwest Environmental Health Science Center Grant Number P30-ES-06694.)

976 DISPOSITION OF N-BUTYLPYRIDINIUM CHLORIDE (NBUPY-CL) BY MALE F-344 RATS FOLLOWING IV OR ORAL ADMINISTRATION.

Y. F. Cheng, R. Kuester, G. A. Knudsen, L. M. Jacobs and I. G. Sipes. *The University of Arizona, Tucson, AZ.*

Studies were conducted to characterize the effect of dose and route of administration on the disposition and metabolism of the ionic liquid, N-Butylpyridinium Chloride (NBuPy-Cl). [14C] NBuPy-Cl was administered intravenously (IV) or orally to male Fischer-344 rats. Following IV administration of [14C] NBuPy-Cl (5 mg/kg), the radiolabel found in the blood decreased rapidly and could be described by a biexponential equation, consistent with a two compartment model. The key calculated kinetic parameters were: $t_{1/2\beta} = 860$ min; $AUC = 179 \mu\text{g} \cdot \text{min}/\text{mL}$; $CL_b = 5.4$ mL/min. Urine was the major route of elimination of [14C] equivalents following both oral (60-70% in 12 h at 50, 5 or 0.5 mg/kg) and IV (80±13% of dose in 12 h) dosing with 5 mg/kg. Systemic bioavailability as calculated from AUC_{oral}/AUC_{IV} was 70% at 48 h. Preliminary results suggest NBuPy-Cl is poorly absorbed after dermal application in an aqueous vehicle (5 mg/kg). Regardless of route of exposure, analysis of urine by UV/Vis-radio HPLC showed a major radiolabeled peak that co-eluted with the NBuPy-Cl standard and a smaller peak representing less than 1% of the administered dose. While metabo-

lism of NBuPy-Cl following oral administration is negligible, and systemic bioavailability is high, that which is absorbed is extensively extracted by the kidney and eliminated in the urine as parent compound. This research was supported by the NIEHS NTP Grant No. N01-ES-45529 and NIEHS-sponsored Southwest Environmental Health Science Center Grant Number P30-ES-06694.

S. G. Gilbert¹, W. F. Sette², L. Scarano³, R. Fortmann⁴ and S. R. Mortensen⁵. ¹INND, Seattle, WA, ²Office of the Science Advisor, U.S. EPA, Washington, DC, ³Office of Pesticide Programs, U.S. EPA, Washington, DC, ⁴National Exposure Research Laboratory, U.S. EPA, Washington, DC and ⁵Toxicologist, Syngenta Crop Protection, Inc., Greensboro, NC.

This symposium will review some of the issues surrounding the scientific and ethical considerations related to intentional human exposure studies and purely observational studies. The relevance and importance of these studies will also be discussed. In early 2006, EPA published a Human Studies Rule that banned all third-party intentional dosing research on pesticides involving children and pregnant women intended for submission to EPA, and required that EPA neither conduct nor support any intentional dosing studies that involve pregnant women or children for all substances EPA regulates. The final rule also adopted stringent enforceable ethical safeguards to protect adult individuals who volunteer to participate in third-party intentional dosing research with pesticides, and called for establishment of a Human Studies Review Board (HSRB) to obtain independent scientific and ethical review on whether to accept certain existing human studies and to review new study protocols. The HSRB then met to review a series of studies on pesticides undergoing re-registration. In a separate effort, EPA has also developed a set of best practices for the design and implementation of observational exposure measurement studies that involve human participants, including children, but do not involve intentional exposures. These activities define a new landscape in which human studies performed or supported by EPA, or performed by third parties to generate data that will be used by them under the pesticide laws, will be reviewed, evaluated, and conducted. We will discuss these new EPA efforts and consider more broadly some of the issues related to defining the scientific value and justification of such studies, and some of the scientific and ethical challenges of conducting them with pesticides.

978 PROTECTION AGAINST IMMUNE-MEDIATED HEPATITIS BY THE SYNTHETIC TRITERPENOID, CDDO-IM.

W. O. Osburn¹, M. S. Yates¹, K. T. Liby², B. D. Roeback², M. B. Sporn² and T. W. Kensler¹. ¹Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and ²Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.

The synthetic triterpenoid, 1-[2-cyano-3,12-dioxooleana-1,9(11)-dien-28-oyl]imidazole (CDDO-Im), is a potent chemopreventive agent protecting against aflatoxin-mediated hepatocarcinogenesis in rodents in part through Nrf2-mediated induction of a cytoprotective response. Co-exposure to aflatoxin together with chronic inflammation from hepatitis B virus infection can drive liver cancer risk in humans. CDDO-Im has also been shown to have anti-inflammatory activity. The present study examined the anti-inflammatory efficacy of CDDO-Im using Concanavalin A (ConA), a mouse model of T-cell mediated hepatitis. Mice treated daily with CDDO-Im (30 $\mu\text{mol}/\text{kg}$, p.o.) for three days prior to administration of a single dose of ConA exhibited dramatically decreased hepatotoxicity and inflammation 24-hr following ConA administration. H&E stained liver sections from CDDO-Im treated mice display decreased manifestations of cell death. CDDO-Im completely inhibited increases in serum liver enzyme levels and blunted ConA-induced biomarkers of oxidative stress. Additionally, the number of inflammatory cells in liver was decreased by CDDO-Im treatment. Similarly, CDDO-Im markedly inhibited hepatic myeloperoxidase activity representing decreased infiltration of neutrophils. These results suggest that CDDO-Im treatment reduces ConA-induced hepatotoxicity by decreasing inflammation. The serum concentration of pro-inflammatory cytokines were measured 3-hr following ConA administration. CDDO-Im treatment strongly decreased the secretion of IL-6, IL-12, IFN- γ , MCP-1 and TNF- α suggesting that CDDO-Im treatment resulted in decreased T-cell activation and a dampened inflammatory response. This study clearly demonstrates the anti-inflammatory potential of CDDO-Im against immune-mediated hepatitis thereby illustrating an additional chemopreventive role of CDDO-Im. 979 RESTRAINT STRESS CAUSES PHOSPHORYLATION OF STAT3 IN LIVER OF C57BL/6J MICE THROUGH ACTIVATION OF ADRENERGIC RECEPTORS.

J. R. Turner, S. A. Benkovic, J. P. O'Callaghan and D. B. Miller. *TMBB, CDC-NIOSH, Morgantown, WV.*

Psychological stress elicits two classical responses: 1) it activates the hypothalamic-pituitary-adrenal axis, resulting in the release of glucocorticoids, and 2) it activates the sympathetic nervous system, which results in the release of norepinephrine and epinephrine. Although these two systems often work in tandem, our studies indicate that activation of the JAK-STAT signaling pathways in livers of mice subjected to restraint stress is solely controlled through the adrenergic stress response. Using a combination of focused-microwave irradiation to preserve protein phosphorylation state, and phospho-specific immunoblotting, we observed a 10-fold increase in PSTAT3^{tyr705} in the livers of mice restrained for two hours. This effect could be blocked by both alpha and beta adrenergic antagonists, but not by adrenalectomy. Additionally, alpha and beta adrenergic agonists (phenylephrine 10 mg/kg or isoproterenol 10 mg/kg s.c., respectively) mimic the stress response in vivo and trigger phosphorylation of liver STAT3. This activation appears to be controlled through the beta-adrenergic receptor, since blocking this receptor precludes PSTAT3 induction upon administration of phenylephrine, an alpha-adrenergic agonist. Histological analysis of livers from saline and phenylephrine treated mice showed a translocation of STAT3 from cytoplasm to the nucleus, respectively, and a blockade of translocation by propranolol pretreatment. Altogether, these data suggest that restraint stress triggers phosphorylation of liver STAT3 through a solely adrenergic pathway, which initially requires beta-adrenergic receptor activation. These findings support the idea the acute psychological stress can elicit STAT3 activation in the liver, and may therefore have ramifications on liver diseases or in modulating hepatotoxicity.

"The findings and conclusions in this report (abstract/presentation) have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy."

980 EFFECT OF AHR NULL ALLELES ON IRON-ENHANCED PORPHYRIA IN MICE.

A. G. Smith, B. Clothier, S. Robinson, R. E. Edwards, T. Chernova, P. Greaves and R. Davies. *MRC Toxicology Unit, University of Leicester, Leicester, United Kingdom.*

A consequence of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in mice is a hepatic dysfunction of heme synthesis (porphyria) similar to human porphyria cutanea tarda. Susceptibility to this type of porphyria in mice is associated with polymorphism of the *Ahr* gene, although not exclusively, and with a threshold for CYP1A2 expression but not always with the degree of induction. The porphyria is potentiated by iron and the heme precursor aminolevulinic acid (ALA) both of which may also cause porphyria. It is unknown whether *Ahr* expression is essential to the probable oxidative mechanisms of all hepatic porphyria developments. Male C57BL/6J *Ahr* ^{+/+}, ^{+/-} and ^{-/-} mice received TCDD (75 µg/kg orally) ± s.c. dosing of iron (800 mg/kg). After 5 weeks liver toxicity as shown by histology and plasma ALT and AST enzymes, occurred in ^{+/+} mice and to a lesser extent in ^{+/-}. Hepatic toxicity in both strains was markedly enhanced by iron. Porphyria, as judged by uroporphyrin levels, occurred in ^{+/+} and ^{+/-} mice especially with iron. Only mild toxic effects of TCDD were observed in ^{-/-} mice even with iron, and there was no influence whatsoever on uroporphyrin levels whatever the iron status. Even 5 weeks after TCDD CYP1A2 levels, as measured by MROD activity and by immunoblotting, were still massively induced in ^{+/+} and to the same degree in ^{+/-} mice, but not in ^{-/-}. However, low basal expression of CYP1A2 (25-40% of wild type) was observed in *Ahr* ^{-/-} mice by RT-PCR and by immunoblotting. When iron-treated *Ahr* null mice were administered ALA in the drinking water (2 mg/ml) for 8 weeks without TCDD, uroporphyrin levels were markedly elevated although less than the wild type. In contrast, C57BL/6J *Cyp1a2* null mice are known to be totally resistant to the development of porphyria with this regimen. The results confirm that a minimum level of CYP1A2 may be required for porphyria development and demonstrate that although expression of *Ahr* appears essential for TCDD-induced porphyria it is not an absolute requirement for every porphyric response of the liver.

981 UROPORPHOMETHENE, THE INHIBITOR OF UROPORPHYRINOGEN DECARBOXYLASE CAUSING PORPHYRIA CUTANEA TARDA IDENTIFIED.

J. D. Phillips², J. P. Kushner², H. A. Bergonia², C. A. Reilly¹ and M. R. Franklin¹. ¹Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and ²Medicine, University of Utah, Salt Lake City, UT.

Porphyria cutanea tarda (PCT), the most common form of porphyria in humans, engaged the toxicology community when it was linked to human ingestion of hexachlorobenzene in Turkey in the 1950s. Porphyrin accumulation in the skin ac-

counts for the photodermatitis. However, the disease is due to reduced activity of uroporphyrinogen decarboxylase (URO-D) in the liver, often in association with increased hepatic iron stores. Protein levels of URO-D do not change when catalytic activity is reduced, suggesting the possible presence of an inhibitor of URO-D. An inhibitor of URO-D has been identified in deproteinized liver cytosolic extracts from two murine models of PCT: wild type mice treated with polychlorinated biphenyls, together with iron and delta-aminolevulinic acid, and mice with one null allele of *Uro-d* and two null alleles of the hemochromatosis gene (*Uro-d*^{-/-}, *Hfe*^{-/-}) which develop PCT with no treatment. The inhibitor presence in the latter model indicates the inhibitor is chemically unrelated to PCBs. The inhibitor has now been characterized by solid phase extraction, chromatography, UV-vis spectroscopy and mass spectrometry and has proven to be uroporphomethene, a compound in which a single bridge carbon in the uroporphyrinogen macrocycle is oxidized, forcing the two adjacent pyrrole rings into a planar conformation. Synthetic uroporphomethenes were prepared by photo-oxidation of enzymatically-generated uroporphyrinogen I or III. Both uroporphomethenes inhibited recombinant human URO-D but the III isomer porphomethene was the more potent (2-3 fold) inhibitor. An inhibitor of rhURO-D has also been detected in cytosolic extracts of liver biopsy samples of patients with PCT. These studies support the hypothesis that the mechanism underlying clinical expression of the PCT phenotype appears to be the oxidation of uroporphyrinogen to uroporphomethene, which acts as a competitive inhibitor of uroporphyrinogen decarboxylation by URO-D. Support:NIH DK20503

982 HEPATIC TRANSPORTER mRNA CHANGES ASSOCIATED WITH TREATMENT REGIMENS LEADING TO UROPORPHYRIA IN A MOUSE MODEL OF PORPHYRIA CUTANEA TARDA.

D. D. Arch¹, J. D. Phillips², J. P. Kushner¹ and M. R. Franklin². ¹Pharmacology and Toxicology, University of Utah, Salt Lake City, UT and ²Medicine, University of Utah, Salt Lake City, UT.

Porphyria cutanea tarda (PCT) is characterized by increased body burdens of uroporphyrin, originating from hepatic accumulations as a result of severely reduced uroporphyrinogen decarboxylase (URO-D) activity. Active transport mechanisms have been implicated in the movement of porphyrins across cellular membranes and it was of interest to examine whether changes in the regulation of transporter transcription was occurring in the livers of animal models of the disease. We have investigated transporter mRNA changes following treatment of female mice possessing one null allele of *Uro-d* with a single dose of polychlorinated biphenyls (PCBs). The mice showed mean hepatic porphyrin levels of 6 nmol/g liver after 1 week and plateau levels of ~750 nmol/g at 2 and 3 weeks. When the mice also received delta-aminolevulinic acid (ALA) in their drinking water, the 1-week level was increased to 373 nmol/g and the 3-week level was increased to 1062 nmol/g if they also received an iron-dextran injection. *Abcc3* mRNA levels correlated with porphyrin levels, with values of 134% (1 week) and 240% (2-3 weeks) of control for the PCB-alone treatment, and 191 and 276% respectively for the two further supplemented regimens. *Slc01b2* showed an inverse correlation with porphyrin levels, reaching 67% depression with the treatment regimen that gave porphyrins of 1062 nmol/g. The only significant changes in *Abcb1a*, *Abcb1b* and *Abcg2* mRNAs were the 301, 490 and 146% elevations, respectively, seen with the 3-week PCB/ALA/iron-dextran treatment regimen giving mean porphyrin levels of 1062 nmol/g. No significant changes were observed in *Abcc2* from any treatment regimen. *Abcb11* was significantly depressed with the 2-week PCB (37%) and 1-week PCB/ALA (60%) regimens, and therefore in a manner unrelated to porphyrin levels. Thus transcript levels of numerous transporters appear responsive not only to PCBs, but stimuli which in many cases arise as the disease-state develops. Support:NIH DK20503

983 QUANTIFICATION OF PROLIFERATING LIVER SINUSOIDAL ENDOTHELIUM USING LASER-SCANNING CYTOMETRY.

R. Garrido, K. Toy, K. McClinchey, J. Wijsman, L. Obert and R. Dunstan. *Drug Safety R&D, Pfizer, Ann Arbor, MI.*

The liver has a major role in storage and metabolism of nutrients, and it is the main organ for drug biotransformation. Liver sinusoidal endothelial cells constitute the lining of the hepatic sinusoid and perform a wide range of important functions: exchange of blood components, endocytosis of xenobiotics, secretion of inflammatory mediators, and antigen presentation. Proliferation of sinusoidal endothelium in the liver has been related to drug toxicity, hemangiosarcoma formation and liver regeneration after acute liver injury.

Laser scanning-cytometry (LSC) analyzes fluorescently-labeled tissue sections in a fashion similar to flow cytometry. LSC collects tissue data by sequential scanning of microscopic fields, while preserving sample integrity and recording spatial localization of data within the tissue.

Here we describe a method to quantify proliferation of liver sinusoidal endothelium in whole sections of mouse liver using fluorescent immunolabeling and LSC analysis. Using VEGF-R2 immunofluorescence, we were able to specifically identify the sinusoidal endothelium in sections of mouse liver. In addition, using dual fluorescent immunolabeling, we labeled endothelium (VEGF-R2) and proliferating cells (Ki-67) concurrently. Using LSC analysis, we quantified co-localization of endothelial and Ki-67 staining across the entire tissue section, successfully obtaining data regarding total tissue area, endothelial sinusoidal area, and proliferating sinusoidal endothelial area.

This method can be used to quantify variations in endothelial sinusoidal area and sinusoidal proliferation due to drug toxicity and/or liver disease.

984 FXR NOT REQUIRED FOR INFLAMMATION DURING CHOLESTASIS.

K. M. Allen, G. L. Guo and B. L. Copple. *Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Cholestasis, a condition that occurs when hepatic bile acid excretion is interrupted, causes liver injury in humans and animals. Recent studies have shown that neutrophils accumulate in the liver and exacerbate injury during cholestasis. What remains unclear is the mechanism by which cholestasis stimulates production of proinflammatory mediators that promote neutrophils to accumulate in the liver and produce injury. Recent studies suggested that farnesoid X receptor (FXR), a bile acid nuclear receptor, regulates expression of proinflammatory mediators in bile acid-treated hepatocytes in vitro, suggesting that FXR is critical for neutrophil accumulation in liver during cholestasis. To test this hypothesis in vivo, wild-type and FXR knockout mice were subjected to bile duct ligation (BDL), a commonly used model of cholestasis. Three days later, levels of intercellular adhesion molecule-1 (ICAM-1) and macrophage inflammatory protein-2 (MIP-2) mRNA in liver, hepatic neutrophil accumulation, and liver injury were measured. ICAM-1 mRNA levels were increased to a similar extent in wild-type and FXR knockout mice subjected to BDL. MIP-2 mRNA was increased in liver after BDL, and was increased to a greater extent in FXR knockouts. Hepatic neutrophil numbers were increased in both wild-type and FXR knockout mice after BDL. Next, liver injury was evaluated by measuring serum levels of alanine aminotransferase (ALT), an indicator of hepatocyte injury. ALT levels were significantly elevated in wild-type mice subjected to BDL, and were increased further in FXR knockout mice after BDL. Results from these studies suggest that FXR is not critical for production of proinflammatory mediators and accumulation of neutrophils in liver during cholestasis.

985 DOSE-RESPONSE OF CHENODEOXYCHOLIC ACID AND LITHOCHOLIC ACID ON MOUSE LIVER PATHOLOGY.

C. D. Klaassen and P. Song. *Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.*

Bile acids not only play important physiological roles in facilitating the absorption of dietary fat and the elimination of cholesterol from the body, but also are important signaling molecules. High doses of bile acids, however, cause hepatotoxicity. Little information is available on the doses of endogenous bile acids that produce hepatotoxicity. Therefore, the purpose of this study was to determine the toxic dose and histopathological effects of chenodeoxycholic acid (CDCA) and lithocholic acid (LCA). Mice were fed CDCA or LCA at concentrations of 0.1, 0.5, 1.0, and 1.5% (W/W) in the diet for one week. Livers were collected for immunohistochemistry of Kupffer cells, neutrophils, and apoptotic cells, as well as for H&E staining. mRNA levels were quantified using the branched DNA assay. Concentrations of 1.0 and 1.5% in the diet of both CDCA and LCA caused lethality. Extensive hepatic necrosis was produced by 0.5% LCA. An increase in apoptosis was observed after 0.5% CDCA, as well as 0.1 and 0.5% LCA. CDCA at 0.5% and LCA at 0.1 and 0.5% caused hepatic inflammation, as indicated by neutrophil infiltration. The number of Kupffer cells was increased by 0.5% CDCA, whereas, they were decreased by 0.5% LCA. The expression of TNF α was increased by 0.1% LCA. Hepatic stellate cell (HSC) activation was evaluated by quantifying the mRNA of α -smooth muscle actin (α SMA) and collagen-1. CDCA did not alter the mRNA levels of either, whereas 0.5% LCA increased mRNA levels of both α SMA and collagen-1 in livers. In summary, CDCA at 0.5% in the diet results in neutrophil infiltration, apoptosis, and activation of Kupffer cells. LCA at 0.1% similarly causes neutrophil infiltration, apoptosis, and activation of Kupffer cells, whereas at 0.5% causes the same effects plus activation of stellate cells. In conclusion, CDCA and LCA appear to produce a similar pattern of hepatocellular injury, but LCA is more potent. (Supported by NIEH grants ES-09649 and ES-09716).

986 REGULATION OF GLUTATHIONE S-TRANSFERASES (GST) IN MOUSE LIVER BY CHEMICAL ACTIVATORS OF RECEPTOR-MEDIATED PATHWAYS.

S. Choudhuri, T. R. Knight and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

KUMC, Kansas City, KS 66160.

Induction of various phase-I and -II drug-metabolizing enzymes is regarded as a mechanism of protection against chemical stress. Gst enzymes are clinically relevant enzymes that conjugate electrophilic xenobiotics and by-products of oxidative stress with glutathione. High Gst levels have been correlated with lower incidences of cancer in rodents and humans. Classical microsomal enzyme inducers increase the expression of some biotransformation enzymes (phase-I and -II) and transporters through transcription factors, such as the aryl hydrocarbon receptor (AhR), constitutive androstane receptor (CAR), pregnane X receptor (PXR), peroxisome proliferator-activated receptor α (PPAR α), and NF-E2 related factor 2 (Nrf2). Because the effects of activators of these 5 transcription factors on the induction of hepatic Gst enzymes in mice have not been comprehensively characterized, the purpose of this study was to fill that knowledge gap. Adult male C57BL/6 mice were treated with different activators of the transcription factors AhR, CAR, PXR, PPAR α , and Nrf2. In general, most Gst isoforms are readily induced. All five transcription pathways appear to play a role in Gst induction, and all Gst enzymes are induced by some of these transcription pathways, except Gst π 1/2. The Nrf2 activators induced the most Gst isoforms, whereas AhR ligands induced the least. Additionally, clofibrate, a PPAR α agonist, was the single compound that induced the most Gst isoforms; however, all three PPAR α agonists decreased Gst π 1/2 mRNA. Of all members of the Gst μ class, Gst μ 3 mRNA expression had the largest increase by all three CAR ligands, PXR ligands, and Nrf2 activators (6- to 13-fold). In conclusion, Gst enzymes are readily inducible, however, not all Gst(s) are induced by all transcription activators. Thus the protection afforded by a ligand for one of these transcription factors will depend on the activator, as well as which Gst that detoxifies the chemical of interest. (Supported by NIH grants ES-09716, ES-013714 and ES-08156)

987 REGULATION OF HEPATIC BILE ACID TRANSPORTERS Ntcp AND Bsep mRNA EXPRESSION IN MICE.

X. Cheng, J. Maher, D. Buckley and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

REGULATION OF HEPATIC BILE ACID TRANSPORTERS Ntcp AND Bsep mRNA EXPRESSION IN MICE. XG Cheng, J Maher, D Buckley, and CD Klaassen. University of Kansas Medical Center, Kansas City, KS 66160.

Na⁺-taurocholate cotransporting polypeptide (Ntcp) and the bile salt export pump (Bsep) are key transporters for hepatic bile acid uptake and excretion. Alterations in Ntcp and Bsep expression have been reported in pathophysiological conditions such as cholestasis, but little is known regarding their regulation under other conditions. Thus in the present study, the effects of age, gender, and prototypical microsomal enzyme inducers on the regulation of these two transporters were determined in mouse livers. Both Ntcp and Bsep are exclusively expressed in liver. Ntcp and Bsep mRNA in mice were low in the fetus, but increased 10 fold to their highest levels at parturition. Mouse Ntcp and Bsep mRNA decreased by more than 50% by day 5 after birth, and then gradually increased to adult levels by day 30. Female-predominant Ntcp mRNA expression in mouse liver was observed in adulthood. In contrast, no gender difference exists in Bsep mRNA expression in mouse liver. To examine whether sex hormones or growth hormone secretion patterns are responsible for the observed Ntcp gender difference, hormone replacements were conducted in gonadectomized, hypophysectomized, and growth-hormone-releasing-hormone receptor mutant (lit/lit) mice. The data indicate that female-predominant Ntcp expression in mouse liver is due to the inhibitory effect of male-pattern GH secretion, but not the effects of sex hormones. A few microsomal enzyme inducers altered Ntcp or Bsep mRNA expression in mice. Specifically, dexamethasone and oltipraz induced Ntcp mRNA expression. Spirolactone induced Bsep mRNA expression. However, Ntcp and Bsep expression are resistant to induction by most of microsomal enzyme inducers. In conclusion, mouse Ntcp and Bsep are extensively regulated by tissue, age, gender, but only a few microsomal enzyme inducers. (Supported by NIH grants ES-09649, ES-09716, and ES-07079)

988 CONSTITUTIVE mRNA EXPRESSION OF VARIOUS GLUTATHIONE S-TRANSFERASE ISOFORMS IN DIFFERENT TISSUES OF MICE.

T. R. Knight, S. Choudhuri and C. D. Klaassen. *University of Kansas Medical Center, Kansas City, KS.*

TR Knight, S Choudhuri, and CD Klaassen. University of Kansas Medical Center, Kansas City, KS 66160.

Glutathione S-transferase (Gst) enzymes are instrumental in protecting cellular macromolecules against electrophiles and products of oxidative stress. The ability of these enzymes to detoxify xenobiotics is of special interest to toxicologists. Constitutive expression of Gst(s) might determine a tissue's ability to respond to certain forms of chemical stress. Therefore, from 13 tissues of adult male and female mice, the mRNA expression of 19 Gst enzymes were quantified by the branched DNA method. In all tissues examined, multiple isoforms of Gst were constitutively expressed, but some isoforms were expressed at higher levels than others. The tissue expression of different isoforms had no relationship to their class designation; members of the same class were often highly expressed in different tissues. Constitutive expression of many Gst isoforms showed gender difference in a few but not all tissues; in most such cases, females had higher expression than males. The majority of cytosolic Gst enzymes in mice were highly expressed in stomach, liver, and kidney. Several other isoforms, such as Gstk1, Gstm1, Gstm4, Gstm6, and Gstt1, were expressed in other parts of the gastrointestinal (GI) tract as well. Gstm1, Gstm6, and Gstt3 were highly expressed in testis. Interestingly, Gstm5 was the Gst isoform that had highest expression in brain, relative to other tissues. The microsomal Gst(s) had the highest constitutive expression in liver and stomach. Specifically, microsomal Gst1 (MGst1) had the highest expression in liver, whereas microsomal Gst2 and 3 (MGst2 and MGst3) had the highest expression in stomach, followed by various sections of the intestine. In summary, most Gst isoforms are highly expressed in the GI tract, liver, and kidney, which strongly suggests an important role of many Gst isoforms in detoxifying ingested xenobiotics. (Supported by NIH grants ES-09716, ES-013714 and ES-08156)

989 NRF2 PROMOTES LIVER INJURY IN CHOLESTATIC MICE.

B. Copple¹, Y. Tanaka¹, A. L. Slitt¹, E. Malle² and C. D. Klaassen¹. ¹Department of Pharmacology, Toxicology, and Therapeutics, University of Kansas Medical Center, Kansas City, KS and ²Institute of Molecular Biology and Biochemistry, Medical University of Graz, Graz, Austria.

Recent studies have shown that nuclear factor E2 p45-related factor 2 (Nrf2) protects the liver from xenobiotic toxicity. Whether it protects the liver from cholestatic injury is not known. Accordingly, the hypothesis was tested that Nrf2 protects the liver from injury during cholestasis. To test this, wild-type and Nrf2-null mice were subjected to bile duct ligation (BDL), an animal model of cholestasis. The results show that liver injury and fibrosis were reduced in Nrf2-null mice suggesting that Nrf2 promotes cholestatic liver disease. Because inflammation is required for liver injury during cholestasis, it was next determined whether liver inflammation was reduced in Nrf2-null mice. The results show that upregulation of several proinflammatory mediators, as well as neutrophil accumulation and activation were reduced in Nrf2-null mice after BDL. Serum and liver bile acid concentrations were reduced in Nrf2-null mice after BDL when compared to wild-type mice, suggesting that Nrf2 promotes bile acid accumulation in liver and serum during cholestasis. Because transporters affect hepatic bile acid accumulation, bile acid transporters were quantified in liver. Multidrug resistance associated protein (Mrp) 3 and Mrp4 mRNA were increased in liver of wild-type but not in Nrf2-null mice after BDL. Organic solute transporter (Ost)β mRNA levels were increased in wild-type mice after BDL and were increased even further in Nrf2-null mice. These results indicate that Nrf2 negatively regulates Ostβ during cholestasis causing bile acid accumulation, which promotes liver inflammation, injury, and fibrosis.

990 ROLE OF ESTRADIOL IN SECRETED PHOSPHOPROTEIN 1 (OSTEOPONTIN) INDUCTION IN A FEMALE RAT MODEL OF ALCOHOLIC STEATOHEPATITIS.

A. Banerjee^{1,2}, R. Rose² and S. K. Ramaiah^{1,2}. ¹Toxicology, Texas A&M University, College Station, TX and ²Veterinary Pathobiology, Texas A&M University, College Station, TX.

Recent studies from our laboratory suggest that higher neutrophil infiltration in females significantly correlate with increased hepatobiliary expression of secreted phosphoprotein 1 [SPP1, commonly referred to as osteopontin (OPN)] in the rat Lieber DeCarli model of alcoholic steatohepatitis (ASH). Confirmation experiments with neutralizing antibody against SPP1 revealed the contributing role of SPP1 in higher hepatic neutrophil infiltration and liver injury. The objective of this study was to first examine the effect of ethanol (EtOH) on estrous cycle and then investigate the potential relationship between estradiol (E2) and hepatobiliary OPN mRNA and protein expression in the female ASH model. When normally cycling adult female Sprague Dawley rats were administered EtOH for a period of six weeks, there was prolongation of diestrus stage of the estrous cycle. Ovariectomized (OVX) and E2-implanted OVX rats (E2; 0.18, 0.36mg, 0.72mg and 1.7mg) in the ASH group (EtOH+LPS), evaluated for OPN mRNA and protein expression by in situ hybridization, RT-PCR and Western Blotting revealed a biphasic pattern. Low

doses (0.18 and 0.36mg) of E2 resulted in significant down-regulation of OPN protein and mRNA as compared to the OVX group. However, with the increasing doses of E2 (0.72 and 1.7mg) there was up-regulation of both OPN mRNA and protein. OPN mRNA and protein was localized mostly to the biliary epithelium and occasionally within mononuclear cells and hepatocytes. Liver injury assessed by serum ALT, AST and histopathology also revealed a biphasic pattern similar to OPN expression. In all the groups, hepatic neutrophilic infiltration correlated positively with OPN protein and mRNA expression. Based on these data, we can conclude that in our ASH model, low doses of E2 are hepatoprotective while the protective effect appears to be negated with increasing doses of E2, both of which are SPP1-mediated.

991 NON-ALCOHOLIC FATTY LIVER DISEASE ALTERS EXPRESSION AND ACTIVITY OF DRUG METABOLIZING ENZYMES.

A. Lickteig¹, L. M. Augustine¹, C. D. Fisher¹, L. M. Aleksunes², J. E. Manautou² and N. J. Cherrington¹. ¹Pharmacology and Toxicology, University of Arizona, Tucson, AZ and ²Pharmaceutical Sciences, University of Connecticut, Storrs, CT.

Non-alcoholic fatty liver disorders (NAFLD) comprise a spectrum of pathologies known to progress from simple fatty liver (SFL) to the severe disease of non-alcoholic steatohepatitis (NASH). Importantly, a number of medical conditions (e.g. type 2 diabetes, dyslipidemia, heart disease, hypertension) are commonly associated with NAFLD. Therefore, a significant portion of NAFLD patients currently takes prescription medications. Of the 2 million adverse drug reactions (ADRs) that occur annually in the US, < 20% are attributable to genetics. Thus a considerable proportion of ADRs are thought to be the result of environmental factors like disease state and nutritional status. Phase I and II drug metabolizing enzymes (DMEs) are essential for the conversion of drugs into hydrophilic, more readily-excretable metabolites. The purpose of this study was to determine the effect of NAFLD on the expression and activity of a number of the major DMEs in rat liver, including cytochrome P450s and UDP-glucuronosyl transferases (UGTs). Male Sprague-Dawley rats were fed a high-fat (SFL model) or a methionine-choline-deficient diet (NASH model) for 8 weeks. H&E staining revealed steatosis in both models, while fibrosis was found only in NASH livers. In SFL, there was a 38% decrease in Cyp2E1 protein expression. In NASH livers, branched DNA analysis of hepatic RNA revealed increased Cyp2E1 (1.4-fold) and Cyp4A2/3 (2.9-fold) mRNA levels, while Cyp3A1/23 and Cyp2C11 mRNA levels decreased by 55% and 74%, respectively. Western blot analysis of NASH livers revealed increased protein expression of Cyp2C11 (~11-fold) and Cyp4A1 (2.7-fold), while Cyp3A1 expression was decreased by 75%. UGT activity increased 1.4-fold in NASH livers. These data reveal significant changes in the expression and activity of several DMEs during NASH. Such alterations are likely to influence the metabolism, efficacy and safety of various clinically relevant drugs in NASH patients. (DK-068039, ES-07091, ES-011646)

992 HEPATIC DRUG METABOLISM ENZYME AND TRANSPORTER EXPRESSION IN HUMANS WITH NON-ALCOHOLIC FATTY LIVER DISEASE.

C. D. Fisher, N. F. Villeneuve and N. J. Cherrington. Department of Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

Severe adverse drug reactions among patients in the USA number as high as two million per year. Less than 20% of these cases are due to genetic polymorphisms, whereas the majority of adverse drug reactions are due to environmental factors such as age, nutrition, or disease state. Non-alcoholic fatty liver disease (NAFLD) encompasses a spectrum of diagnoses ranging from simple fatty liver (SFL) to non-alcoholic steatohepatitis (NASH). NASH can progress to cirrhosis which is irreversible and requires liver transplant. The purpose of the current study was to determine whether human livers diagnosed with mild to severe NAFLD show altered expression of hepatic drug metabolizing enzymes and transporters. Human liver samples diagnosed with normal liver, SFL, NASH with fatty liver (early stage) or NASH without fatty liver (end stage, with cirrhosis) were provided by the Liver Tissue Procurement and Distribution System. Total RNA was isolated from all liver samples and mRNA levels of hepatic Phase I drug metabolizing enzymes and transporters were quantified using branched DNA analysis. While no significant changes were observed in SFL samples, the expression of several hepatic transporters and cytochrome P450s were significantly altered in human NASH livers. In human livers diagnosed with early stage NASH, BCRP, MRP1, MRP4 and MRP5 hepatic transporter mRNA levels were significantly increased relative to normal human liver samples. Similarly, livers diagnosed with end stage NASH displayed significant increases in MRP1, MRP4 and MRP5 expression. CYP2E1 mRNA levels were significantly decreased in human livers diagnosed with early stage and end stage NASH, respectively, while CYP4A mRNA levels were increased only in early

stage NASH livers. These data suggest that the expression of hepatic transporters and drug metabolizing enzymes is altered during the more severe stages of NAFLD, and may result in impairment of hepatic metabolism and disposition of clinically relevant drugs administered to these patients. (DK068039, ES07091, ES011646)

993 FMO MEDIATED METABOLISM AND THE PHARMACOKINETICS OF IN-1130 IS A NOVEL ALK5 INHIBITOR, AN ANTIFIBROTIC AGENT.

Y. Y. Sheen¹, Y. W. Kim¹, K. N. Min¹, J. I. Jee¹, K. J. Kwon¹, S. Y. Go¹, J. H. Kim¹, K. Y. Kim¹, Y. K. Kim² and D. Kim¹. ¹Pharmacy, Ewha Womans University, Seoul, Seoul, South Korea and ²IN2Gen, Seoul, South Korea. Sponsor: J. Chung.

The transforming growth factor- β (TGF- β) plays a central role in the progression of renal fibrosis. TGF- β transduces its signal through the ALK5 serine/threonine kinase receptor. IN-1130 (2-pyridinyl-[1,2,3]triazoles) is a novel small molecule ALK5 kinase inhibitor. We investigated the metabolism, toxicity and pharmacokinetics of IN-1130 in rodents, dog and monkey.

In vitro enzyme assay with human, monkey, dog, rat and mouse microsomes did not show any metabolite from IN-1130 based on the HPLC, and LC-MS analysis (detection limit = 10 nM). Ex vivo enzyme assay with the isolated perfused rat liver system, no metabolite was detected based on the HPLC, and LC-MS analysis (detection limit = 10 nM). These results from the both in vitro and ex vivo studies, indicated that besides CYP system, other enzyme system might be involved in the metabolism of IN-1130. We have carried out the FMO experiment with microsomes of human, rat and mouse livers, and rat kidney, and with human FMO1 cDNA expressed supersona. The results from the experiments showed that IN-1130 was metabolized by FMO. At the moment, we are not certain which isozyme is responsible for the IN-1130 metabolism, although we could exclude FMO1. Most likely FMO3 and/or FMO5 would be involved in the metabolism of IN-1130. IN-1130 was assayed for mutation in two histidine-requiring strains of *Salmonella typhimurium* (TA1535, TA1538) and IN-1130 did not induce mutation in two histidine-requiring strains of *Salmonella typhimurium* (TA1535, TA1538) when tested under the conditions of this study. The approximate minimum lethal intravenous dose levels of IN-1130 in the male and female rats were found to be 250 mg/kg and 300 mg/kg, respectively. The approximate minimum lethal intravenous dose level of SB-505124 in the male and female rat was found to be between 15 and 30 mg/kg. The approximate minimum lethal oral dose level of IN-1130 in both male and female rat was found to be 2000 mg/kg.

994 IN VITRO EXPOSURE OF BILIARY EPITHELIAL CELLS (BEC) TO BILE FROM RATS TREATED WITH CDNB (1-CHLORO, 2,4-DINITROBENZENE) INDUCES DNP ADDUCTS ON PROTEINS.

M. F. Kaniz¹, Y. Chen¹, Z. Wu², R. D. English² and J. E. Wiktorowicz². ¹Pathology, University of Texas Medical Branch, Galveston, TX and ²Biochemistry and Molecular Biology, UTMB, Galveston, TX.

Background. Idiosyncratic drug-induced biliary disease is believed to occur because reactive drugs/ metabolites covalently bind (adduct) endogenous proteins to form abnormal proteins that are recognized as "foreign" by the immune system.

Objectives. Characterize BEC proteins adducted by biliary metabolites of the model compound CDNB using an in vitro system where BEC are exposed to bile collected from CDNB-treated rats. **Methods.** Male SD rats were given 250 mg CDNB/kg po (corn oil); bile was collected for 3 h. BEC were exposed to CDNB-Bile for 5 h at 37°C, washed, fragmented by freeze-thaw + sonication, and separated into cell fractions. Proteins were separated on parallel 2D gels; adducts were identified by Western blot on one gel and protein spots were excised on the other gel for digestion and analysis by MALDI-TOF spectrometry for protein identification.

Results. Adducts were observed by immunohistochemistry in BEC in the livers of rats exposed to CDNB, and by immunocytochemistry and confocal microscopy in BEC exposed to CDNB-Bile in vitro. Nine protein spots that showed adduction by Western blot were identified by peptide mass fingerprints (MS + MS/MS) using NCBI and Swiss-Prot/TrEMBL databases: [Cytokeratin 8] [type II keratin, gene 7] [selenium-binding protein] [ezrin (microvillar protein)] [carbonic anhydrase] [glutathione S-transferase, pi] [dihydrolypoamide acetyltransferase] [prohibitin (mitochondrial chaperone protein)] [MAWDBP (binding protein to MAWD)]. The first 7 proteins are known human or rodent BEC proteins. Moreover, dihydrolypoamide acetyltransferase is the E2 subunit of the pyruvate dehydrogenase complex in mitochondria and the most prominent autoantigen in primary biliary cirrhosis.

Conclusion. An in vitro BEC/ bile-exposure system is an applicable approach to investigate mechanisms of drug-induced bile duct disease. (Supported by John Sealy Memorial Endowment Fund for Biomedical Research, UTMB)

995 EVALUATION OF CHANGES IN MITOCHONDRIAL FUNCTION IN RAT HEPATOCYTES USING FLOW CYTOMETRY AND TWO-PHOTON MICROSCOPY.

B. W. Halstead¹, R. A. Jolly¹, A. R. Irizarry¹, T. K. Baker¹, J. L. Stevens¹ and R. L. Bacallao². ¹Toxicology and Drug Disposition, A Division of Eli Lilly and Company, Eli Lilly and Company, Greenfield, IN and ²Department of Medicine, Division of Nephrology, Indiana Center for Biological Microscopy, Indiana University Medical Center, Indianapolis, IN.

Xenobiotic-induced changes in mitochondrial function are recurring causes of toxicity in organs such as the liver. There is a significant need to identify in vitro and in vivo imaging technologies that assess mitochondrial morphology and function. In vitro experiments using isolated rat hepatocytes were conducted to identify a set of responsive fluorescent probes that would be used for in vivo two-photon imaging. For in vitro experiments, rat hepatocytes were isolated by enzymatic perfusion; plated in tissue culture plates or seeded in suspension cultures; treated with the mitochondrial toxicants CCCP, DNP, oligomycin, or valinomycin; incubated with fluorescent probes; and analyzed by flow cytometry. We observed compound-induced mitochondrial membrane depolarization that preceded loss of cell viability in cultures of isolated rat hepatocytes. For in vivo experiments, anesthetized rats were prepared surgically to expose the liver and to perform blood vessel cannulation. Fluorescent probes were administered intravenously as a bolus and images were acquired over a period of 1 hour using a Zeiss LSM-510 Meta Confocal / Multiphoton Microscope system. Two-photon in vivo imaging of the liver was possible a few minutes after probe delivery and mitochondrial membrane potential depolarization was detected immediately after subsequent administration of valinomycin. In summary, a method for in vivo imaging of mitochondrial functional changes in the rat liver using two-photon microscopy was developed. Evaluating mitochondrial function and morphology in the physiological context of the living animal is a benefit when assessing compound-induced toxicity and supplements traditional labor intensive ex-vivo evaluation techniques.

996 HEPATOCYTE GROWTH FACTOR PROTECTS AGAINST OXIDATIVE STRESS INDUCED BY ETHANOL METABOLISM.

A. Valdés-Arztate¹, V. Souza¹, L. Gómez-Quiroz¹, L. Bucio¹, E. Hernández¹, C. Gutiérrez-Ruiz¹ and D. Kershenovich². ¹Ciencias de la Salud, Universidad Autónoma Metropolitana, México-(c)xico, D.F., Mexico and ²Facultad de Medicina, UNAM, México-(c)xico, Mexico.

Ethanol (EtOH) metabolism-induced cellular damage is a process which involves both generation of reactive oxygen species (ROS) and a decrease in the antioxidant system generating oxidative stress. EtOH is metabolized in chronic intake by cytochrome P450 2E1 which produces ROS and acetaldehyde. Oxidative stress can damage lipids, DNA and proteins which lead an impaired cellular function and eventually cell death. Hepatocyte growth factor (HGF) is a potent mitogenic factor which exerts a protective role inducing activation of NF- κ B survival pathway. Although HGF-induced apoptosis protection is well characterized there is little evidence in protection against EtOH metabolism-induced cellular damage.

HepG2 cells transfected with cytochrome P450 2E1 gene (VL-17A) were seeded and pretreated or not with 50 ng/ml HGF for 12 hr and then treated or not with 100 mM EtOH for 24 and 48 hr. Catalase and superoxide dismutase enzymes were assayed by Western Blot. Protein oxidation was determined using OxyBlotTM kit, ROS production was quantified by FACS flow using DCF-DA and lipid peroxidation was determined by malondialdehyde production. ATP was measured by ApoGlowTM bioassay kit.

EtOH treatment stimulated ROS production in VL-17A cells and induced cellular damage judged by protein oxidation, lipid peroxidation and peroxides production determined by FACS flow. HGF prevented EtOH damage. In order to explore the mechanism of HGF protection we determined the expression of some antioxidants enzymes. We observed that HGF increased SOD1 and catalase expression which is correlated with a decrease in protein oxidation. ATP content was increased as a result of HGF pretreatment.

These data present clear evidence that HGF can modulate redox status in cells subjected to oxidative stress suggesting that HGF-induced protection is mediated by an increment in the antioxidant system.

CONACYT: 45921.

997 ALPHA GST IS A SENSITIVE, TRANSPORTABLE, HEPATOTOXICITY BIOMARKER IN HUMAN HEPATOCYTE CULTURE.

V. P. Miller, Y. Xiang and G. Zhang. *BD Biosciences, Bedford, MA.*

The expectations for new toxicity biomarkers are high. They must be predictive, specific, and early indicators of toxicity. Ideally, they should also be transportable – similar measurements and data interpretations for the same biomarker whether it is

measured in the clinic, in preclinical animal species, or during *in vitro* experiments. There is strong evidence that alpha GST (glutathione S-transferase) leakage into the blood is a sensitive and specific hepatotoxicity biomarker in the clinic and in animal studies. However, little experimental data has been published measuring this biomarker *in vitro* in cell culture media and no data has been published using human hepatocytes. We have examined the use of an alpha GST EIA method to measure the release of alpha GST in human hepatocyte cell culture. We compared alpha GST leakage to the release of LDH (lactate dehydrogenase) under the same experimental conditions. A panel of drugs (including many known hepatotoxins; i.e. tamoxifen) was tested. We found that alpha GST leakage could be detected earlier and was more a more sensitive assay (significant leakage could be detected at 5x lower concentrations) compared to LDH leakage in both cryopreserved and fresh human hepatocyte cultures. We conclude that the measurement of alpha GST leakage in hepatocyte cell culture supernatants is a useful and more sensitive assay for hepatotoxicity assessment *in vitro* than LDH leakage. These data, combined with published data showing GST's utility for measuring hepatotoxicity *in vivo*, indicate that alpha GST leakage is a useful, transportable, hepatotoxicity biomarker.

998 PATHWAYS FOR CHELATABLE IRON MOVEMENT INTO MITOCHONDRIA FROM LYSOSOMES AFTER BAFILOMYCIN INHIBITION OF THE VACUOLAR ATPASE.

A. Uchiyama¹, J. Kim² and J. J. Lemasters^{1,3}. ¹Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC, ²Surgery, University of Florida, Gainesville, FL and ³Biochemistry & Molecular Biology, Medical University of South Carolina, Charleston, SC.

Background: Lysosomes sequester iron, and iron augments alcoholic and other liver diseases in which oxidative stress plays a role. Iron catalyzes reactive oxygen species (ROS) formation and induces the mitochondrial permeability transition. Bafilomycin (Baf), a vacuolar proton pump inhibitor, enhances oxidative injury to hepatocytes (Uchiyama et al., *Hepatology* 42, 636A). Our Aim was to investigate pathways of BAF-induced lysosomal iron release and uptake into mitochondria. Methods: Hepatocytes were isolated from fasted male C3Heb mice and Sprague-Dawley rats. Calcein whose fluorescence is quenched by Fe²⁺ was loaded into the cytosol by warm ester loading (1 μ M for 20 min) or into mitochondria by cold ester loading (1 μ M for 60 min at 4°C) and warm incubation. Some hepatocytes were co-loaded with 70 kDa rhodamine-dextran (50 mg/kg i.p. prior to isolation) to visualize lysosomes and/or tetramethylrhodamine methyl ester (100 nM) to determine mitochondrial polarization. Results: When hepatocytes were treated with 50 nM Baf, cytosolic calcein fluorescence declined by $47.8 \pm 0.7\%$ after 120 min. Desferal and starch-desferal (2 mM) suppressed BAF-induced cytosolic calcein quenching nearly completely, indicating that lysosomes were releasing chelatable iron into the cytosol. Baf also induced quenching of mitochondrial calcein that was blocked by desferal, starch-desferal and Ru360 (20 μ M), the last an inhibitor of mitochondrial Ca²⁺ uptake. After Baf, lysosomes did not release 70 kDa rhodamine-dextran, and mitochondria remained polarized. Conclusions: Lysosomal retention of iron depends on lysosomal Δ pH. Collapse of lysosomal Δ pH with Baf releases chelatable iron into the cytosol, which is taken up into mitochondria via the Ca²⁺ uniporter. Mitochondrial iron may then contribute to ROS formation after oxidative stress.

999 IDENTIFICATION OF LIPID MODIFICATIONS OCCURRING IN 1C1C7 HEPATOMA CULTURES FOLLOWING 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN EXPOSURE.

J. J. Reiners¹, P. A. Mathieu¹, J. Caruso¹ and B. S. Cummings². ¹Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and ²Pharmacology and Biomed. Sciences., University of Georgia, Athens, GA.

Recent studies suggest that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) exposure can profoundly influence both cholesterol and triglyceride content in murine liver and hepatoma cell lines. However, the effects of TCDD on specific classes of lipids, particularly those constituting membranes, are not known. Treatment of the murine hepatoma cell line 1c1c7 with 5 nM TCDD for 72 hr resulted in a modest cyostatic effect, characterized by increased and decreased percentages of cells in G1 and S, respectively. Analysis of cholesterol using HPLC in tandem with atmospheric pressure chemical ionization mass spectrometry (LC-APCI-MS) demonstrated that TCDD increased the abundance of hydroxy-cholesterols and total cholesterol. Fluorescence microscopy of filipin stained cells indicated that TCDD also increased markedly non-esterified cholesterol content. Electrospray ionization-mass spectrometry (ESI-MS) analyses demonstrated that 1c1c7 cells express at least 5 different types of sphingomyelin species, none of which were significantly altered by TCDD. ESI-MS analyses of phosphatidylcholines (PtdCho) identified 17 species, and demonstrated that 16:0-20:4, 18:1-20:4 and 18:0-20:4 PtdCho were all signif-

icantly reduced (25-55%) in TCDD-treated cultures. This pattern of reduction in specific PtdCho species is similar to what occurs in several cell lines following pharmacological inhibition, or siRNA-mediated reduction, of cytosolic calcium-independent phospholipase A₂ beta (iPLA₂β), and has been associated with reduced proliferation. These data demonstrate for the first time that TCDD exposure affects the cellular composition of specific phospholipids, which may influence cell cycle progression/duration. This work was partially supported by RO1 ES009392 and the Georgia Cancer Coalition.

1000 INHIBITION OF PHOSPHOLIPASE C BY A CATIONIC AMPHIPHILIC ANTI-INFLAMMATORY COMPOUND AS A MECHANISM OF PHOSPHOLIPIDOSIS.

H. Powell, J. Eakins, J. Evans, A. Bigley, F. Pognan and P. Duffy. *Global Safety Assessment, AstraZeneca, Macclesfield, Cheshire, United Kingdom.*

Many marketed drugs induce phospholipidosis in preclinical animal toxicity studies and in many cases the compounds belong to a family of molecules referred to as cationic amphiphilic drugs (CAD). This family includes agents like fluoxetine, amiodarone and perhexiline. Possible mechanisms of drug-induced phospholipidosis include modification of lipid handling either by a) modulating the lipid structure (by covalent binding or altered physiochemical environment) or b) competitive or allosteric inhibition of the phospholipase enzymes involved in lipid catabolic processing.

We investigated one of the AZ molecules from a series of anti-inflammatory agents that possesses CAD-like properties of which some have been shown to induce phospholipidosis *in vivo*. We have demonstrated that the myelin bodies, diagnostic by EM of phospholipidosis *in vivo*, can be successfully modelled *in vitro* in rat hepatocytes. We have studied the effects of the AZ compound plus chlorpromazine and perhexiline on the activity of phospholipase C using a modification of the Invitrogen™ Phosphatidylcholine-Specific Phospholipase C Assay Kit. Compounds were tested over a range of concentrations between 10 and 500 μ M and assessed for inhibition of phospholipase C. The AZ compound, fluoxetine and perhexiline produced concentration-dependant inhibition of phospholipase C activity with IC₅₀ values of 91.4 μ M, 49.2 μ M and 51.1 μ M respectively. These concentrations are comparable with those that can produce phospholipidosis in rat hepatocytes *in vitro* suggesting that inhibition of phospholipase C plays a role in phospholipidosis induced by this series of anti-inflammatory agents.

1001 ISONIAZID INDUCES APOPTOSIS AND INHIBITS MMP SECRETION IN HUMAN HEPATOMA CELL LINE SK-HEP-1.

M. Roomi, N. Roomi, V. Ivanov, A. Niedzwiecki and M. Rath. *Dr. Rath Research Institute, Santa Clara, CA.*

Introduction:

The incidence of tuberculosis (TB), a chronic recurrent infection, caused by *Mycobacterium tuberculosis*, has increased alarmingly among persons infected with HIV. Case rates vary by country, age, race, sex and socioeconomic status. Isoniazid (INH), one of the most widely used drugs for the treatment of TB, has proven to be very effective with relatively low toxicity. However, therapeutic doses of INH lead to liver injury in some patients.

Objective:

The aim of the present *in vitro* investigation was to study mechanisms of toxicity, evaluating the effect of INH on viability, apoptosis, MMP secretion and morphology of human hepatoma cell line SK-Hep-1.

Methods:

Human hepatoma cell line SK-Hep-1 (ATCC) was grown in MEM medium with 10% FBS, penicillin and streptomycin in 24-well tissue culture plates. At near confluence, cells were treated with INH at 0, 1, 5, 10, 15 and 20 mM in triplicate at each concentration. Viability was assayed by MTT assay, apoptosis using live green caspase detection kit (Molecular Probe), MMP secretion by zymography and morphology by H&E staining.

Results:

INH inhibited the growth of SK-Hep-1 cells in a dose response fashion, 10% at 5 mM, 20% at 10 mM and 25% at 15 and 20 mM concentration. INH induced slight apoptosis at 5 mM, moderate at 10 and 15 mM and significant at 20 mM. INH also showed a dose-dependent inhibition of MMP-9 activity, 5%, 10%, 20%, 30%, and 40 % at 1, 5, 10, 15 and 20 mM concentration. H&E staining showed no morphological changes even at highest concentration.

Conclusions:

The present study demonstrates that INH causes toxicity by inducing apoptosis and inhibiting MMP secretion.

1002 GINKGOLIDE A CONTRIBUTES TO THE POTENTIATION OF ACETAMINOPHEN TOXICITY BY GINKGO BILOBA EXTRACT IN PRIMARY CULTURES OF RAT HEPATOCYTES.

T. K. Chang and G. Rajaraman. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.* Sponsor: S. Bandiera.

The present cell culture study investigated the effect of *Ginkgo biloba* extract pretreatment on acetaminophen toxicity and assessed the role of ginkgolide A and cytochrome P450 3A (CYP3A) in hepatocytes isolated from adult male Long-Evans rats provided ad libitum with a standard diet for rodents. Acetaminophen (7.5-25 mM for 24 h) conferred hepatocyte toxicity, as determined by the lactate dehydrogenase (LDH) assay. *G. biloba* extract alone increased LDH leakage in hepatocytes at concentrations ≥ 75 μ g/ml and ≥ 750 μ g/ml after a 72 h and 24 h treatment period, respectively. *G. biloba* extract (25 or 50 μ g/ml once every 24 h for 72 h) potentiated LDH leakage by acetaminophen (10 mM for 24 h; added at 48 h after initiation of extract pretreatment). The effect was confirmed by a decrease in [¹⁴C]-leucine incorporation. At the level present in a modulating concentration (50 μ g/ml) of the extract, ginkgolide A (0.55 μ g/ml), which increased CYP3A23 mRNA levels and CYP3A-mediated enzyme activity, accounted for part but not all of the potentiating effect of the extract on acetaminophen toxicity. This occurred as a result of CYP3A induction by ginkgolide A because triacetyloleandomycin (TAO), a specific inhibitor of CYP3A catalytic activity, completely blocked the effect of ginkgolide A. Ginkgolide B, ginkgolide C, ginkgolide J, quercetin, kaempferol, isorhamnetin, and isorhamnetin-3-O-rutinoside did not alter the extent of LDH leakage by acetaminophen. In summary, *G. biloba* pretreatment potentiated acetaminophen toxicity in cultured rat hepatocytes and ginkgolide A contributed to this novel effect of the extract by inducing CYP3A.

1003 EFFECTS OF 18 β -GLYCYRRHETINIC ACID ON THE HEPATIC METALLOTHIONEIN EXPRESSION IN HEPA-1C1C7 CELLS.

D. Kim³, H. Kim^{1,2}, K. Oh^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea and ³Pathology, College of Oriental Medicine, Daejeon University, Daejeon, South Korea.

Glycyrrhizin, a triterpenoid saponin fraction of licorice, is reported to have inducing activity of hepatic metallothionein (MT) and is metabolized to 18 β -glycyrrhetic acid (GA) in the intestine by intestinal bacteria. However, the mechanism underlying its effects is not known. This study investigated the effects of GA on the metallothionein (MT) expression in the murine hepatoma cell line Hepa-1c1c7 cells. Treatment with GA caused increase of MT expression in a dose-dependent manner. This induction was inhibited by addition of AG490, an inhibitor of signal transducer and activator of transcription (STAT) 3. Furthermore, transient transfection experiments showed that MT promoter activities were increased by GA. Taken together, these results demonstrate that MT expression by GA could mediate through STAT3 signal pathway.

1004 NEW THERAPY TO TREATING ACUTE INTOXICATIONS WITH FLUOROACETATE AND OTHER POISONS.

N. Goncharov, A. Kuznetsov, L. Glashkina and A. S. Radilov. *Research Institute of Hygiene, Occupational Pathology and Human Ecology, St Petersburg, Russian Federation.* Sponsor: K. Khamidulina.

Fluoroacetate (FA) and other monofluorides are highly toxic compounds, which action characteristically involves a latent period. We have undertaken large-scale experiments which embraced electrophysiological, biochemical, biophysical and morphological studies mostly with rats, but mice and rabbits were used too. It was found that apart from the classic increase of citrate level, glutamate and glutamine concentrations were sharply decreased in blood and tissues of rats under acute intoxication with FA (1/2LD50). Electron microscopic studies revealed drastic changes of capillary endothelium and the blood-brain barrier. The level of NAD(P)H can affect intracellular calcium homeostasis, together with citrate as calcium chelating agent. In its turn, intracellular calcium disbalance and a primary hypersensitivity of platelets may cause the ischemic disturbances in heart and brain.

As a result of our integrated research, two principal ways of developing effective therapies for FA intoxication have been highlighted. Firstly, competitive inhibition of FA interaction with CoA and fluorocitrate interaction with aconitase, and secondly, channeling the alternative metabolic pathways in order to replenish the Krebs cycle and regulate the cellular NAD(P)H level. An effective therapeutic means called METIS has been developed for treating acute intoxications with FA, the coefficient of efficiency (ratio of LD50 of treated and non-treated rats) being 2.5 and more. Further still, METIS turned out to be a non-specific therapy and

could be applied in some other cases of poisoning (e.g. with ethylene glycol and cyanide), as well as ischemic and coma states, enhancing the efficacy of traditional therapy (e.g. 4-methyl-pyrazol for ethylene glycol).

The work was supported by the BioIndustry Initiative of the U.S. Department of State (Grant# BII-ISTC-2629).

1005 IS THE FARNESOID X RECEPTOR IN JAPANESE MEDAKA (ORYZIAS LATIPES) A TARGET FOR EXOGENOUS COMPOUNDS?

D. L. Howarth¹, D. C. Volz¹, L. R. Hagey², D. E. Hinton¹ and S. W. Kullman¹. ¹Duke University, Durham, NC and ²University of California at San Diego, San Diego, CA.

The farnesoid X receptor (FXR), a nuclear receptor activated by bile acids, results in altered expression of genes involved in bile acid metabolism and transport such as CYP7A1, CYP8B1, and the bile salt export pump (BSEP). In comparative research involving FXRs, it was found that the receptor can also be activated by other compounds such as retinoids, and via synthetic agonists such as GW4064. Co-administration of GW4064 with α -naphthylisothiocyanate (ANIT), a cholestasis-inducing compound widely studied in rodent models, results in an alleviation of liver injury. This finding has opened an avenue of research involving FXR that focuses on exploiting its function for the treatment of cholestasis. Recently, our lab has shown that a single administration of ANIT induces bile preductular epithelial cell injury in medaka liver, resulting in decreased clearance of the bile pigment, biliverdin. Resumption of clearance returns at 72 hours post-exposure, as indicated by a significant change in gallbladder color. However, changes in bile acid levels as a result of ANIT exposure have not been described in this model. Preliminary research shows that exposure to ANIT at 40 mg/kg induces a 2.6 fold increase in taurocholic acid at 72 hours post-exposure compared to 48 hours, indicative of an inability to clear bile constituents from the liver. It is believed that these changes in bile composition are concomitant with alterations in FXR activity. Herein we present the isolation and characterization of FXR alpha from medaka (medFXR α), and demonstrate its activation by bile acids. Experiments are ongoing to determine how ANIT, retinoids and GW4064 alter FXR activity in medaka. We hypothesize that effects of ANIT will be reduced by co-administration of retinoids or GW4064. Supported by the EPA STAR Fellows Program (FP916427); the NIH NCRR R01 RR18583, and Duke University's Cancer and the Environment Program.

1006 GENE EXPRESSION CHANGES IN HUMAN TRACHEAL HS680 CELLS EXPOSED TO FORMALDEHYDE.

G. Li, H. Lee, J. Chung and B. Lee. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Formaldehyde is an occupational and environmental toxicant used extensively in the manufacturing of many household and personal use products. It is known to induce squamous cell carcinomas in the nasal turbinates of rats and mice and nasopharyngeal cancer in human. It is also associated with sick building syndrome, a set of diffuse and irritative symptoms predominantly involving the eyes and the respiratory tract. To identify biomarkers for formaldehyde exposure that might contribute to pathological changes, human trachea fibroblast Hs 680 cells were exposed to formaldehyde at 10 or 100 μ M for 4 h and total RNA was isolated. Microarray hybridization was performed using Sentrix Human-6 Expression BeadChip from Illumina. Data were extracted using the software provided by the manufacturer (BeadStudio v. 1.0.0.5) and normalized by quantile normalization. One-way analysis of variance (ANOVA) and Tukey's HSD test were applied to determine differentially expressed sets of genes across three experimental groups. Statistical significances were adjusted by Benjamini-Hochberg multiple-testing correction. Microarray analysis identified 44 genes as being formaldehyde-responsive, in that their expression levels differed more than 2-fold and significantly from the controls ($p < 0.05$). We confirmed 11 genes induced by formaldehyde using quantitative real time PCR. The changes of these genes in SD rats and human exposed to formaldehyde were analyzed. Our results suggest that the global changes in gene expressions following formaldehyde exposure can be used as biomarkers for formaldehyde toxicity.

1007 GLOBAL GENETIC ANALYSIS OF THE CARDIOVASCULAR EFFECTS OF MAINSTREAM TOBACCO SMOKE.

Mainstream cigarette smoke (MCS) is an important risk factor for diverse cardiovascular ailments. Although the impact of smoking on human health is well defined, little is known about the mechanisms by which MCS mediates its cata-

strophic effects. In the present study, we investigated the effects of MCS on gene expression in heart tissues of mice. Male C57B1/CBA mice were exposed to MCS from two cigarettes daily, 5 days/week for 6 or 12 weeks or to ambient air in restrainers. Mice were sacrificed immediately or 6 weeks following the last MCS exposure. RNA from heart tissue was hybridized against universal mouse reference RNA to Agilent Oligo DNA microarrays containing 22,000 transcripts.

A James-Stein shrinkage test (MAANOVA 2.0) was used to identify 120 genes that were significantly differentially expressed (1.5-14 fold up or down regulated). We have confirmed the altered expression of a select number of genes using real-time quantitative RT-PCR.

Our results revealed up-regulation of Cyp1A1 (14-fold), a key player in the xenobiotic metabolism pathway. A number of genes involved in matrix remodeling, wound healing and fibrinolysis were down regulated (1.5-3 fold). The roles of a subset of these genes involved in MCS response are analyzed in detail including: A disintegrin and metalloprotease 9 (ADAM9), matrix metalloproteinase 25 (MMP25), cysteine-rich angiogenic inducer 61 (Cyr61), the chemokine CXCL-1 and the plasminogen activator inhibitor (PAI-1). Changes in gene expression were transient and were mostly reversed when smoking was discontinued.

Gene expression profiling of heart tissue provides a novel approach to study the molecular mechanisms operating in cardiovascular response to MCS. The present work identifies several novel candidate biomarkers of exposure and potential adverse effect.

1008 CYTOTOXICITY AND GENE EXPRESSION PROFILES IN CELL CULTURES EXPOSED TO WHOLE SMOKE FROM THREE TYPES OF CIGARETTES.

Q. Meng¹, B. Lu², L. Kerepesi³, L. Wisse¹ and K. Hitchman¹. ¹Battelle Toxicology Northwest, Richland, WA, ²Zhengzhou Tobacco Research Institute, Zhengzhou, China and ³Battelle Biotechnology, Columbus, OH.

The purpose of this study was to evaluate and compare the cytotoxicity and gene expression profiles in cell cultures exposed to whole smoke generated from a full flavor cigarette (Test 1), a low tar cigarette (Test 2) and an ultra-low tar cigarette (Test 3). In addition, a reference cigarette 2R4F was evaluated for cytotoxicity. Neutral Red assay was performed to determine relative cell death. LC50 was generated using wet total particulate matter (WTPM), cigarette number, or nicotine concentrations. The overall order of cytotoxicity was Test 1 >> 2R4F ≈ Test 2 > Test 3. Cell samples were collected for RNA extraction at WTPM concentrations of each cigarette that gave similar nicotine concentrations. Affymetrix mouse whole genome 430 2.0 array was used to characterize the gene expression profiles for each cigarette. A total of 598 genes in Test 1, 176 genes in Test 2, and 234 genes in Test 3 samples were differentially expressed compared to sham controls. The major biological processes associated with the changed genes in Test 1 samples were down-regulated DNA replication and cell proliferation; the same biological processes were much less affected in Test 2 and Test 3 samples. The common findings in all three cigarettes were increased glutathione biosynthesis/consumption and inflammatory response, which are known biological effects of smoke exposure. The most significantly up-regulated genes were CYP 1A1, GSTs, Hmox1, and Procr in smoke-exposed samples, which are either related to well-studied mechanisms of smoke exposure-related diseases, or potential new biomarkers for assessing and monitoring biological effects of smoke exposure in vivo and in smokers. In summary, both the neutral red cytotoxicity assay and gene expression profiling were able to differentiate the three types of test cigarettes, and the results demonstrated reduced biological effects for the Test 2 and Test 3 cigarettes compared to the Test 1 cigarette in BALB/c-3T3 Cells.

1009 PULMONARY EFFECTS OF JP-8 JET FUEL EXPOSURE - LABEL-FREE QUANTITATIVE ANALYSIS OF PROTEIN EXPRESSION IN ALVEOLAR TYPE II EPITHELIAL CELLS USING LC/MS.

F. A. Witzmann^{1,3}, K. Lee², M. Wang³, Y. Yemane² and M. L. Witten². ¹Cellular & Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, ²Lung Injury Laboratory, Pediatrics, University of Arizona Health Sciences Center, Tucson, AZ and ³Biochemistry & Molecular Biology, Indiana University School of Medicine, Indianapolis, IN.

Lung epithelial cells are vulnerable to the primary effects of inhaled chemicals. This is true of JP-8 jet fuel, whose untoward effects have been documented in both *in vivo* and *in vitro* exposure systems. The present study was undertaken to assess the effect of JP-8 exposure on rat alveolar type II epithelial cells, at sub lethal levels that are occupationally relevant. An equally important aim was to assess the utility of a novel gel-free/label-free proteomics approach to quantify JP-8-mediated alterations in cellular protein expression. Alveolar type II cells (1×10^6 cells/well) were cultured in 6-well plates and exposed to JP-8 jet fuel (0.1 µg/mL, 0.4 µg/mL, 2.0 µg/mL, vehicle control, and media control) for 24 h. Cells from each of 5 wells

per treatment group (n=5) were solubilized *in situ* and proteins trypsinized. Tryptic peptides from each sample were analyzed serially via linear ion-trap LC-MS/MS. Proteins were identified using SEQUEST and X!Tandem while protein quantification was carried out based on total ion chromatograms using the proprietary technology of Indiana Centers for Applied Protein Sciences (INCAPS). In this approach, the integral volume under each selected peptide peak was measured, normalized, and compared for relative abundance. In this study, 1766 proteins were identified and quantified. Of these, 1135 were identified with high confidence. The identities of the significantly altered proteins will be presented in terms of the functional significance of their JP-8 mediated up- or down-regulation. Supported by AFOSR Grants FA9550-06-1-0083 & FA9550-05-1-0216 to FAW and FA9550-04-1-0231 to MLW.

1010 MICROARRAY ANALYSIS OF CALCINEURIN INHIBITOR IMMUNOSUPPRESSANT-MEDIATED NEPHROTOXICITY IN THE RAT.

J. T. Auman¹, Q. Huang², S. Jayadev², K. Blanchard² and R. S. Paules¹. ¹NIEHS, Research Triangle Park, NC and ²Boehringer Ingelheim, Ridgefield, CT.

The use of calcineurin inhibitor immunosuppressants has revolutionized the clinical practice of organ transplantation. However, chronic nephrotoxicity limits their long-term utility. In order to understand the molecular mechanisms involved in the injury process, a study was designed to investigate changes in gene expression that underlie the development of calcineurin inhibitor immunosuppressant-mediated nephrotoxicity. Male SD rats were dosed daily with cyclosporine A (CsA) at 2.5 and 25 mg/kg/day i.p. or FK506 at 0.6 and 6 mg/kg/day i.p. for 1 to 28 days. Rats were also dosed with rapamycin, a novel immunosuppressant that does not elicit nephrotoxicity at therapeutic levels, at 1 and 10 mg/kg/day i.p. to serve as a negative control. Gene expression profiling was performed on RNA isolated from kidneys 24 hours after 1, 7, 14 and 28 daily doses using the Affymetrix GeneChip Rat Genome 230 2.0 array. Principal components analysis of differentially expressed genes from each treatment group clearly demonstrates a distinction of the rats treated with CsA and FK506 from the rats treated with rapamycin. Examination of the differentially expressed genes across time suggests that CsA and FK506, but not rapamycin, disrupt calcium homeostasis in the kidney as early as the first dose. By 7 doses, gene expression changes consistent with perturbation of the kallikrein-kinin and renin-angiotensin systems are observed only in rats treated with the high doses of CsA and FK506, coinciding with the onset of histopathologically verified renal injury. At the peak of kidney damage (14 to 28 daily doses), kidneys from rats treated with high dose CsA and FK506 exhibit changes in expression for genes involved in cell death and/or apoptosis, response to cellular damage and the development of a fibrogenic response. Thus, using microarrays to assess changes in global gene expression has provided us with insights into mechanisms underlying the development of and cellular responses to nephrotoxicity elicited by calcineurin inhibitor immunosuppressants.

1011 GENE EXPRESSION CHANGES IN KIDNEY FROM RATS EXPOSED TO D-SERINE.

A. Soto¹, A. Stapleton², N. DelRaso¹ and V. Chan¹. ¹HEPB, AFRL, Dayton, OH and ²Henry M. Jackson Foundation, Dayton, OH. Sponsor: S. Hussain.

Renal toxicity commonly occurs after exposure to xenobiotics/pharmaceutical agents or environmental pollutants. Changes in the gene expression in the kidney cells are probably critical events that accompany renal injury. We investigated gene expression changes in kidney after exposure to the nephrotoxin D-serine, which targets the proximal tubule of the kidney. Male F-344 rats (Charles River Laboratories, 222 – 258 g) were injected i. p. with a single dose of D-serine (0, 5, 20, 50, 200 or 500 mg/Kg). Rats were sacrificed 96 hours after the treatment and kidney tissue was collected. Gene expression profiles were determined using DNA microarrays. Gene expression changes including 1158 up-regulated genes and 749 down-regulated genes were identified based on the combined results of t-test ($p < 0.01$ in two consecutive doses) and ANOVA (with Bonferroni correction for multiple testing). Self organized map (SOM) clustering analysis using the expression profiles of the altered (1907) genes as input data showed 2 tight clusters, one of 1158 up-regulated genes and another of 749 down-regulated genes, respectively. Interestingly, there appears to be minimal changes in the expression level of these genes at doses less than 200 mg/Kg, while the most prominent changes were observed at 200 and 500 mg/Kg in both cases. Pathway analysis of the differentially expressed genes showed that at least 27 biochemical pathways are effected including apoptosis, cell cycle, G protein signaling, TGFβ signaling pathway, and transcription initiation. The results of our microarray study showed alterations in the expression of a large number of genes after exposure to D-serine. Further analysis of the biological pathways and processes involved should lead to better understanding of the mechanisms of D-serine toxicity. It would also be of interest to investigate if these genes may serve as organ- and/or region-specific biomarkers for acute renal injury.

1012 KIDNEY TOXICOGENOMICS OF 2-WEEK SODIUM AND POTASSIUM BROMATE EXPOSURE IN F344 MALE RAT.

D. Geter, W. Ward, D. Delker, J. Allen, M. George, G. Knapp, A. DeAngelo and R. Owen. *U.S. EPA, Research Triangle Park, NC.*

Bromate, used in both the food and cosmetics industry, is a drinking water disinfection by-product that is nephrotoxic and carcinogenic to rodents. To gain insight into the carcinogenic mechanism of action, identify possible biomarkers of exposure, and determine if the cation, potassium, significantly alters gene expression, kidney gene expression was examined from male F344 rats exposed to NaBrO₃ and KBrO₃ in drinking water for 2-weeks. Total RNA was isolated from kidney samples and gene expression analyzed using Affymetrix Rat 230A 2.0 GeneChips. Gene expression patterns from two non-carcinogenic (1, and 20 ppm) and one carcinogenic dose (400 ppm) at 2-wk, were compared to each other and to previous gene expression from a 52 wk, 400 ppm KBrO₃ study. Statistical analysis revealed 1, 167, and 229 genes in the NaBrO₃ exposure group and 17, 195, and 139 differentially expressed genes (DEGs) in the KBrO₃ exposure group at the low, medium, and high doses, respectively. Gene ontology classification of the Na- and KBrO₃ groups showed similar expression alterations of genes involved in oxidative stress, lipid metabolism, kidney function/ion transport, and cellular function. Of these, all were equally affected except for an increase in kidney function/ion transport genes observed in the Na- versus KBrO₃ (34 vs. 9 DEGs). In comparing DEGs from 2-week 400 ppm Na- (139 DEGs) and KBrO₃ (229 DEGs) to the chronic 400 ppm KBrO₃ (224 DEGs), there were 14 and 32 shared DEGs respectively that also matched in direction of change. Thus, this study identifies the potential for 2-week bromate gene expression profiles to forecast gene expression changes at chronic time points. However, an important finding was that sodium and potassium bromate treated kidneys yield similar kidney gene expression profiles at two weeks exposure. [This abstract does not necessarily represent EPA policy]

1013 DIFFERENTIAL GENE EXPRESSION BETWEEN TWO SEXES IN HEART OF RAT STRAIN FISHER 344.

T. Han, W. Branham, C. Moland, R. Holland, L. Schnackenberg, R. Beger, R. Jones, R. Edmondson, J. Taylor, W. Tong, Y. P. Dragan and J. C. Fuscoe. *OR/Division of Systems Toxicology, FDA/NCTR, Jefferson, AR.*

Various gender differences in cardiovascular disease and heart failure have been noted in humans, including age of onset, initial manifestations, and drug response. This variability may be reflective of differential gene and protein expression in the two sexes. To understand these sex-associated differences, gene expression profiles in the heart were examined in both males and females at three different ages in a rat model system. In this study, hearts from both sexes of young (8 weeks), middle age (21 weeks) and old age (78 weeks) Fisher 344 rats were ground into powder under liquid nitrogen and aliquots were used for RNA extraction and other analyses. Home-made long-oligonucleotide microarrays of 10,000 rat genes (MWG, Inc.) were used in two-color hybridizations using a reference design experiment. The data were analyzed using ArrayTrack software that was developed at the NCTR/FDA. The raw data were normalized using Total Intensity Normalization method. Welch T-test was used for determining significant changes in gene expression between samples of the two sexes. The results from the microarray experiments showed that the overall gene expression patterns are very similar between the sexes at the three different ages. The data showed much greater gender (sex) difference at 21 weeks compared to 8 weeks and 78 weeks. There are about 218 differentially expressed genes between the male and female at 21 weeks. Among them, many genes are involved in heart structural protein, hormone metabolism and energy metabolism (ATP synthase). These results may lead to more insights of gender-related disease and drug response.

1014 THE ROLE OF THE GUT MICROFLORA IN HYDRAZINE METABOLISM AND TOXICITY: A TRANSCRIPTOMIC AND METABONOMIC APPROACH.

J. R. Swann¹, P. D. Graves², I. D. Wilson³, E. Holmes¹, J. K. Nicholson¹ and J. E. Sidaway². ¹*Biomolecular Medicine, Imperial College, London, United Kingdom*, ²*Safety Assessment, AstraZeneca, Macclesfield, Cheshire, United Kingdom* and ³*DMPK, AstraZeneca, Macclesfield, Cheshire, United Kingdom*. Sponsor: T. Orton.

Symbiotic gut microbes contribute to the health and digestive function of the host, but microfloral differences may also be a factor in idiosyncratic drug toxicity. We have used an integrated transcriptomic (using Affymetrix RG230 genechips) and metabonomic approach to explore the influence of gut microbiota on the toxicity and metabolism of hydrazine, a steatotic hepatotoxin, also known to disrupt the central nervous system. Conventional and germ-free Sprague Dawley rats were administered a single sub-toxic oral dose of hydrazine (60 mg/kg) for four days. Two out of three of the germ-free dosed group were moribund after 24 hours and were sacrificed prematurely; conventional rats were not obviously affected by dosing. ¹H

NMR spectroscopy of urine and plasma indicated that conventional animals excreted hydrazine metabolites more rapidly. Magic angle spinning ¹H NMR of liver showed increased lipid levels in germ-free dosed animals. This was accompanied by decreased expression of genes in sterol and fatty acid metabolism pathways, suggesting that steatosis was more pronounced in germ-free dosed rats. The absence of gut microflora did not influence the hepatic expression of genes associated with xenobiotic metabolism, and most modulated genes were associated with inflammatory pathways. However, the expression of genes for several aminotransferases (alanine aminotransferase, serine dehydratase) was markedly decreased in germ-free animals. The function of aminotransferases is reliant upon the microbial derived co-factor pyridoxal 5' phosphate (PLP). As PLP is sequestered during hydrazine toxicity, this may explain the enhanced susceptibility of germ-free rats to hydrazine. This highlights the potential of gut microbiota imbalances as a factor in drug toxicity.

1015 EFFECTS OF TCDD ON CRANIOFACIAL CARTILAGE GENE EXPRESSION IN DEVELOPING ZEBRAFISH.

K. M. Xiong¹, V. Mehta², R. E. Peterson³ and W. Heideman^{1,3}. ¹*Biomolecular Chemistry, University of Wisconsin, Madison, WI*, ²*Molecular and Environmental Toxicology Center, University of Wisconsin, Madison, WI* and ³*School of Pharmacy, University of Wisconsin, Madison, WI*.

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) produces craniofacial malformation in developing vertebrates. Fish species are especially sensitive to this effect and we have used zebrafish as a model system for studying this process. It is thought that most if not all toxic endpoints caused by TCDD result from activation of the aryl hydrocarbon receptor/aryl hydrocarbon receptor nuclear translocator (AHR/ARNT) transcription factor. Thus, we hypothesized that activated AHR/ARNT misregulates critical genes controlling craniofacial development. We used Affymetrix microarrays to profile gene expression changes occurring in zebrafish jaws after exposure to TCDD at 96 hours post fertilization. Cartilage mRNA samples were collected at 1, 2, 4 and 12 hours after initial exposure to allow us to identify both immediate transcriptional changes as well as genes affected as jaw malformation begins. We identified 204 genes that were altered by at least 2 fold (p-value ≤ 0.05). We found immediate changes in xenobiotic metabolism genes, such as cytochrome p4501a1 (cyp1a1), cytochrome p4501b1 (cyp1b1) and cytochrome p4501c1 (cyp1c1). These are known to be AHR/ARNT targets, and this result is consistent with direct activation. Downregulation of cell replication transcripts, such as minichromosome deficient 2, 3 and 5 (mcm2, mcm3 and mcm5) at 4 hours post TCDD exposure suggests a possible mechanism for the stunted growth in jaw structures caused by TCDD. Finally, upregulation of chondrogenesis pathway genes endothelin 1 (edn1) and exostosin 1c (ext1c) and downregulation of sry-box containing gene 9b (sox9b), hyaluronan and proteoglycan link protein 1 (hapln1a) may indicate that TCDD alters terminal differentiation in the jaw, leading to malformation. Whether these gene expression changes are direct results from AHR/ARNT-mediated transcription remains to be elucidated. (Supported by NIH RO1 ES012716 and UW Sea Grants R/BT17, R/BT20 and R/BT22)

1016 TRANSCRIPTOME ANALYSES OF MULTIPLE ENDOCRINE TISSUES FOLLOWING AN ACUTE EXPOSURE OF MALE RATS TO THE ANTIANDROGEN FLUTAMIDE.

D. Rouquié¹, C. Friry-Santini¹, C. Cayatte², L. Elies¹, H. Tinwell¹, F. Schorsch¹ and R. Bars¹. ¹*Bayer CropScience, Sophia Antipolis, France* and ²*IFR 50, Faculté de Médecine, Nice, France*. Sponsor: N. Carmichael.

Exposure of adult male rats to antiandrogens has been shown to affect the pituitary-gonadal axis and lead to toxicity in the male reproductive organ and tissues. However little is known about the profile of gene expression in multiple target tissues following exposure to antiandrogens. To better assess the coordinated molecular changes induced by antiandrogens in different target tissues, male Sprague Dawley rats were treated with a single dose of vehicle only (methylcellulose) or the androgen receptor antagonist flutamide (150 mg/kg) and were sacrificed 8, 24 or 48 hours after dosing. At necropsy, blood samples were collected for luteinizing hormone and testosterone measurements. Pituitary gland, testis and prostate samples were collected for full genome transcriptome analyses coupled with Gene Ontology and metabolic pathway analyses. Results indicate that testosterone levels were affected from 8 hours after treatment although statistical significance was only achieved at 24h and 48h. Gene expression analysis shows that the largest number of genes affected for the pituitary, the prostate and the testis was found at 8h, 24h and 48h respectively. Overall, lipid and steroid biosynthesis and cell proliferation were the main biological processes affected in the testis whereas cell to cell signaling, inflammatory response and cell proliferation were the main processes affected in the prostate. No histopathological change was observed at any time points. Overall,

these results show that dynamic molecular changes at different organ levels can be studied in short term kinetic studies, well before the presence of histopathological lesion.

1017 CROSS-SPECIES COMPARISON OF TAMOXIFEN & ESTROGEN INDUCED UTEROTROPY IN RODENTS.

J. C. Kwekel, C. J. Fong, L. D. Burgoon and T. R. Zacharewski. *Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI.*

A ligand and species comparative analysis approach was used to systematically assess the physiological, morphological and transcriptional uterine alterations elicited by tamoxifen (TAM) and ethynyl estradiol (EE) in immature ovariectomized Sprague-Dawley rats and C57BL/6 mice. Temporal gene expression was evaluated for each compound in each species. Animals were dosed once or once daily for 3 consecutive days and uteri were harvested 2, 4, 8, 12, 18, 24, or 72 hrs after treatment. TAM responsive genes were filtered by the species-conserved EE genes to distinguish estrogenic and novel effects of TAM. 377 orthologous gene pairs (79%) which overlap with the EE-induced profiles were identified, suggesting conserved gene expression events important in uterine proliferation. In addition, 50 genes with species-conserved TAM regulation that were not previously described as EE responsive were identified, suggesting species-conserved effects that were unique to TAM. Functional annotation for these novel TAM responses were associated with water and solute transport, proliferation, red-ox control, protein synthesis and transport, xenobiotic metabolism, and cell-cell communication which were similar EE regulated endpoints but used different signaling mechanisms. Moreover, several genes were identified which exhibited divergent TAM regulation when compared to EE. This multi-species approach provided insights into compound-specific differences in uterine architecture during uterotrophy. The identification of comparable temporal phenotypic responses linked to related gene expression profiles demonstrates that systematic comparative genomic assessments can elucidate important conserved and divergent uterine proliferation mechanisms in rodent estrogen signaling during proliferation. Funded by US EPA RD 83184701, R21 GM075838 and *NIEHS Training Grant ES07255-16

1018 17 α -ETHINYLESTRADIOL INDUCED GENE EXPRESSION CHANGES AND SUBSEQUENT TESTICULAR PATHOGENESIS AND DECREASED FERTILITY IN THE MEDAKA FISH.

B. W. Clark^{1,2}, H. D. Miller^{1,2}, D. C. Volz^{1,2}, D. E. Hinton^{1,2} and S. W. Kullman^{1,2}. ¹Nicholas School of the Environment, Duke University, Durham, NC and ²Integrated Toxicology and Environmental Health Program, Duke University, Durham, NC.

Currently, several toxicogenomic projects in our lab use microarrays for gene discovery, pathway analysis, and biomarker determination. Each utilizes aquatic vertebrate models for assessments of toxicity and associated phenotypes. Driving this research is the general assumption that there are evolutionarily conserved regulatory processes associated with observed toxicities. We hypothesize that most vertebrate species will activate transcription of a similar set of genes following drug or xenobiotic exposure. Moreover, discovery of this conserved set of responsive genes will focus attention on genes and pathways that have greater predictive relevance to human toxicities and pathology. In this study, changes in testis gene expression following exposure to 17 α -ethinylestradiol (EE2) were examined and linked to subsequent alterations in testis pathology and more apical end points including fertility. Medaka fish were exposed to 0.1, 1.0 or 10 ppb of EE2 and sacrificed at day 1, 3, 7 or 14 for gene expression and pathological analysis. In addition, fertility was assessed after 14 days of exposure to evaluate reproductive capability. Using a custom 277-gene cDNA membrane array, we found that changes in gene expression and histology were dose and time dependent. Putative estrogen response elements (EREs) were identified upstream of the transcriptional start site indicating that a component of the gene response is mediated by the classical ER/ERE mechanism. Several genes demonstrated a lack of ERE binding motifs, suggesting alternate pathways for estrogen mediated gene expression. The relation of gene changes, development of testicular pathologies and ultimate impact of reproductive capacity will be addressed. These data will help correlate the temporal and dose relationship between the transcriptional response to EE2 and associated cellular and reproductive alterations.

1019 TESTICULAR GENE EXPRESSION PROFILING FOLLOWING GLYCOL ETHER SOLVENT EXPOSURE IN MALE RATS.

E. Tonkin, M. Cooper, K. Kolaja, L. Lollini, P. Day-Lollini, S. Platz and S. Chanda. *Non-Clinical Drug Safety, Roche Palo Alto, Palo Alto, CA.*

2-Methoxyethanol (2-ME) and 2-ethoxyethanol (2-EE) are glycol ether solvents that produce testicular toxicity characterized by spermatocyte degeneration and depletion. 2-EE is less potent than 2-ME, while a structurally similar glycol ether, 2-

butoxyethanol (2-BE), produces no testicular lesions. The goal of the current study was to assess the mechanism of glycol ether testicular toxicity using gene expression profiling. Male rats were administered daily oral doses of 2-ME (150 and 500 mg/kg/day), 2-EE (500 mg/kg/d), 2-BE (125 mg/kg/d), or vehicle for 3 days, after which testes were collected for histopathological and gene expression analysis. Histopathological changes were observed only in animals given 150 mg/kg/d 2-ME, consisting of degeneration and necrosis of spermatocytes with reductions in spermatocyte numbers. Microarray analysis was performed using an unpaired t-test following data normalization. There were 28, 1095, 945, and 1721 genes that were differentially expressed at >1.5-fold, $p < 0.05$ versus control in testes from animals exposed to 2-BE, 2-EE, 2-ME (50 mg/kg), and 2-ME (150 mg/kg), respectively. There was an overlap of 525 genes between the 2-EE and two 2-ME treatment groups. To assess what categories of genes were affected by 2-EE and 2-ME, expression data was analyzed using the Expression Analysis Systematic Explorer (EASE) application. This analysis demonstrated statistical enrichment ($p < 0.05$) in genes in categories including protein transport/endocytosis, protein kinase activity, cell cycle, meiosis, transcriptional regulation, and cell death. While enrichment of genes involved in cell death and meiosis are consistent with the morphological changes produced by these compounds, enrichment of genes such as those involved in protein transport represent possible novel targets of glycol ether solvents. Additional experiments will be performed to confirm these findings and to assess their relevance in the mechanism of glycol ether testicular toxicity.

1020 MOLECULAR PROFILING OF FORMALIN-FIXED PARAFFIN-EMBEDDED (FFPE) TISSUES: CONFIRMING DIFFERENTIAL GENE EXPRESSION IN THE RAT UTERUS AND CERVIX.

L. Nelms, P. Koza-taylor, G. Seitis, R. Jamon, M. Mirsky and M. Lawton. *Pfizer, Groton, CT.*

Several approaches have been reported for the isolation of RNA from FFPE tissues for analysis by RT-PCR, microarrays, or other methods for measuring gene expression. However, many of these techniques for RNA isolation suffer from similar limitations, including recovery of degraded RNA, low yields, and time-consuming labor-intensive protocols. We compared several commercially available kits for RNA isolation from FFPE tissues and found the FFPE kit from Qiagen performed the best. To help resolve an issue identified in a microarray study (reported separately by Koza-Taylor et al.), RNA was isolated using the Qiagen kit from FFPE blocks containing uterus and cervix from rats treated with estrogen. The quality of this RNA was compared to RNA isolated from fresh-frozen tissue. Real-time PCR was then performed on the frozen RNA and the FFPE RNA using four different primer/probe sets that were chosen based on Affymetrix RAE230v2 GeneChip data. The gene matrix metalloproteinase 7 (MMP7) was used since microarray data showed that it was highly up regulated with estrogen. The gene Plasminogen activator inhibitor 2 type A (Pai2A) was chosen from microarray data and evaluated as a cervix specific marker present at moderate levels. The results of RT-PCR for all genes evaluated were comparable to the Affymetrix results. Also, the patterns of expression for the frozen and FFPE RNA were the same. Finally, a strong correlation between the presence of cervix, as demonstrated by H&E staining, and a positive signal for Pai2A expression was confirmed by RT-PCR. These results allowed the confirmation of the hypothesis that a few samples used to generate microarray data were contaminated with cervix tissue.

1021 GENE EXPRESSION OF TESTICULAR TOXICITY INDUCED BY EMODIN OR ACRYLAMIDE IN MALE MICE.

K. Ohshida¹, M. Hirakata¹, H. Tainaka², Y. Nishimune², H. Tanaka² and Y. Miyamoto¹. ¹Pharmaceutical Research Laboratories, Toray Industries, Inc., Kamakura, Japan and ²Research Institute for Microbial Diseases, Osaka University, Osaka, Japan.

Emodin is an active constituent isolated from the root of Chinese Rhubarb. Pharmacological studies have demonstrated that Emodin possesses anti-bacterial, anti-inflammatory, vasorelaxant, anti-ulcerogenic, and anti-cancer effects. Our unpublished data indicated that Emodin showed the testicular toxicity in mouse. In this study, we investigated the testicular toxicity of Emodin using a toxicogenomic method in mice, as compared with Acrylamide, known as a testicular toxicant. Emodin or Acrylamide was administered orally to male CD-1 mice for 5 days at a dose of 1000 and 50 mg/kg/day respectively. Twenty four hours after final dosing, testes of all mice were extracted for total RNA, and the gene expression profile in testis of chemical-treated mice were compared to the control mice using a cDNA microarray (Asahi Techno Glass Corporation), Testis-1 (172 genes: haploid germ cells-related) and Testis-2 (2704 genes: testis-related). In all treated groups, degenerative histopathological changes of the testes were observed and the number of TUNEL-positive germ cells, were increased. No changes in haploid germ cell-related gene expression were observed in microarray analysis using Testis-1. The majority of testis-related genes examined showed slight differences in expression between the treated and control groups using Testis-2. However, there were 34 and 30

genes, whose expression was more than 1.5 fold or less than 0.67-fold in the Emodin and Acrylamide treated mice, respectively, as compared with the control mice. Interestingly, it was found that expressions of the same 3 genes, MutS homolog 4, Chromobox homolog 5 and SMC-like 2 were decreased by both compounds. Furthermore, Emodin affected the gene expressions of calpain 3, Dynein, DEAH box polypeptide 8, Cyclin-dependent kinase inhibitor 1B and CD47 antigen. These results suggest that Emodin has a testicular toxicity and specifically affects the expression of some genes not relevant to the testicular toxicity of Acrylamide.

1022 COMPARATIVE ANALYSIS OF TEMPORAL GENE EXPRESSION, MORPHOMETRY AND UTEROTROPY IN O, P'-DDT AND ETHYNYLSTRADIOL TREATED RATS.

A. L. Forgacs¹, J. C. Kwekel^{1,2}, L. D. Burgoon^{1,2} and T. R. Zacharewski^{1,2}.
¹Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI and ²Center for Integrative Toxicology, National Food Safety and Toxicology Center, Michigan State University, East Lansing, MI.

Changes in uterine physiology, cell morphology and gene expression were evaluated in a comprehensive time course study after oral administration of 300 mg/kg o,p'-DDT (DDT) or 100 ug/kg bw ethynylestradiol (EE) to immature, ovariectomized Sprague-Dawley rats. Animals were dosed once or once daily for 3 consecutive days and uteri were harvested 2, 4, 8, 12, 18, 24, or 72 hrs after treatment. EE and DDT elicited uterotrophic EC50s of 16.2 ug/kg and >64.6 mg/kg, respectively, in dose response studies. DDT only induced a 3.3-fold increase in wet weight with a marked decrease in water imbibition compared to the 7-fold induction with EE. Temporal gene expression profiles were measured using custom rat cDNA microarrays with 8,567 features representing 3,042 genes. Genes differentially regulated by either DDT or EE were identified using a model-based t-statistic/Empirical Bayes approach and their temporal expression profiles were compared to identify conserved and divergently regulated genes. In order to phenotypically link these changes in gene expression to the physiological alterations observed in the uterotrophic response, complementary histological and morphometric assessment of uterine mid-horn sections stained with eosin and hematoxylin were performed. DDT treated histological samples were characterized by marked apoptosis increases in the luminal epithelia and stroma at 72 hr compared to EE. Quantitative real time PCR analysis confirmed increased efficacy of genes involved in apoptosis and water shuttling (Pycard, Aqp0/MIP) while classically estrogen regulated genes (C3, Calb3) exhibited equivalent or lower responses in response to DDT. These results suggest that DDT and EE elicit disparate differential gene expression sets responsible for differences in uterotrophic and pathological effects.

1023 USE OF TOXICOGENOMICS DATA IN RISK ASSESSMENT: A CASE STUDY ON DIBUTYL PHTHALATE AND MALE REPRODUCTIVE DEVELOPMENTAL EFFECTS.

A case study to incorporate toxicogenomics data qualitatively into an EPA health assessment has been performed for dibutyl phthalate (DBP), focusing on the male reproductive developmental effects. Using EPA's IRIS external peer review draft DBP assessment as the starting point, the case study asked whether toxicogenomics data could further define the mode(s) or mechanism(s) of action and inform interspecies extrapolation. The modes of action that explain some of the male reproductive developmental effects observed after in utero DBP exposure in rodents are reduced fetal testicular testosterone production and insl3 gene expression. The male reproductive developmental toxicology dataset was assessed for low incidence findings that may indicate additional pathways. The toxicogenomics dataset is composed of eight published microarray or real-time reverse transcriptase-polymerase chain reaction (RT-PCR) rat studies. The microarray data were analyzed using pathway analysis and regulatory network modeling to determine whether additional pathways were affected by in utero DBP exposure. Taken together, the results of the toxicity and toxicogenomics data analyses corroborate the DBP modes of action of reductions in fetal testicular testosterone production and insl3 gene expression, and indicate that additional pathways were also affected. Additionally, research needs for designing gene expression studies for use in risk assessment were identified. The approach for utilizing toxicogenomics data in risk assessment defined in this study may be applied to other chemical assessments. Disclaimer: The views expressed are solely those of the authors and do not represent the policies and/or endorsement of the U.S. Environmental Protection Agency.

1024 HUMAN PBMCs AS AN *IN VITRO* MODEL FOR IDENTIFYING HUMAN BIOMARKERS TO PREDICT MECHANISMS OF COMPOUND INDUCED TOXICITY.

N. S. Patil, L. Brady, S. Brown, N. Faravashi, B. Eynon, J. Gollub, R. Nair, S. Fujimoto, G. Day and D. Halbert. *Molecular & Investigative Toxicology, Iconix Biosciences, Mountain View, CA.*

Using an *in vitro* system to determine a chemical's propensity for inducing particular toxicities in humans would represent a significant advance in drug development. *In vitro* cell systems have the distinct advantage of requiring only milligram amounts of test compound compared to *in vivo* systems. Our library of Drug Signatures® or biomarkers derived from gene expression profiling of compound-treated rat primary hepatocytes *in vitro* has successfully been used to predict *in vivo* rat hepatotoxicity during drug development. To establish a human peripheral blood mononuclear cell (PBMC)-based system to predict mechanisms of drug action and toxicity relevant to humans, cells from normal donors are treated with reference compounds *ex vivo*. Human PBMCs are clinically accessible and therefore ideal to assess the global transcriptional effects of compounds on human primary cells. We have analyzed gene expression profiles of PBMC from multiple donors treated with >40 compounds with well studied toxicity and mechanisms of action. Our data indicate that gene expression changes in response to one compound or compound class are consistent among donors, suggesting that donor-to-donor variability is not a limiting factor in this system. Our data show that compound-induced gene expression responses are specific to different mechanistic classes of compounds and impact specific pathways as expected. Glucocorticoid receptor agonist treatments suppress genes involved in immune response pathways, and DNA alkylator compounds induce genes involved in DNA damage response pathways. We are now adding gene expression data from ~60 more compounds to our PBMC database in order to derive biomarkers for specific pharmacologic mechanisms of action and mechanisms of toxicity. Results to date support the potential of a human PBMC-based *in vitro* system to characterize the toxicological and pharmacological mode of action for experimental compounds in order to better anticipate human clinical responses.

1025 PRIMARY CELLS AS PRIME MODELS: TOWARDS AN EFFECTIVE MODEL SYSTEM FOR PREDICTIVE TOXICOGENOMICS.

S. Rangarajan and J. van der Hoeven. *VitrOmics BV, 's-Hertogenbosch, Netherlands.* Sponsor: H. van Loveren.

Predictive toxicogenomics using *in vitro* systems is emerging as an important tool in determining the toxicities of various chemicals and potential pharmaceutical compounds, with efforts to establish regulatory guidelines in the field. Primary human cells have the advantage of closer correlation to humans *in vivo* with possibilities to extrapolate *in vitro* toxicity signatures. Human peripheral blood mononuclear cells (PBMCs), one of the most clinically accessible primary human cells show promise as a model system to assess global transcriptional effects of compounds. Our main objective was to establish a quality-controlled database of compound signatures for predictive profiling by analyzing gene expression profiles of reference compounds across multiple mechanistic classes. Towards this goal, we performed all studies under GLP-compliance to establish human PBMCs as an effective model system for predictive toxicogenomics. We evaluated differences in human lymphocyte sources, culture conditions and donor variability. We conducted various cytotoxicity, apoptosis and genotoxicity assays. To correlate PBMCs *in vivo* and *in vitro*, we compared lymphocyte subpopulations by flow cytometry and gene expression profiles by transcriptomics. Towards initializing a toxicogenomics database of chemicals we exposed cultured human PBMCs to 6 genotoxic compounds that induce genotoxicity either by direct interaction with DNA (MMC, MMS, CIS) or by indirect secondary mechanisms (ETOP, HU, TAXOL). Using Affymetrix platform for transcriptomics we have shown that gene expression profiling could identify compound-specific signatures and distinguish mechanisms of action of the genotoxic compounds (direct or indirect, aneugenic or clastogenic). Donor variability or technical variations were not limiting factors. Our data support the potential of human PBMCs as a model system to characterize and predict the toxicities of chemical compounds by transcriptional profiling. Future studies will expand the database of expression profiles of a wide range of chemicals to predict toxic outcomes for *in vivo* and other human *in vitro* models.

1026 COMPARISON OF GENE EXPRESSION ANALYSIS METHODS FROM FORMALIN-FIXED PARAFFIN-EMBEDDED TISSUES.

T. L. Hodam, L. O. Whiteley, L. J. Kraus and J. Davis. *DSRD, PGRD, Chesterfield, MO.*

Microscopic evaluation of formalin-fixed paraffin-embedded (FFPE) tissues from preclinical animal studies is the gold standard for identifying safety signals of new chemical entities (NCEs). While formalin fixation is an excellent way to preserve

specimens for these evaluations, there are limitations to the use of these samples when molecular analyses are required. The fixation process itself as well as prolonged storage can cause modifications and degradation to RNA. Coupled with high temperatures used for embedding and the natural degradation of RNA over time, it is very difficult to isolate intact and unmodified RNA. Furthermore, reverse transcriptase is less efficient at converting modified RNA to cDNA. Numerous methods have been proposed to isolate RNA from FFPE tissues for gene expression analysis. This study was designed to compare QuantiGene's branched DNA technology, which does not require RNA purification and target RNA amplification to Ambion's RecoverAll quantitative PCR method for measuring gene expression in FFPE tissues. In addition, these isolation methods were also compared to standard TaqMan analysis when RNA was isolated from flash frozen tissue. Direct comparisons between TaqMan (flash frozen) to QuantiGene (flash frozen & FFPE) demonstrate that both methods yield similar trends in target mRNA induction. Gene expression results from the RecoverAll method were difficult to interpret, the reasons for which are still under investigation. This data clearly indicates it is possible to generate reliable gene expression data from FFPE tissues and could have usefulness in retrospective analyses.

1027 COMPARISON OF 1 COLOUR AND 2 COLOUR METHODS FOR MICROARRAY-BASED TRANSCRIPTION PROFILING ANALYSIS WITH LASER CAPTURE MICRODISSECTED SAMPLES.

E. Hunter², S. M. Plummer¹, R. Finch², T. Hill², S. Kain³, U. Sauer⁴ and S. Smith¹. ¹*cxr biosciences, Dundee, United Kingdom*, ²*Agilent Technologies UK Ltd, Stockport, United Kingdom*, ³*Agilent Technologies Inc., Santa Clara, CA and* ⁴*PALM Microlaser Technologies, Bernried, Germany*. Sponsor: *C. Elcombe*.

Understanding molecular mechanisms of toxicity as reflected by parallel changes in gene expression requires techniques that are capable of measuring alterations in cell types relevant to the toxicity. To determine the utility of applying whole genome microarray-based transcription profiling analysis to laser microdissected tissue sub-regions for mechanistic studies of rat fetal testes toxicity, we have compared data generated using 1 colour (1C) and 2 colour (2C) microarray protocols. Total RNA was isolated from the laser microdissected (PALM microbeamTM) interstitial-Leydig cell (INT) region of in utero dibutylphthalate (DBP)-exposed fetal rat testes at gestational day 19.5. Linear amplification of 500pg of RNA from control- and DBP-treated rats was performed using 2 cycles of cDNA synthesis and T7 polymerase-based RNA synthesis. RNA was fluorescently labelled using Kretech ULSTM cy-dye reagents and hybridised to Agilent whole rat genome oligo microarrays in a one or two colour analysis. GeneSpring software was used to generate signature lists of significantly regulated genes for each region. 1C and 2C analysis identified 511 and 107 genes that were significantly regulated ($p < 0.05$), respectively, in the INT region. Variability in the data between replicate arrays was higher in the 1C compared to the 2C data. Bioinformatic analysis of the 1C and 2C 'signature' gene lists using Ingenuity Pathways AnalysisR (IPA) software indicated that there was some overlap in the biological pathways that were identified as significantly affected. However the 2C data output was more consistent with the published literature for this class of compound than the 1C data. Corroboration of the data generated by the two methods using immunohistochemical staining is required to fully assess the biological relevance of the signature list differences observed.

1028 NEAR-INFRARED LIGHT THERAPY INCREASES CELL SURVIVAL IN A *IN VITRO* MODEL OF PARKINSON'S DISEASE.

K. D. DeSmet¹, E. Buchmann², M. Wong-Riley³, H. T. Whelan^{2,1} and J. T. Eells^{1,2}. ¹*College of Health Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI*, ²*Neurology, Medical College of Wisconsin, Milwaukee, WI* and ³*Cell Biology, Neurobiology, and Anatomy, Medical College of Wisconsin, Milwaukee, WI*.

A large body of evidence supports a central role for mitochondrial dysfunction in the pathogenesis of Parkinson's Disease (PD). PD patients express systemic defects in mitochondrial complex I activity and complex I inhibitors have been shown to produce PD. There are also inherited forms of PD that result from mutations in genes that code for α -synuclein. The underlying pathological feature in both genetic and environmentally induced forms of PD is mitochondrial dysfunction resulting in increased production of reactive oxygen species followed by subsequent cell death of dopaminergic neurons in the substantia nigra. Photobiomodulation by far-red to near-infrared (630 to 1000 nm) light has been shown to enhance mitochondrial energy production and promote cellular survival following a mitochondrial insult. The present studies were undertaken to test the hypothesis that near-infrared (NIR) light emitting diode (LED) photobiomodulation will stimulate mitochondrial function, attenuate oxidative stress and improve cell survival in a cellular model of Parkinson's Disease. Experiments were conducted in human

dopaminergic cell lines (SH-SY5Y) engineered to stably over express mutant human α -synuclein (A30P). Cells were plated at a density of 400,000 cells/mL in 24 or 6 well plates and incubated at 37° C in DMEM supplemented with 10% FBS. At 107 hr cells were exposed to increasing concentrations of MPP+ (1, 2.5, or 5 mM) for 24 hrs. Duplicate cultures were treated with 670 nm NIR-LED light (8 joules/cm²) at 108, 120 and 132 hrs. Cells were harvested at 144 hr for analysis of mitochondrial dehydrogenase activity, hydrogen peroxide production and cellular proliferation. 670 nm light treatment produced a significant increase in mitochondrial dehydrogenase activity and cellular proliferation while hydrogen peroxide production was unchanged.

1029 GENDER SPECIFIC ALTERATIONS IN DOPAMINERGIC FUNCTION IN THE PARAQUAT AND MANEB EXPOSURE ANIMAL MODEL OF PARKINSON'S DISEASE.

Y. Nikpour, J. Kochar, D. A. Cory-Slechta and M. Thiruchelvam. *Department of Environmental & Occupational Medicine, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ*.

Epidemiological and clinical studies suggest a higher incidence of Parkinson's disease (PD) in males than females, suggesting the presence of some neuroprotective mechanisms in the female gender. To determine whether there is a differential susceptibility between genders to paraquat (PQ) and maneb (MB), male and female C57BL/6 mice were treated with saline or 10 mg/kg PQ + 30 mg/kg MB twice a week and sacrificed 24hrs after the 2nd dose. Although lipid peroxidation (LP) levels were elevated in midbrain and striatum of both males and females treated with PQ+MB, the males showed significantly higher LP levels than the females. Western blot analysis of key dopaminergic proteins indicated that tyrosine hydroxylase was unchanged in response to PQ+MB in either gender, however, dopamine transporter levels were significantly decreased in the striatum only in females and vesicular monoamine transporter levels were significantly increased in the striatum in both genders. Acute exposure to PQ+MB significantly increases dopamine levels in the striatum in both genders, which in turn can lead to an increase in dopamine mediated oxidative damage. Determination of concentration of key anti-oxidant proteins within the dopaminergic system revealed a significant increase in Nrf2 and superoxide dismutase (SOD) in females in both the striatum and midbrain in accordance with a protective function, whereas in the males the levels of these proteins were either decreased or unchanged. Cell survival and dopaminergic phenotypic proteins were decreased, especially in the midbrain, of both males and females, with a more pronounced decrease in the males. These observations are consistent with protection conferred in females by increased anti-oxidant capabilities, altered dopamine uptake and storage or increased trophic support. A further understanding of the mechanism of neuroprotection seen in females can lead to the development of possible therapeutic interventions for PD. Supported by APDA & ES10791

1030 INHIBITION OF 3, 4-DIHYDROXYPHENYLACETALDEHYDE METABOLISM LEADS TO PROTEIN MODIFICATION.

J. N. Rees, V. Florang and J. A. Doorn. *Medicinal and Natural Products Chemistry, The University of Iowa, Iowa City, IA*.

Parkinson's disease is a neurodegenerative disorder characterized by cell death of dopaminergic neurons. Current studies have indicated that cell death may originate from increased oxidative stress and reactive dopamine (DA) metabolites. DA undergoes biotransformation through oxidative-deamination catalyzed by monoamine oxidase to 3,4-dihydroxyphenylacetaldehyde (DOPAL), a neurotoxic intermediate. DOPAL is then primarily oxidized to 3,4-dihydroxyphenylacetic acid (DOPAC) by mitochondrial aldehyde dehydrogenase (ALDH). ALDH can be inhibited by aldehydes derived from oxidative stress, e.g. 4-hydroxynonenal (4HNE), which might impair DOPAL metabolism yielding atypical levels of the dopamine metabolite. Based on this information, it is hypothesized that DOPAL, generated at aberrant levels due to impairment of dopamine metabolism, will cause protein modification. This work utilizes rat striatal synaptosomes to demonstrate that upon addition of 4HNE a decrease in DOPAC levels and a corresponding increase in DOPAL concentrations are observed. It was also established that DOPAL will modify proteins using a detection method involving nitro blue tetrazolium, indicating that the catechol-containing adducts undergo redox cycling. Furthermore, DOPAL-modified proteins demonstrate increased oxidative modification when in the presence of either 50 or 100 μ M CuCl₂-H₂O, which may be due to redox cycling of DOPAL. The data establish the ability of DOPAL to modify proteins thus, demonstrating its potential role in the pathogenesis of neurodegenerative diseases.

1031 REACTIVITY OF DOPAMINE OXIDATION PRODUCTS TOWARD PROTEINS.

D. G. Anderson, V. Florang and J. A. Doorn. *Medicinal and Natural Products Chemistry, The University of Iowa, Iowa City, IA.*

Parkinson's disease (PD) is a progressive neurodegenerative disorder that currently affects over a million Americans. Dopaminergic neuronal death is known to be involved in the disease pathology. The loss of such neurons may be due to the inherent toxicity of certain aldehyde intermediates created during neurotransmitter metabolism. For example, oxidative deamination of dopamine results in the formation of 3,4-dihydroxyphenylacetaldehyde (DOPAL). Recently, it has been hypothesized that a possible mechanism for DOPAL toxicity is protein adduct formation via reaction with primary amines such as those found on proteins. In order to test this hypothesis, antibodies were generated toward blue-carrier protein modified by DOPAL. Antibody assays indicated that adduct-formation occurred with bovine serum albumin treated with 1.0-100 μ M DOPAL. Dopamine can be oxidized to the o-quinone, which is known to be reactive with proteins. In order to test this scenario with DOPAL, NaIO₄ was used to oxidize the dopamine-derived aldehyde. Based on spectrophotometric assays this oxidation product rearranges; however it was found to be reactive towards 1.0 mM glutathione but not 1.0 mM N-acetylated-His or 1.0 mM N-acetylated-Lys. Therefore, these data demonstrate that DOPAL and its oxidized product are reactive towards proteins.

1032 GLIAL-NEURONAL INTERACTIONS: ASTROCYTES MODULATE TOXICANT-INDUCED NEURODEGENERATION VIA THE EXTRANEURONAL MONOAMINE TRANSPORTER, OCT3, IN MOUSE BRAIN.

M. Hatwar¹, W. Peng^{2,3}, V. Jackson-Lewis⁴, N. Ballatori¹, J. A. Javitch⁴, M. Nedergaard^{2,3}, S. Przedborski⁴ and K. Tieu^{1,2}. ¹*Environmental Medicine, University of Rochester, Rochester, NY*, ²*Center of Aging and Developmental Biology, University of Rochester, Rochester, NY*, ³*Neurosurgery, University of Rochester, Rochester, NY* and ⁴*Columbia University, New York, NY.*

Astrocytes are increasingly being recognized as playing critical roles in maintaining normal physiological functions as well as in inducing and aggravating neuronal pathology. The neuroprotective and neurodegenerative roles of astrocytes depend largely on the molecules that they remove from or release into the extracellular microenvironment that is shared by astrocytes and neurons. Recently, the extraneuronal monoamine transporter, the organic cation transporter-3 (Oct3) in rodents, was shown to be expressed in astrocytes. The present study tested the hypothesis that astrocytes modulate neurodegeneration by regulating the levels of toxic cations in the extracellular space of neurons. Immunostaining in C57BL mice showed that Oct3 was selectively expressed in astrocytes in the nigrostriatal region but not in the astrocytes that reside in the cerebellum, hippocampus and cortex. Similar pattern of expression was also detected in post-mortem human brain sections. Functional transport studies in cultured primary astrocytes confirmed bi-directional transport of [³H]-MPP⁺ mediated by Oct3, thus supporting its ability to modulate the levels of certain organic cations. To assess the role of astrocyte Oct3 in regulating the extracellular levels of neurotoxic cations, C57BL mice were injected with MPTP, a parkinsonian neurotoxicant, to introduce the cation MPP⁺ (the active metabolite of MPTP) into astrocytes. Stereological cell counts of dopaminergic neurons in the nigra showed significantly less cell death in Oct3-knockout mice and in animals treated with an Oct3 inhibitor, as compared to their respective MPTP treated controls. This study provides insight into a novel mechanism that contributes to selective cell death, as observed in the MPTP animal model of Parkinson's disease.

1033 THE TRIGGER ROLE OF MITOCHONDRIAL PERMEABILITY TRANSITION IN THE DEVELOPMENT OF NEURODEGENERATIVE DISORDERS.

S. O. Bachurin^{1,2}, E. P. Shevtzova¹, E. G. Kireeva¹, I. Y. Kalachev^{2,1}, S. G. Klochkov¹ and N. S. Zefirov^{1,3}. ¹*Institute of Physiologically Active Compounds, Russ. Academy of Sciences, Chernogolovka, Moscow area, Russian Federation*, ²*CFC TRUST, Chernogolovka, Russian Federation* and ³*Non-profit partnership "Orchemed", Moscow, Russian Federation*. Sponsor: K. Khamidulina.

Mitochondrial permeability transition pores represent a multiprotein complex, which includes components of both inner and outer membrane. The pores regulate transport of ions and peptides in and out of mitochondria, and their regulation is associated with a general mechanism of the maintaining Ca²⁺ homeostasis in the cell and apoptosis. Various pathological factors may induce a pathological activation of the permeability transition and an irreversible opening of mitochondria pores. It was supposed that this process is a key step in the development of neurotoxicity and neurodegeneration. The present report explores the effect of model neurotoxins, such as MPP⁺ and beta-amyloid fragment (25-35), which simulate the development of Parkinson's and Alzheimer's disease, on the mitochondrial pores

functioning. Both neurotoxins induced the opening of mitochondrial pores, which is prevented by cyclosporin A, a specific inhibitor of the permeability transition. The effect of MPP⁺ and beta-amyloid may be also prevented by N-acetylsertotonin (an endogenous precursor of melatonin), by natural neuroprotector Ginkgo biloba extract Egb 761, and some drugs (tacrine, memantine) that have been used for treatment of Alzheimer's disease and related disorders. Our study illustrates that the effect on mitochondrial pores is an important aspect of the mechanism of neurotoxicity. Substances that may prevent the opening of mitochondrial pores induced by neurotoxins may preserve the mitochondrial function and, thus, may have a potential as neuroprotective agents. On the ground of this hypothesis the series of novel potential neuroprotectors have been designed and studied. The GLP preclinical trials of drug-candidate agent Dimebon was performed that approved its efficacy as protective agent against development of Alzheimer's type dementia.

1034 AMBIENT PARTICULATE MATTER STIMULATES OXIDATIVE STRESS IN BRAIN MICROGLIA AND DAMAGES NEURONS IN CULTURE.

P. Gillespie¹, P. Sama², J. Parker³, L. C. Chen¹ and B. Veronesi⁴. ¹*Department of Environmental Medicine, NYU, Tuxedo, NY*, ²*Department of Environmental Science and Engineering, UNC, Chapel Hill, NC*, ³*Health Sciences, Constella Group, Durham, NC* and ⁴*NHEERL/NTD/CTMB, U.S. EPA, Research Triangle Park, NC.*

Ambient particulate matter (PM) damages biological targets through oxidative stress (OS) pathways. Several reports indicate that the brain is one of those targets. Since microglia (brain macrophage) are critical to OS-mediated neurodegeneration, their response to concentrated ambient particles (CAPs) collected from Tuxedo, NY was examined in culture. Immortalized, mouse microglial (BV2) were exposed to CAPs for various time points. Significant increases in pro-inflammatory cytokines and reductions of glutathione were measured in these cells. Up-regulation of genes coding for apoptotic and OS were recorded using Affymetrix microarrays. To assess neurotoxicity, immortalized rat, dopaminergic neurons (N27) were exposed to Fine (F=0.18-1 μ m) and Ultrafine (UF<0.18 μ m) PM also collected in Tuxedo, NY. Evidence of reduced nuclear materials, as measured by Hoechst 33258 stain occurred only in response to >12.5 μ g/ml UF and 50 μ g/ml F after 24 hr exposures. Primary cultures, dissociated from embryonic rat brain striatum were exposed to F (75 μ g/ml) and UF (7.5 μ g/ml) to determine if neurotoxicity was particle size-dependent in complex cultures. Equivalent increases of reactive nitrogen species (nitrite) were seen after 24hr in response to both size particles in spite of their 10-fold differences in concentration. A 39% and 47% reduction of immunohistochemically stained neurons relative to controls was measured in cultures treated with F and UF, respectively. Microscopic examination revealed that the majority of PM exposed neurons were apoptotic after 24hr exposure. Together, these data indicate that PM damages isolated neurons directly in the absence of microglia but also through microglia initiated apoptotic pathways in complex cultures. Disclaimer: This abstract has been reviewed by the NHEERL of the EPA and approved for publication.

1035 MPP⁺-INDUCED ALTERATIONS IN SELECTIVE GENE EXPRESSION CORRELATE WITH DOPAMINERGIC DEPLETION IN MN9D CELLS.

J. Wang, H. M. Duhart, Z. Xu, T. A. Patterson, G. D. Newport and S. F. Ali. *Neurochemistry Laboratory, Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR.*

Parkinson's disease (PD) is a common neurodegenerative disease characterized by progressive loss of midbrain dopaminergic neurons with unknown etiology. MPP⁺ (1-methyl-4-phenylpyridinium) is the toxic metabolite of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), which can induce Parkinson's-like symptoms in humans and animals. MPTP/MPP⁺ can produce selective dopaminergic neuronal degeneration; therefore, these agents are commonly used to study the pathogenesis of PD. However, the mechanisms of their toxicity have not been completely elucidated. Recently, we reported in a microarray study using a murine midbrain-derived dopaminergic neuronal cell line, MN9D, that MPP⁺ induced significant changes in a number of genes associated with the dopaminergic system. In this study, we investigated the expression time-courses of six genes using real-time RT-PCR, and compared them with the progressive dopaminergic depletion caused by MPP⁺. Our data showed that the dopamine content was significantly decreased after 0.5 hr of MPP⁺ (200 μ M) exposure and was completely depleted after 40 hr. The expression of Gpr37, which is closely related to the pathogenesis of PD, was up-regulated after 0.5 hr, and remained up-regulated up to 48 hr. Txnip, which is critical to the adjustment of cellular redox status, was down-regulated after 1 hr and remained down-regulated up to 48 hr. Ldh1 and Cdo1, which are also involved in oxidative stress, were down-regulated after 16 hr and remained down-regulated up to 48 hr. Two pro-apoptotic genes, Egl3 and Bnip3, were down-regulated after 2 and 4 hr, and remained down-regulated up to 48 hr. These findings suggested that

multiple systems were involved in MPP⁺-induced dopaminergic neurodegeneration, and MPP⁺-induced neurotoxicity in MN9D cells could be used as a model to further explore the roles of these and other genes in the pathogenesis and possible treatment of PD.

1036 THE USE OF PRIMARY SUBSTANTIA NIGRA NEURONS GENERATED FROM VMAT2 HYPOMORPH MICE AS AN *IN VITRO* MODEL OF ASSESSING THE NEUROTOXICITY OF CYTOPLASMIC DOPAMINE.

K. R. Shepherd^{1,3}, M. Z. Wang^{1,2}, M. Caudle^{1,2} and G. W. Miller^{1,2}. ¹Center for Neurodegenerative Disease, Emory University, Atlanta, GA, ²Environmental and Occupational Health, Emory University, Atlanta, GA and ³Neurology, Emory University, Atlanta, GA.

Neurodegenerative disorders such as Parkinson's disease (PD), is characterized by loss of tyrosine hydroxylase (TH) neurons in the substantia nigra. Although the precise mechanism of how dopaminergic neurons are lost remains unknown, it has been suggested that excess cytoplasmic dopamine (DA) may generate reactive oxygen species (ROS) and cause degeneration of DA neurons. It is widely accepted that the vesicular monoamine transporter (VMAT2), removes DA from the cytoplasm preventing its degradation, and subsequent production of ROS. In the present study, we generated primary substantia nigra chimeric cultures from wild type, heterozygote (expressing 50% VMAT2), and hypomorph (expressing 5% VMAT2) mice to evaluate the neurotoxicity of unsequestered DA. The nigra neurons were harvested from pups at P0-P6 and plated on a glia feeding layer one week before treatment with DA. The findings show that cultures treated with DA 10 μ M resulted in no loss of TH positive neurons in wild type and heterozygote mice, whereas there was a 33.4% loss of TH positive neurons in cultures generated from hypomorph mice. The preliminary results suggest that decreased sequestration of cytoplasmic DA promotes neurodegeneration of dopamine neurons. Studies are ongoing to assess the mechanism(s) of DA mediated neurotoxicity in this model.

1037 AGE-DEPENDENT HETEROGENEITY OF GENE EXPRESSION IN FISHER 344 RAT RETINA.

Z. Li², F. A. Wright² and J. E. Royland¹. ¹Neurotoxicology Division, U.S. Environmental Protection Agency, Durham, NC and ²Biostatistics, the Carolina Environmental. Bioinformatics Research Center, UNC, Chapel Hill, NC.

Recent evidence suggests the elderly may be a sensitive subpopulation with regard to environmental exposure to toxic compounds. One source of this sensitivity within the aged subpopulation could be an enhanced variability in response to exposures. This variability, if sufficient, would require that a larger safety margin for risk management be applied to ensure protection of the entire population. Studies on phenotypic differences have suggested that variation increases with age. However, few reports address the question of variation in gene expression as an underlying cause for increased variability of phenotypic response in the aged. In this study, we compare variation in constitutive gene expression in the retinas of Fisher 344 rats at 3 different ages, 4, 11 and 23 mos (8-9 animals/age group). Global gene expression levels were determined on Affymetrix genomic rat 230A arrays. After removing trend effects of aging using an ANOVA (Analysis of Variance) model, the residuals were examined for evidence of increasing or decreasing variability with age using a variant of a standard approach to test for such trends in which the absolute values of the ANOVA residuals are regressed on age. This approach enabled application of Significance Analysis of Microarrays (SAM) procedure to identify genes for which there exists a significant age-dependent heterogeneity, as well as gene-specific estimations of false discovery rates (FDR) (q) values. Controlling the FDR at $\leq 10\%$, we found 269 genes in which variation in expression significantly increased with age, and 12 genes in which it decreased. These data support the hypothesis that gene expression levels can become heterogeneous with age, and serve as a proof-of-principle to identify genes for further study on the consequences of this variation. (This abstract does not necessarily reflect USEPA policy).

1038 VEGF DERIVED FROM RETINAL GLIAL (MULLER) CELLS IS AN IMPORTANT INITIATOR FOR DIABETIC RETINOPATHY.

L. Cai¹ and Y. Wang^{1,2}. ¹Medicine, University of Louisville, Louisville, KY and ²Medicine, Jilin University, Changchun, China. Sponsor: L. Cai.

Yuehui Wang¹, Ying Leng², Ying Xin², Jiaxiang Wu², Lu Cai^{1,2}, University of Louisville School of Medicine, Louisville, KY and Jilin University, Changchun, China. Diabetic retinopathy (DR) is closely related to retinal neovascularization for which vascular endothelial growth factor (VEGF) plays a critical role. Muller cell as the principal glial cell of the retina is specialized radial glial cell spanning the entire

depth of the retina and may involve in both physiologic and pathologic angiogenesis. In the present study, we investigated whether Muller cells overproduce VEGF in response to high levels of glucose (HG) and whether the secreted VEGF can stimulate endothelial cells proliferation and migration. Muller cells were isolated from the retina of rabbits, and exposed to HG (30 mM) for 72 hr, and VEGF mRNA and protein expressions were found to be significantly increased. In the media of cultured Muller cells exposed to HG, there is a significant increase in VEGF contents, detected by ELISA assay. In order to define the role of VEGF derived from Muller cells, endothelial cells were cultured in the conditioned media that were harvested from HG-exposed Muller cells. These endothelial cells significantly proliferated and migrated in Boyden Migrating Chamber. Addition of anti-VEGF antibody attenuated the increased cell proliferation and migration of endothelial cells, specifying the role of VEGF. Furthermore, PI3K/Akt signaling pathways was found to involve in cell VEGF-stimulated endothelial cell proliferation and migration since endothelial cells cultured in the conditioned media from HG-exposed Muller cells with PI3K inhibitor wortmannin (50 nM), did not show any increase in cell proliferation and migration. These results suggest that VEGF derived from Muller cells under diabetic condition plays an important role in stimulating endothelial cells proliferation and migration through PI3K/Akt-dependent pathway, which is a critical step for the neovascularization in DR.

1039 MICROTUBULE-BASED AXONAL TRANSPORT IS IMPAIRED IN PRIMARY CULTURE OF HIPPOCAMPAL NEURONS FOLLOWING TREATMENT WITH THE NEUROTOXIC γ -DIKETONE 1, 2-DIACETYL BENZENE.

D. Tshala-Katumbay, S. Kaech and P. Spencer. Oregon Health & Science University, Portland, OR.

The protein reactant 1,2-diacetylbenzene (1,2-DAB), but not the non-protein reactant isomer 1,3-DAB, induces proximal giant axonal swellings filled with 10 nm-neurofilaments and organelles in rodents. We asked whether changes in microtubule-based axonal transport contribute to the development of 1,2-DAB axonopathy. A model of rapid-onset aromatic γ -diketone axonopathy provided the substrate to address this question. Rat primary hippocampal neurons (7 days in vitro) were treated with 0.25 mM of either DAB isomer in HBSS imaging medium containing 0.3% DMSO (vehicle). Time-lapse recordings of moving mitochondria stained with MitoTracker Green FM (Molecular probes, Eugene) were taken every 10 min for up to 60 min. Transport events were measured using the kymograph function of the Metamorph software (Molecular Devices, PA). Both 1,2-DAB and 1,3-DAB induced early acceleration of mitochondrial transport; the average initial rate of moving mitochondria was 2.2 times higher (i.e. 0.24 μ m/sec) for 1,2-DAB treated samples ($p = 0.02$) and 1.6 times higher (i.e. 0.17 μ m/sec for 1,3-DAB ($p = 0.06$) relative to vehicle control. The rate decreased significantly over time (i.e. 11 % per 10 min) in 1,2-DAB- treated cultures ($p < 0.001$). Transport rates for vehicle- and 1,3-DAB treated samples remained steady ($p = 0.36$ and 0.85 for vehicle and 1,3-DAB, respectively). Changes in number of moving mitochondria revealed a pattern similar to the one observed for the transport rates. Studies are needed to elucidate susceptibilities of axon transport motor proteins (kinesin and dynein) to chemical attack by neurotoxic γ -diketones. Supported by NIEHS grants ES 10338 and ES 11384, NINDS NS 052183, and the Oregon Workers Benefit Fund.

1040 IMPAIRMENT OF CALCIUM HOMEOSTASIS: RELEVANCE TO THE PATHOGENESIS OF γ -DIKETONE AXONOPATHY.

R. Irwin, P. Spencer and D. Tshala-Katumbay. Oregon Health & Science University, Portland, OR.

The neurotoxic protein reactant 1,2-diacetylbenzene (1,2-DAB), but not its isomer 1,3-DAB, induces an early segregation of cytoskeletal elements and mitochondria in rodent axons, suggesting that changes in axonal proteins may be the key to the pathogenesis of γ -diketone axonopathy. We used 7 day-old rat primary cultures of hippocampal neurons to assess whether disruption of intracellular Ca²⁺ homeostasis was temporally associated with the development of this type of neurotoxicity. Intracellular Ca²⁺ concentration was measured using fluorescence microscopy and the Ca²⁺-sensitive indicator Fura-2/AM at 0, 2, 4, 8, 24, and 48 hours following exposure to 1,2-DAB 250 μ M or vehicle (1% v/v of HBSS containing 0.3% DMSO). 1,2-DAB raised resting estimated intracellular Ca²⁺ concentration ([Ca²⁺]_i) in a time-dependent relationship requiring ~ 3.8 hours to reach half the maximal [Ca²⁺]_i response. At 24 hours, most 1,2-DAB-treated neurons had degraded; however, remaining neurons had a [Ca²⁺]_i $\pm$ SEM of 859 $\pm$ 184 nM ($n=6$), while vehicle-treated neurons remained at 102 $\pm$ 8 nM ($n=42$, $p \leq 0.0001$). [Ca²⁺]_i in vehicle-treated neurons at 24 hours did not differ significantly from controls 116 $\pm$ 5 nM ($n=104$). The number of neurons per low-power field (LPF) at the center

of each dish decreased over time in 1,2-DAB-treated cells. At 24 hours, there were only 2.0 ± 0.6 neurons/LPF in contrast to 14 ± 2.6 neurons for vehicle-treated cells ($P \leq 0.005$). Neuronal degradation was complete by 48 hours of 1,2-DAB treatment. 1,2-DAB markedly impaired calcium homeostasis, but several hours of treatment were required to alter resting $[Ca^{2+}]_i$ and membrane permeability significantly. This suggests the 1,2-DAB-induced effect on Ca^{2+} homeostasis may be a consequence of disruption of integral cellular processes rather than a direct effect of high intracellular calcium concentrations initiating cell death. Supported by NIH grants ES10338 and ES11384, NS052183, and the Oregon Workers Benefit Fund.

1041 EFFECTS OF MEMANTINE, GALANTAMINE AND DONEPEZIL IN THE HIPPOCAMPUS OF APP/PS1 MICE, AN ANIMAL MODEL OF ALZHEIMER'S DISEASE.

G. S. Kulkarni^{1,2}, E. R. Pereira² and E. X. Albuquerque^{1,2}. ¹Toxicology, University Maryland Sch Med., Baltimore, MD and ²Pharmacol Exp Ther, University Maryland Sch Med., Baltimore, MD.

Alzheimer's disease (AD) is a fatal neurodegenerative disorder characterized by progressive cognitive impairment. Although the cause of AD remains unknown, disease progression from mild to severe correlates well with incremental loss of nicotinic receptors in discrete brain areas. The pathophysiology of AD also includes increased brain levels of the amyloid β peptide 1-42 ($A\beta$ 1-42) that have been associated with mutations in the genes coding for presenilin 1 or 2 (PS1, PS2), and amyloid precursor protein (APP). Treatment of mild-to-moderate AD relies on the use of cholinesterase inhibitors, including galantamine and donepezil. More severe forms of the disease are treated with memantine, a non-competitive NMDA receptor antagonist. It has been recently suggested that patients with mild-to-moderate AD could benefit from treatment with both cholinesterase inhibitors and memantine. However, memantine at clinically relevant concentrations inhibits $\alpha 7$ nAChR activity. Thus, this study was designed to analyze in vivo how the association of memantine with galantamine or donepezil alters neuronal functions, structure and viability in mice overexpressing mutant forms of the human APP/PS1 mice. We are studying mice at two specific ages: 2 and 9 months. At 2 months of age, the transgenic mice compared to wild type mice show impairment in long-term potentiation (LTP). At 9 months of age, the transgenic mice show impairments of both LTP and basal synaptic transmission. We are using the patch-clamp technique to identify the effects of long-term treatment with clinically relevant doses of memantine, donepezil and galantamine (alone or in association) on basal synaptic transmission, tonic GABAergic and glutamatergic activities and LTP in the hippocampi of APP/PS1 mice and age-matched wild type mice. Results from this study should lay the groundwork for a better understanding of the benefits of specific drug associations for treatment of AD at different stages. Support: NIH NS25296 & Ortho-McNeil GAL-ALZ-0004

1042 INDUCTION OF APOPTOSIS IN NEURONAL PC-12 CELLS BY SATRATOXIN G FROM THE BLACK MOLD STACHYBOTRYS: ROLE OF DOUBLE-STRANDED RNA-ACTIVATED PROTEIN KINASE (PKR).

J. J. Pestka^{1,2}, Z. Islam^{1,2} and J. R. Harkema^{2,3}. ¹Food Science and Human Nutrition, Michigan State University, East Lansing, MI, ²Center for Integrative Toxicology, Michigan State University, East Lansing, MI and ³Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI.

Satratoxin G (SG) is a macrocyclic trichothecene mycotoxin produced by the black mold *Stachybotrys chartarum* which has been etiologically linked to illnesses associated with water-damaged buildings. Acute SG exposure specifically induced apoptosis of olfactory sensory neurons (OSN) in the olfactory epithelium (OE) of mouse nose. PC-12 neuronal cells were used here as a model to elucidate the mechanisms of SG-induced cell death. SG-induced apoptosis of PC-12 cell was verified by agarose gel electrophoresis, flow cytometry using Annexin V-FITC and propidium iodide uptake and by microscopic morphology. Kinetic studies revealed that apoptosis was maximum between 48 to 96 h after SG (10 ng/ml) treatment. Expression of the pro-apoptotic genes p53, PKR, BAX and CAD were significantly elevated 6 and 18 h after SG treatment. SG also induced significant caspase-3 activity from 18 to 48 h. Chemical inhibition of PKR completely inhibited SG induction of apoptosis and pro-apoptotic gene mRNA expression. Surprisingly, PKR inhibition did not inhibit SG-induced caspase-3 activation, nor did caspase-3 inhibition block SG-induced apoptosis. However, mRNA expression for two alternative nucleases associated with apoptosis, DNase I and DNase II, were also found significantly elevated in SG-treated PC-12 cells and these could be blocked by PKR inhibition. Taken together, PKR appears to play the critical role in SG-induced DNase induction and resultant apoptosis in PC-12 cells.

1043 CELLULAR PRION PROTEIN PREVENTS STAUROSPORINE-INDUCED CYTOTOXICITY VIA PI3K/AKT PATHWAY IN NERVE CELLS.

K. Lee¹ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

Cellular prion protein (PrP^c) plays a protective role in neuronal cells, but the function of PrP^c is not yet understood. Our recent findings suggest that PrP^c specifically prevents pathological protein aggregation in only neuronal cells, but not in non-neuronal cells. The purpose of this study was to elucidate the protective role of PrP^c in neuron cells and non-neuronal cells during staurosporine (STP) induced cell death. In SN56 cells, prion depletion by RNAi treatment caused an increase in the number of apoptotic cells during treatment of STP. In contrast, when non-neuronal Caco2 cells that normally express prion, were depleted of prion, there was no effect. We found that in prion-depleted SN56 cells there was a decrease in PI3K/AKT phosphorylation, but there was no similar effect in prion-depleted Caco2 cells. Therefore, this data suggest that PrP^c may specifically protect against STP-induced toxicity only in neuronal (SN56) cells but not in non-neuronal (Caco-2) cells. The enhanced apoptosis induced by STS was shown by increased p38 and JNK phosphorylation. Therefore, we checked p38 and JNK activity in both neuronal and non neuronal prion-depleted cells. As a result, activation of p38 was significantly increased in prion depleted STP-induced SN56 cells, compared to the control cells. But there was no similar effect in prion-depleted Caco2 cells. As p38 and JNK activation involves Bax mitochondrial translocation, cytochrome c release and caspase activation, we investigated which of these events was inhibited by PrP in SN56 cells and Caco-2 cells. PrP inhibits Bax mitochondrial translocation, cytochrome c release and cell death in SN56 cells but not Caco-2 cells. Moreover, PrP in SN56 cells does not prevent AKT non-involved induced apoptosis, such as active caspase-mediated cell death or Bak induced apoptosis. Overall, we conclude that PrP protects against STP-mediated cell death via PI3K/AKT pathway that blocks initially in p38 and JNK activation in neuronal cells.

1044 NEUROTOXICITY OF METHYL MERCURY AND PCBs: AN IN VITRO APPROACH.

A. Vitalone¹, G. Giordano², V. Fattori³ and L. Costa^{1,2}. ¹University of Parma, Parma, Italy, ²University of Washington, Seattle, WA and ³University of Bari, Bari, Italy.

Methyl mercury (MeHg) and polychlorinated biphenyls (PCBs) are known developmental neurotoxicants. Aim of this study was to evaluate the effect of MeHg (0.1-20 μ M) and PCB126 and 153 (3-200 μ M) in a battery of in vitro cell systems. Cell viability was assessed by measuring MTT reduction and Trypan blue exclusion. The studies were carried out in eight different rat or human cell lines chosen as models of neuronal cells, astrocytic cells and non-nervous-system cells. Primary rat astrocytes and neurons from different brain areas (hippocampus, cortex, cerebellum and brainstem), and cerebellar granule neurons from a mouse genetic model of glutathione deficiency were also utilized. The results indicate that: 1) MeHg is more cytotoxic than PCB126 and PCB153; 2) Nervous system-derived cell lines are in most cases more sensitive than non-nervous cell lines to all compounds; 3) Neuronal cells are more sensitive than astrocytic cells to the toxicity of MeHg, but not of PCBs; 4) Human CNS cells are slightly more sensitive to the toxicity of MeHg and PCBs than rat cells; 5) Primary neurons were the most sensitive to MeHg and PCBs toxicity; 6) Cerebellar neurons from mice with genetically determined low glutathione levels were more sensitive than wild-type neurons to the toxicity of all three compounds, supporting a role for oxidative stress in their cytotoxicity; 7) Thyroid cells (TT), non cancerous prostate cells (PZ-HPV-7), and cerebellar Purkinje neurons were highly sensitive to the toxicity of PCB126. PZ-HPV-7 cells were also highly sensitive to the toxicity of PCB153. Epidemiological and laboratory studies have also suggested that MeHg and PCBs may have synergistic effect on CNS functions; however, in vitro studies in various cell lines indicated an additive effect, at most. This study provides initial evidence that an in vitro screen may provide information useful for assessing neurotoxicity, as well as information on potential new targets of biological action or toxicity. 1045 PCB-INDUCED ALTERATIONS IN THE SEROTONERGIC SYSTEM: A POTENTIAL MECHANISM OF PCB-INDUCED IMMUNOTOXICITY?

J. Duffy and J. T. Zelikoff. Department of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Toxicological studies have shown the serotonergic system to be sensitive to polychlorinated biphenyl (PCB) exposure in both mammals and fish, and epidemiological studies have demonstrated similar findings for humans. Likewise, the sensitivity of the immune system to PCBs has been well established in numerous species.

Given the cross-talk between the immune and nervous systems, PCB-induced alterations in the serotonergic axis is a plausible mechanism by which PCBs may induce their immunotoxic effects. Previous investigations in this lab have demonstrated the sensitivity of the bluegill sunfish immune response to PCB exposure as well as to serotonin (5-HT) – induced alterations in immune function. In order to establish a link between PCB exposure and alterations in the serotonergic system in this species, the impact of PCBs on 5-HT levels, synthesis and metabolism were evaluated. Fish were exposed via i.p. injection to either coplanar PCB 126 (0.01 or 1.0 µg/g BW) or noncoplanar PCB 153 (5.0 or 50 µg/g BW) and sacrificed after 1, 3 or 7 d. Analysis by HPLC demonstrated that both PCB congeners (at all doses) decreased whole brain 5-HT and norepinephrine levels at 3 d post-injection. However, no effects were observed on whole brain tryptophan hydroxylase level (the rate-limiting enzyme in 5-HT synthesis) or on monoamine oxidase activity (the primary enzyme involved in the metabolism of 5-HT) in PCB-exposed fish at any post-injection time point. Results from this study show that while both coplanar and noncoplanar PCBs can alter whole brain levels of 5-HT, this effect does not appear to be due to alterations in neurotransmitter synthesis or metabolism. Taken together with results from previous studies demonstrating immune dysfunction in bluegill with depressed brain 5-HT levels, the PCB-induced decrease in brain 5-HT levels observed in the current study supports a role for 5-HT in PCB-induced immunotoxicity. Hudson River Foundation Graduate Fellowship and USACEHR No. DAMD 17-99-9011.

1046 POLYCHLORINATED BIPHENYL-MEDIATED LOSS OF STRIATAL DOPAMINE TERMINAL MARKERS: POSSIBLE ROLE OF VESICULAR MONOAMINE TRANSPORTER 2 INHIBITION.

J. Watson^{1,2}, W. Caudle^{1,2}, J. R. Richardson³ and G. W. Miller^{1,2}. ¹Center for Neurodegenerative Disease, School of Medicine, Emory University, Atlanta, GA, ²Department of Environmental and Occupational Health, Rollins School of Public Health, Emory University, Atlanta, GA and ³Environmental and Occupational Health Sciences Institute and Department of Environmental and Occupational Medicine, University of Medicine and Dentistry-New Jersey/Robert Wood Johnson Medical School, Piscataway, NJ.

Epidemiological and laboratory studies have identified exposure to polychlorinated biphenyls (PCBs) as a potential risk factor for Parkinson's disease. Previously, our lab has shown that environmentally relevant exposures of PCBs (7.5 or 15 mg/kg/day Aroclor 1254:1260 for 30 days by oral gavage) cause a dramatic dose-dependent decrease in dopamine transporter (DAT) levels. These reductions were specific to striatal DAT, and no change in the level of dopamine (DA) or tyrosine hydroxylase (TH) was observed. To further investigate the potential mechanism of PCB-mediated disruption of the DA system, mice were given 50 mg/kg/day (for 30 days oral gavage) of the Aroclor 1254:1260 mixture. Analysis of dopaminergic brain regions revealed a 60% loss of DAT levels and function. Immunohistochemistry showed reduced staining in DAT and TH. We have hypothesized that these changes may be due to inhibition of the vesicular monoamine transporter 2 (VMAT2). Aroclor and its primary metabolites found in the brain were discovered to be direct inhibitors of VMAT2. Additionally, total DA levels are reduced in the striatum and cortex of the PCB animals. These data further support the suggestion that PCBs damage the nigrostriatal system, leading to the disruption of DA homeostasis and subsequent cell death.

1047 1 α , 25-DIHYDROXYVITAMIN D3 BLOCKS CYANIDE-INDUCED NEUROTOXICITY BY ALTERING PPAR α -MEDIATED UCP-2 EXPRESSION.

L. Li, K. Prabhakaran, X. Zhang, L. Zhang, H. B. Leavesley, J. L. Borowitz and G. E. Isom. *Medicinal Chemistry & Molecular Pharmacology, Purdue University, West Lafayette, IN.*

1 α , 25-dihydroxyvitamin D3 (VD3) is an active metabolite of vitamin D. Recent studies have shown that VD3 is a neuroprotectant that can attenuate 6-hydroxydopamine and L-buthionine sulfoximine (BSO)-induced toxicity. At the mitochondrial level, VD3 inhibits uncoupling protein 2 (UCP-2) expression leading to increased mitochondrial membrane potential ($\Delta\psi$ m) and ATP production. We have shown that Wy14,643, a selective agonist of peroxisome proliferator activated receptor alpha (PPAR α), enhances cyanide neurotoxicity through induction of UCP-2 expression. In this study VD3-mediated neuroprotection was evaluated in cortical cells exposed to Wy14,643 to stimulate UCP-2 overexpression and enhance cyanide toxicity. Pretreatment with VD3 attenuated Wy14,643-mediated enhancement of cyanide-induced necrotic death. VD3 reversed cyanide-induced mitochondrial dysfunction as reflected by restoration of cellular ATP and $\Delta\psi$ m. To investigate the mechanism of the neuroprotection, UCP-2 expression was determined. VD3 blocked Wy14,643-mediated upregulation of UCP-2 at both mRNA and protein levels. This effect was the result of increased I κ B expression, which inhibits

NF- κ B activity. Co-treatment with Wy14,643 and cyanide significantly reduced cellular GSH levels and enhanced ROS generation; these effects were also blocked by VD3. To determine the functional activity of UCP-2, the mitochondrial proton leak, as reflected by state 4 cellular oxygen consumption, was measured by a Clark oxygen electrode. Cyanide markedly increased state 4 oxygen consumption in Wy14,643 treated cells, possibly due to cyanide stimulating formation of superoxide and thus activating UCP-2. Pretreatment with VD3 or other antioxidants attenuated the enhancement of state 4 oxygen consumption. It is concluded that VD3 blocks Wy14,643-mediated enhancement of cyanide neurotoxicity by inhibiting UCP-2 upregulation and the subsequent activation of mitochondrial proton leak. (This study was supported by NIH grant ES04140).

1048 UP-REGULATION OF UNCOUPLING PROTEIN-2 BY WY14, 643 IN DOPAMINERGIC CELLS INVOLVES PPAR ALPHA-DEPENDENT AND INDEPENDENT MECHANISMS.

X. Zhang, L. Li, K. Prabhakaran, L. Zhang, H. B. Leavesley, J. L. Borowitz and G. E. Isom. *Purdue University, West Lafayette, IN.*

Uncoupling protein 2 (UCP-2) is a member of the mitochondrial anion carrier superfamily expressed in the inner mitochondrial membrane. We have shown that up-regulation of UCP-2 expression by treatment with Wy14,643, a selective agonist of PPAR α , increased vulnerability of primary cortical cells to cyanide-induced cytotoxicity. In this study, the mechanism(s) by which Wy14,643 induces up-regulation of UCP-2 in an immortalized dopaminergic cell line (N27 cells) was determined. We have established that Wy14,643 potentiates cyanide-induced cell death through up-regulation of UCP-2. Western blot analysis showed that either treatment of cells with MK-886 (a selective antagonist of PPAR α) or RNAi-mediated knock-down of PPAR α only partially decreased the Wy14,643-mediated up-regulation of UCP-2, thus indicating the possible involvement of a non-PPAR α pathway. Wy14,643 treatment also decreased cellular glutathione (GSH) levels that was accompanied by accumulation of reactive oxygen species (ROS). Supplement of cellular GSH by loading with glutathione ethyl ester (GSH-EE) or pre-incubation with the antioxidant α -tocopherol (Vitamin E) attenuated the Wy14,643 mediated up-regulation of UCP-2. Knockdown of PPAR α by RNAi did not alter the Wy14,643-mediated ROS generation, indicating ROS generation was independent of PPAR α . Co-treatment with PPAR α -RNAi and GSH-EE blocked both Wy14,643-upregulated UCP-2 and potentiation of cyanide cytotoxicity. These findings demonstrate that both PPAR α -dependent and -independent mechanisms are involved in Wy14,643-mediated up-regulation of UCP-2 and the associated increased vulnerability of dopaminergic cells to cyanide. (This study was supported by NIH grant ES04140)

1049 MECHANISTIC ACTIONS OF THE HIV-1 NEUROTOXIN TAT ON NEURONAL MITOCHONDRIA.

J. Norman¹, S. Perry² and H. Gelbard^{2,3}. ¹Environmental Medicine, University of Rochester, Rochester, NY, ²Cr. Aging Dev Biology, University of Rochester, Rochester, NY and ³Department of Neurology, University of Rochester, Rochester, NY.

HIV Associated Dementia (HAD) is a progressive neurological disorder that results in motor, cognitive and social dysfunction. Recent epidemiologic studies suggest that HAD incidence has increased in prevalence since 2000, even in the era of highly active antiretroviral therapy. However, evidence suggests that some aspects of HAD may be reversible. In a previous study, we observed mitochondrial hyperpolarization in cortical neurons treated with the HIV-1 neurotoxin Tat. Mitochondrial hyperpolarization may have profound consequences for synaptic transmission and other energy-dependent processes. The present study investigates the mechanism(s) leading to mitochondrial hyperpolarization, focusing on several mitochondrial systems including: pH, electron transport chain (ETC) complex activity, ion homeostasis, and energy intermediates (NADH). We confirmed our earlier observation that rodent cortical neurons treated with Tat undergo mitochondrial hyperpolarization using the dye rhod123. Application of Tat to cortical neurons elicited a rapid drop in internal mitochondrial pH in concordance with hyperpolarization. The addition of Tat to purified mitochondrial protein not only demonstrated an inhibition of complex IV of the electron transport chain, but also decreased cortical neuron respiration, corroborating the physiological inhibition of complex IV. Using a mitochondrial targeted YFP-calmodulin construct, we observed a decreased in [Ca²⁺]_{mit}. Finally, we measured the energy intermediate NAD(P)H after Tat treatment, and found a 20% decrease in the auto-fluorescence. We speculate that the decrease in calcium and NADH contributes to mitochondrial hyperpolarization after exposure to Tat. Future studies will focus on a detailed examination of the molecular mechanisms involved in these observed mitochondrial deficits and novel treatments to attenuate the hyperpolarization. 1050 EFFECTS ON DOPAMINE (DA) AND SEROTONIN (5-HT) METABOLISM FOLLOWING AN ESCALATING DOSE-BINGE REGIMEN OF METHAMPHETAMINE.

D. L. Graham^{1,2}, P. H. Noailles¹, B. Ladenheim¹ and J. L. Cadet¹. ¹Molecular Neuropsychiatry Branch, DHHS/NIH/NIDA/IRP, Baltimore, MD and ²Program in Toxicology, University of Maryland School of Medicine, Baltimore, MD.

Methamphetamine (METH) is an illicit drug that is experiencing an alarmingly high rate of abuse in the United States and Asia. Initially, METH use is associated with feelings of euphoria to low doses of the drug. Subsequently, users administer the drug at higher doses and at more frequent intervals in attempts to maintain these pleasurable effects. In the present study, we utilized an escalating dose (ED)-binge regimen of METH administration in rodents in order to mimic human drug use patterns. Male Sprague-Dawley rats were given either an ED of METH or an equivalent volume of saline. At the end of the pretreatment regimen, each group was divided again such that half of the animals received either a neurotoxic dose of METH (3x10 mg/kg every 2 hr) or saline. We have previously shown that animals receiving the neurotoxic dose of METH had decreased levels of DA and 5-HT in the striatum at 2 hr following the final treatment. Moreover, there was less depletion of DA in animals that were given the METH ED regimen relative to drug-naïve animals receiving only a METH challenge. Levels recovered significantly by 24 hr. For this study, we approximated the metabolism of DA and 5-HT by calculating ratios with regard to their respective metabolites (DOPAC+HVA and 5-HIAA). This approach would determine whether alterations in their metabolism might account for the protective effects of the repeated METH pre-exposure. At 2 hr following the challenge dose, DA and 5-HT turnover rates are significantly increased in the naïve-challenged animals versus the METH pretreated-challenged rats. However, at 24 hr post-challenge, only drug-naïve animals had significant decreases in both DA and 5-HT turnover rates following the METH challenge. These data suggest that changes in monoamine metabolism following a METH pretreatment may be responsible for the some of the neurochemical changes seen in DA and 5-HT following an ED-binge regimen of METH.

1051 ESTRADIOL AND PHYTOESTROGENS DO NOT ATTENUATE THE INCREASE IN INTRACELLULAR CALCIUM CAUSED BY AMYLOID-BETA PEPTIDE AND MPP+.

I. F. Sorensen¹, S. Purup¹ and M. Ehrlich². ¹Danish Institute of Agricultural Sciences, Tjele, Denmark and ²Virginia Maryland Regional College of Veterinary Medicine, Blacksburg, VA.

Published reports demonstrated that estrogen can protect against amyloid-beta (AB) and 1-methyl-4-phenyl-pyridine (MPP+)-induced cellular death. We investigated MPP+ and AB toxicity in SH-SY5Y cells and their ability to disrupt intracellular Ca²⁺ regulation. Also investigated was possible neuroprotection resulting from pretreatment with estrogen and phytoestrogens. Phytoestrogens, compounds that resemble estrogens structurally, have attracted interest as potential drugs for the treatment of neurodegenerative diseases. MPP+ (2 uM for 48 hr) caused approximately 50% death of SH-SY5Y cells as measured by lactate dehydrogenase (LDH) release. Pretreatment (24 hr) with estradiol and the phytoestrogens apigenin, coumestrol, daidzein, equol, formononetin, genistein, quercetin and resveratrol was not protective. MPP+ (100 uM) caused a rapid 24% increase in Ca²⁺ as measured with the Fluo-4 NW calcium assay kit. Pretreatment (24 hr) with estradiol (0.1 to 10 uM) or the above phytoestrogens (up to 5 uM) did not reduce this Ca²⁺ influx. In fact, 5 uM formononetin increased Ca²⁺ influx significantly (p<0.01). AB at concentrations up to 200 uM did not induce increased LDH release. AB did not cause a rapid increase in Ca²⁺ but 3-4 hr pretreatment with AB (50 uM) increased the Ca²⁺ influx caused by carbachol (200 nM) by an additional 16%. Pretreatment with estradiol and the phytoestrogens had no effect on this Ca²⁺ influx. Pretreatment with the L-type Ca²⁺ channel blocker, nifedipine (100 uM), however, significantly reduced the Ca²⁺ influx caused by MPP+ and AB. We can conclude from these experiments that estradiol and the tested phytoestrogens are not protective against certain neurotoxic insults of MPP+ in the SH-SY5Y cell line, and also did not attenuate the increase in Ca²⁺ caused by exposure to AB and MPP+.

1052 CYTOTOXICITY OF CYCLOTIMETHYLENETRINITRAMINE (RDX) IN RAT AND HUMAN PRIMARY NEURONAL CELLS CULTURES.

M. A. Major², G. Reddy² and A. P. Li¹. ¹In Vitro ADMET Laboratories LLC, Rockville, MD and ²U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.

Cyclotrimethylenetrinitramine (RDX, an explosive and a contaminant at certain disposal facilities and training ranges, has been found to produce convulsions and tremors in animals and in human, suggesting potential neurotoxicity. We report

here the in vitro cytotoxicity of RDX towards primary rat and human astrocyte cultures. Primary rat and human astrocytes were plated at approximately 5000 cells/well and cultured for 24-hours before treatment with RDX. The treatment period was 24-hours. Cellular ATP content was used as a cytotoxicity endpoint. In the first experiment, primary rat and human astrocytes were treated with RDX in complete growth medium. No cytotoxicity was observed up to the highest concentration evaluated of 495 uM. In a second experiment, the cells were treated with RDX in medium with or without serum. Apparent RDX cytotoxicity was observed for rat astrocytes in medium without serum, with >50% cell killing observed at the lowest concentration evaluated of 7.81 uM up to 62.5 uM and no cytotoxicity observed at the higher insoluble concentrations of 125 and 250 uM. As observed in the first experiment, no apparent cytotoxicity was observed for rat astrocytes in medium with serum. For human astrocytes, however, no cytotoxicity was observed in medium with or without serum. To evaluate the role of hepatic metabolism on RDX toxicity, a third experiment was performed to evaluate the role of an exogenous activation system, Aroclor-1254-induced rat liver S9, on RDX cytotoxicity. The exogenous S9 apparently increased the cytotoxicity of RDX in human astrocytes when treatment was performed in medium without serum. The results suggest that RDX toxicity may be attenuated by protein binding, and that hepatic metabolism may lead to the generation of toxic metabolites. These observations need to be further substantiated and defined to evaluate their physiological relevance (Abstract does not reflect U.S. Army Policy).

1053 EFFECTS OF PROPOFOL ON INTRACELLULAR CA²⁺ HOMEOSTASIS IN HUMAN ASTROCYTOMA CELLS.

R. Barhoumi, R. C. Burghardt, Y. Qian and E. Tiffany-Castiglioni. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.*

The effects of propofol, a short-acting general anesthetic, upon cell growth and Ca²⁺ signaling in a human astrocytic cell line (CCF-STTG1) were examined. Exposure of cells for 24 to 72 hr to graded concentrations of propofol resulted in a dose-dependent decrease in cell number with an inhibitory concentration of cell viability of 31.7 ± 1.2 uM. To evaluate the changes in intracellular Ca²⁺ homeostasis induced by propofol, cytoplasmic and mitochondrial Ca²⁺ were measured. Mitochondrial Ca²⁺ increased significantly at a propofol concentration lower than the IC₅₀ (10 uM for 24 hr, 1 uM for 72 hr) while cytoplasmic Ca²⁺ decreased significantly at the same concentrations. In addition, propofol diminished the Ca²⁺ response induced by addition of 10% fetal bovine serum to cells. To determine the source of the Ca²⁺ alterations induced by propofol, several pharmacologic agents that target intracellular Ca²⁺ homeostasis mechanisms were used. Nifedipine, an L-type Ca²⁺ channel blocker and estrogen, which is known to activate K⁺ channels, decreased the FBS-induced Ca²⁺ response of control cells to a level similar to propofol treated cells. However, diazoxide (a K⁺-ATP channel opener) administered 1 hr directly before FBS addition restored the FBS response in propofol treated cells to a level similar to control cells. In addition, diazoxide increased mitochondrial Ca²⁺ in control cells to a level comparable to propofol treated cells suggesting the activation of these channels by propofol treatment. Addition of 1 uM RU-360 (a selective blocker of the mitochondrial Ca²⁺ uniporter) for 30 min prior to propofol treatment had a minimal effect on control cells but significantly decreased the mitochondrial Ca²⁺ and increased the cytoplasmic Ca²⁺ in propofol-treated cells to control levels. These data suggest that voltage operated Ca²⁺ channels, mitochondrial Ca²⁺ and ATP-dependent K⁺ channels may be targets of propofol action in CCF cells and reversal of these actions result from treatment with K⁺-ATP channel activator and mitochondrial Ca²⁺ uniporter blocker.

1054 INITIATION OF APOPTOSIS AFTER 1, 3-DINITROBENZENE EXPOSURE IN IMMORTALIZED PRIMARY ASTROCYTES.

S. A. Runkle, J. A. Miller and M. A. Philbert. *Environmental Health Sciences Toxicology Program, University of Michigan, Ann Arbor, MI.*

Dinitrobenzene (1,3-DNB) is a neurotoxic compound shown to preferentially affect astrocytes within the auditory and vestibular nuclei. Although the exact mechanism of neuropathology is unknown, the lesion mirrors a group of compounds and metabolic disorders classified as Acute Energy Deprivation Syndromes (AEDS). In primary astrocytes, 1,3-DNB inhibits key metabolic enzymes and induces the mitochondrial permeability transition (MPT). We investigated the progression of 1,3-DNB-mediated cell death in order to better understand the pathological timeline and apoptotic mechanisms associated with this compound. Immortalized primary astrocytes (DITNC1) were exposed for various time points to 500uM 1,3-DNB with approximately 80% cell death occurring after 48h. Prior to death (24-48h), extracellular phosphatidylserine staining and DNA condensation were observed by fluorescence microscopy. Western blotting indicated caspase 9 and caspase 3 activation was apparent after 12h exposure. In order to determine if caspase activation was mitochondria dependent, cells were cotreated with 1,3-DNB

and MPT inhibitors (bongkreic acid (BA); cyclosporin A (CsA)) for 24h. Exposure to 0.25% dimethyl sulfoxide (DMSO), 10 μ M BA, and 1 μ M CsA alone showed no apparent activation of caspase 9 or 3. In contrast, cotreatment of 1,3-DNB with either MPT inhibitor reduced caspase 9 activation but significantly increased caspase 3 activation. Although caspase 9 appears to play a role in 1,3-DNB induced glial toxicity, this data suggests that it is not the primary initiating pathway. Further studies are necessary to determine if enhanced caspase 3 activation is due to effects independent of MPT inhibition such as metabolic impairment or whether induction of MPT may mediate protection in 1,3-dinitrobenzene-induced neurotoxicity. This work was supported by NIH T32 ES07062 and RO1 ES08846.

1055 ADDITIONAL INFORMATION FAVORING A NOVEL RECEPTOR ASSOCIATED WITH VOLTAGE-GATED SODIUM CHANNELS.

E. P. Gold^{1,2}, H. K. Jacks² and D. G. Baden^{2,1}. ¹Biology and Marine Biology, University of North Carolina Wilmington, Wilmington, NC and ²Center for Marine Science, UNCW, Wilmington, NC.

Voltage-gated sodium channels (VGSC) are responsible for action potential initiation and propagation in excitable cells including neurons of the central nervous system. Typical VGSC are comprised of an α -subunit and 2 β -subunits. All known pharmacological agents that act on VGSC have receptor sites on the α -subunits. At least six distinct sites for neurotoxins and one for local anesthetics and related drugs have been identified (Cestele and Catterall 2000).

We presented preliminary results suggesting the presence of a novel receptor associated with VGSC characterized by the binding of an antitoxin, brevenal, produced by the dinoflagellate *Karenia brevis*, also known to make the site 5-specific brevetoxins (PbTx)(Gold *et al.*, 2005). Both unlabeled brevenal and the aldehyde-reduced brevenol displaced tritiated brevenol (³H-B) in rat brain synaptosomes but PbTx does not. Here, we further examine the basic characteristics of receptor identification using tritiated receptor binding experiments to support our findings. To show saturation of specific brevenal receptors, ³H-B was bound to rat brain synaptosomes in the presence and absence of brevenal/brevenol. Saturation and distribution of receptors were studied in synaptosomal preparations made of whole brain, cerebrum and cerebellum. Results indicate binding maxima (B_{max}) or the maximum number of binding sites and equilibrium dissociation constants (K_D), the concentration at which half the receptors are occupied, for the whole brain to be lower than those for the cerebrum and cerebellum, respectively. Finally, displacement studies involving ³H-B against several competitors including tetrodotoxin (site 1 neurotoxin), veratridine (site 2 neurotoxin), *Centruroides sculpturatus* venom (site 4 neurotoxin source), aconitine (site 2) and amiloride (inhibitor of sodium transport) demonstrate no inhibition. These findings indicate that ³H-brevenol does not bind to any of the tested receptor sites on VGSC and suggest a novel uncharacterized site on VGSC.

1056 IN VIVO ACRYLAMIDE EXPOSURE PRODUCES CUMULATIVE ADDUCTION OF SYNAPTIC PROTEIN THIOLS.

D. S. Barber¹, R. M. LoPachin² and S. Stevens³. ¹Center for Environmental and Human Toxicology, University of Florida, Gainesville, FL, ²Anesthesiology, Montefiore Medical Center, Bronx, NY and ³ICBR, University of Florida, Gainesville, FL.

We have previously demonstrated that in vivo acrylamide (ACR) intoxication results in the formation of adducts on cysteine residues of synaptic proteins. We have also demonstrated that synaptic protein thiol adduct burden correlates with motor dysfunction and decreased neurotransmitter uptake and release. Using Isotope Coded Affinity Tag (ICAT) labeling, we examined the synaptic proteome of rats treated orally with ACR (21mg/kg/day) for 7, 14 or 21 days. During this time rats progress to slight motor impairment. After 21 days of intoxication, the abundance of most cysteine containing peptides is similar, but more than 35 proteins exhibit at least a 25% reduction in available cysteines in treated rats. Many of these proteins are critical to normal synaptic function including N-ethylmaleimide sensitive factor (NSF), synaptophysin, synaptotagmin, syntaxin-7, complexin-2 and vATPase. Because reduced ICAT incorporation can occur as a result of decreased protein abundance as well as adduct formation, we used multidimensional LC/MS/MS to demonstrate ACR adducts on affected cysteines, strongly suggesting that reduced ICAT incorporation is due to ACR adduction. Differential effects of ACR treatment were observed on individual cysteines within a protein, indicating specificity of adduct formation. Because ACR is a relatively weak electrophile, adducts form primarily on protein thiol groups with high nucleophilic reactivity due to their local environment. In glutamine synthase, Cys346 labeling is reduced by more than 55% in ACR treated animals while Cys99 is only slightly reduced. Because ACR toxicity is a cumulative process, we examined changes in ICAT incorporation over time. Of the set of proteins common to all samples, some proteins exhibited cumulative changes, including syntaxin-7, VDAC and NSF. These proteins are likely critical targets of ACR toxicity in the nerve terminal. Supported by NIEHS grant ESO3830-20.

1057 LUMO ENERGIES PREDICT THE IN VITRO NEUROTOXIC POTENCIES OF TYPE-2 CONJUGATED ALKENES.

R. M. LoPachin¹, T. Gavin² and B. C. Geohagen¹. ¹Anesthesiology, Albert Einstein College of Medicine, Bronx, NY and ²Chemistry, Iona College, New Rochelle, NY.

Acrylamide (ACR) is a conjugated Type-2 alkene and a human neurotoxicant. Because pi electrons in a conjugated system are highly polarizable, ACR is a soft electrophile and will form adducts with soft biological nucleophiles, primarily sulfur. In a study of structure-toxicity relationships we showed that ACR and other Type-2 alkenes; e.g., acrolein (ACL), methylvinyl ketone (MVK), produced in vitro neurotoxicity (synaptosomal dysfunction) mediated by thiol adduct formation (LoPachin *et al.*, 2006). The rank order of neurotoxic potencies (ACL>MVK>ACR) suggested differences in softness among these conjugated carbonyl compounds. Reactions between soft electrophiles and soft nucleophiles is governed by frontier molecular orbital (FMO) interactions and thus, alkenes with low energy FMO's should more readily undergo adduct formation by accepting electrons from soft nucleophiles like thiolates. Since the relevant FMO for electrophiles is the lowest unoccupied molecular orbital (LUMO), we calculated LUMO energies of the Type-2 alkenes using the SPARTAN Molecular Modeling program (Wavefunction, Inc). Results show that for each chemical in a series of Type-2 conjugated alkenes the respective LUMO energies were directly correlated to the corresponding IC50's for inhibition of synaptosomal transmitter uptake and sulfhydryl loss. In contrast, non-conjugated alkene or aldehyde analogs had higher LUMO energies and did not affect synaptosomal function or thiol content. Thus, the relative softness of conjugated alkenes is directly related to respective in vitro neurotoxic potencies. This suggests that LUMO energy calculations might be used to identify Type-2 alkenes with neurotoxic potential. Such screening is important because: 1) our findings indicate that, conjugated alkenes, as a chemical class, might produce neurotoxicity via a common mechanism involving thiol adduct formation and presynaptic toxicity and, 2) the neurotoxic risks associated with human Type-2 alkene exposure have been poorly delineated. (Sponsored by NIEHS ESO3830-20).

1058 CHARACTERIZATION OF THE N27-D_{2L} CELL LINE: ASSESSMENT AS A VIABLE CELL MODEL FOR INVESTIGATING DOPAMINERGIC D_{2L} RECEPTOR-COUPLED FUNCTIONS.

J. D. Urban¹, K. Thornley⁴, M. Wightman^{4,5} and R. B. Mailman^{2,1,3}. ¹Curriculum in Toxicology, UNC, Chapel Hill, NC, ²Psychiatry, UNC, Chapel Hill, NC, ³Pharmacology, UNC, Chapel Hill, NC, ⁴Chemistry, UNC, Chapel Hill, NC and ⁵Curriculum in Neurobiology, UNC, Chapel Hill, NC.

Currently there is no dopaminergic cell model that genuinely reflects typical dopaminergic neurons as they would be found in the CNS. This is an impediment to many lines of research, including understanding of the functional mechanisms of action of intrinsic dopamine D₂ receptors. In this study we assess the characteristics of the N27 cell line in order to determine its utility as such a model system. First, we verified previous reports that this cell line synthesized dopamine and endogenously expressed the dopamine transporter. Using radioligand-based competition isotherms it was determined that the N27 cell line does not endogenously express any type of dopamine receptor. A FLAG-tagged hD_{2L} receptor was stably transfected into the cell line, and was found to couple to adenylyl cyclase inhibition (a G $\alpha_{i/o}$ -mediated functional response). Real time PCR revealed the endogenous expression of a number of G protein isoforms as well as low levels of tyrosine hydroxylase and dopamine transporter. The cells, however, failed to show D_{2L}-mediated effects on dopamine uptake or release assessed using biochemical and electrochemical methods. In addition, agonist-induced D_{2L} receptor internalization also did not occur. The ability of this cell line to synthesize dopamine has made it a viable model for studying certain questions regarding the mechanisms that underlie the effects of neurotoxin activity, oxidative stress, ischemia and cell death in dopaminergic cells. It is our assessment, however, that this cell line is not a practical in vitro cell model for the study of dopaminergic function as it is regulated by D₂ receptors.

1059 LINKING REGULATORY TOXICOLOGICAL INFORMATION ON ENVIRONMENTAL CHEMICALS WITH HIGH-THROUGHPUT SCREENING (HTS) AND GENOMIC DATA.

M. T. Martin, K. A. Houck, K. McLaurin, A. M. Richard and D. J. Dix. U.S. EPA, Research Triangle Park, NC.

The application of high-throughput screening (HTS) and genomic technologies to environmental chemical classification and prioritization requires reference toxicological information for characterizing the associations between toxicological properties and HTS or genomic profiles. Regulatory toxicological data has been produced for thousands of environmental chemicals, and at EPA are used primarily in

hazard characterization and risk assessment of individual chemicals. In order to extend the use of this vast legacy toxicological information, the Toxicological Reference Database (ToxRefDB) captures toxicological endpoints, critical effects and relevant dose-response data from EPA Program Office evaluations in a relational database using a standardized vocabulary. Initially, ToxRefDB is being populated primarily with data for pesticide active chemicals. ToxRefDB provides the ability to cluster and group chemicals based on toxicological outcomes specific to study type, target organ, or effect categories (e.g., tumorigenicity). In addition, ToxRefDB will facilitate ranking of chemicals by relative potency based on specific endpoints, or grouping of chemicals based on mode or mechanism of action. These toxicity-based groupings can then be used to identify predictive HTS bioactivity profiles and genomic signatures. Thus ToxRefDB will be an essential computational tool providing an interpretive context for HTS and genomic data generated in EPA's ToxCast chemical prioritization program. This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy.

1060 THE USE OF NTP-HTS DATA FOR PREDICTIVE COMPUTATIONAL TOXICOLOGY.

H. Zhu¹, K. Wang¹, I. Rusyn², A. Richard³ and A. Tropsha¹. ¹Laboratory for Molecular Modeling, University of North Carolina, Chapel Hill, NC, ²Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and ³National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC.

To explore efficient approaches to assessing the toxicity of environmental chemicals, the NIEHS National Toxicology Program (NTP) recently initiated a High Throughput Screening (HTS) Project. To date, HTS results for a set of 1,408 compounds tested in 6 cell viability assays have been released via PubChem. We explore herein the utility of the HTS data for predicting animal and human toxicity. Initially, we asked if these HTS results could enhance prediction models for rodent carcinogenicity. The Carcinogenic Potency Database (CPDB) includes 383 of the NTP-HTS compounds. Within this subset, HTS-actives have a relatively high correlation with rodent carcinogens (sensitivity 77%); however, HTS-inactives are less informative (specificity 30%). QSAR approaches were applied to 1,289 of the HTS compounds (230 actives and 1,059 inactives). External validation set consisted of 429 randomly excluded agents. The remaining 860 compounds were split into diverse training and test sets. A classification k Nearest Neighbor QSAR approach gave models with prediction accuracies for training, test and external validation sets as high as 88, 83, and 78%, respectively. Similar approaches to model carcinogenicity yielded a prediction accuracy of 53%. Importantly, the model accuracy for carcinogenicity increased to 65% after augmenting chemical descriptors with HTS data as biological descriptors. QSAR analysis of 93 known human carcinogens included in the HTS datasets afforded similarly significant models: HTS-actives had relatively high correlation with human carcinogens (sensitivity 80%) but HTS-inactives poorly correlated with human non-carcinogens (specificity 41%). These preliminary studies suggest that cheminformatics analysis of NTP HTS data, in conjunction with traditional QSAR approaches, may enhance human and animal toxicity prediction models. This abstract does not reflect EPA policy.

1061 TOXICO-CHEMINFORMATICS AND QSPR MODELING OF THE CARCINOGENIC POTENCY DATABASE.

K. Wang¹, A. Richard², I. Rusyn³ and A. Tropsha¹. ¹Laboratory of Molecular Modeling, University of North Carolina, Chapel Hill, NC, ²National Center for Computational Toxicology, U.S. EPA, Research Triangle Park, NC and ³Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.

Combining chemical structure descriptors with systematically organized toxicity and biological activity databases is the next frontier for toxico-cheminformatics and quantitative structure-property relationship (QSPR) modeling in predictive toxicology. Formalized toxicity data models and public toxicity data schemas allow for flexible data mining and relational data searching across layers of chemical and biological information. Here, we analyze data in the Carcinogenic Potency Database (CPDB) that contains animal carcinogenicity bioassay data for over 1000 chemicals, with information on species, sex, target site, mutagenicity, tumor potency, etc. Such a database provides unique opportunities for development of QSPR models for subsets of compounds on the basis of biologically meaningful endpoints. To test the quality of the data and fitness of the methodology, the classification k Nearest Neighbor (kNN) QSPR modeling approach was applied to modeling mutagenicity within a CPDB subset of 693 compounds, where 70 randomly selected compounds were set aside as an external validation set. The compounds were split into diverse training set and test set with chemical descriptor models for predicting mutagenicity yielding prediction accuracies for training, test and external validation sets as high as 0.917, 0.847, and 0.893, respectively. Subsequent analyses use mutagenicity/carcinogenicity status as biological refinements for modeling carcinogenicity for

subsets of compounds within CPDB. We conclude that QSPR approaches combined with toxico-cheminformatics descriptors can enhance predictive toxicology models. This abstract does not reflect EPA policy.

1062 AN INTEGRATED PBPK-QSAR MODELING APPROACH FOR IN VITRO TO IN VIVO EXTRAPOLATION IN RATS.

E. Kamgang¹, T. Parkerton² and K. Krishnan¹. ¹SEST, University of Montréal, Montréal, QC, Canada and ²ExxonMobil Biomedical Sciences Inc., Annandale, NJ.

In vitro data on metabolism and partitioning may be integrated within PBPK models to provide simulations of the kinetics and bioaccumulation of chemicals in intact organisms. QSAR modeling of available in vitro data may be performed to predict metabolism rates and partition coefficients for developing in vivo PBPK models. The objective of the present study was to develop an integrated PBPK-QSAR modeling approach for the conduct of in vitro to in vivo extrapolation. For this purpose, data on rat blood:air partition coefficients (Pb) and fat:air partition coefficients (Pf) obtained using vial equilibration technique, as well as intrinsic metabolic clearance (Clint) obtained using rat liver slices for C5 to C10 volatile organics (VOCs) (n-alkanes, isoalkenes, n-alkenes, naphthenes and aromatic hydrocarbons) were compiled from the literature. Multilinear additive QSAR models for Pf, Pb and Clint were developed based on the number and nature of molecular fragments in these VOCs (CH₃, CH₂, CH, C, C=C, H, benzene ring and H in benzene ring structure) using a commercially available statistical software (SPSS 14.0). The mean experimental/estimated (exp/est) ratios ($\pm$ SD; range) were 1.01 ($\pm$ 0.28; 0.62–1.61) for Pf, 1.16 ($\pm$ 0.81; 0.43–4.44) for Pb, and 0.95 ($\pm$ 0.28; 0.55–1.63) for Clint. By accounting for the difference in the content of neutral lipids in fat and other tissues, the liver:air (exp/est: 1.25 $\pm$ 0.40 (0.78–2.09)) and muscle:air (est/exp: 0.97 $\pm$ 0.26 (0.53–1.48)) partition coefficients were predicted from Pf. Integrating the QSARs for Pf, Pb and Clint within a rat PBPK model, simulations of inhalation pharmacokinetics of several VOCs (ethylbenzene, t-butylbenzene, n-hexane and toluene) were generated on the basis of molecular structure, for a given exposure scenario. The integrated QSAR-PBPK modeling approach developed in this study should be useful for predicting in vivo kinetics and bioaccumulation of chemicals in rats under data-poor situations.

1063 DEVELOPMENTAL TOXICITY PREDICTIONS OF ETHYLENE GLYCOL ETHERS AND THEIR METABOLITES USING STRUCTURE-ACTIVITY RELATIONSHIP (SAR).

P. Ruiz^{1,2}, H. Hansen¹, C. T. De Rosa¹ and M. M. Mumtaz¹. ¹DTEM, CDC/ATSDR, Atlanta, GA and ²Oak Ridge Institute for Science and Education, Oak Ridge, TN.

Ethylene glycol mono-n-alkyl ethers (EGEs) are a family of organic solvents commonly found in industrial and household products which cause a wide range of toxic effects in laboratory animals including reproductive, hemato-, and developmental toxicity. EGE metabolites are considered to approximate the toxicity of their parent compounds. Developmental toxicity studies have been reviewed and evaluated for four EGEs: 2-methoxyethanol (EGME), 2-ethoxyethanol (EGEE), 2-propoxyethanol (EGPE), and 2-butoxyethanol (EGBE). Structure-activity relationships (SARs) have been successfully used to predict the biological activity of potential developmental toxicants. SAR was conducted to investigate the possible role of moieties in the developmental toxicity of Ethylene glycol mono-n-alkyl ethers and their metabolites (Alkoxy acetaldehyde, alkoxyacetic acid and alkoxyethyl acetate). SAR results indicate that the aliphatic oxygen group and the alkyl length may be associated with the developmental toxicity effects of the EGEs and their metabolites. The ranking of the developmental toxicity activity of these compounds was as follows: Alkoxyacetic acid > Alkoxyethanols > Alkoxyethyl acetates > Alkoxyacetaldehydes. This suggests that the presence and position of the ether linkage, and the molecular shape, are critical to the developmental toxicity of EGEs.

1064 PREDICTION OF BIOLOGICAL PARTITION COEFFICIENTS: CALCULATED MOLECULAR DESCRIPTORS VS EXPERIMENTALLY DETERMINED PROPERTIES.

M. M. Mumtaz¹, S. Basak², D. Mills² and B. Gute². ¹DTEM, CDC/ATSDR, Atlanta, GA and ²Natural Resource Research Institute, University of Minnesota, Duluth, MN.

Biological partition coefficients are routinely used as input parameters in physiologically based pharmacokinetic (PBPK) models, which are developed for the assessment of chemical toxicity. In this study, predictive quantitative structure-activity relationship (QSAR) models for rat and human biological partition coefficients,

namely blood: air, fat: air, brain: air, liver: air, muscle: air, and kidney: air, were developed utilizing experimentally determined partition coefficients for 131 chemicals obtained from the literature and calculated molecular descriptors based solely on chemical structure. The descriptors were partitioned into four hierarchical classes, including topostructural, topochemical, 3-dimensional, and ab initio quantum chemical. Three types of regression methodologies—ridge regression, principal components regression, and partial least squares—were used comparatively in the development of these models. In addition to the structure-based models, ordinary least squares regression was used to develop comparative models based on experimentally determined properties including saline: air and olive oil: air partition coefficients. The results of the study indicate that many of the structure-based models are comparable or superior to their respective property-based models. This is an important result considering that structural descriptors can be calculated quickly and inexpensively for both existing chemicals and those not yet synthesized. With respect to the structure-based models, it was also found that ridge regression outperformed principal components regression and partial least squares regression, and that generally the topochemical descriptors alone produced models of good predictive ability. The descriptors found to be most influential in biological partitioning of chemicals include those which encode information regarding hydrogen bonding, polarity, and molecular size and shape.

1065 STRUCTURE-GUIDED VIRTUAL HIGH-THROUGHPUT SCREENING PRIORITIZATION MODELS OF ENVIRONMENTAL CHEMICALS ACTING AT NUCLEAR RECEPTORS.

M. R. Goldsmith^{2,1} and J. Rabinowitz¹. ¹National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC and ²Department of Environmental Science and Engineering, School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC.

High-throughput screening (HTS) and applied chemical genomics methods are becoming essential quantitative in vitro components of environmental prioritization schemes. The use of molecular modeling and Virtual-HTS methods for (1) elucidating molecular-level spatial descriptions of potential toxicant/target interactions and (2) obtaining quantitatively relevant relative binding affinities will complement the other predictive toxicology approaches for prioritizing risk assessment.

We demonstrate the use of docking-pose populations-analysis (DPPA) on poses obtained from exhaustive search molecular docking (ESMD) screens and the use of DPPA in reference standard selection for calibrating and validating relative binding affinities (RBAs). In a test set of 104 estrogen receptor (ER) ligands our in silico approaches afford a correlation between theoretical and experimental relative binding affinities of $R^2 = 0.75$, substantially better than the norm for such an analysis (0.5 and lower). In addition we report a false negative assignment of less than 2%. Finally, using these methods we present affinity fingerprint matrices obtained from structure-guided virtual-HTS of the EPA's pesticide and high-production volume datasets against multiple nuclear receptors (PXR, RXR, CAR, LXR, FXR, ER, AR ...) and their respective isoforms.

The simple, efficient, cost-effective and complementary modeling methods we have investigated afford numerically relevant protein affinity data matrices for the human nuclear receptorome that may have a far reaching effect as an additional tool for prioritizing chemicals. [MRG is supported by NHEERL-DESE Training Agreement, EPA CT829471. [This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy].

1066 DEVELOPMENT OF QUANTITATIVE STRUCTURE ACTIVITY RELATIONSHIPS (QSARS) TO PREDICT TOXICITY FOR A VARIETY OF HUMAN AND ECOLOGICAL ENDPOINTS.

T. Martin¹, P. Harten¹, D. Young¹, R. Venkatapathy^{2,1} and S. Das^{2,1}. ¹NRMRL, U.S. EPA, Cincinnati, OH and ²Pegasus Technical Services, Cincinnati, OH. Sponsor: H. Choudhury.

In general, the accuracy of a predicted toxicity value increases with increase in similarity between the query chemical and the chemicals used to develop a QSAR model. A toxicity estimation methodology employing this finding has been developed. A hierarchical based clustering technique (based on Ward's method) will be used to generate a series of structurally similar groups of chemicals from a toxicity data set. The structural similarity will be defined in terms of more than 3000 physicochemical descriptors which include 2-dimensional descriptors (such as connectivity and E-state indices) and 3-dimensional descriptors (such as surface area and partial charges). A genetic algorithm based technique will be used to generate statistically valid QSAR models for each cluster (using the pool of descriptors described above). The toxicity for a given query compound will be estimated using the model generated from the cluster whose chemicals are the most structurally similar to the query compound.

Initially the methodology described above will be used to develop QSAR models for the acute oral rat toxicity end point. Upon successful validation, the tool is expected to predict toxicities of chemicals for other cancer and non-cancer endpoints. The descriptor generation, clustering, and model building algorithms have been validated against commercial software.

The toxicity models developed using the methodology in this study will be incorporated into a free web-based software tool (written in Java). The tool will enable a user to easily predict the toxicity of a query compound by simply entering its structure in a 2-D chemical sketcher, entering a SMILES string, or entering a CAS number.

1067 PREDICTING BIOCHEMICAL RESPONSES TO ENDOCRINE ACTIVE COMPOUNDS: MATHEMATICAL MODEL OF STEROIDOGENESIS IN SMALL FISH OVARIES.

M. S. Breen¹, D. Villeneuve², M. Breen³, G. Ankley² and R. Conolly¹. ¹NCCT, U.S. EPA, Research Triangle Park, NC, ²Mid-Continent Ecology Division, U.S. EPA, Duluth, MN and ³Department of Statistics, North Carolina State University, Raleigh, NC.

Sex steroids, which have an important role in a wide range of physiological processes, are synthesized primarily in the gonads and adrenal glands through a series of enzyme mediated reactions. The activity of steroidogenic enzymes can be altered by a variety of endocrine active compounds (EAC), some of which are therapeutics and others that are environmental contaminants. A mathematical model of the intraovarian metabolic network was developed to predict the synthesis and secretion of testosterone (T) and estradiol (E2), and the kinetics for steroidogenic enzyme inhibition by EAC. Model predictions were compared to data from an in vitro steroidogenesis assay with ovary preparations from a small fish model, the fathead minnow. Model parameters were estimated using an iterative optimization algorithm. Model predicted concentrations of T and E2 closely corresponded to the experimental time course data from control experiments. In experiments with the EAC, fadrozole (FAD), model predicted behavior was consistent with E2 data, but not fully supported by T data. To address this discrepancy between the data and model predictions, we revised our model by including the additional high dose inhibitory effects of FAD on the steroidogenic pathway as described in the literature. A relative sensitivity analysis of the model parameters identified specific transport and metabolic processes that most influence the steady state concentrations of T and E2 that included secretion of T from the ovary and conversion of T to E2. Our study demonstrates the feasibility of using the model to predict steady state T and E2 concentrations, in vitro. This capability could be useful for environmental health assessments and pharmaceutical development with EAC. This work was reviewed by the U.S. EPA and approved for publication but does not necessarily reflect Agency policy.

1068 A PREDICTIVE SYSTEM FOR COMPUTATIONAL MOLECULAR TOXICOLOGY BASED ON NEURAL NETWORKS.

P. Piotrowski¹, B. Sumpter¹, P. Lu¹, S. Martin¹, M. Parang¹ and J. Wassom². ¹Oak Ridge National Laboratory, Oak Ridge, TN and ²YAHSGS LLC, Richland, WA.

A Multi-Intelligent System for Toxicogenomic Applications (MISTA) program has been developed to assess human health impacts from pharmaceuticals and chemicals. The MISTA program includes a dynamic and thoroughly reviewed database, as well as LiverTox, a liver toxicity prediction tool that uses computational neural networks (CNNs) linked to modern computational chemistry and wavelet methods. Several techniques were employed to make high-accuracy predictions using (1) Quantitative Structure-Activity Relationships, (2) microarray data, (3) data from other gene expression assays, (4) total gene expression analysis, (5) subtraction hybridization, (6) serial gene analysis expression, (7) proteomics, and (8) metabolomics and metabolomics. This highly innovative approach ensures that LiverTox takes full advantage of other key in silico resources currently available to keep it up to date with new developments. The accuracy and flexibility of this approach has been demonstrated for predicting (1) Lipophilicity, log P, for a large number of diverse compounds, (2) acute inhalation toxicity, (3) Carcinogenic Potency, and (4) mutagenicity in Salmonella. LiverTox is expected to correctly predict liver toxicity at rates in the 90th percentile with some endpoints predicted at rates greater than the 95th percentile. In addition, LiverTox is designed to accommodate future development of toxicogenomic tools and techniques to improve and expand the prediction of toxicity endpoints in other body organs. As CNNs are designed for each new predictive organ toxicity module, the predictive platforms for each new module will be optimized by drawing on the strengths (or weaknesses) of the LiverTox predictive platform.

1069 ESTIMATING SAFE WITHDRAWAL TIMES FOR DRUGS GIVEN TO FOOD-PRODUCING ANIMALS USING PBPK MODELING AND MONTE CARLO ANALYSIS.

R. E. Baynes¹, J. L. Burr¹, A. L. Craigmill² and J. E. Riviere¹. ¹*Food Animal Residue Avoidance Databank (FARAD), North Carolina State University, Raleigh, NC* and ²*Food Animal Residue Avoidance Databank (FARAD), University of California at Davis, Davis, CA.*

Contamination of meat and milk products with drugs/xenobiotics is not only a public health concern, but it can also influence consumer confidence in the safety of these food items. One important method in avoiding the occurrence of drug residues, is to improve estimates of withdrawal times (WDT); that is, the time it takes for the drug to be cleared from the animal's body to levels in meat and milk that are safe for human consumption. Our research group has utilized physiologically based pharmacokinetic (PBPK) models with Monte Carlo analysis to estimate safe WDT of oral sulfamethazine in swine. The PBPK model contained five tissue blocks and plasma compartment which were linked through the liver to a two-tissue compartment (liver and body) model for the N4-acetyl metabolite of sulfamethazine. Following sensitivity analysis, five kinetic parameters were subjected to Monte Carlo analysis. Each Monte Carlo run consisted of a series of 100 simulations for validation and 1000 simulations each to determine the meat WDT for each run. The resulting distributions from a single Monte Carlo analysis of 100 simulations were comparable to the distributions of an external data set and in vivo pilot study. WDT estimates were based on US FDA Center of Veterinary Medicine regulatory requirements. The calculated meat WDT covered the upper 95% confidence interval of the 99th percentile of the pig population. Our calculations derived a more conservative meat WDT (21 days) than the approved WDT (15 days) established by US FDA. This work demonstrated that the use of PBPK modeling with probabilistic analysis techniques such as Monte Carlo analysis can have applications in determining safe WDTs that are transparent and reproducible. Current work is focused on how other physiological parameters such as drug protein binding can influence WDT. This research was supported by a USDA CSREES grant.

1070 INTEGRATION OF MICROARRAY AND PROTEOMIC DATA WITH TRADITIONAL TOXICITY DATA REVEALS DISEASE PATHOGENESIS PATHWAYS IN MOUSE MODEL OF COPD.

S. Bandyopadhyay¹, M. Matzke¹, S. Harbo², K. Gideon², R. Renne², K. M. Lee², J. G. Pounds¹ and K. M. Waters¹. ¹*PNNL, Richland, WA* and ²*Battelle Toxicology NW, Richland, WA.*

Chronic inflammation and long-term exposure to cigarette smoke (CS) are the leading causes of Chronic Obstructive Pulmonary Disease (COPD). Co-administration of lipopolysaccharide (LPS) with CS augments the degree of pulmonary inflammation and has been proposed as a mouse model for COPD progression. AKR/J mice were exposed to CS and/or LPS via inhalation for 3 weeks and pulmonary responses were evaluated. Microarray and mass spectrometry-based proteomic analyses of lung were performed to support the traditional toxicological endpoints of pathology and bronchoalveolar lavage (BAL) parameters such as cytology and cytokines. Data were integrated on gene/protein and pathway levels to characterize the relationship between the mouse model and reported human disease phenotypes. Concordance of gene expression to protein abundance was better for BAL cytokines ($r=0.54$) than for lung proteomic data ($r=0.37$). Transcription factor analysis demonstrated significant overlap for more than 80% of the significant gene and protein changes in the lung, with a regression coefficient of $r=0.84$. Statistical enrichment of biological processes from the combined data demonstrates that the combined CS/LPS treatment displays several hallmarks of human COPD, such as high levels of response to reactive oxygen species, high proteolytic activity, and dysregulation of calcium homeostasis. CS appears to suppress the innate immune response to LPS treatment through decreased cytokine production by macrophages, despite increased cell numbers in the BAL fluid. Also, increased numbers of apoptotic cells from CS and LPS measured by TUNEL staining appear to arise through distinct mechanisms, which synergize in the combined CS/LPS treatment group. Thus, it appears that inflammation without proper immune surveillance/regulation is leading to disruption of oxidant versus antioxidant and cell death versus proliferation balances in the lungs of CS/LPS mice, which is consistent with early stages of COPD development in humans.

1071 AGGLOMERATION STATE AFFECTS *IN VITRO* NANOPARTICLE DOSIMETRY AND TOXICITY ASSESSMENTS.

P. M. Hinderliter, J. G. Teeguarden and J. G. Pounds. *Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA.*

In vitro cellular dose of nanoparticles is a function of the sedimentation and diffusional transport rates of the particles of interest. We have previously constructed a computational model of particle deposition kinetics and dosimetry in vitro for sin-

gle particles based on media and particle properties. However, the initial model analyses were conducted under the simplifying assumption that particles are non-interacting rather than agglomerating due to attractive forces or chemical or mechanical binding (as has been shown for metal oxides, C60 fullerenes, and carbon nanotubes). Agglomeration shifts the size class distribution of particles from its initial state to one with a larger mean and greater dispersity. Agglomerates have a higher mass but a larger surface area than the primary particles. The net impact of agglomeration is to lower both gravitational sedimentation (due to the increase in buoyancy from the increased surface area:mass ratio) and diffusion (due to the larger particle size). Agglomeration rate and extent were added to the dosimetry and kinetic model to improve basis for the calculation of deposited particle surface area. The difference between agglomerate and primary particle kinetics can yield cases where increased particle concentration can actually lower the delivered dose due to the higher rate of agglomerate formation. This model refinement improves predictions regarding the cellular dosimetry and the dynamics of cellular response. Funded through U.S. Department of Energy under Contract DE-AC05-76RL01830.

1072 PREDICTING AGE-DEPENDENT PHARMACOKINETICS OF SIX VOLATILE ORGANIC COMPOUNDS IN THE RAT UTILIZING PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING.

C. E. Rodriguez and H. A. Barton. *National Center for Computational Toxicology, Environmental Protection Agency, Research Triangle Park, NC.*

The capability of physiologically-based pharmacokinetic (PBPK) models to incorporate age-appropriate physiological and chemical-specific parameters was utilized to predict changes in internal dosimetry for six volatile organic compounds (VOCs) across different ages of the rat. Typical 6 h animal inhalation exposures to 500 ppm benzene, chloroform, methyl ethyl ketone (MEK), methylene chloride, perchloroethylene, or trichloroethylene were simulated for postnatal day 10 (PND10), 2 month old (adult) and two year old (aged) rats. With the exception of MEK, predicted peak venous blood levels of VOCs in PND10 and aged rats were equal or up to 1.5-fold higher when compared to the adult rat. Predicted peak venous blood levels of MEK, the most water soluble VOC examined, were similar in the adult and aged rat, but were greater than 5-fold for PND10 rats, reflecting the lower metabolic capability and greater loading by more rapid ventilation. Steady state venous blood levels of VOCs, simulated by modeling constant exposure, were predicted to be achieved in the order PND10 > adult > aged, largely due to increasing fat volume. The dose metric, total amount of VOC metabolized per unit liver volume, was generally much lower in PND10 than adult rats. The blood:air partition coefficient, fat volume, and fat blood flow were identified to be the most important parameters accounting for the predicted differences in venous blood levels of VOCs between the aged and adult rat. The lower metabolic capability, largely due to smaller liver size, and higher ventilation rate per unit body weight of PND10 animals appear to contribute the most to the differences between PND10 and adult rats. This study highlights the pharmacokinetic parameters that may contribute to the differential susceptibility to the toxic effects of VOCs across lifestages. (This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy).

1073 INSIGHTS INTO THE DETOXIFICATION OF CYANIDE WITH SULFURATING AGENTS.

M. A. Zottola and S. I. Baskin. *USAMRICD, Aberdeen Proving Ground, MD.*

The standard treatment of acute cyanide intoxication involves the use of sodium thiosulfate to convert cyanide into the significantly less toxic SCN which is excreted from the body. However, the exact details of this mechanism are currently unknown. This work seeks to probe the reaction between cyanide and various sulfurating agents in order to enhance our understanding of this important detoxification process. In this work we have addressed the following questions: 1. Does cyanide react with sulfurating agents directly to form SCN? Or, does isothiocyanide (SNC) form then rearrange to the observed thiocyanide? 2. Can a computational model be developed to evaluate the potential efficacy of sulfur donors? 3. Do Efficacy predictions change when examining thiosulfonates? To address these questions, we employed quantum mechanics. For the evaluation of the interconversion of SNC and SCN the method MPW1PW91/6-311++g(2d,p) was used. Calculation of the enthalpy of formation for the efficacy model was accomplished using the B3LYP/6-31g* level of theory. This level of theory was also used for the evaluation of thiosulfonates. Wave function files for each structure were evaluated using the AIM2000 program. Quantum mechanics calculations were carried out using the Gaussian03 program Revision C02. We have found the following: 1. In the gas phase, SCN is favored over SNC by nearly 36 kilocalories. Conversion of SNC to SCN occurs via an unusual two-step process with interconversion barriers approximately 2 Kcal/mol. Therefore, formation of SNC is highly unlikely; if such

were formed, it would spontaneously rearrange to SCN. 2. The enthalpy of formation for disulfides reacting with HCN is keenly dependent on their substituent organic groups. The bonding between sulfurs is almost exclusively between p-orbitals. That direct cleavage of disulfides by cyanide may be a good model for predicting the efficacy was indicated by the enthalpy values of several compounds, including those found in garlic.

1074 PREDICTION OF AIRFLOW AND PARTICLE DEPOSITION IN THE HUMAN LUNG.

K. Nazirdoust and B. Asgharian. *Division of Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC.*

The study of particle transport and deposition in the human lung is critical in health risk assessment of air pollutants and pharmaceutical drug delivery. A number of computational fluid dynamics (CFD) studies have investigated particle deposition in the lung by identifying various parameters such as lung ventilation and particle characteristics that influence particle deposition behavior. In this study, CFD simulations of airflow and particle deposition in geometries representing the human tracheobronchial tree were performed. Two cases of interest were modeled: (1) Nine common airways of human lung including the trachea, main, lobar, and segmental bronchi connected as a branching network of cylindrical tubes with dimensions based on available morphometric measurement; (2) the same geometry with a lobe attached to the distal end of each segmental bronchus. A three dimensional computational model of the lung was created for each case. Airflow field in both geometries was solved numerically for a 4-second breathing cycle. To evaluate particle deposition patterns during inhalation, about 10,000 particles of sizes from 1nm to 10µm were injected at the inlet to the trachea. A Lagrangian particle tracking method was used that included the effect of random motion (Brownian motion). The resulting airflow and deposition patterns varied significantly between cases (1) and (2) which indicated the significance of realistic boundary characteristics for accurate assessment of flow field and particle deposition. Applications of these results could assist scientists in identifying vulnerable and preferred sites in the respiratory tract and would help to set standards for minimizing exposure to environmental pollutants and develop techniques to enhance particle deposition in drug delivery to improve effective inhalation therapy for lung illnesses.

1075 EFFECTIVE TORTUOSITY APPLIED TO INTER-SPECIES SCALING OF PARATHION DERMAL ABSORPTION IN BOVINE AND RAT SKIN.

D. Van der Merwe, L. Wellman and R. Gehring. *College of Veterinary Medicine, Kansas State University, Manhattan, KS.*

Skin contact is an important route of exposure to many industrial and agricultural chemicals, naturally occurring chemicals, therapeutic drugs, cosmetics and chemical warfare agents. Quantitative models that relate chemical exposure to internal dose are critical to our ability to estimate the risks and therapeutic potential associated with exposures to chemicals. The scarcity of dermal absorption data in humans forces a reliance on animal data in human risk assessment. Quantitative knowledge of inter species differences in dermal absorption is therefore essential to the reliable use of available data in risk assessment. Differences in parathion dermal absorption between bovine and rat skin were studied using flow-through diffusion cells over an 8-hour experimental period. The results were compared to differences in skin structural parameters between the two species using a physiologically based pharmacokinetic model of dermal absorption that includes a calculation of stratum corneum resistance based on effective tortuosity derived from quantifiable stratum corneum structural parameters. Bovine and rat skin were dosed with 20.5 µg/cm² and 21.6 µg/cm² 14-C parathion, respectively. The bovine skin studies indicated a peak parathion flux at 360 minutes and 8.76 % (SE 0.02 %) of the parathion dose was absorbed through the skin after 8 hours. In rat skin, peak flux was at 420 minutes and total absorption was only 2.03 % (SE 0.30 %). Assuming that diffusivity and partitioning parameters were similar between the species, scaling from the rat to the bovine data could be achieved by decreasing the number of corneocyte layers, decreasing the volume of the lipid-filled gap between corneocyte layers and increasing the diameter of corneocytes. The differences in structural parameter values required for scaling in the model were consistent with species differences in microscopically observable structural parameters, indicating potential value of the model for use in inter-species scaling.

1076 EVALUATION OF PHOTOTOXICITY ALERTS IN DEREK AND USE OF A FINGERPRINT-BASED DECISION TREE APPROACH TO IDENTIFY POTENTIAL NOVEL ALERTS.

D. Pelletier and N. Greene. *Pfizer Inc., Groton, CT.*

Phototoxicity refers to a wide range of adverse events that occur within the integumentary system (i.e. skin) in response to a combination of compound and absorbed light energy. Requests for information regarding the phototoxic potential of drugs

undergoing regulatory review have risen over the past few years. This has led to an increased desire among medicinal chemists to be able to predict and potentially use structural activity relationships (SAR) to select chemical structures not associated with this adverse effect. One of the screening options available early in the lifecycle of a program to identify phototoxicity potential has been the DEREK system – Lhasa Ltd). DEREK is an in silico solution which contains a chemical rule base linking chemical substructures with known associated adverse effects. The analysis presented here was performed in order to understand the predictive ability of DEREK's phototoxicity alerts. In this work, we have compiled and submitted to DEREK, compounds with defined phototoxicity profiles to assess its ability to identify phototoxicity potential. Results suggest that the system does a good job identifying compounds with well known phototoxicant substructures, while novel positive compounds were generally not flagged. Positive compounds that did not alert were evaluated further using a structural fingerprint-based decision tree approach to identify potentially undiscovered substructural alerts for phototoxicity. This analysis identified a single putative structural feature for follow-up and potential inclusion as a new rule within the rule base.

1077 NEW ORLEANS BASELINE SOIL MAPS OF LEAD, ARSENIC AND MERCURY: AN APPLIED TOXICOLOGY APPROACH FOR EXPOSURE PREVENTION.

H. Mielke, C. Gonzales and E. Powell. *Center for Bioenvironmental Research, New Orleans, LA.*

This urban soil metal research focuses on lead (Pb), mercury (Hg) and arsenic (As) in residential communities of New Orleans. The soil survey of metropolitan New Orleans (n = 5,467 samples stratified by 286 census tracts) was completed before Hurricane Katrina. Composite soil samples (n = 19) for each census tract were analyzed for Pb and As by ICP and for Hg by direct mercury analysis (Milestone DMA-80). The findings were integrated into a GIS system and the resulting maps show the spatial distribution of Pb, Hg and As in the city. The patterns for Pb and Hg are similar (correlation = 0.9) while the pattern for As is dissimilar to the other two metals (correlation = 0.6). The largest amounts of Pb and Hg (Pb ~1,000 mg/kg; Hg ~1,000 µg/kg) were in residential census tracts within the inner ring of communities surrounding the central business district. The sources of Pb were commercial products with large quantities of Pb such as paint, and vehicle fuels with Pb additives. Hg is associated with sulfur in fuels. Pb and As are associated with lead arsenate insecticides that were commonly used before the advent of synthetic organic insecticides. Arsenic is associated with CCA-treated wood (i.e., chromated copper arsenate). The soil metal maps of New Orleans show that the urban environment is a historic sink of metals and their pattern in soil delineates the chemical milieu of the city. These maps serve as a foundation for developing a science-based strategy for reducing the high childhood prevalence of chronic exposure (~ 14% in pre-Katrina New Orleans) and health effects associated with these toxic metals. They also supplied the critical information necessary to evaluate the environmental impact of flooding of New Orleans after Hurricane Katrina. Acknowledgement: This project was funded by an ATSDR/MHPF Cooperative Agreement to Xavier University of LA # 5 U50 TS 473408.

1078 ANALYSIS OF HEPATIC GENE EXPRESSION PATTERNS OF FISHER 344 RATS EXPOSED TO Pb2+ USING AFFYMETRIX MICROARRAY AND TAQMAN RT-QPCR.

W. E. Gato and J. C. Means. *Chemistry, Western Michigan University, Kalamazoo MI, MI.*

Lead contamination of soil and drinking water represent a significant risk to human health, especially for developing infants. Methods employed in determining lead toxic effects on humans using animal models include; histopathological analysis, biochemical analysis such as glycogen levels, aminolevulinic acid (ALA) and DNA and RNA contents and more recently toxico-genomics analysis (study of gene and protein activity response to toxicants). In this study Affymetrix DNA Microarray analyses were used to assess transcriptional profiles due to dose levels and characterize changes in hepatic gene expression in response to Male Fisher 344 rats exposed to 0 ppm, 50 ppm and 500 ppm lead (as acetate) for up to 90 days. To validate gene expression data acquired by Affymetrix Microarray, Taqman RT-qPCR was used to quantify the relative expression levels of selected genes already known to play important roles in mediating Pb2+ toxicity and others identified in our study that might be equally important in this process. Using Taqman RT reagents and Assay-On-Demand offered by Applied Biosystems, the expression of *calm1*, *calm2*, *Alas1*, *Atp5o*, *Ppp3ca*, *Cyp3a13* and *Mapk1* were measured relative to β -Actin. Raw data was exported for normalized gene expression (NGE) analysis using data analysis for real-time PCR (DART-PCR) and relative expression software tool (REST©). Most of the transcripts in the 30d exposure group were up-regulated while most genes in the 90d treatment were down-regulated, relative to controls. *Calm1*, *Calm2*, *Atp5o*, *Ppp3ca* and *Mapk1* were all upregulated in the short treatment regime. For

the chronic exposure group, Calm1, Calm2, Atp5o, Ppp3ca, Mapk1 were all down-regulated except Calm2 in the 50 ppm treatment group, relative to controls. Similarly, Alas1 was negatively regulated in all treatment groups except the 90d 50 ppm group. Cyp3a13 was negatively regulated in all treatment groups during all time points. Confirming microarray results are the down-regulation of Calm2 -3.886, Alas1 -1.616, Atp5o -2.706 and Cyp3a13 -1.79 genes in the long term exposure group

1079 ASSOCIATIONS BETWEEN LONGITUDINAL MEASURES OF OCCUPATIONAL LEAD DOSE AND RENAL FUNCTION.

V. M. Weaver¹, B. Lee², M. Griswold³, B. Jaar⁵, A. Todd⁴ and B. Schwartz^{1,5}.
¹EHS, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD,

³Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,
⁴Community and Preventive Medicine, Mount Sinai School of Medicine, New York, NY and ⁵Epidemiology, Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.

Introduction: The exposure range associated with lead-related nephrotoxicity in the occupational setting has not been clearly established. With the exception of two small studies, prior research has been cross-sectional thus limiting inferences regarding causality.

Methods: We evaluated associations between lead dose and serum creatinine from three annual evaluations in a cohort of 803 Korean lead workers. Blood lead was measured via atomic absorption spectrophotometry; tibia lead was measured via ¹⁰⁹Cd X-ray fluorescence. Generalized estimating equations were used to evaluate annual change in serum creatinine in relation to tibia lead concentration at the beginning of each follow-up period and concurrent change in blood lead. Models were adjusted for age, sex, body mass index, hypertension, days between evaluations, current/former lead worker status, time since retirement, plant of employment, and baseline blood and tibia lead.

Results: 75.5% of the 575 participants who completed all three evaluations were male. At baseline, 7.7 % and 0.5 % reported diagnoses of hypertension and diabetes, respectively. Mean (SD) age and lead job duration were 41.4 (9.5) and 8.5 (6.3) years, respectively. Mean (SD) blood and tibia lead levels were 31.3 (14.1) µg/dL and 35.1 (32.6) µg/g bone mineral, respectively. Concurrent change in blood lead was associated with an annual increase in serum creatinine of 0.012 (95% confidence interval, 0.003, 0.020) mg/dL for each 10 µg/dL increase in blood lead per year. In contrast, tibia lead was not significantly associated with change in serum creatinine.

Conclusions: These results support the inference that occupational lead exposure contributes to renal function decline.

1080 ACUTE LUNG INFLAMMATORY RESPONSE FOLLOWING PHARYNGEAL ASPIRATION OF STAINLESS STEEL WELDING FUME OR SOLUBLE CHROMIUM IN A/J AND C57BL/6J MICE.

P. C. Zeidler-Erdelyi, S. Young, J. R. Roberts and J. M. Antonini. *Health Effects Laboratory Division, NIOSH, Morgantown, WV.*

Previous data from our laboratory showed a greater lung inflammatory response in tumor susceptible (A/J) versus resistant (C57BL/6J) mice to aspirated chromium-containing manual metal arc-stainless steel welding fume (WF) at 7 and 28 days post-exposure. To gain further insight into the mechanisms and time course underlying this inflammatory response to WF, an acute time point was completed. Mice were exposed by pharyngeal aspiration to four doses (one dose every three days), of 5mg/kg WF, 1.5mg/kg soluble chromium (S-Cr), or saline vehicle. Bronchoalveolar lavage (BAL) and histopathology were done 2 days after the fourth dose. Lung injury (lactate dehydrogenase [LDH] and albumin), cytokines (IFN-γ, IL-6, MCP-1, and TNF-α), inflammatory cell influx (% polymorphonuclear leukocytes [PMN] and lymphocytes), and nitric oxide (NO) were measured in the BAL. At 2 days, both strains had increased lung injury, cytokines, and % PMN following exposure to WF or S-Cr but only the WF-exposed A/J mice had significantly increased NO levels. The C57BL/6J had equal degrees of inflammatory cell influx, lung injury, and cytokines following exposure to either WF or S-Cr. In contrast, the A/J mice exhibited a more heightened response to WF than to S-Cr, which was significantly higher than the C57BL/6J. Lung lesions, observed by histopathology, ranging from multifocal, minimal to moderate in severity, were found to be similar between the two strains and the exposure groups. It was also observed that the exposed C57BL/6J mice had higher lymphocyte numbers compared to the susceptible A/J strain. In conclusion, the mechanisms responsible for the lung inflammatory response to WF versus S-Cr appear to differ in the A/J but not in the C57BL/6J mice. These data suggest components, other than chromium, in the stainless steel WF exert additional toxicological effects in the A/J strain.

1081 CHROMIUM(VI) INDUCES GENES THROUGH STAT1 TRANSACTIVATION OF INTERFERON-STIMULATED RESPONSE ELEMENTS.

A. A. Nemec, K. A. O'Hara, L. R. Klei, R. J. Vaghjiani and A. Barchowsky. *Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.*

There is a traditional view that Cr(VI) suppresses inducible gene expression. However, recent evidence has shown that Cr(VI) stimulates cell signaling that activates nuclear translocation and DNA binding of the members of the STAT family of transcription factors. To investigate whether this binding leads to acute induction of STAT-driven genes, human airway epithelial (BEAS-2B) cells were transiently transfected with luciferase reporter constructs driven by STAT1 responsive ISRE or gamma interferon activated sites (GAS). Addition of 5 µM Cr(VI) stimulated only the ISRE reporter, suggesting that Cr(VI) mimics the action of interferon α/β. This was confirmed by demonstrating that Cr(VI) only induces the endogenous, ISRE driven gene, IRF7, but not IRF1, which is predominantly GAS site-driven. Induction of IRF7 mRNA levels occurred within 2 h of Cr(VI) exposure and Western analysis of nuclear proteins correlated this induction with a rapid increase in tyrosine phosphorylated STAT1. Cr(VI)-stimulated IRF7 mRNA expression was blocked in cells expressing STAT1 siRNA, but was not blocked in cells incubated with a neutralizing antibody to interferon α/β receptor (CD118). Cr(VI) inhibits certain gene induction by retaining histone deacetylase-1 (HDAC) activity in their proximal promoters (Wei, Y.D., et al. *J. Biol. Chem.* 279:4110-4119 2004). In contrast, Cr(VI)-stimulated transactivation of the ISRE reporter and induction of endogenous IRF-7 mRNA and was inhibited in cells previously incubated with the HDAC inhibitor sodium butyrate. These data demonstrate that Cr(VI) does induce acute phase genes and present a novel mechanism in which Cr(VI) acts at the level of cell signaling to activate STAT1 to induce interferon (IFN)-stimulated genes through a HDAC-dependent mechanism. *Supported by NIEHS grant ES10638.*

1082 MICROARRAY ANALYSIS OF PARTICULATE CHROMATE-INDUCED GENE CHANGES IN HUMAN LUNG CELLS.

S. Huang^{1,2}, H. Xie¹, C. Peng², B. C. Gupta² and J. P. Wise¹. ¹Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and ²Department of Mathematics and Statistics, University of Southern Maine, Portland, ME.

Hexavalent chromium (Cr(VI)) is a widespread environmental contaminant and a well-established human lung carcinogen with solubility playing an important role in its carcinogenicity. However, the carcinogenic mechanism remains unknown. Our study showed that particulate Cr(VI) is cytotoxic and genotoxic to human lung cells. Functional changes within the cell are believed to depend on the number of gene expression differences and the actual functional relationships between them. To identify genes that are induced by particulate Cr(VI) in human lung cells, microarray analysis was used allowing the measurement of the expression level of thousands of genes simultaneously. We treated the cells with lead chromate (0, 0.5 µg/cm²) for 24 hours and hybridized RNA onto oligo microarrays. After normalizing and filtering the data from two color oligo microarray scans, we found that 515 of a total of 887 genes have changed expression including 24 genes that are significantly up-regulated (fold change greater than or equal to 1.5), and 97 genes are significantly down-regulated (fold change less than or equal to 0.67). In addition, we identified a list of particulate Cr(VI) inducible genes which plays important role in cell cycling pathways. This work was supported by NIEHS grant ES10838 (J.P.W.).

1083 PARTICULATE HEXAVALENT CHROMIUM INDUCES CHROMOSOME INSTABILITY AND DECREASED EXPRESSION OF SPINDLE ASSEMBLY CHECKPOINT PROTEINS.

L. C. Savery^{1,2}, H. Xie^{1,2}, A. L. Holmes^{1,2}, S. S. Wise^{1,2} and J. P. Wise^{1,2}. ¹Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME and ²Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME.

The spindle assembly checkpoint (SAC) pathway ensures cells do not prematurely enter anaphase causing the formation of aneuploid cells. Aneuploidy is a type of chromosome instability (CIN) involving the loss or gain of chromosomes. CIN is a hallmark of lung cancer with 70-80% of lung tumors having severe aneuploidy including triploid and tetraploid complements and is proposed as an early event in carcinogenesis. Hexavalent chromium (Cr(VI)) is a known lung carcinogen. Cr(VI)-induced tumors exhibit chromosome instability (CIN), but the mechanisms underlying these effects are unknown. We have found chronic, low doses of lead chromate, a particulate Cr(VI) compound, causes increased aneuploidy with many aneuploid cells being able to continue to grow and persist. Specifically, after 120 h treatment of 5 µg/cm² lead chromate, 55% of the cells were aneuploid. Additionally, this treatment caused an increase in anaphase, often disorganized

anaphase, suggesting a SAC effect. We found further evidence that SAC was bypassed thru observations that lead chromate induced increases in premature centromere division and premature anaphase. To confirm the role of the SAC pathway in lead chromate-induced chromosome instability, we examined expression of key genes. After 120 h, 5 µg/cm² lead chromate caused decreased expression levels of SAC proteins, Cdc20 and Mad2. Lower levels of Cdc20 and Mad2 may allow for SAC bypass permitting cells with defective spindle assembly to enter into anaphase and divide forming aneuploid cells. These data suggest that one mechanism for lead chromate-induced carcinogenesis is through the bypass of the SAC pathway leading to the induction of CIN.

1084 RAD51D, XRCC3, AND RAD51C PROTECT CELLS FROM PARTICULATE CHROMATE-INDUCED CHROMOSOME INSTABILITY IN MAMMALIAN CELLS.

M. M. Stackpole¹, S. S. Wise^{1,2}, E. Grlickova Duzevik¹, R. C. Munroe¹, L. H. Thompson³, J. Thacker⁴ and J. P. Wise^{1,2}. ¹Wise Laboratory of Environmental and Genetic Toxicology, University of Southern Maine, Portland, ME, ²Maine Center for Toxicology and Environmental Health, University of Southern Maine, Portland, ME, ³Lawrence Livermore National Laboratory, Livermore, CA and ⁴Medical Research Council, London, United Kingdom.

Particulate hexavalent chromium (Cr(VI)) compounds are well-established human carcinogens. Chromosomal instability (CIN) is widely recognized as a characteristic of Cr(VI) induced tumors, however the mechanism of this effect is still unknown. We are investigating the hypothesis that homologous recombination (HR) repair of DNA double strand breaks protects cells from Cr(VI)-induced CIN. We investigated this repair pathway by utilizing cells that are defective in Rad51D, XRCC3, and Rad51C, known genes in the HR pathway and the ability of Cr(VI) to induce CIN in them. Lead chromate (LC), a particulate model for Cr, was more cytotoxic in repair-deficient cells than in the wild-type. There was a 1.2, 1.5 and 1.5-fold increase in the cytotoxic effects of LC in Rad51D, XRCC3 and Rad51C deficient cells, respectively. There was a concentration-dependent increase in chromosomal damage in all HR repair defective cells. The highest concentration, 1 µg/cm² LC, induced chromosome damage in 22, 20 and 46 percent of metaphases with the total damage in 100 metaphases reaching 36, 27 and 102 aberrations in Rad51D, XRCC3 and Rad51C, respectively. A notable shift in the spectrum of chromosomal damage occurred with a dramatic increase in chromatid exchanges in all mutant cells. For example, 1 µg/cm² induced 19, 20 and 32 exchanges in Rad51D, XRCC3 and Rad51C deficient cells respectively while in the wild-type cells there were no exchanges. These observations suggest that HR does indeed protect cells from Cr(VI)-induced CIN. This work was supported by NIEHS grant #ES10838 (J.P.W.).

1085 A GENETIC APPROACH TO DISCOVERING THE MOLECULAR MECHANISM OF MANGANESE TOXICITY.

L. Rosenfeld, E. Leung, M. C. Carroll and V. C. Culotta. *Environmental Health Sciences, Johns Hopkins School of Public Health, Baltimore, MD.*

Manganese is an essential metal that can cause neurodegenerative disease upon chronic over-exposure. The molecular targets of manganese toxicity and pathways influencing sensitivity to manganese are not well understood. We studied this problem using baker's yeast, *Saccharomyces cerevisiae*, as a model system. We examined yeast with a genetic deletion of *pho80*, a cyclin that pairs with a non-essential cyclin dependent kinase to regulate phosphate metabolism. The genetic deletion of *pho80* (*pho80Δ*) causes the yeast to become very sensitive to manganese toxicity. Therefore we hypothesized that there is a connection between manganese toxicity and genes regulated by Pho80 and the phosphate metabolism pathway that are currently unknown. In order to discover the components downstream of Pho80 that influence the sensitivity of yeast to manganese and their function and thereby gain knowledge that may help us understand the molecular mechanism of manganese toxicity and its potential connection to phosphate metabolism, we conducted a genetic screen to find genes that reverse the *pho80Δ* deletion strains sensitivity to manganese. Five classes of genes were uncovered which can reverse the sensitivity of the *pho80Δ* strain to manganese. These include a new metal transport gene, and three genes involved in chromatin remodeling and DNA repair.

1086 MANGANESE (MN) IN SALIVA AS AN INDICATOR FOR OCCUPATIONAL EXPOSURE IN CHINESE SMELTING WORKERS.

D. M. Cowan¹, Q. Fan², X. Shi², Y. Zou², F. S. Rosenthal¹, M. Aschner³ and W. Zheng¹. ¹Health Sciences, Purdue University, West Lafayette, IN, ²Preventive Medicine, Zunyi Medical College, Zunyi, Guizhou, China and ³Pediatrics, Vanderbilt University, Nashville, TN.

Exposure to Mn occurs in both environmental and occupational settings, leading to various degrees of neurotoxicity. This cross-sectional study was designed to test the hypothesis that occupational exposure to airborne Mn among active smelting

workers was associated with elevated metal concentrations, i.e., Mn and iron (Fe), in body fluids. Our goal is to investigate 100 subjects each in control, low- and high-Mn exposed workers. The cohort is located in Zunyi City, Southwest China. We have completed 23-42% of sample collections (n=42, 23, and 30 for control, low and high exposed workers, respectively). Subjects were randomly selected, based on airborne Mn levels and job classification, to control group (airborne Mn <0.01 mg/m³), low-exposed group (<0.1 mg/m³), or high-exposed group (>0.3 mg/m³). Blood, urine, saliva, and hair samples from all subjects were obtained to determine Mn and Fe levels by AAS. No age difference was identified among the 3 study groups. Mn concentrations in the whole blood (WB), plasma, urine, hair, and saliva in high-exposed workers were significantly higher than those in controls (p<0.05). Among low-exposed workers, significant differences were observed only in the WB, plasma, and hair. The increase in Mn levels in body fluids appeared to be associated with airborne Mn levels except for plasma Mn. Linear regression analyses revealed that saliva Mn concentration was significantly associated with years of employment (r=0.40, p<0.05). Mn saliva level was also significantly correlated with Mn WB concentration. (r=0.32, p<0.05). Additionally, we found that Fe levels in saliva and urine were significantly higher in high-exposed workers than in controls (p<0.05). These preliminary data indicate that among active smelting workers, Mn concentration in body fluids reflect environmental Mn exposure. Mn levels in saliva may represent a useful non-invasive indicator of Mn exposure. (NIEHS ES 08164 and DoD USAMRMC W81XWH-05-1-0239).

1087 CHELATION THERAPY OF MANGANESE (MN) INTOXICATION WITH P-AMINOSALICYLIC ACID (PAS) IN SPRAGUE-DAWLEY RATS.

W. Zheng¹, Y. Jiang², W. Jiang¹, Y. Zhang¹, X. Wang¹ and D. M. Cowan¹. ¹School of Health Sciences, Purdue University, West Lafayette, IN and ²Occupational Health and Toxicology, Guangxi Medical University, Nanning, Guangxi, China.

Our recent human studies indicate that PAS, a classic antituberculosis drug, can effectively treat severe Mn Parkinsonism with a promising prognosis (Jiang et al., JOEM 48:644, 2006). This study was designed to test the hypothesis that PAS may act as a chelating agent to remove Mn in targeted brain regions, giving rise to its clinical benefit. Groups of 8-10 male rats (220±10g) received saline or Mn (6 mg/kg daily, 5 days/wk, ip) for 4 wks followed by PAS injection (100 and 200 mg/kg as the low and high dose group, respectively, daily, 7 days/wk, sc) for another 3 wks. Mn concentrations in tissues and body fluids were determined by AAS. Exposure to Mn caused significantly increases of Mn concentrations in plasma, cerebrospinal fluid (CSF) and red blood cells (RBC) by 1.5, 2.2 and 25 fold, respectively, as compared to controls (p<0.05). Mn levels in striatum and frontal cortex were also markedly increased by 1.8 and 1.6 fold, respectively (p<0.05). Three-week treatment with PAS significantly reduced Mn concentrations in the RBC (down 21.1% compared to Mn-exposed animals, p<0.05 with high dose of PAS) and in the CSF (28.3%, p<0.05 with low dose of PAS), while it had no effect on plasma Mn levels. Among brain regional samples analyzed by far, the high-dose PAS treatment significantly reduced Mn levels in striatum (down 16.4%, p<0.05), but it did not affect Mn levels in frontal cortex. Further analysis of Mn as well as iron concentrations in the choroid plexus and other brain regions is currently in progress. These preliminary data suggest that PAS appears capable of chelating Mn and therefore mobilizing Mn from its brain storage area. Conceivably, PAS and possibly its analog may serve as a new category of chelating agents for treatment of Mn Parkinsonism. (Supported in part by NIEHS RO1 ES08146 and DoD USAMRMC W81XWH-05-1-0239)

1088 COBALT ACTIVATION OF THE LYSYL OXIDASE PROMOTER MEDIATED BY THE HYPOXIA-INDUCIBLE FACTOR 1.

S. Gao¹, Y. Zhao¹, P. Toselli¹, J. Chou², P. Stone¹ and W. Li¹. ¹Biochemistry, Boston University School of Medicine, Boston, MA and ²Microbiology, Boston University School of Medicine, Boston, MA.

Cobalt (Co), an essential trace element critical for the synthesis of vitamin B12, stabilizes the hypoxia inducible transcription factor 1α (HIF 1α), which cooperates with HIF 1β, regulating the transcription of a gene in response to hypoxia. At high concentrations, Co is also toxic and carcinogenic for mammals. Lysyl oxidase (LO) is a key enzyme for stabilization of the extracellular matrix by crosslinking collagen and elastin. To elucidate LO transcriptional regulation, we cloned the 5'-flanking region (3,979 nt) of the rat LO gene and showed the maximal promoter activity obtained from the fragment containing 804 base pairs upstream of ATG. Computational analysis revealed at least 4 hypoxia-response element (HRE) consensus sequences (ACGTG) existing in this LO promoter region. CoCl₂ at 0-100 µM enhanced LO promoter activities in a dose-dependent manner in transfected RFL6 lung fibroblasts. The increased level of the HIF 1α mRNA was associated

with upregulation of LO transcripts in Co-treated cells. Cells co-transfected with the LO promoter-reporter construct and the HIF 1 α and HIF 1 β expression vectors in the presence of 100 μ M Co exhibited a 2.55-fold increase in the LO promoter activity in comparison to only a 1.32-fold increase in the LO promoter activity in the absence of Co. Dominant negative HIF 1 α inhibited LO promoter activities stimulated by Co. Electrophoretic mobility shift, oligonucleotide competition and in vitro translation of HIF 1 α assays indicated that only one HRE mapped at -194/-190 using the first nucleotide preceding the ATG codon as -1 was functionally active among 4 consensus. Site-directed mutation of this HRE significantly decreased the LO promoter-directed expression of the reporter gene. These results strongly support the conclusion that cobalt activation of the LO promoter is mediated by the HIF 1, a potential mechanism for Co-induced lung fibrosis in human (Supported by NIH grant R01-ES11340).

1089 DEPLETED URANIUM GENOTOXICITY IN HUMAN BRONCHIAL EPITHELIAL CELLS.

M. Yellowhair¹, E. R. Abril², K. Dvorak², V. H. Coryell³, D. M. Stearns³ and R. C. Lantz². ¹Pharmacology & Toxicology, The University of Arizona, Tucson, AZ, ²Cell Biology & Anatomy, The University of Arizona, Tucson, AZ and ³Biochemistry & Chemistry, Northern Arizona University, Flagstaff, AZ.

Cellular oxidative stress has been implicated in the genotoxicity of many heavy metals. In addition, airway epithelial responses to metals may depend on the physical form of the metal. The aim of this study is to evaluate the genotoxicity of depleted uranium (DU) as soluble (uranyl acetate (UA)) and particulate (uranium oxide (U₃O₈)) uranium in human bronchial epithelial cells (16-HBE). 16-HBE cells were exposed, in vitro, to 300 ppb of soluble depleted uranium (UA) or insoluble depleted uranium (U₃O₈) for 2 – 4 hr. Oxidative stress was assessed in vitro by fluorescent microscopy using dihydroethidium (HE) (2 μ M). GSH and TNF- α levels were quantified to support the fluorescent microscopy assay. Results indicate that 16-HBE cells treated with UA and U₃O₈ induced minimal oxidative stress compared to untreated cells in 2 – 4 hr time points. However, the formation of apoptotic bodies in both UA and U₃O₈ treatments were observed after 4 hr. These results are consistent with our previous studies that did not observe oxidative stress in DU treated cells. Interestingly, there was an increase in GSH levels of DU treated cells compared to untreated cells. Measured TNF- α levels did not change with DU treatments. These results suggest that: (1) cellular oxidative stress may not be a major pathway of DU genotoxicity, and (2) DU induces apoptosis in vitro. This study is supported by NIH Grants CA096281, CA096320, ES006694, F31ES014971, and The Alfred P. Sloan Foundation.

1090 CUMULATIVE EXPOSURE ASSESSMENT IN DU EXPOSED GULF WAR SOLDIERS: RELATIONSHIP TO HEALTH EFFECTS.

K. S. Squibb¹, M. Oliver¹, P. Gucer¹, S. Engelhardt² and M. McDiarmid^{1,2}. ¹University MD, Baltimore, MD and ²VA Med. Ctr., Baltimore, MD.

A cohort of Gulf War soldiers exposed to depleted uranium (DU) by inhalation, ingestion and embedded DU shrapnel has been followed since 1993 to determine whether DU exposure under combat conditions is associated with adverse health effects. Exposure assessment has been challenging due to the unique routes of exposure. The DU exposure metric used to date has been a 24 hr urine U concentration at the time of each surveillance visit. This measure represents a soldier's current level of exposure. Because U accumulates in tissues under chronic exposure conditions, and because soldiers with DU shrapnel have had high urine U levels for more than 15 years, a cumulative measure of exposure to DU has been determined using an area under the curve (AUC) calculation. Comparison of the two exposure metrics showed a close association ($R^2 = 0.827$; $p < 0.001$), however changes did occur in the assignment of soldiers to high vs low urine U groups used to statistically test differences in health measures. Thus, the relationship of exposure to health effects was examined using both exposure metrics based on the hypothesis that adverse effects in organs known to accumulate U would be more closely associated with cumulative U exposure. Results showed that high vs low DU group differences in renal proximal tubule function were not greater using the cumulative exposure metric, despite the expectation that renal U accumulation over time would increase effects on this organ. Analysis of chromosomal aberration (CA) data obtained by FISH, however, showed that differences in mean number of CAs between the high/low DU groups were larger and more significant when the cumulative exposure metric was used. Such a result was expected for this marker of stable aberrations. Results support the importance of considering both current and cumulative exposure to DU in this chronically exposed cohort for determining whether health changes over time are related to DU exposure. (Supported by Department of Veterans Affairs)

1091 COPPER REVERSES HYPERTROPHY IN PRIMARY CULTURES OF NEONATAL RAT CARDIOMYOCYTES.

Y. Zhou¹, Y. Jiang², W. Feng² and Y. Kang^{1,2}. ¹Pharmacology and Toxicology, University of Louisville, Louisville, KY and ²Medicine, University of Louisville, Louisville, KY.

Previous studies have shown that dietary copper deficiency causes cardiac hypertrophy along with depression of vascular epithelial growth factor (VEGF) expression in mouse model. Copper replenishment in the diet reverses cardiac hypertrophy and restores VEGF expression. The present study was undertaken using primary cultures of neonatal rat cardiomyocytes to examine the effect of copper on phenylephrine (PE)-induced hypertrophy and the relation to VEGF signaling pathway. Cardiomyocytes were treated with 100 μ M PE for 48 h to develop cell hypertrophy which was characterized by increases in cell size and volume, and increases in cellular protein content. Flow cytometry was also applied to further characterize cell hypertrophy. Copper in the form of copper sulfate at a final concentration of 5 μ M in cultures was added at the end of PE treatment and presented in the cultures for 24 h. The PE-induced cell hypertrophy was not further increased during the additional 24 h exposure, but copper significantly reversed cell hypertrophy, as indicated by reduction in the size and volume, and decreases in protein content in the PE-induced hypertrophic cardiomyocytes. However, copper did not change the phenotype of non-PE-treated control cells. To determine the involvement of VEGF signaling pathway in the copper-induced regression of hypertrophy in cardiomyocytes, anti-VEGF antibody at 2 ng/ml was added in the cultures one hour before copper addition. In addition, VEGF at 200 ng/ml was used to replace copper. In the presence of anti-VEGF antibody, copper-induced regression of cell hypertrophy was blunted, and VEGF alone reversed cell hypertrophy as the same as copper did. These results thus demonstrate that copper regression of cardiomyocyte hypertrophy may require VEGF signaling pathway. This study provides novel insights into copper supplementation for alternative therapy for hypertrophic cardiomyopathy. Supported in part by NIH grants HL63760 and HL59225.

1092 THE EFFECTS OF COPPER DIMETHYLDITHIOCARBAMATE ON LONG-EVANS RATS.

B. Scharf¹ and L. D. Trombetta². ¹Biology, St. Johns University, New York, NY and ²Pharmaceutical Sciences, St. Johns University, New York, NY.

For several decades, chromated copper arsenate (CCA) has been the principal preservative for treated wood utilized in residential and nonresidential areas. However, the repercussions of heavy metals present in CCA on human health and the environment resulted in industry halting production of CCA-treated wood products for most residential uses at the end of 2003. Previous data from this lab showed that copper dimethyldithiocarbamate (CDDC), one of the copper-based alternatives to CCA, caused stress protein induction and lipid peroxidation in maternal hippocampi and newborn whole brains of Long-Evans rats as compared to control animals. Graphite furnace atomic absorbance spectrophotometry analysis demonstrated a dose-dependent increase in the bioaccumulation of copper in adult hippocampi and livers and newborn whole brains of Long-Evans rats. Bioaccumulation of copper in tissues has been linked to oxidative damage and lipid peroxidation. In this study, Long-Evans rats (220-270 g) were treated with 25, 50, or 75 mg/Kg CDDC by oral gavage for 3 weeks. Renal and liver tissues were collected and fixed for microscopy. Hematoxylin and eosin staining revealed that 50 and 75 mg/Kg CDDC exposure induced diffuse necrosis, loss of sinusoids, the presence of foam cells, and cytoplasmic vacuolization in the livers of Long-Evans rats. Swelling of hepatocytes was evident in the livers of rats treated with the 25 mg/Kg dose. In the kidneys, animals treated with 50 and 75 mg/Kg CDDC showed distortion and swelling of both the proximal and distal convoluted tubules, prominent retraction of the glomeruli with mesangial distortion and areas of parenchymal necrosis. Adult rats treated with the 25 mg/Kg dose of CDDC displayed glomerular retraction. It is concluded that a 3 week exposure to 25mg/Kg CDDC induces morphological changes in renal and liver tissues whereas exposure to 50 and 75 mg/Kg CDDC results in overt necrosis in the same tissues.

1093 FAILURE OF ANTIMONY TRIOXIDE TO INDUCE MICRONUCLEI OR CHROMOSOMAL ABERRATIONS IN RAT BONE MARROW AFTER SUB-CHRONIC ORAL DOSING.

T. L. Serex¹, D. Kirkland², J. Whitwell² and J. Deyo³. ¹Sciences, BBL Sciences, Walnut Creek, CA, ²Covance Laboratories Ltd., Harrogate, United Kingdom and ³Eastman Chemical Company, Kingsport, TN.

Antimony trioxide (ATO), Sb₂O₃, CAS 1309-64-4, is widely used as a flame retardant synergist in a number of household products, as a fining agent in glass manufacture, and as a catalyst in the manufacture of various types of polyester plastics. It does not induce point mutations in bacteria or mammalian cells, but is able to in-

duce chromosomal aberrations (CA) in cultured cells *in vitro*. Although no CA or micronuclei (MN) have been induced after acute oral dosing of mice, repeated oral dosing for either 14 or 21 days resulted in increased CA in one report but did not result in increased MN in another. In order to further investigate its *in vivo* genotoxicity, ATO was dosed orally to groups of rats for 21 days at 250, 500 and 1000 mg/kg/day. There were no clinical signs of toxicity in the ATO-exposed animals except for some reductions in body weight gain in the top dose group. Toxicokinetic measurements in a separate study confirmed bone marrow exposure, and at higher levels than would have been achieved by single oral dosing. Large numbers of cells were scored for CA (600 metaphases/sex/group) and MN (12000 PCE/sex/group) but frequencies of CA or MN in ATO-treated rats were very similar to controls at all doses, and not biologically or statistically different. These results provide further indication that ATO is not genotoxic to the bone marrow of rodents after 21 days of oral administration at high doses close to the maximum tolerated dose.

1094 ZINC DEFICIENCY ENHANCES OZONE-INDUCED INFLAMMATION.

S. Z. Jones¹, K. Bridge⁴, W. Zhang³ and I. Jaspers^{2,3,1}. ¹*Curriculum of Toxicology, University of North Carolina, Chapel Hill, NC*, ²*Pediatrics, University of North Carolina, Chapel Hill, NC*, ³*Environmental Medicine, Asthma & Lung Biology, University of North Carolina, Chapel Hill, NC* and ⁴*School of Medicine, The University of North Carolina, Chapel Hill, NC*.

Previous studies have demonstrated that several factors, both intrinsic and extrinsic, can cause humans to be differentially susceptible to the adverse health effects of exposure to air pollutants, such as ozone. These factors can include age, ethnicity, gender, and nutritional status. Zinc is an essential trace element, and it is estimated that approximately 10% of the U.S. population consumes less than half of the recommended daily allowance of zinc. Few studies have addressed the effects of zinc deficiency on the health effects induced by ozone exposure. An *in vitro* model of human respiratory epithelial cells, grown under either zinc deficient or zinc adequate conditions, was used to determine whether intracellular levels of zinc affected the responsiveness to ozone. Zinc deficiency was confirmed by measuring the activity of the zinc-dependent enzyme, Cu/Zn superoxide dismutase. This study specifically examined the effects of zinc deficiency on ozone-induced inflammation (IL-8 production), NF-KB activation, and MAP kinase activation. Our data demonstrate that zinc deficiency enhanced ozone-induced production of IL-8 as well as the activation of NF-KB and p38 MAP kinase, while ozone-induced cytotoxicity was unaffected. Taken together these data suggest that deficiency in the nutritional trace element, zinc, can increase susceptibility to the adverse health effects induced by ozone exposure.

1095 EXPRESSION OF ZINC TRANSPORTER mRNA IN NORMAL HUMAN PROSTATE TISSUE, THE NORMAL PROSTATE CELL LINES, RWPE, AND HUMAN PROSTATE CARCINOMA CELL LINES.

A. Albrecht and S. H. Garrett. *Pathology, University of North Dakota, Grand Forks, ND*.

The prostate accumulates and stores the highest amount of zinc of all soft tissues within the body, yet during prostatic neoplasia, the zinc content of this organ falls to much lower levels. There are specialized membrane bound transporters that help to regulate the zinc homeostasis of the prostate. These transporters have been categorized into two families: ZnT (SLC30) and Zip (SLC39). Many of these genes have been newly discovered and their function and role is not known. The ZnT family pumps zinc out of the cell or into intracellular vesicles, decreasing the intracellular levels of zinc. In contrast, the Zip family increases the zinc concentration by transporting the metal into the cell or out of the vesicles. The gene sequence is known for each family member, which allows for the production of PCR primers and the ability to measure the amount of messenger RNA present within cultured cells and tissues. Real-time PCR was used to quantitatively measure the amount of mRNA present in normal prostate tissues, the normal prostate cell line, RWPE, and commonly utilized prostate carcinoma cell lines. Results show that the main efflux transporter, ZnT-1, is expressed in prostate tissues and cell lines, and within RWPE was highly inducible by zinc. ZnT-2 and ZnT-4, transporters responsible for vesicular sequestration were found to be variably expressed in tissues and cell lines. ZnT-5, -6, and -7, transporters thought to transport zinc into the cellular secretory pathway were expressed in all cell lines and tissues. ZnT-3 and -10 were not detected. The expression of the Zip class of transporters was equally as complex. Zip-1, a major plasma membrane uptake transporter was expressed in all prostate cell lines and most but not all prostate tissues. Many other uptake transporters were also expressed: Zip-3A, -6, -7, -8, -10, and -14. There was no expression of Zip-2, -4, or -5. These data indicate that the transport of zinc in the prostate is complex and involves a potentially redundant array of transporters.

1096

BRAIN AND BLOOD TIN LEVELS IN A DEVELOPMENTAL NEUROTOXICITY STUDY OF DIBUTYL TIN.

V. C. Moser¹, K. D. Ehman¹, P. M. Phillips¹, K. L. McDaniel¹ and J. K. McGee². ¹*NTD, U.S. EPA, Research Triangle Park, NC* and ²*ETD, U.S. EPA, Research Triangle Park, NC*.

Dibutyltin (DBT), a widely used plastic stabilizer, is detected in the environment and human tissues. While teratological and developmental effects are known, we could find no published report of DBT effects on the developing nervous system. As part of a developmental neurotoxicity study of DBT, we periodically collected samples to determine the distribution of tin (Sn). Pregnant Sprague-Dawley rats were exposed to 0, 10, or 25 ppm DBT in drinking water from gestational day 6 to weaning. Beginning on postnatal day (PND) 3, half of the litters were directly dosed (DD group) every 2 to 3 days via gavage with 0, 1, or 2.5 mg/kg DBT such that the dose level matched the water concentration (i.e., litters with 25 ppm DBT in the water received 2.5 mg/kg). For Sn analysis, brain and blood samples were collected from culled pups on PND2 (sex combined), from pups (both sexes) as well as the dams at weaning (PND21), and from adult offspring (both sexes) at PND93. Total Sn was quantified using ICP-MS. At all ages, brain Sn levels were higher than in blood. At culling and in the DD pups at weaning, Sn levels in both tissues were linearly related to dose. Weanling pups without direct dosing showed lower levels than either the culled pups or the dams, indicating that lactational exposure is minimal or negligible even while maternal exposure is ongoing. In the adults, there was still Sn present in the brains of DD rats, but only females had measurable blood Sn levels, perhaps indicating more rapid clearance from blood in the males. The remaining adults had very low, but still measurable, Sn in the brain but not at all in blood. Thus, during exposure to DBT in drinking water, Sn is placentally, but not lactationally, transferred to the offspring. Our data suggest that Sn is concentrated in the brain compared to the blood, and its elimination with cessation of exposure is protracted, on the order of months. This exposure to the developing brain suggests the potential for neurotoxic effects. This is an abstract of a proposed presentation and does not necessarily reflect US EPA policy.

1097

CHARACTERIZATION OF HEAVY METAL EFFECTS OF TUNGSTEN ALLOYS ON THE RAT AIRWAY.

H. J. Fullenkamp, E. W. Johnson, E. R. Wilfong, D. P. Arfsten and G. D. Chapman. *Naval Health Research Center Detachment, Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH*.

A number of direct fire munitions are made with tungsten alloys (WA) including armor piercing kinetic energy penetrators. When WA munitions strike hard targets, aerosol clouds containing respirable particles as small as 0.2 µm are formed. Since military personnel near impact sites may be acutely exposed to high concentrations of aerosolized metals, the effects of WA on the airway were investigated. Male Sprague-Dawley rats (n=36/group) were intratracheally instilled with 1, 5, 15 mg of WA1 (91.1% W, 6.0% Ni, 2.9% Co) or WA2 (97.2% W, 1.7% Ni, 1.1% Fe) suspended in 400 µl of sterile saline or saline alone (control). At select times (24 hours, 3 days, 7 days and 6 months), the lungs were lavaged with cold phosphate buffered saline and the bronchoalveolar lavage fluid (BALF) was analyzed for markers of inflammation and injury such as lactate dehydrogenase (LDH), total protein (TP), N-acetylglucosaminidase (NAG), cytokines, cell number, type, and viability. As was previously reported, significant positive trends were observed in the concentrations of TP, NAG and LDH in the BALF of the WA1 and WA2 (15mg & 5mg) from 24 hours to 7 days post-exposure. However, at 6 months the results were comparable to the controls. Cell differential counts were significantly different (P<0.001, n≥3) for both WA1 and WA2 (15mg) from 24 hours to 7 days but were comparable to the controls at 6 months. Macrophages were increased from 34.6% and 26.0% to 65.5% and 74.7% for WA1 and WA2 (15mg), respectively. Polymorphonuclear neutrophils (PMN) were decreased from 60.9% and 70.1% to 29.1% and 19.7% for WA1 and WA2 (15mg) respectively. The results suggest that inhalation of WA aerosols may have at minimum an acute effect on the airway. Investigation involving histology, genotoxicity and long-term systemic effects are on-going.

1098

BRAIN ALUMINUM INFLUX RATE DETERMINED WITH THE TRACER ²⁶AL IN THE RAT.

R. A. Yokel. *Pharmaceutical Sciences, University of Kentucky Medical Center, Lexington, KY*.

Aluminum (Al) is a neurotoxicant. It can enter the brain through the blood-brain barrier (BBB). Al-transferrin and Al-citrate account for ~ 93 and 7% of plasma Al, respectively. It has been suggested that Al is transported across the BBB by transferrin-receptor mediated endocytosis and that Al citrate can cross the BBB. There is concern that Al-fluoride can enter the brain. The *in situ* brain perfusion method was used to determine brain Al entry rates. Fisher rats received perfusion, via a

carotid artery, at 10 ml/min for 1 min, of a solution containing, in mM: Na 153, K 4.2, (Ca 1.5, Mg 0.9 omitted for Al-citrate), glucose 9, and [^{14}C]-sucrose 0.2, at pH 7.4. To study Al-transferrin and Al-citrate, the perfusate had 1 μM Al (containing 0.005 μM ^{26}Al ; 2.5 nCi/L) and 35 μM transferrin (plus 15 μM carbonate) or 99 μM citrate. To study Al-fluoride, the perfusate had 3 μM Al and 20 μM fluoride, at pH 5.5. Speciation calculations suggested ~90% of the Al would be as Al-transferrin or Al-citrates and >80% as Al-fluorides. Control rat perfusate contained no Al. Results from rats with brain vascular space, determined from brain/perfusate ^{14}C , <25 $\mu\text{l/gm}$ brain were used. ^{26}Al was quantified by AMS. The influx rate constants (K_{in}) for Al-transferrin and Al-citrate were $\sim 2 \times 10^{-5}$ ml/sec/gm, whereas Al-fluoride was much higher. These rates are less than the K_{in} of 800 to 1340 and 200 to 400 reported for the Al ion and Al partially complexed with transferrin from a study also using the same method, but ^{27}Al , which is prone to interfering contamination (Jagaramudi and Melethil (1995), Pharm. Res. 12, S-350). These rates are greater than the 0.03 to 0.04 reported after a 50 hour Al perfusion, which provides time for significant brain Al efflux (Radunovic et al (1997) Biometals 10, 185-191). The Al-transferrin and Al-citrate results are intermediate to K_{in} values reported for iron (reviewed in Yokel (2006) J. Alz. Dis. 10 (2-3)). The results support conclusions that Al can enter the brain as Al-transferrin and as Al-citrate, and suggest Al-fluoride as well. Supported by NIH Grant R01 ES11305.

1099 REGULATION OF ZINC TRANSPORTERS IN ZEBRAFISH IN RESPONSE TO CHANGES IN ZINC STATUS.

C. Hogstrand¹, D. Zheng¹, G. Feeney² and P. Kille². ¹Nutritional Sciences Research Division, King's College London, London, England, United Kingdom and ²Cardiff School of Biosciences, Cardiff University, Cardiff, Wales, United Kingdom. Sponsor: G. Cherian.

Zinc is an essential micronutrient and zinc deficiency is a global problem among human populations. However, dysregulation of zinc by cells can lead to zinc toxicity and this may be common particularly in neurodegenerative diseases. Fish can use the gills to take up zinc from the water and they regulate gill zinc uptake according to the water zinc concentration, which may vary five orders of magnitude. The objective of our research has been to study zinc transport in zebrafish as a model for vertebrate regulation of zinc in general. There are several transporters that control zinc in vertebrate tissues. In zebrafish, there are at least 8 genes encoding slc30 zinc transporters and 11 genes that encode zinc transporters of the slc39 gene family. With few exceptions, these appear to have direct orthologues in human. Whereas slc30 and slc39 proteins appear to be dedicated zinc transporters that move zinc out and in of the cytoplasm, respectively, TRPV6 is an epithelial calcium channel (ECaC) that is highly permeable to zinc. Expression of slc30 and slc39 transporters zebrafish is tissue specific with ovary showing the highest level of expression and muscle the lowest. In the gill of zinc deficient zebrafish, expression of slc30a1 was downregulated while slc30a5 and slc39a3 were upregulated. During treatment with zinc excess condition, the concentration of mRNA for slc30a1 was increased and those for slc30a5 and slc39a10 were decreased. Upregulation of slc30a1 during zinc exposure was likely mediated by MTF-1 binding to multiple MRE motifs in the 5'-flanking region. The decrease of slc39a10 mRNA in response to excess zinc was caused by repression of transcription as demonstrated by reporter-gene assays. This was in spite of the presence of four consensus MRE located within 1.2 kb upstream of the translation start site.

1100 MODULATION OF MRP-TRANSPORTERS BY HEAVY METALS IN HUMAN LUNG CELLS.

F. Glahn, H. W. Foth, A. W. Torky and E. Stehfest. *Institute of Environmental Toxicology, Martin Luther University, Franzosenweg 1a, Martin Luther University, Halle / Saale, Saxony Anhalt, Germany.*

Human lung has to cope with exposure to low doses of heavy metals from various sources and the chronic uptake might lead to adaptation. It is not known whether metals will modulate the expression of multidrug resistance associated proteins (MRP) and may thus interfere with the extrusion of metal complexes by MRPs. Primary cultures of normal bronchial epithelium (NHBE) and primary peripheral lung cell cultures (PLC) were grown from human lung tissue. We have conducted long term experiments with As(III), Cu(II) and Hg(II) salts in NHBEs cultured from three individuals (B182/1, B201/1, B222/1). The experimental conditions were selected in the MTT assay for well tolerated non toxic concentrations of these metals in PLCs, NHBEs and in two human tumor cell lines (H 322, H 358). Neither As (1 and 2.5 mM), Cu (1 and 2.5 mM) nor Hg (1, 2.5 and 5 mM) had substantial effects within 24 h on MRP 1, 3, 4, 5 RNA expression in H 322, H 358 and PLC. In NHBEs only MRP 5 RNA increased after Hg (24 h) and MRP 3 after Cu (24 h). Repeated exposure to As down-regulated MRP1, MRP3 and MRP4 in B201/1 (0.4 to 0.6fold). In cultures derived from B182/1 As led to an up-regulation of MRP3 (1.3 fold), MRP4 (1.8 to 2 fold) and MRP5 (2.3 fold). Cu

had no effect on MRPs, in B201/1 and B222/1 except MRP1 which was down regulated by Cu only in B201/1 (2 weeks). In B182/1 Cu increased expression of MRP3 and MRP4 (1.9 fold). Repeated exposure of NHBE (2 weeks) with Hg led to a down regulation of MRP1; MRP3, MRP4 and MRP5 in NHBE B201/1. In contrast treatment with Hg increased expression of MRP3 significantly in B182/1 and also that of MRP5 (1.7 fold) in B222/1.

Primary NHBEs are more sensitive towards metal stressors with respect to MRP regulation than tumor cell lines and PLCs. Clear inter individual differences became obvious for MRP RNA upregulation after arsenite, copper or mercury after repeated exposure which indicate that responders (B183/1) and non responders (B201/1; B222/1) might exist.

1101 RENAL ELIMINATION OF INORGANIC MERCURY AND THE ROLE OF THE MULTIDRUG RESISTANCE PROTEIN 2.

C. Bridges and R. K. Zalups. *Mercer University School of Medicine, Macon, GA.*

One of the current therapies for inorganic mercury (Hg^{2+}) intoxication involves administration of a metal chelator, either 2, 3-dimercapto-1-propanesulfonic acid (DMPS) or meso-2, 3-dimercaptosuccinic acid (DMSA). Following exposure to these chelators, Hg^{2+} can be detected in the urine, presumably conjugated to DMPS or DMSA. The actual mechanisms involved in the renal elimination of these conjugates are unclear; however, indirect data implicate a role for the multidrug resistance protein 2 (MRP2), which is localized to the luminal membrane of proximal tubular cells. We hypothesize that MRP2 mediates the export of DMPS- or DMSA-S-conjugates of Hg^{2+} from these cells. To test this hypothesis, the disposition of Hg^{2+} was examined in control and TR- rats, which do not express MRP2. Rats were injected intravenously with 0.5 $\mu\text{mol/kg/2ml}$ HgCl_2 , containing ^{203}Hg . After 24 hours, rats were injected with saline, DMPS, or DMSA. Blood, liver, and kidneys were harvested after 48 hours. The renal and hepatic burden of Hg^{2+} in the saline-injected TR- rats was significantly greater than that of the control rats. Accordingly, the content of Hg^{2+} in the urine and feces was less in the TR- rats than in controls. DMPS and DMSA significantly reduced the renal and hepatic content of Hg^{2+} in both groups of rats, with the greatest reduction in the controls. A significant increase in urinary and fecal excretion of Hg^{2+} , which was greater in the controls, was also observed. These data indicate that MRP2 plays a role in the DMPS- and DMSA-mediated elimination of Hg^{2+} from proximal tubular cells.

1102 THE MULTIDRUG RESISTANCE PROTEIN 2 AS A MECHANISM INVOLVED IN THE RENAL ELIMINATION OF ORGANIC MERCURY.

R. K. Zalups and C. C. Bridges. *Mercer University School of Medicine, Macon, GA.*

Intoxication of organic mercury (CH_3Hg^+) is treated often by administering a metal chelator, either 2, 3-dimercapto-1-propanesulfonic acid (DMPS) or meso-2, 3-dimercaptosuccinic acid (DMSA). These chelators extract mercuric ions, likely as CH_3Hg^+ -chelator conjugates, from proximal tubular cells for excretion in urine. The actual mechanisms by which these conjugates are exported from cells have not been identified; however, it is likely that the multidrug resistance protein 2 (MRP2), localized in the luminal plasma membrane of proximal tubular cells, plays a role in this process. Therefore, the current study tested the hypothesis that MRP2 mediates the export of DMPS- or DMSA-S-conjugates of CH_3Hg^+ from proximal tubular cells. To test this hypothesis, the disposition of CH_3Hg^+ was examined in TR- rats, which have a mutation in the *mnp2* gene. Normal male Wistar and TR- rats were injected intravenously with 5 mg/kg/2ml CH_3HgCl , containing ^{203}Hg , followed 24 hours later with an injection of saline, DMPS, or DMSA. After an additional 24 hours, the renal and hepatic burden of CH_3Hg^+ was found to be significantly greater in saline-injected TR- rats than in corresponding controls. Accordingly, the CH_3Hg^+ content of the urine and feces was less in TR- rats than in controls. Treatment with DMPS or DMSA reduced significantly the body burden of CH_3Hg^+ in both groups of rats and increased the urinary and fecal excretion of this metal. Interestingly, there were still significant differences between the two groups of rats. These data implicate MRP2 in the DMPS- and DMSA-mediated elimination of CH_3Hg^+ from proximal tubular cells.

1103 MURINE PULMONARY PATHOLOGY AND ALTERATIONS IN SYSTEMIC IMMUNE FUNCTION FOLLOWING 7, 14, AND 30 DAY EXPOSURES TO INHALED MULTIWALL CARBON NANOTUBES (MWCNTS).

L. Mitchell^{1,2}, J. Gao², S. W. Burchiel² and J. D. McDonald¹. ¹Lovelace Respiratory Research Institute, Albuquerque, NM and ²College of Pharmacy, University of New Mexico, Albuquerque, NM.

Nanotoxicology has emerged as an important field in the evaluation of the health effects of various nanoparticles. There is current concern that humans may be exposed to nanoparticles, such as MWCNTs, by inhalation and contact exposures.

Previous studies have reported that MWCNTs produce pulmonary inflammation and pathology in rodent species. However, MWCNTs have not been studied for inhalation toxicity. Therefore, the purpose of the present studies was to conduct 7, 14, and 30 day exposures to an industrial MWCNT to assess potential lung and immune system toxicities. Adult Male C57Bl/6N mice (n= 5-7/group) were exposed to clean air or particle mass concentrations of 100, 300, or 1000µg/m³ MWCNTs 6 hours/day for 7, 14, or 30 consecutive days. Mice were sacrificed the morning after the last exposure. One group of mice was held 14 days after the 30 day exposure period. Pulmonary endpoints included white blood cell counts/differentials in bronchial alveolar lavage and tissue pathology. Immune function endpoints in splenocytes included T and B cell mitogenesis and the T cell-dependent antibody response to sheep erythrocytes analyzed ex-vivo. Following 14 days of exposure, animals subjected to 300 and 1000µg/m³ had suppressed antibody response as well as decreased T cell mitogen response. By 30 days exposure, T cell mitogen responses were back to normal; however in 1000µg/m³ exposed animals, B cell mitogen and antibody responses were increased. Gross pathology on high dose exposed lungs was altered compared to control lungs. Lavage fluid was taken from 30 day time point animals and showed that treatment resulted in influx of macrophages, and macrophage engulfment of black particulate. Current studies are aimed at elucidation of the mechanism of MWCNT-induced immune alterations. This work supported by NIEHS P30-0120720 and by EPA STAR Grant R832527.

1104 INDUCTION OF DNA DAMAGE AND MICRONUCLEI BY NANOSIZED TITANIUM DIOXIDE IN HUMAN BRONCHIAL EPITHELIAL CELLS.

H. Norppa, G. C. Falck, H. Lindberg, S. Suhonen and K. Savolainen. *New Technologies and Risks, Finnish Institute of Occupational Health, Helsinki, Finland.*

Nanoparticles are increasingly utilized in pharmaceuticals, cosmetics, biomedical, plastics, building materials, and other products. Because of their small size (diameter < 100 nm), nanoparticles readily pass through cell membranes and may possess unique physicochemical properties and show unpredictable toxic effects. Since the applications of nanoparticles are rapidly growing, information on their possible genotoxic properties is urgently needed. Nanoparticles might be genotoxic either directly or indirectly, possibly acting through oxidative stress and inflammatory responses. There are some indications that nanoparticles such as nanosized titanium dioxide can elicit inflammation and evoke the generation of reactive oxygen species and of lipid peroxidation products. The aim of the present study was to examine *in vitro* the potential genotoxicity of nanosized titanium dioxide used, e.g., in the production of cosmetics. As lungs cells are expected to be the primary target of nanoparticle effects, we treated human bronchial epithelial cells (BEAS-2B) with various concentrations (1-100 µg/cm²) of titanium(IV)oxide nanopowder (rutile, 99.5%). DNA strand breaks were assessed with the single cell gel electrophoresis (comet) assay. The induction of micronuclei was examined by the cytokinesis-block method 24, 48, and 72 h after the treatment. Titanium dioxide induced a dose-dependent increase in DNA damage, but the effect was not high in absolute terms. In the micronucleus assay, titanium dioxide produced no clear positive effects when tested up to 100 µg/cm². High concentrations were not readable due to titanium dioxide sedimented on the chamber slide. Thus, our results suggest that rutile, a phase of titanium dioxide known to be relatively poor in generating reactive oxygen species, is slightly genotoxic in the *in vitro* conditions examined.

1105 COMBINING A MAGNETIC NANOPARTICLE TECHNIQUE WITH THE DT40 CELL MODEL TO EVALUATE THE DNA DAMAGE RESPONSE TO TOBACCO SMOKE.

J. Nakamura and M. Jang. *Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.* Sponsor: J. Swenberg.

Magnetic nanoparticles (MNPs) suspended in the air can serve as an excellent exposure technology for directly targeting atmospheric airborne matter onto a specific area of *in vitro* and *in vivo* biological systems. This innovative methodology could significantly advance the evaluation of the health impacts of atmospheric airborne matter and identify relevant biological responses. In this *in vitro* study, isogenic chicken DT40 B-lymphocyte cells deficient in a DNA damage response gene were exposed to MNPs coagulated with tobacco smoke residue (MNPs-TS) to evaluate the cellular response to tobacco smoke. Cells were first exposed to air-suspended MNPs-TS for thirty minutes in the presence of an external magnetic field, which directed particle deposition into the culture medium thereby increasing cellular exposure to TS constituents, including insoluble residues. Cells were then washed by PBS and were cultivated in fresh medium for ten cell replication cycles. Cell survival was then determined by an XTT-based cell proliferation assay at the end of cultivation. Wild-type DT40 cells showed a dose-dependent reduction in growth after MNPs-TS treatment but not after exposure to MNPs alone, without TS. It has been reported that nucleotide excision repair (NER) plays an important role in the

removal of PAH-modified base lesions. Therefore, we applied this exposure technique to DT40 cells deficient in xeroderma pigmentosum A (*xpa*), a gene involved in NER. MNPs-TS exposure slightly reduced cell survival in *xpa* mutant cells relative to wild-type DT40 cells. These results indicate that, when coupled with an appropriate biological system, this novel exposure technique is a valuable approach for evaluating toxicity caused by atmospheric combustion particles. (This research was supported in part by P42-ES05948, ES11746, P30-CA16086, and P30-ES10126 from the National Institutes of Health.)

1106 *IN VITRO* TOXICITY OF SILICA NANOPARTICLES IN HUMAN LUNG CANCER CELLS.

Y. Ma¹, W. Lin¹, Y. Huang² and X. Zhou³. ¹*Chemistry, University of Missouri-Rolla, Rolla, MO,* ²*Biological Sciences, University of Missouri-Rolla, Rolla, MO* and ³*Pacific Northwest National Laboratory, Richland, WA.*

The cytotoxicity of 15 nm and 46 nm silica nanoparticles was investigated by using crystalline silica (Min-U-Sil 5) as a positive control in cultured human bronchoalveolar carcinoma-derived cells. Exposure to 15 nm or 46 nm SiO₂ nanoparticles for 48 h at dosage levels between 10 and 100 µg/mL decreased cell viability in a dose-dependent manner. Both SiO₂ nanoparticles were more cytotoxic than Min-U-Sil 5; however, the cytotoxicities of 15 nm and 46 nm silica nanoparticles were not significantly different. The 15 nm SiO₂ nanoparticles were used to determine time-dependent cytotoxicity and oxidative stress responses. Cell viability decreased significantly as a function of both nanoparticle dosage (10-100 µg/mL) and exposure time (24 h, 48 h, and 72 h). Indicators of oxidative stress and cytotoxicity, including total reactive oxygen species (ROS), glutathione, malondialdehyde, and lactate dehydrogenase, were quantitatively assessed. Exposure to SiO₂ nanoparticles increased ROS levels and reduced glutathione levels. The increased production of malondialdehyde and lactate dehydrogenase release from the cells indicated lipid peroxidation and membrane damage. In summary, exposure to SiO₂ nanoparticles results in a dose-dependent cytotoxicity in cultural human bronchoalveolar carcinoma-derived cells that is closely correlated to increased oxidative stress.

1107 ASSESSING THE ADEQUACY OF *IN VITRO* CELL CULTURE SYSTEMS TO ACCURATELY PREDICT THE *IN VIVO* PULMONARY TOXICITY OF FINE AND NANO-SIZED PARTICULATES.

C. M. Sayes, K. M. Reed and D. B. Warheit. *DuPont Haskell Laboratory, Newark, DE.*

Previous studies have reported little correlation between the relative lung toxicity of particle-types when comparing *in vivo* effects vs. *in vitro* cell culture exposures. This study was designed to assess the capacity of *in vitro* screening studies to predict *in vivo* pulmonary toxicity of several fine or nanoscale particle-types in rats. In the *in vivo* component, rats were exposed by intratracheal instillation to 1 or 5 mg/kg of the following particle-types: 1) carbonyl iron; 2) Min-U-Sil quartz; 3) amorphous silica; 4-5) nanoscale or fine zinc oxide. Following exposures, the lungs of exposed rats were lavaged and inflammation and cytotoxicity endpoints were measured at 24 hrs, 1 week, 1 and 3 months postexposure.

For the *in vitro* study, three different culture conditions were utilized. Cultures of 1) rat lung epithelial cells, 2) primary alveolar macrophages, as well as 3) alveolar macrophage – L2 lung epithelial cell co-cultures were incubated with the particle-types listed above and the culture fluids were evaluated for cytotoxicity endpoints (LDH, MTT) as well as inflammatory cytokines (MIP-2, TNF-α, and Interleukin-6). Initially, the particle-exposed, 3 different culture-types were assessed for cytotoxicity biomarkers at 4 different time periods – 1 hr, 4 hrs, 24 hrs or 48 hrs. Subsequently, MTT endpoints were measured following incubation for 4 or 24 hours and the cytokine secretions into the culture fluids were measured after treatment for 24 hours.

When considering the range of toxicity to 5 different particle-types, the comparisons of *in vivo* and *in vitro* measurements demonstrated little correlation, particularly when considering many of the variables assessed in this study – such as cell-types to be utilized, culture conditions and time course of exposure, as well as measured endpoints. It seems clear that *in vitro* cellular systems will need to be developed, standardized and validated (relative to *in vivo* effects) in order to provide useful screening data on the relative toxicity of inhaled particle-types.

1108 THE EFFECT OF NANO-SIZED TITANIUM DIOXIDE PARTICLES ON PULMONARY INFLAMMATION IN MICE.

L. Pylkkänen, H. Wolff, H. Alenius and K. Savolainen. *Finnish Institute of Occupational Health, Helsinki, Finland.*

Strong evidence exist that ultrafine airborne particles (e.g. diesel exhaust particles) pose considerable health risks in the airways and lungs. However, there is extremely limited information of the potential health effects of engineered nanomaterials on

the airways. We used a mouse model to elucidate inflammatory effects of nano-sized titanium dioxide (TiO₂) particles in the lungs of BALB/c mice that were exposed to intranasally administered fine (particle size ca. 1µm) or nano-sized (diam. x length ca. 10nm x 40nm) TiO₂ at three different concentrations (1, 100, and 1000 µg/ml) twice a week for three weeks. Inflammatory cell infiltration was defined in the bronchoalveolar lavage (BAL) fluid. Expression of cytokines and chemokines relevant to inflammation in the lung tissue was assessed by using real-time PCR. Bronchial responsiveness to methacholine was determined by whole body plethysmography. An increase in the expression of chemokine MIP-2, a potent chemotactic factor for neutrophil recruitment, in the lung tissue of mice exposed to high concentrations (1000µg/ml) of nano-sized TiO₂ particles, when compared with mice exposed to the same concentration of coarser particles, was detected. In addition, increased infiltration of macrophages and neutrophils in the BAL was seen after the installation of high concentrations of TiO₂. The increase was lightly higher in mice exposed to nano- sized than to coarser particles. These data suggest that nano-sized particles of titanium dioxide may be more potent than larger particles in evoking inflammatory responses in the lungs of mice. Supported by The Finnish Work Environment Fund, project no 105097.

1109 A TWENTY-EIGHT DAYS INHALATION TOXICITY STUDY OF SILVER NANOPARTICLES IN SPRAGUE DAWLEY RATS.

Yu⁷. ¹Samsung Electronics Co., Suwon, South Korea, ²Mechanical Engineering, Korea Advance Institute of Science and Technology, Daejeon, South Korea, ³HCT Co., Icheon, South Korea, ⁴Preventive Medicine, Chung-Ang University, Seoul, South Korea, ⁵Occupational Safety and Health Research Institute, KOSHA, Daejeon, South Korea, ⁶Toxicologic Pathology Division, National Institute of Toxicological Research, Seoul, South Korea and ⁷Biosafety Evaluation Headquarter, KEMTI, Incheon, South Korea.

Silver nanoparticles (SNP), second most widely used nanomaterials, have been used in health, electronic, and home products. Although previous studies on silver dust, fume and silver compounds suggested some insights on their toxicity, the toxicity of SNPs, in which size and surface area are recognized as important determinants for toxicity, is little known about. Especially inhalation toxicity of SNPs is foremost information to protect workers and consumers' health, despite difficulties in inhalation study of NPs. Accordingly, we have designed a device to generate SNPs by evaporation/condensation, using a small ceramic heater. The generator was able to distribute desired concentrations of SNP to chambers containing experimental animals. The concentrations and distribution of the NP with respect to size can be measured directly by a differential mobility analyzer and an ultra condensation particle counter. SNPs were tested for 28 days for inhalation toxicity. Eight-week-old rats weighing about 283 g for male and 192 g for female were placed in to four groups (10 rats in each group); fresh air control, low (1.73×10⁴), middle (1.27×10⁵), and high-dose (1.32×10⁶ particles/cm³, 61 µg/m³). The animals were exposed to SNPs 6 hours each day, 5 days per week, for a total 4 weeks. The male and female rats did not show any significant changes in body weight depending on the concentration of SNPs during the 28-day of the experiment. There were no significant changes in hematology and blood biochemical values either both in male or female rats. Our initial results indicated that SNPs at a concentration near to current ACGIH silver dust (100 µg /m³) may not have significant health effect.

1110 PULMONARY AND CARDIOVASCULAR TOXICITY OF MULTIWALL CARBON NANOTUBES IN MICE.

S. Han¹, D. Howatt², A. Daugherty² and C. Gairola¹. ¹Graduate Center for Toxicology, University of Kentucky, Lexington, KY and ²Gill Heart Institute, University of Kentucky Medical Center, Lexington, KY.

Manufactured nanoparticles possess unique properties and may have a potential to cause toxicity. In the present study, pulmonary and cardiovascular toxicity of multi-wall carbon nanotubes (CNT) was studied in apoE-deficient mice maintained on standard mouse diet. CNT (>95% purity, diameter 20-30nm and length ~50 micron) were suspended in sterile PBS and introduced into mice lungs @ 40µg/mouse, once/wk for 16 consecutive weeks by pharyngeal aspiration. Age-matched mice receiving sterile PBS served as controls. Twenty four hour urine samples were collected from animals after the 1st and 15th CNT treatment to assess oxidative stress. Animals were sacrificed on day-1 and day-7 after the last CNT treatment. Markers of pulmonary toxicity and inflammation were measured in bronchoalveolar lavage (BAL) by standard techniques. The formation of atherosclerotic lesions in the aorta was evaluated by *en face* lesion planimetry. The results showed significant increases in total BAL cells and polymorphonuclear neutrophils in CNT-treated mice on day-1 and day-7 post treatment. Analyses of cell-free BAL fluids showed significant increases in total proteins, LDH and mucin levels in CNT-treated mice given multiple treatments suggesting toxic and inflammatory re-

sponses. The lung tissue levels of CuZn-SOD and Mn-SOD proteins did not differ significantly in the control and CNT-treated groups. However, a significant increase in the urinary levels of 8-OHdG in mice within a day after the first CNT treatment indicated development of oxidative stress. Yet, multiple weekly exposures to CNT for 16 wks failed to influence the plasma cholesterol and the area of atherosclerotic lesions covering aortic intima of apoE-deficient mice. The results suggest that multiple exposures to CNT evoke a toxic and inflammatory response in the pulmonary system but are unable to promote atherosclerosis for up to 16 weeks in a susceptible mouse model of human atherosclerosis.

1111 INFLAMMATION AND FATE OF QUANTUM DOTS FOLLOWING PULMONARY TREATMENT OF RATS.

J. R. Roberts, R. R. Mercer, S. Young, D. W. Porter, V. Castranova and J. M. Antonini. HELD/PPRB, NIOSH, Morgantown, WV.

Inhalation of nanoparticles may affect the respiratory, cardiovascular, and central nervous systems. The mechanism by which nanoparticles translocate from the air-spaces into the bloodstream is unknown. The goal was to investigate the fate and inflammatory effects of fluorescent quantum dots (30-50 nm; coated with carboxyl terminal groups) after pulmonary exposure. To monitor phagocytosis of quantum dots by non-primed and primed alveolar macrophages (AM) *in vitro*, AM were collected by bronchoalveolar lavage (BAL) from untreated rats or rats that had been treated by pulmonary inoculation with *L. monocytogenes*. AM were incubated for 2 hr with 0 (control), 2.5, or 25 µg/ml of quantum dots and mounted for laser scanning confocal microscopy (LSCM) or analyzed by flow cytometry to quantify phagocytosis. For *in vivo* studies, male Sprague-Dawley rats were intratracheally instilled with saline or quantum dots on day 0 at a dose of 12.5 µg/rat. At 2 hr post-instillation, and on days 1, 3, and 5, the left lungs were cryopreserved and sectioned for LSCM. BAL was performed on right lungs, and indicators of lung damage were measured. Collected lavage cells were differentiated to assess inflammation. Recovered AM also were mounted onto slides and analyzed by LSCM to assess uptake of the quantum dots *in vivo*. A concentration-dependent increase in the phagocytosis of the quantum dots by AM *in vitro* was observed. A greater number of quantum dots were phagocytized by the primed AM. At 2 hr post-instillation, quantum dots were located in the AM and airspaces, as well as on the epithelial surfaces, in the alveolar region. By 24 hr, most of the quantum dots had been phagocytized by AM, and localized areas of quantum particles were observed in interstitial areas of lung parenchyma. Lung injury and inflammation were found to be elevated in the BAL of animals treated with quantum dots on 1, 3 and 5 days post-exposure compared to saline controls. Due to their high intensity fluorescent signal, quantum dots appear to be appropriate for studying the pulmonary deposition and fate of nanoparticles.

1112 PULMONARY INFLAMMATORY AND SYSTEMIC IMMUNE RESPONSES TO INHALED OIL NANOCONDENSATES.

J. McDonald, J. Seagrave, L. Mitchell, A. Giggliotti and J. Mauderly. Lovelace Respiratory Research Institute, Albuquerque, NM.

This study was conducted to follow up on our previous finding of a statistical association between chemical components of oil and pulmonary toxicity of collected automobile and diesel exhaust that was extracted and instilled into rat lungs. Organic condensates derived from unburned or partially burned oil and fuel account for the majority of the particle emissions, especially nanoparticle emissions, from motor vehicles. Despite significant interest in the toxicity of nanoparticles in the environment, this class of materials has not been well studied. We report results from a recent study that characterized the pulmonary inflammation and systemic immune effects of inhaled organic condensates of used engine oil. Used 15w/40 (Shell, Rotella T) motor oil was obtained after 200 hours of operation in a 2000 Model Cummins 5.9L diesel engine operated on a slightly modified (no motoring) FTP engine cycle. Organic aerosol condensates of oil were generated by evaporation and condensation. C57Bl/6 mice (n=7) were exposed to oil droplets of approximately 20 nm in size in a nose-only inhalation exposure system. An equal number of mice were exposed to clean air as controls. Mice were exposed for 7 consecutive days, 6 hr/day at a particle mass concentration of 300 µg/m³ and number count of ~1 x 10⁶ particles/cm³. On day 7, the mice were sacrificed. Lungs were lavaged for determination of total and differential inflammatory cell populations and indicators of toxicity. Lung tissue pathology was assessed by light microscopy of hematoxylin/eosin stained sections. Biochemical indicators of inflammation and oxidant stress were analyzed in lung tissue. Immunotoxicity was analyzed by splenic B and T cell proliferation in response to mitogens. We observed modest to no response in most of the pulmonary indicators of toxicity and oxidant stress. However, we did observe significant changes in B and T cell proliferation. Supported by DOE FreedomCar and Vehicle Technology Program.

1113 COMPARATIVE *IN VITRO* PULMONARY TOXICITY OF ENGINEERED, MANUFACTURED, AND ENVIRONMENTAL NANOPARTICLES.

K. Dreher¹, S. Rhodes², Z. Tycz³ and R. Snyder¹. ¹U.S. EPA, Research Triangle Park, NC, ²North Carolina State University, Raleigh, NC and ³University of North Carolina, Chapel Hill, NC.

Engineered nanomaterials display many unique physicochemical properties for a variety of applications and due to their novel properties/applications may have unique routes of exposure and toxicity. This study examines the: 1) ability of the MTT assay to generate false positives or negatives when examining the cellular toxicity of single wall carbon nanotubes (SWCNTs); 2) comparative cellular toxicity using BEAS 2B human airway cell line of three different commercially manufactured SWCNTs (#1-3), nanographite fiber (nGF), ultrafine carbon black particles (ufCB), diesel exhaust particles (DEPs), and residual oil fly ash particles (ROFA); and 3) relationship between nanoparticle surface reactivity and *in vitro* pulmonary toxicity. The MTT assay did not produce either false positive or negative results since SWCNTs alone were negative in this assay and did not bind the reduced formazan dye. BEAS 2B cells were exposed to various doses of each nanoparticle and their viability assessed using the MTT assay at 24 hr post-exposure. These studies identified a hierarchy of BEAS 2B cellular toxicity with SWCNT#1 (ED50= 12.5 ug/ml) = SWCNT#2 > SWCNT#3 (ED50=50 ug/ml) >> ROFA (ED50=75 ug/ml) > DEP (ED50=100 ug/ml) > nGF (ED50>200 ug/ml) = ufCB. Nanoparticles were tested for their ability to generate thiobarbituric acid reactive substances in an acellular assay and demonstrated the following hierarchy of reactivity: ROFA >> DEP > ufCB = SWCNTs #1- #3. These results demonstrate that engineered nanoparticles display a significantly greater *in vitro* pulmonary toxicity when compared to manufactured and environmental particles. In addition, SWCNTs *in vitro* pulmonary toxicity did not correlate with their "reactivity". (Funding: USEPA-NCSU Cooperative Training Agreement CT 829470. This abstract does not necessarily reflect EPA Policy)

1114 LUNG TOXICITY STUDIES WITH NANOSCALE AND FINE-SIZED QUARTZ PARTICLES IN RATS: TOXICITY IS NOT DEPENDENT UPON PARTICLE SIZE BUT ON SURFACE CHARACTERISTICS.

D. B. Warheit¹, T. R. Webb¹, V. L. Colvin², K. L. Reed¹ and C. M. Sayes¹. ¹DuPont Haskell Laboratory, Newark, DE and ²Chemistry, Rice University, Houston, TX.

Pulmonary toxicology studies in rats demonstrate that nanoparticles are more toxic than fine-sized particles of similar chemistry. This study, however, provides evidence to contradict this theory. The aims of the study were 1) to compare the toxicity of synthetic 50 nm nanoquartz-I particles vs. (mined) Min-U-Sil quartz (~500 nm); the toxicity of synthetic 12 nm nanoquartz-II particles vs. (mined) Min-U-Sil (~500 nm) vs. (synthetic) fine quartz particles (300 nm); and 2) to evaluate the surface activities among the samples as they relate to toxicity. Well characterized samples were tested for surface activity and hemolytic potential. In addition, groups of rats were instilled either with doses of 1 or 5 mg/kg of carbonyl iron or various alpha-quartz particle-types in phosphate buffered saline solution and subsequently assessed using bronchoalveolar lavage fluid biomarkers, cell proliferation, and histopathological evaluation of lung tissue at 24 hrs, 1 week, 1 month and 3 months postexposure.

Exposures to the various alpha-quartz particles produced differential degrees of pulmonary inflammation and cytotoxicity, which were not always consistent with particle size but correlated with surface activity, particularly hemolytic potential. Lung tissue evaluations of three of the quartz samples demonstrated "typical" quartz-related effects – dose-dependent lung inflammatory macrophage accumulation responses concomitant with early development of pulmonary fibrosis. The various alpha-quartz related effects were similar qualitatively but with different potencies. The range of particle-related toxicities and histopathologic effects in descending order were nanoscale quartz II = Min-U-Sil quartz > fine quartz > nanoscale quartz I > carbonyl iron particles. The results demonstrate that the pulmonary toxicities of α -quartz particles appear to correlate better with surface activity than particle size and surface area.

1115 DISPERSION SIGNIFICANTLY ENHANCES THE PULMONARY TOXICITY OF SINGLE WALLED CARBON NANOTUBES.

R. R. Mercer, J. F. Scabilloni, L. Wang, D. Schwegler-Berry, A. A. Shvedova and V. Castranova. HELD, NIOSH, Morgantown, WV.

All nanomaterials have a fundamental dimension less than 100 nanometers. However, agglomerates of nanomaterials, micrometers in diameter, are the more common form of the material. This is particularly evident in prior studies of the

pulmonary toxicity of single walled carbon nanotubes (SWCNT) where large granulomatous lesions encased by epithelioid macrophages were produced by large agglomerates of SWCNT (~15 μ m diameter). In this study, a highly dispersed preparation of SWCNT with a mean geometric diameter of 1.1 μ m was given by pharyngeal aspiration to C57BL/6 mice in order to determine the pulmonary toxicity. Lung responses were studied by lavage and morphometry of lung sections at 1 hour, 1 day, 7 days and 1 month after a single SWCNT exposure of 10 μ g/mouse. A PBS aspiration group served as the negative control. Examination of lung sections and lavage cell differential demonstrated an early, transient neutrophilic, inflammatory phase which rapidly resolved and was similar to that observed with large agglomerates. However, no granulomatous lesions or epithelioid macrophages were detected. Electron microscopy demonstrated a highly dispersed, interstitial distribution of SWCNT deposits by 1 day. The deposits were generally less than 1 μ m. Alveolar macrophage phagocytosis of SWCNT was minimal at all times. Morphometric measurement of the Sirius red staining in sections was used to assess the connective tissue response. The average thickness of Sirius red stained connective tissue in alveolar regions, excluding alveoli adjacent to CNT deposits, was 0.10 $\pm$ 0.02, 0.10 $\pm$ 0.03, 0.09 $\pm$ 0.02, 0.51 $\pm$ 0.05 and 1.10 $\pm$ 0.35 μ m (mean $\pm$ SE N=6) for PBS, 1 hour, 1 day, 7 days and 1 month groups, respectively. The results demonstrate that dispersed SWCNT are rapidly incorporated into the alveolar interstitium and produce a generalized fibrotic response. Alveolar macrophage clearance is not a significant component of the lung response.

1116 INTERACTION BETWEEN CARBON NANOTUBES AND OZONE IN THE INDUCTION OF PULMONARY TOXICITY IN MICE.

C. Gairola¹, S. Han¹, R. Andrews¹ and D. K. Bhalla². ¹Graduate Center for Toxicology, University of Kentucky, Lexington, KY and ²Fund/Appl. Sciences, Wayne State University, Detroit, MI.

Manufactured nanoparticles have received considerable attention recently due to their potential to cause pulmonary injury. Ozone (O₃), on the other hand is a well defined air pollutant known to produce acute and chronic toxicity to the respiratory system. Whether pre-exposure to nanoparticles influences the O₃ toxicity is not well studied. To examine the extent of toxicological interactions between such particulate and gas exposures, we determined acute pulmonary effects of a 3-hr ozone exposure (0.5ppm) in female C57Bl mice administered 12 hrs earlier a single dose of 20 μ g multiwall carbon nanotubes (CNT) by pharyngeal aspiration. A total of four groups were compared: 1) PBS/air-control, 2) PBS/O₃, 3) CNT/air, and 4) CNT/O₃. Analyses of the bronchoalveolar lavage fluid (BALF) and lung tissue samples collected at 5 and 24 hrs post-O₃ exposure were performed for various markers of cytotoxicity and inflammation using standard ELISA and immunoblot procedures. The results showed a pronounced cellular response and increase in various cytotoxicity/inflammatory markers in the lungs of CNT-exposed mice. Ozone, by itself, produced minimal effects, but in CNT-exposed animals there was a significant increase in total BAL cells and polymorphonuclear neutrophils. Additionally, protein, LDH, TNF α , IL-1 β and mucin levels in BALF at 5 and 24 hrs were higher in CNT-exposed animals than corresponding air-exposed controls or animals exposed to O₃ alone. A comparable increase over the controls was also observed in the CNT/O₃ group but neither an additive nor a synergistic interaction was observed in mice that received sequential exposures to CNT and ozone. In fact some CNT-induced cytotoxic/inflammatory responses were attenuated in mice following exposure to both CNT and a low level of ozone. These results are opposite to enhanced responses that we were anticipating and may represent the development of "cross tolerance" reported by others for some sequentially administered pollutants.

1117 *IN VIVO* PULMONARY TOXICITY STUDY IN RATS WITH FULLERENE WATER SUSPENSIONS (NANO-C60 & C60(OH)24).

D. B. Warheit¹, C. M. Sayes¹, A. Marchione² and K. L. Reed¹. ¹DuPont Haskell Laboratory, Newark, DE and ²Central Research and Development, DuPont Co., Wilmington, DE.

Due to the increased attention on nanoparticle toxicity, specifically that of water-suspendable fullerene systems, we studied the *in vivo* pulmonary effects of rats intracheally instilled with an aggregated form of C60, termed nano-C60, and a highly water soluble derivative, C60(OH)24. Previously, it was reported that "the cytotoxicity of water-soluble fullerene species are a sensitive function of their surface derivatization". In this regard, *in vitro* toxicity studies with human dermal fibroblasts and human lung epithelial cells indicated that the pristine nano-C60 particles were significantly more toxic than the fully derivatized C60 particulates. We set out to validate this *in vitro* finding using an *in vivo* pulmonary bioassay system, wherein rats were exposed to 1.5 or 3 mg/kg of the two C60 forms or a quartz positive reference particulate control. In addition to BAL fluid analyses, oxidative damage was also probed. Results demonstrated that increased lipid peroxidation was measured

in the lung recovered cells of pristine nano-C60 exposed rats at the 1 day time point, but decreased over time. However, no increases in lung cell inflammatory responses, i.e. % neutrophils, were measured between the two forms of C60 at any of the postexposure time points evaluated. We show that under ambient conditions in water, fullerenes can generate carbon centered radicals detected by electron spin resonance spectroscopy. These oxygen radicals may be responsible for increased lipid peroxidation at the 1 day time point. This work demonstrates both the difficulty in interpreting/extrapolating in vitro toxicity measurements and highlights the complexities associated with probing the toxicological response of nanoparticle systems.

1118 NANO-PARTICLES - A SHORT-TERM INHALATION TEST WITH TiO₂ IN RATS LINKED TO *IN VITRO* SYSTEMS.

R. Landsiedel, L. Ma-Hock, K. Wiench, S. Burkhardt, V. Strauss, A. Gamer and B. van Ravenzwaay. *Product Safety, BASF, Ludwigshafen, Germany.*

Inhalation exposure is the route of most concern for nano-particles. There is that nano-particles in aerosols agglomerate to larger clusters affecting their deposition, distribution and effects in the lung.

Various testing methods are currently used to estimate the effects of nano-scaled materials in the lung, i.e. inhalation, intra-tracheal instillation and various cell culture systems. Compared to inhalation studies, these systems are relatively simple but the exposure is, considering the complex processes in nano-particle aerosols. Alternative exposure routes will need validation by inhalation studies covering the appropriate endpoints.

Therefore an inhalation study with rats was performed with exposure to 50, 10 and 2 mg/m³ nano-TiO₂ for 6 hours on 5 days. At the end of the exposure, and two and twelve days thereafter, animals were examined for an extensive set of parameters: Organ burdens were estimated in 7 tissues and electron microscopy was used to characterize the particles deposited in the tissues.

The particles in the atmosphere had a median diameter of 2 µm and less than 1% were actually in the nano-range (<100 nm), indicating agglomeration. Agglomerates in airways and alveoli (extra-cellularly and within activated macrophages) had a similar size distribution. 10 organs were examined by histopathology. S-phase response and apoptosis was examined in the lung.

Cytokine profiles, indicators of oxidative stress (malondialdehyde, carbonylmethyllysine, 8OHdG) and indicators of complement activation, as well as standard clinical pathology parameters were analyzed in lung lavage fluid and blood.

Signs of inflammatory response were observed in the lung and the results correlated well with results from a previous subchronic inhalation study. However, the wide range of examined parameters in this study, revealed a much more differentiated picture of the effects of nano-TiO₂ in the lung. The results will be discussed in detail and compared to intra-tracheal instillation studies as well as tests with cell cultures.

1119 ROLE OF PARTICLE AGGLOMERATION IN NANOPARTICLE TOXICITY.

B. Cohen, M. Blaustein, L. Chen and T. Gordon. *Environmental Medicine, NYU School of Medicine, Tuxedo, NY.*

Particle agglomeration can affect the physical characteristics of airborne particles and influence deposition and toxicity. We hypothesized that there will be a difference in the toxicity of fresh (predominantly singlet) vs. aged (predominantly agglomerated) carbon nanoparticles. We measured the agglomeration rate of freshly generated carbon nanoparticles and determined whether agglomeration is affected by residence time, particle charge, or humidity. To examine the role of these parameters on carbon nanoparticle toxicity, we exposed BALB/C mice for 5 hrs to filtered air or carbon nanoparticles generated by spark discharge and examined lung injury and inflammation 24 hrs after exposure. Freshly generated carbon nanoparticles (60 nm, count median diameter, CMD, with a minor peak around 10 nm) produced significantly greater lung inflammation compared to nanoparticles aged approximately 3 minutes (260 nm CMD). This fresh nanoparticle-induced inflammation was concentration dependent with lavage fluid neutrophils at 2%, 4%, 14%, and 35% for 0, 1, 2.5, and 5 mg/m³ nanoparticle concentrations, respectively. There was little difference, however, in total protein concentrations in the lavage fluid of mice exposed to fresh vs. aged nanoparticles. Moreover, despite the role of particle charge in the physics of agglomeration processes, there was no significant difference in the response of mice exposed to charged nanoparticles vs. nanoparticles that were brought to charge equilibrium with a Kr source. Thus, the aging of freshly generated carbon nanoparticles has a profound effect on toxicity but it is unclear if this decrease in toxicity is due solely to particle agglomeration or changes in surface chemistry of the carbon nanoparticles. Ongoing studies are examining the effect of: 1) particle agglomeration on the toxicity of nanoparticles generated from metals and 2) low and high humidity on the pulmonary toxicity of freshly generated carbon nanoparticles.

1120 AN IMPROVED METHOD TO PREPARE SUSPENSIONS OF NANOPARTICLES FOR TREATMENT OF LUNG CELLS IN CULTURE OR *IN VIVO* EXPOSURE BY PHARYNGEAL ASPIRATION OR INTRATRACHEAL INSTILLATION.

T. M. Sager^{1,2}, V. A. Robinson¹, D. W. Porter^{1,2}, D. Schwegler-Berry¹, W. G. Lindsley¹ and V. Castranova^{1,2}. ¹National Institute for Occupational Safety and Health, Morgantown, WV and ²West Virginia University School of Medicine, Morgantown, WV.

Occupational health risks associated with the production and use of nanomaterials are at this time undefined. Therefore, a need to conduct studies examining the health effects of nanoparticle exposure is of great importance. However, nanoparticles agglomerate and clump in solution, making it difficult to accurately deliver nano-sized particles in an in vivo or in vitro experimental procedure. Therefore, a dispersal method which does not alter the biological activity of the particles surface and is not toxic to the lungs was developed. Experiments were conducted to determine the best method to suspend nanosized particles. Ultrafine and fine carbon black and titanium dioxide were suspended in a variety of suspension medias including phosphate buffered saline (PBS), rat and mouse bronchoalveolar lavage fluid (BALF), and dipalmitoyl phosphatidylcholine (DPPC). To assess and compare how the various suspension medias dispersed the particles, images were taken using light microscopy, scanning electron microscopy (SEM), and transmission electron microscopy (TEM). The results of this study show that PBS is not a satisfactory media to prepare particle suspensions of nanosized particles. However, BALF is an excellent vehicle in which to suspend ultrafine particles. The use of protein alone or DPPC alone, in concentrations found in BALF, did not result in satisfactory dispersions. However, the combinations of protein plus DPPC are satisfactory, although slightly less effective, substitute for BALF.

The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy.

1121 ARE POLY(ETHYLENE GLYCOL)-FUNCTIONALIZED NANOPARTICLES BIOCOMPATIBLE?

A. Rinderknecht¹, A. Elder¹, R. Prud'homme², M. Gindy² and G. Oberdorster¹. ¹Environmental Medicine, University of Rochester, Rochester, NY and ²Chemical Engineering, Princeton University, Princeton, NJ.

Nanoparticles engineered for biomedical application need to be biocompatible to avoid adverse health effects. Surface-coating with poly(ethylene glycol) (PEG) is being used for this purpose. Since pulmonary delivery of nanoparticles is of great interest for therapeutic treatments targeting both pulmonary and extrapulmonary tissues, we sought to evaluate in the respiratory tract the biocompatibility of different nanoparticle coatings. We looked at the effect of two commonly used coatings, PEG (Mw = 5 kg/mol) and serum albumin (SA, Mw = 66 kg/mol), on pulmonary inflammation, cytotoxicity, and particle translocation. Single doses of saline and citrate-stabilized-, PEG-coated- or SA-coated- 50nm Au particles were intratracheally microsprayed into male F-344 rats. 24-hours after delivery, Au from all particle-exposed groups was detected in all regions of the lung analyzed, with the smallest amount being found in regional lymph nodes and the highest amount being found in lung tissue and cells of the bronchoalveolar lavage fluid (BALF). Rats exposed to SA- and PEG-coated Au, relative to citrate-stabilized Au, showed higher Au concentration in the BALF supernatant (p<0.05). This indicates that surface coatings prevent particle uptake by mononuclear phagocytic cells. Surprisingly, PEG-, but not SA-coated Au particles induced large increases in biochemical markers of cell toxicity (2-fold, p<0.05), polymorphonuclear neutrophils (60-fold, p<0.0001), and lymphocytes (10-fold, p<0.01), as measured in the BALF one day after exposure. These findings of severe pulmonary inflammation due to PEGylation differ with the generally held view of PEG biocompatibility. Future studies with different PEG-nanoparticle formulations will determine the mechanism of this unexpectedly high inflammatory response.

1122 COMPARATIVE SOLUBILITY OF NANOPARTICLES AND BULK OXIDES OF MAGNESIUM IN LUNG SIMULANT FLUIDS.

M. Dhakal¹, J. A. Pickrell¹, S. D. Castro², K. J. Klabunde³, L. E. Erickson² and F. W. Oehme¹. ¹Diagnostic Medicine/Pathobiology, Kansas State University, Manhattan, KS, ²Chemical Engineering, Kansas State University, Manhattan, KS and ³Chemistry, Kansas State University, Manhattan, KS.

Nanoparticles (NP), with > 1 dimension < 100 nanometers (nm) can clear airborne smoke particles. NP deposit in the deep lung, evade phagocytosis (< 1,000 nm diameter) and enter the lung interstitial space; if dissolved rapidly, we predict minimal health effects. We compared the solubility of Nanoactive [NA]TM MgO Plus

and Na^{TM} MgO; NanoScale, Manhattan, KS) with bulk macrocrystalline (MC) MgO at 50 mg/L and 250 mg/L MgO. Dissolved magnesium was measured using ion coupled plasma (ICP) – atomic emission spectroscopy (AES); Accuris-141, Fisons Instruments, Beverly, MA at 3, 6, 12, and 24 minutes, as well as 1, 3, 24, 48, 72, 96 and 120 hours (hr) in Hanks Basic Salt Solution (HBSS) and Dulbecco's Modified Eagles Medium (DMEM) to simulate lung epithelial lining fluid (ELF). Incubation was at 37°C and 37°C in the presence of 5% CO_2 . To maintain better contact of CO_2 , samples for HBSS and DMEM with CO_2 were taken at 15 and 30 min and at similar times through 120. We hypothesized that both NA MgO particles would be dissolved more quickly in fluids simulating lung ELF. This was true only for the smallest nanocrystalline size (4–6 nm Na^{TM} MgO Plus) relative to MC- and Na^{TM} MgO (nanocrystalline size 8 nm) at < 1 hour of dissolution. Secondly, we hypothesized that the composition of lung ELF would affect MgO solubility; dissolved DMEM > HBSS at 24–120 hours and proportional to the HCO_3^- concentration to simulate lung ELF ($p < 0.001$). Dissolution of HBSS in the presence of 5% CO_2 was greater than HBSS alone. For HBSS and DMEM alone or in the presence of 5% CO_2 , > 50% of the MgO dissolved was in the first 3 hr. These data suggested that significant rapid dissolution would occur for MgO deposited in deep lung that evaded phagocytosis, this minimized risk of health effects. This research was partially funded through the award of a contract from the Marine Corps Systems Command to M2 Technologies Inc.

1123 THE MECHANISM OF SOLUBILITY OF MAGNESIUM OXIDE NANOPARTICLES AND NANORODS IN FLUIDS THAT SIMULATE LUNG EPITHELIAL LINING FLUIDS.

F. Oehme¹, M. Dhakal¹, J. A. Pickrell¹, L. Erickson², S. Castro², K. Klabunde³ and R. Maghirang⁴. ¹Diagnostic Medicine/Pathobiology, Kansas State University, Manhattan, KS, ²Chemical Engineering, Kansas State University, Manhattan, KS, ³Chemistry, Kansas State University, Manhattan, KS and ⁴Biological and Agricultural Engineering, Kansas State University, Manhattan, KS.

Nanoparticles (NP), with > 1 dimension < 200 nanometers (nm) clear airborne smoke particles. Nanorods (NR) tumble in air and obscure visibility. Particles deposit in deep lung, evade phagocytosis at < 1,000 nm diameter (D) and enter the lung interstitium; if they dissolve rapidly, we predict minimal health effects. We compared the solubility of nanoactive $[\text{Na}]^{\text{TM}}$ magnesium oxide (MgO) Plus nanocrystalline (NC) size 4–6 nm and Na^{TM} MgO, NC size 8 nm NP with bulk (MC) MgO and NanoScale (Manhattan, KS) nanorods with D ~ 200 nm and an aspect ratio (L/D) ~ 35 at 50 mg/L and 250 mg/L MgO. Solubility was measured in Hanks Basic Salt Solution (HBSS) to simulate lung epithelial lining fluid (ELF) at 37°C and 37°C in the presence of 5% CO_2 . Dissolved magnesium was measured using ion coupled plasma (ICP) – atomic emission spectroscopy (AES); Accuris-141, Fisons Instruments, Beverly, MA at 3, 6, 12, and 24 minutes, as well as 1, 3, 24, 48, 72, 96 and 120 hours (hr) for HBSS. A pH was measured at the same times as Mg. We hypothesized lung ELF HCO_3^- would affect MgO solubility; dissolved DMEM > HBSS at 24–120 hours and proportional to the HCO_3^- concentration ($p < 0.001$). We hypothesized the chemical form and dissolution of MgO would affect pH; pH increased from 9.5 to 10.6 for HBSS. Mg carbonate was formed as indicated by > 1/2 the MgO solubility at < 24 hr, and a pH increase. $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ is stable at 37°C and 40 torr PCO_2 . We hypothesized based on NR shape that solubility/unit mass would be less (~1/length) than for NP, yet no differences in MgO solubility were noted, suggesting that NR shortened during solubility. That almost no MgO remained predicted no health effects from inhaled MgO. This research was partially funded through the award of a contract from the Marine Corps Systems Command to M2 Technologies Inc.

1124 ACCUMULATION RATES OF 26 NM DIAMETER PARTICLES BY MACROPHAGES AND EPITHELIAL CELLS.

O. R. Moss and V. A. Wong. Biological Sciences, CIIT Centers for Health Research, Research Triangle Park, NC.

The rate that nanoparticles are accumulated by cells should reflect differences in molecular and cellular function. For fluorescent 26 nm diameter polystyrene latex (PSL) beads this expectation was tested with an epithelial cell line (A549 — Human lung adenocarcinoma alveolar type-2-like epithelial cells) and macrophages (alveolar macrophages from 12-week old F-344 female rats). The cells were mounted on a heated stage for observation with a confocal Laser Scanning Microscope (LSM 510 META microscope; Zeiss, Thornwood, NY). A549 cells were grown overnight in the wells of a cover-glass chamber at approximately 40,000 cells per well (The surface area of each well was approximately 0.8 cm²). The macrophages were obtained from 12-week-old F-344 female rats by bronchial-alveolar lavage. (Recovered cells — 97–99% macrophages — were resuspended in medium at a final concentration of 2 or 6.6 x 10⁵ macrophages/ml, allowed to attach to the well surface, and immediately exposed to PSL beads.) Cells were exposed to approximately 2x10⁷ beads per cell. During a 5 or 25 minute time course

the focal plane of the LSM detector was adjusted to step — optical-slice by optical-slice — through the entire volume of a macrophage or epithelial cell. The LSM was calibrated before and after each time course (Moss and Wong, Inhal Toxicol 18:711–716, 2006). For both cell types the uptake rate during the first minute was 10 to 20 beads per 10 ms. For the macrophages the uptake rate during the next 25 minutes was constant for a specific macrophage; although, between macrophages the uptake rates ranged from 2 to 10 beads per 10 ms. For the epithelial cells there was a plateau: During minutes 1 to 5 the uptake rates ranged from 1 to 2 beads per 10 ms. Subsequently, for exposure times longer than 6 minutes, the uptake rate ranged from 2 to 8 beads per 10 ms.

1125 ENHANCED TOXICITY OF CHARGED CARBON NANOTUBES AND ULTRAFINE CARBON BLACK PARTICLES.

I. Gilmour¹, W. Williams^{1,2}, J. K. McGee¹ and R. K. Saxena¹. ¹Immunotoxicology, NHEERL, U.S. EPA, Research Triangle Park, NC and ²School of Life Sciences, Jawaharlal Nehru University, New Delhi, India.

Man-made carbonaceous nano-particles such as single and multi-walled carbon nano-tubes (CNT) and ultra-fine carbon black (UFCB) particles are finding increasing applications in industry, but their potential toxic effects is of concern. In aqueous media, these particles cluster in large aggregates and their interactions with lung cells is rather inefficient. Nonetheless, these particulates have a time and dose dependent toxic effect on lung epithelial cells in culture. Recently, a method to solubilize carbon nano-tubes by heating the nano-tubes in a microwave oven with a mixture of sulfuric and nitric acid under high pressure, was described in order to improve the dispersal property and utility of SWCNTs (Wang et al J Am Chem Soc 128, 95, 2006). By using this procedure we generated particles that dispersed much more efficiently in aqueous media because of the introduction of negatively charged sulfonate and carboxy groups on carbon atoms. Compared to control untreated preparations of nano-particles, acid functionalized carbon nano-tubes as well as ultrafine carbon black were significantly more toxic to LA4 lung epithelial cells in culture as measured by the reduction in cell viability. Microscopic examination showed increased uptake of acid functionalized nano particles (AFNP) by the epithelial cells and flow cytometric studies indicated a significant decrease in the proportion of LA4 cells in S phase of the cell cycle. Pretreatment with poly L-lysine, a polymer that is positively charged and hence could neutralize the negative charge on AFNPs, resulted in abrogation of the toxic effects of AFNPs. These results indicate that dispersability and charge are important criteria in determining the toxicity of nano-particles to lung epithelial cells. This abstract does not reflect EPA policy.

1126 TARGETED DELIVERY OF PHOSPHATIDYL SERINE-COATED SINGLE WALLED CARBON NANOTUBES TO MACROPHAGES.

V. E. Kagan¹, Y. Y. Tyurina¹, N. Konduru¹, L. V. Basova¹, D. Stolz², E. R. Kisin³, A. R. Murray³, B. Fadeel⁴ and A. A. Shvedova³. ¹Center for Free Radical and Antioxidant Health, Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA, ²Department of Cell Biology & Physiology, University of Pittsburgh, Pittsburgh, PA, ³Pathology/Physiology Research Branch, HELD, NIOSH, Morgantown, WV and ⁴Division of Biochemical Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Non-functionalized single walled carbon nanotubes (SWCNT) are not effectively taken-up by phagocytes. In contrast, apoptotic cells with externalized phosphatidylserine (PS) and non-apoptotic cells enriched with PS on their surface are well recognized by macrophages resulting in the suppression of their ROS and RNS production. We hypothesized that coating of SWCNT with PS could interface them with macrophages and stimulate their recognition and engulfment. SEM imaging revealed engulfment of PS-SWCNT by RAW264.7 macrophages and protrusions of SWCNT fibers through the surface into the interior of macrophages. Non-coated and PC-SWCNT were less attractive targets for the macrophages. TEM evaluations of the uptake of SWCNT showed that RAW264.7 macrophages expeditiously phagocytosed PS-SWCNT while less pronounced engulfment of PC-SWCNT and non-coated SWCNT was detected. In addition, macrophages co-incubated with PS-SWCNT had more endocytotic vesicles with entrapped SWCNT compared to macrophages exposed to PC-SWCNT or non-coated SWCNT. PS-SWCNT pretreated with Annexin V were phagocytosed at a much lower frequency. PS-SWCNT (but not PC-SWCNT) effectively suppressed LPS-induced production of $\text{TNF-}\alpha$ by macrophages. Interestingly, in vivo, PS-SWCNTs caused a more robust inflammatory response as compared with PC-SWCNT or non-coated SWCNT. This was documented by a greater total number of cells and PMNs as well as by increased production of $\text{TNF-}\alpha$. PS-SWCNT were preferably phagocytosed by macrophages obtained from BAL as compared to PC-SWCNT or non-coated SWCNT. Supported by NIOSH OH008282, NIH HL70755, HL70807, Human Frontier Science Program.

1127 TISSUE DISTRIBUTION OF FLUORESCENT NANOPARTICLES AFTER INTRAVENOUS INJECTION OR PHARYNGEAL INSTILLATION INTO THE AIRWAYS OF RATS.

K. Sarlo¹, J. Grothaus¹, J. Chaney¹, D. Abbott¹, M. Kuhn¹ and E. D. Clark².
¹Miami Valley Laboratories, Procter & Gamble Company, Cincinnati, OH and
²HESA, Cincinnati, OH.

Rats were exposed to nanoparticles via IV tail vein injection or pharyngeal instillation into the airways to compare the effects of route of exposure and particle size on particle distribution over time. F344 female rats were exposed to saline, 40nm or 100nm polystyrene nanoparticles loaded with an infrared or far red fluorescing dye. One hour or 1, 7 and 28 days after exposure, whole blood was collected, the organs perfused with saline and tissues excised and homogenized for measure of fluorescent signal (normalized to organ weight). The total fluorescent signal of the tissue was calculated as the difference from control. 97% of the total signal was found in the liver and spleen from rats injected with 100nm particles; 3% of signal was found in gut, lung, heart, kidney, uterus + ovaries, blood and brain. A statistical significant drop in signal was measured in the liver, spleen, gut and lungs over time; signal from brain tissue was absent by day 7. Similarly, >95% of signal was found in the liver and spleen from rats injected with 40nm particles; remaining signal was detected in brain, gut, lung, heart, kidney and uterus + ovaries. A statistical significant drop in signal was measured in the liver, spleen, gut and lungs; all signals were absent in the brain, heart, kidney and uterus + ovaries by day 28. In contrast, the lung retained >99% of the fluorescent signal over 28 days from rats instilled with 100nm or 40nm particles. Statistical significant drop in signal was detected in the gut 1 hour and 1 day after exposure with no signal at days 7 and 28. Very low fluorescent signal was detected in the spleen and periphery of 1 to 2 rats over time in both the 100nm and 40nm groups. The significant retention of signal in lung tissue suggests little movement from the airways to other organs over the 28 day observation period. These data show a difference in the tissue distribution of 40nm and 100nm particles in rats exposed via IV injection or by instillation into the airways.

1128 NOSE-TO-BRAIN TRANSLOCATION OF INHALED NANOPARTICLES.

L. Hopkins¹ and K. E. Pinkerton^{2,1}. ¹Pharmacology & Toxicology Graduate Group, University of California, Davis, Davis, CA and ²Center for Health and the Environment, University of California, Davis, Davis, CA.

There is clear epidemiological evidence associating the particulate component of air pollution with adverse health effects such as respiratory distress, elevated blood pressure, heart attack, and stroke. The mechanisms underlying this association are not well understood. However, there is evidence to suggest that particle size may be an important feature of toxicity, and that the smallest particles (100 nm or less in diameter) may have the greatest toxic potential. Dosimetry studies have shown that the majority of such particles are trapped in the nose.

To test the hypothesis that the nasal cavity contributes to the observed particulate-associated health effects by serving as a port of entry to the central nervous system, we exposed adult mice to aerosolized fluorescent semi-conductor nanocrystals (quantum dots) for 3 hours in a nose-only inhalation chamber delivering a mean particle concentration of 1.5 ppb. The CdSe-ZnS quantum dots were encapsulated in phospholipid micelles to minimize aggregation and improve aqueous solubility. Mice were sacrificed 2, 2.5, 4.5, and 5 hours post-exposure. Brains, lungs, and nasal cavities were fixed for histological analysis. Sectioned paraffin-embedded tissues were imaged using standard fluorescence and confocal microscopy methods tuned for the detection of dots emitting maximally at 580 nm. Quantum dots were detected in a punctate pattern throughout the olfactory epithelium of the nasal cavity and in the olfactory bulb region of the brain. No dots were detected in the sham control mice.

To our knowledge, this is the first reported use of quantum dots as a model particle in an inhalation exposure and the first evidence of them translocating to the central nervous system by this route.

1129 CROSS REACTIVITY IN ALLERGIC ASTHMA-LIKE RESPONSES BETWEEN MOLD AND HOUSE DUST MITE IN MICE.

Y. Chung, L. B. Copeland, J. Lehmann and M. D. Ward. U.S. EPA, Research Triangle Park, NC.

Molds are ubiquitous in the environment and exposures to molds contribute to various human diseases including allergic asthma. Some mold allergens have been implicated as the causal agent for allergic asthma. Western blot analysis demonstrated IgE-binding cross-reactivity among mold extracts. However, the physiological relevance of this cross-reactivity to exacerbate asthma-like responses in house dust mite (HDM) and other mold sensitized mice is not well characterized. We hypothesized

that mold extracts can exacerbate allergic asthma-like responses in a BALB/c mouse model. Mice were sensitized to HDM or *Penicillium chrysogenum* extract (PCE) by intratracheal aspiration two times in 14 days. Seven days later, both HDM- and PCE-sensitized mice were challenged to mold extracts (PCE, *Stachybotrys chartarum* extract [SCE], or *Metarhizium anisopliae* crude antigen [MACA]) and HDM. Two days after challenge, serum and bronchoalveolar lavage fluid (BALF) were collected and analyzed for allergic and immunologic responses. Immediate airway responses were also assessed by whole-body plethysmography. Both HDM-sensitized, MACA-challenged mice and PCE-sensitized, MACA or HDM-challenged mice had pulmonary edema. PCE-sensitized, MACA-challenged mice had cellular damage in the lung. BALF total cell counts, especially macrophage counts, and BALF IL-5 levels were significantly increased in PCE-sensitized, MACA-challenged mice compared to PCE-sensitized mice. Serum total IgE levels were elevated compared to controls but were not different among sensitized mice regardless of challenge. Immediate airway responses were significantly elevated in HDM-, PCE-sensitized and mold-challenged mice compared to those of control mice. Taken together, mold extracts can exacerbate allergic responses in HDM-, PCE-sensitized mice including inflammatory, Th-2 cell, and airway responses through cross reactivity. (This abstract does not reflect EPA policy.)

1130 TESTING THE RESPONSE OF PROTEINS IN THE LOCAL LYMPH NODE ASSAY.

N. Berg¹, U. Festersen¹, C. Rasmussen¹, N. K. Soni¹ and D. Basketter².
¹Novozymes A/S, Bagsvaerd, Denmark and ²SEAC, Unilever, Sharnbrook, United Kingdom.

No animal model has been validated for assessing the ability of protein-based preparations to behave as skin sensitizers. Still some authorities request skin sensitization data on materials such as industrial enzymes. As the local lymph node assay (LLNA) is regarded as the preferred model, the aim of the present work was to gain experience with the model and see whether it could provide useful information, even though the model was validated only for chemicals. The standard protocol was used, in which groups of CBA/Ca mice (n=5) received 3 consecutive daily topical applications of test material at 3 dose levels. The following protein allergens were tested: A protease and an amylase from *B. licheniformis*, a protease from *B. subtilis*, and Ovalbumin. The contact allergen hexyl cinnamic aldehyde and the vehicles were positive and negative controls. As the test materials were water soluble, the work included the investigation of several vehicles. The result was that some of the protein-based preparations were classified as skin sensitizers. The vehicle Propylene glycol was the most suitable for some of the test materials, while ethanol/water was best for others. The classification of enzymes as contact sensitizers is consistent with existing data from the guinea pig skin sensitization models, but conflicts with human data as it is well documented that enzymes are not skin sensitizers in man. Enzymes are known to be human respiratory allergens however and it is of note that the LLNA does not discriminate between chemical contact and respiratory sensitizers. Thus the results demonstrate a need to add other parameters to the traditional endpoint of tritiated thymidine incorporation if the model is to discriminate skin allergens from respiratory allergens such as enzymes. Cytokine profiling already achieves this for chemicals. Our efforts continue to investigate cytokine or lymph node cell markers that could discriminate the predominant T-helper 2 cell activation of protein respiratory allergens in contrast to the T-helper 1 cell activation after exposure to chemical contact allergens.

1131 DIGESTIBILITY AND ORAL TOLERANCE IN A MOUSE MODEL FOR FOOD ALLERGY.

C. C. Bowman and M. K. Selgrade. NHEERL/Immunotox, U.S. EPA, Research Triangle Park, NC.

An animal model for food allergy is needed to test novel proteins produced through biotechnology for potential allergenicity. We demonstrate that mice can distinguish allergens from non-allergens when exposed to foods orally, both in terms of oral tolerance and allergic antibody responses generated by concomitant exposure to cholera toxin. Female 8-10 week-old C3H/HeJ mice were orally treated with 1, 2, or 5 mg of roasted peanut, egg white, or spinach extract, with or without cholera toxin, two or four times at weekly intervals. Peanut was the most potent antigen in eliciting allergic antibody responses, followed by egg white and spinach. Differences among antibody responses to allergens and non-allergens were greatest at low doses over a shorter dosing regimen. Alternatively, animals were orally exposed once to various food extracts or purified soluble or encapsulated ovalbumin prior to parental immunization to gauge induction of oral tolerance. Tolerance was observed in animals exposed to soluble ovalbumin, but not encapsulated ovalbumin or peanut extract. These differences appear to be related to digestibility or solubility, as indicated by the lack of oral tolerance to proteins known to be indigestible (peanut) or rendered indigestible by encapsulation (ovalbumin). Allergic antibody responses in mice orally exposed to food extracts with cholera toxin also reflect differences in

digestibility observed for these antigens, and parallel allergic responses observed in humans. Oral administration of proteins to mice with adjuvant may be a good model for predicting allergenicity of novel proteins. (This abstract does not reflect EPA policy.)

1132 UNDERSTANDING ALLERGENIC PROPERTIES OF PROTEINS: PROTEASE ALLERGEN AND INDUCTION OF M-CSF FROM HUMAN AIRWAY EPITHELIAL CELLS.

M. Baccam¹, J. Kennedy¹, K. Sarlo¹, E. Roggen², N. Kristensen Soni² and L. Fridthjof². ¹Procter & Gamble Company, Cincinnati, OH and ²Novozymes, Bagsvaerd, Denmark.

Type I respiratory allergy is a Th2 dominated immune response to a protein allergen with development of allergen-specific IgE. The initial interaction of allergen with airway epithelial cells may be crucial in determining whether a Th2-dominated (vs Th1-dominated) immune response will be generated. In previous studies we showed that protease allergens (Alcalase®, Savinase®, BPN'Y217L) induced, in a dose dependent manner, the production of M-CSF from human airway type II-like bronchial epithelial cell line A549 grown submerged or in an air/liquid interface. In this study we assessed whether other human airway epithelial cells also produced M-CSF in response to exposure to protease allergens. The SV40-transformed human bronchial epithelial cell BEAS-2B was incubated with 0.1 - 10 ug/ml Alcalase, Savinase and Der p 1 for 24 hours. M-CSF was detected in culture supernatant of BEAS-2B cells treated with Alcalase as low as 0.1 ug/ml and was maximal between 1 - 10 ug/ml. Normal, human derived tracheal/bronchial epithelial cells from a non-asthmatic healthy individual and from an asthmatic individual (EpiAirway Tissue Model System) were exposed to 1 - 100 ug/ml Alcalase for 24 hours. M-CSF was produced by both cell types with no difference between asthmatic and non-asthmatic epithelial cell responses. Neither the primary human airway epithelial cells nor the BEAS-2B cells generated M-CSF upon exposure to 100 or 10 ug/ml BSA, respectively. These data show that M-CSF production may be a universal response of human airway epithelial cells when exposed to protease proteins and that the A549 air/liquid interface model may be a good surrogate for future studies on understanding the allergenic properties of protease allergens.

1133 ENVIRONMENTAL TOBACCO SMOKE SYNERGIZES WITH PROGESTERONE TO ENHANCE ALLERGIC ASTHMA IN A MOUSE MODEL.

V. Mitchell and L. J. Gershwin. *School of Veterinary Medicine: Pathology, Microbiology, Immunology, University of California, Davis, Davis, CA.*

Background: Exposure to Environmental Tobacco Smoke (ETS) is known to both trigger and exacerbate the asthmatic phenotype. Previous studies performed by our laboratory have shown that exposure to ETS enhances the immune response to allergens by increasing T-helper 2 (TH2) type cytokines. Females have a higher incidence of asthma than males after the onset of puberty. This suggests a hormonal component to the development of the disease. Progesterone has previously been shown to illicit TH2 type immune response similar to that seen in allergic asthma. **Objective:** To determine if the combination of exposure to ETS and progesterone would further exacerbate the immune response in a mouse model of allergic asthma. **Methods:** Female mice were ovariectomized and then implanted with time-release progesterone pellets. Mice were housed in either ETS or Filtered Air (FA) chambers and half were exposed to aerosolized house dust mite allergen (HDMA). Bronchoalveolar lavage was performed for cell differentials; lung and spleen cells were harvested to compare IL-4 and IFN- γ production by ELISPOT. **Results:** Progesterone pellet implantation resulted in significantly increased serum progesterone levels vs. placebo treated mice, $p < 0.0001$. Serum total IgE levels were significantly greater in progesterone vs. non-progesterone treated animals that were also exposed to HDMA; these levels were further exacerbated by ETS exposure. HDMA/ETS treated animals had higher eosinophilia in lavage than all other groups. Lung homogenate cells from HDMA/Progesterone treated animals stimulated with Concanavalin A produced significantly more IL-4 compared to HDMA/Placebo treated animals (200 ± 17.6 vs. 146 ± 17.5 spots/well, $p < 0.01$ in ETS exposed animals and 221 ± 28.9 vs. 167 ± 23.4 spots/well, $p < 0.01$ in animals housed in FA). **Conclusion:** Increased serum progesterone levels exacerbate the allergic asthmatic phenotype in a mouse model. These effects are further exacerbated by the addition of environmental tobacco smoke.

1134 ENHANCEMENT OF ALLERGIC REACTION BY TRICHLOROETHYLENE EXPOSURE WITH DRINKING WATER IN MICE.

R. Kobayashi¹, T. Ikemoto¹, M. Satoh² and H. Nagase¹. ¹Gifu Pharmaceutical University, Gifu, Gifu, Japan and ²School of pharmacy, Aichi Gakuin University, Nagoya, Aichi, Japan.

The number of allergic patients has been increasing rapidly in industrialized countries in last 2 or 3 decades. The causes of rapid increase of the patients are considered to be due to environmental chemicals. As the contamination of ground water

by chloride organic chemicals has been social problem, we paid attention to the chemicals that have toxicity and persistency. We reported that these exposures enhanced passive sensitized reaction such as passive cutaneous anaphylaxis (PCA) reaction, and trichloroethylene (TCE) had the strongest effect among the chemicals. In this study we investigated a relationship between TCE exposure and active sensitized reaction. BALB/c mice were given TCE (0.03 mg/L and 3 mg/L) as drinking water for 2 or 4 weeks, and mice were immunized with ovalbumin (OVA) twice. On the final day in TCE exposing period, active cutaneous anaphylaxis (ACA) reaction was elicited in the ear of mice by injecting of OVA. Blood and spleen were collected from each mouse under diethylether anesthesia. Antigen-specific IgE and histamine levels in serum were measured and T lymphocyte proliferation in spleen cells was assayed. As a result ACA reaction was enhanced by TCE exposure in a dose-dependent manner. OVA specific IgE level in mice exposed to 0.03 mg/L TCE for 4 weeks was enhanced compared with control. Spleen T cell proliferation was enhanced in mice exposed to 3 mg/L TCE. From these results, TCE exposure is considered to relate with T lymphocyte proliferation, not with antigen-specific IgE production. TCE exposure by drinking water may increase allergic patients and exacerbate allergic disease.

1135 VALIDATION OF LLNA-DA ASSAY FOR ASSESSING SKIN SENSITIZATION POTENTIAL.

Objectives: The local lymph node assay (LLNA) is a stand alone test method using mice to assess skin sensitization potential of chemicals. The LLNA-DA is a non-radioisotopic modification of the LLNA, in which ATP instead of 3H-thymidine is measured for lymphocyte proliferation. The objectives of this study are to experimentally evaluate the inter-laboratory reproducibility and predictability of LLNA-DA.

Materials and Methods: 10 laboratories participated in the study to conduct experiment. Twelve chemicals were uniformly selected from strong-, mild-, weak- or non-sensitizers. 3 chemicals were examined by all laboratories, while 9 chemicals were examined by 3 laboratories under a balanced allocation design. The cut-off value for the stimulation index (SI) was set as 3.0.

Results and Discussion: The results for common 3 chemicals and 5 allocated chemicals were consistent with small variances in SI. Achieved sensitivity, specificity and concordance were 87.5% (7/8), 100% (3/3) and 90.9% (10/11), respectively, which showed good reproducibility and predictability.

1136 USE OF AN ENHANCED LOCAL LYMPH NODE ASSAY TO CORRECTLY CLASSIFY IRRITANTS AND FALSE POSITIVE SUBSTANCES.

M. K. Reeder, Y. M. Broomhead, L. DiDonato and G. L. DeGeorge. *MB Research Laboratories, Spinnerstown, PA.*

A major weakness of the local lymph node assay is that irritants can produce increases in the stimulation index (SI<3) in a manner analogous to true sensitizers or allergens. Due to the short-duration of the LLNA, many known human irritants are not detected as such during the course of the test (ear swelling and edema). The prototypical false positive irritant in the LLNA is SLS at concentrations above 20-25%. Herein we use an enhanced LLNA with immunophenotypic endpoints and measurements of ear thickness to characterize, identify, and correctly classify additional irritants, including benzalkonium chloride and ethylenediamine. Treatment with these irritants can result in maximum SI values from 5.4 to 13.3. Using flow cytometric analysis of surface markers on lymphocytes, including B220, CD3, I-Ak (MHC), and CD69, we are able to distinguish true sensitizers from these from

other anomalous test substances that increase Stimulation Index by unknown mechanisms. None of the false positive irritants exhibited the hallmarks of true sensitizers, specifically increases in percent B220+, I-Ak + and cd69/iak++ cells. In contrast, irritants tended to decrease the percent of B-lymphocytes while increasing the percent of T-lymphocytes in the draining lymph node. Thus, in the event that irritancy is present or suspected as a known property of the test substance, we herein define a tier-testing approach which integrates additional endpoints including ear thickness measurements and immunophenotypic analysis. This Enhanced LLNA (E-LLNA) allows a more thorough assessment and accurate classification of problematic substances.

1137 CHARACTERIZATION OF PHOTO-ALLERGIC PROPERTIES OF PSORALENS USING A FLOW CYTOMETRY-BASED PHOTO-LLNA WITH IMMUNOPHENOTYPE MARKERS.

G. L. DeGeorge, M. K. Reeder and Y. M. Broomhead. *MB Research Laboratories, Spinnerstown, PA.*

The phototoxicity of psoralens, specifically 8-methoxypsoralen (8-MOP) and 5-methoxypsoralen (5-MOP), commonly found in teas, celery, parsley and at least 12 other plant species, evoke a variety of phototoxic effects, including photo-genotoxicity, photo-irritation (dermatitis) and therapeutic uses as in PUVA therapy for psoriasis. Historically, 8-MOP has been classified as a very strong photo-irritant, in both in vivo and in vitro phototoxicity assays. There are sporadic reports of the photo-sensitization potential of the psoralens, however, due to their potent dermal irritation properties, it is difficult to establish their allergenic properties based on skin erythema or edema endpoints. To determine if psoralens possess photo-allergic (DTH) properties, in addition to their irritative effect, we employed a modified LLNA using solar simulated UVA light source following topical application 0.01% to 1.0% 8-MOP or 5-MOP). All concentrations above 0.03% were photo-irritating, causing maximum ear swelling up to 97%, accompanied by dose dependent increases in the Stimulation Index (SI) up to 13.7 for 8-MOP and 10.9 for 5-MOP. The positive photo-sensitization responses were all accompanied by dermal irritation. Using flow cytometric measurement of %B and T lymphocytes, as well as % CD69 and MHC+ subsets, we confirmed that both 8-MOP and 5-MOP increased the % of B cells and CD69/MHC positive lymphocytes, consistent with the profile of dermal sensitizers. In addition, the typical decrease in %T cells induced by irritants, was not observed, but rather the opposite, further supporting the strong allergenic potential of these psoralens.

1138 EFFECT OF UVB LIGHT ON THE DETECTION OF PHOTOSENSITIZING POTENTIAL OF CHEMICALS WITH THE MURINE UV-LLNA.

P. Ulrich, N. Runser, S. Jeannine and R. Schaffner. *Safety Profiling & Assessment, Novartis Pharma AG, Basel, Switzerland.*

We investigated the influence of UVB light on the detection of photosensitizing potential of chemicals and drugs in the murine local lymph node assay (LLNA). Two light sources were used: a mercury vapor lamp ($\lambda_{max}=365nm$; UVB filter < 320nm) and a xenon lamp simulating natural sun light including UVB. Female BALB/c mice were treated either topically on the dorsum of the ears or orally for 3 days followed by exposure to light. In a first experiment mice received 3 daily UVB doses of 0.02, 0.1, 0.5 J/cm² (mercury vapor lamp w/o UVB-filter) including controls without light or a UVA exposure w/o UVB. A light dose-dependent skin irritation (ear weight) and hyperplasia of the ear draining LN (weights and cell counts) was observed on day 4 with a NOEL of 0.02 J/cm² UVB. UVA light (5 and 10 J/cm²) from the xenon lamp induced skin photoirritation due to the lamp's UVB (0.15 and 0.3 J/cm²), however no effects were seen in the LN on necropsy day 4. Sacrifice of similarly treated mice on day 9 revealed that LN hyperplasia had developed over this time period. With topical tetrachlorosalicylanilide (TCSA, a contact photoallergen), we could demonstrate the confounding activity of UVB (Xenon) in the detection of chemically induced photoirritation of the skin after 4 days, whereas the LN showed the same photoreactivity to TCSA regardless whether UVB was included or not. Oral application of Sparfloxacin (20, 60, 180mg/kg b.w.), a photo-sensitizing antibiotic, led to dose-dependent increase in ear weight and LN hyperplasia on day 4, when animals were exposed to UVA light (10 J/cm²). Using the sunlight simulator in the same experimental setting, similar confounding activity of UVB was observed in the skin, whereas the LN activation was not affected by the UVB. After 9 days, confounding activity of UVB was clearly visible in the ear skin and the ear-draining LN at the high dose of Sparfloxacin. Our results demonstrate that the use of sun light simulators in in vivo photosensitization testing is possible, however with careful adjustment of experimental conditions.

1139 IDENTIFICATION OF SKIN SENSITIZING CHEMICALS IN A REDUCED LLNA.

D. Basketter¹, G. Patlewicz², E. Gerberick³, C. Ryan³, P. Kern⁴, C. Betts⁵, R. Dearman⁵ and I. Kimber¹. ¹SEAC, Unilever, Sharnbrook, United Kingdom, ²European Chemicals Bureau, JRC Ispra, Italy, ³Procter & Gamble Company, Cincinnati, OH, ⁴Procter & Gamble Company, Brussels, Belgium and ⁵Syngenta CTL, Macclesfield, United Kingdom.

For the identification of potential skin sensitizing substances, the local lymph node assay (LLNA) has, for many years, been accepted as a full replacement for guinea pig methods. In part this was due to the scientific advantages provided by the LLNA, but also due to the significant animal welfare benefits this method offers. However, the desire to reduce further animal usage is in conflict with the need to complete toxicological evaluations of tens of thousands of chemicals under new European legislation (REACH: Registration, Evaluation and Authorisation of Chemicals). Consequently, we have conducted a retrospective evaluation of a recently published LLNA dataset comprising 211 chemicals. The work addressed whether it is possible to obtain a satisfactory identification of skin sensitization hazard using only a comparison of the top dose group with the concurrent vehicle treated control. In these analyses, negative results were not accepted as secure negatives if the top dose group was treated with <10% of the test chemical. The results indicated that a reduced LLNA employing on the top dose group (as per OECD Guideline 429) would provide about 99% accurate identification of sensitizers and non-sensitizers: 166 of 168 sensitizers were correctly identified, as were all non-sensitizers (42/42). Only one chemical was tested below 10% and, being negative, had a result which was regarded for these purposes as invalid. Thus, overall, the reduced LLNA gave 208/210 predictions that were identical to the full assay, including a 100% accurate identification of non-sensitizers; in only a single instance was the interpretation inconclusive due to the use of a low test concentration. In our view, it would be possible, for certain specific purposes, and in some circumstances, to consider the utility of a reduced LLNA as a contribution to a reduced requirement for animal numbers.

1140 THE IMPACT OF REDUCING ANIMAL NUMBERS IN THE LOCAL LYMPH NODE ASSAY.

J. Chaney¹, C. Ryan¹, P. Kern², G. Patlewicz³, D. Basketter⁴, C. Betts⁵, R. Dearman⁵, I. Kimber⁵ and E. Gerberick¹. ¹Procter & Gamble Company, Cincinnati, OH, ²Procter & Gamble Company, Brussels, Belgium, ³European Chemicals Bureau, JRC, Ispra, Italy, ⁴SEAC, Unilever, Sharnbrook, United Kingdom and ⁵Syngenta CTL, Macclesfield, United Kingdom.

New European legislation requires complete toxicological profiles for a large number of chemicals, including evaluations for skin sensitization potential. The Local Lymph Node Assay (LLNA) is an accepted alternative to guinea pig methods for skin sensitization testing which provides important animal welfare benefits. OECD guideline 429 for the LLNA requires 3 test concentrations and a vehicle control group with a minimum of 4 animals per group. Conduct of the assay in this manner to satisfy REACH will result in significant animal usage. Therefore the possibility of conducting the assay as a screening test with a single high dose test group and a concurrent vehicle control has been evaluated and was found to provide an accurate identification of sensitizers and non-sensitizers. To reduce further animal usage, the impact of conducting this LLNA screen using 2 mice per group has been explored. To determine the effect on the stimulation index (SI), 34 datasets with individual animal data comprising 23 chemicals were used. SIs were calculated based on every possible combination of 2 control group dpm values and 2 high-dose dpm values. For most studies, there were 5 control values and 5 high dose values, so there were 10 possible pairs of control values and 10 possible pairs of high dose values and therefore 100 possible sets of 4 values (2 control + 2 high-dose). Of the sensitizer datasets, 20 of 26 had 96% or more of the possible SI combinations greater than 3. The sensitizer with the lowest number of positive combinations was the very weak allergen, isopropyl myristate, at 61%. Excluding the 3 sodium lauryl sulfate datasets, a reported false positive in the LLNA, all non-allergen datasets had $\leq 13\%$ positive combinations. Based on this analysis, conduct of a cut-down LLNA with 2 mice per group provides a means for further reduction of animal usage.

1141 EVALUATION OF HIGH THROUGHPUT METHODS TO SCREEN FOR GENE EXPRESSION CHANGES FOR PREDICTING THE SKIN SENSITIZATION POTENTIAL OF CHEMICALS.

C. Ryan, S. Torontali, L. Foertsch, J. Kennedy, K. Juhlin, L. Gildea and E. Gerberick. *Procter & Gamble Company, Cincinnati, OH.*

Twenty nine genes that are regulated following the interaction of chemical allergens with peripheral blood-derived dendritic cells (PBMC-DC) have been identified as potential endpoint measures for use in an in vitro assay for assessing the skin sensi-

tization potential of chemicals. These genes, derived using real-time PCR (RT-PCR), now require further evaluation with a larger test chemical set. For this purpose two multiplexed assays using fluorescent microspheres based on Luminex® xMAP® technology are being evaluated as potential high throughput put screening (HTS) methods, the Radix bead assay and Panomics QuantiGene® Plex. The Radix assay uses a single 25-mer oligonucleotide probe selected from the Affymetrix GeneChip® probe set linked to xMAP® beads and biotinylated cRNA targets as input samples. The QuantiGene® Plex platform uses probe sets based on automated probe selection criteria, xMAP® beads, branched DNA signal amplification technology and total RNA as input samples. The performance of these platforms was evaluated in studies conducted using RNA obtained from PBMC-DC treated with doses of the contact allergen dinitrobenzenesulfonic acid. In both assays, for all genes there was agreement between the bead data and the RT-PCR data in the direction of the gene expression change, either up- or down-regulated, relative to control for at least one of two allergen doses. However, for most genes, the RT-PCR treatment-versus-control fold-change values tended to be larger than the Radix assay fold-changes. Run-to-run variability of the Radix assay was assessed and overall, the fold-changes were quite similar. Studies with the QuantiGene® Plex platform showed a better correlation of fold change values with RT-PCR, especially for genes with large changes across treatment. Based on this initial examination both platforms appear to be potential HTS methods for evaluating gene expression changes, with the QuantiGene® Plex data having a better correlation with RT-PCR data.

1142 ECPA INTERLABORATORY STUDY INVESTIGATING THE SUITABILITY OF AN AQUEOUS VEHICLE IN THE MOUSE LOCAL LYMPH NODE ASSAY.

M. Woolhiser¹, C. Wiescinski¹, P. Botham², D. Lees², E. Debruyne³, M. Repetto-Larsay³, G. Ladics⁴, D. Hoban⁴, A. Gamer⁵, M. Remmele⁵, W. Wang-Fan⁶, L. Ullmann⁶, R. Billington⁷ and J. Mehta⁷. ¹The Dow Chemical Company, Midland, MI, ²Syngenta Crop Protection, Inc., Alderley Park, United Kingdom, ³Bayer CropScience, Sophia Antipolis, France, ⁴The DuPont Company, Wilmington, DE, ⁵BASF Aktiengesellschaft, Ludwigshafen, Germany, ⁶RCC Ltd., Itingen, Switzerland and ⁷Dow AgroSciences, Oxford, United Kingdom.

The mouse LLNA has become broadly accepted and is requested as the primary animal test for evaluating the dermal sensitization potential of chemicals. As pesticides formulations are typically a specific complex blend of chemicals, traditional vehicles prescribed for the LLNA can be incompatible with these formulations leading to inaccurate test results and hazard identification. The objective of this study was to evaluate the effectiveness of an aqueous dilution of Pluronic® L92 block copolymer surfactant (L92) as a vehicle in the mouse LLNA amongst 5 labs using 3 chemicals with known sensitization potential, hexylcinnamaldehyde (HCA), 36.5% formaldehyde in water (FOR) and potassium dichromate (PDC). Identical LLNA protocols and test material lots were used. Female CBA mice were treated on 3 consecutive days with HCA (3 – 30%), FOR (1 – 20%) or PDC (0.02 – 0.5%) diluted in 1% L92. After 2 days rest, lymph nodes were harvested for evaluation of cell proliferation (³H-thymidine incorporation). All labs observed positive LLNA responses (SI > 3) for the 3 chemicals. For HCA, the range of concentrations (6.7 – 17.6%) calculated to elicit 3-fold increases in proliferation (EC3 values) were similar with that reported (8%) using acetone and olive oil. PDC elicited EC3 values (0.06 – 0.33%) which encompass that reported using L92 (0.17%) or DMSO (0.06 – 0.18%). EC3 values for 36.5% FOR ranged from 3.8 – 12.3% v/v. These data reproduced previous results using L92 and are only slightly above the EC3 measured with FOR in acetone. LLNA results using 1% L92 as a vehicle were reproducible amongst 5 labs and support the use of 1% L92 as a vehicle in the mouse LLNA. This work was sponsored and funded by the European Crop Protection Association.

1143 USE OF AN EX VIVO LOCAL LYMPH NODE ASSAY FOR CONTACT HYPERSENSITIVITY ASSESSMENT.

J. R. Piccotti, K. L. Donahoo and S. A. Knight. *Drug Safety R & D, Pfizer Global Research & Development, Ann Arbor, MI.*

The murine local lymph node assay (LLNA) is used to assess the contact hypersensitivity potential of compounds. In the standard assay, mice are treated topically with test compound to the dorsum of both ears on Days 1-3. The induction of a hypersensitivity response is assessed on Day 6 by injecting ³H-thymidine into a tail vein, and measuring thymidine incorporation into DNA of lymph node cells draining the ears. The *ex vivo* LLNA is conducted similarly except lymphocyte proliferation is assessed after *in vitro* incubation of lymph node cells with ³H-thymidine, which significantly reduces the amount of radioactive waste. We recently developed this alternative method with the contact sensitizers hexylcinnamic aldehyde and oxazolone, and the nonsensitizer methyl salicylate. In the current study, additional compounds were tested to further validate the assay for hazard assessment of con-

tact hypersensitivity, and to evaluate the ability of the assay to estimate allergenic potency. Female BALB/c mice were treated on Days 1-3 with 2 nonsensitizers (4'-methoxyacetophenone, diethyl phthalate), 3 weak sensitizers (hydroxycitronellal, eugenol, citral), 2 moderate sensitizers (isoeugenol, phenyl benzoate), and 1 strong sensitizer (dinitrochlorobenzene). Hexylcinnamic aldehyde also was tested, and served as a positive control. On Day 6, lymph nodes were removed, and single-cell suspensions were prepared. Cells were incubated overnight with ³H-thymidine. The *ex vivo* LLNA accurately estimated the relative potency of the compounds tested. The EC3 values were as follows: 4'-methoxyacetophenone (>50%), diethyl phthalate (>50%), hydroxycitronellal (20.4%), eugenol (13.6%), citral (8.9%), isoeugenol (3.8%), hexylcinnamic aldehyde (2.7%), phenyl benzoate (2%) and dinitrochlorobenzene (0.02%). These results were consistent with published reports using the standard LLNA, and provided further evidence that supports the use of this approach for hazard assessment of contact dermatitis. Further, these data demonstrated that the *ex vivo* LLNA could be used to estimate allergenic potency.

1144 COMPARATIVE EVALUATION OF THE *IN VITRO* SKIN SENSITIZATION TEST; HUMAN CELL LINE ACTIVATION TEST (H-CLAT) WITH LLNA AND HUMAN DATA.

T. Ashikaga¹, N. Kosaka², S. Sono¹, S. Hitoshi², S. Hiroyuki² and H. Itagaki¹. ¹Quality Assurance Center, Shiseido Co., Ltd., Yokohama, Kanagawa, Japan and ²Safety and Microbial Control Research Center, Kao Corporation, Ichikai, Tochigi, Japan.

We have reported that a 24-hr exposure of THP-1 cells (human monocytic leukemia cell line) to sensitizers was sufficient to induce augmented CD86 and/or CD54 expression, and we have developed *in vitro* skin sensitization test named h-CLAT on the basis of that finding. Our previous inter-laboratory study in Japan revealed that the protocol of h-CLAT is easy to transfer, and inter-laboratory reproducibility is basically good. The aim of this study is to confirm the predictive capacity of h-CLAT for skin sensitization activity by employing a larger number of chemicals. In this study, more than 60 known chemicals were evaluated with h-CLAT. We selected these chemicals according to the results of LLNA in the following categories: extreme, strong, moderate, and weak sensitizers, and non-sensitizers. Correspondence with LLNA was about 90%. h-CLAT could predict not only extreme and strong sensitizers, but also moderate and weak sensitizers as positive. There were a few false-negatives (e.g., benzoyl peroxide, hexyl cinnamic aldehyde) and false-positives (e.g., 1-bromobutane, diethylphthalate), but most chemicals were evaluated correctly. Among sensitizers, some enhanced both CD86 and CD54, and some enhanced only one of them. The use of the combination of CD86 and CD54 as a positive indicator improved the accuracy of the test. We calculated the estimated concentration to induce CD86 or CD54 expression with RFI ≥ 150% for CD86 (EC150) or RFI ≥ 200% for CD54 (EC200) in h-CLAT and compared these values with the EC3 values of LLNA. Especially, there was a good correlation between EC150 of CD86 and EC3. These data suggest that h-CLAT could be useful not only for hazard identification, but also for estimating the allergic potency of chemicals. Furthermore, comparing h-CLAT with human test data, the correspondence was more than 80% (for about 50 chemicals). In conclusion, h-CLAT is a useful cell-based *in vitro* skin sensitization method.

1145 USE OF A B CELL MARKER TO DISCRIMINATE BETWEEN THE IRRITANT AND ALLERGENIC POTENTIAL OF D-LIMONENE.

J. Lalko and A. Api. *Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ.*

The local lymph node assay (LLNA) is a validated method for the identification of potential contact allergens. History has shown the LLNA to be a reliable model, though a small number of irritants result in false positives. The use of a B cell marker, specifically the % increase in B220⁺ cells in the draining lymph nodes, has been demonstrated to discriminate between allergens and irritants in the LLNA. *d*-Limonene is a cyclic terpene that rapidly autoxidizes. The oxidation products are known to be contact allergens, while un-oxidized/high purity *d*-limonene (HDL) is not considered sensitizing. However, HDL has been reported to result in positive responses in the LLNA and is a strong irritant in human dermal primary irritation tests. These facts have lead to the question 'Are HDL responses in the LLNA irritant or allergenic?'. To answer this we conducted a series of LLNAs utilizing the B220 endpoint. Groups of mice (n=5, CBA/Ca) were treated on the ears for 3 consecutive days with neat HDL or 50% HDL in one of four vehicles - ethanol (EtOH), 1:3 EtOH:diethyl phthalate (DEP), 3:1 EtOH:DEP, DEP. Controls received dinitrochlorobenzene (DNCB, allergen); Benzalkonium chloride (BZC, irritant), vehicle or left naïve. Draining lymph nodes were excised on day 6; a single cell suspension was prepared and stained with fluorescent-labeled anti-B220 antibody. The suspensions were analyzed by flow cytometry. A % test:vehicle B220⁺ ratio of > 1.25 is typically indicative of an allergenic response. In the present study the 1.25 cutoff could not be relied upon, due to a slight decrease in the background B220⁺ population. Therefore, each group was compared to the appropriate controls on its own

merits. There was good discrimination between the responses to BZC (mean B220⁺ ratio = 1.48) compared to DNCB (mean B220⁺ ratio = 3.09). Both neat (mean B220⁺ ratio = 1.57) and each of the 50% solutions (mean B220⁺ ratio = 1.44) of HDL resulted in B220⁺ ratios similar to that of BZC, indicating that HDL was acting as an irritant. The vehicle employed appeared to play no role in the response.

1146 PLASMACYTOID DENDRITIC CELLS AS A TOOL FOR TESTING ALLERGENICITY OF CHEMICALS.

M. Snell, M. Klausner, S. Ayeahunie and P. J. Hayden. *R & D, MatTek Corporation, Ashland, MA.*

A predictive test system for assessing the allergenicity potential of chemicals will have enormous significance in industries involved in cosmetic, personal hygiene and topical medication products and in the fields of dermatology and immunology. Since dendritic cells/Langerhans cells (DC/LC) are the first cells responsible for sampling skin and mucosal surfaces for changes in the antigen microenvironment, we investigated whether phenotypic and functional changes to subset of DC, plasmacytoid dendritic cells (pDC), could be used to identify contact allergens. To achieve this goal, normal human DC were generated from CD34⁺ progenitor cells and were cryopreserved. Frozen DC were thawed and the pDC fraction (CD123⁺/CD11c⁻) was collected using FACS sorting. The pDC were cultured, expanded, and pulsed with chemical allergens (n=12) or irritants (n=7). Sub-toxic concentrations of each chemical was determined using FACS analysis on propidium iodide stained cells. Concentrations that resulted in >75% cell viability were used in the study. Results showed that exposure of pDC (n=6 donors) to allergens induced an increase (≥ 1.5 fold) in surface expression of CD86 for 11 of the 12 allergens; however, 6 of 7 irritants did not result in increased CD86 expression. Based on these findings, a prediction model was developed with a sensitivity of 92%, specificity of 86%, and an accuracy of 89%. Increased levels of released IL-6 were also detected in culture supernatants of allergen-pulsed pDC (6 of 6) but not from cultures of non-allergen-treated pDC. In conclusion, the use of CD86 expression on pDC appears to be a sensitive and specific predictor of allergenicity of chemicals. When compared with existing animal models, the assay is advantageous because high throughput screening of chemicals using cells of human origin is possible at low cost.

1147 ROLE OF CELL-SURFACE THIOLS IN ACTIVATION OF HAPTEN-TREATED THP-1 CELLS AND EVALUATION AS A BIOMARKER FOR IN VITRO SENSITIZATION TEST.

M. Hirota¹, M. Suzuki¹, S. Hagino¹, S. Kagatani², Y. Sasaki², S. Aiba² and H. Itagaki¹. ¹Quality Assurance Center, Shiseido Co Ltd., Yokohama-shi, Kanagawa, Japan and ²Department of Dermatology, Tohoku University of Medicine, Sendai-shi, Miyagi, Japan.

It is known that in the induction phase of skin sensitization, antigen-presenting cells (APC), including dendritic cells (DCs), migrate into lymph nodes and present antigens to T cells after having been activated by haptens. Furthermore, the activation is accompanied with the augmentation of CD86 expression. Human monocytic cell line THP-1 is used as an indicator for predicting skin sensitization potential because its response to haptens is similar to that of DCs. Although p38 mitogen-activated protein kinases (MAPKs) and intracellular redox imbalance play crucial roles in the activation of THP-1 by skin sensitizers, the trigger of cell activation has not been identified. Therefore, we examined whether haptens induce THP-1 activation directly or indirectly. 2,4-Dinitrochlorobenzene (DNCB), but not DNP-BSA conjugate, induced CD86 expression. DNCB and nickel sulfate (NiSO₄) induced related changes of cell-surface thiols and phosphorylation of p38 MAPK. However, DNCB is membrane-permeable, and so its direct effect may not be confined to cell membrane proteins. Furthermore, we found that CD86 expression and macrophage inflammatory protein-1 β (MIP-1 β) production were augmented by the membrane-impermeable thiol blocker 5,5'-dithiobis(2-nitrobenzoic acid) (DTNB), and these changes were suppressed by an inhibitor of the p38 MAPK pathway, SB203580. These results suggest that cell-surface thiols are one of the triggers of cell activation. Finally, we evaluated about 60 chemicals, including allergens and non-allergens. When tentative criteria for a significant change of surface thiols (RFI $\leq$ 85% and RFI $\geq$ 115 %) were applied, the accuracy of in vitro assay vs. in vivo assay was 80 %. Taken together, our data indicate that cell-surface thiols might be useful as a biomarker for an in vitro sensitization assay.

1148 THE PREDICTION AND CONFIRMATION OF POTENTIAL RESPIRATORY SENSITIZERS GENERATED FROM INDOOR AIR SAMPLES.

S. Anderson, R. Wells, A. Fedorowicz, B. J. Meade, L. F. Butterworth and A. E. Munson. *NIOSH, Morgantown, WV.*

Of the 89 million people in the US working in indoor office environments, between 35 and 60 million experience symptoms such as eye, nose and throat irritation, headache, and fatigue. Several investigations into these complaints have as-

cribed the effects to volatile organic compounds (VOC) emitted from building materials, cleaning formulations or other consumer products. Additional compounds can result from these VOC's, being transformed by hydroxyl or nitrate radicals and ozone, present in indoor environments. Several dicarbonyls, such as glyoxal (GX), methylglyoxal (MG), glycolaldehyde (GA) and diacetyl (DA) have been identified as VOC reaction products of indoor environment chemistry. The sensitization potential of these compounds was assessed using three quantitative structure-activity relationship (QSAR) programs. DEREK for Windows and Logistic Regression predicted all compounds as sensitizers, while TOPKAT 6.1 predicted all compounds except for MG. Next the compounds were tested in a combined irritancy and local lymph node assay (LLNA). Mice were exposed dermally to GX (0.35-1.5%) MG (0.05-1%), GA (0.8-3.2%) or DA (1.25-12%). All compounds except for GX were found to be irritants. All compounds were found to be sensitizers resulting in EC3 values of 0.74, 0.18, 1.8, and 1.9%, respectively. No changes in organ, body weight, or serum IgE levels were observed following exposure to the compounds. MG, GX, and GA did not significantly increase IgE+B220⁺ cell populations in the draining lymph nodes, but 5% DA resulted in significant increases in both B220⁺ and IgE+B220⁺ cells. The four compounds generated by indoor air chemistry were predicted by QSAR analysis to be sensitizers and confirmed using an animal model. The identification of these compounds as sensitizers may help to explain some of the health effects associated with indoor air complaints.

"The findings and conclusions in this report are those of the author(s) and do not necessarily represent the views of the National Institute for Occupational Safety and Health."

1149 EVALUATION OF THE SENSITIZATION POTENTIAL OF CHEMICALS USING IL-8 RELEASE IN NAIVE THP-1 CELLS.

E. Corsini, L. Lucchi, C. L. Galli and M. Marinovich. *Department Pharmacological Sciences, University of Milan, Milan, Italy.*

At present, the assessment of the allergenic potential of chemicals is carried out using experimental models. Over the last decade, several in vitro methods have been proposed to identify the potential of chemicals to induce skin sensitization to meet current animal welfare and public opinions. Many attempts have been made to develop in vitro sensitization tests using primary dendritic cells derived from peripheral blood mononuclear cells or from CD34⁺ hematopoietic progenitor cells. The major limitations of such tests are donor-to-donor variability, low levels in the source, and a possible shortage of human sources.

The aim of this study was to establish an in vitro test to identify chemical allergens using the human monocytic leukemia cell line, THP-1, in order to avoid some of these difficulties. Many chemokines, including eotaxin, macrophage inflammatory protein-1 α , RANTES and interleukin (IL)-8 have all been consistently reported to be up-regulated in allergic inflammation. Among them, we investigated whether IL-8 production can provide a methodology for the detection of allergens. THP-1 cells were exposed to contact allergens (nickel sulfate, p-phenylenediamine, dinitrochlorobenzene, cinnamaldehyde, tetramethylthiuram disulfide), to respiratory allergens (diphenylmethane diisocyanate, trimellitic anhydride, ammonium hexachloroplatinate) and to irritants (sodium lauryl sulphate, salicylic acid, phenol). Following 48 h of incubation, IL-8 production was significantly increased after stimulation with all allergens tested, with the exception of trimellitic anhydride, whereas irritant exposure failed to induced IL-8 release. The lack of IL-8 production by trimellitic anhydride can be explained by the readily hydrolysis of this chemical in water to trimellitic acid, which is not an allergen.

In conclusion, IL-8 production by THP-1 cells provides a promising in vitro tool for identification and discrimination between allergens and irritants.

1150 CAN LOW MOLECULAR WEIGHT (LMW) CONTACT ALLERGENS INDUCE ALLERGY IN THE RESPIRATORY TRACT?

F. Kuper, R. Stierum, A. Boorsma, J. Bruijntjes, M. Schijf and J. Arts. *Toxicology and Applied Pharmacology, TNO Quality of Life, Zeist, Utrecht, Netherlands.* Sponsor: V. Feron.

Most LMW allergens cause contact allergy in the skin, whereas only a small number are known to cause respiratory allergy. These respiratory allergens are all positive in the LLNA and are thus able to induce skin sensitization as well. The question therefore is: can skin allergens induce allergy in the respiratory tract when inhaled, and, if so, what are the consequences? BN rats were sensitized by two dermal applications of dinitrochlorobenzene (DNCB; 1% at day 0; 0.5% at day 7). Controls received the vehicle. The challenge consisted of nose-only inhalation of 20 mg/m³ of

DNCB for 15 min, at day 21. Four groups were used: unsensitized/unchallenged or -/-; +/-; -/+ and +/+. The following parameters were examined: breathing frequency and pattern, total IgE, specific IgG, histopathology of the respiratory tract and bronchoalveolar lavage (BAL) cells. Lungs were examined immunohistochemically or were analyzed for clusters of activated genes (Affymetrix microarrays). Sensitization via the skin induced upregulation of a cluster of immune-related genes in lung. Inhalation challenge with DNCB in sensitized animals did not provoke respiratory allergy based on breathing parameters, airway inflammation, IgE, and gene activation. However, the total cell number in BAL in the +/- group was about 3 times higher than in the other 3 groups, largely due to an increase in eosinophils. Thus, the immune system of the BN rat recognizes the contact allergen DNCB but is only minimally affected by the compound. This implies that the hazard of inhaling contact allergens may be of a completely different magnitude than that of typical respiratory allergens. It is important to realize that this is based on a single inhalation exposure. To substantiate the conclusion, the response upon repeated exposure should be investigated, because, if 'contact' allergy can be evoked in the respiratory tract by allergens like DNCB, it is possibly an insidious process. The research was funded by CEFIC-LRI

1151 THE RESPIRATORY LOCAL LYMPH NODE ASSAY (RESPIRATORY LLNA) AS A TOOL TO STUDY RESPIRATORY SENSITIZERS.

J. Arts¹, W. de Jong², M. Schijf¹, A. de Klerk², F. Kuper¹ and H. van Loveren^{2,3}.
¹TNO Quality of Life, Zeist, Netherlands, ²RIVM, Bilthoven, Netherlands and
³Maastricht University, Maastricht, Netherlands.

The LLNA is used to test the potential of low molecular weight (LMW) compounds to induce sensitization via the skin. All LMW respiratory allergens tested, have also tested positive in this dermal assay. However, it is unknown if potential and potency via this route are comparable to those via the inhalation route. In the present study, BALB/c mice were exposed nose-only to trimellitic anhydride (TMA; 30 mg/m³), phthalic anhydride (PA; 15 mg/m³), hexamethylene diisocyanate (HDI; 15 mg/m³), or toluene diisocyanate (TDI; 7.5 mg/m³), or to 30 mg/m³ of dinitrochlorobenzene (DNCB) or oxazolone (OXA). The animals were exposed during 3 days for 45, 90, 180 or 360 min/day. The animals were necropsied 3 days after the last exposure, the draining lymph nodes (LNs) were excised and harvested cells were processed with 3H-thymidine to determine proliferation. For comparison, the dermal LLNA was performed as well. Negative (vehicle) controls were exposed by ear application to acetone-olive oil (4:1) and by inhalation to acetone. In addition, cytokine production (IFN- γ and IL-4) was measured in the LNs using ELISA. All allergens induced grossly observed enlargement of and proliferation in the mandibular LNs draining the upper respiratory tract. Increased INF- γ was found with all allergens tested: DNCB, OXA, TMA and HDI, whereas increased IL-4 was found with the typical respiratory allergens TMA and HDI only. With regard to potency ranking: the typical contact allergens DNCB and OXA were at least of comparable potency as TMA in the respiratory LLNA. In analogy to the dermal LLNA, the present results in the respiratory LLNA suggest that strong contact allergens such as DNCB and OXA can also act as potent sensitizers by inhalation. The risk of humans of course depends on exposure. With regard to cytokine production IL-4, but not IFN- γ , seems to be able to discriminate between typical respiratory and contact allergens. This research is funded by the Dutch Ministries of VWS and SZW.

1152 LACK OF EFFECT OF PHTHALATES ON TYPE 2 CYTOKINE EXPRESSION PROFILES.

C. J. Betts, L. Beresford, H. Caddick, R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, CHESHIRE, United Kingdom.*

The prevalence of IgE-mediated allergic diseases (including respiratory allergy and asthma) in Western Europe and the US has been increasing over the last decades. It has been suggested that one possible cause is the presence in the environment of chemicals that may act as adjuvants, including certain commonly used phthalate plasticizers, such as di-(2-ethylhexyl) phthalate (DEHP) or diisononyl phthalate (DINP). The induction of IgE antibody is orchestrated by the development of T helper (Th) cells with a type 2 cytokine secretion profile (interleukins [IL]-4, -5, -10 and -13). In the current experiments we have examined the ability of the phthalates DEHP and DINP to influence cytokine production by activated murine lymph node cells (LNC). LNC preparations were isolated after *in vivo* priming by subcutaneous injection of the antigen keyhole limpet hemocyanin (KLH) and alum (an adjuvant for IgE responses). Culture of KLH-primed LNC with KLH for 96 hr resulted in marked lymphocyte activation characterised by vigorous proliferation and expression of a preferential Th2 type cytokine profile with relatively low levels

of Th1 cytokines interferon γ and IL-12. Co-culture with DEHP or DINP (0.1 to 1000 μ M) in the presence of various concentrations of KLH (incorporating suboptimal doses for both read outs) failed to impact on either proliferation or cytokine secretion profiles. These data indicate that the reported adjuvant effects of phthalates are not as a result of the ability of these chemicals to modulate cytokine secretion profiles of activated LNC.

1153 DIACETYL, AN ARTIFICIAL FLAVORING COMPOUND IN POPCORN, INDUCES CONTACT SENSITIZATION IN FEMALE BALB/C MICE.

W. Auttachoat, K. L. White and T. L. Guo. *Phar/Toxicology, Virginia Commonwealth University, Richmond, VA.*

Diacetyl (2,3-butanedione: BTD) is a natural by-product of secondary or malolactic fermentation. BTD is used for artificial flavoring, which adds the characteristic flavor most commonly associated with butter and cream in food products (e.g., popcorn). It has been reported that exposure to diacetyl can result in damages to the skin, eyes, mucous membrane and respiratory system. The objective of the present study was to evaluate the hypersensitivity inducing potential of BTD using Local Lymph Node Assay (LLNA), Irritancy Test (IRR), Mouse Ear Swelling Test (MEST), flow cytometric analysis, and cytokine production. Female BALB/c mice were exposed to BTD at levels of 1%, 2.5%, 5%, 10% and 25% (w/v) in acetone: olive oil (4:1 AOO) vehicle by dermal application in LLNA and IRR. In the MEST assay, animals were sensitized with either 10% or 25% (w/v in AOO) and challenged with 25% BTD. There were no significant changes in the body weight for BTD treatment groups in any of the studies when compared to the vehicle controls. An increase in the proliferation of auricular lymph node cells was observed at all BTD, reaching the level of 3-fold increases at the 10% and 25% concentration as evaluated by LLNA. However, BTD did not cause irritant effects at any concentrations. In the MEST assay, the animals which were sensitized with either 10% or 25% BTD and challenged with 25% BTD exhibited significant increases in the percent ear swelling when compared to the challenge only group at both 24 and 48-h post challenge. In addition, a significant increase in the percentage of B lymphocytes (B220+) was also observed. Furthermore, dermal exposure to BTD (25%) for 3 days also significantly increased the production of IL-13 and IFN- γ , evaluated by ELISA, in the auricular draining lymph node cells after concanavalin A stimulation for 24 h in culture. Taken together, BTD can be classified as a sensitizer at the concentrations tested in female BALB/c mice (Supported by the NIEHS NO1-ES-05454).

1154 EVALUATION OF THE SYSTEMIC SENSITIZATION POTENTIAL OF 2, 3 BUTANEDIONE (DIACETYL) IN BALB/C MICE.

R. M. Patterson¹, Y. Reboloso¹, M. Carey¹, P. Blackshear², D. Morgan¹ and D. Germolec¹. ¹NIEHS, Research Triangle Park, NC and ²ILS, Research Triangle Park, NC.

Inhalation of and contact with high concentrations of diacetyl (2,3 butanedione)-containing butter flavor seasoning vapors have been associated with an increased prevalence of airway obstruction (asthma, bronchitis, bronchiolitis obliterans), skin irritation and severe fatigue among employees at microwave popcorn plants. Several reports suggest that diacetyl targets the respiratory epithelium, leading to inflammation, fibrosis, necrosis and irreversible tissue damage. C57/BL6 mice exposed to diacetyl by inhalation developed rhinitis, laryngitis and bronchitis, while mice exposed by oropharyngeal aspiration developed foci of pulmonary fibrosis without inflammation. We are using a BALB/c mouse hypersensitivity model to investigate the mechanisms of diacetyl-induced hypersensitivity. Diacetyl stimulated lymph node cell proliferation following subcutaneous exposure in a dose dependant manner at concentrations as low as 2.5 mg/kg/day. At 25 mg/kg/day diacetyl, an increase in total cell number of all lymphocyte sub-populations tested (CD3+ T-cell, B220+ B-cell, CD4+ T-helper cell, CD8+ cytotoxic T-cell, Mac3+ macrophage) was observed in both lymph nodes and spleen, indicating possible generalized systemic inflammation. At 10 mg/kg/day diacetyl, only B-cells were altered in the spleen. However, in the draining lymph nodes, both T-cell (CD3+, CD4+ and CD8+) and B-cell numbers were elevated. Diacetyl also regulated synthesis of several inflammatory cytokines, including IL-1 α and IL-4 in lymph nodes and spleen, and IL-2, IL-10, MIG, and TNF- α in lymph nodes. The lymph node cytokine profile suggests alteration of both Th1 and Th2 cytokines. Collectively these data suggest that exposure to diacetyl induces inflammation, systemic hypersensitivity, and functional changes in immune responses. Further investigation will more fully elucidate the mediators, mechanisms and cell populations involved, and may offer potential strategies for therapeutic intervention in exposed humans.

1155 AGE AND SEX CONTRIBUTE TO ASTHMA HETEROGENEITY IN ANIMAL MODELS.

J. F. Regal¹, A. L. Greene¹, M. S. Rutherford², R. R. Regal³, M. Duan³, V. Haynes¹, J. Meehan² and M. Mohrman¹. ¹Biochemistry & Molecular Biology, University of Minnesota Medical School, Duluth, MN, ²Veterinary & Biomedical Sciences, University of Minnesota, St Paul, MN and ³Mathematics & Statistics, University of Minnesota, Duluth, MN.

Asthma is a lung disorder characterized by eosinophil infiltration and airway hyper-responsiveness (AHR). However, the predominance of airway obstruction vs inflammation differs in asthmatics, with numerous asthma phenotypes being described (eosinophilic, neutrophilic, childhood onset, steroid-resistant, etc). The purpose of the present study was to assess contributions of age and sex to the profile of asthma symptoms in guinea pig and mouse models of asthma. Female and male Hartley guinea pigs and Balb/c mice were sensitized and challenged with ovalbumin (OVA) before sexual maturity (Y/Y) or after sexual maturity (A/A) and eosinophil infiltration and AHR determined. For mice, Y/Y and A/A animals were sensitized 19 or 82 days postnatal, respectively. With guinea pigs, Y/Y and A/A animals were sensitized at 9 or 57-84 days postnatal, respectively. Eosinophil peroxidase in homogenized lung was used as an indicator of eosinophilia. In guinea pigs, AHR was assessed by measurement of pulmonary resistance to i.v. methacholine in anesthetized animals. In mice, AHR to aerosolized methacholine was determined using unrestrained barometric plethysmography to measure PenH. In the guinea pig, 24 hours after OVA challenge, eosinophils increased significantly in the lung in Y/Y females with minimal airway hyperresponsiveness detected. In contrast, A/A female guinea pigs accumulated very few eosinophils into the lung after OVA challenge, but the airway hyperresponsiveness was marked. In contrast to guinea pigs, OVA challenge of mice resulted in greater increases in eosinophils in A/A animals than Y/Y animals whether male or female. Marked AHR was evident in both Y/Y and A/A mice. These studies clearly indicate that age and sex contribute to asthma heterogeneity and need to be carefully considered when using animal models of asthma. 1156 ZN/CU SUPEROXIDE DISMUTASE AUTOANTIBODY IN CEMENTED TUNGSTEN CARBIDE WORKERS.

P. D. Siegel, J. M. Hettick, T. Bledsoe, B. F. Law and N. Sahakian. NIOSH/CDC, Morgantown, WV.

Asthma and hard metal pneumoconiosis have been associated with exposure to aerosols containing nickel, cobalt, and tungsten in the cemented tungsten carbide industry. Only a few studies reported metal-specific IgE in sera of hard metal aerosol exposed workers, but antibody prevalence was very low. In the present study, sera from 140 cemented tungsten carbide workers were screened for specific IgG against chromium (Cr³⁺), copper (Cu²⁺), cobalt (Co²⁺), zinc (Zn²⁺) and nickel (Ni²⁺), haptenized to albumin (HSA) and superoxide dismutase (SOD). SOD was used as a protein carrier for haptenization, because its physiologically active form is Zn/Cu-SOD and it is an important endogenous antioxidant enzyme. Antigens were characterized using MALDI-TOF mass spectrometry (MS). Mass spectra of haptenized SOD showed 0-3 Co, 0-3 Zn, and 0-1 Ni ions bound per SOD molecule. Quantification of specific binding of Cu was not possible due to the large numbers of copper ions bound to SOD, consistent with non-specific binding. Haptenization to HSA was evident by color change resulting from binding of the metals to HSA. Specific chromium and cobalt IgGs were not found using either of the haptenized proteins. Casein was not sufficient to block non-specific IgG binding from 19 sera. These sera were re-screened using bovine serum albumin blocked ELISA plates. Within this subgroup, specific-IgG was found for Ni-SOD in one worker, and IgG specific to both Cu- and Zn-SOD was found in the sera of 10 workers. Anti-apo-SOD IgG was not found. This is the first report of autoantibody against Zn/Cu-SOD. It is not known if the 7.1% prevalence rate of anti-Zn/Cu-SOD IgG in this group of cemented tungsten carbide workers is excessive. The relationship of Zn/Cu-SOD autoantibody to reported respiratory symptoms and respiratory disease has not yet been established in this workforce. The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent agency determination or policy.

1157 THE ROLE OF THIOLS AND DISULFIDE FORMATION IN MERCAPTOTENZOTHIAZOLE ALLERGENICITY.

I. Chipinda^{1,2}, J. M. Hettick¹, R. H. Simoyi², X. Zhang¹ and P. D. Siegel¹. ¹HELD, NIOSH/CDC, Morgantown, WV and ²Department of Chemistry, Portland State University, Portland, OR.

The rubber accelerator, 2-mercaptobenzothiazole (MBT), can cause allergic contact dermatitis (ACD) from gloves and other rubber products, but the chemical mechanism leading to MBT's allergenicity is unknown. It was hypothesized that the thiol

group is critical to MBT's covalent binding/haptenation to nucleophilic protein residues. Oxidative transformation of MBT to the disulfide 2, 2'- dithiobis(benzothiazole) (MBTS) was observed within the glove matrix when hypochlorous acid, iodine or hydrogen peroxide were used as oxidants. Cysteine reduced MBTS to MBT with subsequent formation of the mixed disulfide 2-amino-3-(benzothiazol-2-yl disulfanyl)-propionic acid. Simultaneous reduction of MBTS and disulfide formation with Cys34 on bovine serum albumin was observed, suggesting a potential route of protein haptenation through covalent bonding between cysteinyl residues on proteins and the MBT/MBTS thiol moiety. MBT metabolites were not found following incubation with isoniazid and dexamethasone-induced rat liver microsomes and a NADPH regeneration system. Guinea pigs were sensitized to MBT using a modified guinea pig maximization assay (GPMT) and cross-reactivity towards MBTS and the free thiol lacking or blocked compounds benzothiazole (BT), 2-hydroxybenzothiazole (HBT) and 2-(methylthio)benzothiazole (MTBT) assessed. MBT and MBTS, but not BT, HBT or MTBT elicited ACD in MBT-sensitized animals. Both chemical and experimental animal studies demonstrate that the thiol group is required for MBT allergenicity and also suggest that MBT first undergoes non-enzyme mediated oxidation to MBTS with subsequent haptenation via the formation of mixed disulfides with sulfhydryl groups on proteins. This work was supported by an interagency agreement with the NIEHS (Y1-E50001-06). The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent agency determination or policy.

1158 ANTI-INFLAMMATORY ACTIVITY OF Fisetin IN HUMAN MAST CELLS (HMC-1).

H. Park, S. Lee and S. Kim. Department of Pharmacology, Kyungpook National University Medical School, Daegu, South Korea.

Mast cells play an important role in the pathogenesis of allergic diseases through the release of inflammatory mediators such as, histamine, cysteinyl leukotrienes, cytokines, and chemokines. Flavonoids, like fisetin are naturally occurring molecules with antioxidant, cytoprotective, and anti-inflammatory actions. The aim of our study was to examine whether fisetin modulates the inflammatory reaction in a stimulated human mast cell (HMC-1). HMC-1 cells were stimulated with 40 nM of phorbol-12-myristate 13-acetate plus 1 µM of calcium ionophore A23187 (PMACI). The expression of pro-inflammatory cytokines was measured by reverse transcriptase-polymerase chain reaction. The nuclear transcription factor (NF)-κB promoter-mediated luciferase activity and the DNA-binding activity were detected by luciferase assay and electrophoretic mobility shift assay. Nuclear translocation of p65 NF-κB and phosphorylation of mitogen-activated protein kinases such as, p38, extracellular signal-regulated kinase (ERK) and c-Jun N-terminal kinase (JNK) were detected by the Western blotting. Fisetin decreased the gene expression and production of PMACI-stimulated tumor necrosis factor-α (TNF-α), interleukin (IL)-1β, IL-4, IL-6 and IL-8 in HMC-1. Fisetin suppressed NF-κB activation induced by PMACI, leading to expression of IκB-α phosphorylation and degradation. Fisetin also suppressed NF-κB promoter-mediated luciferase activity and DNA-binding activity. In addition, fisetin inhibited PMACI-induced phosphorylation of p38 MAPK, ERK, and JNK. We observed that the selective inhibitors of p38 MAPK, ERK, JNK and NF-κB reduced PMACI-induced cytokine expression in activated HMC-1 cells. These data display that the inhibitory effect of fisetin on the pro-inflammatory cytokines was p38 MAPK, JNK, ERK and NF-κB dependent. Pharmacological actions of fisetin produce new suggestion that fisetin is a potential medicine for treatment of inflammatory diseases through the down-regulation of mast cell activation.

This work was supported by Brain Korea 21.

1159 DOSE METRICS IN THE ACQUISITION OF SKIN SENSITIZATION : THRESHOLDS AND DOSE PER UNIT AREA.

R. J. Dearman¹, D. A. Basketter², C. A. Ryan³, F. Gerberick³, P. M. McNamee⁴, J. Lalko⁵, A. Api⁵ and I. Kimber¹. ¹Syngenta CTL, Macclesfield, CHESHIRE, United Kingdom, ²Unilever Safety and Environmental Assurance Centre, Bedford, United Kingdom, ³Procter & Gamble Company, Cincinnati, OH, ⁴Procter & Gamble Company, Egham, United Kingdom and ⁵Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ.

Allergic contact dermatitis is a common occupational and environmental health problem. Skin sensitization is acquired following topical exposure of an inherently susceptible individual to an appropriate amount of a contact allergen; that required to induce a cutaneous immune response of the magnitude necessary for a degree of immunological priming (sensitization) that will result in a dermal inflammatory reaction being provoked following subsequent exposure. The amount of chemical necessary to result in the acquisition of skin sensitization will be determined primarily by two factors: (a) the inherent potency of the contact allergen, and (b) the con-

ditions of exposure (the site, extent, frequency and duration of exposure). The available human and experimental animal data derived from contact allergens of varying potencies demonstrate that under most normal conditions of exposure it is the dose per unit area of chemical, rather than the total delivered dose, that has the over-riding impact on the effectiveness of sensitization. The interpretation is that there is a certain critical level of chemical allergen and LC availability for transport required in the area of skin from which there is lymphatic drainage to a single lymph node, or to a single series of lymph nodes. The exception to this rule is when the area of the application site drops below a certain critical level. Under such circumstances, there will be insufficient numbers of primed LC transporting antigen to the draining lymph node to reach the threshold of activation necessary for an effective immune response.

1160 CHARACTERIZATION OF MALE REPRODUCTIVE TOXICANTS IN AN IN VITRO 3-D SERTOLI CELL/GONOCYTE CO-CULTURES.

X. Yu, S. Hong, E. Kim and E. M. Faustman. *Environmental Health, IRARC, UW, Seattle, WA.*

The development of *in vitro* models for testicular toxicity can provide important mechanistic tools for the assessment of reproductive toxicity induced by environmental agents. In our previous study, we reported a significantly improved 3D-Sertoli cell/gonocyte co-culture (SGC) system that utilizes an extracellular matrix Matrigel (ECM) applied as an overlay instead of a substratum. Our findings have demonstrated that application of an overlay of ECM to SGC permitted the formation of testicular-like multilayered architectural structure that mimics *in vivo* characteristics of seminiferous tubules. The purpose of this study is to refine and characterize our *in vitro* 3-D SGC culture using testicular specific toxicants and comparing molecular and cellular response endpoints. A range of known *in vivo* male reproductive toxic phthalate esters such as dibutyl phthalate (DBP), diethylhexyl phthalate (DEHP), dipentyl phthalate (DPP) and three non-developmental testicular toxic phthalates such as diethyl phthalate (DEP), dimethyl phthalate (DMP), dioctyl tere-phthalate (DOTP) were evaluated. We compared their differential effects on morphology and cell viability 24 h after treatment. We also compared their differential impacts on cell stress signaling pathways such as phosphorylated p38, SAPK/JNK by Western blot analysis using phospho-specific antibodies. We observed that treatments with phthalates that had been identified as developmental testicular toxicants induced significantly more dose-dependent morphological changes and decrease in cell viability than those treated with non-developmentally toxic phthalates. Our results support the expansion of 3-D SGC as an *in vitro* model useful for assessment of male reproductive developmental toxicity. (This work was supported in part by EPA R826886, NIEHS 1P01ES09601, R01-ES1063, P30 ES07033 and Colgate-Palmolive Grants for Alternative Research, Society of Toxicology)

1161 BOVINE SPERMATOZOA: AN IN VITRO MODEL FOR REPRODUCTIVE TOXICITY?

M. M. Tegelbosch¹, S. Arabi², D. Balduzzi², J. H. van Bilsen¹, M. H. Brouwer¹, A. Dijkstra¹, A. Galli², L. J. van der Horst-Groeneveld¹, C. A. Krul¹, P. T. Theunissen¹, M. Verwei¹, A. P. Wolterbeek¹ and I. D. Waalkens-Berendsen¹. ¹Toxicology and Applied Pharmacology, TNO Quality of Life, Zeist, Netherlands and ²Instituto Sperimentale Italiano "Lazzaro Spallanzani", Rivolta d'Adda, Italy. Sponsor: V. Feron.

As part of the EU ReProTect project, an *in vitro* method is developed to test chemicals for their toxic effect on thawed mature bovine spermatozoa using Computer Assisted Sperm Analysis (CASA). Motility parameters and membrane integrity were used to determine toxicity.

Bovine mature spermatozoa were thawed and exposed to chemicals for one hour at 37°C. After incubation, motility parameters were determined in a dose range finding study (DRF) at concentrations of 10, 100 and 1000 µg/ml. Based on the outcome of the DRF a main test was performed using seven concentrations in a narrowed range to determine the motility IC50 for each compound. Positive and negative controls were included. A viability test was performed to distinguish between deactivation of sperm motility and cell death due to unspecific toxicity. Approximately 30 chemicals were tested at two laboratories. The IC50 for motility ranged from 0.06mM to 6 mM. In 20% of the chemicals the IC50 was not reached within the interval tested.

This test appeared to be a simple, fast and consistent method to predict potential impact of chemicals on male fertility using endpoints motility and membrane integrity. Since, for some chemicals, percentages viable cells differed from percentages motile cells, inclusion of a viability test seems useful in order to set up a prediction model. Besides, specific motility parameters (e.g. velocity) easily measured with CASA could give useful information on working mechanisms of specific chemicals. Whether this *in vitro* test could be used as part of high throughput *in vitro* tests in reproductive toxicological evaluation should be evaluated within the EU ReProTect project.

COMBINATION OF GROWTH FACTORS AND EXTRACELLULAR MATRIX COMPONENTS INDUCE EPIDERMAL/EPITHELIAL DIFFERENTIATION IN MOUSE EMBRYONIC STEM CELLS. A.R.CALABRO AND F.A.BARILE ST JOHN'S UNIVERSITY COLLEGE OF PHARMACY AND ALLIED HEALTH PROFESSIONS DEPARTMENT OF PHARMACEUTICAL SCIENCES, TOXICOLOGY DIVISION, JAMAICA, NEW YORK 11439.

A. R. Calabro and F. A. Barile. *Pharmaceutical Sciences, St Johns University, Jamaica, NY.*

Mouse embryonic stem (ES) cells (ES-D3, ATCC) are undifferentiated pluripotent cells derived from the inner cell mass of mouse blastocysts capable of forming embryoid bodies (EBs) as an intermediate stage of differentiation. Since several growth factors (GFs) direct differentiation of EBs, we examined the effect of four GFs (EGF, KGF, TGFβ1, and amphiregulin) on the expression of primers for gene markers (OCT3/4, for undifferentiated cells; AFP, for EBs; ARNT and EGFR, for differentiated cells; TGFβR2, for transformed cells) in cells cultured on filter inserts and coated with extracellular matrix (ECM) proteins (collagen types I&IV, fibronectin, laminin). Gene expression was detected using RT-PCR from RNA purified from confluent ES cells after 14-16 days on the inserts. The results suggest that, in general, EBs preferentially differentiate in response to specific combinations of GFs and ECM components, and express the gene markers accordingly. The data supports our previous paracellular permeability and acute cytotoxicity studies suggesting that specific GFs and ECM proteins induce formation of epidermal-like membranes with high transepithelial electrical resistance. Thus, the cell culture insert model represents a novel approach for inducing membrane formation in drug screening and cytotoxicity testing protocols.

1163

EXPRESSION AND FUNCTIONALITY OF P-GLYCOPROTEIN IN HUMAN AND RAT TROPHOBLASTS USING *IN VITRO* PRIMOCULTURES BEGHIN D.1, 2, DELONGEAS J.-L.2, CLAUDE N.2, FARINOTTI R.1 AND GIL S.1 1 DEPARTMENT OF CLINICAL PHARMACY (UPRES EA2706), PARIS XI UNIVERSITY, FRANCE. 2 DRUG SAFETY ASSESSMENT, SERVIER GROUP, GIDY AND PARIS, FRANCE.

J. Delongeaes¹, D. Beghin^{1,2}, N. Claude¹, R. Farinotti² and S. Gil². ¹Drug Safety Assessment, Servier Group, Gidy and Paris, France and ²Department of Clinical Pharmacy, Paris XI University (UPRES EA2706), Paris, France.

The placenta assumes several functions during pregnancy which are essential for the fetal development and plays an important role in drugs metabolism. However a better understanding is needed in order to evaluate some pharmacological and toxicological aspects of xenobiotics used during pregnancy. It is now well established that P-glycoprotein (P-gp) participates in the efflux of maternal drugs thereby reducing chemical fetal exposure.

The goal of our study was to evaluate expression and functionality of P-gp in human and rat trophoblasts using *in vitro* primoculture models.

P-gp expression was evaluated by western blot analysis and activity by rhodamine uptake in presence or absence of the inhibitor cyclosporine A. Human and rat trophoblasts were cultured 5 and 7 days, respectively.

i) Differences in P-gp expression were observed in primocultures: in human trophoblasts, P-gp expression was stable during the first 3 days then decreased. In rat trophoblasts, a time dependent increase in P-gp expression was notified from day 2 to day 4 followed by a plateau.

ii) Activity of P-gp was confirmed in both placental primocultures, by a 60% inhibition with Cyclosporine A.

iii) Moreover, expression and activity of P-gp was also observed with cryopreserved rat trophoblasts.

This preliminary study shows that these models are able to quantify the expression and the activity of P-gp both in human and rat trophoblast primocultures. These primocultures seem promising for a better understanding of the role of efflux transporters in the toxicity of drugs administered during pregnancy but need to be confirmed in larger series.

1164

FORMATION OF INTACT MEMBRANES WITH HIGH TRANSEPITHELIAL ELECTRICAL RESISTANCE IN MOUSE EMBRYONIC STEM CELLS.

R. Konsoula¹, A. R. Calabro¹, J. Rollins² and F. A. Barile¹. ¹Pharmaceutical Sciences, St. John's University College of Pharmacy, Jamaica, NY and ²Biological Sciences, St. John's University, Jamaica, NY.

Mouse embryonic pluripotent stem cells (mES, ES-D3) were induced to form membrane structures in cell culture inserts, using combinations of extracellular matrix (EM) components and growth factors (GFs). The ability of the stem cells to

form intact membranes and construct tight junctions (TJs) was assessed by measuring transepithelial electrical resistance (TEER) and passage of TJ markers. Confirmation of differentiation and formation of epidermal/epithelial-like membranes is supported by the expression of gene markers for embryoid bodies (EBs), differentiated and undifferentiated cells. Further evidence for formation of TJs in differentiated cultures is demonstrated by immunohistochemical localization of TJ markers occludin and F-actin. Mouse ES cells were inoculated on mitomycin-inactivated 3T3 mouse embryonic fibroblasts plus LIF factor, to maintain the undifferentiated state, after which mES cells were stimulated to form EBs. After 4 days EBs were transferred to culture inserts coated separately with EM components (collagen I or IV, fibronectin and laminin) in the presence of a GF (amphiregulin, EGF, KGF or TGF β 1). After 10 to 14 days, TEER was measured at 700 Ω -cm². After exposure to 19 chemicals for 24-h, cell viability and paracellular permeability (PP) were measured. The data indicate that cell viability decreases before the integrity of the membrane is compromised. Also, TEER measurements inversely correlated with increased passage of TJ markers for most chemicals. We conclude that mES cells can be induced to form TJs in coated inserts after treatment with specific GFs as evidenced by progression of high TEER values comparable to those seen previously with Caco-2 cells. The extent and direction of differentiation is time- and GF-dependent. This represents the first study describing the manipulation of mES cells toward specific tissue organization, with potential for use as an *in vitro* model for biological membrane formation and cytotoxicity testing.

1165 RESULTS OF A PROTOCOL STANDARDIZATION STUDY FOR THE LUMI-CELL® ESTROGEN RECEPTOR (ER) TRANSCRIPTIONAL ACTIVATION (TA) BIOASSAY.

F. Deal¹, P. Ceger¹, G. Clark³, J. Gordon³, J. Charles¹, R. Tice² and W. Stokes². ¹ILS, Inc., Research Triangle Park, NC, ²NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC and ³Xenobiotic Detection Systems, Inc. (XDS), Durham, NC.

In 2003, the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) concluded that none of the ER TA assays considered for inclusion in the EPA Endocrine Disruptor Screening Programs Tier 1 battery had been adequately validated. NICEATM subsequently conducted a study to standardize protocols to be used in formal validation studies for the XDS LUMI-CELL® ER TA test method, a proposed Tier 1 *in vitro* screening assay for the detection of ER agonists and antagonists. The objective of the study was to develop standardized protocols that can be easily transferred to other laboratories and be used to obtain reproducible results for the detection of ER agonists and antagonists. The study included optimization of the use of reference standards and controls, and compared quantitative and qualitative methods for evaluating cytotoxicity. The intralaboratory reproducibility and accuracy of the standardized protocols was demonstrated using eight coded substances covering a range of ER agonist activities, including negatives (atrazine [ATZ], bisphenol A [BPA], bisphenol B [BBP], corticosterone [COR], o,p'-DDT [DDT], diethylstilbestrol [DES], 17 α -ethinyl estradiol [EE], and flavone [FLA]) and eight coded substances covering a range of ER antagonist activities, including negatives (butylbenzyl phthalate [BBP], dibenzo[a,h]anthracene [DBA], flavone [FLA], genistein [GEN], nonylphenol [NON], progesterone [PRO], o,p'-DDT [DDT], and tamoxifen [TAM]). EE, DES, BPA, BBP, DDT, and FLA were classified as estrogenic agonists, while ATZ and COR did not induce a significant ER TA response. TAM, DBA, FLA, and GEN, were classified as antagonists, while BBP, PRO, NON, and DDT did not affect ER TA response. This study demonstrated the intralaboratory reproducibility and accuracy of this test method and indicated its readiness for a multi-laboratory validation study. Supported by NIEHS Contract N01-ES-85424.

1166 NICEATM/ECVAM/JACVAM MULTI-PHASED INTERNATIONAL VALIDATION STUDY OF A STABLY-TRANSFECTED ESTROGEN RECEPTOR (ER) TRANSCRIPTIONAL ACTIVATION (TA) TEST METHOD.

W. Stokes¹, S. Bremer², M. Jacobs³, H. Kojima³, P. Ceger⁴, F. Deal⁴ and R. Tice¹. ¹NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC, ²ECVAM, Ispra, Italy, ³JacVAM, Tokyo, Japan and ⁴ILS, Inc., Research Triangle Park, NC.

The U.S. EPA proposed Tier 1 endocrine disruptor screening program (EDSP) includes validated *in vitro* test methods to determine if chemicals bind to the ER. A stably transfected ER TA method (LUMI-CELL®, Xenobiotic Detection Systems, Inc.) to detect ER agonists and antagonists was subsequently nominated to the Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM) and recommended for validation studies. NICEATM, ECVAM, and JacVAM designed and initiated a four phase international validation study to evaluate the reproducibility and accuracy of the LUMI-CELL® ER bioassay. The study is using three laboratories, one each in Japan, the U.S., and Europe. A standardized test method protocol incorporating ICCVAM recommended ER TA essential test

method components is being used to evaluate 78 coded reference substances recommended by ICCVAM for validation of *in vitro* ER test methods. The first phase will evaluate positive and vehicle controls and establish test acceptance standards for each laboratory. The second phase will evaluate 12 coded reference substances in each lab in two stages. Intra- and inter laboratory reproducibility and accuracy will be assessed during and after each of the first two phases. Excessive variation and discordance will be investigated and protocols modified accordingly. The third phase will evaluate the performance of the optimized test method protocol using the remaining coded 41 minimum validation substances. The final phase will test the final 25 substances in one laboratory. Performance standards will be developed to serve as the basis for determining if similar ER TA methods have comparable or better performance. This multi-phased approach is expected to identify and resolve sources of variation early in the validation process and to generate a highly reproducible test method protocol for international regulatory use. Supported by NIEHS Contract N01-ES-85424.

1167 ICCVAM REVISED RECOMMENDED SUBSTANCE LIST FOR THE EVALUATION OF *IN VITRO* TEST METHODS FOR IDENTIFYING POTENTIAL ENDOCRINE DISRUPTORS.

D. Hattan¹, M. Wind², F. Deal³, P. Ceger³, J. Charles³, R. Tice⁴ and W. Stokes⁴. ¹FDA, College Park, MD, ²CPSC, Bethesda, MD, ³ILS, Inc., Research Triangle Park, NC and ⁴NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

NICEATM recently reviewed the commercial availability and cost for the 78 substances recommended by ICCVAM for use in *in vitro* ER and AR binding and TA validation studies. A minimum of 44 substances are recommended for AR binding and TA assays, while a minimum of 53 substances are recommended for ER binding and TA assays. This review indicated that three substances [anastrozole, CGS 18320B, fadrozole] are not commercially available, one substance has restricted commercial availability [ICI 182,780], and the cost to conduct a validation study with six others [actinomycin D, hydroxyflutamide, 4-hydroxytamoxifen, methyl-trienolone, 12-O-tetradecanoylphorbol-13-acetate, zearalenone] was considered to be relatively expensive (>\$2000/lab). ICCVAM subsequently replaced the four original substances that are not commercially available or have restricted availability with ones having similar ER and AR activity profiles [4-hydroxyandrostenedione, chrysin, dicofol, raloxifene HCl]. Suitable replacements (19-nortestosterone and resveratrol) were identified to replace two of the six expensive substances, methyl-trienolone and zearalenone, respectively. NICEATM also preferred to replace the other four expensive substances but was unable to identify suitable replacements because of their unique activity profiles and/or chemical/physical properties. The revised list of reference substances has now been published*, and is being used for validation of *in vitro* ER TA methods by NICEATM, ECVAM, and JacVAM. Supported by NIEHS Contract N01-ES-85424.

1168 CYTOTOXICITY IN HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS EXPOSED *IN VITRO* TO GLYPHOSATE.

N. Reyes^{1,2,3}, I. Reyes⁴ and A. Martinez^{1,3}. ¹Molecular Biology Group, University of Cartagena, Cartagena, Colombia, ²University of Cartagena, Cartagena, Colombia, ³Rafael Nunez University, Cartagena, Colombia and ⁴Science and Research Development Corporation, Cartagena, Colombia. Sponsor: D. Singh.

Glyphosate is a broad-spectrum, non-selective herbicide and commonly used in the world to eliminate weeds in agricultural and forest settings. Studies evaluating glyphosate toxicity in animals and environment have been controversial. Additionally, it has been reported that commercial formulations based on glyphosate, are more toxic than pure glyphosate. Accordingly, the purpose of this study was to evaluate cytotoxicity of glyphosate (technical grade) and the commercial formulation Roundup on human peripheral blood mononuclear cells (PBMCs). PBMCs were isolated from healthy volunteers using ficoll-hypaque and exposed to different concentrations of glyphosate (Sigma-Aldrich) and commercial Roundup for 24, 48, 72 and 96h. After treatment, cell viability was determined by trypan blue exclusion method and reduction of XTT reagent (Sigma). We found that both glyphosate (Sigma) and Roundup were cytotoxic to human PBMCs and that cell viability decreased in a concentration-dependent manner. Cytotoxicity of Roundup was significantly higher than cytotoxicity of glyphosate (Sigma), since we found that LC50 (50 lethal concentration) analyzed with trypan blue exclusion method at 24h was 56,4 μ g/ml for Roundup and 1,64 mg/ml for glyphosate (Sigma). Nevertheless, evaluation of cytotoxicity using XTT reagent revealed that PBMCs treated with concentrations of glyphosate (Sigma) equal or higher than

400 µg/ml were metabolically inactive. In summary, these results confirm the cytotoxic effects to human cells reported for glyphosate and the commercial preparations based on it. Also, our results corroborate that commercial formulations are more cytotoxic than the active component, which supports the idea that additives present in commercial formulations, such as Roundup, play a crucial role in the toxicity attributed to glyphosate. Project code: 1419-04-16299. Supported by Colciencias Grant # 282-2004 awarded to Niradiz Reyes, PhD.

1169 FRONTLOADING THE EVALUATION OF BONE MARROW TOXICITY USING A THREE-TIERED APPROACH.

D. Brott¹, T. Kelly¹, K. Capobianchi¹, T. Huggett¹, J. Goodman², A. Saad³ and F. Pognan². ¹Global Safety Assessment (GSA), AstraZeneca Pharmaceutical (AZ), Wilmington, DE, ²GSA, AZ, Macclesfield, United Kingdom and ³GSA, AZ, Sodertälje, Sweden.

Bone marrow toxicity is a cause of late stage compound attrition in the pharmaceutical industry, but is typically not assessed prior to the pre-Candidate Drug (CD) phase. The objective of this project was to develop assays such that chemistry-associated liabilities can be evaluated earlier in drug-discovery. To this end, a three-tiered approach has been developed that enables a large number of compounds to be evaluated around early 'Lead Optimisation' phase with more thorough analyses during latter stages of drug discovery. Multiple assays using cell lines representative of broad bone marrow lineages (myeloid, erythroid, lymphoid and stromal) and a non-hematopoietic cell line were developed to assess chemical series (Tier 1). There was a good correlation between the mouse myeloid cell line and the mouse 35mm dish Colony Forming Unit-GM (CFU-GM) assays ($r^2=0.8046$). Additionally, compounds with lineage-specific in vivo bone marrow toxicity showed similar lineage specificity with these tier 1 assays. For example, chloramphenicol, an erythrototoxicant, had IC50 values of 8mM in the erythroid cell line assay and >100mM for the other cell line assays. CFU-assays (Tier 2) are then run to qualify and confirm the findings of tier 1. Tier 2 consists of mouse, rat, dog and human 35mm dish CFU-GM assays to predict species sensitivity. However, these assays are tedious and time-consuming, enabling only a limited number of compounds to be evaluated each month. A mouse 96-well CFU-GM assay that correlated well with the mouse 35mm dish CFU-GM assay ($r^2=0.7666$) was developed to increase throughput capabilities. Results from the tier 1 & 2 assays may also trigger frontloading in vivo studies that are evaluated using flow cytometry (Tier 3). In summary, a three-tiered approach allows compounds with chemistry-related bone marrow toxicity to be eliminated early from the research project pipeline while still evaluating in vivo bone marrow toxicity later in drug discovery.

1170 MODULATION OF THE 3'IgH REGULATORY REGION, A PROSPECTIVE *IN VITRO* SCREENING TOOL FOR IDENTIFYING POTENTIAL IMMUNOTOXICANTS.

R. A. Henseler, E. J. Romer and C. E. Sulentic. *Pharmacology & Toxicology, Wright State University, Dayton, OH.*

The immune system is critical to human survival. However, assessing alterations of immune function by potential immunotoxicants is complicated by the diffuse nature of the immune system which is composed of various effector cells each with differing effector functions. Current immunotoxicity testing is limited to animal studies. We have developed a model which may provide an in vitro alternative to animal studies in identifying immunotoxicants that specifically target B cell function (i.e., alteration of immunoglobulin (Ig) expression and antibody secretion). This model consists of a well-characterized B cell line, CH12.LX, which appears to appropriately model primary B cell function. We have stably transfected the CH12.LX cell line with a transgene regulated by an enhancer, the 3'Ig heavy chain regulatory region (3'IgH RR), purported to control Ig heavy chain gene expression. Our previous work has identified the 3'IgH RR as a sensitive target of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) possibly mediated by activation of the aryl hydrocarbon receptor (AhR) signaling pathway. We have tested our model with several structurally diverse chemicals shown to activate the AhR signaling pathway and found an association between AhR activation and inhibition of both 3'IgH RR activation and Ig protein expression. We have also tested two chemicals previously shown to activate humoral immunity through non-AhR receptors. Results indicate that our model appropriately identifies immunomodulators of two receptor signaling pathways each leading to altered immunoglobulin expression. To further validate our in vitro model and assess its applicability in identifying potential B cell immunotoxicants, future studies include evaluating chemicals that have been previously screened for immunotoxicity but likely have little information regarding their mechanism of action. (Supported by the Colgate-Palmolive Grants for Alternative Research and the Boonshoft School of Medicine, WSU)

1171 USE OF THE COMET ASSAY TO DETECT GENOTOXIC EFFECTS IN RECONSTITUTED HUMAN SKIN.

S. Pfuhrer, A. Zeller and L. Richoz. *Procter & Gamble, Cosmital SA, Marly, Switzerland.* Sponsor: F. Gerberick.

The 7th amendment to the EU Cosmetics Directive obliges the cosmetics industry to phase out animal-based genotoxicity experiments by March 2009. However, the current in vitro alternatives have serious drawbacks in terms of specificity and metabolic competence. The rate of false positives (positive results for non-carcinogens) lies above 70 % if at least two standard tests are included in the battery. Therefore, the development of reliable alternatives is a must for the cosmetic industry. The skin is the main route of exposure for cosmetics and the similarity to human skin predestinates 3D skin based models as a potential replacement for in vivo testing. These models, unlike standard cell culture assays, possess in vivo skin features like the barrier function of the stratum corneum and relevant metabolizing capacity.

As the Comet assay is able to detect a broad spectrum of primary DNA damage, we applied this methodology to human reconstituted skin models. In this procedure, the critical step is the generation of single cells without causing primary DNA damage. Although several standard enzymes could not be used due to their DNA damaging properties, a protocol to gently disintegrate the epidermis was successfully developed. The results show that single cells with a low background of DNA damage can reproducibly be generated with our method. Moreover, the application of the standard positive control methyl methane sulfonate to the stratum corneum of the 3D model caused a significant increase in percentage of tail DNA as compared to the negative control.

Based on the results generated so far we propose the Comet assay applied to 3D human skin models as a useful tool to evaluate genotoxicity of dermally applied compounds. For the micronucleus assay this has been shown earlier by Curren et al, *Mutat Res* (2006). For both methods the robustness of the protocol, transferability of the method, reproducibility between different labs as well as the sensitivity and specificity for a set of chemicals will be studied in a project sponsored by the European Cosmetic Toiletry and Perfumery Association (COLIPA).

1172 BHAS CELL TRANSFORMATION ASSAY AS A PREDICTOR OF CARCINOGENICITY.

A. Poth, S. Kunz and A. Heppenheimer. *Genetic Toxicology and Alternative Methods, RCC Ltd., Rossdorf, Germany.*

Carcinogenesis is a multistep process which involves sequential genetic alterations in a single target cell ultimately leading to malignant transformation and tumour development. Carcinogen-induced alterations in DNA as well as non-genotoxic mechanisms can play a causal role. In vitro cell transformation tests using BALB/c3T3 or C3H10T1/2 cells simulate the process of animal two-stage carcinogenesis. A limitation of these methods however is the time (4-8 weeks) required for focus formation as a morphological indicator of transformation. Thus Sasaki et al developed the cell line Bhas 42 by transfecting BALB/c 3T3 cells with the v-Ha-ras oncogene. Using these cells, transformed foci can be efficiently induced within 2-3 weeks by treatment with initiating and promoting agents.

The Bhas-system was established and seven known carcinogens and non-carcinogens with results from other cell transformation assays (SHE- and BALB/c 3T3 assay) were compared to that of the Bhas 42 assay. By adding a metabolic activation system (S9 mix) all seven compounds showed corresponding results compared to the bioassay data.

By selective trypsinization separate cultures could be established from foci cells and from normal cells. Parallel staining of microfilaments and nuclei clearly displayed a dense and multilayered piling-up of cells in foci. Thus alterations in adhesion protein profiles and enzyme activities modulating cellular adhesion and migration seem to be involved in the process of focus formation. In various tumour an increased cholinesterase activity is found. Thus the cholinesterase activity was investigated by a selective stain. A higher activity and intensity was found in the transformed foci compared to normal cells. This may be a promising candidate for the identification of molecular markers leading to a more objective scoring of foci and a greater acceptance of cell transformation tests in general.

1173 MECHANISMS OF DMN-INDUCED HEPATIC PRENEOPLASIA IN THE F344 RAT VERSUS THE MEDAKA FISH MODEL.

K. Hobbie^{1,2}, A. DeAngelo² and J. M. Law¹. ¹Department of Population Health & Pathobiology, NCSU College of Veterinary Medicine, Raleigh, NC and ²Environmental Carcinogenesis Division, United States Environmental Protection Agency, Durham, NC.

To determine the roles of transforming growth factor-β1 (TGF-β1) and hepatic stellate cells (HSCs) in hepatic fibrosis and liver carcinogenesis, we performed parallel dimethylnitrosamine (DMN) exposures in F344 rats (drinking water) and

Japanese medaka (ambient water). DMN, an alkylating carcinogen, is used to model fibrosis/cirrhosis and neoplasia in the rat liver. TGF- β 1 has been associated with hepatic neoplasia and fibrosis in humans and rodents. Liver injury induces HSCs to transdifferentiate to myofibroblast-like cells. Activated TGF- β 1 stimulates transdifferentiated HSCs to produce collagen type-1. TGF- β 1 has tumor suppressor activity through growth-inhibition and apoptosis of hepatocytes. Mutations in the TGF- β 1 pathway have been associated with hepatic neoplasia. TGF- β 1's role as a tumor suppressor protein has been documented in humans and rodents, and DMN-induced lesions in rodents are TGF- β 1 dependent. DMN is also a potent hepatotoxin and carcinogen in fish and is associated with hepatocellular and biliary carcinomas. Mutagenesis studies in DMN-exposed medaka have demonstrated DNA lesions similar to those seen in rodents, but the mechanisms by which liver morphologic changes occur are unknown. In our study, fish were exposed to 0, 10, 25, 50, or 100 ppm DMN and rats to 0, 0.1, 1, 5, 10, and 25 ppm DMN for 14 days. Post-exposure, specimens were intermittently sacrificed for histopathology and immunohistochemistry. In the medaka, results included: hepatocellular necrosis, apoptosis, regeneration, and dysplasia; HSC and spindle cell proliferation; and hepatocyte TGF- β 1 expression. An association between TGF- β 1 and hepatic lesions in DMN-exposed fish suggests a similar dependence to that in rodents. Direct comparisons between animal models at different phyletic levels will help facilitate the interspecies extrapolations that are so vital in toxicological risk assessment.

1174 PERMEATION OF BENZENEARSONATES PROVIDES SUFFICIENT CONCENTRATIONS TO CAUSE ALTERATION IN CACO-2 CELL PROLIFERATION.

G. S. Bayse¹, L. P. Hammonds-Odie², K. M. Jackson¹, W. G. Kirlin³, D. K. Robinson¹ and A. M. Rollins-Hairston³. ¹Chemistry, Spelman College, Atlanta, GA, ²Biology, Spelman College, Atlanta, GA and ³Pharmacology/Toxicology, Morehouse School of Medicine, Atlanta, GA.

Roxarsone (4-hydroxy-3-nitrobenzenearsonate), used to control microbial infections and to promote growth in poultry, has been approved by FDA since the 1960s as a feed additive. More than 90% of the additive is excreted. This has resulted in over 2 million pounds of Roxarsone and its metabolites being introduced into waterways. USGS and EPA have declared Roxarsone an organic water contaminant. Roxarsone's reduction product 3-amino-4-hydroxy-benzenearsonate (AHBA) has been identified in the literature as a metabolite, and is a potential substrate for multiple enzymes. The presumed detoxification N-acetylation reaction by NAT1 is poor for AHBA. Bioactivation can be catalyzed by oxidative enzymes such as the cytochrome P450s. Our *in vitro* experiments have confirmed the NADPH-dependent oxidation of AHBA, catalyzed by cloned human CYP 3A4, 1A2, and 2E1 isoforms. Previously we found a proliferative effect of these compounds on Caco-2 cells at 1.0-10 μ M levels as monitored by flow cytometry and [³H]-thymidine uptake into DNA. To assess potential human impact of these compounds, it was important to study their absorption characteristics in the gastrointestinal tract. For this study of intestinal absorption, human Caco-2 adenocarcinoma cells were grown to confluency on collagen-coated Transwells, then dosed on the apical side. After dosing at 10-50 μ M for 24-48 hours, media from apical and basolateral sides were collected and analyzed by HPLC. Roxarsone permeation of 1.4 μ M (14%) to basolateral side can be detected from a 10 μ M dose (48 hrs). Acetarsone permeation of 2.55 μ M (10.2%) to basolateral side can be detected from a 25 μ M dose (24 hrs). Therefore, it appears that the benzenearsonates permeate to the basolateral side at concentrations that are capable of stimulating cell proliferation. (Support: NIGMS/NIH GM008241-220S1-220S2; NIH/RIMI MD00215-01; RCMI RR 03032; MBRS/GM-028248; MIE/NASA NCC8-227).

1175 TARGET IDENTIFICATION OF DRUG-INDUCED MITOCHONDRIAL TOXICITY BY ANTIDIABETIC AND ANTILIPEDOMIC DRUGS.

R. Capaldi², S. Nadanaciva², A. Bernal², R. Aggeler² and Y. Will¹. ¹Drug Safety Research and Development, Pfizer, San Diego, CA and ²MitoSciences LLC, Eugene, OR.

Almost all pharmaceuticals are prescribed with a risk-benefit analysis implicit in the clinician's decision where side effects are weighed against therapeutic potential. Recent data are increasingly implicating deleterious effects on mitochondrial function in the etiology of iatrogenic toxicities. For example, experiments on isolated mitochondria reveal that many prescription drugs with a variety of untoward side effects uncouple or inhibit the mitochondrial electron transport system from oxidative phosphorylation.

Although such assessments can identify compounds with a potential mitochondrial liability, the existing techniques do not identify specific targets or mechanism(s) responsible for dysfunction and this is critical to understand in both mechanistic work and for the future monitoring of possible liabilities *in vivo*. Here, we report

the use of our five previously described MitoProfile™ assays in identifying possible targets of antidiabetic and antilipemic drugs. We confirmed the complex I and V inhibition at high drug concentrations previously reported for certain fibrates. In addition we found, that certain glitazones not only inhibited complex I, but also targeted complex IV and V with higher potency. Several statins also targeted complex IV and V. Thus the use of the MitoProfile™ assays provided mechanistic information, which when applied to the anti diabetic and antilipemic drugs together, focuses attention on the potential enhanced toxicities when these classes of drugs are used in concert.

1176 ISOLATED MITOCHONDRIAL RESPIRATION AND VIABILITY OF GALACTOSE-GROWN HEPG2 CELLS PROVIDE ROBUST ASSESSMENT OF DRUG-INDUCED MITOCHONDRIAL TOXICITY.

L. D. Marroquin, J. A. Dykens and Y. Will. *Drug Safety Research and Development, Pfizer, San Diego, CA.*

Despite regulatory vigilance, untoward toxicity and other side effects of ethical pharmaceuticals remain a major health concern. Mitochondrial integrity is essential for viability of aerobically poised cells, and many of these drugs have deleterious mitochondrial effects leading to toxicity of the liver, cardiovascular system, skeletal muscle, nervous system, and kidneys. Recent technological developments are fostering large-scale assessments of potential mitochondrial liabilities of drugs with an eye towards improving safety profiles.

We have shown preliminary data suggesting that mitochondrial toxicity can be readily detected in isolated mitochondria, and in galactose-grown (OXPHOS competent) intact HepG2 cells, using novel fluorescent oxygen sensors. Here we provide an extensive validation of both models using >100 commercially available drugs, both with and without reported *in vivo* toxicities and mitochondrial liabilities. Drugs included were: hepato-, cardio-, and myo-toxicants, compounds with no known toxicity, as well as compounds that require bioactivation. Data from isolated mitochondria provided mostly mechanistic insights, such as uncoupling and/or OXPHOS inhibition, and also correlated well with the cell-based assay. On the other hand, the cell-based assays provided the necessary toxicity readout and distinguished between primary and secondary mitochondrial effects. Many compounds with previously unreported clinical liabilities also induced mitochondrial dysfunction. Post-facto examination of adverse event reports revealed that such drugs frequently induce lactic acidosis, exercise intolerance, fever or sensory impairment, among others, which are all clinical manifestations of mitochondrialopathies having known genetic etiologies. Together, these assays provide a powerful predictive tool for understanding the mechanism(s) underlying the toxicities encountered with certain drugs.

1177 ASSESSMENT OF COMPOUND INDUCED HEART, GASTROINTESTINAL TRACT, LIVER, AND KIDNEY TOXICITY IN ZEBRAFISH.

P. McGrath¹, C. Parng¹, K. A. Augustine² and W. L. Seng¹. ¹Phylionix Pharmaceuticals, Inc., Cambridge, MA and ²Reproductive Toxicology, Bristol-Myers Squibb, Hopewell, NJ. Sponsor: C. Zhang.

Zebrafish have several advantages for assessing drug induced organ toxicity, including transparency, rapid development, easy drug delivery, and use of small quantity of drug per experiment. Here, we describe *in vivo* assays for assessing drug induced organ toxicity, including heart, gastrointestinal tract, liver, and kidney. Developmental or non-developmental toxicity can be assessed by choosing the appropriate zebrafish stage and drug dosing regimen.

Toxicity evaluation is conducted by assessing a series of physiologic and morphologic endpoints. Compound effects on heart rate and A/V ratio are assessed using a stop watch or a video camera. Contractility and circulation can be visualized in the transparent animal. To determine compound-induced effects on the intestine, the morphology of the epithelial layer, bleeding, and structural abnormalities are visually examined. To assess liver damage, size can be quantified using image analysis. Overt hepatic necrosis can also be visually assessed and apoptosis can be analyzed using acridine orange staining. Level of carboxylase enzymes containing biotin covalently bound as co-enzyme can be assessed in the liver and gut. In addition, after drug treatment, abnormal CYP gene expression, indicating cytotoxicity and mutagenicity, can be assessed by *in situ* hybridization. After staining with alcian blue, pancreas size can be measured by image analysis. In addition, level of carboxypeptidase, a digestive enzyme, can be determined using a whole animal ELISA. Nephrotoxicity can be visually assessed by examining kidney cysts and trunk edema; renal tubules and nephrons can be examined after antibody staining. Glomerular filtration rate can also be measured.

After compound treatment, the phenotypes of common organ toxicity in zebrafish present a striking correlation with results in mammals. Studies in this model organism are designed to complement in vitro and rodent methods for assessing toxicity.

1178 MODELING THE NEUROTOXICITY OF AN EXCITATORY AMINO ACID RECEPTOR POTENTIATOR IN ZEBRAFISH.

Y. Guo¹, D. G. Hall¹, S. Babb², J. Marrs² and T. P. Ryan¹. ¹Eli-Lilly & Company, Greenfield, IN and ²IUPUI, Indianapolis, IN.

The zebrafish has several features that make it an attractive model system for developmental neurotoxicity, including conserved genetics, anatomical structures, biological pathways, and neuronal cell types with other vertebrates. To explore the applicability of zebrafish as a model for neurotoxicity screening in pre-clinical drug safety assessment, we investigated nervous system effects caused by exposure to an excitatory amino acid potentiator in zebrafish larva. The similarities and differences between responses of zebrafish larva and those reported in earlier rat studies were evaluated from three aspects: behavior, histology, and the expression patterns of target receptors. After exposure, zebrafish larvae exhibited characteristic changes in locomotor behavior, such as increased motility and tremor, which were consistent with behavior abnormalities observed previously in rat. Histologic changes within the central nervous system after exposure ranged from decreased size and abnormal shape of the cerebellum or of the entire brain, with dilated ventricles and overall decreased cellularity in the most severely affected larvae. Histologic changes previously reported in rat were limited to necrosis of cerebellar Purkinje cell neurons. Interestingly, no major morphological changes were detected during the first three days in zebrafish development by BODIPY-ceramide staining, suggesting temporal specificity in lesion progression. In addition, primary sequence, syntenic and phylogenetic relationships between zebrafish and human receptors were characterized. All zebrafish receptors were increasingly expressed in a linear manner as assessed using quantitative real time PCR assay, with subtype specific expression in telencephalon, cerebellum and myelencephalon. Altogether, this work provides evidence that zebrafish is a valuable model not only for neurotoxicity screening, but also for dissecting the molecular mechanisms underlying the neurotoxicity of excitatory amino acid potentiators.

1179 FINAL RESULTS OF THE NICEATM/ECVAM VALIDATION STUDY OF *IN VITRO* CYTOTOXICITY TEST METHODS FOR ESTIMATING RAT ACUTE ORAL TOXICITY.

J. Strickland², M. Paris², S. Casati³, H. Raabe⁴, C. Cao⁵, R. Clothier⁶, G. Mun⁴, A. Sizemore⁴, G. Moyer⁴, J. Madren-Whalley⁵, C. Krishna², M. Owen⁶, N. Bourne⁶, E. Harvey⁷, R. Lee⁷, W. Jones⁷, M. Wenk⁸, M. Vallant⁹, J. Charles², R. Tice¹ and W. Stokes¹. ¹NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC, ²ILS, Inc., Research Triangle Park, NC, ³ECVAM, JRC, Ispra, Italy, ⁴IIVS, Gaithersburg, MD, ⁵U.S. Army, ECBC, Aberdeen Proving Ground, MD, ⁶University of Nottingham, Nottingham, United Kingdom, ⁷Constella Group, Durham, NC, ⁸BioReliance Corp., Rockville, MD and ⁹NIEHS/NIH/DHHS, Research Triangle Park, NC.

A multi-laboratory validation study evaluated the reduction in animal use and deaths produced by using in vitro neutral red uptake (NRU) basal cytotoxicity test methods to predict starting doses for acute oral toxicity test methods [Up-and-Down Procedure (UDP) and Acute Toxic Class (ATC) method]. Regression models developed from in vitro NRU IC50 values (from testing up to 68 coded chemicals in BALB/c 3T3 murine fibroblasts or normal human keratinocytes) and the corresponding rat oral LD50 values from the Registry of Cytotoxicity were used to estimate LD50 values to determine starting doses for computer simulated UDP and ATC testing. For each chemical, the number of animals used and that died using the default starting dose or the IC50-determined starting dose for each NRU method was computed. Average animal savings when using the NRU methods were 5-8% for the UDP and 5-10% for the ATC method, and were highest for chemicals with low in vivo toxicity (11-21% for the UDP [for LD50 > 2000 mg/kg] and 17-28% for the ATC [for LD50 ≥ 5000 mg/kg]). Compared with the default starting dose, the IC50-based starting doses produced fewer deaths (0.5-0.6 animal) for the ATC but not for the UDP. The recommended IC50-LD50 molar unit regression cannot be used with mixtures. A weight unit regression produced comparable animal savings but has not been tested with mixtures. This demonstrates that using data from in vitro cytotoxicity methods can reduce the number of animals required for acute oral toxicity determinations. 1180 CYTOTOXICITY ASSAYS USING HL-60 CELLS AND COMPARISON WITH RODENT 4-DAY TOXICITY DATA.

Y. Iwase, N. Matsuoaka, K. Ohfuji and N. Tsutsui. *Toxicology Laboratory, Mitsubishi Pharma Corporation, Kisarazu, Japan.* Sponsor: J. Sugimoto.

To estimate the rodent 4-day repeated dose toxicity, cytotoxicity of 93 pharmaceutical compounds in Mitsubishi Pharma Corporation (MPC) was examined. At first, to determine a sensitive parameter and a cell line, cytotoxicity of 9 compounds (acetaminophen, acetylsalicylic acid, sodium phenobarbital, isoniazid, verapamil hydrochloride, orphenadrine hydrochloride, quinidine sulphate, chloramphenicol, and caffeine) was evaluated in the HL-60 and Hep G2 cells at 3 endpoints (ATP, Alamar Blue, and LDH) after a 24h-treatment. In these experiments, the HL-60 ATP assay was the most sensitive. Furthermore, 46 MPC compounds were evaluated on ATP in HL-60 and Hep G2 cells. Cytotoxicity of 40 compounds was more potent in the HL-60 cells than the Hep G2 cells. As for the rest 6 compounds, the cytotoxicity was equivalent in both cells. Therefore, cytotoxicity data in the HL-60 ATP assay was compared with the 4-day toxicity data on 93 MPC compounds. Among the 37 compounds detected lethality in the 4-day toxicity studies, 33 compounds could be provided IC50s (the median was 9.9 uM) and the rest 4 compounds revealed to be less than 50% on ATP depletion at 100 uM. A compound group classified into IC50s < 1 uM showed 10 mg/kg of the minimum approximately lethal dose (ALD), and mainly induced hepatotoxicity, gastrointestinal (GI) toxicity, and myelosuppression. A compound group with IC50s ranging from 1 to 30 uM showed 30 mg/kg of the minimum ALD, and induced the hepatic and GI toxicity. An IC50 ranking of the compounds tested in HL-60 cells was comparable to the potency of the rodent toxicity except some compounds that were insufficiently absorbed in the rodents. These data show that the HL-60 ATP assay may be a useful method in estimating toxicity before the rodent 4-day toxicity study in the early phase of drug discovery.

1181 *IN VITRO* PREDICTION OF TOXIC POTENTIAL BASED ON MULTIPLE PARAMETER CYTOTOXICITY ANALYSIS.

L. A. VanderVeen¹, M. Sung², R. Phadnis², B. Jiang², K. L. Kolaja¹ and A. R. Tabatabaei². ¹Investigative Toxicology, Roche Palo Alto, Palo Alto, CA and ²Drug Metabolism and Pharmacokinetics, Roche Palo Alto, Palo Alto, CA.

One frequently cited reason for the discontinuation of a compound is unacceptable toxicity, therefore an early and appropriate prediction of toxicity would greatly contribute to the drug discovery process. To develop and validate a cell-based model to predict toxicity of novel compounds, we employed a multiplexed approach using multiple parameters to detect cell membrane integrity, mitochondrial membrane potential, and glutathione status, which were intended to be representative of different mechanisms of toxicity. The model was applied to drug metabolizing-competent (primary cultured rat hepatocytes) and non-competent (CHO) cells. Using cytotoxicity measurements from cells treated with 18 reference compounds, threshold values were derived to predict the development of toxicity in vivo. These included TC50 ≤ 100 uM for cell membrane permeability, ≥ 250% loss in mitochondrial membrane potential, and TC50 ≤ 100 uM in glutathione concentration. The second step involved evaluating the performance of the model across 27 additional compounds with varying degrees of toxicity. For positive assay results, a similar percentage of test compounds affected membrane integrity and mitochondrial membrane potential, whereas decrease in glutathione was observed for a lesser proportion of compounds. The parameters derived from the training set accurately identified the ability of test compounds to induce toxicity with approximately 80% sensitivity. When examined across classes of molecules, the model was more predictive for certain classes of toxicants, i.e. hepatotoxicants vs. inflammatory-mediated toxicities. This study demonstrates that in vitro data can be used as a sensitive method for the early prediction of compound-induced toxicity.

1182 ESTIMATING SYSTEMIC TOXICITY IN VITRO USING AN ADENOSINE TRIPHOSPHATE CYTOTOXICITY (ATP) ASSAY IN NORMAL HUMAN EPIDERMAL KERATINOCYTES.

H. A. Raabe², J. Kelly¹, I. Rybina¹, A. Hilberer², G. Moyer² and R. D. Curren². ¹Cambrex Bio Science, Walkersville, MD and ²Institute for In Vitro Sciences, Inc., Gaithersburg, MD.

Ekwall *et al* (ATLA 17:83-100, 1989) have proposed that ≈80% of chemical-induced systemic toxicity is the result of disruption of basic cellular processes common to most cell types in the body, and that systemic toxicity for many chemicals could be estimated in *in vitro* cultures. Accordingly, Strickland *et al* (The Toxicologist, Abs#761, 2003) reported on a joint European/USA validation study initiated to evaluate two cytotoxicity assays using normal human epidermal keratinocytes (NHEK) and BALB/c 3T3 with a neutral red uptake (NRU) viability

endpoint to predict acute systemic toxicity. We have previously reported on a proof of concept study to evaluate the ATP endpoint to assess viability of NHEK using the same cell culture and test chemical exposure protocol optimized during the aforementioned validation wherein 20 coded chemicals were tested in 3 valid assays (The Toxicologist, Abs#1958, 2006). Cytotoxicity was measured as a dose-dependent reduction in ATP from which an IC_{50} was determined. The relationship between the ATP IC_{50} values *in vitro* and published human 50% lethal serum concentrations (LC_{50}) was presented [$r^2 = 0.887$]. Recently, 50 of the chemicals tested in the NHEK cytotoxicity validation study with the NRU endpoint were tested using the ATP endpoint. The relationship between the ATP IC_{50} values *in vitro* and published rodent oral LD_{50} values was determined [$\log LD_{50} \text{ mmol/kg} = 0.461(\log IC_{50} \text{ mM}) + 0.449$; $r^2 = 0.367$] and is similar to the prediction model published in the Registry of Cytotoxicity (Halle, 1998). A comparison of the ATP IC_{50} values showed a high correlation to the NRU IC_{50} values obtained in the NHEK cytotoxicity validation study with the NRU endpoint ($r^2 = 0.930$). The results demonstrate that the NHEK assay with the ATP endpoint may be used to predict systemic toxicity, or rodent oral LD_{50} doses, and that the ATP endpoint is an acceptable alternative to the NRU endpoint.

1183 EFFECT OF SUBACUTE DAILY REPEATED EXPOSURE OF 18 CHEMICALS ON CELL VIABILITY, DNA SYNTHESIS, AND RECOVERY OF HUMAN INTESTINAL EPITHELIAL CELLS.

S. J. Pai and F. A. Barile. *Pharmaceutical Sciences, St. John's University College of Pharmacy and Allied Health Professions, Jamaica, NY.*

The effect of repeated administration of 18 cytotoxic compounds on human immortal intestinal epithelial cell cultures was investigated using Caco-2 cells. Confluent monolayers were exposed for 48-h and 96-h repeated daily concentrations of chemicals. Effects were monitored using MTT cell viability and paracellular permeability (PP) assays. IC_{50} s were calculated from concentration-effect curves and the data was subjected to Students' t-test for paired sample means. In addition, confluent monolayers were radiolabeled with [^3H]-thymidine for the last 24-h of a 48-h exposure period and during a post-48-h recovery phase. Cell viability data suggests that there was a significant difference between the IC_{50} s of the 48-h & 96-h repeated dosing schedules. PP data indicates a significant difference between 72-h single dosing and 96-h repeated dosing. In fact, IC_{50} s from 96-h repeated exposure were consistently lower than 48-h repeated exposures. Other comparisons, including 48-h repeated dosing vs. 24-h single dosing (from previous data), and 96-h repeated dosing vs. 72-h single dosing (from previous data), did not demonstrate statistical significance. Also, uptake of [^3H]-thymidine was significantly greater in recovery experiments suggesting that the DNA repair mechanisms are at least partially responsible for cell recovery. The study demonstrates that repeated daily dosing of cultured cells for at least 96-h is necessary to simulate *in vivo* chronic exposure to chemicals.

1184 A HIGH-THROUGHPUT METHOD FOR ASSESSING CHEMICAL TOXICITY USING A *C. ELEGANS* FEEDING RESPONSE ASSAY.

W. A. Boyd¹, S. J. McBride² and J. H. Freedman^{1,2}. ¹Laboratory of Molecular Toxicology, NIEHS, Research Triangle Park, NC and ²Nicholas School of the Environment and Earth Sciences, Duke University, Durham, NC.

Feeding in *Caenorhabditis elegans* is a complex behavior controlled by an integrated and well-regulated neuromuscular system. *C. elegans* feed via constant pharyngeal pumping while moving through the environment. Exposures to neurotoxic chemicals have been shown to affect feeding in *C. elegans* making this response a sensitive endpoint in toxicological testing. Previous feeding assays required microscopic examinations of individual nematodes, limiting the number of samples that could be observed. We present a method that uses flow cytometry technology that can measure the size and fluorescence characteristics of hundreds of nematodes per minute. After chemical exposures, *C. elegans* are allowed to feed on red fluorescent microspheres such that accumulated red fluorescence is used as a measure of feeding response when compared to non-exposed control nematodes.

To validate our system, we first compared the feeding responses in the *C. elegans* wild type N2 strain with 18 different Eat mutant strains that are known to express abnormal pharyngeal pumping. The Eat mutations known to affect feeding most severely exhibited the lowest feeding responses with our assay. Next, we assayed two chemicals known to either stimulate (serotonin) or uncouple pharyngeal pumping (arecoline) in the presence or absence of a food source. Concentration-dependent increases in feeding responses after serotonin exposures were dependent on food availability while feeding responses decreased in arecoline-exposed nematodes regardless of the presence of food.

Using our feeding assay, the effects of more than 50 chemicals on the feeding response of *C. elegans* have been assessed. Cadmium and chlorpyrifos, potent neurotoxins, will be used to illustrate the effects of toxicants on *C. elegans* feeding. Cadmium chloride exposures led to a sharp drop in the feeding response above 200 μM while feeding of chlorpyrifos-exposed nematodes decreased in a concentration-dependent fashion with an EC_{50} of 2 μM .

1185 CHEMICAL COMPOUND PROFILING OF CELL-BASED TOXICITY ASSAYS USING QUANTITATIVE HIGH-THROUGHPUT SCREENING.

M. Xia¹, K. Witt², N. Southall¹, M. Cho¹, A. Jadhav¹, R. Huang¹, C. Smith², J. Fostel², R. Tice², J. Inglese¹ and C. Austin¹. ¹NIH Chemical Genomics Center, Bethesda, MD and ²National Toxicology Program/NIEHS, Research Triangle Park, NC.

Traditionally, toxicological profiles of drugs or chemicals rely on *in vivo* studies in laboratory animals. While these profiles provide useful information about the safety of chemical compounds, this approach is expensive, low-throughput, and inconsistently predictive of human biology and pathophysiology. To overcome these limitations, we have begun to develop a battery of cell-based assays to profile the toxicity of chemical compounds in a variety of cell types using quantitative high throughput screening (qHTS). The ultimate goal is to identify *in vitro* chemical signatures that could act as predictive surrogates for *in vivo* toxicity. Importantly, and distinct from conventional single concentration HTS screening, qHTS is capable of generating high-confidence positive and negative activity data, making it suitable for the comprehensive profiling of potentially toxic compounds. Thus far, the activity of 1,408 compounds from the National Toxicology Program (NTP) has been determined in assays for cytotoxicity and caspase 3/7 activity. Corresponding human and rodent cell lines derived from 6 tissues that are common targets of xenobiotic toxicity (liver, blood, kidney, brain, lung, and skin) were used in these assays. Data analysis has identified compounds that are toxic to all cell types at similar concentrations, as well as compounds that exhibit selective toxicity to particular cell types. In addition, some compounds appear to utilize the caspase 3/7 pathway as a mechanism for cytotoxicity, while others exhibit cytotoxicity independent of this pathway. These proof-of-principle data are being used to scale-up the profiling effort to incorporate more assay conditions, assay and cell types, and compounds. The resulting large data sets will provide a rich source of information for the development of *in vitro* toxicological signatures and the prediction of toxic effects of new chemical entities.

1186 THE NATIONAL TOXICOLOGY PROGRAM (NTP) HIGH THROUGHPUT SCREENING (HTS) INITIATIVE: CURRENT STATUS AND FUTURE DIRECTIONS.

R. R. Tice¹, J. Fostel², C. S. Smith¹, K. Witt¹, J. H. Freedman¹, C. J. Portier¹, A. D. Dearry¹ and J. R. Bucher¹. ¹NTP/NIEHS/NIH/DHHS, Research Triangle Park, NC and ²Alpha-Gamma Tech., Raleigh, NC.

Since mid-2005, the NTP has participated in the NIH Molecular Libraries Initiative (MLI) by collaborating directly with the NIH Chemical Genomics Center (NCGC) to use quantitative HTS (qHTS) assays to test compounds for activity against defined targets. This collaboration benefits to both programs by adding toxicity testing capabilities to the MLI, and by allowing rapid implementation of NTP's HTS program designed to screen large numbers of compounds for activity against targets and pathways believed to have toxicological relevance (e.g., oxidative stress, inflammation, apoptosis). The NTP plans to link HTS-produced toxicity data to data from standard *in vivo* toxicological assays, with the goal of identifying mechanisms of action requiring additional investigation, developing predictive models for biological response, and prioritizing substances for further evaluation. In addition to the collaboration with NCGC, a medium throughput screen using *Caenorhabditis elegans* has been established to provide *in vivo* data on the same chemicals screened at the NCGC. Another aspect to this collaborative effort is a joint NTP/EPA "faculty" that shares ideas and strategies and provides a broader venue for scientific debate on HTS. The NTP had provided 1353 unique compounds (55 in duplicate to assess assay reproducibility) with known toxicological effects to the NCGC (see C. Smith et al. poster). The NTP has also provided six cell-based HTS assays to the NCGC; these assays evaluate cytotoxicity (2), caspase activation (3), and a cell membrane efflux pump (1). The first set of NTP compounds has been tested in several of these assays in up to 7 human and 6 rodent cell types (see M. Xia et al. Poster). The resulting data are posted on PubChem and are being evaluated internally by the NTP for patterns of response potentially indicative of toxicological effects. Efforts are underway to identify other potentially useful assays and the second set of ~1408 compounds.

1187 CHEMICAL SELECTION FOR NTP'S HIGH THROUGHPUT SCREENING INITIATIVE - ROUND 1.

C. S. Smith, J. Bucher, A. Dearry, C. Portier, R. Tice, K. Witt and B. Collins. *Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.*

In support of a new HTS Initiative, the NTP is collaborating with the NIH Chemical Genomics Center (NCGC) to use quantitative HTS (qHTS) assays to test compounds for activity against defined biological targets (see Tice et al. Poster). This collaboration benefits both programs by adding toxicity testing capabilities to the NIH Molecular Libraries Initiative (MLI), and by allowing rapid implementation of NTP's HTS program designed to screen large numbers of compounds for activity against targets and pathways with toxicological relevance (e.g., oxidative stress, inflammation, apoptosis). The NTP will link HTS-produced toxicity data to data from traditional toxicity assays, with the goal of identifying mechanisms of action requiring additional investigation, developing predictive models for biological response, and prioritizing substances for further evaluation. For the first round of testing, the NTP provided 1408 compounds (1353 unique, 55 duplicates to assess assay reproducibility) selected because they were soluble in dimethylsulfoxide at 10 mM and because they were associated with publicly available bioassay results. Most of these compounds originated as nominations to the NTP for toxicity testing of various types, and of these, virtually all have been tested in the Salmonella mutagenicity battery, while many have been studied in reproductive and chronic rodent bioassays. Also, reference sets of compounds proposed for developing *in vitro* assays for endocrine disruption or ocular toxicity were included. The set sent to the NCGC include nearly every chemical class of small molecules imaginable. Molecular weights ranged from approximately 100 to 400. Functionally, the set includes solvents, fire retardants, preservatives, flavoring agents, plasticizers, therapeutic agents, inorganic and organic pollutants, drinking water disinfection byproducts, pesticides and natural products. A second set of compounds is currently being chosen based on the knowledge gained from this first set.

1188 MODE OF ACTION-BASED EVALUATION OF RAPID CELL-BASED TOXICITY SENSORS.

B. Gadagbui, A. Maier, A. Parker and P. Nance. *Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH.*

Water supplies are potential targets for contamination with a broad spectrum of industrial and agricultural chemicals. Rather than relying on biosensor technologies that identify specific analytes or a very limited number of analytes in water samples, current research is focusing on the use of rapid responses of cell-based systems to identify toxicity associated with a broad range of chemicals. The goal of the current work was to develop a prioritized list of candidate toxicity sensor endpoints for further evaluation or development by: (1) identifying new technologies and novel modes of action that can detect broad classes of chemicals relevant to human health risk prediction; (2) critically evaluating cell or macromolecule-based processes that may serve as suitable endpoints for rapid toxicity assessment of water; (3) ranking candidate endpoints based on a set of criteria; and (4) evaluating the strengths and limitations of various toxicity assays. About 150 cell-based assay technologies were identified and categorized by relevant modes of action or toxicological endpoints. Based on this analysis, current assays are likely to provide adequate detection in the human acute toxicity range of chemicals that act through well-conserved cell biology pathways. For example, agents that cause chemical or physical effects on cell membranes affect cellular energetics or cause cell death through formation of reactive electrophiles that bind nonspecifically. However, other specific cellular or tissue-specific targets may not be well represented by such general assays. Our analysis indicates that assays that target key neuroreceptors, ion transport mechanisms, and selected signal transduction pathways as well as whole tissue or systemic responses would benefit most from further research as potential toxicity biosensor assays.

1189 CYTOTOXICITY OF ORGANOSELENIUM COMPOUNDS IN NORMAL, IMMORTALIZED AND TRANSFORMED HUMAN BREAST CELLS CO-CULTURED IN A NOVEL CELL CULTURE SYSTEM, IDMOC.

A. P. Li¹, N. M. Li¹ and R. Sinha². ¹*Advanced Pharmaceutical Sciences, Columbia, MD* and ²*Biochemistry and Molecular Biology, Penn State College of Medicine, Hershey, PA.*

We report here an application of a novel cell culture system, the Integrated Discrete Multiple Organ Culture (IdMOC) in the evaluation of the cytotoxicity of anticancer agents towards the target cancer cells, and the nontarget normal cells. The IdMOC utilizes a wells-in-a-well concept, allowing multiple cell types to be cultured as physically discrete cultures but interconnected by an overlying medium. In this study, we evaluated the anticancer agent methylseleninic acid (MSA) and its inactive structural analogs Se-methylselenocysteine (MSC) and selenomethionine (SM). Human normal mammary epithelial cells (HMEC) were cocultured with an

immortalized mammary epithelial cell line (MCF10A) and a mammary adenocarcinoma cell line (MCF10AT). The IdMOC therefore models a breast tissue containing both a normal epithelium and cancer cell populations. The cells were treated with the selenium compounds for 24 hours up to the highest concentration of 100 μ M. MTT metabolism was used as a viability endpoint. MSA was found to be cytotoxic to all three cell types, while MSC and SM had no apparent cytotoxicity. The results show that MSA had slightly higher cytotoxicity towards the transformed cells than towards the normal cells. The calculated EC₅₀, EC₉₀ and EC₉₉ values were 14, 51 and 104 μ M for HMEC; 4, 24 and 53 μ M for MCF10A, and 8, 30, and 61 μ M for MCF10AT. The results show IdMOC can distinguish between cytotoxic (MSA) and noncytotoxic agents (MSC, SM) and, more importantly, can provide information towards differential cytotoxic effects towards normal and transformed cells.

1190 APPLICATION OF PREDICTION MODELS TO THE DEVELOPMENT OF A PEPTIDE REACTIVITY ASSAY FOR SCREENING CONTACT ALLERGENS.

L. Foertsch¹, B. Price¹, J. Chaney¹, J. Lepoittevin² and F. Gerberick¹. ¹*Procter & Gamble Company, Cincinnati, OH* and ²*Universite Louis Pasteur, Strasbourg, France.*

Currently, the skin sensitization potential of chemicals is assessed using the Local Lymph Node Assay (LLNA). In the interest of reducing animal use, *in vitro* alternatives to skin sensitization testing are under development. One characteristic of a chemical allergen is its ability to react with proteins prior to the induction of skin sensitization. The majority of chemical allergens is electrophilic and as such react with nucleophilic amino acids like cysteine or lysine. In order to determine if reactivity correlates with sensitization potential, 82 chemicals representing allergens of different potencies (weak to extreme) and non-sensitizers were evaluated for their ability to react with glutathione (GSH) or two synthetic peptides containing either cysteine or lysine. Following a 15 minute reaction time for GSH or a 24 hour reaction period for the 2 synthetic peptides, the samples were analyzed by HPLC. UV detection was used to monitor the depletion of GSH or the peptide following reaction. To determine whether reactivity can be used as a potential skin sensitization screening tool, the peptide reactivity data were analyzed against existing LLNA data using recursive partitioning methodology in order to build a classification tree that allowed a ranking of reactivity. An optimal split variable and a corresponding threshold value were selected to rank peptide reactivity as minimal, low, moderate and high using the available LLNA data on each of the tested chemicals. Non-allergens and weak allergens demonstrate minimal to low reactivity whereas moderate to extreme allergens demonstrate moderate to high reactivity. Finally, classifying minimal reactivity as non-sensitizers and low, moderate and high reactivity as sensitizers it was determined that models based on cysteine alone or with GSH and/or lysine have accuracies of greater than 87%. These models are currently ongoing further evaluation using additional test chemicals.

1191 INTER-LABORATORY EVALUATION OF A CYSTEINE AND GLUTATHIONE (GSH) PEPTIDE REACTIVITY ASSAY FOR SCREENING SKIN ALLERGENS.

B. Price¹, L. Foertsch¹, J. Chaney¹, H. Sakaguchi², Y. Takahashi², F. Sato², H. Suzuki² and F. Gerberick¹. ¹*Procter & Gamble Company, Cincinnati, OH* and ²*Kao Corporation, Tochigi, Japan.*

A direct peptide reactivity assay has been developed as a potential screening assay for assessing skin sensitization potential. This assay involves the examination of peptide depletion by HPLC after incubation of the peptide with chemicals. Previous results using 52 allergens and 30 non-allergens have demonstrated a good correlation between reactivity and allergenic potency. In order for the assay to gain acceptance, it is necessary to demonstrate that the assay is robust and transferable. To investigate this an inter-laboratory study was designed to evaluate the peptide reactivity of 15 chemicals (4 non-sensitizers and 11 sensitizers). In order to determine whether reactivity can be used as a potential skin sensitization screening tool, measurements of peptide reactivity were taken for the cysteine peptide at a 1:10 or 1:50 ratio and GSH at a 1:10 ratio. The majority of the 15 chemicals showed similar peptide depletion values for both the GSH and cysteine peptides. The results indicate that the more potent allergens give the greatest amount of peptide depletion. The data were analyzed using recursive partitioning methodology that incorporates a classification tree. The algorithm involves starting with the complete data set and seeking to partition it into separate subgroups. An optimal split variable and a corresponding threshold value were selected to rank reactivity as minimal, low, moderate and high using available Local Lymph Node Assay data on each of the tested chemicals. Classifying minimal reactivity as non-sensitizers and low, moderate and high reactivity as sensitizers it was determined that Kao and P&G classified 15/15 and 14/15, respectively. This ranking of peptide reactivity allows the potential to use the data in combination with other *in vitro* data (e.g., cell-based work, skin penetration data) in a battery approach for replacement of *in vivo* skin sensitization testing.

1192 DEVELOPMENT AND PRELIMINARY EVALUATION OF A MONOCLONAL ANTIBODY BASED ASSAY FOR DETECTING PROTEIN REACTIVE CHEMICALS.

P. Aeby¹, P. Griem², F. Gerberick³ and C. Goebel⁴. ¹Experimental Product Safety, Procter & Gamble Co., Wella-Cosmital SA, Marly, Switzerland, ²Clariant GmbH, Sulzbach am Taunus, Germany, ³Central Product Safety, Procter & Gamble Co., Cincinnati, OH and ⁴Human Safety Assessment, Procter & Gamble Co., Wella Service GmbH, Darmstadt, Germany.

In order to elicit a sensitization reaction, a chemical has to penetrate into the skin, react with proteins, be presented by antigen presenting cells and be recognized as an antigenic haptenized peptide by immune cells. Since a correlation between protein reactivity and skin sensitization has been established, the measurement of the protein binding properties of a chemical may represent a promising endpoint for the development of an *in vitro* approach to detect the sensitizing potential of chemicals. With the support of The European Cosmetic Toiletry and Perfumery Association (Colipa) we have developed monoclonal antibodies (MoAbs) against CLIP (class II-associated invariant-chain) peptides with Lysine or Cysteine substituted side chains. These synthetic CLIP peptides represent a functional target for reactive chemicals. Modification of the side chains by a test chemical or its metabolites (haptenization) can be detected as a decrease of the binding affinity of the MoAbs specific for the unmodified CLIP peptides. In this assay, the synthetic CLIP peptides coated on Dextran beads are first incubated with a range of test chemical concentrations for 1 to 30 hours. The beads are then transferred and coated to 96 wells plates, and incubated with the specific MoAb-peroxidase conjugates in an ELISA-like assay format. First results demonstrate that modification (haptenization) by test chemicals of the sulfhydryl or amino functional group in the peptide-side-chain led to a concentration dependent loss of reactivity when the appropriate matching pairs of monoclonal antibody - peptide dextran-conjugate are used. Further work is ongoing in order to test more chemicals and to establish a correlation between the protein binding capacity measured in our assay and the sensitization potential of a chemical.

1193 MEASUREMENT OF CD86 EXPRESSION AND IL-8 SECRETION FOR THE DETECTION OF CONTACT ALLERGENS IN THE U937 CELL LINE.

F. Python¹, C. Goebel², S. Python¹, F. Protopapa¹ and P. Aeby¹. ¹Experimental Product Safety, Procter & Gamble Co., Wella-Cosmital SA, Marly, Switzerland and ²Human Safety Assessment, Procter & Gamble Co., Wella Service GmbH, Darmstadt, Germany. Sponsor: F. Gerberick.

The human myeloid cell line U937 is being evaluated as a test system for the detection of contact allergens based on the CD86 expression and IL-8 secretion. In a previous *in vitro* test protocol called "U937 activation test", we demonstrated the capacity of this cell line to discriminate sensitizers from non-sensitizers according to CD86 expression and gene expression of interleukin-1 β (IL-1 β) and IL-8 at three different time points (work recently submitted for publication). In the present study, we evaluated a simplified version of the test procedure by analyzing the expression of CD86 by flow cytometry and the secretion of IL-8 by Enzyme-Linked Immunosorbent Assay (ELISA) after a 72 hrs exposure period. About 20 chemicals have been evaluated in this new assay format. Most of sensitizers induced a dose-dependent increase in CD86 expression and IL-8 production. Most of non-sensitizers induced no relevant increase in the expression of these two markers. Based on the relative CD86 and IL-8 expression levels, a simple and empirically defined approach is proposed to evaluate the sensitizing potential of each chemical. These *in vitro* data were finally compared with the *in vivo* data obtained by the local lymph node assay (LLNA). We conclude that the combination of CD86 protein expression and IL-8 secretion allowed to discriminate sensitizers from non-sensitizers, indicating that the U937 cell line is a promising test system that may contribute to reduce animal testing.

1194 METHOD OPTIMIZATION OF A PEROXIDASE PEPTIDE REACTIVITY ASSAY FOR SCREENING THE SKIN SENSITIZATION POTENTIAL OF PROHAPTENS.

J. Troutman¹, F. Gerberick¹, L. Foertsch¹, M. Quijano¹, R. Dobson¹ and J. Lepoittevin². ¹Procter & Gamble Company, Cincinnati, OH and ²Universite Louis Pasteur, Strasbourg, France.

Reactivity of electrophilic sensitizers (haptens) to protein nucleophiles is considered a necessary event in the induction skin sensitization. With the desire to develop non-animal screening methods to reduce our reliance on animal testing, an *in vitro* model that measures the reactivity of chemical allergens to nucleophilic peptides (e.g., cysteine) was developed. Analysis of 82 chemicals, including sensitizers and non-sensitizers, confirmed the correlation between reactivity and sensitization potential. A challenge of this assay is that some chemical sensitizers are non-reactive (prohaptens) and require bioactivation to a reactive metabolite (electrophilic hapten) prior to initiating a skin sensitization response *in vivo*. By incorporating a

mechanism for metabolic activation of prohaptens, the use of peptide reactivity data would improve prospective evaluations of novel chemicals and potentially reduce misclassifications due to false negatives. The purpose of this work was to optimize assay parameters for determining the reactivity of prohaptens using peroxidase and peroxide. An anchoring approach was employed to evaluate the effect of altered experimental conditions as well as incorporating appropriate controls to compensate for loss of peptide monomer due to the effects of peroxidase and peroxide. Incubation time, enzyme concentration and pre- and post-incubation treatment of chemical reactions with dithiothreitol were examined using prototypical prohaptens. Results indicate that peptide reactivity profiles in the presence and absence of peroxidase and peroxide is a useful approach for identifying prohaptens from directly reactive haptens. Enhancement of reactivity has been demonstrated with classic prohaptens such as cinnamyl alcohol, eugenol, and 3-aminophenol. Additional testing will be required to determine the usefulness of this approach for predicting the skin sensitization potential of novel compounds in a battery approach.

1195 IN VITRO GENOTOXICITY-TESTING USING THE PHENION® FULL THICKNESS SKIN MODEL.

K. Reisinger¹, B. De Wever¹, C. Wiegand¹, J. Scheel² and D. Eschrich¹. ¹Phenion GmbH & Co KG, DNE-sseldorf, Germany and ²Corporate SHE and Product Safety / Human Safety Assessment, Henkel KGaA, DNE-sseldorf, Germany.

Currently existing *in vitro* genotoxicity assays demonstrate high sensitivity but low specificity resulting in a high number of false positive results. Additionally, with regard to cosmetic ingredient and product testing, the most relevant tissue for genotoxicity testing is considered to be human skin, the primary target. Therefore we established a genotoxicity assay using the Phenion® Full Thickness Skin Model featuring tissue- and species-specific metabolism. The model consists of a dermal and an epidermal equivalent and represents a physiologically relevant model for testing the influence of xenobiotics. Our work focuses on the Micronucleus Assay for detecting the genotoxic impact of substances after topical application. This assay accounts for persisting damages of chromosomal structure or deficient segregation. A protocol was established for isolating both keratinocytes and fibroblasts from the *in vitro* skin model. First results with isolated keratinocytes are presented showing the suitability of this test system.

1196 PERFORMANCE OF EPISKIN™ AND EPIDERM™, TWO IN VITRO SKIN IRRITATION TEST METHODS, USING THE EPA AND GHS HAZARD CLASSIFICATION SYSTEMS.

D. Allen¹, J. Truax¹, A. Jacobs², A. Rispin³, R. Tice⁴ and W. Stokes⁴. ¹ILS, Inc., Research Triangle Park, NC, ²FDA, Silver Spring, MD, ³EPA, Washington, DC and ⁴NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

The European Centre for the Validation of Alternative Methods (ECVAM) recently completed a skin irritation validation study (SIVS) to evaluate EPISKIN™ and EpiDerm™, two test methods using *in vitro* human skin constructs optimized to detect skin irritation, as potential replacements for the *in vivo* rabbit dermal irritation test when using the EU hazard classification system. Because U.S. and United Nations regulatory hazard classification systems differ from the EU system in having three categories vs two, NICEATM/ICCVAM conducted additional analyses of the SIVS database using decision criteria based on those developed by ECVAM. The accuracy of the two test methods to identify skin irritants using the EPA and GHS systems ranged from 43-58%, depending on the test method used and classification system employed. The major limitation is their inability to identify mild and moderate irritants, which are over- and under-predicted up to 87% and 14% of the time, respectively, depending on the test method [and with or without the inclusion of IL-1 α analysis] and the classification system used. However, when predictivity for the irritant category according to the EPA and GHS systems is compared to predictivity for the mild irritant and nonirritant combined categories, the false negative rate for EPISKIN™ is 0% for both classification systems vs 33%-35% for EpiDerm™, and the false positive rate for EPISKIN™ is 37%-47% vs 22%-28% for EpiDerm™. Because the false negative rate is 0%, EPISKIN™ may be useful as a screening test to identify substances that are not irritants (e.g., GHS Category 2/EPA Category II). However, the performance characteristics for these *in vitro* test methods, when using three-category hazard classification systems, indicate that further optimization would be needed before they can be used to fully support U.S. regulatory decisions. Supported by NIEHS contract N01-ES-35504.

1197 EVALUATION OF EYE IRRITATION POTENTIAL USING IN VITRO SHORT TIME EXPOSURE (STE) METHOD.

Y. Takahashi¹, T. Hayashi², M. Ohzeki¹, H. Kuwahara², Y. Ito¹, H. Sakaguchi¹ and H. Suzuki¹. ¹Kao Corporation, Tochigi, Japan and ²Kanebo Cosmetics INC., Kanagawa, Japan. Sponsor: J. Avalos.

There is a greater urgency to develop non-animal safety tests in view of the forthcoming EU ban on *in vivo* testing (7th amendment to the Cosmetic Directive). For the evaluation of eye irritation, some *in vitro* assays are used, but none are accepted

as an OECD test. Previously we reported a good predictive capacity for eye irritation of personal care and household products using Short Time Exposure (STE) method. The method involved assessing cytotoxicity with SIRC (rabbit corneal cell line) cells following a one 5 minute dose treatment. In the current study, the aim was to confirm the predictive capacity of the STE method for assessing eye irritation of cosmetic ingredients and chemicals in the ECETOC database. First, we selected test concentrations with good correlation between the Draize MAS and cell viability in the STE using 31 cosmetic ingredients. Physiological saline or EMEM/FBS medium was the vehicle and test concentration was 0.05%. We repeated the process for 20 more chemicals. For some organic solvents (e.g. acetone, toluene), mineral oil was used as the vehicle and test dose was 5%. The results of the 51 chemicals were analyzed. Chemicals with a MAS ≥ 15 for Draize test or cell viability $\leq 70\%$ for STE method were classified as irritants. Those chemicals outside of these parameters were classified as non-irritants. The accuracy of this classification for the 51 chemicals was about 78%. For our second goal, an inter-laboratory study was conducted with 31 cosmetic ingredients to confirm inter-laboratory reproducibility using same protocol, treatment dose, and cell lot. The two laboratories obtained identical data classifications for our STE method. These data suggest that the STE method has a good predictive capacity, easy transferability, and good reproducibility. The advantage of using this method as a useful *in vitro* eye irritation test is that it is a easy (5 min., one-dose) and fast method to use plus and it has the ability to evaluate eye irritation potential of both products and ingredients.

1198 ASSESSMENT OF OCULAR RESPONSE TO COMPOUNDS USING AN *IN VITRO* HUMAN CORNEAL EPITHELIAL CULTURE MODEL.

L. Amenuvor, P. Rodin, S. A. Hauber, K. N. Roberts and M. J. Powers. *Cambrex Bio Science Walkersville, Inc., Walkersville, MD.*

These studies were designed to evaluate the performance of the Clonetics® Human Corneal Epithelial Model in assessing ocular barrier function and irritancy response. Trans epithelial electrical resistance (TEER) was used to assess barrier function of the models. TEER measurement results for multiple lots of models averaged >1700 ohms $\times$ cm², which approaches the values observed in *ex vivo* corneal tissue. Test chemicals for evaluating ocular irritancy response were selected from the ECETOC Eye Irritation Reference Chemicals Data Bank (Second Edition). The cytotoxicity response of the model system to 34 test compounds at concentrations correlating to a full range of ocular irritancy categories was evaluated. Time-to-toxicity was determined using the MTT cytotoxicity assay. The compounds were applied topically at sequential time points to calculate the time at which 50% of cells are rendered non-viable (ET50). In order to distinguish irritants from non-irritants, a prediction model cutoff was identified at ET50 = 15 minutes. The ET50 results were compared with Draize Modified Maximum Average Scores (MMAS), and with the irritancy categories of the Globally Harmonized System of Classification and Labeling of Chemicals (GHS). Irritancy response showed sensitivity (percent of irritating chemicals identified correctly) of 100% (11/11), and specificity (percent of non-irritating chemicals identified correctly) of 70% (16/23), and an overall concordance of 79% (27/34). Lot-to-lot consistency in tissue response was demonstrated with statistical analysis of irritancy data of the positive control (0.3% Triton X-100). These results indicate that the Clonetics Human Corneal Epithelial Model is a robust platform for the evaluation of corneal epithelial function and response.

1199 USE OF THE EPIOCLAR ASSAY FOR PRECLINICAL QUALIFICATION OF FORMULAS FOR HUMAN CLINICAL STUDIES.

P. Niranjani, A. H. Dang, B. G. January, C. Gómez and J. W. Harbell. *Mary Kay Inc., Dallas, TX.*

Cosmetic products applied around the eyes must be extremely mild because of the sensitivity of the skin in this region and the chronic use of such products. The topical application, assay using the EpiOcular tissue construct (Ghassemi et al 1997), is being extensively evaluated for the prediction of product mildness. In this study, we report the correlation between ET50 (exposure time required to reduce cell viability to 50%) responses in the EpiOcular assay and eye-area irritation in human clinical testing. Formulations were applied neat to the EpiOcular construct (MatTek) for up to 4 hours or 20 hours (depending on the expected degree of irritancy) and the ET50 of the water-treated controls were measured using tetrazolium dye (MTT) reduction. The EpiOcular assay was used as part of the preclinical qualification of products for subsequent *in vivo* studies. The *in vivo* studies were safety-in-use studies performed to evaluate eye irritation potential in individuals with self-perceived sensitive eyes or who were contact lens wearers. These studies are intended to evaluate eye-area products under "real-world use." These studies were conducted under the supervision of an ophthalmologist. The ophthalmologic evaluation included a gross exam, slit-lamp exam, and visual acuity exam. After baseline exams, subjects were instructed to use the eye area formulation over the next several weeks. Final examinations were conducted to determine eye irritation after the use period. The eye irritation scale ranged from no irritation (0) to severe irritation (4).

Ten eye area products were evaluated in the Epiocular assay with ET50 values ranging from >240 min to >1440 min. Products with ET50 values >240 min were evaluated clinically and showed no to minimal irritation in the clinical studies. These observations establish that the data from an epiocular assay lend support to the results of an *in vivo* assessment of the product. In addition, the lack of ocular irritation potential established, by these studies also indicate that the product is not likely to induce dermal irritation.

1200 EVALUATION OF VIABILITY MEASUREMENT (MTT) AND HISTOLOGY AS PARAMETERS FOR THE *IN VITRO* ASSESSMENT OF THE EYE IRRITATION POTENTIAL OF HAIR DYES WITH A RECONSTITUTED HUMAN CORNEAL EPITHELIUM MODEL.

C. Faller¹, P. Aeby¹, K. Smith², P. McNamee², R. Roggeband³ and C. Goebel⁴. ¹Experimental Product Safety, Procter & Gamble Co., Wella-Cosmital SA, Marly, Switzerland, ²Central Product Safety, Procter & Gamble Technical Centres Ltd., Egham, Surrey, United Kingdom, ³Central Product Safety, Procter & Gamble Eurocor, Strombeek-Bever, Belgium and ⁴Human Safety Assessment, Procter & Gamble Co., Wella Service GmbH, Darmstadt, Germany. Sponsor: F. Gerberick.

The evaluation of the human corneal epithelium (HCE) SkinEthic model to assess acute ocular irritation of chemicals has been the subject of a formal prevalidation study. This model was shown to be able to discriminate between irritants and non-irritants by means of a prediction model based on viability measurement in the MTT assay. In a preliminary study using this *in vitro* approach with six hair dyes, we had evaluated the *in vivo/in vitro* concordance by comparing MTT viability and histology with existing *in vivo* Draize data and had concluded that the use of the HCE model with evaluation of histology as additional endpoint was a promising tool for the detection of the ocular irritation potential of hair dyes. In this study, the applicability of this *in vitro* approach (using both MTT and histology) for hair dyes has been further evaluated *in vitro* only, with additional dyes with different coloring and/or physico-chemical properties. The materials were applied topically, either neat or diluted, for different time periods onto the surface of HCE constructs. First results demonstrate that MTT can be used to differentiate between cytotoxic and non-cytotoxic hair dyes. Possible interference of the dyes with the test system was evaluated to exclude artefacts. Preliminary histology results show that the assessment of the time-dependent morphological changes can also be useful to discriminate the dyes based on their capacity to damage the corneal epithelium structures, either as a confirmatory endpoint, or if needed, as a possible replacement of MTT.

1201 AN ALTERNATIVE MODEL OF CORNEAL IRRITATION AND REVERSIBILITY IN EXCISED PORCINE CORNEAS.

A. C. Gilotti, D. R. Cerven and A. Ball. *MB Research Laboratories, Spinnerstown, PA.*

We have developed an alternative to the Draize Eye Irritation Test in rabbits. The Porcine Corneal Opacity Reversibility Assay (PorCORA) determines eye irritancy as well as reversibility. Although a number of alternative assays exist for the determination of irritancy (eg. BCOP, HET-CAM, CAMVA, EpiOcular), none address the important endpoint of reversibility. The failure of present assays to determine reversibility may account for the delay in regulatory acceptance of other alternative methods because recovery time is used to categorize potential irritancy.

The assay can be used to evaluate chemicals for ocular irritancy and reversibility using excised porcine corneas (usually discarded by the meat industry). Excised corneas were maintained for over three weeks with minimal morphological changes to the corneal epithelium. Corneas were treated one day after excision with 100% EtOH, 3% SDS, 1N NaOH or 1% Benzalkonium Chloride. The area of damage on the corneal surface was visualized with brief fluorescein staining under UV illumination. This visualization method is not destructive to the sample enabling repeated measurements of fluorescein retention on the same tissue. With the exception of NaOH, the area of damage decreased over time in culture. Histological analysis showed re-epithelialization of the tissues where they had been previously damaged by chemical irritants. The decrease in fluorescein retention area correlated favorably with the time to recovery in published Draize rabbit eye test results. The PorCORA may fill the gap that is left by current alternative eye irritation assays since it has the potential to determine recovery after initial eye irritation. The PorCORA, is a good candidate for a tier testing strategy to replace the Draize eye test.

1202 THE COMPARATIVE TOXICOGENOMICS DATABASE: CONNECTING CHEMICALS, GENES AND DISEASES.

A. P. Davis¹, C. Mattingly¹, M. Rosenstein¹, T. Wiegiers¹, J. Forrest^{1,2} and J. Boyer^{1,2}. ¹The Mount Desert Island Biological Laboratory, Salisbury Cove, ME and ²Yale University School of Medicine, New Haven, CT. Sponsor: W. Toscano.

The etiology of most chronic diseases involves interactions between environmental factors and genes that modulate important physiological processes. One critical environmental factor is chemical exposure. Understanding interactions between

chemicals and genes/proteins at the molecular level will help resolve questions concerning disease predisposition, therapeutic drug interactions, and health risks associated with differential susceptibility to exposures. Towards this end, we are developing the Comparative Toxicogenomics Database (CTD; <http://ctd.mdibl.org>) as a public resource to integrate and curate diverse data to promote the understanding of chemical interactions with genes and proteins.

CTD currently incorporates 59,000 chemicals, 1.2 million sequences (with Gene Ontology annotations), 83,000 taxonomic terms, 6,000 human diseases, and 78,000 references to produce a unique database for the cross-species analysis of chemical, gene/protein, and disease interactions. We also now manually curate the literature to capture specific details of every chemical-gene/protein interaction using searchable controlled vocabularies. To date, more than 22,000 interactions have been curated for 2,200 chemicals and 3,500 genes. Currently, over 650 genes have both a disease association and a curated chemical interaction, opening up the way to explore putative chemical-disease connections. User-friendly query pages and vocabulary browsers allow scientists to ask sophisticated questions and explore the data in detail from a chemical, gene, and disease perspective; all results can be downloaded in spreadsheets for further analysis.

CTD is a public information resource that supports hypothesis-driven research about chemical actions, enhances understanding about complex chemical-gene/protein networks and their impact on human health, and helps turn dispersed toxicology information into knowledge.

1203 CEBS 2.0.7 - INTEGRATING TOXICOLOGY AND TOXICOGENOMICS.

H. Gong², J. Fostel^{1,4}, M. Waters¹, S. Stasiewicz¹, B. Merrick¹, K. Tomer¹, P. Bushel¹, R. Paules¹, N. Stegman¹, G. Nehls^{1,4}, J. Yost², H. Johnson², S. Gustafson², S. Xirasagar², N. Xiao², H. Cheng-Cheng², P. Boyer², S. Bittenbinder², S. McCrimmon², J. Taylor³, D. Choi^{4,5}, A. Rashid³, S. Skutnick^{1,4}, J. Selkirk¹ and R. Tennant¹. ¹NIEHS, Research Triangle Park, NC, ²Science Applications International Corporation, Germantown, MD, ³Large Scale Biology Corporation, Vacaville, CA, ⁴Lockheed Martin Information Technologies, Research Triangle Park, NC and ⁵Research Triangle Institute, Research Triangle Park, NC.

The Chemical Effects in Biological Systems (CEBS) Knowledgebase has been under development at the National Institute of Environmental Health Science (NIEHS) for four years. Earlier versions of CEBS have been reported, and now we report the completion of CEBS version 2, which fully integrates study design and toxicity data with data obtained from microarray and proteomics studies. Using CEBS v.2, the user can filter the database on the basis of biological responses of subjects and other characteristics of the subject or study, and then navigate to the microarray domain in CEBS for analysis of the associated gene expression data. Additionally, CEBS users can annotate lists of genes using more than 50 public annotation resources, managed by the caBIO engine developed by the NCICB. Gene lists may result from analysis within CEBS or may be entered by the user. CEBS contains both private and public data; public data, including toxicity findings, microarray data and proteomics images and spectra can be downloaded from CEBS. CEBS now resides at the NIEHS, on three state-of-the-art servers, and has been subjected to multiple cycles of stress testing. CEBS can be accessed at <http://cebs.niehs.nih.gov>.

1204 TOXICOGENOMICS APPLICATIONS OF THE BIOMEDICAL INVESTIGATION DATABASE (BID).

J. Fostel^{1,2,3}, A. Rashid^{1,2}, D. Choi^{1,4}, A. Ahmed³, R. Howle³, M. Waters¹, M. ILSI HESI Committee on Genomics in Mechanism Based⁵, M. National Toxicology Program (NTP)³ and M. OBI Ontology for Biomedical Investigations Working⁵. ¹NIEHS, Research Triangle Park, NC, ²Lockheed Martin Information Technologies, Research Triangle Park, NC, ³Alpha-Gamma Technologies, Raleigh, NC, ⁴Research Triangle Institute, Research Triangle Park, NC and ⁵affiliated committee, Research Triangle Park, NC.

Several collaborative efforts to create large, public toxicogenomics datasets are underway, including efforts by members of the HESI Genomics Committee, and the NTP High Throughput Screening Faculty. Data exchange among laboratories reveals that while inter-laboratory agreement is generally high, a variety of metadata are needed to properly interpret the collaborative data set. Such metadata are described in the Chemical Effects in Biological Systems (CEBS) Data Dictionary (Tox.Sci. 2006). The BID, Biomedical Investigation Database, is used to manage and curate data prior to loading into a public repository such as CEBS (<http://cebs.niehs.nih.gov>). BID has been shared with major data contributors such as Health Canada, for use behind their firewall prior to publishing data in CEBS. BID is a flexible data repository for *any* deposited data, and at the moment houses toxicogenomics data, PCR data from genetic toxicology studies performed by ILSI HESI members, and cheminformatics data from high throughput screening carried out by the NTP and the National Chemical Genomics Center (NCGC). Looking

towards the future, BID development parallels the development of OBI, Ontology for Biomedical Investigations, an ontology under development by the OBI Working Group (<http://fugo.sourceforge.net/>). Once completed and fully integrated with OBI, BID will be accessible via the semantic web. Additional information about BID is at <http://www.niehs.nih.gov/cebs-df/>.

1205 ADVERSE EFFECTS OF PHARMACEUTICALS: I. CONSTRUCTION OF A RELATIONAL DATABASE OF ADVERSE HUMAN EFFECTS USING FDA ARCHIVES, PHARMAPENDIUM, AND PUBLIC SOURCES.

C. J. Ursem¹, E. J. Matthews¹, N. L. Kruhlak¹, R. Benz¹, P. MacLaughlin² and J. F. Contrera¹. ¹CDER / OPS / ICSAS, Food and Drug Administration, Silver Spring, MD and ²Elsevier MDL, San Ramon, CA.

The Informatics and Computational Safety Analysis Staff at the US FDA's Center for Drug Evaluation and Research has created a database of pharmaceutical adverse effect (AE) and toxicology findings linked to pharmaceutical chemical structure, drug class, clinical indication, receptor target, and estimated patient exposure. The database is being used to develop quantitative structure activity relationship (QSAR) models and to identify possible mechanisms for AEs (see related poster). The pre-clinical, clinical, and post-marketing observations contained in the database were obtained from FDA's Spontaneous Reporting System, PharmaPendium software, and public sources using Micromedex Integrated Index. PharmaPendium includes information from FDA drug approval packages, Meyler's Side Effects of Drugs, drug monographs from Mosby's Drug Consult, FDA's Adverse Event Reporting System, and the published literature. The data describing drug class, clinical indication, and pharmacological target were derived from PharmaPendium and the literature, with the addition of predicted target sites from the Prous Institute for Biomedical Research's BioEpisteme mechanism of action module. In order to integrate the data from multiple sources, PharmaPendium's standard vocabulary was employed for all AE endpoints and pharmaceutical generic names. The database now contains 4,849 unique pharmaceutical compounds and 11,211 AE endpoints. To account for variations in the AE reports due to different patient populations for each drug, we estimated patient exposure based on the number of reports for each drug expressed as a percentage of the total number of reports in the AE database. This denominator was applied to data from all endpoints to identify chemicals that could be scored positive in the training data sets of QSAR models predicting AEs.

1206 ADVERSE EFFECTS OF PHARMACEUTICALS: II. PREDICTION OF HUMAN LIVER AND KIDNEY EFFECTS USING AN ADVERSE EFFECTS DATABASE, MC4PC, AND BIOEPISTEME.

E. J. Matthews¹, C. J. Ursem¹, N. L. Kruhlak¹, R. Benz¹, J. Prous², D. Aragonés², J. Ivanov³, G. Klopman³ and J. F. Contrera¹. ¹CDER / OPS / ICSAS, Food and Drug Administration, Silver Spring, MD, ²Prous Institute for Biomedical Research, Barcelona, Spain and ³MultiCASE, Inc., Cleveland, OH.

The Informatics and Computational Safety Analysis Staff at the US FDA's Center for Drug Evaluation and Research conducted an investigation employing in silico methods to predict possible human liver and kidney adverse effects (AEs) of drugs. The investigation used an AE database (see related poster) combined with a weight of evidence (WoE) paradigm to identify drugs with significant findings. Quantitative structure activity relationship (QSAR) models were constructed using the MC4PC (MultiCASE, Inc.) and BioEpisteme (Prous Institute for Biomedical Research) programs to predict the activities of drug molecules. The number of AE reports for each drug was expressed as a percentage of the total number of reports in the AE database to provide a background (expected) level of reporting. Using a WoE approach, a biologically significant finding was defined as one having positive findings for more than one toxicologically related endpoint, a method which was validated using data on drugs withdrawn from the market with significant post-marketing AEs. Fragment-based MC4PC models were constructed using liver and kidney AE data sets and model predictive performance was optimized using 10% Leave-Many-Out internal validation experiments to yield high specificity (>85%) and receiver operating coefficients (>2.0). Molecular descriptor-based BioEpisteme models were used to predict the most probable mechanisms of action of a drug molecule based upon 3D molecular conformations and a training set of known drug receptor site targets reported in >200,000 drug patents. BioEpisteme predictions were validated by comparing known and predicted drug receptor site targets. Results are presented for adverse human liver and kidney effects in terms of MC4PC model predictive performance and BioEpisteme predicted mechanisms for drug toxicity experiments.

1207 THE MOUSE GENOME INFORMATICS DATABASE: INTEGRATING SEQUENCE, GENE FUNCTION, AND MOUSE MUTANT PHENOTYPE DATA.

S. M. Bello, C. L. Smith, H. Dene, D. L. Burkart, L. L. Washburn, I. Lu, M. Tomczuk, A. Anagnostopoulos, B. Richards-Smith, M. Updegraff, H. Onda, R. Babiuk and J. T. Eppig. *Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME.*

The Mouse Genome Informatics Database (MGI, <http://www.informatics.jax.org>) is a free international resource for the genetics, genomics, and biology of the laboratory mouse. MGI includes annotations of descriptions of mouse mutant phenotypes and relationships of genes and gene products to molecular function, biological process, and cellular component using controlled vocabularies. These annotations are integrated with other biological data in MGI allowing users to search, compare, and analyze data that are not effectively retrieved through text searches. To access these integrated resources, database query forms are structured to allow complex queries that can simultaneously include parameters for phenotype, expression, biochemical function, subcellular location, sequence, and genome location. Complex queries can be posed to identify candidate genes using select phenotype characteristics, gene functions and/or gene expression profile. For example one can ask "What genes are expressed in the liver, have mutations resulting in increased susceptibility to induced tumors, and are known to be involved in the cell cycle?" MGI may also be used to identify strains with sequence differences (SNPs) in select genes or chromosome regions that can then be evaluated for differences in susceptibility to one or more compounds. In addition MGI provides access to prototype tools that use Gene Ontology (GO) annotations to aid in microarray analysis and candidate gene identification. Finally, MGI links to the International Mouse Strain Resource to aid in locating and obtaining mice. Integration and the use of structured vocabularies for annotations assists in robust and accurate data mining when posing such complex questions in both computational and individual formats at MGI.

The Mouse Genome Database (MGD) at MGI is supported by NIH/NHGRI grant HG000330.

1208 EXAMINATION OF GENETIC NETWORKS THAT REGULATE GENE EXPRESSION IN LIVER USING COMPLEX TRAIT ANALYSIS.

D. Gatti¹, A. Maki¹, E. J. Chesler², R. Kirova², L. Lu³, J. Wang³, Y. Qu³, R. W. Williams³, A. Perkins⁴, M. A. Langston⁴, D. W. Threadgill⁵ and L. Rusyn¹. ¹Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC, ²Life Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN, ³Department of Anatomy and Neurobiology, University of Tennessee Health Science Center, Memphis, TN, ⁴Department of Computer Science, University of Tennessee, Knoxville, TN and ⁵Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Liver is a primary site for metabolism of nutrients, drugs and chemical agents. While metabolic pathways are complex and tightly regulated, genetic variation among individuals introduces yet another level of complexity into research on liver disease. This study aimed to dissect genetic networks that control liver-specific gene expression by combining large-scale mRNA expression analysis and gene mapping in a reference population of BXD recombinant inbred strains for which extensive SNP, haplotype and phenotypic data is publicly available. We profiled gene expression in livers of naive mice of both sexes from C57BL/6J, DBA/2J, B6D2F1, and 37 BXD strains, using Agilent oligonucleotide arrays. This data was used to map quantitative trait loci (QTLs) associated with variation in expression of about 19,000 transcripts. We identified polymorphic cis- and trans-acting loci, including several loci that control expression of large numbers of genes in liver, by comparing the physical transcript position with the location of the controlling QTL. The data is available through public web-based resource (www.genenetwork.org) that allows custom genetic linkage analysis, identification of co-regulated transcripts and correlated phenotypes, cross-tissue and -species comparison, as well as testing of a broad array of hypotheses.

1209 QUANTIFICATION OF GENOMIC DATA: VALUE-ADDED ASSESSMENT AND APPLICABILITY TO TOXICOLOGICALLY SIGNIFICANT ENDPOINTS.

M. Vredevoogd, X. Yu, B. Griffith and E. M. Faustman. *Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

The use of genomic methodologies has emerged as a valuable tool to assess toxicological responses through its ability to measure the expression patterns of thousands of genes within a single experiment. Translating genomic information into metrics that are easily used within toxicological and risk assessments, however, has been an

ongoing issue and difficult problem. In addition, the complexity of array data itself creates challenges for interpretation and subsequent application in areas such as risk assessment. Several research groups have proposed methods to address these issues, including the use of Gene Ontology (GO) mapping and pathway analysis, approaches that allows for the interpretation of array data within the context of biological or pathway response. The recently developed GO-Quant method (Yu et al 2006), takes the application of these methods further by creating an avenue for quantitative assessment of toxicogenomic data within specific biological pathways. This type of analysis gives quantitative functional information in terms of dose- and time providing a powerful tool for genomic interpretation and global pathway response. To further characterize and assess the general applicability of this approach, we applied the GO-Quant method to genomic data sets for endocrine disruptors found within the publicly available National Center for Biotechnology Information (NCBI) database. Our results delineate examples of the specific quantitative metrics that can be gained through the use of GO-Quant such as the characterization of effect levels (i.e. benchmark dose). This ability allows for improved toxicological interpretations, such as mode of action and biological pathway response, information critical to the development of risk assessment profiles.

1210 AUTOMATED QUANTITATIVE TOXICOGENOMIC DOSE-RESPONSE MODELING.

L. D. Burgoon^{1,2,4}, D. R. Boverhof^{2,3,4} and T. R. Zacharewski^{1,3,4}.

¹Toxicogenomic Informatics & Solutions, LLC, Lansing, MI, ²Department of Biochem and Molec Biol, Michigan State University, East Lansing, MI, ³Ctr for Integrative Toxicology, Michigan State University, East Lansing, MI and ⁴National Food Safety & Toxicology Ctr, Michigan State University, East Lansing, MI.

Toxicogenomics applied to dose-response studies yields hundreds of putative biomarkers of exposure and toxicity. Through phenotypic anchoring, functional annotation, and pathway analysis differential gene expression associated with toxicity may be identified, allowing investigators to develop novel quantitative, mechanistically-based biomarkers of toxicity to more accurately monitor and assess risk. Typically linear or other low-dose extrapolation models are fit manually to identify points of departure, however, this is difficult and time-consuming when many toxicogenomic responses (e.g., differential gene expression) do not exhibit sigmoidal, linear, or exponential dose-response characteristics. To facilitate high throughput model-fitting, we developed the ToxResponseModeler, a Java application capable of fitting: 1) sigmoidal, 2) linear, 3) quadratic, 4) exponential, and 5) modified gaussian function models. The ToxResponseModeler identifies the most suitable model for each gene using the particle swarm optimization algorithm (PSO) to identify the optimal set of parameters to model the response of interest. The best fitting models are then compared, and the optimal model is chosen for each gene based on the Euclidean distance between the model predicted and observed data. The nth percent effective dose (EDn), including points of departure, may be calculated using the optimal model. Vehicle-based points of departure are also calculated based on the intersections of the 95% or 99% confidence intervals for the vehicle and dose-response data. Collectively, this yields a point of departure with a known confidence interval, based on measurement variance. The utility of ToxResponseModeler is demonstrated using published toxicogenomic dose-response data from the livers of TCDD treated C57BL/6 mice. This work has been supported by NIEHS Suprefund grant P42 ES04911.

1211 ELUCIDATION OF DIFFERENTIAL RESPONSE NETWORKS FROM TOXICOGENOMICS DATA.

A. Bugrim¹, Z. Dezso¹, R. Welch², A. Naito², J. Fuscoe², C. Melvin², Y. Dragan², Y. Nikolsky¹ and T. Nikolskaya¹. ¹GeneGo, Inc., St. Joseph, MI and ²#U.S. Food and Drug Administration, National Center for Toxicological Research (NCTR), U.S. FDA NCTR, Jefferson, AZ.

We describe a novel approach for the analysis of toxicogenomics data and elucidation of biological networks impacted by drug treatment. Approximately 15,000 interconnected modules were generated from manually assembled human pathways maps in MetaCore (GeneGo, inc.). Next, microarray expression data from rats livers chronically exposed to phenobarbital, mestranol and tamoxifen were mapped onto these modules. Using different statistical and clustering procedures, we have identified the sets of pathways featuring "synchronous", highly correlated expression among multiple repeats of the same treatment while showing strong anti-correlation across different treatments. We identified a large number of pathways specifically differentiating phenobarbital from mestranol and tamoxifen treatments, and fewer pathways distinguishing tamoxifen from mestranol treatments. Reconstruction of network modules that distinguish chemical treatments also provides insights into mechanisms of such differences. Unlike traditional statistical and clustering procedures of gene expression profiling, our method is applicable to raw expression data, regardless of amplitude and statistical significance of expression change at individual data points. Statistical validity of expression data is determined

by signal correlation when mapping to functional pathways, not at the level of individual signals. This advance allows to substantially increase the pool of differentially expressed gene in analysis and avoid statistical bias in microarray gene expression studies.

1212 NONPARAMETRIC AND GRAPHICAL METHODS REVEAL NEW GENE PATTERNS IN LOW DOSE ARSENIC MICROARRAY EXPERIMENTS.

T. Hampton^{1,2}, J. C. Davey^{1,2}, J. A. Gosse^{1,2}, L. A. Warnke⁴, M. A. Ihnat⁴, A. S. Andrew², J. R. Shaw² and J. W. Hamilton^{1,2}. ¹Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, ²Center for Environmental Health Sciences, Dartmouth College, Hanover, NH, ³Dartmouth Toxic Metals Research Program, Dartmouth College, Hanover, NH and ⁴Cell Biology, University of Oklahoma, Oklahoma City, OK.

Gene microarrays can reveal informative patterns of gene regulation, providing a means to test hypotheses, generate new mechanistic hypotheses, and identify potential biomarkers of exposure, susceptibility and effect. However, applying these approaches to experiments using low doses or where there are modest treatment effects can yield non-informative, unstable results. Small changes in statistical parameters can lead to large changes in candidate gene list composition, and replicate experiments using the same approach may lead to lists that exhibit poor overlap. Using simpler, more direct alternatives to commonly used microarray statistics reduced these problems. We found that graphical techniques such as scatterplots of raw expression values, coupled with methods that allow for data that fails to follow a normal distribution, achieved better concordance between replicate experiments than standard parametric methods such as SAM. There is a strong biological and biochemical foundation for why gene regulation might behave in a non-parametric rather than a parametric manner, particularly in whole animal systems. Our methods found individual genes and groups of biologically related genes that the more common approaches missed, for example, identifying genes that are both up down and up-regulated, whereas SAM found only up-regulation. Comparison of these methods also shows how certain assumptions about data distribution can result in lists that are too short (false negatives) or long lists biased in favor of genes that do not show treatment specific effects (false positives) in low dose arsenic gene expression changes in mouse lung and Daphnia. (NIH-NIEHS ES07373, NSF DEB-0221837)

1213 IDENTIFICATION OF GENE EXPRESSION SIGNATURE IN BLOOD ASSOCIATED WITH ACETAMINOPHEN-INDUCED LIVER TOXICITY.

R. Shah¹, J. Parker¹, R. Fannin³, M. Russo², P. Watkins² and R. Paules³. ¹Constella Group, Durham, NC, ²UNC, Chapel Hill, NC and ³NIEHS, Research Triangle Park, NC.

Acetaminophen (APAP) is a widely used analgesic-antipyretic drug and its overdose (OD) is a leading cause of drug induced liver injury (DILI) and related fatalities. Current methods for diagnosing DILI are highly inadequate. This necessitates the discovery of novel biomarkers which may also shed light on mechanistic basis of liver toxicity.

We explored whether peripheral blood gene expression (PBGE) profiles could (1) distinguish individuals exposed to therapeutic or toxic doses of APAP from placebo; and (2) mimic the gene expression changes occurring in rat liver due to APAP treatment.

We analyzed PBGE resulting from 3 studies: (1) 6 subjects (4g APAP) + 3 placebo. PBGE was determined 24/48hr post-dosing when blood APAP levels were undetectable. (2) 5 subjects with OD (>10g APAP) with undetectable APAP levels at time of PBGE. (3) Gene expression from rat livers 12/24hrs post-dosing (1500/2500mg/kg APAP); using Agilent oligonucleotide arrays. PBGE was analyzed using Significance Analysis of Microarray (SAM) and enrichment of biological processes was examined using Significance Analysis of Function & Expression (SAFE). Prediction Analysis of Microarray (PAM) was used to identify genes that can predict APAP exposure.

We identified a minimal (16) and a maximal (6640) set of genes which can identify subjects exposed to APAP (either 4g or OD) with a predictive accuracy of 100% & 86%, respectively. Of the 6440, 1248 genes have orthologs in rat; and 474 of them differentially expressed in the same direction in rat liver & human blood. Within 474 genes, we find induction of apoptosis (p=0.007), ATP binding & synthesis (p=0.012), & cellular defense response (p=0.056) among the most significantly enriched biological processes.

We report a set of genes for which PBGE can (1) distinguish individuals exposed to APAP from controls with high accuracy even in absence of detectable APAP levels; and (2) mimic the changes occurring in liver. This approach can be helpful in diagnosing DILI and investigating mechanistic basis of toxicity by APAP and possibly other drugs.

1214 EVALUATION OF METRICS FOR ASSESSMENT OF MICROARRAY ASSAY PERFORMANCE USING A MIXED TISSUE RNA REFERENCE SAMPLE.

P. S. Pine¹, M. Boedigheimer², B. A. Rosenzweig¹, Y. Turpaz³, Y. He⁴, G. Delenstarr⁵, R. Shipley⁶, B. Ganter⁷, K. Jarnagin⁷, W. Jones⁸, L. Reid⁸ and K. Thompson¹. ¹CDER, U.S. FDA, Silver Spring, MD, ²Amgen Inc., Thousand Oaks, CA, ³Affymetrix Inc., Santa Clara, CA, ⁴Rosetta Inpharmatics LLC, Seattle, WA, ⁵Agilent Technologies, Santa Clara, CA, ⁶GE Healthcare, Tempe, AZ, ⁷Iconix Biosciences Inc., Mountain View, CA and ⁸Expression Analysis Inc., Durham, NC.

Data quality and comparability remain an issue with microarray technology, due in part to incomplete application of proper methods for performance monitoring. We have previously introduced a rat mixed tissue RNA reference sample that allows defined target ratios to be measured on multiple microarray platforms (Nucleic Acids Res. 33: e187, 2005). Using this material, we evaluated several metrics for monitoring and standardizing the performance of laboratories that run microarray assays. A quantitative assessment of performance should include measurements of assay selectivity and sensitivity as these parameters underlie most types of data analysis. The area under the curve (AUC) from receiver-operator characteristic (ROC) plots was found to be a good overall indicator of performance. More detailed information on precision and accuracy was derived from metrics that evaluated the reproducibility of the observed ratios and their deviation from target values. The applicability of these metrics to different testing paradigms, such as proficiency testing, process drift monitoring, and protocol optimization was also explored. The establishment of suitable metrics to assess the performance of microarray assays is essential for effective use of this technology in clinical and regulatory applications.

1215 SOURCES OF VARIABILITY IN BASELINE GENE EXPRESSION IN RAT LIVER AND KIDNEY.

K. Thompson¹, M. Bass², M. Boedigheimer², P. Bushel³, J. Chou³, J. C. Corton⁴, J. Fostel³, F. Liu⁵ and R. Wolfinger⁶. ¹CDER, U.S. FDA, Silver Spring, MD, ²Amgen, Thousand Oaks, CA, ³NIEHS, Research Triangle Park, NC, ⁴EPA, Research Triangle Park, NC, ⁵Dana-Farber Cancer Institute, Boston, MA and ⁶SAS, Cary, NC.

Toxicogenomic studies are typically variable in design, but the impact of variations in study design and conduct on control animal gene expression has not been well characterized. A working group of the Health and Environmental Sciences Institute (HESI) Technical Committee on the Application of Genomics in Mechanism Based Risk Assessment was formed to assess baseline gene expression variability from microarray data derived from control or vehicle-treated animals across multiple studies and sites. Eighteen sites voluntarily contributed a total of 536 Affymetrix data sets of rat liver and kidney samples from control animals. Thirty-five biological and technical factors were obtained for each animal, describing a wide range of study characteristics. Thirteen of these factors with complete data were evaluated in detail for their contribution to total variability using multivariate statistical and graphical techniques as well as pattern analysis of the expression data. Certain factors emerged as key sources of variability, including gender, organ section, strain, and fasting, although a significant degree of confounding occurred due to the observational nature of the data and missing value patterns. The most variable and least variable probe sets within and between factors were identified and classified according to their gene ontology annotation. Better characterization of gene expression variability in control animals will aid in the design of toxicogenomic studies and in the interpretation of their results.

1216 IDENTIFICATION OF BIOLOGICALLY RELEVANT GENES USING A DATABASE OF RAT LIVER AND KIDNEY BASELINE GENE EXPRESSION.

J. Chou¹, J. Liu¹, S. Hester², J. S. Lee², K. Thompson³, M. Bass⁴, M. Boedigheimer⁴, J. Fostel¹, F. Liu⁵, R. Wolfinger⁶, P. Bushel¹ and C. Corton². ¹NIEHS, Research Triangle Park, NC, ²NHEERL, U.S. EPA, Research Triangle Park, NC, ³CDER, U.S. FDA, Silver Spring, MD, ⁴Amgen, Thousand Oaks, CA, ⁵Dana-Farber Cancer Institute, Boston, MA and ⁶SAS, Cary, NC.

Microarray data from independent labs and studies can be compared to potentially identify toxicologically and biologically relevant genes. The Baseline Animal Database working group of HESI was formed to assess baseline gene expression from microarray data derived from control or vehicle-treated rats across multiple studies and sites. We determined whether this database could be used to identify genes clearly associated with a number of biological factors that were part of the database. We used Extracting Patterns and Identifying Genes (EPiG) to identify gender-specific and fasting-specific genes from each institute in which the factor could be examined in isolation. Gender-specific genes were identified in liver and kidney from a total of 5 different institutes using a total of 134 liver and 58 kidney

transcript profiles. A total of 266 liver genes and 313 kidney genes were identified that exhibited similar behavior (both direction of change and degree of gender difference) in at least 2/4 and 2/3 institutes, respectively. Surprisingly, approximately 1/3 of the kidney genes were regulated in an opposite manner in liver. The gender genes overlapped with well-characterized genes from earlier studies. Using in silico approaches, we identified a number of known response elements in the promoters of co-regulated genes including those involved in determining gender-specific gene expression. Fasting-specific genes were also identified in a similar manner and significantly overlapped with those that were known to be regulated by fasting in rodents. Our results demonstrate that biologically relevant genes that are associated with a number of biological variables common to toxicology studies can be identified using a well annotated database of microarray data from multiple sources. This abstract does not necessarily reflect EPA policy.

1217 TARGET KINASE PROFILING DATABASE: A TOOL FOR THE MECHANISTIC ASSESSMENT OF POTENTIAL TOXICITY FINDINGS AND THEIR HUMAN RELEVANCE.

M. Venturi, G. Saturno, D. Radice and G. Ukmar. *Preclinical Development, Nerviano Medical Sciences, Nerviano, Italy.* Sponsor: *M. Brughera.*

Pharmaceutical research is showing increasing interest in protein-kinases as pharmacological targets, and in developing molecules that are selective or pan-target protein-kinases inhibitors in many therapeutic areas. Since the majority of kinase inhibitors in development act via an ATP competitive mechanism, there is significant potential for cross-reactivity. Each compound is generally tested experimentally against members of diverse protein-kinases families in order to assess molecular specificity and to identify early off-target interactions. Typically, when a compound is active not only on the targeted kinase but cross-reacts with some other kinases, two types of pharmacological effects can be observed: the "on-target" effect, due to the interaction with the targeted enzyme, and the "off-target" effect, due to the interaction of the compound with a highly homologous or different kinase. During the early phase of the drug development process, a number of in vitro assays are performed to test cross-reactivity. At the same time, gene expression profiling of the kinases in healthy tissues derived from both human and pre-clinical animal species can be performed in order to predict the possible toxic effects due to their inhibition in a particular organ.

In the present work, we measured by Real-Time PCR the gene expression profile for 162 kinases in human, 146 in mouse, 110 in rat, 36 in dog and 25 in nonhuman primate, across approximately 50 healthy tissues. Our aim was to build an expression profiling database that prompted hypotheses on potential toxic liabilities when inhibiting a particular kinase or a set of kinases in a specific tissue. The resulting database is a valuable tool that proves useful in assessing the presence or absence of a kinase in a particular tissue, in comparing different expression profiles among species, in identifying new target protein kinases, and in building mechanistic hypotheses to understand and predict species sensitivity and human relevance of a candidate drug's side effects.

1218 COMPARATIVE NETWORK ANALYSIS OF THE TOXICANT DOSE RESPONSE: ACETAMINOPHEN TOXICITY.

S. Ekins^{1,2} and C. N. Giroux³. ¹ACT LLC, New York, NY, ²Department of Pharmaceutical Sciences, University of Maryland, Baltimore, MD and ³Institute of Environmental Health Sciences, Wayne State University, Detroit, MI.

Chemical exposure profiling with microarray and high content screening technologies is increasingly used to investigate the mode of action of toxicants. Databases of these profiles linked to phenotypic endpoints of toxicity are being established to support comparative and predictive modeling of new compounds. This modeling requires new computational approaches to extract the biological significance from the large amount of noisy data in these microarray profiles. Previously we have demonstrated that toxicant exposure data can be mapped to a system-wide gene interaction network in which differentially expressed genes identify toxicant-specific gene network signatures. We now extend this approach to functionally characterize the dose response of a reference hepatotoxicant, acetaminophen (APAP) using two manually curated databases (Ingenuity Pathways Analysis, IPA, and GeneGo MetaCore, MC). As a proof of concept for our comparative network approach, we performed an integrated analysis of several published APAP microarray profiling datasets that cover the dose response range from sub-toxic (50 mg/kg, 24 hr.) to acutely toxic (4250 mg/kg, 24 hr.) exposure in the rat liver model. We demonstrate that dose-specific gene network signatures can be identified that reveal the dynamic, modular nature of the response to APAP exposure. At a sub-toxic APAP dose, a protective module of Phase II detoxification pathways is linked to an oxidative stress response module by a signaling hub of highly connected stress response and nuclear receptor genes. In contrast, as the APAP dose increases to an acutely

toxic exposure, linked modules for the DNA damage and inflammatory responses become activated. Significantly, our network-based approach allows the dynamics of the toxicant dose response to be visualized as statistically validated, functional modules supporting subsequent biomarker and drug target discovery, key considerations for future development of the IPA and MC platforms.

1219 DEVELOPMENT OF A NMR-BASED METABOLOMIC ANALYSIS METHODOLOGY FOR TOXICOLOGY.

G. L. Jahns², N. V. Reo³, M. Kent³, D. R. Boverhof^{1,5}, L. D. Burgoon^{1,5}, N. DelRaso⁴ and T. R. Zacharewski^{1,5}. ¹Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI, ²BAE Systems, San Diego, CA, ³Biochemistry and Molecular Biology, Wright State University, Dayton, OH, ⁴Human Effectiveness Directorate, Air Force Research Laboratory, Wright-Patterson AFB, OH and ⁵Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

Metabolomics is the simultaneous measurement of metabolites from endogenous and exogenous chemicals, which may be used to identify putative biomarkers of exposure and toxicity. Currently, most metabolomics studies focus on using pattern recognition techniques to cluster spectrometric peaks, but most fail to statistically identify peaks associated with exposure. We have developed a data analysis and processing methodology for Nuclear Magnetic Resonance (NMR) spectrometry to 1) identify and eliminate spectral regions with no signal, 2) statistically characterize the significance of differentially expressed metabolite signals, and 3) quantify the change in these signals. The method identifies spectral regions with no signal by scanning spectra with a low-level threshold. Detection Theory is used to produce probabilistic estimates of the presence of a treatment effect, based on either a minimum Bayesian risk cost or a constant false alarm rate. The treatment effect is then quantified by either absolute or relative (fold) changes of the significant bins. As an example, hepatic lipid extracts from mice dosed with 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) were analyzed using ¹³C NMR. Noise screening eliminated channels for which there was no signal in both control and treatment replicates, a reduction from 1024 to 192 active bins. The Bayesian-cost significance metric was then used to reduce the data further to 77 channels that had a high probability of treatment effect. We ranked these bins both by absolute and by fold change to identify those channels showing the largest effect. These results are valuable as they stand, or can serve as a screened basis for further classification and identification analysis. Supported by NIH R21 GM75838.

1220 DEVELOPMENT OF A COMPUTATIONAL TOXICOLOGY COURSE AS A COMPONENT OF THE MOLECULAR TOXICOLOGY CURRICULUM AT UC BERKELEY.

A. D. Rodgers^{1,2}, L. Aristilde¹, J. K. Morrow¹ and D. E. Johnson^{1,2}. ¹Nutritional Sciences and Toxicology, UC Berkeley, Berkeley, CA and ²Research, Emiliem Inc., Emeryville, CA.

A Computational Toxicology course taught in the instructional laboratory of the College of Natural Resources Geospatial Imaging and Informatics Facility, is required as part of the curriculum of the Molecular Toxicology major at the University of California, Berkeley. This course is the first of its type in toxicology curricula in the United States. The course focuses on both environmental and physiological risk assessments of unknown chemicals using a variety of computational methods. Using both SAR and QSAR approaches, toxicophore identification and elucidation of mechanism of toxic action are emphasized. The software programs used are freely available on the internet or commercially-available via subscriptions. The programs can be categorized into: (1) predictive software where no new data are required and results were thus based on existing databases within the software for specific toxicological endpoints, (2) data mining software where correlations between chemical structures and toxicity are obtained by entering data from published datasets, (3) model building software that allows for the generation of QSAR predictive models, and (4) systems biology software that can infer pharmacodynamic pathways of chemicals in human biological systems based on published *in vitro* and animal studies. A detailed laboratory manual was developed for this course, which can serve as both an instructional tool and a guide for the design of a similar course. The manual provides instructions on how to use the different computational approaches to systematically identify toxicophore components and the molecular actions of unknown compounds.

1221 TOXIPEDIA – CONNECTING SCIENCE AND PEOPLE.

A. Hayes² and S. G. Gilbert¹. ¹INND, Seattle, WA and ²Northeastern University, Boston, MA.

One of the great challenges facing the toxicological sciences is communicating scientific information in a manner that creates an informed public. Toxicological research and experience provides a seemingly overwhelming, and expanding, amount

of information. To keep abreast of the growing amount of information on any one agent or issue, scientists and public health professionals must specialize. Currently there is no easy way for specialist to easily share their knowledge with the public or even other scientists. Toxipedia (www.toxipedia.org) is a new wiki-site concept that is designed to encourage toxicology specialists and public health professionals to share their knowledge of agents that affect human and environmental health. The goal of toxipedia is to be a definitive, yet accessible, information resource on the hazards and history of chemical and physical agents, regulatory requirements, and risk management. As an inter-related web, toxipedia is a new tool for scientific information exchange and communication to and with the public, the media, students, NGOs, legislators, and practicing professionals. This unique platform provides an interrelated web of information that grows as the toxicological sciences advance and reshapes how we communicate scientific information. The accuracy and credibility of Toxipedia will be supported by subject-specific associate editors using a four-tiered review system. The highest level of review will require peer review, not unlike peer-reviewed professional publications, that can be periodically updated through a rigorous review process. There will be extensive reference list that will encourage users to explore the primary literature. Lower levels of review will have progressively less oversight coupled with review-level disclaimers. In this session you will learn more about the goals and structure of Toxipedia, how to contribute to this wiki site, and how to be part of a growing movement to share our knowledge for the common good. Providing information on toxipedia is a way to satisfy our ethical responsibility to share knowledge and a primary goal of SOT to "advance the science of toxicology to enhance human, animal and environmental health".

1222 HUMAN HEALTH RISK ASSESSMENT TOOLS: SUPPORTING THE RISK ASSESSMENT PROCESS AT THE NATIONAL HOMELAND SECURITY RESEARCH CENTER.

C. Moudgal², K. Garrahan², C. Sonich-Mullin², E. Brady-Roberts², N. Gavrelis³, M. Arbogast³, S. Dunn³, S. Collie⁴ and J. Smith⁴. ¹U.S. EPA, Washington, DC, ²NHSRC/ORD, U.S. EPA, Cincinnati, OH, ³Eastern Research Group, Lexington, MA and ⁴Tetra Tech EMI, Dallas, TX. Sponsor: F. Adeshina.

EPA's National Homeland Security Research Center (NHSRC), Threat and Consequence Assessment Division (TCAD), evaluates the human health risks associated with the release of contaminants into the environment. To support this evaluation, TCAD develops risk assessment methods and tools and risk communication techniques that will be of practical assistance to government agencies and first responders dealing with threats from chemical, biological, and radiological contamination. Two tools being developed to assist EPA first responders, risk assessors, and decision-makers are the Data Dictionary (DD) and the Emergency Consequence Assessment Tool (ECAT).

The DD includes a compilation of primary and secondary data on toxicity, infectivity, dose-response, and health effects for NHSRC's priority list of chemical, biological, and radiological agents.

The ECAT is an interactive web-based software tool designed to provide a wide range of emergency response officials with accurate information in a rapid manner during a major environmental crisis caused by a terrorist attack or natural disaster. Both these tools will undergo rigorous internal and external peer review to ensure scientific credibility and technical quality. In combination, these tools offer a powerful means to quickly and efficiently gather pertinent information on the health risks posed by agents that are of primary concern to the Nation's security. These tools will play an important role in understanding human health risks and will provide the means for risk assessors and managers within and outside the Agency to make informed decisions that can be utilized to conduct innovative human health risk assessments.

1223 THE INTERAGENCY COORDINATING COMMITTEE ON THE VALIDATION OF ALTERNATIVE METHODS (ICCVAM) RECOMMENDATIONS FOR THE USE OF *IN VITRO* CYTOTOXICITY TEST METHODS TO REDUCE ANIMAL USE FOR ACUTE ORAL TOXICITY TESTING.

M. Wind¹, L. Schechtman², A. Rispin³, R. Tice⁴ and W. Stokes⁴. ¹CPSC, Bethesda, MD, ²FDA, Rockville, MD, ³EPA, Washington, DC and ⁴NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

Cytotoxicity methods are proposed as a way to reduce animal use by using the *in vitro* data to estimate starting doses for *in vivo* acute oral toxicity studies (i.e., the Up-and-Down Procedure [UDP] and the Acute Toxic Class [ATC] method). ICCVAM evaluated two *in vitro* methods proposed for this purpose, and published recommendations on their usefulness and limitations. ICCVAM reviewed validation study results for two *in vitro* neutral red uptake (NRU) basal cytotoxicity test methods (BALB/c murine fibroblasts [3T3] and primary normal human epidermal ker-

atinocytes [NHK]) used for estimating the LD50 of 72 substances. Animal savings were calculated using the *in vitro* estimates for the starting doses for the UDP and ATC method. Based on computer simulations and compared to using default starting doses, use of these *in vitro* methods reduced animal use from 5 to 28%, (0.5 to 3.3 animals) per test with savings greatest for chemicals that do not require acute oral toxicity hazard classification. These NRU test methods correctly predicted (29-31%) the UN Globally Harmonised System (GHS) acute oral toxicity category for 67-68 substances. ICCVAM concluded that the two NRU test methods are not sufficiently accurate to predict acute oral toxicity for the purpose of hazard classification. However, ICCVAM recommends that the *in vitro* test methods be considered in a weight-of-evidence approach to determine the starting dose for the UDP and the ATC. Consistent with U.S. Animal Welfare Policies and Guidelines, ICCVAM further recommends that such *in vitro* test methods be considered and used before testing is conducted using animals. The ICCVAM evaluation report also provides recommended test method protocols, performance standards, and future studies that might advance the use of *in vitro* methods for estimating acute systemic toxicity (<http://iccvam.niehs.nih.gov/>). Supported by NIEHS contract N01-ES 35504.

1224 EFFECT OF TOPICAL ANESTHETIC PRE-TREATMENT ON *IN VIVO* OCULAR IRRITATION HAZARD CLASSIFICATION.

N. Choksi¹, J. Haseman², J. Truax¹, J. Charles¹, G. Wnorowski³, D. Merkel³ and W. Stokes⁴. ¹ILS, Inc., Research Triangle Park, NC, ²Consultant, Raleigh, NC, ³Product Safety Labs, Dayton, OH and ⁴NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

The ocular irritation or corrosion potential of substances to which humans may be exposed has been evaluated since 1944 using the Draize rabbit eye test. Due to the potential for pain and distress that may occur in rabbits after application of a severely irritating or corrosive substance, alternative approaches have been proposed and developed to reduce the number of such substances that require animal testing (e.g., a weight-of-evidence approach, use of topical ocular anesthetics prior to test substance administration). This evaluation focuses on the effect of topical application of 0.5% (w/v) tetracaine hydrochloride on the irritancy potential of 97 proprietary formulations, tested in 339 rabbits, evaluated using a sequential testing scheme. In this testing scheme, the first rabbit did not receive topical anesthetic pre-treatment. If a rabbit appeared to exhibit pain or suffering after formulation administration, subsequent rabbits were pre-treated with the topical anesthetic. For all formulations, the final rabbit tested was pre-treated with the topical anesthetic. Irritancy classifications were assigned to each rabbit according to three regulatory hazard classification systems (i.e., EU, EPA, GHS). Although none of the observed differences were statistically significant, rabbits pre-treated with anesthesia appeared to produce slightly more severe responses for all three hazard classification systems than rabbits that were not pre-treated. Further, studies indicated that anesthetic pre-treatment had no impact on the variability of rabbit irritancy classifications for the same formulation. Finally, analyses indicated that anesthetic pre-treatment did not significantly increase the number of days needed for opacity, iris, or conjunctival lesions to fully reverse. Combined, these findings support the routine use of 0.5% (w/v) tetracaine hydrochloride as a pre-treatment in the *in vivo* Draize rabbit eye test. ILS, Inc. staff supported by NIEHS contract N01-ES-35504.

1225 ICCVAM/NICEATM/ECVAM SCIENTIFIC WORKSHOP ON ALTERNATIVE METHODS TO REFINE, REDUCE AND REPLACE THE MOUSE LD50 ASSAY FOR BOTULINUM TOXIN TESTING.

J. Kulpa-Eddy², A. Jacobs³, M. Halder⁴, T. Burns⁵, N. Choksi⁵, D. Allen⁵, R. Tice¹ and W. Stokes¹. ¹NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC, ²USDA, Riverdale, MD, ³FDA, Silver Spring, MD, ⁴ECVAM, Ispra, Italy and ⁵ILS, Inc., Research Triangle Park, NC.

A mouse LD50 assay is used by U.S. and European regulatory agencies to detect botulinum toxin in food and environmental samples, and to assess the potency of therapeutic toxin. Recent advances provide new prospects for the development and validation of alternative methods that may be faster, more accurate, and may refine (cause less pain and distress), reduce, and replace animal use. ICCVAM, NICEATM, and ECVAM co-sponsored a public workshop in November 2006 to review the state-of-the-science and current knowledge of alternatives to the mouse LD50 assay. The workshop reviewed public health needs, current regulatory requirements, structural aspects and mechanisms of action of botulinum toxin, and specific alternative methods and approaches for their potential to reduce, refine, and replace the mouse LD50 assay. Specific alternative methods considered included *in vitro* (e.g., endopeptidase assays, cell-based methods), *ex vivo* (e.g., mouse phrenic nerve-hemidiaphragm assay), and *in vivo* test methods (e.g., mouse hind limb assay, mouse abdominal ptosis assay). Alternative approaches considered included evaluation of earlier more humane endpoints. Panel discussion outcomes

identified hindrances to further development of alternative methods, including knowledge gaps, and suggested future research initiatives to address them. Panel discussion addressed the current development and validation status of specific alternative methods and approaches, their strengths and limitations, and their potential to reduce, refine, and replace the mouse LD50 assay. Implementation of some of these alternative methods could decrease the number of animals tested and reduce animal pain and suffering. ILS, Inc. staff supported by NIEHS contract N01-ES 35504.

1226 ICCVAM RECOMMENDATIONS ON THE USE OF FOUR *IN VITRO* TEST METHODS FOR THE CLASSIFICATION OF OCULAR CORROSIVES AND SEVERE IRRITANTS.

L. Schechtman¹, M. Wind², J. Merrill³, K. Hamernik³, R. Tice⁴ and W. Stokes⁴.
¹FDA, Rockville, MD, ²CPSC, Bethesda, MD, ³EPA, Washington, DC and ⁴NICEATM, NIEHS/NIH/DHHS, Research Triangle Park, NC.

Animal welfare concerns about the Draize rabbit eye test have led to the development of numerous proposed alternative *in vitro* test methods. ICCVAM recently completed an evaluation on the validation status of and published recommendations for four of these methods for identifying ocular corrosives and severe irritants: IRE, ICE, BCOP, and HET-CAM. *In vivo* results were classified based on regulatory eye hazard classification systems and *in vitro* results were classified based on decision criteria obtained from literature reviews or personal communications with test method developers. Accuracy statistics for each *in vitro* test method were similar across all regulatory classification systems (i.e., EPA, EU, GHS). Where data permitted, reliability analyses indicated that the methods were generally reproducible within and between laboratories. Based on the available data, ICCVAM recommends that BCOP and ICE can be used in appropriate circumstances and with certain limitations as screening tests for the detection of ocular corrosives and severe irritants in a tiered-testing scheme, using a weight-of-evidence approach. Since test method performance varied for different chemical and physical classes, ICCVAM recommends that the current database and performance be reviewed to determine the suitability of a method for specific testing situations. Consistent with U.S. Animal Welfare Regulations, ICCVAM further recommends that *in vitro* ocular test methods be considered for specific testing situations prior to testing in animals and that an alternative test method be used when appropriate. When used in this manner, these methods should reduce the pain and distress associated with testing ocular corrosives and severe irritants. The ICCVAM report also provides recommended test method protocols and substances for validation studies, and recommendations for future studies that might improve the usefulness of these test methods. Supported by NIEHS contract N01-ES-35504.

1227 EVALUATION OF CURRENT EPA CANCER POTENCY ESTIMATES BASED ON THE 2005 CANCER GUIDELINES.

C. J. Saranko¹, T. Bingman², M. E. Schuck¹ and J. K. Tolson¹. ¹Geosyntec Consultants, Tampa, FL and ²DuPont, Sewickley, PA.

Cancer potency estimates (cancer slope factors and unit risk factors) developed by the EPA are widely used in human health risk assessment and regulatory decision making. The EPA's Final Guidelines for Carcinogen Risk Assessment, released in March 2005, heralded several significant changes to the development of cancer potency estimates. This guidance describes what types of toxicity data are suitable for making a determination about whether a chemical should be evaluated as a human carcinogen. It also describes the methods used to develop human potency estimates based on available toxicity data. Although there is a formal peer review process for re-evaluating existing potency estimates under the new Guidelines, progress is slow. This results in a situation in which potency estimates developed based on older guidance and methodologies are still being used to make regulatory decisions. All cancer potency estimates published in the EPA's Integrated Risk Information System (IRIS) database were evaluated. Of the chemicals with cancer potency estimates listed in IRIS that are based on animal data, only a few have potency estimates developed using the new Guidelines. Most current animal toxicity data were scaled to a human equivalent dose based on the outdated method of body weight raised to the 2/3 power. Revised cancer potency estimates are provided using the current recommended scaling factor of body weight raised to the 3/4 power. This new scaling factor alone lowers slope factors by 1.9-fold for values based on mouse studies. For several chemicals, the data previously used to derive potency estimates are likely insufficient to warrant quantitative cancer potency estimates under the new Guidelines. These chemicals are identified with respect to their potentially unreliable cancer potency estimates.

1228 THE PRESENCE OF DRUG IN CONTROL SAMPLES: MINIMIZING RISK OF CONTAMINATION IN TOXICOLOGY STUDIES.

P. Colombo, M. Breda, F. Fiorentini, P. Grossi and M. Brughera. *Preclinical Development, Nerviano Medical Sciences, Nerviano, Italy.*

In 1999, during the assessment of a centralized application, serious concerns were raised on mouse and rat carcinogenicity studies where variable amounts of test substance were detected in samples from control animals. One of these studies was considered invalid and had to be repeated. Since then, several applications have been identified where samples from control animals showed some levels of test substance in pivotal repeated dose, reproductive and carcinogenicity studies. The source of contamination could not be identified and an appropriate risk assessment related to carcinogenicity and reproductive toxicology could not be performed because safety margins could not be established. As a consequence, this issue has led to delays in Marketing Authorization, and in some cases to the issuing of "Warning letters" from the FDA, especially in cases of bioequivalence studies. An EFPIA survey conducted in 2003 showed that contamination occurs in toxicology studies regardless of the route of administration used, the dose levels or the duration of the treatments. As nowadays, analytical methods are becoming more and more sensitive, the possibility of detecting test substance in controls is increased. Industry has recommended best practices to reduce this event, but it is not a realistic expectation that it will be possible to completely eliminate it. The causes may be multiple and it is often not possible to identify the source and/or the precise cause of the presence of drug in control samples. Therefore, a weight of evidence approach is needed to evaluate the validity of the study data in assessing risk to humans. With this aim, an EMEA guideline came into operation on September 2005. Potential sources of contamination, internal policies, and training of personnel are presented in this poster, and data from bioanalysis conducted during the 2005-2006 toxicology studies performed in our department are also shown. Conclusions and best practices to address this issue based on our acquired experience are drawn.

1229 ACCEPTABLE LEVELS OF RISK - A SURVEY OF STATE REGULATIONS.

M. E. Schuck, E. M. Tufariello, J. K. Tolson and C. J. Saranko. *Geosyntec Consultants, Tampa, FL.*

Risk-based corrective action (RBCA) is a process for remedial decision-making predicated on the concept that there is an acceptable level of risk from residual contamination in the environment. For carcinogens, the National Oil and Hazardous Substances Pollution Contingency Plan authorized the EPA to use a risk range between 1 in 1,000,000 (1E-06) to 1 in 10,000 (1E-04) for determining when remediation is required at contaminated sites based on the belief that this range represents de minimus excess risks to the public. With the maturation of risk assessment methodology, many states have adopted their own RBCA programs. Most of these programs rely heavily on guidance from the EPA and/or the American Society for Testing and Materials (ASTM) for their basic framework. However, there is significant disparity in the way that acceptable risk is handled among various programs. A comprehensive review of U.S. state environmental agency regulatory program approaches for establishing acceptable risk was conducted. Sources included agency guidance documents, state legislation, and phone interviews with state regulators. Detailed information was identified for most states. Of the states with their own RBCA programs or guidance, more than three quarters have established chemical-specific default remediation goals using a target cancer risk of 1E-06 while the remainder set these default levels using a target risk of 1E-05. Most states have guidance on managing cumulative site risks and more than half of these have either explicitly or implicitly adopted EPA's target risk range. However, a significant number have opted to manage cumulative risks at a bright-line 1E-05 level and at least one state does so at a 1E-06 level.

1230 A TECHNICAL ANALYSIS OF THE PROPOSED REACH REGULATION.

T. Petry and N. Rangasami. *The Weinberg Group LLC, Brussels, Belgium.*

REACH (Registration, Evaluation, and Authorization of Chemicals) is the European Union's proposed strategy for the management of risk to human health and the environment posed by chemical substances. At its core, REACH will require producers and users of chemical substances to register these uses in a volume-triggered system. It demands the submission of chemical assessment reports containing information on the hazards, exposures and risks associated with the uses of chemical substances for review by the competent authorities and government-appointed expert committees. Chemicals deemed to be of very high concern, e.g., carcinogens, mutagens or substances toxic to reproduction, will trigger a complex authorization procedure in which the ultimate political goal is to substitute those

chemicals with safer alternatives. REACH is now in its final stages of the political review process. It is expected that the political and regulatory hurdles will be cleared by the end of 2006 and REACH will enter into force in mid' 2007. In parallel with the regulatory review, stakeholder expert working groups have been charged to develop the necessary guidance and support tools that are essential to help industry and regulators understand their tasks and fulfill their obligations under REACH. These guidance documents produced through various REACH Implementation Projects are essential for the workability, smooth transition and successful implementation of REACH. This paper will present the results of a study to characterize the key requirements, obligations and review processes specified under REACH. Specific focus will be on the identification of the toxicological data requirements as specified in Annexes VII to X of the current REACH proposal, the role of alternative methodologies such as in vitro testing, (Q)SARs (structural activity relationships) and read-across. Moreover, it analyses the possibilities of chemical grouping and the application of 'weight of evidence' approach to justify data waiving, and the methodological approaches applied to characterize risks associated with the use of chemical substances.

1231 CONSIDERATION OF THERAPEUTIC DOSE FOR DEVELOPMENT OF PROVISIONAL REFERENCE DOSE (P-RFD) FOR NITROGLYCERIN.

H. Choudhury¹ and J. Klotzbach². ¹ORD/NCEA, U.S. EPA, Cincinnati, OH and ²SYRACUSE RESEARCH CORP, SRC, SYRACUSE, NY.

Nitroglycerin, has been used for over 100 years in the treatment of angina pectoris (myocardial ischemia). The mechanism of action involves vasodilatation, thereby, lowering blood pressure and reducing cardiac load. In addition to clinical usage, contact with nitroglycerin can occur through occupational exposure in the explosive industries and through contamination of drinking water. There is no information to determine the minimum effective dose of nitroglycerin to assess the safe level of exposure in sensitive individuals. The lowest available single oral dose of sustained-release nitroglycerin is 2.5 mg (equivalent to 0.036 mg/kg-day) with a recommended maximum total daily oral dose of 38 mg/day. Adverse effects, such as headache, nausea and hypotension associated with therapeutic and occupational exposure to nitroglycerin are secondary to actions on the cardiovascular system, with vasodilatation as the initiating event. Therefore vasodilatation can be considered as the critical effect upon which to base the p-RfD. Furthermore, due to rapid elimination of nitroglycerin, bioaccumulation is not expected in long-term exposure, thus suggesting the possibility that the adverse effect level for long-term exposures may not be different than the adverse effect level for acute exposure. No evidence is available to suggest that chronic exposure to therapeutic doses of nitroglycerin by any route of exposure results in toxicity to the liver or other organs, as reported in animal studies. This presentation will discuss approaches for using a therapeutic dose to support risk assessment of exposures at contaminated site(s).

1232 EXPANDING THE ROLE OF EXPERT PEER INVOLVEMENT IN RISK ASSESSMENT: PART 1, A COMPREHENSIVE PROCESS.

J. Patterson¹, J. E. Strawson¹, M. E. Meek² and R. Liteplo². ¹TERA, Cincinnati, OH and ²Health Canada, Ottawa, ON, Canada. Sponsor: M. Dourson.

Many organizations (OMB, 2004; IPCS, 2005; IARC, 2006; Health Canada, 2006) use peer review to obtain external opinions on the scientific and technical merit, as well as the strength of assumptions and conclusions of risk assessment documentation. Typically, peer review is employed at the end of the document development process; however, by incorporating peer involvement earlier in the process, organizations can improve the overall quality of their risk assessment documents. This poster examines peer involvement techniques and presents a comprehensive process for expanding the use peer involvement in risk assessment to insure completeness and quality at various stages in a risk assessment document's development. Peer involvement includes peer input, peer consultation, and peer review. Peer input involves solicitation of information, data, or issues at an early stage. Peer consultation may be a formal or informal process to gather expert peer advice on a specific issue or work product during its development. Peer review is a formal, external, and independent review of an intended final work document. Techniques for peer involvement include data call ins, expert elicitation, requests for written comments, open workshops, conference calls, public meetings, peer consultation meetings, and formal peer review meetings. Four broad principles are important for consideration and organization of peer involvement activities – independence, inclusion of appropriate experts, transparency, and a robust scientific process. Attention to these principles insures that expert peer involvement is credible and valuable.

1233 EXPANDING THE ROLE OF EXPERT PEER INVOLVEMENT IN RISK ASSESSMENT: PART 2, USE OF PEER EXPERTS IN CEPA EXISTING SUBSTANCES PROGRAM.

M. E. Meek¹, R. Liteplo¹, J. Patterson² and J. E. Strawson². ¹Health Canada, Ottawa, ON, Canada and ²TERA, Cincinnati, OH. Sponsor: M. Dourson.

Part 1 of this study described a process for expanding the role of peer involvement in risk assessment that would improve the overall quality of risk assessment products. This poster describes examples of how this process has been used for risk assessments under the Canadian Environmental Protection Act (CEPA). Canada is the first country to introduce a legislative requirement for systematic priority setting of all chemicals in commerce, necessitating the categorization and prioritization health risk assessments for approximately 23,000 substances. This has provided opportunity to expand the incorporation of the input of peers within the program both for the development of methodology and assessments of individual chemicals and/or groups. Peer input has been used to guide in the development of priority setting tools such as ComET (Complex Exposure Tool), resulting in participation of multiple stakeholders and acquisition of data not previously available. Peer consultations have assisted in the design of methodologies for development of the weight of evidence component of the Complex Hazard Tool (ComHaz), as well as advice on chemical specific risk issues, such as design of studies for aluminum. These peer consultations focused development and stimulated additional thought thereafter, which has contributed to development of predictive tools not only to address the Canadian but other jurisdiction's mandates. Peer review has been used for chemical assessments to evaluate the adequacy of coverage and identify if key information or data are missing, as well as review of supporting documentation, hazard characterization, and dose-response analysis. These peer reviews have resulted in maximal utilization of available data in drawing conclusions, verified the need for additional analyses of key studies, and have led to the conduct of more appropriate investigations to inform conclusions.

1234 BIOLOGICAL EVALUATION OF THE OREGON WATER QUALITY CRITERIA: NEW APPROACHES IN ANALYZING PROTECTION OF ENDANGERED SPECIES.

J. Zodrow, B. Shephard and D. Keenan. U.S. EPA, Seattle, WA.

The Clean Water Act requires the U.S. Environmental Protection Agency (EPA) to develop water quality criteria and approve water quality standards for the protection of aquatic life. Under the Endangered Species Act (ESA), U.S. federal agencies are required to ensure that their actions are not likely to jeopardize the continued existence of threatened or endangered species. EPA's approval of state water quality standards is considered an action that could potentially jeopardize threatened or endangered species, thus requiring consultation with natural resource agencies under the ESA. The state of Oregon recently submitted new or revised water quality criteria for 19 freshwater chemicals and 13 saltwater chemicals to EPA's Region 10 office for approval. Four major types of evaluations were performed by EPA Region 10 to evaluate potential adverse effects of water quality criteria on the 16 threatened or endangered aquatic species (14 fish, 2 aquatic invertebrates) and 11 threatened or endangered wildlife species in Oregon (5 aquatic-dependent birds, 6 marine mammals). These evaluations analyzed effects on listed aquatic species from direct exposure to chemicals in water; effects on prey of listed aquatic species; effects on listed aquatic species from multiple routes of exposure to criteria chemicals (i.e. from direct water column toxicity and dietary toxicity due to ingestion of contaminated prey); and toxicity to listed wildlife species whose diet consists of an appreciable proportion of aquatic prey potentially contaminated from exposure to criteria concentrations. New approaches were used to analyze effect concentrations in listed aquatic species including Interspecies Correlation Estimation (ICE) models and species sensitivity distributions. Descriptions of the methodology used for each type of evaluation and how this relates to determining potential adverse effects of criteria approval on ESA listed species will be presented for representative chemicals.

1235 BEYOND RISK ASSESSMENT – INCORPORATING OUR VALUES AND ETHICS IN PRECAUTIONARY ASSESSMENT.

S. G. Gilbert. INND, Seattle, WA.

Risk assessment is an expression of our values and ethical decision-making. Classical risk assessment was defined in a 1983 report by the National Research Council as including four basic elements: hazard identification, dose-response assessment, exposure assessment, and finally risk characterization. Initial efforts were focused on defining a numeric probability for developing cancer, which evolved

into quantitative risk assessment. This approach become highly technical and dominated by experts in risk assessment. While the initial goals of risk assessment were laudable, it has degenerated into defining how much hazard is tolerable or is necessary in any given situation. Quantitative risk assessment has a number of weaknesses. It was said "We should remember that risk assessment data can be like the captured spy: If you torture it long enough, it will tell you anything you want to know." (William Ruckelshaus (1st administrator of U.S. EPA) 1984.) The goal of precautionary assessment (PA) is to move beyond risk assessment and allow communities and individual to incorporate their knowledge, values and ethics into a more comprehensive evaluation of a hazardous condition. The PA combines the philosophy and ethics of the precautionary principle with the standard scientific evaluation of the hazards. Precautionary assessment contains three basic elements: a) community and social issues, b) exposure, and c) hazard and toxicity. Each element is broken down into a series of questions that are scored numerically to produce a summary score for each element. The PA is designed to help place the knowledge available within the context of the community. In contrast to the traditional risk assessment, the PA is a more comprehensive approach to evaluating the human and environmental health risks. Overall, the PA is a more reasonable, rational, and responsible approach to evaluating risk of hazardous chemicals.

1236 CRITICAL ROLES OF COACTIVATORS AND COREPRESSORS DURING TRANSCRIPTIONAL ACTIVATION BY XENOBIOTIC RECEPTORS.

R. S. Pollenz, *Biology, University of South Florida, Tampa, FL.*

The aryl hydrocarbon receptor (a member of the basic-loop-helix-PAS family of transcription factors), peroxisome proliferator-activated receptor α (PPAR α), estrogen receptor, and pregnane X receptor (PXR) are xenobiotic activated nuclear receptors. Each receptor can bind with a distinct set of xenobiotics to mediate biological/toxicological effects in species from fish to human. For each activated receptor, toxicity is initiated to a large degree through transcriptional activation/repression of a particular set of target genes by the liganded receptor. In most cases, the ability of the DNA bound receptor to modulate gene regulation is dependent on its interaction with coactivator and corepressor proteins. Some of these coactivators and corepressors covalently modify histones, thereby relieving or enhancing their repressive effects on transcription. Over the past several years, there has been intense investigation to identify the specific coactivator and repressor proteins that interact with nuclear receptors and to determine how they impact gene regulation. Interestingly, it appears that many divergent receptor proteins associate with similar coactivator/corepressors proteins to modulate gene regulation. In addition, recent findings suggest that inter-individual response to xenobiotic ligands may be related to variations in coactivator or corepressor expression or activity. These variations may underlie tissue-specific differences in sensitivity to xenobiotics during development, and in adulthood. Studies have also demonstrated that there is functional cross-talk between different xenobiotic receptors that can be mediated by coactivators or corepressors. Thus, this session is aimed at exploring the direct interaction of several toxicologically relevant receptors with coactivator/corepressors proteins and how these interactions impact response of humans and other mammals to xenobiotics.

1237 ROLE OF CO-REPRESSOR SMRT IN REGULATION OF PREGNANE X RECEPTOR (PXR).

J. Chen, *Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ*. Sponsor: R. Pollenz.

The orphan nuclear receptor PXR (pregnane X receptor, also known as SXR) is expressed primarily in liver and intestine, and coordinates hepatic responses to prevent liver injury induced by toxins, such as rifampicin and clotrimazole. It is well documented that PXR activates cytochrome P450 (CYP) gene expression by recruiting transcriptional co-activators such as p160's. However, little is known about the function of unliganded PXR and the role of co-repressors in regulation of PXR activity. We have recently found that the co-repressor SMRT (silencing mediator of retinoid and thyroid hormone receptors) may play a role in regulating the activity of unliganded PXR by direct interaction. The PXR-SMRT interaction is generally sensitive to species-specific ligands, causing an exchange of the co-repressor with co-activator. Homology models of intact LBD with two SMRT nuclear receptor (NR)-interacting domains have also been constructed. These modeling studies reveal key interactions that account for the binding preference. Furthermore, preferential association of PXR with distinct SMRT isoforms was observed. Our data suggest that the co-repressor SMRT may regulate the transcriptional activity of unliganded PXR. Thus, co-repressors may play a role in regulating PXR function in response to environmental toxins.

1238 LIGAND-DEPENDENT COACTIVATOR RECRUITMENT BY PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS (PPARs).

J. Vanden Heuvel, *Veterinary and Biomedical Sciences, Penn State University, University Park, PA.*

The regulation of gene expression by nuclear receptors (NR) is dependent on the recruitment of coactivators to the transcriptional complex. With many NRs, the ability to interact with these proteins is ligand-specific. In these studies we examined the ligand-dependent recruitment of coactivator proteins to peroxisome proliferator-activated receptor α (PPAR α , NR1C1). Of the several coactivators that were tested, PPAR binding protein (PBP), PPAR γ coactivator 1 α (PGC-1 α), steroid receptor coactivator-1 (SRC-1) and CBP/p300-interacting transactivator with ED-rich tail 2 (CITED2) were the most efficacious at affecting PPAR α activity in the presence of the peroxisome proliferator (PP) Wy-14,643. Interestingly, overexpression of PBP or PGC-1 α resulted in a more pronounced increase in PPAR α activity when activated by fatty acids relative to xenobiotic PPs. In contrast, CITED2 and SRC-1 had equal effects on PPAR α activity whether activated by Wy-14,643 or fatty acids. When expression of PGC-1 α , SRC-1 or PBP is diminished through the use of RNAi plasmids, Wy-14,643-induced PPAR α activity is only affected by PGC-1 α RNAi whereas conjugated linoleic acid (CLA) and ciprofibrate are affected by decreasing expression of all three coactivators. A LXXLL containing peptide library was screened for its ability to interact with PPAR α under various ligand treatments using a mammalian two-hybrid assay. The affinity of these peptides to interact with PPAR α was dependent on the ligand examined. To further define coactivator recruitment to PPAR α , a portion of the ligand-dependent transactivation domain (AF2, 456LHPLL) was mutated (456LHPAA). This mutation resulted in a dominant negative construct that inhibited PPRE-driven transcription. Together, this research shows that coactivator recruitment to PPAR α is dependent on the ligand used to activate the receptor.

1239 MODULATION OF ARYL HYDROCARBON RECEPTOR-DEPENDENT TRANSCRIPTION BY ESTROGEN RECEPTOR ALPHA.

J. Matthews, *Pharmacology, University of Toronto, Toronto, ON, Canada.*

New mechanisms of AhR/ER α crosstalk have recently been described that have profound implications on AhR and ER α signal transduction. We have shown that dioxin induces recruitment of ER α to the AhR regulated promoter, cytochrome P4501A1. ER α recruitment was enhanced by co-treatment with 17 β -estradiol (E2), but E2 alone had no effect. Analysis of several AhR agonists revealed ligand-specific oscillatory recruitment of AhR and ER α , a differential ability to recruit ER α to AhR target genes, and that the influence of E2 co-treatment on ER α promoter occupancy exhibited ligand and promoter specificity. For example, 3,3'-diindolylmethane (DIM) strongly induced promoter occupancy of ER α to CYP1A1 and CYP1B1, which was not further increased by co-treatment with E2. Although co-treatment with E2 had no effect on CYP1A1 mRNA levels, siRNA mediated suppression of ER α significantly inhibited dioxin-induced CYP1A1 mRNA expression. Chromatin immunoprecipitation assays revealed this to be due to reduced promoter occupancy of AhR at CYP1A1. ER α directly interacts with AhR via a sequence motif in its N-terminal ligand-independent activation domain (AF1). Deletion of this domain prevented TCDD-induced recruitment of ER α to CYP1A1, highlighting the importance of the AF1 domain in mediating interactions between AhR and ER α . Currently, we view the recruitment of ER α at AhR as two distinct processes; (1) unliganded ER α (no E2) acts as an AhR ligand-dependent coregulator of AhR transcription; and (2) the increased recruitment of ER α by cotreatment of AhR agonist and E2 represents a mechanism for AhR-dependent inhibition of ER α activity by sequestering E2-bound ER α away from ER α target genes. The signals that induce ER α recruitment to AhR target genes and the biological consequences of these findings remain elusive, but provide further evidence for strong functional crosstalk between these two receptor systems. This work was supported by the David and Astrid Hagelén Foundation and the Swedish Cancer Fund.

1240 COACTIVATOR RECRUITMENT AND HISTONE MODIFICATION DURING DIOXIN INDUCTION OF HUMAN CYP1A1, CYP1B1 AND CYP2S1.

O. Hankinson, R. T. Taylor, S. Beedanagari and I. Bebenek, *Pathology and Laboratory Medicine, University of California, Los Angeles, CA.*

The inducibilities of CYP1A1, CYP1B1 and CYP2S1 by 2,3,7,8-tetrachlorodibenzo-p-dioxin (dioxin) differ from one another in different tissues and organs, and the maximally induced levels of these P450s can also differ substantially

from one another. Differences in these parameters also occur in established mammalian cell lines. We have found that these differences between cell lines can occur even when the dioxin-dependent recruitment of the aryl hydrocarbon receptor (AHR) and aryl hydrocarbon receptor nuclear translocator (ARNT) proteins to the enhancer regions of the individual P450 genes are equivalent. However, we have found that these differences, in some instances, correlate with differences in transcriptional coactivator recruitment to and/or covalent histone modifications at, the P450 genes in question. We are manipulating the expression levels of particular coactivator proteins in order to address the notion that differential coactivator recruitment is causally related to the variation in inducibility and maximally induced levels of the P450s in the cell lines. These investigations are providing further insight into the molecular mechanism underlying tissue-specific variations in P450 induction, which are, in turn, likely to be associated with tissue-specific variations in sensitivities to xenobiotics.

1241 EMERGING TECHNOLOGIES IN IMAGING FOR TOXICOLOGY.

C. Marcus. *Toxicology, University New Mexico, Albuquerque, NM.*

This session will present overviews of exciting new and emerging imaging modalities and technologies that will be of interest to toxicologists. These are new technologies and rapid advances in existing technologies that will provide powerful new tools for toxicologists to address important new questions in toxicology and the biomedical sciences. Speakers will present overviews of the new technologies, potential applications to the field of toxicology, and sample data. The first presentation will describe new applications of in vivo EPR imaging for non-invasive spatial mapping of tissue oxygenation and redox status in small animals. The second presentation will present new applications of in situ molecular imaging and profiling of proteins and drugs in tissues by mass spectrometry for biological and clinical research. The third presentation will present advances and applications in imaging by microCT and microPET scanning for small animal in vivo imaging. The fourth presentation will focus on non-invasive in vivo optical imaging techniques for disease diagnosis and therapeutic monitoring. The fifth presentation will discuss the utilization of virtual microscopy for high throughput image analysis for automatic assessment of morphological changes.

1242 IN VIVO ELECTRON PARAMAGNETIC RESONANCE (EPR) IMAGING.

K. Liu¹, J. Shen³, G. Timmins¹ and G. M. Rosen². ¹College of Pharmacy, University of New Mexico, Albuquerque, NM, ²Department of Pharmaceutical Sciences, University of Maryland, Baltimore, MD and ³School of Chinese Medicine, University of Hong Kong, Hong Kong, Hong Kong, China. Sponsor: C. Marcus.

Electron paramagnetic resonance (EPR) imaging is an emerging technique for non-invasive spatial mapping of tissue oxygenation and redox status in living small animals, such as mice and rats. With the recent improvement of low frequency EPR instrumentation and the synthesis of better imaging agents, many exciting results have been obtained. This presentation will highlight the latest developments in EPR imaging techniques and some of recent results, with particular emphasis on their application in toxicology research. EPR and MRI imaging are both based on the same principle of paramagnetic resonance, and each can provide unique information that is complementary to each other. Utilized effectively together, they are more powerful than being used alone. Advances for in vivo EPR imaging now permit synthesis with MRI imaging and these two imaging modalities can now be utilized together in vivo (and also in combination with histological studies in post-mortem studies). Integration of these two complementary imaging modalities to create novel image reconstructions will be discussed along with applications for toxicology research.

1243 IN SITU MOLECULAR PROFILING/IMAGING OF PROTEINS BY MALDI MS.

R. Caprioli. *Vanderbilt University, Nashville, TN.* Sponsor: C. Marcus.

Imaging Mass Spectrometry (IMS) is a new molecular discovery technology that takes advantage of the methodology and instrumentation of MALDI mass spectrometry. It can be used to locate specific molecules such as drugs, lipids, peptides and proteins directly from the surface of fresh frozen tissue sections. Frozen tissue specimens are cut in very thin (~10 µm) sections and thaw-mounted on flat metallic target plates. Matrix can be manually or automatically deposited on the sections. Molecular profiles recovered upon analysis typically contain from 300 to 500 or more distinct signals in the m/z range beyond 200,000. When imaging from a tissue section, matrix is deposited in a homogeneous manner minimizing the lateral

dispersion of molecules of interest. This can be achieved by automatically printing arrays of small droplets. Each microspot is then automatically analyzed generating a mass spectrum. When monitoring the intensity of a signal within the data array, a two-dimensional ion density map (or image) can be reconstructed giving information on the location and relative abundance of a given analyte.

IMS is an effective discovery tool for the qualitative and quantitative analysis of molecular signatures that may differentiate unhealthy and normal tissues and for identification of potential protein markers in disease progression. In this regard, histology directed profiling permits higher sample throughput and reproducibility. The visual specificity of histology is combined with the positioning accuracy of the robotic microdispenser to direct placement of matrix drops onto specific cells with high placement accuracy. The ability to construct 3-D molecular images will also be shown. In addition, IMS technology has been successfully applied to drug targeting and metabolic studies and the measurement of concomitant protein changes in specific tissues after systemic drug administration. Identification of statistically significant protein markers can be identified in high throughput mode by mass spectrometry based proteomic approaches.

1244 MICROCT SCANNING WITH MOLECULARLY TARGETED CONTRAST AGENTS.

J. Weichert, B. Durkee, J. Grudzinski, G. Ton and M. Longino. *Departments of Radiology and Medical Physics, University of Wisconsin-Madison, Madison, WI.* Sponsor: C. Marcus.

The recent explosion in the generation of spontaneous models of disease including transgenic mice and rats has fueled the rapid development of high-resolution, 3-dimensional noninvasive, small animal imaging technologies, including microCT and microPET. MicroCT is now capable of providing exquisite 3D anatomic detail at resolutions exceeding 20 microns in live mice and rats, whereas microPET scanning affords 3D localization of radiolabeled molecular imaging agents. Acquisition times of several minutes preclude the use of conventional CT contrast agents in preclinical studies conducted on high resolution microCT scanners. Our lab has developed two new long-acting hepatocyte and vascular microCT-contrast agents which enhance the soft tissue capabilities of microCT significantly, thus permitting novel applications of this technology for rendering 3D tissue images in living animals. The design of these agents is based on a biochemical approach, whereby naturally occurring compounds known to be stored and/or metabolized in the organ or tissue of interest serve as carriers for the radiologic moiety. These types of novel targeted molecular imaging agents are extending the utility of CT, MRI, and PET imaging including potential applications to the field of toxicology. Moreover, recent introduction of multimodal hybrid scanners, including the world's first commercial microCT/microPET hybrid scanner (Siemens Inveon) now allows automatic dual modality image coregistration so that the functional PET image can be precisely located within the anatomic CT framework. The anatomic and functional strengths of microCT and microPET will be stressed and exemplified by 3-D liver images from intact live mice obtained with our novel liver contrast agent, and 3D "fly through" imaging of biological structures including blood vessels and colon will be presented, accompanied by discussions of how this new imaging approaches might be utilized in the field of toxicology.

1245 ADVANCED OPTICAL IMAGING FOR TOXICOLOGY, PATHOLOGY, MEDICINE AND SURGERY.

D. L. Farkas. *Surgery, Cedars-Sinai Medical Center, Los Angeles, CA.* Sponsor: C. Marcus.

Toxicology and pathology are becoming more quantitative and molecular, medicine is benefiting from developments in biology, and surgery is moving towards minimally invasive intervention. These advances necessitate new approaches, and biophotonics represents a major new area of hope and growth (1,2). The use of photonic tools and methods will be reviewed, with emphasis on our advances.

The central challenge is the identification and characterization of abnormalities. Photonic imaging has been lagging in clinical acceptance, in spite technological advances in laboratory research and preclinical trials (3), and a clear need for the kind of resolution (spatial, temporal, spectral) and specificity that optical imaging alone can offer. Our approach integrates the use of light intensity, coherence, polarization, temporal gating, and spectral features into a multimode implementation, to improve imaging-based quantitation and sensitivity in vivo, and build a new clinical armamentarium (4). One goal is mesoscopic imaging, enabling microscopic-level spatial resolution within the body without forsaking specificity and temporal resolution, while emphasizing imaging methods that do not require contrast agents (5).

Results presented will also include the imaging of very fast calcium transients (6); early cancer detection by spectral imaging (5); hyperspectral Mie scattering imaging for endoscopy (7); improved OCT imaging (8); monitoring of stem cell fate in vivo (9) and the design of an advanced multimode imaging endoscope.

1246 THE USE OF VIRTUAL MICROSCOPY FOR HIGH THROUGHPUT IMAGE ANALYSIS.

R. W. Dunstan¹, J. Wijsman¹, C. S. Zurenko¹, D. T. Stephenson², A. C. Opsahl², M. L. Mirsky², S. Carvajal-Gonzalez² and R. Virgile³. ¹*Drug Safety Research and Development (DSRD), Pfizer Global Research and Development (PGRD), Ann Arbor, MI*, ²*DSRD, PGRD, Groton, CT* and ³*DSRD, PGRD, Sandwich, United Kingdom*.

Digitizing a glass slide at a high magnification (20x to 40x) so the representative pixels can be manipulated into stitched virtual images at smaller magnifications is starting to revolutionize anatomic pathology. Virtual microscopy is evolving from a teaching tool to a diagnostic method as accurate as the standard light microscope. An added benefit of these digital images is that they allow for high throughput image analysis. This presentation will describe virtual microscopy and the adaptation of virtual images to object based morphometry. High throughput image analysis on virtual images requires an investment for a high resolution image scanner, servers to store large data files, a program for image analysis adapted to virtual images and computers to analyze the data. Equally important is establishing a team of pathologists, computer technicians, laboratory scientists and statisticians to optimize the computer environment, standardize the slides from which the images will be obtained and define data analysis parameters. However, once established, this technology allows for an almost "set it and forget it" quantitative evaluation of microscopic slides. This is largely because virtual images allow for the capture of an area of interest at one magnification and its analysis in greater detail at a higher magnification. To demonstrate the potential of this emerging technology, lessons learned from attempts at its implementation will be presented. These will include methods to standardize the image digitized, benefits of evaluating immunostained versus hematoxylin and eosin stained sections and establishing a balance between magnification, image compression, speed of image acquisition/analysis and storage costs. Finally, we will demonstrate examples of the successful use of image analysis on virtual images of the skin, immune system and pancreas.

1247 AN OVERVIEW OF THE USE OF WILDLIFE SPECIES IN IMMUNOTOXICOLOGY.

J. DeWitt¹ and J. T. Zelikoff². ¹*Curriculum in Toxicology, University of North Carolina, Research Triangle Park, NC* and ²*Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY*.

Although rodents have been the traditional models of choice in immunotoxicology, phyla outside of the murine family can serve as warnings of pollutant immunotoxicity or of emerging infectious diseases that could affect humans. For example, marine organisms warned of the immunotoxic effects of tributyltin oxide, an agent used in marine antifouling paints and the mute swan proved a sensitive sentinel for avian influenza. Alternative, most commonly wildlife species, are undeniably valuable for evaluating immunotoxicity of a particular phyla, however, the question remains as to whether information gained from such species is applicable across phyla for the purposes of evaluating risks to ecosystems, to humans, or to both. To determine the applicability of wildlife species to the risk assessment process, the breadth of the knowledge base about the immune systems of non-rodent species, the relative costs and benefits of using non-rodent species to assess immunotoxicity, and the phylogenetic extent of immune system pathology and dysfunction must first be understood.

1248 THE INVERTEBRATE IMMUNE SYSTEM AS A TARGET ORGAN OF TOXICITY.

T. S. Galloway. *school of biological sciences, university of plymouth, Plymouth, United Kingdom*. Sponsor: J. DeWitt.

In contrast to the complexity of the vertebrate immune system, the relative simplicity of invertebrate immune systems makes them a potentially sensitive and accessible means of monitoring the effects of immunotoxic chemicals and the com-

plex interactions that ultimately affect host resistance. In this presentation, the effects of chemicals on immune function in different invertebrate species will be considered and biomarkers of immunotoxicity identified. Recent research results will be presented in which links between endocrine and immune toxicities are explored, using the periwinkle *Littorina littorea* as a case study. The presentation will finish with a discussion of the relevance of the results for environmental monitoring programmes.

1249 CHEMICAL-INDUCED IMMUNOTOXICITY IN FISH: TRANSLATION ACROSS PHyla FOR PREDICTING RISK.

J. T. Zelikoff¹, E. Carlson² and J. E. Duffy¹. ¹*environmental medicine, new york university school of medicine, Tuxedo, NY* and ²*Toxicology, General Electric Global Research, Niskayuna, NY*.

Fish share a number of immunological properties with their mammalian counterparts including phenotypically similar immune cells, lymphoid tissue structure and function, biologic mediators, and the ability to mount innate and adaptive immune responses. Because of these similarities, fish are emerging as an alternate species for assessing immunotoxicity in higher vertebrates. In this presentation, the effects of aromatic hydrocarbons such as benzo(a)pyrene (BaP) and coplanar and noncoplanar polychlorinated biphenyl (PCB) congeners on the immune system of laboratory fish models, will be examined. Mechanistic underpinnings of the observed effects will be discussed for each agent and used to link chemical-induced immune dysfunction across species. Just how these mechanistic similarities between fish and mammals can be used to establish risk will also be conferred.

1250 ASSESSING IMMUNOLOGICAL HEALTH IN WILD BIRDS: GENERAL, INTEGRATIVE, AND MECHANISTIC METHODS AND ECOLOGICAL RELEVANCE.

K. A. Grasman. *Biology, Calvin College, Grand Rapids, MI*. Sponsor: J. DeWitt.

Over the past 4 decades numerous studies have shown that environmental contaminants can alter immune function in wild birds. Methods employed in these studies have ranged from general indicators of immunological status (e.g., blood cell counts, immune organ masses) to functional assays (e.g., sheep red blood cell hemagglutination test, phytohemagglutinin skin test). The latter, which integrate the functions of multiple cell types, are similar to assays used to screen for immunotoxicity in laboratory rodents. While often difficult to implement in field studies, cellular and molecular methods (e.g., lymphocyte culture, apoptosis assays, genomic methods) hold much potential for monitoring immunological effects and providing mechanistic information to link these effects to particular contaminants. Increasing evidence in the field of immunotoxicology demonstrates the ecological relevance of reduced immune function in wild birds, including increased rates of infection and decreased rates of survival and colonization of new habitats.

1251 DEVELOPMENT AND UTILIZATION OF A STANDARDIZED SUITE OF IMMUNE ASSAYS IN HEALTHY AND NON-HEALTHY BOTTLENOSE DOLPHIN.

M. M. Peden-Adams^{1,2}, C. D. Rice^{3,1}, D. Muir⁴, M. Houde⁴, G. Mitchum⁶, G. Bossart^{5,1}, P. Fair^{6,1} and T. Romano^{2,1}. ¹*Medical University of South Carolina, Charleston, SC*, ²*Mystic Aquarium and Institute for Exploration, Mystic, CT*, ³*Clemson University, Clemson, SC*, ⁴*Environment Canada, Burlington, ON, Canada*, ⁵*Harbor Branch Oceanographic Institute, Ft. Pierce, FL* and ⁶*NOAA/NOS/CCEHBR, Charleston, SC*.

Increases in the incidence of mass mortality events (MMEs) involving bottlenose dolphins (BND) has lead to concern over their health. Many of these mortality events are thought to be caused by infectious microbes such as morbillivirus. It is unclear if these agents were the primary cause of the MMEs or if compromised immunity, related to contaminant exposures, caused increased susceptibility to infectious agents. Studies with terrestrial and marine mammals have shown that various contaminant classes suppress immune function. A suite of assays for assessment of immune function in marine mammals, that can be performed from non-lethal blood collection was developed based on the NTP Immunotoxicity testing scheme. Samples from approximately 200 resident bottlenose dolphin in Indian River Lagoon, FL and Charleston, SC were collected during the summers of 2003-2005 and assessed for immune function using the developed suite. Each location has different primary contaminant classes of concern based on tissue residue analysis. Associations between contaminants and immunity were determined. Additionally, dolphins in Indian River Lagoon were noted to have higher rates of gastritis in 2003, which corresponded with associated immune data, and they were also found

in general to have higher rates of skin disease than animals in Charleston. Immune function is currently being assessed in relation to various disease types such as Lobomycosis. Information from this study allows us to begin to assess the utility of dolphins as sentinel species for identifying estuarine areas of concern for human health and allows us to begin to determine associations between contaminants, immune, function, and diseases in populations and ecosystems.

1252 INCORPORATING IMMUNOLOGY INTO ECOLOGICAL RISK ASSESSMENT.

D. Nacci. *U.S. EPA, Narragansett, RI*. Sponsor: J. DeWitt.

Immunological effects of chemical exposures are seldom considered qualitatively and almost never considered quantitatively in ecological risk assessments (ERAs). However, the impacts of chemicals on immunological competence must be accounted for because disease is one of the most important factors regulating wildlife populations. Here, we describe a research strategy to enhance the incorporation of immunology into ERAs. First, basic knowledge about immunological variation across species will benefit ERAs and human health RAs, as well. From this knowledge, functional tests of immunological responses may be used to infer mechanisms for categories of chemicals of concern, and ultimately develop inter-species extrapolations. Of particular importance are cellular and molecular methods for which samples may be obtained nondestructively, and whose results may be relevant across a relatively broad range of species. Secondly, methods are needed to extrapolate from measurement endpoints at lower levels of biological organization to ecologically relevant (population-level) effects. Whole animal challenges using acute exposures to pathological agents in combination with mechanistic indicators may provide quantitative links between immunological changes and functional responses. But these exposure methods may not provide insight into responses under real world (low level exposure) conditions. Population ecologists and ecotoxicologists need to consider epidemiological methods that take account occasional, sometimes catastrophic effects of infectious disease, to begin prediction and testing of population-level outcomes associated with chemical effects on immunological performance. In summary, research is needed to extrapolate immunological effects taxonomically and across levels of biological organization. Interdisciplinary collaborations will be necessary to integrate theory and practice from the fields of immunology, biology, and ecology to inform ERAs about potential impacts of chemicals on disease susceptibility and responses in wildlife and aquatic populations.

1253 PHYSIOLOGICAL PARAMETERS AND PBPK MODELING FOR CHILDREN'S RISK ASSESSMENT.

T. L. Leavens¹ and H. A. Barton². ¹*CIIT Centers for Health Research, Research Triangle Park, NC* and ²*ORD National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC*.

Evaluation of potential risks for children has become a regular aspect of many regulatory activities in state and Federal agencies including the U.S. Environmental Protection Agency and Food and Drug Administration. Pharmacokinetics plays a key role as the interface between external exposure and internal dosimetry for environmental compounds, dietary constituents, and pharmaceuticals. A range of pharmacokinetic modeling approaches are used, in part, dependent upon the availability of in vitro or in vivo data for the compound of interest. Physiologically based pharmacokinetic (PBPK) modeling is a valuable tool for estimating internal dosimetry across ages based upon information describing physiological, metabolic, and other chemical specific parameters. While standard values for adult physiological parameters have been compiled and published, physiological parameter values for pregnancy (mother and fetus), lactation (mother and offspring), and growing offspring are less readily available. Compilations of information in the literature and collection of new laboratory data are ongoing for physiological parameters including tissue volumes, blood flows, liver metabolism, and kidney function. Models are being developed to describe the pharmacokinetics of volatile organics, pesticides, and pharmaceuticals in young rats and humans. Modeling children's variability is also important. These efforts are designed to improve estimates of internal dosimetry for toxicological studies of pregnant and developing animals and for use in risk assessments for infants and children. (This abstract does not present US EPA policy.)

1254 CHILDREN'S RISK ASSESSMENT AND PBPK MODELING.

C. Thompson and S. Barone. *National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC*.

Federal agencies are increasingly employing PBPK models as a preferred approach for performing extrapolations in risk assessment. In this context, susceptible populations, particularly children, are receiving greater focus in risk assessment than in

the past. While much of this focus represents a shift within the scientific and risk assessment community, federal laws (e.g. Food Quality Protection Act, FQPA) have also helped foster a focus on children's health protection. In addition to testing programs, the U.S. EPA is developing more formalized approaches for evaluating risks to children's health. For instance, the U.S. EPA "Supplemental Guidance for Assessing Cancer Susceptibility from Early-Life Stage Exposure to Carcinogens" and "A Framework for Assessing Health Risks of Environmental Exposures to Children" address how risks to early life stages can be addressed within the existing risk assessment framework by encouraging the consideration of data in children and young test animals. By incorporating pharmacokinetic and pharmacodynamic differences (and variability) across ages and species, PBPK models represent a powerful tool to help evaluate the life stages most sensitive to an environmental toxicant of interest. Not only are these models useful in assessing risks to environmental toxicants, but also have the potential for improving pharmaceutical safety – by relating effective doses in clinical trials to likely safe and effective doses in groups (e.g. children) that rarely participate in such studies. Despite these new and innovative efforts, challenges remain for protecting children's health: collection of accurate physiological parameter values, development of accurate algorithms for predicting values based on indexes (e.g. height, age, etc.), ontogeny of xenobiotic metabolizing enzyme systems and transporters, body and tissue composition, and more). The views expressed herein are solely those of the authors and do not represent the policies and/or endorsement of the U.S. Environmental Protection Agency.

1255 THE PHYSIOLOGICAL PARAMETERS FOR EARLY LIFE STAGES DATABASE.

R. Gentry¹ and S. Olin². ¹*ENVIRON, Ruston, LA* and ²*ILSI, Washington, DC*.

Recent initiatives with regards to children's health have resulted in the development of physiologically-based pharmacokinetic (PBPK) models to address the question of whether children of a specific age receive a higher dose than adults for a given chemical exposure. As the use of these models in regulatory risk assessment increases to attempt to understand age-specific risk, it is critical that these models reflect age-specific animal and human physiological processes. Currently available PBPK models demonstrate a lack of consistency in the age-specific parameters incorporated. This identified the need for the development of a central database made available to both modelers and risk assessors for the use of PBPK or biologically-based dose-response (BDDR) modeling. Use of consistent physiological parameters across modelers will decrease the uncertainty that may be introduced by using parameters from different sources. A multi-year multi-sector effort, coordinated in part through ILSI, has been ongoing to develop a database of physiological and pharmacokinetic parameters in the neonatal and developing rat and mouse, as well as for early lifestages in humans. The goal throughout the development of the database has been to identify the most appropriate parameters, insuring accuracy and scientific quality as well as the identification priority data needs. In the case of rats, in addition to parameter identification, comparisons have been made of critical parameters across selected strains, the results of which indicated that combinations of information across strains may be appropriate and may help to form a comprehensive dataset needed for PBPK modeling in the neonatal rat. In the development of the human database, case studies have also been conducted for kidney function and liver volume/blood flow in the perinatal period. The intent is that this database will provide not only a source in which researchers and modelers can readily access the information on age-specific physiological parameters, but that this database will be a "living" database, to which researchers or modelers will contribute data to in the future.

1256 AGE-DEPENDENT PBPK MODEL FOR THE PYRETHROID, DELTAMETHRIN (DLT), IN RATS.

J. V. Bruckner. *Pharmaceutical and Biomedical Sciences, University of Georgia, Athens, GA*.

Pyrethroid insecticides have largely replaced organophosphates in the U.S., but very little is known about their ADME in adults or children. Our objectives were to: 1) characterize the age-dependency of the metabolism and systemic disposition of DLT, a potent neurotoxicant, in preweanling, adolescent and adult S-D rats; and 2) utilize these data and other age-related input parameters to develop an age-specific PBPK model for DLT. Metabolic inactivation of DLT by hepatic P450s and hepatic and plasma carboxylesterases progressively increased with age. Blood and brain DLT concentrations varied inversely with age, as did the incidence and severity of acute neurotoxicity. Organ and body weights (BW) were recorded for rats from 1 – 280 days of age. A generalized Michaelis-Menten (GMM) BW growth model was used to forecast organ weights/volumes of specific age groups. The GMM equation yielded much more accurate predictions of organ weights than the standard allometric approach. An adult PBPK model was developed and refined, such that it reliably simulated DLT time-courses in blood, plasma, brain and fat for different iv and oral doses. Input of age-specific parameters resulted in reliable

blood and tissue time-course predictions in immature rats. These data suggest that age-dependent differences in DLT dosimetry account for some but not all of the susceptibility of preweanling rats to DLT acute neurotoxicity. This first-generation model can be improved and utilized for other pyrethroids, as more is learned about basic processes that govern the internal dosimetry of this class of chemicals. Such models can be used to predict total pyrethroid concentrations in different immature brain regions for aggregate and cumulative exposures to pyrethroid mixtures. (Supported by U.S. EPA STAR Grant R830800). Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

1257 MODELING VOLATILE ORGANIC COMPOUND PHARMACOKINETICS IN RAT PUPS.

H. A. Barton and C. E. Rodriguez. *ORD National Center for Computational Toxicology, U.S. Environmental Protection Agency, Research Triangle Park, NC.*

Toxicity studies in developing animals exposed to volatile organics are important for risk assessments of cancer, neurotoxicity, and other endpoints. PBPK model predictions of internal dosimetry in young rats were compared to adult animals for benzene, chloroform (CHL), methylene chloride, methyl ethyl ketone (MEK), perchloroethylene, and trichloroethylene. Modeling used partition coefficients for six volatile organic compounds measured in tissues from pups (postnatal day 10) and young adult (60 days), which were similar across ages (e.g., MEK) or varied up to 50% (CHL). Literature data on developing enzyme systems and physiological parameters for growing rats provided other parameter values. Steady state blood levels for all the chemicals except MEK are predicted to be <50% higher in pups than adults. MEK was >6-fold higher in pups than adults due to loading by more rapid ventilation per unit body weight, but limited exhalation of this water soluble compound. Although the blood:air partition coefficient is the major determinant of steady state blood concentration, it is as much as 50% lower in pups than adults. The higher pup blood levels reflect more rapid ventilation and decreased metabolism due to lower fractional liver volume. Pups come to steady state more rapidly than adults largely due to smaller fat volume. Brain concentrations are generally predicted to be slightly higher in pups than adults, except for MEK reflecting its much higher blood levels. The dose metric, total amount metabolized normalized for liver volume (AM/VL), was generally much lower in pups than adults. This modeling indicates that differences across ages reflect the integrated effect of all the relevant physiological, metabolic, and biochemical determinants of pharmacokinetics rather than the changes in the most sensitive parameter. (This abstract does not represent US EPA policy.)

1258 MODELING OF HUMAN PHYSIOLOGICAL AND METABOLIC VARIABILITY DURING EARLY LIFE STAGES.

A. Nong¹, G. McCarver², R. N. Hines² and K. Krishnan³. ¹CIIT Centers for Health Research, Research Triangle Park, NC, ²Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI and ³SEST, University of Montréal, Montréal, QC, Canada.

Pharmacokinetic modeling in children needs to account for the substantial variability in tissue volumes, blood flow rates and metabolizing enzyme levels observed during childhood. Availability of data on physiological parameters and liver metabolic capacity of individual children allows modeling to simulate individual variability in internal dose within the population. This presentation demonstrates the usefulness of physiologically-based pharmacokinetic (PBPK) models for predicting the inter-individual variability of internal dose of volatile organic chemicals in children, using toluene as the model substance. PBPK models were constructed for children (newborn to 17 years old; n=116) on the basis of subject-specific CYP2E1 protein levels obtained from autopsy samples. The physiological flows and volumes of organs (except liver) were computed as a function of body weight of children, using higher order polynomial equations. Liver volume for each subject was known. On the basis of subject-specific and age-specific data on physiology and metabolic capacity in children, the PBPK model provided simulations of kinetics and internal dose of toluene for various exposure scenarios. The modeling results indicated that the variability in the rate of metabolism and the area under the concentration vs time curve for toluene would be greater in the neonatal group than in older children and adults. This marked variability in the neonate group would appear to be a direct consequence of the variability of CYP2E1 levels and the age-dependency of the limiting factor of metabolism (i.e., enzyme levels in neonates vs liver blood flow in older children). Overall, the PBPK modeling approach allows the integration of subject-specific and age-specific data on the variability of metabolic and physiological factors to assess their combined impact on the variability of tissue dose of chemicals in children.

1259 THE VASCULAR SYSTEM AS A TARGET OF METAL TOXICITY.

W. Prozialek and J. Edwards. *Pharmacology, Midwestern University, Downers Grove, IL.*

The functioning of the vascular system involves complex interactions among the vascular endothelium, smooth muscle, the immune system and the nervous system. The toxic metals Cd, As and Pb can target the vascular system at multiple levels and these vascular effects appear to play pivotal roles in mediating the pathophysiologic effects of the metals in specific target organs. Acute exposure to Cd can cause selective increases in microvascular permeability and hemorrhagic injury in some organs but not others. One possible factor in determining if a vascular bed is sensitive to these Cd effects may be the expression of the *Slc39a8* gene, which encodes the ZIP8 ion transporter. This transporter may play a key role in mediating Cd toxicity in Cd-sensitive organs such as the testis and kidney. Additional studies indicate that Cd, at non-cytotoxic concentrations of 10-100 nM, can inhibit chemotaxis and vascular endothelial cell tube formation. These Cd-induced angiostatic effects may be mediated through disruption of VE-cadherin, a Ca-dependent cell adhesion molecule. Other studies have shown that exposure to arsenic in drinking water increases the incidence of cardiovascular diseases and is associated with blood vessel growth and remodeling in vivo. Ingestion of water containing toxicologically relevant concentrations of As promotes capillarization of liver sinusoidal endothelium. Since capillarization is a hallmark precursor for liver fibrosis and contributes to an imbalance of lipid metabolism, this effect of As on the liver endothelial cells may be a pathogenic mechanism underlying arsenic-related vascular diseases. Other studies indicate that early exposure to Pb, may be a factor in the development of hypertension in genetically-prone individuals. It has been suggested that Pb-induced alterations in vascular smooth muscle intracellular Ca signaling may contribute to hypertension by enhancing vascular contractility through actions on L-type Ca channels. Taken together, these findings indicate that the vascular system may be a critical target of metal toxicity in vivo.

1260 IDENTIFICATION OF A GENE RESPONSIBLE FOR CADMIUM-INDUCED VASCULAR DAMAGE.

D. W. Nebert, L. He, B. Wang, S. N. Schneider, M. Soleimani and T. P. Dalton. *University of Cincinnati Medical Center, Cincinnati, OH.*

Cadmium (Cd²⁺, Cd) is a nonessential metal, an environmental toxicant, and a lung carcinogen in humans. Cd induces testicular necrosis in all species having testes. Of 45 inbred mouse strains, 31 are sensitive and 14 are resistant (autosomal recessive mutant trait) to Cd-induced testicular necrosis. Screening BXD/Ty recombinant inbred lines and using B6 x D2 genetic crosses, we narrowed down the *Cdm* locus on a ~24-cM region on Chr 3 ultimately to an 880-kb region, which includes the *Slc39a8* gene, encoding the ZIP8 transporter. By Northern or Q-PCR analysis, ZIP8 mRNA levels are the same in testis, kidney, liver, intestine, lung and brain of both sensitive and resistant inbred strains; however, by in situ hybridization, we showed a robust ZIP8 mRNA signal in vascular endothelial cells of the testis in two sensitive, but not in two resistant, inbred mouse strains [PNAS 2005; 102: 3401]. From a 129/Sv BAC (bacterial artificial chromosome) library, we isolated a 168.7-kb clone containing only the *Slc39a8* gene (63.8 kb) plus 87 kb of 5'-flanking and 18 kb of 3'-flanking sequences. We inserted the (Cd-sensitive) transgene onto the B6 (Cd-resistant) background: the transgene converts the phenotype from resistance to sensitivity (testicular necrosis) in BTZIP8-3 mice. These data unequivocally confirm that *Slc39a8* is the *Cdm* locus, and that regulatory sequences conferring this organ- and cell-type-specific expression of ZIP8 are contained within the 168,720 bp of this BAC. The blood-testis barrier differs from the blood-brain barrier, and both are different from any other endothelial vascular cells. We have now found that ZIP8 probably functions normally as a Zn²⁺ or Mn²⁺/HCO₃⁻ symporter and is present at high levels on the apical side of kidney proximal tubule epithelial cells; its high affinity for the hitchhiker Cd leads to Cd-induced renal proximal tubular damage and osteomalacia. The mechanism of organ damage by Cd therefore differs between testis and kidney—Supported in part by NIH grants R01 ES10416 and P30 ES06096.

1261 A NOVEL ANGIOSTATIC FUNCTION FOR CADMIUM ACTING THROUGH VE-CADHERIN.

J. M. Woods¹, M. Leone³, K. Klosowska¹, P. C. Lamar², T. J. Shakhnovsky¹ and W. C. Prozialek². ¹Microbiology & Immunology, Midwestern University, Downers Grove, IL, ²Pharmacology, Midwestern University, Downers Grove, IL and ³College of Health Sciences, Midwestern University, Downers Grove, IL.

This study originated with the observation that human endothelial cells (ECs) grown in a monolayer culture physically separate from each other in the presence of cadmium (Cd). The vascular endothelium appears to be a primary target for Cd,

yet very little is known about the effects of Cd on angiogenesis, and even less is understood in regards to a potential mechanism. We hypothesized that Cd disrupts angiogenesis through decreasing cell surface VE-cadherin. ECs were exposed to Cd at various doses and tested in viability assays, chemotaxis assays, and tube formation assays, in addition to localizing VE-cadherin via immunofluorescence. Toxicity studies in the presence of 0.1% FBS suggest that a dose of 100 μ M Cd has no deleterious consequences after a 24 hr exposure, whereas a dose of 1 mM Cd appears to kill approximately 50% of macrovascular ECs. Despite the absence of a toxic effect, doses as low as 10 μ M Cd significantly decreased migration of ECs to a powerful chemoattractant. Similarly, the presence of as little as 1 μ M Cd significantly disrupts EC tube formation ($p < 0.05$). To eliminate the possibility that Cd was acting on the Matrigel, we pre-incubated ECs with Cd and then performed the assay in the absence of the heavy metal. Our results demonstrate that doses as low as 100 nM Cd can significantly disrupt PMA-induced tube formation when the assay is performed in the absence of Cd. Finally, immunolocalization studies reveal consistent VE-cadherin expression around the perimeter of confluent ECs that are not Cd-treated. In contrast, VE-cadherin expression is significantly decreased following an overnight incubation with doses of Cd ranging from 100 nM to 100 μ M. We conclude that Cd acts in an angiostatic manner on ECs, having low toxicity, yet significantly disrupting EC migration and tube formation. Moreover, Cd disrupts VE-cadherin expression on the cell surface of ECs, an adhesion molecule that is critical for angiogenesis.

1262 ARSENIC-INDUCED ENDOTHELIAL CELL ACTIVATION AND VASCULAR REMODELING.

A. Barchowsky¹, A. C. Straub¹ and D. B. Stolz². ¹*Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA* and ²*Cell Biology, University of Pittsburgh, Pittsburgh, PA.*

The vascular effects of drinking water arsenic (AsIII) are a global public health concern that contribute to disease in millions of people. Arsenic (AsIII) causes ischemic vascular diseases, atherosclerosis, hypertension, and diabetes. In addition, the angiogenic effects of AsIII contribute to tumorigenesis. The mechanisms for the pathogenic effects and health risks of chronic low to moderate AsIII exposures remain unresolved. However, research identifying AsIII health risks and filling the knowledge gaps for mechanisms of AsIII action has been complicated by a lack of sensitive animal models. Previous *in vivo* mouse studies from this laboratory demonstrate that 5-500 ppb AsIII in drinking water stimulated vessel growth in surrogate models of angiogenesis. To examine whether AsIII affected pathogenic endothelial cell activation and vascular remodeling in an endogenous bed, mice were fed drinking water containing 250 ppb AsIII for 1, 2, and 5 wk and then evaluated for changes in liver sinusoidal and peribiliary blood vessels. These exposures did not affect the overall health of the animals and did not cause cytotoxicity in the liver. However, AsIII caused significant vascular remodeling with sinusoidal endothelial cell (SEC) defenestration, increased SEC capillarization, vascularization of the peribiliary vascular plexus, and constriction of hepatic arterioles. In addition to ultrastructural changes SEC morphological, quantitative immunofluorescence revealed increased sinusoidal PECAM-1 and laminin-1 protein expression suggesting gain of adherens junctions and a basement membrane. After 5 wk of exposure, these vessel changes were accompanied by increased staining of CD45/CD68 positive inflammatory cells. *Ex vivo* exposure of primary isolates of mouse SEC demonstrated dose-dependent defenestration and capillarization in response to AsIII. In conclusion, these data demonstrate that SEC capillarization is a sensitive, early human-relevant marker of AsIII-stimulated vascular dysfunction in intact mice.

1263 MECHANISM OF PB-INDUCED HYPERTENSION: ROLE OF CA^{2+} HOMEOSTASIS.

B. Atchison. *Pharmacology/Toxicology, Michigan State University, East Lansing, MI.*

Evidence suggests that chronic low-level Pb exposure can cause small, though persistent and significant elevations in mean arterial blood pressure. The mechanisms by which this occurs are not known. We hypothesize that alterations in intracellular Ca signaling induced by Pb contribute to hypertension by enhancing vascular contractility through actions on L-type Ca channels. Pregnant female spontaneously hypertensive rats (SHR) were given 100 ppm Pb in their drinking water, or water alone. After weaning at 21 d, one group of pups received only tap water to drink, the other received tap water containing 100 ppm Pb acetate. This procedure generated 4 groups: WW received only water perinatally and post-weaning; PbW received Pb perinatally but water only after weaning; WPb received water perinatally but Pb post-weaning; and PbPb received Pb both perinatally and post-weaning. Blood Pb levels were undetectable in WW and PbW rats; they ranged from 0-12.5 μ g/dL in PbPb and WPb rats. SHR became hypertensive as expected, but no significant differences occurred among treatment groups in either blood pressure or body weight over the entire 6 mo study period. Radiotelemetric recordings of blood pressure were collected. Prior to treatment with L-type Ca channel blocker nifedip-

ine, basal blood pressure was not affected in any Pb exposure group. However, treatment with nifedipine for one wk caused a differential pattern of blood pressure response based on the timing of Pb exposure. Rats exposed to Pb perinatally (PbPb and PbW) had a markedly larger decline in daily average blood pressure during nifedipine treatment than did control rats (WW) or rats exposed to Pb only after weaning (WPb). Hydralazine, a nonspecific vasodilator caused equivalent reductions in blood pressure in control and Pb treated rats. Thus the enhanced response to nifedipine in Pb-treated animals is not due to nonspecific actions. These preliminary data suggest that perinatal exposure to Pb can produce alterations in L-type Ca channel function sufficient to modify cardiovascular responses to Ca channel blockers into adulthood. Supported by NIH grant R21ES012349-01.

1264 WOMEN'S HEALTH INITIATIVE: LESSONS LEARNED AND FUTURE DIRECTIONS.

M. H. Bhattacharyya¹ and O. A. Olivero². ¹*Biosciences Division, Argonne National Laboratory, Argonne, IL* and ²*National Cancer Institute, Bethesda, MD.*

The Women's Health Initiative (WHI) was one of the largest research studies devoted entirely to issues of postmenopausal women. Over 160,000 women aged 50-79 were enrolled at 40 clinical sites across the United States. WHI was comprised of two separate trials of menopausal hormone therapy (MHT), a diet intervention trial, and a trial of calcium and vitamin supplementation, plus an observational cohort. Issues examined included cardiovascular disease, cancer, bone fractures, and memory/cognition. WHI results have been instrumental in changing clinical practice and provided valuable insights into women's healthcare. They have also been the source of considerable controversy. This symposium will provide insight into results obtained and directions for future research that have emerged for this exceptional undertaking.

1265 BREAST AND COLORECTAL CANCER: EFFECTS OF MENOPAUSAL HORMONES, A LOW-FAT EATING PATTERN AND DIETARY SUPPLEMENTS (CA + VITAMIN D).

M. L. Stefanick^{1,2}. ¹*Medicine, Stanford University, Stanford, CA* and ²*Obstetrics & Gynecology, Stanford University, Stanford, CA.* Sponsor: M. Bhattacharyya.

The WHI trials of combined estrogen plus progestin in women with a uterus (E+P trial), estrogen only in women post-hysterectomy (E-Alone trial), and a low-fat eating pattern intervention (diet modification, DM, trial), as well as the trial of Calcium and Vitamin D supplements (CaD trial), investigated breast and colorectal cancer outcomes. Invasive breast cancer was significantly increased by conjugated equine estrogens (CEE) combined with daily medroxyprogesterone acetate (MPA) over the average 5.6 year follow-up period, and played a major role in the early stopping of the trial, whereas there was no increase in breast cancer with CEE only during 7.1 years of follow-up in the E-Alone trial. Colorectal cancer, on the other hand, was significantly reduced by CEE+MPA, but not affected by CEE in the respective MHT trials. Although the 9% reduction in breast cancer in women assigned to the low-fat diet failed to reach significance and there was no difference in colorectal cancer, there was a significant reduction in breast cancer in women who had the highest initial dietary fat intake, and there was a significant reduction in polyps/adenomas in the overall DM intervention group versus control. In contrast, there was no evidence that calcium and vitamin D supplements benefited colorectal cancer or polyps. This presentation will provide information on cancer outcomes in subgroups which may be of particular interest to women and their clinicians regarding menopausal hormones and diet.

1266 FRACTURE PREVENTION: MENOPAUSAL HORMONE THERAPY AND DIETARY SUPPLEMENTS (CA + VITAMIN D).

J. McGowan. *Musculoskeletal Diseases, NIAMS/NIH, Bethesda, MD.* Sponsor: M. Bhattacharyya.

Two of the randomized clinical trials in the Women's Health Initiative investigated fracture outcomes. In both parts of the trials of menopausal hormone therapy (MHT) – that is, both with estrogen alone as well as combination estrogen/progestin – hip, spine and total fractures were reduced. In the trial of calcium and vitamin D there was a modest effect of the dietary supplements on bone density at the hip but not at other sites. Hip but not other fractures were reduced in women over 60 and in adherent women but not in the overall group. Assessing and communicating the results of these trials to the public has been very challenging. MHT with very positive effects on fracture has some risks that must also be considered. Calcium and vitamin D supplements had modest effects in the overall population

of healthy postmenopausal women. Nevertheless, adding more calcium and vitamin D to the diet of particular groups can reduce the rate of hip fractures. This presentation will discuss the options for osteoporosis and fracture prevention in the light of the Women's Health Initiative.

1267 CARDIOVASCULAR DISEASE AND MHT: READING THE FINE PRINT.

D. Bonds^{1,2}, ¹*Epidemiology and Prevention, Wake Forest University School of Medicine, Winston-Salem, NC* and ²*Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC.* Sponsor: M. Bhattacharyya.

In the last 10 years, postmenopausal estrogen and progesterone have gone from therapies essential for women to stay "feminine forever" to drugs with significant side effects to be used with caution if at all. Contributing to this paradigm shift were the results of the Women Health Initiative, the largest trial of postmenopausal hormone therapy. Although stopped early for increased risk, the results are conflicting for some cardiovascular disease outcomes when treatment with estrogen alone is compared to estrogen plus progesterone. This presentation will compare the cardiovascular results of the two arms and present possible hypotheses for the differences and similarities seen.

1268 AGE-ASSOCIATED COGNITIVE DECLINE: EFFECTS OF HORMONE THERAPY.

S. Shumaker. *Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, NC.* Sponsor: M. Bhattacharyya.

A major concern of most aging adults is that they will suffer from memory loss, severe cognitive impairment or even some form of dementia. As people live longer, there has been a significant increase in the number of people who suffer from various forms of cognitive impairment and dementia, with the concomitant growth in economic, health and family burdens associated with these debilitating conditions. In response to the increased numbers of older adults with cognitive decline, there has been a growing demand for effective methods to treat and prevent this health problem. Based on observational studies in women, and data from animal and basic science studies, post-menopausal hormone therapy (HT) appeared to address this growing need and led to an increased use of HT "off label" for the prevention and treatment of cognitive decline. The WHI Memory Study (WHIMS) provided the first, long-term, randomized placebo controlled clinical trial designed to investigate the effects of hormone therapy on cognitive functioning, mild cognitive impairment, and dementia in post-menopausal women. In a study of 7,500 women 65 years and older, it was learned that estrogen plus progestin or estrogen alone do not protect against cognitive decline or dementia; rather, they increase women's risk for cognitive decline and all-cause dementia. These results led to questions that are currently under investigation, including: What happens to women's cognitive functioning once HT is stopped? What are the underlying mechanisms that might explain the increased risk of dementia associated with HT and what will the WHIM-MRI study be able to tell us? Are there subgroups of women who may be more susceptible to the negative effects of HT on cognition? And, is there a "window of opportunity" among younger post-menopausal women where HT is beneficial rather than harmful?

1269 COMMUNICATING SCIENCE: WRITING FOR TECHNICAL AND LAY AUDIENCES.

J. S. Kimbell¹, M. Alley², L. Lehman-McKeeman³, H. Chickering⁴ and C. McGowan⁵. ¹*CIIT Centers for Health Research, Research Triangle Park, NC,* ²*Virginia Polytechnic Institute and State University, Blacksburg, VA,* ³*Bristol Myers Squibb Co., Princeton, NJ,* ⁴*NBC News Channel, Chapel Hill, NC* and ⁵*Johnson & Johnson, Skillman, NJ.*

Research in toxicology often produces results that are significant for regulators and the general public as well as scientists. In addition to technical reports, written material is needed for information resources such as web sites, press releases, prospectus blurbs, and package inserts, making written communication skills essential for toxicologists. One key to the success of a scientific document is the scientist's style which should structure the content in a logical and persuasive fashion, include informative and persuasive illustrations, and express ideas in clear, connected sentences. Getting research published in a good journal is a fundamental requirement for all scientists. A good scientific paper should be clearly focused from title to discussion, provide adequate information regarding how experiments were carried out and make it easy for any scientist to understand the significance of the work. Yet bridging the gap between technical publication and other public media can be difficult. The lay media often have a tough time digesting complex scientific jargon.

Scientists, fearing their message will be lost in the translation, may be reluctant to share their research. These barriers prevent interesting and important science developments from making the news. Exploring how the media evaluate science news helps break down these barriers and encourages scientists to accurately translate their message to a lay audience. Discussion among the participants in this session will address practical questions regarding how one translates scientific jargon into a form that non-professionals can appreciate, why non-professionals should care about the latest advances in toxicology, and how toxicologists can clarify messages for the larger public.

1270

CHEMICALLY INDUCED CELL DEATH AND PROLIFERATION DURING MULTIPLE GENERATIONS OF HUMAN PROXIMAL TUBULAR (HPT) CELLS.

L. H. Lash and D. A. Putt. *Pharmacology, Wayne State University Sch. Med., Detroit, MI.*

Primary cultures of hPT cells undergo a range of responses when exposed to the nephrotoxic and nephrocarcinogenic metabolite of trichloroethylene, S-(1,2-dichlorovinyl)-L-cysteine (DCVC), which vary according to dose and time and include cell death by necrosis or apoptosis, growth arrest, and enhanced proliferation. To investigate the ability of DCVC to induce proliferation, longer exposure times than are possible with primary cell cultures are needed. Therefore, we studied the responses to hPT cells cultured and passaged for up to six generations. At several passages up to passage 6, morphology, cytokeratin and vimentin staining, protein and DNA synthesis, cytotoxicity and expression of heat shock protein 27 (Hsp27) and p53 in response to DCVC or two oxidants, tert-butyl hydroperoxide (tBH) or methyl vinyl ketone (MVK), were studied. hPT cells in either primary culture (hPT-p) or at passages 1, 2, 4, or 6 (hPT-1, -2, -4, or -6) exhibited similar morphology and staining for cytokeratins. Growth rate of cells slowed moderately through the second passage (time to confluence increased 25% to 100%) but slowed markedly (time to confluence increased > 250%) thereafter. Confluent hPT cells, from primary cultures through passage 4, exhibited similar sensitivity to DCVC-induced necrosis or apoptosis. In contrast, sensitivity to both tBH and MVK was markedly increased in hPT-2 and hPT-4 cells as compared with hPT-p and hPT-1 cells. Decreased activities of glutathione peroxidase and reductase in later passages may contribute to the greater sensitivity to injury from oxidants. Modest staining for vimentin, increased fraction of S-phase cells, and increased fluorescence of MTT (3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyltetrazolium bromide) was observed in hPT-p through hPT-4 when these cells were exposed to 10 μ M DCVC, indicating growth and proliferation. These results suggest that hPT cell cultures can be used over several passages to investigate mechanisms of DCVC-induced cell proliferation, although changes occur in sensitivity of cells to oxidants.

1271

GENE EXPRESSION CHANGES IN HUMAN RENAL PROXIMAL TUBULE CELLS (HRPTC) EXPOSED TO LOW CONCENTRATIONS OF S-(1, 2-DICHLOROVINYL)-L-CYSTEINE (DCVC), A METABOLITE OF TRICHLOROETHYLENE.

E. A. Lock¹, J. L. Barth², S. W. Argraves² and R. G. Schnellmann¹.

¹*Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC* and ²*Cell Biology and Anatomy, Medical University of South Carolina, Charleston, SC.*

Trichloroethylene (TCE) is an important industrial solvent that causes renal injury in rats and mice following chronic exposure. Primary HRPTC were exposed daily to DCVC, a minor metabolite of TCE, for 10 days. Confluent cells 8-10 days after seeding were exposed to DCVC at 0.1 to 10 μ M. Cytotoxicity was determined using MTT following 1, 3, 7 and 10 days exposure. RNA was isolated from cells exposed to medium alone or DCVC 0.1 μ M or 1 μ M for 10 days and the integrity and concentration determined. Gene expression levels were measured using Affymetrix human genome U133A Gene chips. Comparisons were conducted for each DCVC concentration with respect to control treatment derived from the same sample. Daily doses of 10 μ M DCVC/day for 7 days resulted in 75% loss of MTT activity, which was confirmed microscopically as extensive cell necrosis. No significant loss in MTT activity was seen at 3 μ M/day over 10 days, with no loss at 1 and 0.1 μ M/day over 10 days. The IC₅₀ for DCVC was 7.5 μ M after 7 and 10 days. Two doses 0.1 and 1 μ M DCVC were used to examine changes in gene expression. Using the criterion of a mean 2-fold change over control for the four samples examined, 3 genes at 0.1 μ M DCVC increased namely, adenosine kinase, zinc finger protein X-linked and an enzyme with lyase activity. At 1 μ M DCVC two genes showed a >2-fold decrease, N-acetyltransferase 8 and complement factor H. At a lower stringency (1.5-fold change), a total of 63 probe sets were altered at 0.1 μ M DCVC and 45 at 1 μ M DCVC. Genes associated with stress, apoptosis, cell proliferation and repair and DCVC metabolism were altered as were a small number of genes that did not appear to be associated with the known mode of action of

DCVC. Some of these genes may serve as molecular markers of TCE exposure and effects in the human kidney. Supported by Department of Energy Cooperative Agreement DE-FC09-02CH11109.

1272 ROLE OF ORGANIC ANION TRANSPORTER 3 (OAT3) IN THE RENAL TRANSPORT OF GLUTATHIONE (GSH).

L. H. Lash¹, D. A. Putt¹, F. Xu¹ and L. H. Matherly^{1,2}. ¹Pharmacology, Wayne State University Sch. Med., Detroit, MI and ²Karmanos Cancer Institute, Wayne State University Sch. Med., Detroit, MI.

The tripeptide GSH is important in maintenance of renal redox status and defense against reactive electrophiles and oxidants. Previous studies showed that GSH is transported across the basolateral plasma membrane (BLM) into the renal proximal tubule by both sodium-coupled and sodium-independent pathways. Substrate specificity and inhibitor studies in renal proximal tubular cells and BLM vesicles suggested the potential function of several carriers, among them the organic anion transporters 1 and 3 (Oat1 [Slc22a6] and Oat3 [Slc22a8]), in the uptake process. To investigate the potential role of Oat3 in GSH uptake, the cDNA for rat Oat3 was expressed as a His₆-tagged protein in *E. coli*, purified from inclusion bodies and by Ni²⁺-affinity chromatography, and reconstituted into proteoliposomes. Reconstituted Oat3 transported both GSH and the prototypical substrate *p*-amino-hippurate (PAH) in exchange for 2-oxoglutarate (2-OG) and 2-OG and PAH in exchange for GSH, and PAH uptake was inhibited by both probenecid and furosemide, consistent with the function of Oat3. To investigate the function of Oat3 in GSH uptake in an intact cellular model, the rat proximal tubular cell line NRK-52E cells was assessed as a potential model. Analysis of mRNA expression by RT-PCR of Oat3 and other potential carriers in homogenates of both rat kidney cortex and NRK-52E cells revealed that whereas rat kidney cortex expressed all the potential GSH carriers (i.e., Oat1, Oat3, the sodium-dicarboxylate carrier 2 [NaC2; Slc13a3], organic anion transporting polypeptide 1a1 [Oatp1a1; Slco1a1], and multidrug resistance proteins 2 and 5 [Mrp2/5; Abcc2/5]), NRK-52E cells failed to show any expression. Analysis of GSH uptake across the BLM of NRK-52E cells showed little PAH- or 2-OG-stimulated GSH uptake. These results support the suggestion that Oat3 can function in GSH uptake and that NRK-52E cells possess a low background rate of GSH uptake and can thus be a good model for overexpression of specific, putative GSH carriers.

1273 THE ROLE OF iPLA₂ GAMMA IN OXIDANT-INDUCED ENDOPLASMIC RETICULUM LIPID PEROXIDATION AND RENAL CELL NECROSIS.

A. C. Eaddy, G. R. Kinsey and R. G. Schnellmann. *Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.*

We have previously demonstrated that inhibition of calcium-independent phospholipase A₂γ (iPLA₂γ), located in the endoplasmic reticulum (ER) and mitochondria of rabbit renal proximal tubular cells (RPTC), potentiates oxidant-induced lipid peroxidation and necrotic cell death. Because oxidant-induced ER lipid peroxidation may result in membrane disruption and lead to the release of ER Ca²⁺, an important trigger for RPTC necrosis, we investigated the role of ER-iPLA₂γ on oxidant-induced ER lipid peroxidation and the role of ER Ca²⁺ release in oxidant-induced necrosis. Using the fluorescent lipid, cis-parinaric acid, as a marker of lipid peroxidation, *t*-butylhydroperoxide (TBHP) treatment of rabbit kidney cortex microsomes produced lipid peroxidation and prior inhibition of iPLA₂γ with BEL potentiated the lipid peroxidation. TBHP-induced RPTC necrosis, measured by flow cytometry using propidium iodide (PI) staining, was potentiated by prior treatment with the iPLA₂ inhibitor BEL. Depletion of ER Ca²⁺ with thapsigargin (Tg) prior to TBHP exposure reduced RPTC necrosis and reduced the potentiation of TBHP-induced necrotic cell death by BEL (Control, 0.4%; TBHP, 29%; TBHP + BEL, 42%; TBHP + Tg, 17%; TBHP + BEL + Tg, 22%). These data reveal that 1) TBHP produces ER lipid peroxidation, 2) inhibition of ER-iPLA₂γ potentiates TBHP-induced ER lipid peroxidation, and 3) prior depletion of ER Ca²⁺ blocks the potentiation of TBHP-induced necrotic cell death produced by iPLA₂γ inhibition. We suggest that iPLA₂γ is cytoprotective against oxidant injury by blocking ER lipid peroxidation, which in turn, minimizes ER Ca²⁺ release and necrotic cell death in RPTC.

1274 ROLE OF iPLA₂γ IN RENAL CELL MITOCHONDRIAL PERMEABILITY TRANSITION.

G. R. Kinsey¹, J. McHowat², K. S. Patrick¹ and R. G. Schnellmann¹. ¹Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC and ²Pathology, St. Louis University, St. Louis, MO.

Our laboratory has previously demonstrated calcium-independent phospholipase A₂ gamma (iPLA₂γ) is localized to renal cell mitochondria and iPLA₂ inhibition blocks caspase-mediated, cisplatin-induced renal proximal tubule cell (RPTC)

apoptosis. The mitochondrial permeability transition (MPT) is a key control point for apoptosis in many cell types. The goal of the present study was to determine the role of iPLA₂γ in renal cell MPT. MPT of isolated renal cortex mitochondria (RCM) was induced by Ca²⁺/PO₄¹⁻ and measured as the decrease in optical density at 540 nm. iPLA₂ activity was assessed by measuring the abundance of free fatty acids in isolated mitochondrial suspensions in the presence and absence of Ca²⁺ and the iPLA₂ inhibitor bromoenol lactone (BEL) by GC-MS. Ca²⁺/PO₄¹⁻ induced mitochondrial swelling was blocked by the MPT inhibitors, cyclosporine A (1 μM) and ATP (500 μM). The R-enantiomer of BEL, which specifically inhibits iPLA₂γ, inhibited Ca²⁺-induced RCM MPT, while S-BEL (negative control) had no effect. Ca²⁺ treatment resulted in a significant increase in free arachidonic acid (~70 μM) in the mitochondrial suspension that was blocked by pretreatment with BEL. No increases in free myristic, palmitic, stearic, oleic or linoleic acid were detected after Ca²⁺ treatment in this model. Addition of arachidonic acid (18 μM) to mitochondria, pretreated with BEL, restored Ca²⁺-induced MPT. Taken together these findings suggest that iPLA₂γ catalyzed arachidonic acid liberation mediates the MPT in renal cell mitochondria exposed to Ca²⁺/PO₄¹⁻.

1275 THE URINARY PROTEIN RESPONSE TO TOXICITY OF ETHYLENE GLYCOL IN KIDNEY TISSUE.

Y. Li and K. McMartin. *Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.*

Ethylene glycol (EG) exposure above threshold doses can lead to renal toxicity. EG is not toxic, but its metabolite—oxalic acid, which precipitates with calcium as calcium oxalate monohydrate (COM), produces the renal toxicity. In vivo studies show a greater accumulation of COM in the kidney of Wistar than in F-344 rats, which explains the higher sensitivity of the Wistars to EG. Urinary proteins can inhibit or promote crystal adhesion to renal tubular cells, which could alter the accumulation of COM in the tissue. Tamm-Horsfall protein (THP) and osteopontin (OPN) are two proteins that appear to inhibit COM adhesion. We hypothesize that the accumulation of COM crystals is regulated by the different expression of urinary proteins between the rat strains. To identify the role of these proteins, we treated F-344 and Wistar rats with 0.75% EG in drinking water for 4 weeks, and collected 24 hour urine samples from fasted rats before and after 1, 2, 3, and 4 weeks. Protein levels were identified in urine samples by Western blotting. COM crystal accumulation was observed in the kidneys of treated Wistar rats but not in F-344 rats. In Wistar rats, total THP levels increased over treatment time, but similarly in both EG-treated and control rats. THP levels in F-344 appeared higher than in Wistar before treatment, but did not change with treatment. A much higher OPN level was observed in F-344 than Wistar rats before treatment, but this decreased to the same levels as in Wistar after 1 week treatment. The lower levels of OPN and THP, as inhibitors of COM adhesion, in untreated Wistar rats could explain a higher degree of COM accumulation. However, the fact that the strain differences diminish in time after treatment with EG suggests that these two proteins may not be involved in the strain difference regarding COM accumulation after EG exposure. Supported in part by a research agreement with the American Chemistry Council.

1276 BINDING AND INTERNALIZATION OF OXALATE CRYSTALS BY PROXIMAL TUBULE CELLS FROM HUMANS AND RATS IS RELATED TO OXALATE CYTOTOXICITY.

K. McMartin and C. Guo. *Pharmacology, Toxicology & Neuroscience, LSU Health Sciences Center, Shreveport, LA.*

Ethylene glycol (EG) produces renal failure due to its metabolism to oxalate. Pathologic images have shown that accumulation of calcium oxalate monohydrate (COM) crystals in the kidney is associated with tubular cell necrosis. This mode of action is consistent between rats and humans, although there are pharmacokinetic and pharmacodynamic differences in sensitivity. Our previous studies have demonstrated that COM crystals produce greater cytotoxicity in proximal tubule (PT) cells from rats than from humans. The present studies compared the binding and internalization of [14C]-COM crystals to PT cells between human and Wistar and F-344 rats. Binding was determined by incubation of cells with COM at 40°C, followed by solubilization of cells. Internalization was determined by incubation of cells with COM at 37°C, then removal of bound COM with an EDTA incubation, followed by solubilization of cells. The results indicated that COM crystals bound to and were internalized by PT cells in concentration-dependent manners. Both the amounts of COM crystals bound to and internalized by rat PT cells were about five times more than by human cells, with no differences between Wistar and F-344 cells. Both binding and internalization of COM were highly correlated with the degree of cell death produced in cells (*r* = 0.97 and 0.92, respectively). These studies demonstrate that surface binding of COM to and internalization by PT cells plays a critical role in its cytotoxicity and explain why rat PT cells are more sensitive to

the cytotoxicity of COM crystals. At the same level of COM accumulation after EG exposure in vivo, rats would appear to be more susceptible than humans to COM-induced tissue damage. Supported in part by a research agreement with the American Chemistry Council.

1277 ROLE OF ORGANIC ION TRANSPORTERS AND ESTROGEN ON CISPLATIN [CDDP] TOXICITY IN HUMAN PROXIMAL TUBULAR CELLS.

K. Tuiskula, M. Bunch, S. Singh and R. Sarangarajan. *Pharmaceutical Sciences, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA.* Sponsor: *S. Cohen.*

Organic cation- and anion-transporters (OCT, OAT) influence CDDP induced nephrotoxicity. Although OCT/OAT expression can be modulated by sex steroids in animal models, the role of OCT/OAT and estrogen on CDDP toxicity in human proximal tubular cells (hPTC) is unclear. In this study, we utilized an immortalized normal hPTC (HK-2) cell line to characterize functional role of OCT, OAT and 17 β -estradiol (17BE) on CDDP toxicity in-vitro. HK-2 cells (approx 2.0x10⁵) were seeded in 96-well plates and maintained for 24h in Dulbecco's Minimum Essential Media (10%FBS, 1% antibiotics) in a CO₂ (5%) incubator at 37°C. After 24h, cells were treated with fresh media containing 10 μ M, 20 μ M or 50 μ M (triplicate/treatment) of CDDP (dissolved in 0.9% sterile saline) for 24, 48, 72 & 96 hour respectively alone or in the presence of (100 μ M) prototypal OCT/OAT substrates, tetraethylammonium (TEA)/p-aminohippuric acid (PAH) respectively. To determine effect of 17BE, HK-2 cells were treated with (1, 5, 10, 20, 50 μ M) 17BE for 8h followed by treatment with CDDP (10, 20, 50 μ M) for 48 hours. Toxicity was determined using CellTiter Aqueous96 cell proliferation assay (Promega Corp, Madison, WI) and data expressed in terms of cell survival (Mean $\pm$ SD; n $\geq$ 4). HK-2 cells exhibited a dose- and time-dependent increase in susceptibility to CDDP, and was unchanged in presence of TEA or PAH. 17BE did not influence HK-2 cell survival nor exposure to 10 μ M CDDP. However, 1 & 5 μ M 17BE conferred significant (p < 0.05) protection against CDDP (20 & 50 μ M) concentrations, a phenomenon that was abrogated at > 5 μ M 17BE concentration. In conclusion, results demonstrate that in normal hPTC HK-2 cells, OCT/OAT substrates does not influence CDDP toxicity. However, low levels of 17BE confers protection against higher concentrations of CDDP. [Funds for this study was provided via MCPHS Faculty Seed Grant to SR, 2006].

1278 METALLOTHIONEIN ISOFORM 3 DEPENDENT REGULATION OF E-CADHERIN EXPRESSION IN HUMAN PROXIMAL TUBULE CELLS.

S. H. Garrett, S. Somji, C. Bathula, X. Zhou, M. A. Sens and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Metallothioneins are metal-binding proteins that provide protection against the toxic affects of heavy metal including Cd²⁺ that induces nephrotoxicity. Previous studies from this laboratory have implicated the expression of the third isoform of metallothionein (MT-3) in the maintenance of proximal tubule vectorial active ion transport through an analysis of dome formation by human renal epithelial cell lines. It was shown that HK-2 cells have no expression of MT-3 and do not form domes in culture; whereas, the HPT cells and HK-2 cells stably transfected with MT-3 form these structures. Domes are a hallmark of cell cultures derived from transporting epithelium that retain the in situ property of vectorial active transport. In the present study, this association was further explored by determining the effect that the presence or absence of MT-3 had on the expression of the E-, P-, N-, K-, and KSP - cadherins in these cell lines. It was demonstrated that the HPT cells and HK-2(MT-3) cells had significant elevations in the expression of mRNA and protein for the E-, P-, K-, and KSP - cadherins compared to that of the HK-2 cells. In contrast, it was shown that the HK-2 cells had significantly elevated expression of N - cadherin compared to both the HPT and HK-2(MT-3) cell lines. These patterns of cadherin expression provide strong evidence that MT-3 might be involved in epithelial to mesenchymal transition (EMT) that is postulated to occur during disease states such as cancer or renal fibrosis and in the mesenchymal to epithelial transition (MET) that occurs during normal kidney morphogenesis.

1279 CHEMICALS AND GENDER DIFFERENCES.

G. Johanson¹, T. Bellander¹, M. Berglund¹, L. Ernstgard¹, A. Hanberg¹, J. Hogberg¹, I. Johansson¹, M. Oberg¹, K. Victorin¹, M. Wallen² and M. Vahter¹. ¹Institute of Environmental Medicine (IMM), Karolinska Institutet, Stockholm, Sweden and ²National Chemicals Inspectorate (KemI), Stockholm, Sweden.

With reference to a government instruction, we have reviewed the scientific documentation on gender differences in the protection against harmful effects of chemicals. The tasks specified were:

- Review the state of art with respect to gender differences in uptake, disposition and health impact of chemicals during different stages in life.
- Describe if and how potential gender differences are considered in the design and evaluation of toxicity tests of chemicals and implementation of safety factors and guidance values.
- Propose actions so that both sexes are equally protected from harmful effects.

Gender differences in exposure, toxicokinetics, toxicodynamics, odor perception, sensory irritation and health effects of endocrine disruptors, metals (arsenic, lead, methyl mercury), carcinogens and urban air pollution, as well as testing procedures, use of safety factors and limit setting procedures were reviewed.

In summary, there is a considerable lack of knowledge about potential gender differences. Such differences have rarely been analysed, neither in experimental, nor epidemiological studies. Above all, knowledge about adverse effects of chemicals in women is lacking. Although available data suggest that gender differences in health effects are generally relatively small, examples of potentially significant differences in exposure, uptake, metabolism and sensitivity with respect to certain chemicals and environmental pollutants are found. The group of chemicals judged to have the biggest significance for gender-specific toxic effects are the endocrine disruptors. Although testing of chemicals includes both sexes, gender differences are seldom evaluated. Further, possible such differences are rarely taken into account in risk assessment and management.

In conclusion, there is a great need for research and compilations and analyses of existing data, particularly to identify research needs and how gender differences might be addressed in risk assessment and management.

1280 RISK ASSESSMENT ON VETERINARY DRUGS RESIDED IN LIVESTOCK PRODUCTS FOR RISK MANAGEMENT.

S. Jeong, H. Ku, S. Son, G. Chung and J. Cho. *Toxicology & Chemistry Division, National Veterinary Research & Quarantine Service, Anyang, KyungGi, South Korea.*

Veterinary drugs are inevitably used for growth promotion and disease control of livestock animals. However, concerns on the safety of livestock products and prevalence of antimicrobial resistance have been increased. The present study was performed to develop risk assessment strategy apt to residual veterinary drugs in food and to rank the risk priority for risk management. We assessed the 269 veterinary drugs following to risk assessment steps as hazard identification, hazard characterization, exposure assessment and risk characterization. All scientific information of each drug were compiled and classified into direct and indirect hazardous factors, exposure factors and reference factors. The data on toxicity (T), antimicrobial resistance (AR), impact on human intestinal microflora, regulatory concerns for prohibition, acceptable daily intake, maximum residue limit (MRL) and residue violation rate for recent 5 years were allocated into hazardous factors and data on withdrawal period (WP), production quantity of each drug for five years (PQ) and food consumption amount were considered as exposure factors. The limit of information on residue violation rate (LI) was referred as reference factors. All factors were ranked into 0 to 5 and risk of each drug was scored according to the equation drawn by optimal weighing on toxicity, MRL and withdrawal period. The equation for risk scoring was: {residue violation rate (or estimated risk: 0.16667(3*MRL+2*WP+PQ))}x{AR+3*T}/4x{1+0.06667(LI-1)}. Among the 269 veterinary drugs assessed, furazolidon was the highest risky residual drug scored as 25.33 and followed by dimetridazole, carbadox, hygromycin B, avoparcin, olaquinoxid, metronidazole, chloramphenicol and enrofloxacin in order. Diaveridine, fenitrothion and fluralinate were allocated into the lowest risk grade. The highly ranked drugs in risk priority were assumed to have potent public health impact and should be controlled more carefully for the prevention of residue in food.

1281 COMMUNICATING CHEMICAL SAFETY, RISK PERCEPTION AND HAZARD TO LAY PUBLIC: THE GLOBAL HARMONIZED SYSTEM OF CLASSIFICATION AND LABELLING OF CHEMICALS IN THAILAND (GHS).

S. Lapyai¹. ¹Faculty of Communication Arts, Rangsit University, Pathumthani, Thailand and ²The Committee of Food and Drug, Ministry of Public Health, Nonthaburi, Thailand. Sponsor: *P. Sinhaseni.*

The Global Harmonized System of Classification and Labelling of Chemicals or GHS is the result from the 1992 United Nations Conference on Environment and Development (UNCED) on developing a single but globally harmonized system to manage classification of chemicals and labels. The key message of GHS is a global system of hazard management. GHS is to be implemented as a national programme in Thailand in 2007. A practical and appropriate hazard communication is needed in order to protect people and the environment from chemical exposures, ensuring chemical safety use and to provide a comprehensive hazard communication system. A research project- GHS: Comprehensibility Testing is a part of GHS implementation, it is designed to find out the best-practice of risk communication. Target population covers all sectors; industrial, agriculture, consumer, transport, public health service and emergency responders.

GHS develops hazard communication tools to convey information that can be easily recognized and understandable, these tools include hazard symbols, hazard statements, safety data sheets and labels.

GHS hazard communication system is the source of information on total risk management and offers guidance on protective measures, hazard, avoidance of adverse effects, safety use measures, chemical storage/disposal, transporting, handling measures and emergency responding.

The result at this period covers two sectors; industrial and consumer group in Thailand. Findings show that each sector perceive hazard differently according to how high they are exposed to chemicals. Risk assessment and perception effects these two groups differently. It can be concluded that sufficient risk information effects risk-related behaviours and levels of self-protection. Information sufficiency is a potential factor in risk perception.

1282 CONCENTRATION/DURATION/EFFECT ($C \times T$) RELATIONSHIPS IN ASSESSMENTS OF HEALTH RISK FROM ACUTE INHALATION EXPOSURES – COMPARISON OF APPROACHES.

G. M. Woodall, J. S. Gift, A. S. Howard, I. Pagan, J. Stanek and G. L. Foureman. NCEA, U.S. EPA, Research Triangle Park, NC.

Assessments of health risk from acute exposures (≤ 24 hours) often require extrapolation to a duration of interest. Traditionally, this extrapolation has been performed using Haber's rule where the product of the concentration multiplied by the duration results in a constant ($C \times T = k$). More recently, risk assessors have used the approach proposed by ten Berge et al. (1986) that the formula $C^n \times T = k$, with an exponent n on the concentration term, is more appropriate in defining this relationship. Categorical regression analysis also provides the capability for duration extrapolation. In this presentation, we compare the approaches that have been used in acute assessments for a few model compounds (acrolein, ethylene oxide, hexachlorocyclopentadiene [HCCPD], hydrogen sulfide, and phosgene), and explore some of the issues being addressed as the US EPA develops a method for performing assessments of health risk from acute inhalation exposures. The relevance of lethality to other less severe endpoints (e.g., irritation, neurotoxicity) when developing the value for the exponent n in the $C^n \times T$ formula are considered in the assessments of ethylene oxide and HCCPD. The assessment for acrolein was data limited, allowing extrapolation to durations no longer than 6-hours. The application of categorical regression analysis is investigated in the assessments of hydrogen sulfide and phosgene. General issues also discussed include dosimetry, estimating a time to recovery following an acute exposure, and toxicokinetic and toxicodynamic considerations when validating extrapolations from observed data. This comparative review leads to the conclusion that the appropriate approach is most often dependent on the available data, but requires additional toxicological judgment as to which data are most biologically relevant. [Disclaimer: The views expressed in this abstract are those of the authors and do not represent the policy of the U.S. Environmental Protection Agency.]

1283 LEAD (PB) EFFECT LEVELS AND TOLERABLE LEVELS OF EXPOSURE.

P. M. Bolger and C. D. Carrington. Department of Health and Human Services, U.S. FDA, College Park, MD.

Lead exposure causes permanent neurobehavioral deficits, particularly in children at relatively low exposure levels. Exposure is also associated with peripheral and central nervous system dysfunction and hematological changes, among others. Children, especially young children, show adverse health effects at lower blood lead levels and attain higher blood lead levels per μg ingested than adults because they absorb lead more readily and consume more food, and thus retain more lead on a body weight basis. While no safe level of lead exposure has been identified practical threshold levels have been developed. These have been used as screening tools to assess the impact of various sources of exposure on overall population body burdens. A steady state blood level of $10 \mu\text{g}/\text{dL}$ has been used as a lowest observed adverse effect level and was derived from studies in children. This blood level was used to identify a steady state provisional total tolerable intake level (PTTIL) of $6 \mu\text{g}/\text{day}$ in young children. Population studies of blood lead levels below $10 \mu\text{g}/\text{dL}$ have also identified adverse effects, but until recently these associations have not been clearly established. More recent studies have substantiated lead induced decrements in cognitive function in children below $10 \mu\text{g}/\text{dL}$. In one recent study blood levels as low as $2 \mu\text{g}/\text{dL}$ appear to be associated with the incidence of ADHA. A reduction in the PTTIL for young children of several-fold on the basis of effects noted below $10 \mu\text{g}/\text{dL}$ is warranted. A drawback of relying entirely on the PTTIL in assessing the risks of food borne lead is that it may not provide a clear basis for effective risk management strategies. As a complimentary approach a dose-response function with a slope ranging from 0 to 0.6 IQ points per $\mu\text{g}/\text{dL}$ was used to quantify effects that

may be expected from levels of lead in food that would result in blood lead levels below $10 \mu\text{g}/\text{dL}$. This approach will provide a robust scientific basis for weighing risk against the difficulty of avoiding or mitigating exposure

1284 LOWER SENSITIVITY OF HUMANS COMPARED TO RATS TO 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD), 2, 3, 4, 7, 8-PENTACHLORODIBENZOFURAN (PCDF) OR 2, 3, 7, 8-TETRACHLORODIBENZOFURAN (TCDF) -INDUCED CYP1A EXPRESSION.

C. Rowlands¹, B. Gollapudi¹, E. LeCluyse², S. Ferguson², D. Fontaine¹ and R. Budinsky¹. ¹The Dow Chemical Company, Midland, MI and ²CellzDirect, Inc., Pittsboro, NC.

The relative toxicological potencies of dioxin-like compounds (DLCs) in a mixture are estimated using the Toxic Equivalency Factor (TEF) approach. The TEF for a given DLC is an estimate of its toxicity relative to TCDD. Almost without exception, data from animal or in vitro studies provide the underlying basis for the TEFs used in the risk assessment of DLCs. Human data for use in the development of TEFs, while desirable and preferred, are largely unavailable. In order to gain insight into species-specific differences in the biological activities of DLCs, we studied CYP1A mRNA expression and 7-ethoxyresorufin-O-deethylase (EROD) and phenacetin-O-deethylase (POD) activities in cultures of primary hepatocytes from adult human female donors and female Sprague-Dawley rats exposed to three different dioxin/furan congeners. Cells were exposed for 24 or 48 hours to TCDD, PeCDF or TCDF and full concentration-response (0.00001 - 100 nM) profiles were characterized. Cell viability and cytotoxicity was monitored by ATP quantitation and LDH-release as well as by visual inspection of cell morphology. TCDD demonstrated a clear threshold for gene and enzyme expression in both humans and rats with human cells being less sensitive for CYP1A1- and CYP1A2-induction. The rank order for potency was maintained between the species (TCDD>PeCDF>TCDF). The relative potency estimates varied depending on the species and endpoint. This study provides useful new information for addressing the TEF concept and certain questions related to human sensitivity to dioxins and furans.

1285 PREDICTIVE HUMAN HEALTH RISK ASSESSMENT FOR A NEW ALUMINUM SMELTER IN ICELAND.

R. S. Kaetzel¹, L. J. Yost², R. A. O'Boyle¹, C. H. Shirley¹ and P. N. Booth¹. ¹Exponent, Bellevue, WA and ²Exponent, St. Paul, MN.

Alcoa is constructing the Fjarðal aluminum smelter in Reyðarfjörður, East Iceland. The smelter includes extensive design and operation features to reduce or eliminate environmental impacts. The Fjarðal facility will use imported anodes and spent pot liners will be exported rather than being placed in an onsite landfill. A predictive risk assessment was conducted to determine whether there was a consequential difference in human health risk related to air emissions from Fjarðal with and without the use of seawater scrubbers. Air dispersion modeling results for particulate matter (PM₁₀), sulfur dioxide, hydrogen fluoride, and PAHs were compared to the corresponding ambient air standards or guidelines from Icelandic or European directives, Norway, and U.S. EPA. Risk estimates were calculated for PAHs under current and future use scenarios for the following receptors: onsite outdoor worker, seagoing worker, hypothetical fenceline resident, future hypothetical resident, closest resident, residents in nearby villages, closest agricultural farmer and a visitor to the Holmanes Reserve. Use of seawater scrubbers decreased average SO₂ air concentration estimates in the short term; however, annual estimates were lower without seawater scrubbers. In the short term, both with and without seawater scrubbers, the number of exceedances of SO₂ predicted per year was well below the maximum number of allowed exceedances. Modeled concentrations of fluoride and PM₁₀ in air were well below health standards and risk based concentrations in soil. All risk estimates for carcinogenic PAHs were lower than the 10⁻⁶ risk, and hazard indices were well below the threshold of 1.0 for noncarcinogenic PAHs. The use of seawater scrubbers did not result in a consequential decrease in emissions, which were already within applicable guidelines and acceptable risk levels.

1286 HUMAN CELLS ARE LESS SENSITIVE THAN RAT CELLS TO PCB 126 AND AROCLOR 1254 ACROSS SEVERAL AHR-DEPENDENT GENES.

E. Carlson¹, K. Illouz¹, A. Possolo¹, A. Koganti², K. Holtzclaw³, S. Goodwin⁴, T. R. Sutter⁴ and J. Silkworth¹. ¹GE Global Research, Niskayuna, NY, ²In Vitro Technologies, Baltimore, MD, ³GE, Corporate Environmental Programs, Fairfield, CT and ⁴Feinstein Center for Genomic Research, University of Memphis, Memphis, TN.

In their evaluation of the EPA's 2003 dioxin reassessment draft, the National Academy of Sciences (NAS) stated that use of the toxic equivalency factor (TEF) methodology for estimation of non-cancer human health risks of dioxin-like com-

pounds (DLCs) was a reasonable approach (NAS, 2006). However, the NAS report emphasized that, "If significant differences in the REP (relative potency) of DLCs are found between humans and other species, then adjustments should be made in the TEFs." Our previous studies determined that human primary hepatocyte-derived REPs based on CYP1A activity and expression for PCB 126 and Aroclor 1254 are 10-1000 fold lower than those for rat primary hepatocytes. We extend these comparative studies by calculating species-specific REPs based on expression values for all genes responding to TCDD, PCB 126, and Aroclor 1254 using Affymetrix Genechips. Primary rat or human hepatocytes were treated with concentrations from -14 to -4 Log M. Human PCB 126 REPs for the well known aryl hydrocarbon receptor (AHR) battery genes Cyp1a1, Cyp1a2, Cyp1b1, and Aldh3a1 ranged from 10 – 1000 fold less than the WHO 2005 TEF value for PCB 126 of 0.1. However, rat PCB 126 REPs for these same genes failed to differ from the WHO TEF by more than 1 order of magnitude. The rat-specific Aroclor 1254 REP for Cyp1a1 induction was in line with the estimated Aroclor 1254 TEQ (based on WHO 2005 TEFs). At most, human cultures responded only at the highest concentration preventing calculations of human Aroclor REPs. We are extending these analyses to include other TCDD- and DLC-responsive genes. Overall, this study adds to the ever-growing body of scientific evidence demonstrating that humans are orders of magnitude less sensitive to DLC toxicity than rodents.

1287 ESTIMATION OF ATRAZINE IN STRATUM CORNEUM AND ITS TOXIC EFFECTS IN SKIN FOLLOWING TOPICAL APPLICATION.

F. Muhammad, A. Riaz, M. I. Anwar, I. Javid and T. Khaliq. *Physiology and Pharmacology, University of Agriculture Faisalabad, Faisalabad, Punjab, Pakistan.*
Sponsor: J. Riviere.

For risk assessment, a workable non invasive method for the estimation of atrazine in skin was needed. Moreover, the dermato-toxic effects of different concentrations of atrazine have not been studied so far. 15mg of 37% solution of atrazine in ethanol was topically applied to 6 different shaved sites on the back of rabbits (n=6). Each site was tape stripped with 10 consecutive adhesive tapes at 0.5, 1, 2, 3, 4, & 6 h of topical dosing to remove the stratum corneum (SC). Atrazine in tapes was extracted with methanol and analyzed with HPLC. In dermal toxicity studies, 500µl of 37%, 74% atrazine in ethanol and a commercial preparation (Atrazine® Ali Akbar Enterprises, Pakistan) was dosed on shaved backs of rabbits (n=4) for 4 days under occluded vs. non occluded conditions. Ethanol alone served as control. On 5th day, rabbits were euthanized and skin was scored for erythema and then examined microscopically. About 13.03 % of applied dose of atrazine was detected in SC of rabbits in 6 h. This finding warrants the dermal absorption of atrazine in persons exposed for longer duration. Significant differences ($P<0.05$) in erythema scores were observed with 74% atrazine and Atrazine® as compared to the control under occluded conditions. Similarly, significant differences in epidermal thickness & cell layers were observed in Atrazine® & 74% atrazine as compared to control in both dosing conditions. There were non significant differences in erythema, epidermal thickness or cell layers in occluded vs. non occluded regimen, indicating that atrazine is equally toxic regardless of its application procedures. Moreover, under non occluded application, no erythema was observed but microscopically significant epidermal hyperplasia was noticed. This indicates that even if there are no gross skin manifestations of atrazine yet this can produce significant damage to the epidermal barrier and hence can result in increase in penetration of self or other toxic substances.

1288 MOUSE SKIN INFLAMMATION BY LIPOPOLYSACCHARIDE: PRODUCTION OF HYDROXYL- AND LIPID-DERIVED FREE RADICALS REQUIRES INOS AND POSSIBLY XANTHINE OXIDASE.

M. B. Kadiiska, K. Nakai, J. Jiang, K. Stadler and R. Mason. *NIH/NIEHS, Research Triangle Park, NC.*

Free radical formation has been investigated in diverse experimental models of lipopolysaccharide (LPS)-induced inflammation. Here, using electron spin resonance (ESR) and the spin trap α -(4-pyridyl-1-oxide)-N-tert-butyl nitron (POBN), we have clearly detected an ESR spectrum of POBN radical adducts in the lipid extract of mouse skin treated with LPS for 6 h. The ESR spectrum was consistent with the trapping of a lipid-derived radical adduct. A hydroxyl radical detection technique with dimethyl sulfoxide demonstrated methyl radical formation, which implies of hydroxyl radical formation. The radical adduct formation was suppressed by aminoguanidine, and in inducible nitric oxide synthase knockout (iNOS $-/-$) mice, demonstrating the involvement of iNOS. As allopurinol suppressed the radical adduct formation, xanthine oxidase (XO) is presumably also involved in the free radical formation. NADPH oxidase was not required in the formation of these rad-

ical adducts, since the ESR signal intensity was increased by LPS treatment in NADPH oxidase knockout (gp91phox $-/-$) mice as much as it was in the wild type mouse. Nitric oxide end products were increased in LPS-treated skin at 6h. As expected, the nitric oxide end products were not suppressed by allopurinol but were by aminoguanidine. Interestingly, nitrotyrosine formation in LPS-treated skin was also suppressed by aminoguanidine and allopurinol independently. Our results imply that iNOS and XO, but not NADPH oxidase, work synergistically to form lipid radicals and nitrotyrosine in the LPS-treated skin.

1289 INDUCTION OF THE PGE2 BIOSYNTHETIC PATHWAY BY UVB LIGHT IS REGULATED BY THE P38 AND JNK MAP KINASES IN PRIMARY CULTURES OF MURINE KERATINOCYTES.

A. T. Black¹, M. P. Shakarjian³, J. P. Gray³, V. Mishin², D. E. Heck^{1,2} and J. D. Laskin^{1,3}. ¹Toxicology, Rutgers University, Piscataway, NJ, ²Pharmacology-Toxicology, Rutgers University, Piscataway, NJ and ³Env & Occupational Med., UMDNJ-RWJMS, Piscataway, NJ.

Exposure to ultraviolet light, in particular the high-energy wavelengths of the ultraviolet B (UVB) spectra (290-320 nm), is a major causative factor in skin carcinogenesis. It is well recognized that an array of lipid mediators, including prostaglandins (PG), contribute to the carcinogenic process and that UVB light causes the release of arachidonic acid, a PG precursor. Prostaglandin E2 (PGE2), the primary PG in the skin, is synthesized through the sequential actions of cyclooxygenase (COX-2) and microsomal prostaglandin E synthases (mPGES) 1 and 2. Once formed, PGE2 binds to its receptors, EP1, EP2, EP3 and EP4, initiating biological activity. Numerous studies have shown that in many cancers, COX-2, mPGES1 and PGE2 as well as several of the PGE2 receptors are upregulated and are essential for tumor progression. In the present studies, we analyzed the effects of UVB on the expression of these proteins in undifferentiated and calcium-differentiated primary mouse keratinocytes. Using realtime PCR and western blotting, respectively, we found that UVB (2.5-25 mJ/cm²) caused dramatic dose-dependent increase in COX-2 mRNA (25-35 fold) and protein in both cell types. UVB also caused a 4-6 fold increase in mPGES mRNA expression. We found that the mRNA expression of only two of the four PGE2 receptors (EP1 and EP2) was induced by UVB (4-7 fold). In these cells, UVB was found to cause a dose-dependent activation of the p38 and JNK MAP kinases. Inhibition of these enzymes with SB203580, a p38 inhibitor, or SP600125, a JNK inhibitor, markedly inhibited mRNA expression of COX-2, mPGES1 and EP1. Taken together, these data demonstrate that UVB light effectively induces the PGE2 biosynthetic pathway in keratinocytes and that the activation of this pathway is regulated by MAP kinase activity. Supported by NIH grants ES05022, CA100994, CA093798 and NJ Commission on Cancer Research Fellowship 05-2413-CCR-E0.

1290 LYMPH NODES FROM TATTOOED MICE EXPOSED TO SIMULATED SOLAR LIGHT HAVE SUSTAINED PROTEIN EXPRESSION CHANGES.

P. C. Howard^{1,2}, R. D. Edmondson¹, R. C. Jones¹, S. P. Thyparambil¹, J. T. Taylor¹, W. G. Wamer³ and N. V. Gopee^{1,2}. ¹National Center for Toxicological Research, U.S. FDA, Jefferson, AR, ²National Toxicology Program Center for Phototoxicology, U.S. FDA, Jefferson, AR and ³Center for Food Safety and Applied Nutrition, U.S. FDA, College Park, MD.

Approximately 24% of the US population has at least one tattoo. Although there are some reports of adverse reactions to tattoos, there is a paucity of data on tattoo pigment toxicity. We have examined inguinal and axillary lymph node protein expression in female SKH-1 hairless mice following tattooing and exposure to simulated sunlight. Groups consisted of no tattoo, tattooed with vehicle (10% aqueous glycerol), and tattooed with 20% w/v cadmium sulfide (CdS) or Pigment Red 22 (PR22) in vehicle. Mice were held for 2 weeks and exposed for 13 weeks to simulated solar light (1.4 SED/day). The mice (4/group) were sacrificed and the axillary lymph nodes removed, combined, frozen, and pulverized in liquid-nitrogen. Duplicate samples from each group were analyzed using polyacrylamide gel electrophoresis, the entire gel lane was excised into 30 bands, and each band subjected to in-gel trypsin digestion. The resulting peptides were analyzed using an automated nano-HPLC MS/MS system, and proteins were identified using the Mascot database search engine. ProteinTrack software was used to filter the protein results. In this first report of murine lymph node proteome more than 1700 proteins were identified. Hierarchical analysis of the total protein expression demonstrated that the non-tattooed and control (aqueous glycerol) proteomes were significantly different ($p<0.05$). Protein expression in mice tattooed with PR22 or CdS were different from each other and from the vehicle control. Analysis of the altered genes as a

result of tattooing with PR22 or CdS suggests there are changes in pathways involved in cell proliferation and inflammation. These results suggest (a) tattooing induces persistent changes in regional draining lymph node protein expression, (b) tattooing with PR22 and CdS induces changes above those detected with vehicle control.

1291 EXTRACELLULAR PROTON TRANSPORT BY SKIN KERATINOCYTES AS A TARGET FOR DERMATOTOXINS.

D. Heck^{1,5}, M. P. Shakerjian^{6,5}, J. P. Gray^{1,6}, R. Malchow^{3,4,5}, P. J. Smith⁵ and J. D. Laskin^{6,5}. ¹Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, ²Pharmacology and Toxicology, Rutgers University, Piscataway, NJ, ³Department of Biological Sciences, University of Illinois at Chicago, Chicago, IL, ⁴National Science Foundation, Arlington, VA, ⁵Biocurrents Research Center, Marine Biological Laboratory, Woods Hole, MA and ⁶Environmental & Occupational Health Sciences Institute, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ.

The mammalian epidermis is a multilayered organ serving to control and protect the organism from external toxins. Basal keratinocytes, grow and differentiate, ultimately forming the cell layers above. In this process an extracellular pH gradient, in which the outermost layers are most acidic, is formed. Epithelial permeability, barrier function, and wound healing processes including matrix proteinase, glucocerebrosidase, and sphingomyelinase activities are all dependent on the acidification of the epidermis. In the current studies proton extrusion was examined in PAM212 and primary cultures of murine keratinocytes (MEK). The process was measured using a self-referencing H⁺ microsensor. We found a H⁺ gradient that decreased with increasing distance from the cells. H⁺ efflux properties were similar in both cell types. Amiloride 10-100 μ M did not alter the H⁺ flux, arguing against involvement of epithelial Na⁺ channels (ENaC) or the Na⁺/H⁺ antiporter (NHE). V-ATPase inhibitor bafilomycin A (1 μ M) and Na⁺/K⁺-ATPase inhibitor Ouabain (1 μ M) also had no effect on H⁺ efflux. While H⁺ extrusion was not altered by Ca²⁺ levels, it was diminished in the absence of Na⁺, and restored upon returning cells to Na⁺-containing buffer. Glucose addition caused a marked stimulation of H⁺ efflux, but only in the presence of Na⁺. We conclude that PAM212 and MEK dynamically acidify their extracellular environment, and that H⁺ efflux is not reliant upon Ca²⁺, or the NHE, ENaC, Na⁺/K⁺ ATPase, or V-ATPase transporters. Furthermore, we found that basal as well as glucose stimulated acidification is Na⁺ dependent. Supported by NIH grants 1U54AR055073-01, ES07148, CA100994, CA093798 and P41RR001395.

1292 INCREASED INCIDENCE OF CUTANEOUS MELANOMA IN TYR-HRAS+ INK4A/ARF+/- MICE CORRELATES WITH UV-INDUCED PHOTODAMAGE IN THE ANAGEN HAIR FOLLICLE BULBS OF NEONATES.

W. H. Tolleson¹, P. C. Howard¹, W. B. Melchior¹, L. Muskhelishvili², A. R. Warbritton², J. R. Latendresse², A. Hay³ and A. R. Tolleson³. ¹National Center for Toxicological Research, Jefferson, AR, ²Toxicologic Pathology Associates, Jefferson, AR and ³Biomatrix, Inc., Columbia, SC.

Intermittent solar overexposure is associated with increased risk for cutaneous melanomas (CM) in humans. An animal model associating UV dosimetry with melanoma outcome is needed to test mechanisms of melanomagenesis and strategies for prevention. Our prior studies showed increased cyclopurimidine dimers (CPD) and photooxidative stress in whole skin samples collected from neonatal Tyr-HRAS+ Ink4a/Arf+/- transgenic mice exposed on postnatal days 3-8 to daily UV treatments (0.0, 1.0, or 2.0 J/cm²). Decreased latency for skin lesions was associated with increased CPD and oxidative stress in identically treated animals.

These skin lesions were evaluated histologically and classified as CM based on gene expression patterns (HRAS, Mitf, Trp-1, Trp-2, and 'silver') using laser microdissected tumor specimens and immunohistochemical detection of characteristic antigens (pan-RAS, S-100, Melan-A, neuron-specific enolase, and pan-keratins). Despite increased photooxidative stress and CPD detected in whole skin samples from both UV-treated dose groups, increased incidence of CM in photoexposed regions was observed in the 2.0 J/cm² dose group only.

The depth profile of CPD formation was then assessed by applying an object-oriented neural net-based image analysis algorithm (Feature Analyst; Visual Learning Systems, Missoula, Montana) running as an extension to ArcGIS (ESRI, Edmonds, CA) to detect and quantify immunolabeled CPD-bearing cells, within or outside of hair follicles, in large format (ca. 15 mm x 0.7 mm) digital image files. The incidence and latency of CM was closely associated with CPD detected in anagen hair follicle bulbs, the most mitotically active cutaneous melanocyte population in rodents. In contrast, weaker association was found between CPD detected in upper skin regions and CM.

1293 ADVANCES IN HEALTH ASSESSMENT IN U.S. EPA'S INTEGRATED RISK INFORMATION SYSTEM (IRIS) PROGRAM.

A. M. Kadry, K. Hammerstrom, L. Flowers, J. Vandenberg and P. Preuss. Office of Research and Development, National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC.

The Integrated Risk Information System (IRIS) Program develops Environmental Protection Agency (EPA) scientific positions on potential adverse human health effects from exposure to various chemical substances found in the environment. The program follows EPA guidelines for health risk assessment and fosters consistent risk assessments across EPA program offices and regions. The IRIS database contains over 540 chemical-specific IRIS summaries, many with complete toxicological reviews or similar background documents. The assessments provide qualitative hazard identification, cancer weight of evidence characterizations, and quantitative toxicity values, i.e. oral reference doses and inhalation reference concentrations for noncancer effects and oral slope factors and inhalation unit risks for carcinogenic effects. IRIS users include EPA program and regional offices, other federal agencies, state and local agencies, international agencies, and the public. The IRIS web site receives over 21,000 hits per day.

The current process for developing an IRIS assessment consists of a public nomination process including announcement of substance selections, development of a draft assessment, internal Agency review, interagency review by interested federal agencies, external peer review with public comment period, final EPA approval and posting on the IRIS database. EPA is incorporating advances in the field of risk assessment in its assessment development process. These include greater use of mode-of-action data to inform hazard identification and cancer characterization and to identify appropriate low-dose extrapolation methods in cancer assessments, quantitative methods for expressing uncertainty, physiologically-based pharmacokinetic modeling, and approaches for assessing mixtures.

The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U. S. Environmental Protection Agency.

1294 THE USE OF MODE OF ACTION DATA IN INTEGRATED RISK INFORMATION SYSTEM (IRIS) HEALTH ASSESSMENTS.

L. Flowers, L. Cote, K. Hogan, C. Keshava and N. Keshava. NCEA, U.S. EPA, Washington, DC.

USEPA's Guidelines for Carcinogen Risk Assessment and Supplemental Guidance for Assessing Susceptibility from Early-Life Exposure make greater use of the increased scientific understanding of the biological mechanisms leading to cancer following environmental exposures. The IRIS Program is considering mode of action (MOA) data in evaluating the carcinogenicity of environmental chemicals. Due to significant scientific advances in the field of both cancer and non-cancer effects, elucidation of a MOA for a particular response in animals or humans can inform human health risk assessments in a number of ways. The Guidelines suggest that MOA data, when available and of sufficient quality, can be useful for understanding whether findings in animals are relevant to humans, the potency of a chemical, its potential effects at low doses, and which populations or lifestages may be particularly susceptible. However, the increasing availability of MOA data raises several questions as to its application to risk assessment. For example, how can qualitative biological information on a MOA for chemical-induced carcinogenesis be linked with appropriate mathematical and statistical considerations for quantitative risk evaluations? What data are needed to determine whether a MOA supports particular approaches to low dose extrapolation? Other key implementation issues include a focus on the weight of evidence for a hypothesized MOA, lifestage issues related to carcinogenesis, and data needs for determining a MOA. This presentation will provide an overview of the understanding of MOA and its application to health assessment in the IRIS Program.

1295 EXTENDING IRIS TO INCLUDE LESS-THAN-LIFETIME REFERENCE VALUES.

S. Rieth¹, R. Benson³ and G. M. Woodall². ¹NCEA/ORD, EPA, Washington, DC, ²NCEA/ORD, EPA, Research Triangle Park, NC and ³Region 8, EPA, Denver, CO.

The EPA's Integrated Risk Information System (IRIS) Program is engaged in developing reference values [oral reference doses (RfDs) and inhalation reference concentrations (RfCs)] for less-than-lifetime exposures, including acute (less than or equal to 24 hours), short-term (up to 30 days), and subchronic (up to 10% of aver-

age lifespan) exposure durations. The intent is to include these less-than-lifetime reference values on the IRIS database, which has traditionally provided RfDs and RfCs for chronic exposure durations only. Pilot health assessments for 8 chemicals are in progress, 5 of which focus on the development of acute inhalation RfCs. In conducting these assessments, EPA has addressed a number of methodological issues, including endpoint selection, dose-response approaches (e.g., benchmark dose and categorical regression methods), duration extrapolation, physiologically-based pharmacokinetic (PBPK) modeling, and uncertainty factor application. As with chronic reference values, these guideline values are intended to be safe, i.e., likely to be without appreciable risk of adverse health effects to the human population, including sensitive subgroups, over a lifetime.

Case studies for 3 chemical assessments currently in progress – 1,1,1-trichloroethane, ethylene oxide, and dibutyl phthalate – are presented to illustrate issues encountered in developing less-than-lifetime reference values. Among the issues addressed in these case studies are the appropriateness of given study designs as the basis for a duration-specific reference value, considerations in endpoint selection, development of reference values based on either the same or different endpoints/modes of action for different exposure durations, and data extrapolation across exposure durations. Finally, the case studies illustrate considerations in the final review of a set of duration-specific reference values for a given chemical (e.g., Do values show a logical progression?).

Disclaimer: The views expressed in this abstract are those of the author and do not represent the policy of the U.S. Environmental Protection Agency.

1296 ADVANCES IN CANCER RISK QUANTITATION.

K. A. Hogan¹, P. White², W. Chiu², J. Jinor² and L. Kopylev².

¹ORD/NCEA/IRIS, U.S. EPA, Washington, DC and ²ORD/NCEA-W, U.S. EPA, Washington, DC. Sponsor: A. Kadry.

This presentation will focus on recent advances in quantifying cancer risk and their uncertainties across animal and human carcinogenicity data. Issues requiring consideration when quantifying cancer risk include the contributions of pharmacokinetic models and biologically-based dose-response models, additivity to ongoing biological processes, and the combined impact of both mode-of-action information and population variability on dose-response relationships at low dose. In addition, there now is a greater need for broader characterization of uncertainty, integration of the results when multiple alternatives (models, data sets, modes of action, etc.) are being developed and explored, and enhanced summary presentation of toxicological databases. For instance, current work to better estimate point of departure uncertainty supports development of central estimates and bounds of risk. It is also anticipated that sensitivity analyses will be more routinely performed. All of these efforts contribute to a better quantitative characterization of cancer risk.

(Disclaimer: The views expressed in this abstract are those of the author and do not represent the policy of the U.S. Environmental Protection Agency.)

1297 UPDATING THE IRIS HEALTH ASSESSMENT FOR DICHLOROMETHANE (METHYLENE CHLORIDE).

C. Hsu¹, P. Schlosser¹, G. S. Cooper¹, J. C. Lipscomb¹ and P. McClure².

¹National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC and ²Syracuse Research Corporation, Syracuse, NY.

The IRIS Program is updating the dichloromethane (methylene chloride) health assessment. The current assessment on the IRIS database, completed in 1990, concluded that dichloromethane is a probable human carcinogen based on inadequate human data and sufficient evidence of carcinogenicity in animals. The reassessment will include evaluation of more recent human studies and an in-depth evaluation of issues regarding the mode of action of dichloromethane-induced carcinogenicity. Mutagenic activity has been demonstrated in short-term bacterial assays both with and without metabolic activation, although metabolic activation generally enhances dichloromethane mutagenicity. The results from in vitro genotoxicity assays with mammalian cells are equivocal (e.g., a dose-related increase in the occurrence of chromosome aberrations, but contradictory information concerning sister chromatid exchange). Evidence from in vivo studies indicates dichloromethane-induced clastogenicity, including chromosome aberrations, sister chromatid exchange, micronucleus, and DNA damage. Dichloromethane may undergo glutathione transferase-catalyzed bioactivation to yield S-(chloromethyl)glutathione as a reactive intermediate. This intermediate is likely to be involved in the carcinogenic mode of action. This presentation will summarize the available data and describe the challenges associated with interpretation of the data for human health risk assessment. (Disclaimer: The views expressed in this abstract are those of the authors and do not represent the policy of the U.S. Environmental Protection Agency.)

1298 EPA TOXICOLOGICAL REVIEW OF ACRYLONITRILE.

D. Wong, A. Persad and L. Kopylev. ORD/NCEA, U.S. EPA, Washington, DC.

EPA is preparing an IRIS Toxicological Review of Acrylonitrile. The assessment is an update to the current assessment which has been on the IRIS database since the early 1990's. Voluminous new data from epidemiological and animal studies have since become available. In addition, new methodologies and guidelines have been developed and utilized by the Agency. The assessment evaluates both cancer and noncancer hazards from human and animal studies for derivation of a Reference Dose (RfD), Reference Concentration (RfC), oral slope factor and inhalation unit risk using new information.

This presentation will provide an up-to-date overview of the ongoing assessment. Specific areas that will be covered include epidemiology studies, animal studies, effects for derivation of RfC and RfD, mode of action for carcinogenicity, and cancer quantification.

(The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA.)

1299 RELEVANCE AND FOLLOW-UP OF POSITIVE RESULTS FROM IN VITRO GENETIC TOXICITY TESTING.

B. Gollapudi¹ and M. P. Holsapple². ¹The Dow Chemical Company, Midland, MI and ²ILSI-Health and Environmental Sciences Institute, Washington, DC.

A battery of in vitro and in vivo genetic toxicity tests has been a critical component of the safety assessment of drugs, pesticides, and chemicals for many years. It is generally considered that results from in vitro studies demonstrate the intrinsic genotoxic properties of the test compounds. Accumulated knowledge has shown that the rate of positive in vitro tests, including the rate of positive findings not confirmed in vivo as well as false positives for non-carcinogens, has been high. There is a sense of urgency on the need to modify genotoxicity testing paradigms so as to generate useful information not only for hazard identification, but also for human risk assessment. The relevance of positive results obtained at concentrations that induce high levels of cytotoxicity, a requirement under current testing guidelines, is often questioned. A pertinent issue in this context is the necessity for testing in vitro at concentrations that far exceed any attainable in vivo exposures. Currently, there is a debate on the assumption that mutagenicity is equivalent to a mutagenic mode of carcinogenic action when positive results are obtained in both genotoxicity and carcinogenicity assays. A framework to establish whether or not genotoxicity is a key event in the observed carcinogenic response is needed to address this issue. In addition, it is suggested that the interpretation of dose response relationships for genotoxicity should be similar to that of other toxicity end points and non-linearity in dose-response should be applicable for both mutagenic and non-mutagenic carcinogens. The issue of applying uncertainty factors to an experimentally derived or modeled "no observed adverse effect level" or "benchmark dose" deserves further consideration for establishing human exposure levels for potential genotoxins. In addition, there is a need to develop follow-up testing strategies and weight of evidence approaches for the interpretation of positive in vitro genetic toxicity tests and their relevance to human health.

1300 RELEVANCE OF IN VITRO POSITIVE RESULTS IN GENETIC TOXICOLOGY: PLACE FOR IMPROVEMENT.

V. T. Thybaud. Drug Safety Evaluation, sanofi aventis, Vitry sur Seine, France. Sponsor: B. Gollapudi.

The in vitro genotoxicity tests are key components of the regulatory test battery for safety assessment. Data accumulated during the past years demonstrate a high rate of positive results, especially in the in vitro chromosome damage tests, for compounds found devoid of genotoxic or carcinogenic effects in animals. Several initiatives (e.g. International Workshop on Genotoxicity Testing, Health and Environmental Sciences Institute of International Life Sciences Institute) are on going to help consider how the relevance of in vitro positive findings could be improved. Several aspects of the assay performance and data interpretation are being considered for improvement. These include 1) the use of historical data in interpreting results from in vitro assays, 2) weight of evidence across assays, 3) mode of action (e.g. DNA reactive versus non-DNA reactive mechanisms) approaches to better define the level of concern for humans, 4) defining the limitations of the current in vitro models (e.g. human versus rodent cells, p53 status), 5) the impact of using extreme experimental conditions (e.g. criteria for the selection of the top concentration, cytotoxicity), and 6) further evaluation of the relationship between in vitro and in vivo potencies and of concentration/dose-response curves to move from qualitative to (semi) quantitative risk assessment. A collaborative work, involving scientists from regulatory authorities, academic laboratories and industries, will be needed to help advance the scientific basis for the interpretation of positive results and facilitate the development of follow-up testing strategies and criteria for determining the relevance of findings to human health.

1301 DON'T FORGET PARACELSUS: QUALITATIVE SCREENING ISN'T RISK ASSESSMENT.

J. T. MacGregor. *Toxicology Consulting Services, Arnold, MD.*

Paracelsus' insight that "the dose makes the poison" underpins the practice of toxicology, which is concerned in large part with determination of the biological effects expected under conditions of the exposure of interest based on knowledge of dose-response relationships. However, in the area of genetic toxicology regulatory practice frequently involves decision-making based on qualitative results from in vitro screening methods conducted under conditions designed to maximize exposure to active forms of the test article in cells with a reduced DNA repair capacity. Recent analyses have shown that qualitative categorization of results in such systems often over-predicts in vivo outcomes. It is clear that a re-evaluation of the history that led to current practices and default assumptions for regulatory decision-making is needed, and that regulatory practice should incorporate a risk-based approach that considers relevant in vivo exposure and response relationships. The historical basis of key assumptions about genetic testing strategies will be presented and, based on selected examples, current dogma regarding threshold vs. linear dose-response assumptions and possible steps toward an improved and economically feasible risk-based regulatory testing paradigm will be examined.

1302 CDER PERSPECTIVE ON POSITIVE RESULTS FROM IN VITRO GENETIC TOXICOLOGY ASSAYS.

D. Jacobson-Kram. *CDER, FDA, Silver Spring, MD.*

Results from carcinogenicity studies are generally not available for drugs until the time of approval. Many people, including healthy volunteers are often exposed to pharmacologically active doses of the drug before carcinogenicity results are available. FDA's Center for Drug Evaluation and Research (CDER) uses results of genetic toxicology studies as a surrogate for carcinogenicity during the drug development phase (clinical trials). A number of issues are considered in deciding whether drugs which give positive results in genetic toxicology studies can be given to subjects in clinical trials. These relate to the drug indication, the target population, duration of treatment and importance of the drug. For phase 1 studies in healthy subjects, no risk/benefit paradigm exists and for this population, risks must be minimal. ICH guidance recommends a test battery including a bacterial reverse mutation assay, an in vivo test for chromosome damage and an in vitro mammalian cell assay for cytogenetic damage or mutation at the thymidine kinase locus. Positive responses in the first two assay types are relatively rare; these assays have relatively high specificities and relatively low sensitivities. The in vitro mammalian assays have high sensitivity and low specificity. A review of the PDR indicates that 11 drugs with positive carcinogenicity results are uniquely identified by a positive in vitro mammalian cell assay, i.e. other assays are negative (personal communication, R. Snyder). Examination of this list of drugs suggests that factors other than genetic damage (e.g., exaggerated pharmacology) may be causally related to the carcinogenicity findings. These observations leave open the question of the contribution of mammalian in vitro assays in protecting the public health. CDER recently published guidance entitled Recommended Approaches for Integration of Genetic Toxicology Data. The guidance discusses various follow-up strategies to positive genotoxicity data. The strategies include assessing "weight of evidence" and "mode of action" as well as alternative follow-up testing.

1303 THE ROLE OF GENETIC TOXICOLOGY DATA IN THE EVALUATION OF MODE OF CARCINOGENIC ACTION FOR PESTICIDE CHEMICALS.

V. L. Dellarco. *Office of Pesticide Programs, U.S. EPA, Washington DC, DC.*

A pivotal focus of EPA's 2005 guidelines for cancer risk assessment is the carcinogenic mode of action (MOA) for a chemical (i.e., a biologically plausible sequence of key events that are obligatory and measurable steps leading to tumor development). This concept has permitted information on critical precursor events to be incorporated into the assessment of potential cancer risk and has led to a better scientific basis for the characterizing human relevance of laboratory animal responses and for informing quantitative estimates of risk. Similar MOA Frameworks have been developed by the International Programme on Chemical Safety and the U.S. EPA to guide transparent and structured analyses. The MOA Framework approach is based on Bradford Hill like criteria for establishing causality (i.e., a determination of whether a biological event is causal to the tumor response). Not only has the MOA framework become an increasingly valuable tool for organizing and analyzing data, but also for identifying data deficiencies. It is applicable to all MOAs, and has permitted the important distinction mutagenic and non-mutagenic MOAs. In

this presentation, case studies will be presented to illustrate the usefulness of the MOA Framework in evaluating mutagenic MOAs. The issues encountered with incorporating standard genetic toxicology data into the analysis will also be discussed.

1304 CONSULTANT IN TOXICOLOGY - A PERSPECTIVE.

R. A. Parent. *Consultox Ltd., Damariscotta, ME.*

INTRODUCTION

Although there are many retirees, academicians and governmental people who do consultations in Toxicology on a part time basis, there are more and more well qualified toxicologists who make a career out of doing consulting work in a variety of areas as is evidenced by close to one hundred registered toxicologists listed with the Roundtable of Toxicology Consultants.

Today, we present four highly successful consultants who have achieved a high level of success in attaining the height of their profession as Toxicology Consultants. They will share their insights into the tasks to be addressed in the various industries that they service.

1305 THE CHEMICAL SECTOR.

R. C. Kraska. *President, Kraska Consultants Inc., Aurora, OH.*

There are many consulting opportunities for toxicologists for both large and small companies in the Industrial Chemical Sector. Many large companies have fewer staff toxicologists due to employee down-sizing and attrition. Smaller companies who can not afford or justify a full time toxicologist need to turn to consultants when the need arises. It is common for major issues to be managed through trade associations who higher consultants and divide the cost among their members.

Usually opportunities arise from regulatory issues from the main federal laws which affect chemical products. EPA administers the Toxic Substances Control Act (TSCA) which provides authority over new chemicals coming on to the market and can require testing or controls of existing chemicals. OSHA administers the hazard Communication Standard (HCS) which requires company to provide MSDSs to customers and to label products with appropriate warnings. In addition, FDA issues arise with companies who supply the food packaging, food additive, cosmetic and medical device industries.

Some of the common tasks toxicology consultants have been involved in the past five years include:

- * Writing literature summaries and test plans for the High Production Volume (HPV) Chemicals Program under TSCA.
- * Guiding companies through HCS issues arising over the listing of new chemicals as carcinogens by IARC or NTP.
- * Assisting companies and trade associations comment on IARC and NTP nominations and ACGIH notices of intended changes for workplace threshold limit values.
- * On FDA issues, toxicologists can assist in the preparation of food or color additive petitions and food contact notifications or managing biocompatibility testing on materials supplied to the medical device industry.
- * Companies who export chemicals can have problems managing toxicological issues arising out of counterpart laws with different standards in Canada, the EU, Japan and Australia. China has been very active lately with new regulatory requirements for industrial chemicals.

1306 THE PHARMACEUTICAL INDUSTRY.

P. Frank. *Patricia Frank & Associates, Inc., Evansville, IL.*

Consultants to the pharmaceutical industry are a vital part of the preclinical development process, particularly in the small to medium size company. Pharmacodynamics, pharmacokinetics and metabolism and toxicology skills are all needed in order to bring a compound to the stage of clinical testing. Toxicology consultants with experience in developing drugs, including working with the FDA and comparable regulatory agencies world-wide, serve a vital function in companies without the internal skills or resources to define a development program based on the specific mechanism of action and proposed claim for the compound. These consultants work with the company to prepare briefing summaries and attend meetings with regulators. In addition, they place the pivotal toxicology studies in appropriate CROs, monitor those studies and prepare the summaries of the pre-

clinical work for regulatory submission. In many cases, the toxicology consultant becomes an integral part of the development team, participating in person or by conference call on a regular basis.

1307 THE MEDICAL DEVICE INDUSTRY.

S. C. Gad, *President, Gad Consulting Services, Cary, NC.*

While smaller in total sales than the pharmaceutical industry, the medical device industry (both domestic and International) is extensive and poorly equipped with internal resources to deal with questions as to the biocompatibility and safety of their products. Consulting practices in this area deal with both devices and the materials used in their construction, plus the growing field of drug/device combination products, and their evaluation under ISO and national standards. Few consultants are active in the field, and the opportunities and challenges will be presented and discussed from the perspective of 13 years experience as a toxicology and regulatory consultant in the field.

1308 LITIGATION SUPPORT.

R. A. Parent, *Consultox Ltd., Damariscotta, ME.*

Being involved in litigation involves continuing conflict. You are on one side of a case and the other side is trying to destroy you. In this kind of situation, your involvement must sit firmly on a solid base fact and truthfulness otherwise you will be destroyed. It's not enough to have the facts on your side, you must now present them in such a manner to survive pre-emptive motions and efforts toward summary judgments that are all laid out to destroy your credibility. That is still not enough. If you are lucky enough to get to a jury with a plaintiff's case, then your challenge is to break down these complex scientific issues into simple concepts that a lay jury off the street can understand. "Keep it simple stupid".

Of course, it goes without saying that your credentials must be accurate, extensive and impeccable. When I first became involved in litigation support, I asked a good friend for his insights and he told me that I had to choose sides and only work for either the plaintiff or defense. This, to my great satisfaction, is just not true. You can work for anyone who wants to hear the truth. Sometimes when you tell someone that they don't have a case, they are extremely grateful because you have saved them lots of money. Working for both sides also increases your credibility with judges and juries.

Litigation is not for the faint hearted. It is a challenge to remain cool when you are under attack. Most attorneys are quite civil and polite, but I have had some who have pounded on the table during a deposition. Of course, the deposition is the most trying time in a case. If you get to testify to a jury, everyone will treat you with respect because they don't want the jury to see their real personalities. It's a challenge

1309 BILIARY HYPERPLASIA AND CHOLESTASIS: RELEVANCE TO HUMAN RISK ASSESSMENT.

J. E. Klaunig¹ and M. J. Santostefano². ¹*Toxicology, Indiana University School of Medicine, Indianapolis, IN* and ²*Safety Assessment, GlaxoSmithKline, Research Triangle Park, NC.*

Drug-induced hepatic injury is the most frequent reason cited for the withdrawal of drugs from the marketplace and is quite common in non-clinical studies. Many mechanisms for liver injury exist. Although primary hepatocellular injury is most often emphasized, biliary and cholestatic liver injury is also been noted. Biliary hyperplasia can result from cholestasis, hepatocellular injury, alterations in bile constituents, or through hormonal and vascular disruption. In preclinical species, depending on the underlying cause, biliary hyperplasia may resolve, stabilize or rarely progress to a more advanced proliferative lesion. While no data are readily available directly correlating non-clinical cholangiopathies with responses of patients in clinical studies, cholangiopathies also do cause morbidity and mortality in humans, and are a major cause of transplantation. Cholangiocarcinoma is a lethal disease, afflicting 3000 individuals in the US and many thousands worldwide. Cholangiocarcinomas are epithelial neoplasms that originate from cholangiocytes and may be found at any level of the biliary tree. The relationship of cholestatic biomarker to cholangiopathies is assumed for most cases and yet clear correlations between clinical markers and histological findings are not always apparent. This symposium will focus on anatomy and physiology of the biliary tree with emphasis on species differences that may impact human risk assessment, strengths and limitations of non-clinical and clinical monitoring paradigms, use of knockout mice in understanding mechanism, identification of novel biomarkers, and potential correlations or lack thereof between non-clinical and human findings.

1310 BILIARY EPITHELIAL HYPERPLASIA: ADVERSE, NON-ADVERSE, OR RELEVANT.

R. T. Miller and J. R. Hailey. *Safety Assessment, GlaxoSmithKline, Research Triangle Park, NC.* Sponsor: M. Santostefano.

Critical to the assessment of adversity and the relevance of the toxicity to humans is determination of what the lesion represents in the test species and whether the lesion that occurs in preclinical species may also occur in humans under similar conditions of exposure. Biliary hyperplasia, a relatively common finding in preclinical species, may be indicative of cholestasis, hepatobiliary injury, a static primary proliferative effect, or a precursor lesion to a more advanced proliferative lesion. In the absence of contrary information, the default assumption is that the lesion(s) may occur in humans. This presentation will focus on interspecies comparative pathophysiology responses in the liver. In addition, a summation of non-clinical data in rodents and potential correlation(s) in humans will be presented. Lastly, proposed approach and position relative to assessing the potential adversity of biliary epithelium hyperplasia in preclinical species will be discussed.

1311 BILE ACID BIOTRANSFORMATION AND TRANSPORT IN THE HEPATOBILIARY UNIT.

A. F. Hofmann. *Department of Medicine, University of California, San Diego, CA.* Sponsor: M. Santostefano.

Work over the past six decades in vitro and in vivo has elucidated principles of biotransformation and transport of bile acids relevant to the metabolism and toxicity of drugs. Bile acids consist of a steroid nucleus containing 1-4 hydroxy groups and an isopentanoic acid side chain. Both the pattern of nuclear substituents and the side chain length effect biotransformation and transport (PK), function (PD) and toxicity. Because of efficient intestinal conservation (enterohepatic circulation), most bile acids transported by the hepatocyte have their origin in intestinal absorption. Modification of bile acids by the intestinal bacteria converts 1° bile acids (formed in the hepatocyte) to 2° bile acids (formed by intestinal bacteria), with the result that the hepatocyte must transport a mixture of both 1° and 2° bile acids. After biosynthesis from cholesterol, bile acids are conjugated (N-acylamidated) with glycine or taurine; conjugates are impermeable to cell membranes enabling high (micellar concentrations of bile acids in the biliary tract and small intestine. Bile acids with a shortened side chain (nor- or dinor- bile acids) are not substrates for the enzymes of N-acyl amidation, and instead are metabolized by the hepatocyte as drugs - secreted into bile as such and/or hydroxylated and/or glucuronidated. Dihydroxy nor bile acids are absorbed passively by biliary epithelial cells, and return to the hepatocyte via the periductal capillary plexus, thus undergoing a cholehepatic circulation. Basolateral transporters involved in bile acid uptake from sinusoidal blood, and apical (canalicular) transporters involved in bile acid secretion into bile have been identified, as well as nuclear receptors that regulate bile acid biosynthesis and biotransformation. Bile acid toxicity occurs when there is excessive accumulation of toxic 2° bile acids or impaired canalicular secretion. An understanding of bile acid metabolism in the hepatobiliary unit appears useful for characterizing the handling of newly developed drugs.

1312 BILE DUCT OBSTRUCTION AND DESTRUCTIVE CHOLANGITIS IN MICE: INSIGHTS INTO PATHOGENESIS AND TREATMENT OF CHOLESTATIC LIVER DISEASES.

M. Trauner. *Department of Medicine, Medical University Graz, Graz, Austria.* Sponsor: M. Santostefano.

Cholestasis is an impairment of bile secretion which results from a functional defect in bile formation at the level of hepatocytes or obstruction/destruction of bile ducts. Animal models of cholestasis such as bile duct ligated mice and the Mdr2 (Abcb4) knockout mouse model of sclerosing cholangitis have permitted major insights into the molecular mechanisms of cholestasis. Exposure to cholestatic injury (results in reduced expression and function of hepatic uptake and excretory systems, changes which may maintain and contribute to cholestasis and jaundice. Recruitment of alternative efflux pumps and induction of phase I and II detoxifying enzymes may limit hepatic accumulation of potentially toxic biliary constituents in cholestasis by providing alternative metabolic and elimination routes. These molecular changes are mediated by bile acids, proinflammatory cytokines and hormones at a transcriptional and posttranscriptional level. Ligand-activated nuclear receptors (e.g., bile acid receptor FXR, xenobiotic sensors PXR and CAR) play a key role in mediating these changes and represent a worthwhile therapeutic target for cholestatic liver diseases. Sclerosing cholangitis in Mdr2 (Abcb4) knockout mice results from bile acid toxicity in the absence of mixed micelle formation with phospholipids. Modulation of bile composition and induction of bile acid detoxification and transport by side-chain shortened nor-ursodeoxycholic acid (norUDCA) heals

sclerosing cholangitis in this model, while conventional UDCA has no benefit. Future clinical studies will have to demonstrate whether norUDCA is suitable for the treatment of cholestatic liver diseases such as PSC and PBC in humans.

1313 VASCULAR ENDOTHELIAL GROWTH FACTOR REGULATION OF BILIARY GROWTH.

G. Alpini. *College of Medicine, Texas A&M University, College Station, TX.* Sponsor: M. Santostefano.

The proliferation of cholangiocytes (lining the biliary tree) is a typical hallmark of cholangiopathies, where it counteracts the loss/damage of intrahepatic bile ducts to compensate for the structural and functional derangement of the intrahepatic biliary tree. Proliferating cholangiocytes display enhanced secretory activity, which is important for maintaining a normal ductal secretion in spite of the loss of damaged bile ducts. Growth factors, neuropeptides and hormones modulate cholangiocyte proliferation. Vascular endothelial growth factor is secreted by several epithelia and modulates cellular functions by autocrine and paracrine mechanisms. The role of VEGF in the regulation of growth of cholangiocyte growth is unknown. We aim to: (i) evaluate the expression of VEGF-A and VEGF-C and their receptors in normal and proliferating cholangiocytes after extrahepatic bile duct obstruction (BDL); and (ii) determine the role and transduction mechanisms by which VEGF-A and VEGF-C regulate cholangiocyte proliferation.

1314 NON-CLINICAL AND CLINICAL CORRELATIONS OF HEPATOBILIARY TOXICANTS.

J. Cullen. *College of Veterinary Medicine, North Carolina State University, Raleigh, NC.* Sponsor: M. Santostefano.

The assessment of the safety of novel compounds is typically conducted in several animal species, including rats, mice, dogs and nonhuman primates. Currently, there is little information available on the concordance of the responses of the biliary tree in these species with the human response. Accordingly, this presentation will focus on the evaluation of a number of chemicals that produced histologic evidence of biliary injury in animals with respect to the serum biochemical responses indicative of biliary injury in exposed humans. In addition, a thorough review of non-clinical toxicity data for compounds that have been reported to cause cholestatic injury will be discussed.

1315 EPIGENETIC REGULATION IN REPRODUCTION, DEVELOPMENT AND DISEASE: IMPLICATIONS FOR TOXICOLOGY.

D. L. Shuey¹ and R. Watson². ¹*Endo Pharmaceuticals Inc., Chadds Ford, PA* and ²*Mittek Systems Inc., Falls Church, VA.*

Epigenetics is the study of events that regulate gene expression without change in DNA sequence. Evidence for the critical role of epigenetic events in normal and abnormal cellular function is rapidly expanding. DNA methylation, histone modification and RNA interference are important mechanisms by which gene expression is regulated. These events have been associated with control of cell proliferation, growth and differentiation, and alterations in epigenetic regulation have been associated with a variety of disease states. Genomic imprinting, which involves the monoallelic expression of a gene in a maternal or paternal specific fashion, also appears to be regulated by epigenetic mechanisms. Despite the clear, fundamental role of epigenetic mechanisms in controlling normal and abnormal cell function, the potential importance of epigenetic events as toxicologic mechanisms is just emerging. There are few examples of direct effects of toxicants on epigenetic regulation. The objective of this symposium is to provide an introduction to epigenetic regulation and the importance of epigenetic mechanisms in normal and abnormal cellular function in a variety of systems in order to stimulate thinking about these events as potential targets for toxicologic actions.

1316 INTRODUCTION TO EPIGENETIC MECHANISMS.

R. E. Watson. *Mittek Systems, Falls Church, VA.*

With the sequencing of the human genome, a great deal of attention has been paid to the significance of various polymorphisms and mutations, and which of these are likely to be linked to various phenotypes. Such analysis has indeed led to an improved understanding of which genes are involved in particular diseases, and how to better prevent or treat these diseases. However, the maintenance of normal patterns of genetic expression is a multidimensional process, and DNA sequence alone is only one of those dimensions. Another dimension involves epigenetic mechanisms

that regulate the level of genetic expression without altering the DNA sequence itself. Thus, the phenotype is changed while the genotype remains the same. DNA methylation, histone modifications, and RNA interference are examples of epigenetic mechanisms. This symposium will underscore the importance of epigenetics in a number of normal biological processes, including development, gene imprinting, and X-inactivation. Epigenetic aberrations have also been linked to various adverse conditions such as cancer, reproductive and developmental disorders, and neurological deficits. Overall, the study of epigenetics is an exciting, emerging field with great potential to enhance our understanding of biological phenomena and improve human health.

1317 EPIGENETICS AND CARCINOGENESIS: THE ROLE OF ALTERED DNA METHYLATION.

J. I. Goodman. *Pharmacology & Toxicology, Michigan State University, East Lansing, MI.*

The involvement of mutagenesis in carcinogenesis needs to be reconciled with the fact that not all carcinogens are mutagens and the view that nonmutagenic events play key roles in the transformation of a normal cell into a cancer cell. This apparent paradox can, in part, be resolved by considering the roles that altered DNA methylation, an epigenetic mechanism, play in carcinogenesis.

Inheritance occurs on two levels. Transmission of genes either in the somatic sense or from generation to generation is distinct from mechanisms involved in transmission of alternative states of gene activity. Epigenetics describes the latter and involves regulation of temporal and spatial control of gene activity, e.g., changes in gene expression during development, imprinting, segregation of gene activities such that daughters of a cell exhibit different patterns of gene expression, and mechanisms that permit the somatic inheritance of a specific set of active and quiescent genes. DNA methylation is an epigenetic mechanism controlling gene activity. Changes in DNA methylation are not mutations, i.e., 5MeC and cytosine base pair with guanine. Increased methylation may silence tumour suppressor genes (functionally equivalent to inactivation due to point mutation or allelic loss) and decreased methylation may up-regulate expression of oncogenes. Thus, altered DNA methylation can facilitate the aberrant gene expression underlying carcinogenesis. The role of DNA methylation in the regulation of gene expression will be juxtaposed with a discussion of how altered methylation is a fundamental, epigenetic mechanism involved in carcinogenesis. Data from my laboratory will illustrate both a novel PCR-based approach to assess methylation status in multiple regions of the genome simultaneously and progress towards our goal of identifying genes involved in transformation by virtue of altered methylation. Emphasis will be placed on showing how we test the hypothesis that susceptibility to carcinogenesis is related inversely to the capacity to maintain normal patterns of methylation, and implications for safety assessment will be noted.

1318 EPIGENETIC REGULATION OF OVARIAN FUNCTION.

H. A. LaVoie. *Cell and Dev. Biol. and Anat., University of South Carolina School of Medicine, Columbia, SC.* Sponsor: D. Shuey.

The ovary is a dynamic tissue. A subset of ovarian genes silent during the follicular phase is activated during the luteal phase, a time when many follicular phase genes are turned off. Changes in transcription are driven by hormonal cues, which lead to histone modifications facilitated by specific transcription factors. Transcription factors recruit their coactivators or corepressors to the 5'-regions of target genes. Many of these cofactors are histone acetyltransferases and deacetylases mediating the hyperacetylation and hypoacetylation of histones, respectively. Hyperacetylation of lysine (K) residues in the core histone tails (e.g., H3K9 and H3K14) promotes chromatin alterations that favor transcription, whereas hypoacetylation of histones promotes gene silencing or repression. Specific histone phosphorylations can also facilitate transcription. For example, phosphorylation of histone H3 serine 10 co-operates with acetylated K9 to promote transcription. Methylation of histones occurs at lysine and arginine residues and can be either permissive or repressive. For instance, methylation of histone H3K9 represses transcription, whereas trimethylation of H3K4 is associated with active transcription. Most studies of histone modifications in the ovary have evaluated the highly regulated steroidogenic acute regulatory protein (STAR) gene. STAR is silent in granulosa cells of the immature follicle and expressed robustly after the LH surge. In vivo studies of monkey and murine granulosa cells have shown that an ovulatory stimulus of hCG leads to increased acetylation of histone H3K9 or reductions in H3K9 methylation within the STAR gene promoter, respectively (1,2). In cultured porcine granulosa cells, FSH stimulates H3K9/K14 acetylation within the promoter coincident with STAR transcription and coculture with STAR transcriptional repressor EGF blocks the increase in H3 acetylation (3). Modification of histones may be a mechanism by which environmental stimuli can impact ovarian gene expression.

1319 EPIGENETIC PROGRAMMING BY MATERNAL BEHAVIOR.

M. Szyf^{1,3}, I. C. Weaver^{1,3}, N. Provencal^{1,3,4}, P. McGowan^{2,3}, R. Tremblay⁴ and M. J. Meaney^{2,3}. ¹Pharmacology, McGill University, Montréal, QC, Canada, ²Douglas Hospital research center, McGill University, Montréal, QC, Canada, ³McGill Program for the Study of Behavior, Genes and Environment, McGill University, Montréal, QC, Canada and ⁴GRIP, University of Montréal, Montréal, QC, Canada. Sponsor: D. Shuey.

Maternal care has long term effects on health outcomes and behavior, which last through life. How is maternal behavior, which is restricted to early childhood, memorized through life long after maternal behavior is gone? We will present a hypothesis, which is based in our work on maternal care in rats that epigenetic processes program critical genes in response to maternal care. Stress responses in the adult rat are programmed early in life by maternal care and are associated with epigenetic marking of the hippocampal exon 17 glucocorticoid receptor (GR) promoter. This stable epigenetic programming is nevertheless reversible in adult brain by treatment with either the HDAC inhibitor TSA or central infusion of the essential amino acid methionine a precursor to S-adenosyl-methionine (AdoMet) the donor of methyl-groups for DNA methylation. A molecular mechanism responsible for this dynamic equilibrium of the DNA methylation pattern is proposed here. High levels of maternal licking/grooming (LG) behavior over the first week of post-natal life results in induction of the transcription factor NGFI-A within the hippocampus of the offspring. Binding of NGFI-A to the exon 17 GR promoter within the 6-day-old offspring permanently marks the promoter sequence for histone acetylation and DNA demethylation. We will also present preliminary data from our human studies suggesting that epigenetic differences correlate with behavioral differences in humans as well. Our data illustrates a possible mechanism for how behavioral cues mediate epigenetic programming of genes within the brain. We propose that the epigenome mediates between the dynamic environment and our static genomes and provides a molecular link between nurture and nature. Supported by a grant from the CIHR, NIH to MS and MJM and NCIC to MS

1320 VALPROATE: NOVEL ANALOGUES, APPLICATIONS AND MECHANISMS.

H. Nau. Food Toxicology, Veterinary University, Hannover, Germany.

Valproate (Valproic Acid, VPA) was originally developed as antiepileptic agent, but was shown to be effective also for treatment of bipolar disorders, cancer, migraine prophylaxis, schizophrenia, as well as for neuroprotection in Alzheimer Disease and cerebral ischemia. However, VPA is teratogenic in animal models and the human, leading to neural tube defects (exencephaly in the mouse, Spina bifida in the human). We have now synthesized a number of analogous structurally related to VPA in order to study if the mechanisms of some VPA-induced effects are related. Furthermore, we developed analogues which are 10-40-fold more potent than VPA in vitro (e.g. differentiation of cancer cells such as leukaemia cells (Deubzer, 2006)), and up to 4-fold more potent in vivo (teratogenicity). VPA was shown to be a histone deacetylase inhibitor causing hyperacetylation of core histone proteins leading to an open chromatin conformation, derepression and transcriptional activation of a number of genes (Phiel, 2001; Göttlicher, 2001). We studied - with a large set of structurally diverse analogues of VPA - if HDAC-inhibition is related to the teratogenic effect. We demonstrate that only teratogenic analogues are able to induce differentiation in F9-teratocarcinoma cells, to activate PPARdelta, to increase NCAM/PSA in F9-cells, and to inhibit histone deacetylation. Latter effect was demonstrated by Western blotting of hyperacetylated core histone H4 and by a human HDAC enzyme test system. We also show a quantitative correlation between the IC50(HDAC) values and the teratogenic potency of these analogues which clearly points to HDACs as the previously described theoretical "teratogenic receptor" for this class of compounds (Bojic, 1998). In conclusion: We have developed VPA-analogues which are many-fold more potent than the lead substance VPA. Some of these compounds could be useful in cancer therapy, neuroprotection, cognitive enhancement and further applications. It is not clear if teratogenicity can be dissociated from these desired effects, as HDAC-inhibition is a crucial part of the molecular mechanisms of this compound class in multiple experimental models.

1321 PATERNAL EXPOSURE TO CYCLOPHOSPHAMIDE (CPA) DISTURBS EPIGENETIC PROGRAMMING DURING EARLY EMBRYO DEVELOPMENT.

B. F. Hales¹, T. S. Barton¹ and B. Robaire^{1,2}. ¹Pharmacology & Therapeutics, McGill University, Montréal, QC, Canada and ²Obstetrics & Gynecology, McGill University, Montréal, QC, Canada.

Paternal exposures may impact negatively on progeny outcome. Exposure of male rats to a male mediated developmental toxicant and anticancer alkylating agent, CPA, resulted in increased pre- and post-implantation loss, and malformations in

the offspring. CPA induced a stage specific stress response in male germ cells. The DNA damage induced by CPA was germ cell phase specific, with the greatest damage occurring during sperm chromatin remodeling. Drug induced insults to sperm chromatin may affect the function of the paternal genome in the zygote. Zygotes sired by drug-treated males displayed advanced developmental progression. In 1- and 2-cell embryos sired by CPA-treated males, the relative abundance of candidate gene transcripts was elevated significantly. We hypothesized that paternal CPA exposure disrupts epigenetic programming in the early embryo. To test this hypothesis, we examined the temporal patterns of histone H4 acetylation at lysine 5 and 5-methylcytosine immunostaining in zygotes sired by CPA-exposed and control males. Both the male and female pronuclei in embryos sired by CPA-treated males were significantly hyperacetylated, beginning in G1 and lasting into S-phase; in later stages of zygotic development, the extent of H4 acetylation did not differ. DNA methylation reprogramming was also dysregulated. In control zygotes, the male pronuclei underwent a gradual genome-wide demethylation, while the female pronuclei remained hypermethylated; in contrast, the male pronuclei in zygotes fertilized by drug-exposed sperm were dramatically hypomethylated. In 2-cell embryos sired by CPA-exposed sperm the number of micronuclei was substantially elevated. Thus, paternal drug exposure affected the epigenetic programming of not only the male, but also the female pronucleus, demonstrating the existence of pronuclear cross talk during zygotic development. Deregulation of epigenetic programming in the zygote may contribute to heritable instabilities later in development. Supported by CIHR.

1322 MODELING A MIXTURE: PBPK/PD APPROACHES FOR PREDICTING CHEMICAL INTERACTIONS.

V. C. Moser¹ and K. Krishnan². ¹NTD/NHEERL, U.S. EPA, Research Triangle Park, NC and ²SEST, University of Montréal, Montréal, QC, Canada.

Since environmental chemical exposures generally involve multiple chemicals, there are both regulatory and scientific drivers to develop methods to predict outcomes of these exposures. Even using efficient statistical and experimental designs, it is not possible to test in vivo all possible mixtures. Interactions could be based on kinetic (e.g., enzymatic, metabolic interactions) and/or dynamic (e.g., receptor interactions) factors. Recent advances in physiologically based pharmacokinetic/dynamic (PBPK/PD) modeling have confirmed the usefulness of these tools in predicting tissue levels of chemicals and biological responses. Mathematical predictions may be integrated with focused toxicology studies to improve the models, decreasing the amount of animal testing needed. With PBPK/PD modeling, the binary level interactions are interconnected within the mixture model, which can then be used to simulate the kinetics of chemicals in mixtures of higher levels of complexity. The unique ability of PBPK models to facilitate extrapolation of interactions from binary to more complex mixtures arises from the mechanistic basis of the methodology, i.e., linking all mixture components on the basis of interaction mechanisms. The methodology has been shown to be applicable to different mixtures of volatile organic chemicals. Furthermore, the modeling work with organophosphates illustrates how to address interactions in mixtures based on kinetic as well as dynamic factors. Progress in estimating interaction thresholds and employing different approaches for designing complex mixtures (e.g., chemical lumping) have extended the predictability of these models. Thus, the PBPK/PD modeling approach can be used in a range of experimental situations to predict the magnitude of chemical interactions and to assist in determining mechanisms for the interactions. Such information is critical to enhance the scientific basis of extrapolations (species, route, dose) essential for chemical mixture risk assessments. This is an abstract of a proposed presentation and does not necessarily reflect US EPA policy.

1323 PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) AND PHYSIOLOGICALLY BASED PHARMACODYNAMIC (PBD) MODELING: TOOLS FOR EXAMINING INTERACTIONS BETWEEN CHEMICALS.

M. Andersen. CIIT Centers for Health Research, Research Triangle Park, NC.

Chemical mixture toxicity has largely remained mired in exposure based approaches examining interactions in relatively high dose studies without sufficient attention to the influence of mixture exposures on delivery of active chemical to target tissues. Elaborate statistical models for mixture toxicity based solely on exposure levels, a common outcome goal of mixture research, are likely to be misleading about nature of interactions among chemicals when the study designs do not examine tissue doses separate from administered dose or do not provide model structures for in vitro-in vivo extrapolations. Interactions would better be described as consisting of two types - PK interactions where co-exposures alter the relationship between administered dose and tissue doses compared to the chemicals delivered individually. PD interactions would occur when tissue response to a unit dose to the

tissue is altered by exposure to the mixture compared to exposure to the single chemical. Physiologically-based pharmacokinetic/pharmacodynamic (PBPK/PD) models simulate target tissue dose based on exposure levels (PBPK models) and simulate tissue responses based on target tissue doses (PBPD models). The PK models are much better developed than the PD models. Nonetheless, these two types of model structures describe the quantitative interrelationships among critical biological and physiological determinants regulating toxic responses. These models can account for PK and PD interactions and account for the changing nature of apparent interactions as doses escalate, for instance, the change from no interactions and additive toxicity at low doses to less than additive responses at higher doses. Furthermore, interactions examined in vitro can be used to generate predictions of in vivo responses using these PK/PD models. This talk details the role these models should play in studying mixtures and the value of PD model predictions in defining interactions among groups of chemicals.

1324 DEVELOPMENT OF PHYSIOLOGICALLY BASED PHARMACOKINETIC AND PHARMACODYNAMIC (PBPK/PD) MODELS TO DETERMINE DOSIMETRY AND CHOLINESTERASE INHIBITION FOLLOWING EXPOSURE TO BINARY MIXTURES OF ORGANOPHOSPHORUS INSECTICIDES.

C. Timchalk¹, A. Kousba², A. L. Busby¹ and T. S. Poet¹. ¹Pacific Northwest National Laboratory, Richland, WA and ²TargeGen Inc., San Diego, WA.

PBPK/PD models have been developed for the organophosphorus (OP) insecticides chlorpyrifos (CPF) and diazinon (DZN). These insecticides share common metabolic activation/detoxification pathways and a common mechanism of neurotoxicity associated with excessive cholinergic stimulation. To develop a binary OP PBPK/PD model, rats were orally administered CPF, DZN or a CPF/DZN mixture (0, 15, 30 or 60 mg/kg) and blood (plasma and RBC), brain and urine were collected for analysis. Chlorpyrifos, DZN and their respective metabolites, trichloropyridinol and isopropyl-methyl-hydroxypyrimidine were quantified in blood and/or urine and cholinesterase (ChE) inhibition was measured in brain, RBC, and plasma. Co-exposure to CPF/DZN at the low dose (15/15 mg/kg) did not alter the pharmacokinetics of CPF, DZN or their metabolites in blood. Whereas, a high binary dose (60/60 mg/kg) increased the C_{max} and AUC and decreased the clearance for both parent compounds, likely due to competition between CPF and DZN for CYP450 metabolism. At lower doses the pharmacokinetics appeared linear. A dose-dependent inhibition of ChE was noted in tissues for both the single and co-exposures, and the extent of inhibition was plasma > RBC ≥ brain. The overall relative potency for ChE inhibition was CPF > CPF/DZN > DZN. A comparison of the ChE response at the low binary dose (15/15 mg/kg), where there were no apparent pharmacokinetic interactions, suggested that the overall ChE response was additive. Based on these pharmacokinetic results a binary OP PBPK/PD model has been developed. This model facilitates understanding the mixture interactions and the potential for additivity, synergism or antagonism from multi-OP exposures. It is envisioned that this binary model will be useful for assessing exposure and health risk to a wide range of exposed individuals. (Supported by CDC/NIOSH grant 5 R01 OH003629-03)

1325 PBPK MODELING OF METABOLIC INTERACTIONS: EXTRAPOLATING FROM BINARY TO MORE COMPLEX MIXTURES.

K. Krishnan¹, S. Haddad², C. Emond¹ and R. Tardif¹. ¹SEST, University of Montréal, Montréal, QC, Canada and ²Dép. sciences biologiques, TOXEN, UQAM, Montréal, QC, Canada.

One of the challenges in risk assessment relates to the inability to make use of binary interaction data. The nature and magnitude of an interaction between two chemicals may be further altered by other chemicals in a mixture. This presentation will focus on the novel application of physiologically-based pharmacokinetic (PBPK) models to predict the kinetics of chemicals in mixtures of increasing complexity, solely on the basis of binary interaction data. In this methodology, individual chemical PBPK models are developed and interconnected on the basis of binary-level interactions. As such, with a single set of physiological parameters and multiple sets of chemical-specific parameters, the simulations of the kinetics of mixture components can be obtained. Binary connections between mixture components, where feasible, are established within the model on the basis of interaction mechanisms. Studies conducted so far have focused on the modeling of competition among CYP2E1 substrates for hepatic metabolism. Data collected in rats exposed to binary, ternary, quaternary and pentameric mixtures of toluene, m-xylene,

benzene, dichloromethane and ethyl benzene have been used to validate the predictions of the binary-based PBPK model. When all binary level metabolic interactions in a mixture can neither be identified nor characterized, the limits of metabolic interaction (0 – 100%) have been used to simulate the potential consequences of mixed exposures. Such an approach has been validated using several mixtures of volatile organic chemicals. The PBPK modeling approach has also been used to simulate the kinetics of mixtures of PCBs in rats, on the basis of metabolism constants that reflect the net effects of inhibition and induction. Overall, the PBPK modeling approach allows the prediction of the kinetics and internal dose of mixture components on the basis of binary level interactions as well as the net effect of processes affecting the rate of metabolism.

1326 DEVELOPMENT OF A PBPK MODEL FOR GASOLINE AND SEVERAL OF ITS COMPONENTS EXHIBITING METABOLIC INHIBITION.

J. E. Dennison. *Environmental Health, Colo State U, Ft. Collins, CO.*

Gasoline contains benzene and hundreds of other chemicals that are carcinogenic, neurotoxic, or systemically toxic. Exposure to gasoline mixtures reduces metabolism of individual components through metabolic inhibition. We explored this issue by conducting gas uptake pharmacokinetic (PK) experiments in F344 rats. Total metabolism of components was reduced, for example, by 4% – 27% during a six-hour exposure to 300 ppm gasoline. To develop a better quantitative understanding of this issue, a PBPK model was developed for gasoline PKs in the rat. Rather than attempting to develop inhibitory constant estimates for each component, the majority of the mixture was incorporated into the model as a lumped chemical with single parameter estimates for biochemical and partitioning processes. In addition, five individual chemicals (benzene, toluene, ethylbenzene, xylene, and n-hexane) were treated as single chemicals. Competitive inhibition was inferred from PK data and treated as occurring between each binary combination of chemicals within the mixture. Estimates of the inhibitory constant (K_i) for each non-lumped chemical were developed from initial PK experiments where one chemical was provided at very high levels and other chemicals were at low levels, to improve sensitivity. These constants were then used in the PBPK model without further refinement, and a constant for the lumped chemical was estimated from the whole gasoline studies. Finally, experiments and models were developed for lighter fractions of gasoline that would evaporate during a gasoline spill. The model provides an excellent description of gasoline PKs in the rat, and demonstrates the utility of the chemical lumping approach within the context of PBPK modeling. A model such as the one described can be used in risk assessment to determine the extent of metabolism of carcinogenic metabolites under various exposure conditions, and in other applications. [Supported in part by a Cooperative Agreement from ATSDR (U61/ATU 881475) and the NIEHS Quantitative Toxicology Training Grant T32 ES07321].

1327 MODELING THE INTERACTION THRESHOLD: THE BREAK-POINT BETWEEN ADDITIVITY AND NON-ADDITIVITY.

H. A. El-Masri. *NHEERL, U.S. EPA, Research Triangle Park, NC.*

Dose-dependent changes in toxicity mechanisms of single chemicals can possibly take place along the full dose-response spectrum. At high doses, the possibility exists for some steps in the principle mechanism of toxicity to shift to other mechanisms. The possibility of mechanism shifts for single chemicals can also be observed for interaction mechanism of chemical mixtures. For instance, interactions (synergism or antagonism) taking place at high individual doses of a mixture, may not be significant at low levels. One of the early experiments indicating a change of the mechanism of interaction with dose was conducted using chloral hydrate and ethanol. The boundary that separates the dose space into regions of interaction and additivity is called the interaction threshold boundary. The interest in defining this region is important because it signifies the need to include or exclude interactive effects in the calculations of health risks of the mixtures, specifically at low environmentally relevant doses. The interaction threshold boundary may take a variety of different shapes, and the shape of this boundary is not likely to be known. Hamm et al. (2005) developed a general procedure to accommodate various potential shapes for this boundary. Predictive modeling (such as PBPK/PD models) along with mode-designed experiments provides an efficient methodology for the identification of interaction thresholds. Based on mechanistic consideration of enzyme inhibitions, prediction of the presence of an interaction threshold between binary chemicals was performed using PBPK models for two different set of chemicals; volatiles (TCE and 1,1-DCE), and pesticides (chlorpyrifos and parathion).

1328 ADVANCES IN CAUSATION AND THERAPY OF PARKINSON AND PARKINSON-LIKE MOVEMENT DISORDERS: VIEWS FROM TOXICOLOGISTS AND CLINICIANS.

W. Zheng¹, G. W. Miller², E. Pira³, J. S. Rutchik⁴ and J. Zhang⁵. ¹Purdue University, West Lafayette, IN, ²Emory University, Atlanta, GA, ³University of Turin, Turin, Italy, ⁴UCSF, San Francisco, CA and ⁵UC Seattle, Seattle, WA.

Parkinson-like movement disorders, caused by environmental or occupational exposure to neurotoxins such as manganese or pesticides, are characterized by increased bradykinesia, rigidity, resting tremor, or posture difficulties. Key issues in clinical intervention include the lack of reliable means for diagnosis, as clinical signs and symptoms are not specific for each etiology, and the lack of therapeutic strategies. Thus, the translational research possesses the paramount importance for clinical management of neurotoxin-induced movement disorders. The purpose of this workshop is to address, mainly from the clinical point of view, the current understanding of causes, diagnosis, and therapeutic strategies in dealing with chemical-induced parkinsonian type of disorders, by using advanced clinical techniques and improved animal models. The workshop first discusses the challenge of identifying patients with idiopathic Parkinson's disease (PD) and manganism by an occupational neurologist, followed by discussion on the similarities and disparities of various toxicant-induced animal PD models and the possible uses of these models in searching for new treatment for PD. Recent advancement in developing biomarkers for IPD by proteomic technique is then presented. Cases of clinical application of magnetic resonance imaging (MRI) in diagnosis of asymptomatic manganism is also extensively discussed. Finally, the efficacy, application, and perspectives of metal chelating agents in clinical treatment of manganism patients with regard to the disease state is addressed. Not only does the workshop offer rationalized advices for researchers on diagnosis and treatment of chemical-induced Parkinson-like movement disorders, but more importantly it reveals theories underlying these advancements and thus suggests the future direction in environmental PD research. The workshop is of interest to those who are engaged in pesticide toxicology, metal toxicology, neuroscience, neurotoxicology, risk assessment, regulatory management, occupational health, and toxicology education.

1329 CLINICAL PRESENTATION OF PATIENTS WITH IDIOPATHIC PARKINSON'S DISEASE AND MANGANISM: SIMILARITIES AND DIFFERENCES.

J. S. Rutchik. *Occup & Env Medicine, UCSF, Mill Valley, CA.* Sponsor: W. Zheng.

Idiopathic Parkinson's disease (IPD) was initially described as a shaking palsy in 1817 by James Parkinson. The earliest report on Parkinson-like syndromes among manganese (Mn) ore crushers was described by Couper in 1837. Neurological sequelae from occupational exposure to Mn has been suspected to lead to an atypical parkinsonian syndrome, including bilateral simultaneous and symmetric low amplitude postural tremor with no rest tremor. Frequently, early dysarthria, gait and balance abnormalities, dystonia in limbs and face and action myoclonus and hyperreflexia are also observed in clinics. Most significantly, manganism displays early personality changes, emotional lability, visual and auditory hallucinations. The onset develops weeks and months after exposure to toxic metal, with poor or no response to levodopa without related psychiatric symptoms, initial rapid progression followed by stable course, and initial and transient elevation of Mn in blood, urine and hair. Recent MRI technology allows to detect bilateral hyperintensities in the globus pallidus and substantia nigra on T1 images which may be transient. In addition, pathological findings have revealed the degeneration and gliosis of the globus pallidus but without the presence of Lewy's bodies. Recently, some researchers based on diagnosis of welders with parkinsonism report that parkinsonian welders have a younger age of onset but otherwise no clinical differences from IPD. These investigators further report that PET scans of patients with manganism show a reduced uptake in the striatum. Thus, the question as to whether the clinical presentations of manganism and IPD are the same or different remains unsolved. This presentation discusses the research performed by a team consisting of a physician with American board certifications in neurology, occupational and environmental medicine, a U.S. neurotoxicologist, and two Chinese occupational medicine physicians to assess six workers with different exposure backgrounds in order to confirm a diagnosis of manganism. The current state of the art in the body of knowledge developed regarding the topic of manganism and parkinsonism is also discussed.

1330 TOXICANT-BASED MODELS OF PARKINSON'S DISEASE AND THEIR IMPACT ON CLINICAL CARE.

G. W. Miller. *Center for Neurodegenerative Disease, Emory University, Atlanta, GA.*

Exposure to various pesticides and other environmental chemicals has been suggested to be associated with the clinical occurrence of Parkinson's disease (PD). In animal models, these chemicals can reproduce certain neurobehavioral and neuro-

chemical changes typical of PD, but do not reproduce all of the clinical symptoms. Ideally, animal models used to identify causes, improved diagnosis, and treatments of the disorder should closely resemble the human condition. While several genetic abnormalities have been associated with early onset forms of PD, no clear genetic component has been associated to the more common late onset form. Given the substantial evidence that the environment participates in the pathogenesis of PD, our laboratory has focused on environmentally-relevant models of PD. The hope is that by using models that mimic the environmental component of the disease, we can improve our understanding of the disease process that can aid in the development of strategies to mitigate the adverse effects of the environmental toxicants. This presentation will evaluate the toxicant-based (MPTP, 6-OHDA, paraquat, rotenone, dieldrin) and genetic-based (knockout of alpha-synuclein, DJ-1, PINK1, Parkin, or transgenic over expressors of the aforementioned genes) models of PD. Particular attention will be given to the behavioral, biochemical, and neuropathological differences. While many of the genetic models for PD have provided useful information on disease pathogenesis, they consistently fail to show a substantial reduction in striatal dopamine, which is thought to be the major contributor to the bradykinesia observed in PD. Thus, an ideal model of Parkinson's disease must exhibit a progressive loss of striatal dopamine, in addition to the presence of the neuropathological hallmark Lewy bodies. Further model development and judicious selection of the most appropriate model should enhance our ability to develop novel diagnostic, preventive, and therapeutic strategies aimed at reducing the personal and societal burden of this disease.

1331 DEVELOPMENT OF PROTEIN BIOMARKERS WITH PROTEOMICS FOR DIAGNOSIS AND MONITORING THE PROGRESSION OF PARKINSON'S DISEASE.

J. Zhang. *Pathology, University of Washington, Seattle, WA.* Sponsor: W. Zheng.

Patients with Parkinson's disease (PD) typically lose significant neurons in the substantia nigra prior to development of significant symptoms for them to seek medical treatment. Conceivably, any therapy starting at clinically confirmed 'advanced stage' of PD might fail to stop the degenerative process. This presentation describes the latest findings on early diagnosis of PD by using recently developed high throughput proteomics to identify biomarkers in body fluids, particularly in human cerebrospinal fluid (CSF). More specifically, we have utilized a multiplex quantitative proteomics method, iTRAQ (isobaric Tagging for Relative and Absolute protein Quantification), in conjunction with multidimensional chromatography, followed by tandem mass spectrometry (MS/MS), to simultaneously measure relative changes in the CSF proteome of individuals with PD, Alzheimer's disease (AD), and dementia with Lewy body (DLB) as well as age-matched controls. The diagnosis of AD and DLB was confirmed by autopsy, whereas the diagnosis of PD was based on clinical criteria. The proteomic findings showed quantitative changes in PD, AD, and DLB as compared to controls; among more than 1,500 identified CSF proteins, 72, 136, and 101 of the proteins displayed quantitative changes unique to PD, AD, and DLB, respectively. Eight unique proteins were confirmed by Western blot analysis, and the sensitivity at 95% specificity was calculated for each marker alone and in combination. Several panels of unique markers were capable of distinguishing PD, AD and DLB patients from each other as well as from controls with high sensitivity at 95% specificity. Although these preliminary findings must be validated in a larger and different population of patients, they suggest that a roster of proteins may be generated and developed into specific biomarkers that could eventually assist in clinical diagnosis and monitoring disease progression of PD, AD and DLB. It is also expected that these markers may be useful in differentiating PD from parkinsonism caused by other etiology, including manganese induced neurotoxicity.

1332 CLINICAL APPLICATIONS OF MAGNETIC RESONANCE IMAGING (MRI) IN DIAGNOSIS OF ASYMPTOMATIC MANGANISM: DIFFERENCES FROM IDIOPATHIC PARKINSON'S DISEASE.

E. Pira¹, H. Hernandez¹, C. Valentini² and M. Ferraris². ¹Occupational Health, University of Turin, Turin, Italy and ²Neuroradiology Unit, Affiliated Hospital of University of Turin, Turin, Italy. Sponsor: W. Zheng.

Recent clinical reports have suggested that clinical and pathophysiological features of manganese-induced Parkinson-like movement disorder may, at times, overlap those of idiopathic Parkinson's disease (IPD). Clinical studies in humans and basic research on animal models have demonstrated that T1- and T1 MT-weighted MRI is able to detect abnormal deposits of this paramagnetic metal in the globus pallidus and substantia nigra. This presentation first discusses these characteristics among manganism patients in comparison to the MR imaging in IPD patients, where the MRI can evidence nigral changes in T2 and T2* signal associated with modifications in the iron deposition. The presentation then describes a series of clinical cases

where MRI has been used to investigate symptomatic Italian welders and asymptomatic Chinese miners. In former cases, the subjects had a well-documented manganese-induced Parkinson-like syndromes; application of MRI technique was able to allow for the setting up of a successful therapy programme in the early phase of the disease, which led to an ending in a clinical improvement along with the normalisation of the neuro-radiological parameters. In the latter cases, the possibility to identify significant MRI changes in pre-symptomatic subjects has been explored, allowing for development of preventive measures. In addition, the opportunity to make use of this technique in routine screening is discussed.

1333 EFFICACY AND SELECTIVITY OF METAL CHELATORS IN TREATMENT OF MANGANESE-INDUCED PARKINSON-LIKE MOVEMENT DISORDER.

W. Zheng¹ and Y. Jiang². ¹*School of Health Sciences, Purdue University West Lafayette, IN* and ²*Department of Epi. & Toxicol, Guangxi Med. University Nanning, Guangxi, China.*

A major challenge in clinical aspects of manganese (Mn) toxicity study is the lack of effective therapeutic strategy for Mn-induced neurological impairment. Without treatment, the signs and symptoms progress and chances of recovery are usually poor. Treatment with levodopa has been used in most clinics for initial control of extrapyramidal symptoms or for intention to distinguish manganism from IPD. However, levodopa therapy generally exhibits limited benefits in improving clinical symptoms among manganism patients. Alternatively, chelation therapy has been recommended for the purpose of expelling Mn ions so to reduce the body burden. Based on our own experience and data available in literature for several known metal chelating agents, dimercaptosuccinic acid (DMSA) has no effect on manganism patients. EDTA treatment in manganism welders has shown an increased Mn excretion in urine and a decreased Mn concentrations in blood, although the clinical symptoms appear to be unaffected. Extracellular distribution and a less selective chelation spectrum may restrict the efficacy of EDTA in treatment of manganism. Recently, an antibacterial drug, sodium para-aminosalicylic acid (PAS), has emerged as an effective drug in treatment of Mn-induced Parkinson-like disorder. PAS is an FDA-approved drug for treatment of tuberculosis. Clinical trials with PAS on severe manganism cases show that the drug not only reverses extrapyramidal syndromes immediately after drug treatment, but it also has a stable prognosis long after therapy, suggesting a possible repair of damaged neurons. The exact mechanism(s) of PAS therapy remain unknown. Based on animal studies, PAS appears to chelate and therefore remove the toxic metal ions from their intracellular deposits. Noticeably, the aspirin moiety in PAS structure may render the drug more preferable in combating against inflammatory processes, which are known to participate in induction and progression of neurodegeneration in Parkinson's disease. (Supported in part by U.S. NIH/NIEHS ES08146 and China NSF#30070663)

1334 APPROACHES TO ASSESSING WHETHER A CARCINOGEN IS ACTING VIA A GENOTOXIC MODE OF ACTION.

C. Hsu. *National Center for Environmental Assessment, U.S. Environmental Protection Agency, Washington, DC.*

Genetic toxicology data are used worldwide in regulatory decision-making. For example, US EPA and FDA use genetic toxicology information, such as the International Conference on Harmonization (ICH) genotox battery and the EPA mutagenicity testing scheme, for regulatory decisions including setting standards for acceptable exposure levels in air, water, and food, as well as approval and registration of pesticides, pharmaceuticals, medical devices, and medical-use products. This workshop focuses on genotoxic carcinogens, although the role of epigenetic changes in the etiology of human cancers is also important. Due to the limitations of commonly used genotoxicity tests, it may be useful to develop approaches, such as toxicogenomics, computational structure-activity-relationship, and genetically-engineered mammalian cell tests and mouse models, which will provide better information as to whether specific chemicals are genotoxic carcinogens or epigenetic carcinogens. To determine if chemicals act via a genotoxic or epigenetic mode of action, a weight-of-the-evidence evaluation of the available data including an analysis based on the Hill criteria, i.e., temporal and dose-response relationship, biological plausibility, etc., is recommended.

1335 THE NEED TO IMPROVE THE PREDICTIVITY OF IN VITRO GENOTOXICITY TESTS IN TERMS OF CARCINOGENIC POTENTIAL.

D. J. Kirkland. *Scientific & Regulatory Consulting, Covance Laboratories Ltd., Harrogate HG3 1PY, United Kingdom.* Sponsor: A. Jacobs.

Analysis of nearly 1000 chemicals tested for carcinogenesis in rodents in terms of published genotoxicity results from the most commonly used in vitro tests has shown an acceptable sensitivity but a very poor specificity (Kirkland et al, 2005,

Mutation Research 584, 1-256). The mammalian cell tests (mouse lymphoma mutation, chromosomal aberrations in hamster cell lines etc.) were particularly prone to giving positive results with non-carcinogens. More than 50% of mammalian cell genotoxicity tests with non-carcinogens gave positive results. Analysis of in vitro genotoxicity tests submitted to regulatory agencies (e.g. German BfArM) in support of pharmaceutical safety has shown similar high frequencies of positive results in mammalian cells with non-carcinogens. As long as these in vitro tests are so inaccurate in predicting rodent carcinogenicity they are of no help in assessing whether a carcinogen is acting via a genotoxic mode of action. The potential mechanisms for false positive results need to be better understood and, in the long term, more reliable assays are needed. Several initiatives (from organisations such as IWGT, ECVAM, ILSI/HESI) are therefore underway to:

1. improve the interpretation of genotoxicity results from existing in vitro assays and protocols;
2. determine whether lower top concentrations (for non-toxic substances) and lower levels of toxicity (for toxic substances) can be used and yet still allow the detection of all important in vivo genotoxins and DNA-reactive mutagenic carcinogens;
3. investigate whether new approaches to in vitro genotoxicity testing with p53 and DNA repair competent cells that are genomically stable can be achieved.

1336 A NEW STRATEGY TO IDENTIFY CHEMICALS THAT ARE MUTAGENS AND CARCINOGENS BUT NOT NECESSARILY MUTAGENIC CARCINOGENS.

M. Moore¹, R. Heflich¹, L. Haber³, B. Allen⁵, M. Dourson³, A. Shipp⁴ and R. Kodell². ¹*DGRT, NCTR, Jefferson, AR*, ²*DBRA, NCTR, Jefferson, AR*, ³*TERA, Cincinnati, OH*, ⁴*ENVIRON, Ruston, LA* and ⁵*ENVIRON, Chapel Hill, NC.*

Currently mutagenic chemicals are identified using a number of well-validated mutation or genetic toxicology tests. The routine test battery was selected to be a sensitive indicator of mutagenic potential and to have the ability to detect chemicals inducing point mutation and/or chromosomal alterations. The ability to detect the full spectrum of genetic damage is important for hazard identification. The routine battery is heavily focused on in vitro assays. It is widely recognized that, while these in vitro assays are very sensitive to genetic damage, they may not always reflect the ability of the test chemical to cause genetic damage in vivo. The in vivo component of the routine battery is generally conducted in bone marrow and measures chromosomal damage, in particular micronuclei. When one moves past hazard identification to assess the mode of action (MOA) for carcinogens, it is important to determine whether the chemical can, in fact, cause mutation in the cancer target tissue. We propose a new strategy to help determine whether carcinogenic chemicals assessed to be mutagens or genotoxins in the routine battery are, in fact, causing cancer via a mutagenic or non-mutagenic MOA. The approach involves using transgenic rodent mutation models, chronic treatment, assessing time to mutation, and performing a quantitative comparison between the mutation and tumor dose response curves in the target tissue.

1337 IDENTIFICATION OF PRESUMPTIVE HUMAN CARCINOGENS AND THEIR MODE OF ACTION USING TOXICOGENETICS.

J. E. French. *Laboratory of Molecular Toxicology, NIEHS, NIH, Research Triangle Park, NC.*

Humans are a genetically diverse population with a variety of age, environmental, and behavioral factors that affect their risk and potential for developing complex genetic and environmentally related diseases, such as asthma, cardiovascular disease, cancer, etc. Remarkably, genes and their functions that are known to be critical to the development of neoplasia are highly conserved and function similarly in humans and rodents. Significant genetic diversity is present between inbred (homozygous) laboratory and wild-derived mouse strains that captures much of the genetic diversity in humans. We are using genetically engineered mouse models (GEMM) on different genetic backgrounds to anchor an induced phenotype to tumor development with reduced latency as well as genetically diverse inbred mouse strains with dense single nucleotide polymorphism (SNP) maps (Perlegen-NIEHS SNP maps) for defining haplotype structure. Using a sufficient number of inbred mouse strains, we will identify genetic loci associated with toxicity to genotoxic or non-genotoxic human carcinogens associated with neoplasia by haplotype association analysis. By identifying haplotypes in common between mouse strains and humans that segregate with the observed phenotype, we aim to determine predictability of toxicity phenotypes and induction of neoplasia between rodents and humans. With this knowledge, we can employ reductive approaches to determine the gene-specific mechanistic basis associated with an environmentally related disease. With the sequencing of the human, mouse, and rat genomes and a significant increase in our understanding of their genomic structure and the diversity of environmentally-responsive genes with specific single nucleotide polymorphisms, new tools for inves-

rigating biology and toxicology at the systems level have been developed. We have the potential to significantly improve our analytic and predictive potential for identifying both genetic and epigenetic mechanisms relevant to cancer and other complex diseases.

1338 MUTAGENIC CARCINOGENS AND THE U.S. EPA CANCER RISK ASSESSMENT PROCESS.

R. J. Preston. *U.S. Environmental Protection Agency, Research Triangle Park, NC.*
Sponsor: A. Jacobs.

Genotoxicity covers a broad range of endpoints including mutations, sister chromatid exchanges, DNA damage and DNA repair. In contrast, mutagenicity is restricted to gene mutations and chromosomal mutations. For cancer risk assessment, mutagenicity is the appropriate endpoint because tumors are formed by a multi-step process characterized by specific genetic alterations. Mutations can be induced by direct interaction of a chemical with DNA or by indirect action with DNA (e.g., through the production of reactive oxygen species). In general, extrapolation from a LOEL for tumors (rodent or human) is deemed to be linear, unless specific mechanistic data are available. The more we learn about tumor induction, the more unlikely it becomes that a single mode-of-action (MoA) will produce the multiple key events that are required to convert a normal cell into a transformed one. For example, mutations induced by environmental chemicals are almost exclusively the result of replication errors. Enhanced replication will increase mutation rate, such that cytotoxicity and regenerative cell proliferation are components of MoA for a so-called "mutagenic carcinogen". Similarly, the production of ROS can also be considered a key event for a mutagenic MoA. The impact of these types of key event on tumor dose response curve shape has to be considered. Additional data from molecular approaches will better define the key events involved in the induction of tumors (rodent and/or human) by environmental chemicals. The U.S. EPA cancer risk assessment framework provides a clear picture of the data that are required to move from a default, linear extrapolation for mutagenic chemicals. The significant components are definition of mode(s)-of-action by considering the key events for tumorigenicity, the human relevance of these MoAs and the dose-response characterization for key events. The bar is quite high, but through the use genomic and other molecular techniques to identify informative biomarkers of response for key events, it is certainly feasible to move to more science-based risk assessments. (This abstract does not necessarily reflect U.S. EPA policy).

1339 FDA PERSPECTIVE ON GENOTOXIC CARCINOGENS.

A. Jacobs. *CDER, U.S. FDA, Silver Spring, MD.*

For a pharmaceutical product, the risk/benefit from a nongenotoxic carcinogen differs greatly from that from a genotoxic carcinogen, all other factors being the same. Sometimes a pharmaceutical product is positive in genotoxicity assays but the mode of action is not direct DNA reactivity. Thus, being positive in assays in the International Conference on Harmonization (ICH) genotoxicity battery and giving positive results in a carcinogenicity study does not mean that the mode of action was direct genotoxicity or even any mechanism relevant to humans. Only by a determination of the mode of action of the carcinogenicity could such an evaluation be made. Approaches to elucidating the mode of action of drug-related carcinogenic effects in rodents have included an understanding of the pharmacologic effects, evaluation of formation of DNA adducts, and the use of transgenic mutation models and transgenic carcinogenicity models to aid in distinguishing genotoxic from nongenotoxic mechanisms.

1340 CAN SPECIES AND STRAIN DIFFERENCES IN DIOXIN SENSITIVITY BE EXPLAINED BY DIFFERENCES IN THE AHR RECEPTOR?

J. Rowlands¹ and T. R. Zacharewski². ¹*Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI* and ²*Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI.*

There are large differences in species- and strain-dependent susceptibility to dioxin (TCDD)-induced toxic responses. Classic examples of species differences in experimental effects include the 1000 to 5000-fold difference in dioxin-induced lethality in sensitive guinea pigs and resistant hamsters and dioxin-induced cleft palate where mice are more than 200 times more sensitive than rats or humans or conversely dioxin-induced developmental toxicity where mice more resistant than rats or hamsters. The toxicity of dioxin and related compounds involves initial binding to and activation of the AHR receptor (AHR) and multiple mechanisms of AHR signaling have been identified, such as: (1) AHR/ARNT gene regulation through

DNA enhancer XRE sequences; (2) AHR/ARNT interactions with coregulatory proteins (e.g., coactivators, corepressors, mediators) and other transcription factors (e.g., Rb, NF-κB) and receptors (estrogen and others), and; (3) modulation of protein kinase signaling and ligand-independent AHR activation via phosphorylation. In addition, a number of species and strain specific AHR polymorphisms have been identified, for example in the ligand binding domain (LBD) and transactivation domain (TAD) that can affect AHR function and genetic loci have been recently identified that can also affect AHR mediated toxicity. This workshop will discuss the differences in the structure and function of the AHR and non Ahr genetic loci in different animal species and strains and their relevance to dioxin sensitivity. Molecular aspects of AHR signaling are conserved across other nuclear receptor pathways and therefore the issues discussed may have relevance in explaining differences in species and strain sensitiveness for other receptor mediated toxins.

1341 COMPARATIVE ASPECTS OF AHR LIGAND BINDING AND LIGAND-DEPENDENT AHR ACTIVATION.

M. Denison¹ and L. Bonati². ¹*Department of Environmental Toxicology, University of California, Davis, CA* and ²*Dipartimento di Scienze dell'Ambiente e del Territorio, Università degli Studi di Milano-Bicocca, Milano, Italy.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD, dioxin) and related dioxin-like compounds (DLCs) produce a variety of toxic and biological effects, the majority of which are mediated by the Ah receptor (AhR), a ligand-dependent transcription factor. While TCDD and related DLCs can produce a variety of species- and tissue-specific toxic and biological effects, significant species and strain differences exist in the sensitivity and susceptibility to these chemicals. This variation in species responsiveness to TCDD and related DLCs can result from differences in many distinct physiological and biochemical characteristics in these species. Although the AhR present in various species has very similar characteristics, significant differences exist in AhR ligand binding affinity and specificity and ligand-dependent AhR transformation and DNA binding. Homology modeling and site-directed mutagenesis of the AhR ligand binding domain (LBD) provides a plausible explanation to account for some of this variation, particularly that of the lower binding affinity of human AhR and mouse AhRd alleles (which contain a naturally occurring polymorphism at Ala375 in the LBD). Additional amino differences exist between the AhR LBD of various species that may contribute to some of the observed variation in ligand binding and ligand-dependent AhR activation. Although DNA binding analysis reveals quantitative differences in TCDD-dependent transformation and DNA binding of hepatic AhR from various species, the nucleotide specificity of DNA binding of these TCDD:AhR complexes are similar. The relative transformation efficiency of AhR from various species appears to be both dependent upon differences in the AhR itself as well as regulatory actors, such as a small molecular weight heat-stable negative modulatory factor(s) that we have identified in cytosol. While multiple mechanisms certainly contribute to species differences in responsiveness to DLCs, some of these differences reside at the level of the AhR.

1342 COMPARATIVE TOXICOGENOMICS OF TCDD-MEDIATED HEPATIC RESPONSES: EVIDENCE FOR SPECIES-SPECIFIC AHR REGULONS.

T. Zacharewski. *Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI.*

TCDD and related compounds elicit a broad spectrum of significant age, gender, strain and species-specific toxic and biochemical effects. Most, if not all, of these effects are due to alterations in gene expression mediated by the AhR. Although the importance of the AhR in TCDD and related compound toxicity is well established, the roles of differential gene expression in eliciting species-specific effects have yet to be elucidated. In order to further investigate differential gene expression in TCDD elicited hepatotoxicity, comparative temporal and dose-dependent toxicogenomic studies were conducted in human HepG2, mouse Hepa1c1c7 and rat H4IIE hepatoma cell lines and in hepatic tissue from Sprague Dawley rats, and C57BL/6 mice which were phenotypically anchored to histopathology, clinical chemistry and hepatic lipid accumulation. Data comparisons were facilitated through the use of comparable study designs, cDNA microarray platforms, and data analysis methods. Although TCDD induced similar increases in liver weight, significant differences in histopathology, clinical chemistry and hepatic lipid content were observed between Sprague Dawley rats and C57BL/6 mice, consistent with the marginal overlap of differentially expressed orthologous genes. Comparison of TCDD mediated gene expression responses between HepG2, Hepa1c1c7 and H4IIE cells also identified minimal conservation between orthologs, consistent with results from comparative computational DRE searches. Therefore, despite significant conservation in human, mouse and rat AhR biology, these data indicate that differences in TCDD elicited hepatotoxicity are mediated by different gene expression profiles suggesting the existence of species-specific AhR regulons. Funded by R01 ES12245 and Superfund P42 ES04911.

1343 VARIATION IN AH RECEPTOR STRUCTURE IN MOUSE, RAT AND HUMAN IN RELATION TO DIOXIN TOXICITY.

A. B. Okey. *Department of Pharmacology, University of Toronto, Toronto, ON, Canada.* Sponsor: J. Rowlands.

Major toxic effects of dioxins are mediated by the AH receptor (AHR). Therefore variation in AHR structure/function can have substantial impact on dioxin susceptibility. In mice, an AHR polymorphism in the ligand-binding domain reduces binding affinity for 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) about 10-fold in the DBA/2 strain vs the C57BL/6 strain; consequently, dose-response curves for numerous biochemical & toxic effects are shifted about one log to the right in DBA/2 mice. In the Han/Wistar(Kuopio) rat strain a polymorphism that deletes 38 or 43 amino acids from the AHR transactivation domain (TAD) is associated with a >1000-fold resistance to TCDD lethality. Genes in the conventional AH gene battery remain TCDD-responsive in H/W rats despite the large deletion in the TAD. The TAD deletion may selectively alter the AHR's ability to dysregulate particular genes that are key to dioxin toxicity. We use gene expression arrays in H/W rats vs dioxin-sensitive strains to identify genes whose dysregulation by TCDD underlie major dioxin toxicities. In human cells/tissues we found that the AHR's binding affinity for TCDD generally is lower than in cells/tissues of most standard laboratory rodent species & strains. Lower affinity for TCDD in humans may partially account for the apparent lower sensitivity of humans to the predominant types of toxicity observed in rodents. However, affinity varies more than 10-fold within the human population. Individual human samples that exhibit the highest affinity for TCDD have affinity similar to that in C57BL/6 mice. No polymorphisms have yet been identified in human AHR that explain the basis for variation in affinity. The effect of varied affinity on individual human susceptibility to dioxin toxicity also is unknown. The extant polymorphisms in the human AHR gene predominantly lie in the TAD but none of these seems to exert a substantial effect on receptor function assessed *in vitro*. However, it is possible, as in the H/W rat model, that structural variation in the human AHR may selectively affect only a limited set of specific responses.

1344 A NEW KNOCK-IN MOUSE MODEL FOR MECHANISTIC STUDIES OF DIOXIN ACTION.

R. Pohjanvirta^{1,2}. ¹*University of Helsinki, Helsinki, Finland* and ²*Finnish Food Safety Authority Evira, Kuopio, Finland.* Sponsor: M. Viluksela.

Han/Wistar (Kuopio; H/W) rats are extremely resistant to acute lethality of TCDD with an LD50 value of over 10,000 µg/kg. However, this resistance is response-dependent. Some biochemical and toxic effects of TCDD (dubbed type I effects) such as CYP1A1 induction, thymus atrophy and fetotoxicity are fully manifested also in H/W rats. Conversely, type II effects parallel acute lethality and display prominent interstrain differences; they include liver toxicity, wasting syndrome and tumor promotion. Breeding studies indicate that the peculiar selective responsiveness of H/W rats to TCDD emanates from two genes, by far the most important of which is the AH receptor (AHR). Wildtype rat AHR is 106 kDa in molecular mass but the H/W AHR is only ca. 98 kDa due to a point mutation in the first nucleotide of intron 10, which disrupts the exon/intron junction and results in 3 altered mRNA species that give rise to 2 different AHR proteins, both restructured at the transactivation domain. The deletion variant lacks 43 amino acids near the C-terminus, while the insertion variant (AHRsiv) is devoid of the last 38 amino acids but has 7 novel amino acids inserted at its C-terminal end. To gain further insight into the roles played by the AHR variants in TCDD responsiveness, we expressed wildtype and variant rat AHRs in mice. Their cDNAs were subcloned into modified pTransgene vectors carrying human elongation factor-1α promoter, chicken β-globin core insulators, 95 proximal nucleotides of the mouse AHR 5' leader and about 700 nucleotides from authentic rat AHR 3' UTR. The constructs were microinjected into C57BL/6J pronuclei, and construct-positive mice were crossed with AHR-deficient mice to eliminate the mouse innate AHR. Liver biopsies revealed a high expression level for all three constructs. Our pilot studies show that the transgenic constructs are functional *in vivo* and indicate that mice with the AHRsiv are resistant to acute lethality of TCDD. These studies provide important new evidence in support of the AHR's primary structure as a major determinant of susceptibility to dioxin toxicity.

1345 LOCI THAT INFLUENCE DIOXIN TERATOLOGY IN MICE.

C. Bradfield. *McArdle Laboratory for Cancer Research, Madison, WI.* Sponsor: C. Rowlands.

In an effort to understand how genes other than *Ahr* can influence individual sensitivity to environmentally induced disease, we performed a linkage analysis to identify murine loci that influence the incidence of cleft palate and hydronephrosis

in developing mice exposed to the pollutant 2,3,7,8-tetrachlorodibenzo-p-dioxin (dioxin). Administration of 64 µg/kg dioxin to C57BL/6J (B6) dams at embryonic day 9 (E9) led to palatal clefting and hydronephrosis in nearly 100% of embryos by E17. In contrast, similar exposure of CBA/J (CBA) dams led to cleft palate in only 8% and hydronephrosis in 69% of embryos. To determine the genetic basis for this strain dependent sensitivity, linkage analyses on the progeny of a B6CBAF1 intercross and a CBAB6CBAF1 backcross were performed. The incidences of cleft palate and hydronephrosis were assessed and genomic DNA from embryos was analyzed at informative simple sequence length polymorphism (SSLP) markers. One locus segregating with dioxin-induced cleft palate was identified ($p < 0.01$) and designated as chemically mediated teratogenesis number 1 (Cmt1). The Cmt1 locus is located on chromosome 3.

1346 CURRENT CONSIDERATIONS IN SETTING EXPOSURE GUIDANCE FOR SENSORY AND RESPIRATORY TRACT IRRITATION.

A. Maier¹ and G. Alexeeff². ¹*Toxicology Excellence for Risk Assessment, Cincinnati, OH* and ²*OEHHHA, California EPA, Oakland, CA.*

A fundamental aspect of worker and public health protection is the development of exposure guidance levels that protect exposed groups from critical adverse health effects. For many occupational exposures, exposures in emergency situations due to chemical releases, and for other acute exposures situations, inhalation is a primary exposure route of concern. There are numerous organizations and agencies that establish guidance levels for acute inhalation, and among the guidance levels that are developed sensory irritation is the single most common critical end point. Acute sensory irritation has been a central issue in setting occupational exposure guidance since the inception of the field. In addition, issues related to potential chemical exposure due to accidents, terrorism, and natural disasters has increased the emphasis on setting acute exposure levels for public health protection. Thus, health guidance related to irritation impacts risk management decisions for most workplaces, chemical emergency response events, and acute chemical releases to communities. Despite the importance of judgments about human irritation for public health protection, uniform guidance on many of the key evaluation and interpretation issues related to irritant response is lacking. The goal of this workshop is to present and discuss new developments in the fields of chemosensory irritation and risk assessment to inform methods for setting exposure guidance for irritants. Current and evolving drivers for exposure limit development and risk assessment practices for assessing irritant response are described. Several areas are highlighted where the science continues to evolve, including the developing methods for evaluating and interpreting human olfaction and irritant responses, approaches and research tools for interpreting animal findings, and application of new risk assessment techniques for setting human exposure guidance levels.

1347 ISSUES AND APPROACHES FOR SETTING HEALTH-BASED EXPOSURE LIMITS FOR IRRITANTS.

G. V. Alexeeff, R. Broadwin and A. G. Salmon. *OEHHHA, Cal/EPA, Oakland, CA.*

Sensory irritation is a common effect on which to base exposure guidelines. Key issues addressed by the risk assessor for setting exposure guidance for irritants, include: whether the irritation should be considered an adverse effect; the application of animal test methods, such as the RD₅₀, to guidance setting; the extrapolation of irritation effects across time; the application of new dose-response methodologies, such as benchmark dose (BMD) modeling, to irritant evaluation; and the size of the uncertainty factor to apply in risk assessment, especially to protect sensitive subpopulations such as asthmatics. Strategies for standard setting based on irritation may depend on whether the effect is considered adverse in the traditional sense. Occupational and emergency standards strive to minimize but not necessarily eliminate irritation in their guidance levels. In contrast, ambient standards or reference levels are more likely to treat sensory irritation as an undesirable effect, if not an adverse effect. The RD₅₀ method has been shown to be correlated with occupational exposure levels and has been used as the basis for setting a number of standards. We have found that the RD₅₀ correlates with human exposure levels reporting minimal irritation, thus supporting its use in occupational and public standard setting. Extrapolation of adverse effects across time is often based on a function of concentration and time. However, recent analyses suggest the irritant effects are best described as a function of concentration, irrespective of time, after the first few minutes. Application of BMD modeling can provide insight on the protectiveness of the standard as well as the size of UFs to use in the analysis. Concentrations producing irritation in human and animal studies may be adjusted using uncertainty factors (UFs) such as 3 or 10. The UF of 3 is more of an average value, and may not be protective of the full population distribution, particularly if the point of departure is derived from animal data.

**1348 UNDERSTANDING THE MECHANISTIC BASES OF CHEMOSENSATION: OLFACTION AND SENSORY IRRITATION.**P. Dalton. *Monell Chemical Senses Center, Philadelphia, PA.* Sponsor: A. Maier.

Sensory irritation associated with the manufacture and use of volatile materials has been an occupational health concern for many years. Many organizations that establish exposure guidelines distinguish between olfaction and irritant responses. Because odor properties can often be detected at much lower concentrations than those capable of eliciting upper respiratory tract irritation, confusion between odor and irritation coupled with variability in odor sensitivity and response can produce significant obstacles for evaluating the potential for adverse effects or annoyance from worker or environmental exposures. Although rigorous research methods have been developed to accurately quantify sensory irritation in human evaluations, many studies fail to incorporate key elements necessary to adequately distinguish between olfactory vs. irritant responses. Specifically, research studies evaluating sensory irritation from volatile materials should be capable of (1) distinguishing between the annoyance or concern elicited by odor sensation and that elicited by true sensory irritation, (2) evaluating exposure-related factors that affect odor or irritancy responses, and (3) separating physiologically-mediated symptoms from psychogenically-mediated symptoms. This presentation will describe the state-of-the-science in our understanding of the biological bases for distinguishing between odor and irritation perception and the current measurement methods and techniques used for assessing each endpoint for the purpose of defining human response thresholds. Objective measures of ocular and upper respiratory tract irritation onset obtained in conjunction with subjective reports can lend valuable input to the decision process for determining occupational, community or emergency exposure limits. Distinguishing between the exposures that elicit local effects of sensory irritation in the eyes and upper respiratory tract and the exposures that elicit self-reports of irritation due to cognitive or emotional factors is a key component in establishing guidance protective of exposed individuals.

**1349 CONVERGENCE OF PSYCHOPHYSICAL AND PHYSIOLOGICAL METRICS FOR ASSESSMENT OF HUMAN SENSORY IRRITATION.**W. S. Cain. *Surgery (Otolaryngology), UCSD, La Jolla, CA.* Sponsor: A. Maier.

When exposure to an airborne substance reaches a point where a person can feel sensory irritation, some local physiological responses often accompany the sensation. For example, a brief burst of just threshold irritating vapor can cause a reflex response in an ocular muscle. The magnitude of the response, quantifiable by the movement of tiny targets on the skin, varies with the magnitude of stimulation and can therefore serve as a metric for it. Exposure may also cause the nose to run. A sponge placed for some seconds on the septum can absorb mucus commensurate with level of stimulation. The biochemical composition of the mucus can also represent the presence of irritation. An electrode placed on the septum can record a receptor potential with sensitivity almost identical with that measured psychophysically. Nasal resistance can increase with presence of an irritating vapor. The level of nitric oxide emitted from the nose may increase with exposure to an irritating vapor. The pattern of breathing may also change. All such effects offer a second view, beyond the perceptual response, but each presumably grants a different view. Some likely serve best as an index for just brief stimulation and some for longer stimulation. This presentation will illustrate the effects and highlight their potential usefulness as "tracks" for sensory irritation. Suitable indices should help us understand vulnerabilities to low-level irritating, or chemesthetic, effects of vapors, such as whether sensitivity varies with age, sex, previous exposure to contaminants, and existing condition of the airways, e.g., chronic inflammation. Their adoption in studies of exposure may help us converge on protocols that may bring some uniformity to decision-making about permissible levels of sensory irritation in the workplace and the environment.

**1350 INTEGRATING PATHOLOGY AND DOSIMETRY TO ASSESS THE TOXICITY OF INHALED IRRITANTS.**J. R. Harkema, S. A. Carey and J. G. Wagner. *Pathobiology, Michigan State University, East Lansing, MI.*

The objectives of this presentation are to 1) provide a brief overview of the comparative anatomy and physiology of the respiratory tract in laboratory animals and humans, and 2) discuss various methods used by the pathologist to assess injury and remodeling of the upper and lower conducting airways caused by exposure to airborne irritants. Examples of assessment will include methods at the macroscopic, microscopic and molecular levels of analysis. While the general organization of respiratory system is fundamentally the same in all mammals, there is sufficient species variation in the structure of the upper and lower respiratory tract and its cellular

makeup to produce considerable differences in response to inhaled irritants. The nature, severity and distribution of airway lesions caused by inhaled irritants are due to an integration of several factors including physicochemical characteristics of the inhaled irritant, exposure regimen, local airway dosimetry, and cellular susceptibility. Airway lesions induced by inhaled irritants are site specific and range from death of surface epithelial cells with concurrent acute inflammation, to remodeling of the airway wall due to intramural fibrosis and epithelial cell proliferation. A variety of state-of-the-art imaging techniques, such as magnetic resonance imaging, for visualizing macroscopic changes in airways, along with light, electron, and confocal microscopy for assessing cellular injury and tissue remodeling may be used by the pathologist. Examples will be provided on how computational models of geometrically correct airways are being used along with standard morphometric techniques to better define dose-response relationships along the respiratory tract of laboratory animals, and to estimate the risk of an inhaled irritant to human health.

**1351 EVALUATING IRRITANT RESPONSES FOR LIMIT SETTING IN EUROPE.**G. Johanson. *Work Environment Toxicology, Inst. of Environ Med., Karolinska Institutet, Stockholm, Sweden.*

For many airborne chemicals, and about one third of the occupational exposure limits (OELs), the critical effect is irritation. According to the guidance document developed by the Scientific Committee on Occupational Exposure Limits (SCOEL) of the European Commission, responses to irritants may be viewed as a continuum, ranging from no effects to serious health effects. In proposing health-based OELs SCOEL considers adversity/nuisance to occur somewhere between "very slight effects/awareness of exposure" and "slight irritant effects or nuisance/easily tolerable". The application of these criteria is often complicated by lack of data and/or different types of data for different chemicals. When available, SCOEL always considers reports of controlled human exposures, including objective (e.g. blink frequency, tear film stability, nasal swelling, inflammatory markers in nasal lavage) as well as subjective (symptom questionnaires, visual analog scales) measurements. As such studies have several limitations (e.g. costs, ethics, few subjects, selection bias, reporting bias), there is a need for additional, more easily obtained data, such as RD50s and lateralization (as presented by other speakers at this workshop). Although occasionally included in the SCOEL evaluations (e.g. RD50 data on formaldehyde, methyl isocyanate and phenol), such data have not yet been directly translated into health-based OELs.

The globally harmonized system for classification and labelling of chemicals (GHS) also has a number of qualitative criteria for respiratory irritation, according to which chemical may be classified as Category 3 (transient target organ effects). Efforts are now underway to integrate the GHS into the European legislation. Respiratory irritation is not an issue in the REACH legislation but may be included at a later stage.

New data on acute effects of ammonia, acetic acid and n-hexanal obtained in controlled chamber exposures of volunteers will be presented as case studies to illustrate how substances might be handled within the SCOEL and GHS frameworks.

1352 TRANSCRIPTOMIC ANALYSIS OF CARDIAC ENLARGEMENT IN FEMALE SD RATS TREATED WITH INSULIN SENSITIZER DRUGS.B. A. Rosenzweig, A. Knapton, P. Espandiari, E. Herman and K. Thompson. *CDER, U.S. FDA, Silver Spring, MD.*

Thiazolidinedione (TZD) drugs for lowering insulin resistance induce a potential dose-limiting cardiac hypertrophy in patients. Similar effects can be observed in animal models. This study was initiated to identify gene expression markers of cardiotoxicity induced by the TZD rosiglitazone (ROSI) and the isoxazolidinedione PNU-182716 (PNU) in female Sprague-Dawley rats. Groups of 10 week old rats received daily doses of ROSI (80 mg/kg), PNU (800 mg/kg), 1% carboxymethyl cellulose, or water by gavage for up to 14 d. Heart, liver, and kidney tissues were collected for gene expression analysis. Affymetrix array analysis of the 7 and 14 d samples was performed to identify differentially expressed genes (DEGs). Treatment-induced changes in the expression of a subset of DEGs at 1, 3, 7, and 14 d were assayed using qRT-PCR. ROSI-treated rats had a statistically significant elevation in heart weight at 14 d that was not seen in PNU-treated groups, or at earlier time points. Although cardiac histopathology was normal in all groups, cytometric analysis showed evidence of cardiac hypertrophy in ROSI-treated rats. ROSI induced a greater effect on the phenotype of brown and white adipose tissue than PNU, which could be observed after 3 d of treatment and increased with dosing. mRNA levels of the cardiac hypertrophy markers ANF and BNP were significantly increased by ROSI, with maximal levels observed by 7 d. Little or no effect on these 2 genes was induced by PNU. ROSI and PNU both induced similar levels of

change in the cardiac expression of the PPAR target genes FABP4, RBP7, aquaporin 7, and monoglyceride lipase in rats dosed for 7 or 14 d. The induction in FABP4 expression was near maximal after 1 d of treatment with ROSI or PNU and remained relatively constant for the duration of the study. These results are in concordance with other lines of evidence that support an indirect mode of action in the induction of cardiac enlargement by TZD drugs and suggest that natriuretic peptides might be useful as biomarkers to detect the onset of the toxicity.

1353 EVALUATION OF CARDIOTOXICITY POTENTIAL OF THE CANCER THERAPEUTIC AGENT GLEEVEC BASED ON GENE EXPRESSION DATA IN RAT.

A. Vladimirova, D. N. Halbert and M. Fielden. *Iconix Biosciences, Mountain View, CA.*

Gleevec (Imatinib mesylate) is a small molecule protein tyrosine kinase inhibitor that inhibits the Bcr-Abl fusion protein implicated in chronic myeloid leukemia (CML). Recently this anti-cancer drug was reported to promote heart failure in some patients with no previous history of heart disease. A study in mice (Kerkela et al. *Nature Medicine*. 2006;12:908) determined that Gleevec led to significant deterioration of contractile function and ventricular dilation after 3-4 weeks of treatment. We administered Gleevec at 15 and 150 mpk for 1, 3 and 5 days in male SD rats and studied the patterns of gene expression changes in heart relative to controls and reference compounds. Gene expression data were analyzed using DrugMatrix™, a large toxicogenomic reference database that includes over 200 compounds profiled in heart in short term repeat-dose studies. Histopathological profiles of Gleevec-treated animals did not reveal myocyte degeneration or fibrosis, yet gene expression profiles reveal perturbations of stress-responsive genes as well as muscle contraction and development processes. The stress-inducible gene ATF3 was consistently induced over 10-fold relative to controls. Over-expression of ATF3 in hearts of transgenic mice has been shown to cause hypertrophy, reduced contractility and abnormal conduction, suggesting a role of ATF3 in Gleevec-induced cardiotoxicity. Pathway analysis also indicates modulation of genes involved in cardiac hypertrophy, cAMP and Ca++ signaling, and cardiac muscle contraction. Gleevec treatment induced MEF2, known to be activated by stress signaling and during pathological cardiac hypertrophy. We will also present findings that may implicate regulation of histone acetylation in the development of heart pathology. The pattern of gene induction is highly similar to that of idarubicin and epirubicin, known to be cardiotoxic. These results lead to hypotheses to explain Gleevec-induced heart disease and demonstrate that gene expression data may provide early insight into mechanism of toxicity in the absence of histopathological changes.

1354 TIME COURSE OF TRANSCRIPTIONAL CHANGES PRODUCED BY RETINOIC ACID IN THE ZEBRAFISH EMBRYONIC HEART.

J. Chen¹, S. A. Carney², R. E. Peterson¹ and W. Heideman¹. ¹Pharmaceutical Sciences Division, University of Wisconsin - Madison, Madison, WI and ²Skin Science Research, P&TD Technology, Kimberly-Clark Inc., Madison, WI.

All-trans retinoic acid (RA) and 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) both cause cardiac toxicity in developing zebrafish. Both agents produce functional and morphological heart defects that are ultimately associated with circulatory collapse. Furthermore, both RA and TCDD are thought to work by activating transcription factors. We were interested in determining whether the genes affected by RA overlap those affected by TCDD from the time of exposure to the point of heart failure. We characterized the effects of RA (1μM) exposure on embryonic heart morphology and function beginning at 72 hours post fertilization (hpf), and measured changes in heart mRNA abundance using AffyMetrix GeneChips. Cardiac toxicity was assessed at 2, 8, 12, 24, 30, and 48 hr after exposure and heart tissues were collected for microarray analysis at 1, 2, 4, and 12 hr after exposure. Self-Organizing Map clustering of the RA microarray results revealed 5 clusters of genes with distinct expression patterns over time, showing groups of genes up or down regulated immediately after RA exposure as well as groups that changed expression later in the course of toxicity. Early responses were consistent with homeostatic responses aimed at maintaining retinoid metabolism, as well as regulation of known retinoic acid receptor targets. Interestingly, RA and TCDD did not produce similar transcriptional responses at early time points, suggesting that they induce heart failure through distinct mechanisms. However, at late stages the RA and TCDD expression profiles revealed a common cluster of genes involved with chromosome assembly, cell cycle control, and DNA replication. The reduced expression of this common gene cluster may contribute to the impaired cardiomyocyte proliferation seen in both RA and TCDD treated embryos. We speculate that this may be a common response to agents that damage the developing heart. (Supported by NIH RO1 ES012716 and UW Sea Grants R/BT17, R/BT20 and R/BT22).

1355 ZEBRAFISH AS A MODEL FOR ENVIRONMENTAL TOXIN-INDUCED HYPOPLASTIC LEFT HEART SYNDROME.

A. C. Grimes^{2,1}, H. A. Stadt¹, P. Zhang¹, G. Hunter¹, K. Erwin¹, L. L. Satterwhite¹ and M. L. Kirby^{1,2}. ¹Duke University, Durham, NC and ²MUSC, Charleston, SC. Sponsor: E. Levin.

Hypoplastic left heart syndrome (HLHS) is a devastating congenital cardiovascular malformation of unknown etiology. In a recent epidemiological study, a cluster of HLHS occurring in the 1980's in the Baltimore-Washington area has been linked to the environmental release of dioxins and polychlorinated biphenyls (PCBs). These compounds are known to act through the aryl hydrocarbon receptor (AhR), but the mechanisms by which the AhR pathway elicits its toxic effects are poorly understood. Having previously shown evolutionary conservation in the cardiac out-flow tract of the zebrafish, we are utilizing this species and a model PCB (PCB126), to investigate mechanisms of toxicity of such compounds. We have found that cardiac tissues are specifically targeted in early development, leading to a phenotype we describe as 'stringy heart'. Prior to 24 hours post-fertilization (hpf), cardiac markers appear unaffected by PCB126 exposure, but by 72hpf, exposed fish exhibit extreme pericardial and yolk-sac edema, jaw malformations, a stretched, 'stringy' heart, a severely reduced bulbus arteriosus and diminished or absent blood circulation. By performing cell counts, we have found that, similar to cases of HLHS, PCB126 specifically affects ventricular, but not atrial, myocardium. Between 36 and 72hpf, there is a marked reduction in proliferation in affected tissues, as shown by BrdU incorporation, and the lack of a corresponding increase in apoptosis suggests cell-cycle arrest. This led us to hypothesize that the tumor suppressor protein, p53, acts downstream of the AhR to induce cell-cycle arrest and senescence. We have subsequently shown that inhibition of p53 activity, using a chemical suppressor, pifithrin-α, rescues the 'stringy heart' phenotype. Furthermore, we have found that levels of both p53 protein and mRNA are elevated following PCB126 exposure. This work validates the use of zebrafish for the study of environmental toxin-induced HLHS and is the first report of a potential mechanism by which activation of the AhR may lead to cardiac-specific toxicity.

1356 ASSESSMENT OF DRUG EFFECTS ON CARDIAC REPOLARIZATION IN ADULT ZEBRAFISH BY ECG.

C. Parng, W. L. Seng and P. McGrath. *Phylonix Pharmaceuticals, Inc., Cambridge, MA.* Sponsor: C. Zhang.

In this study, we assessed drug effects on cardiac repolarization by conventional ECG techniques adapted for performance on adult zebrafish. To validate this method, 10 well characterized antiarrhythmics from different classes (Class 1A: procainamide, disopyramide; Class 1B: lidocaine, and mexiletine; 1C: flecainide, and propafenone; Class II: propranolol, and metoprolol; Class III: dofetilide, and Class IV: verapamil) and two vessel dilators (clonidine and terfenadine) were tested. μ-conotoxin GIIIB (CTX), which has been shown not to affect zebrafish heart rate, was used to control zebrafish movement. Baseline heart rate before drug treatment was recorded and served as an internal control for each compound. The length of the PR interval, QT interval, QRS complex and ST segment were analyzed and compared. Normally distributed values were displayed as mean ± standard deviation (n=4). The mean of normally distributed continuous variables were compared using unpaired two-tailed t-tests. P values of 0.05 or less were considered significant. QT intervals were plotted against the associated RR intervals and fit to the equation $QT = QT_c * RR^\alpha$ by the method of least squares. The resulting equation was used to correct the observed QT interval for variations in heart rate. Our results showed that zebrafish ECG is highly reproducible. Zebrafish resting heart rate and conduction intervals are similar to those observed in adult humans. Drugs including procainamide, disopyramide, dofetilide, and terfenadine which cause QT prolongation in humans also resulted in QT prolongation in zebrafish. Lidocaine and mexiletine, causing QT shortening in human resulted in QT shortening in zebrafish. Propranolol and metoprolol, causing prolonged PR intervals in human, resulted in abnormal PR intervals in zebrafish. These results indicate that zebrafish can be a predictive model for drug induced cardiotoxicity in humans.

1357 HERG-LITE®: THE COMPLETE SCREEN FOR HERG RISK.

B. Wible, P. Hawryluk, Y. Kuryshev and A. Brown. *ChanTest, Inc., Cleveland, OH.*

Direct block of the hERG potassium channel by non-antiarrhythmic drugs (NARDs) is a major cause of QT prolongation and torsades de pointes (TdP). Recently, we showed that certain NARDs may produce hERG risk by inhibition of channel trafficking. HERG-Lite® (HL) is the only high-throughput, comprehensive assay for hERG risk that predicts whether compounds are hERG blockers, trafficking inhibitors, or both. This antibody-based chemiluminescent assay uses two cell lines to monitor hERG surface expression: hERG-WT (wild-type) is a biosensor for trafficking inhibitors while hERG-SM (single mutant) detects channel

blockers. To determine the accuracy with which HERG-Lite predicts hERG risk, we are screening an 1120 compound library from Prestwick Chemical Company in HERG-Lite and FASTPatch (FP), our automated patch-clamp system. To date, 611 compounds have been tested in both assays: HL at 1, 10 and 30 μ M and FP at 10 μ M. There is 90% agreement between the hERG assays with respect to hERG risk prediction. Of the 611 compounds screened, 338 (~55%) are null in both assays while 273 (~45%) were positive in one or both of the assays. Of those 273, 131 were predicted to be blockers in HL and have been confirmed in FP, 62 were identified in HL and FP as dual risk compounds, i.e. both direct block and trafficking inhibition, and 17 were shown to be trafficking inhibitors without block. Importantly, 29% of hERG blockers are also trafficking inhibitors. Overall the incidence of hERG trafficking inhibition in the Prestwick library is 12.9% making this an important consideration in hERG risk assessment. In this first round of screening, the incidence of HL false negatives for blockers was only 3.3% as 20 compounds showed greater than 15% hERG current inhibition in FP but no significant rescue of hERG-SM. Forty-three compounds (~7% of the total) rescued hERG-SM but were not detected as blockers in FP. These may be FP false negatives or they may be rescuing hERG-SM without block. If the latter possibility is correct, these compounds may be useful hERG "agonists" by increasing channel surface expression.

1358 BRADYARRHYTHMIA INDUCED BY OXIDANT ATMOSPHERE INHALATION IN CONSCIOUS RATS. A TELEMETRY STUDY IN HEALTHY AND MYOCARDIAL INFARCTED (MI) RATS.

J. Morin¹, S. Lioriot¹, D. Preterre², J. Henry¹ and F. Dionnet². ¹U644, INSERM, ROUEN, France and ²CERTAM, ROUEN, France. Sponsor: R. FORSTER.

Increasing evidences of cardiorespiratory responses to urban atmospheric pollutant have been published during the past few years. The oxidant potential of Diesel emissions has increased due to oxidation catalysis setup. This can be probed by the NO₂/NO_x ratio which correlates with the amount of reactive oxygen species to be generated during the test atmosphere contact with aqueous media containing CPH as a spin probe and assayed by electron spin resonance (ESR). We assess the impact of inhalation for 3 hours of diluted untreated (UDE) (low oxidant) and Oxycat treated (ODE) (high oxidant) Euro3 Diesel engine emissions and of Ozone on Heart rate variability (RMSSD) and arrhythmia occurrence. Beat to beat interval (RR) time series were obtained using the ECG-Auto (EMKA Paris France) software from continuous telemetry recordings (DSI international). Automated analysis procedure of arrhythmia identification and quantification have been developed using a dynamic symbol encoding process application on RR time series. UDE proved to decrease RMSSD in both healthy and MI rats, and to induce extrasystoles and tachyarrhythmia in MI rats only. ODE, and ozone induced a marked bradycardia (increased RR values), and bradyarrhythmia, with a latent period of 1-2 hours. These bradycardia and bradyarrhythmia events which were never observed in unexposed healthy nor MI rats led to increased RMSSD and Shannon entropy values signing most probable impacts on heart autonomic control. While no adaptative process was evidenced upon repeated exposure to UDE, with ODE and Ozone, maximal impacts where seen at first exposure and reduced impacts where seen after 3 daily exposures when increased lung and heart SOD and GPx activity levels were observed signing activation of antioxidant defenses.

In conclusion, inhalation of atmospheres containing oxidant pollutants induce numerous arrhythmias in both healthy and MI rats. These arrhythmia may be part of the mechanisms contributing to the growing evidences of atmospheric pollutant induced cardiac injuries.

1359 A NOVEL MURINE MODEL OF OCCUPATIONAL RHINITIS FOLLOWING INHALATION OF TOLUENE DIISOCYANATE.

V. J. Johnson, B. Yucsoy and M. I. Luster. *Toxicology and Molecular Biology Branch, NIOSH/CDC, Morgantown, WV.*

Diisocyanates are low molecular weight chemicals that have been identified as the leading cause of occupational asthma. Epidemiological evidence suggests that diisocyanate-induced rhinitis is a comorbid and often preceding condition in patients with occupational asthma. Understanding the pathogenesis of occupational rhinitis and its biological and chronological relationship with asthma will be critical for disease prevention. In this regard, we have developed a murine model of toluene diisocyanate (TDI)-induced rhinitis. Female C57BL/6 mice were exposed to TDI vapor via inhalation for 4 hours/day for 12 days with or without a 2 week rest period and TDI challenge. The nasal mucosa was examined after each experimental stage for alterations in cytokine expression and pathology. Mice exposed to TDI vapor for 2 weeks showed elevated expression of IL-4, IL-5, IL-13, IL-10 and IFN γ suggesting a mixed Th1/Th2 immune response. Expression of proinflammatory cytokines (TNF α and IL-1 β) and adhesion molecules (VCAM-1 and ICAM-1) was also up-regulated. These cytokine changes corresponded to a marked influx of inflama-

tory cells into the nasal mucosa, eosinophils being the predominant cell type. Removal from exposure for 2 weeks resulted in a reduction in cytokine expression and pathology to control levels. Subsequent challenge with TDI vapor resulted in robust upregulation of the same cytokine genes as well as eosinophilic inflammation. The present model shows that TDI inhalation induces allergic rhinitis displaying many of the cardinal features of human disease. Future work will use this model to define the immune mechanisms and also examine the temporal/dose relationship between TDI-induced rhinitis and asthma.

The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy.

1360 LEAD SKEWS THE DEVELOPMENT AND FUNCTION OF BONE MARROW-DERIVED DENDRITIC CELLS TOWARD THE TYPE-2 IMMUNE PHENOTYPE.

D. A. Lawrence, D. Gao and T. K. Mondal. *Wadsworth Center, Albany, NY.*

Although lead (Pb) has significant effects on the development and function of macrophages, B cells, and T cells and has been suggested to promote allergic asthma in mice and humans, Pb modulation of bone marrow (BM)-derived dendritic cells (BM-DC) and the resultant DC effects on Th1 and Th2 development had not been examined. Thus, we developed BM-DCs with murine granulocyte macrophage-colony stimulatory factor (mGM-CSF) $\pm$ PbCl₂ to evaluate any phenotypic changes of BM-DC derived in the presence of Pb (Pb-DC). Pb-DCs after ten days of development in vitro had significantly lower expression of CD11c. Although fewer CD11c+ DCs (% and MFI) were generated with Pb, Pb-DCs had significantly greater MHC class II (I-A) expression than the day-10 non-Pb-exposed DCs (DCs). However, these differences diminished upon LPS stimulation for two days. After LPS stimulation, CD80, CD86, CD40, CD54, and MHC-II were all up-regulated on both Pb-DCs and DCs, but Pb-DCs expressed significantly less CD80 than DCs. The CD86:CD80 ratio suggests a PB-DC potential for Th2 cell development and enhanced immunity, since CD80 has preferential interaction with CTLA-4, which affects immunosuppression. After LPS stimulation, IL-6, IL-10, IL-12 and TNF α levels significantly increased with both Pb-DCs and DCs, although Pb-DCs produced significantly less cytokines than DCs, except for IL-10, which further supports preferential skewing toward type-2 immunity by Pb-DCs. In vitro studies confirm that Pb-DCs have the ability to polarize antigen-specific T cells to Th2 responses. Pb-DCs also enhanced allogeneic and autologous T cell proliferation in vitro, and in vivo studies suggest that Pb-DCs inhibited Th1 effects on humoral immunity. The Pb effect was mainly on DC and not T cells, and its modification of DC function appears to be the main cause of its promotion of type-2 related immunity, which may relate to its enhanced activation of the Erk/MAP kinase pathway.

1361 CONTACT AND RESPIRATORY CHEMICAL ALLERGENS INDUCE DIFFERENTIAL CUTANEOUS CYTOKINE SECRETION PATTERNS.

M. Cumberbatch¹, L. Schneider¹, R. J. Dearman¹, I. Kimber¹ and C. E. Griffiths². ¹Syngenta CTL, Macclesfield, CHESHIRE, United Kingdom and ²Dermatology Centre, Manchester University, Manchester, United Kingdom.

Prolonged topical exposure of BALB/c strain mice to the contact allergen dinitrochlorobenzene (DNCB), or to the respiratory allergen trimellitic anhydride (TMA), promotes the selective development of type 1 and type 2 immune responses, respectively. The early events which may play a role in the initiation of polarized immune responses to different classes of chemical allergen are of particular interest. In the current experiments we have examined the kinetics of cutaneous cytokine expression induced following exposure of BALB/c mice to 1% DNCB or to 25% TMA. Expression of the proinflammatory cytokines tumor necrosis factor α (TNF- α) and interleukin (IL)-1 β and the anti-inflammatory cytokine IL-10 has been analyzed by cytokine protein array. Groups of mice (n=10) were exposed on the dorsum of both ears to chemical 30 min, 2h, 4h, 24h, 48h and 72h prior to preparation of dorsal ear explants for culture on medium for 16h. Exposure to DNCB was associated with a rapid increase in TNF- α secretion 2h following exposure that had declined by 4h, and a subsequent up-regulation of IL-1 β expression that was sustained from 4h to 72h. In contrast, treatment with TMA was associated with a very rapid induction of IL-10 (within 30 min) which did not return to basal levels until after 24h of exposure. At the later time points (24 to 72h), TMA stimulated increased expression of TNF- α and IL-1 β . Taken together with previous observations on the tempo and vigor of epidermal Langerhans' cell (LC) migration by chemical allergens, this suggests that treatment with DNCB provokes the cytokine milieu (TNF- α and IL-1 β) necessary for rapid and vigorous LC migration. In contrast, the early expression of IL-10 induced by exposure to TMA results in delayed kinetics of LC migration until later time points when the cytokine balance is in

favor of proinflammatory cytokine expression. These data suggest suggests that epidermal LC are important targets for the polarization of immune responses to chemical allergens.

1362 CHEMICAL RESPIRATORY ALLERGENS UP-REGULATE GRANZYME B GENE EXPRESSION.

H. T. Caddick, C. J. Betts, R. J. Dearman and I. Kimber. *Syngenta CTL, Macclesfield, CHESHIRE, United Kingdom.*

Selective T helper (Th) 1 and Th2 type responses are induced following repeated topical exposure of BALB/c strain mice to chemical contact and respiratory allergens, respectively. In previous experiments, gene expression profiles following exposure of mice to the chemical respiratory allergen trimellitic anhydride (TMA) have been analyzed using oligonucleotide microarrays. Mice received a single topical exposure of 10% TMA on the dorsum of each ear and auricular lymph node tissue was isolated 24 h to 120 h later. Of the 34,000 probe sets represented on the array, 21,000 were detected in lymph node tissue, but only 46 genes with statistically significant allergen-specific alterations were identified. The most strongly up-regulated gene was the T cell cytolytic molecule granzyme B. In the current experiments, changes in granzyme B expression in tissue isolated from mice treated with TMA, or with the contact allergen 2,4-dinitrochlorobenzene (DNCB), have been measured using real time PCR. Mice were exposed to 10% TMA, to 1% DNCB or to vehicle alone on the dorsum of both ears. Draining lymph nodes were excised 24 to 120h later, total RNA prepared and changes in gene expression quantified by real time PCR. Levels of granzyme B were normalized against the housekeeping gene HRPT and expressed as fold changes relative to naïve (untreated) controls. Treatment with TMA resulted in a marked increase in granzyme B expression (fold changes of 5.7+/-2.4, 20.7+/-1.9 and 9.0+/-0.9 induced 48, 72 and 96h after exposure, respectively, n=3). Less marked changes were observed for DNCB-activated cells (fold changes of 3.51+/-0.1, 5.6+/-0.7 and 3.11+/-1.0 induced 48, 72 and 96h after exposure, respectively). Less than 2fold changes were observed throughout the time course for tissue derived from vehicle-treated animals. Selective up-regulation of granzyme B gene expression has been observed following exposure to the respiratory chemical allergen TMA, consistent with recent observations that granzyme B may be the preferential mechanism for Th2 cell death.

1363 ASSESSMENT OF PROTEIN ALLERGENIC POTENTIAL IN MICE : RESPONSES TO ARA H 1, ARA H 2 AND POTATO LECTIN.

I. Kimber and R. J. Dearman. *Syngenta CTL, Macclesfield, CHESHIRE, United Kingdom.*

Assessment of the potential allergenicity of novel proteins is an important issue, particularly for those derived from genetically modified plants. We have shown previously that the measurement of specific IgE antibody production induced by systemic (intraperitoneal) exposure of BALB/c strain mice to a range of proteins correlates with allergenic potential. In the current investigations, immune responses to the purified peanut allergens ara h 1 and ara h 2 and to potato agglutinin, a material considered to lack allergenicity, have been compared. Specific IgE antibody was measured by homologous passive cutaneous anaphylaxis assay and specific IgG antibody measured by enzyme-linked immunosorbent assay. Intraperitoneal administration of peanut agglutinin (1%w/v) induced relatively vigorous IgG antibody production but failed to cause detectable IgE antibody production. Treatment with 1% w/v ara h 1 stimulated a comparatively weak IgG antibody response but nonetheless IgE antibody production was detected. In contrast, exposure to ara h 2 under the same conditions failed to induce either detectable IgG or IgE antibody. The relatively poor immunogenicity of both peanut proteins in the BALB/c strain mouse may be a reflection of prior dietary exposure to cross reactive soy proteins. Further experience with a wider range of proteins is required, but results to date are encouraging that this approach may constitute a method for the prospective identification of protein allergens, provided that lack of allergenicity (IgE) is only considered a secure negative when robust immunogenicity (IgG) is demonstrated.

1364 THE SENSITIZER NISO4 TRIGGERS THE PRODUCTION OF THE BIO-ACTIVE FORM OF INTERLEUKIN-12 BY HUMAN DENDRITIC CELLS.

D. Antonios, S. Kerdine-Römer and M. Pallardy. *Toxicologie, Faculté Pharmacie, University Paris-Sud, Chatenay-Malabry, France.*

Dendritic cells (DCs) are professional antigen presenting cells which capture and process antigens such as invading bacteria, viruses and haptens. After antigen uptake, DC undergo a maturation process leading to the upregulation of surface markers and production of cytokines. We and others have already shown that NiSO₄, a metallic hapten, induces the maturation of human DCs, in vitro.

In this work, we address the question whether NiSO₄ by itself or in synergy with other signals can induce the secretion of Interleukin-12 (IL-12) by human DCs derived from CD34+ progenitor cells (CD34-DC) or from human monocytes (Mo-DC).

In CD34-DC, NiSO₄ alone induces the secretion of IL-12p40 but not the production of IL-12p70, the bio-active form of IL-12. The production of IL-12p70 induced by NiSO₄ in CD34-DC needs a complementary signal provided by IFN-gamma. IL-1 beta, a proinflammatory cytokine, synergizes with both signals to augment the production of IL-12p70. We then analysed the expression of IL-12p35 mRNA using RT-PCR and found that IL-12p35 mRNA was expressed only in the presence of NiSO₄ and IFN-gamma and further enhanced with the addition of IL-1 beta.

Mo-DC activated with NiSO₄ alone produce a high level of IL-12p40. The presence of IFN-gamma is sufficient for a strong induction of IL-12p70 showing differences with CD34-DC. We also show that the bacterial lipopolysaccharide (LPS) can act in synergy with NiSO₄ to induce the production of IL-12p70.

These results suggest first that NiSO₄ alone is able to induce the production of high levels of IL-12p40 in human DCs but no detectable amounts of IL-12p70 are measured. Second, IL-12p70 production induced by NiSO₄ in both models needs the presence of IFN-gamma. Finally, a bacterial product such as LPS in combination with NiSO₄ produce high levels of IL-12p70 in Mo-DC. Signalling pathways induced by these different combinations are still to identify.

1365 PHARMACOLOGICAL DIFFERENTIATION OF EARLY AND LATE PHASE ASTHMA-LIKE RESPONSE IN TRIMELLITIC ANHYDRIDE (TMA) SENSITIZED AND CHALLENGED BROWN NORWAY RATS.

X. D. Zhang and P. D. Siegel. *HELD, NIOSH/CDC, Morgantown, WV.*

Trimellitic anhydride (TMA) is a low molecular weight chemical that may induce specific-IgE and occupational asthma. We have previously demonstrated that dermal exposure to dry TMA powder with subsequent TMA challenge produces asthma-like early (EAR) and late airway responses (LAR) in Brown Norway rats (BNR), as indicated by Penh (an index of airway resistance). Potential mediators involved in LAR or EAR were examined, using selective pharmacological inhibitors, in the present study. Eight BNR were sensitized by 4, weekly, 4 hr dermal exposures to 40 mg dry TMA powder. Two weeks following the final dermal exposure, BNR were given a 10 min, 40 mg/m³ TMA nose-only aerosol challenge. Pharmacological agents were administered either prior to and/or 1 hr after EAR, and Penh was recorded every 0.5 min for 16-20 hrs. Results: Dexamethasone (2 mg/kg, i.p.) inhibited TMA induced EAR or LAR in TMA sensitized and challenged BNR. Intranasal steroid, fluticasone, (10µl/nostril, daily for 3 days before airway challenge) did not inhibit EAR and LAR, suggesting that the Penh changes were not due primarily to upper airway responses. An aerosol of 1% Salbutamol, a β₂ agonist neither prevented or reversed the EAR or LAR. Both Ketanserin, (10 mg/kg, i.p.) a 5-HT₂-receptor antagonist, and Cetirizin, a H1-blocker, (30 mg/kg, i.p.) administered 1 hr after TMA challenge inhibited the subsequent LAR. Montelukast (10 mg/kg, i.p.), a leukotriene receptor antagonist, inhibited EAR, but not LAR, when administered either before or 1 hr after challenge. The adenosine antagonist, aminophylline (30 mg/kg, i.p.) also inhibited LAR in some, but not all treated/challenged rats. Selective pharmacological inhibition of mediators demonstrates different pathophysiological mechanisms of EAR and LAR for the asthma-like responses in the BNR TMA model.

The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent agency determination or policy.

1366 OPTIMIZATION OF THE HUMAN CD34+-DENDRITIC CELLS MODEL FOR DETECTION OF CHEMICAL SENSITIZERS.

H. Assaf-Vandecastee and M. J. Pallardy. *Toxicologie, Faculté Pharmacie, University Paris-Sud, Chatenay-Malabry, France.*

Allergic contact dermatitis is a delayed-type hypersensitivity reaction caused by exposure to contact allergens. Animal assays are currently used to identify the sensitizing potential of new chemicals. However, such studies must be replaced by alternative methods in a near future due to public concern for using animal testing. Our laboratory is part of a national project launched by AFSSAPS (French Medicinal Products Agency) to develop in vitro models for allergy prediction. Due to the variability of different dendritic cell (DC) and langerhans cell (LC) models described in the literature, our initial goal is to characterise and optimize the CD34+-DC model to obtain a robust test system. Another laboratory will optimize the monocytes-DC system in view of comparing both models. CD34+-DCs were cultured in RPMI medium supplemented with 10% of foetal bovine serum (FBS) in the presence of GM CSF (200 U/ml) and TNF-alpha (50 U/ml), as well as Flt3-L (50 ng/ml)

and/or SCF (50 ng/ml), two cytokines needed for cell proliferation. Our results show that the association of Flt3-L and SCF versus Flt3-L or SCF alone increases by two-fold the number of DCs at day 7. The addition of GM-CSF and TNF- α at day 4 and 7 was tested and the phenotype was determined (CD1a, CD14, CD34, langerin, CD83, e-cadherin, CLA, HLA-DR, CD40, CD86). These DCs do not express langerin and e-cadherin. On the other hand, CD34⁺-DC cultured with TGF- β (10 ng/ml) added at day 0 and 5 express langerin, e-cadherin and CLA, different markers of the LC. Moreover, the effect of substituting serum AB (SAB) to FBS in culture was tested. Culturing DC in SAB did not improve differentiation especially with TGF- β since there was an increase in CD14⁺ cells, and a decrease in langerin, e cadherin, and CLA expressions.

Finally, the two models (DCs and LCs) have been tested with prototype haptens such as nickel sulfate and dinitrochlorobenzene to induce maturation, and their functionality has been evaluated using a mixed lymphocyte reaction and allogeneic T-lymphocytes.

1367 CYP1B1 AND EPHX1 ARE ASSOCIATED WITH P53 ACTIVATION AND SUPPRESSION OF HUMORAL IMMUNITY BY 7, 12-DIMETHYLBENZ(A)ANTHRACENE(DMBA) IN C57BL/6N MICE.

J. Gao and S. W. Burchiel. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

7,12-Dimethylbenz(a)anthracene (DMBA) is a potent carcinogen that induces immunosuppression of both humoral and cell-mediated immunity in mice and other species. It is widely accepted that DMBA is metabolically activated by phase I enzymes to reactive intermediates. Our previous studies have shown that P450 CYP1B1 and EPHX1 (microsomal epoxide hydrolase, mEH) appear to be important enzymes in the metabolic activation of DMBA. Certain metabolites of DMBA may cause DNA damage leading to immunosuppression. The tumor suppressor protein p53 plays a pivotal role in the cellular response to the DNA damage and in the maintenance of genomic stability. Previous studies have shown that DMBA-induced bone marrow toxicity is dependent on the activation of p53 (Page et al. *Tox Sci* 74, 85-92, 2003). Therefore, the purpose of the present studies was to determine whether p53 activation is associated with DMBA-induced suppression of humoral immunity. Female C57BL/6N wild-type (WT), CYP1B1 ^{-/-}, EPHX1 ^{-/-}, and AhR ^{-/-} mice were treated with 0, 17, 50, or 150 mg/kg (cumulative dose) DMBA in corn oil by oral gavage once a day for 5 days. Western blot and flow cytometry assays were used to assess p53 levels in mouse splenocytes. Following 5 days of DMBA treatment, total p53 levels were significantly increased in the nuclear portion of spleen cell lysates in all of the DMBA treated WT mice in a dose-dependent manner, as compared to control mice. Western blots showed that p53 was activated by phosphorylation at Ser15. In contrast, the total p53 and phospho-p53 (ser15) levels in both CYP1B1 ^{-/-} and EPHX1 ^{-/-} mice showed no significant p53 activation. AhR ^{-/-} mice demonstrated the same response as WT mice; therefore, AhR does not appear to play a role in DMBA-induced p53 activation. In summary, metabolic activation of DMBA by CYP1B1 and EPHX1 appears to be important in p53 signaling and subsequent immunosuppression. These effects are AhR-independent. This work was supported in part by NIH RO1 ES05495.

1368 RESVERATROL (TRANS-3, 5, 4'-TRIHYDROXYSTILBENE) PROTECTS T CELLS FROM 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD)-INDUCED APOPTOSIS *IN VITRO* AND REDUCES TCDD-INDUCED THYMIC APOPTOSIS *IN VIVO*.

N. P. Singh, M. Nagarkatti and P. Nagarkatti. *Pathology, Microbiology, & Immunology, School of Medicine University of South Carolina, Columbia, SC.*

Resveratrol, a compound found in red grapes, acts as an antagonist of aryl hydrocarbon receptor (AhR) and blocks AhR-mediated signaling. In the present study, we examined whether resveratrol would prevent TCDD-induced immunotoxicity *in vitro* and *in vivo*. For *in vitro* study, we cultured primary T cells from C57BL/6 mice in the presence of ConA for 24 hrs, treated with TCDD (100-1000 nM) in the absence or presence of resveratrol for 24 hrs, and determined apoptosis. Similar studies were also performed with ConA-activated EL-4 T cells. We observed significant reduction in TCDD-induced apoptosis in both primary T cells and EL4 cells in the presence of resveratrol *in vitro*. Next, we examined whether resveratrol would neutralize the effects of TCDD *in vivo*. We treated C57BL/6 mice with TCDD (10 mg/kg body weight) before or after resveratrol treatments. On day 4-5, thymuses of treated mice were characterized. We observed significant reduction in thymus size and weight loss in mice treated with TCDD when compared to mice that were treated first with resveratrol and then TCDD, demonstrating effectiveness of resveratrol in neutralizing TCDD-induced thymic toxicity. We also observed TCDD-induced upregulation of CYP1A1 expression in thymic cells but significantly reduced

CYP1A1 expression in the presence of resveratrol. Furthermore, upon examination of apoptosis in thymic cells, we observed significant TCDD-induced apoptosis but reduced apoptosis in the presence of resveratrol. Resveratrol was also effective in neutralizing TCDD-induced thymic toxicity in mice that were first exposed to TCDD and then treated with resveratrol. Taken together, our data demonstrate that resveratrol being a natural product can be used as a prophylactic agent to neutralize the toxic effects of TCDD (This work was supported in part by NIH grants R01AI053703, R01ES09098, R01 AI058300, R01DA016545, R01HL058641).

1369 EXAMINING THE GENETIC SUSCEPTIBILITY TO THE IMMUNOTOXICITY OF A TRICHLOROETHYLENE METABOLITE.

K. Gilbert¹, N. Pumford⁴, J. Doss² and S. Blossom³. ¹Microbiology and Immunology, University of Arkansas for Medical Sciences/Arkansas Children's Hospital Research Institute, Little Rock, AR, ²Pathology, University of Arkansas for Medical Sciences, Little Rock, AR, ³Pediatrics, University of Arkansas for Medical Sciences/Arkansas Children's Hospital Research Institute, Little Rock, AR and ⁴Cell and Molecular Biology Program, University of Arkansas, Fayetteville, AR.

MRL ^{+/+} mice exposed to occupationally relevant doses of the environmental contaminant trichloroethylene (TCE) in drinking water had been shown to develop autoimmune disease associated with the expansion of activated apoptosis-resistant CD4⁺ T cells. Subsequent experiments tested whether the effect of TCE on CD4⁺ T cells was mediated by its oxidative metabolite, trichloroacetaldehyde hydrate (TCAH). The genetic susceptibility to TCE/TCAH was also examined by comparing the response of autoimmune-prone MRL ^{+/+} mice to genetically-related, but not autoimmune-prone, C3H/HeJ mice.

Female MRL ^{+/+} mice exposed to TCAH for 40 weeks in drinking water developed skin inflammation and hair loss similar to autoimmune alopecia. CD4⁺ T cells in the TCAH-treated MRL ^{+/+} mice were resistant to activation-induced apoptosis, and expressed decreased levels of FasL, a cell surface molecule that mediates apoptosis. A matrix metalloproteinase that cleaves FasL from the cell surface, MMP-7, was increased in these mice.

Unlike MRL ^{+/+} mice, C3H/HeJ mice treated with TCAH for 40 weeks did not demonstrate alopecia or increased levels of MMP-7. Correspondingly, the CD4⁺ T cells from the TCAH-treated C3H/HeJ mice were not resistant to activation-induced apoptosis and expressed normal levels of FasL.

These results suggest that TCE works via its metabolite TCAH to inhibit activation-induced apoptosis in the CD4⁺ T cells of susceptible mouse strains. This effect may promote autoimmunity by suppressing the deletion of activated self-reactive T cells. Genetic susceptibility to the immunotoxicity of TCE/TCAH may reflect a propensity to produce metalloproteinases. This work was supported by the EPA and the Arkansas Biosciences Institute.

1370 EVIDENCE FOR IMMUNE DYSREGULATION AND POSTNATAL AUTOIMMUNE DISEASE FOLLOWING DEVELOPMENTAL EXPOSURE TO TCDD.

A. Mustafa², S. D. Holladay², M. Goff², R. Kerr², S. Witosky³ and R. M. Gogal^{1,2}. ¹Biomedical Sciences, EVVCOM, Va Tech, Blacksburg, VA, ²Biomedical Sciences & Pathobiology, Va Tech, Blacksburg, VA and ³Large Animal Clinical Sciences, Va Tech, Blacksburg, VA.

Immune development is altered following perinatal exposure to the environmental immunotoxic contaminant 2,3,7,8-tetrachlorodibenzo-dioxin (TCDD). Furthermore, the effects from such exposure may be more dramatic or persistent than following exposure into adulthood. Whether perinatal TCDD exposure predisposes or enhances postnatal autoimmune disease is unknown. To address this, we conducted a study to evaluate the influence of perinatal TCDD exposure on 24 week-old offspring of high affinity AhR C57BL/6 mice and low AhR affinity autoimmune-prone NZB X SWR (SNF1) mice. Time-pregnant C57BL/6 (10 dams/treatment) and time-pregnant NZB X SWR (10 dams/treatment) female mice were gavaged on gestational day (GD) 12 with a single dose of 0, 5 or 10 μ g/kg and 0, 40 or 80 μ g/kg, respectively. Examination of the splenic phenotypes showed that perinatal exposure to TCDD caused marked increase in the percentage of CD8⁺ T cells in C57BL/6 splenocytes compared to controls. TCDD perinatal exposure also generated a marked increase in the percentages and total cellularity of autoreactive V β 3⁺ and V β 17⁺ T cells in C57BL/6 spleen. However, no significant changes in autoreactive V β 3⁺ and V β 17⁺ T cells were observed in SNF1 spleens. Interestingly, a high percentage of autoreactive V β 3⁺ and V β 17⁺ T cells were seen in the SNF1 control lymph nodes and even higher concentrations observed in the TCDD-exposed SNF1 mice. Moreover, splenocytes from C57BL/6 mice exposed perinatally to TCDD showed elevated levels of marginal zone B cells characterized by an increase in expression of CD1high/CD23neg-low marker while no significant phenotypic changes were observed in SNF1 splenic B cells. Furthermore, both strains showed no significant changes in the phenotypic expression of CD4 and

CD8 markers in thymocytes when compared to controls. These results suggest that perinatal exposure to TCDD may lead to immune dysregulation and postnatal expression of autoimmunity.

1371 THE EFFECTS OF TCDD ON THE FATE OF NAÏVE DENDRITIC CELLS.

J. Bankoti¹, A. Burnett¹, S. Navarro¹, P. Shaw¹ and D. M. Shepherd^{1,2}. ¹Center for Environmental Health Sciences, University of Montana, Missoula, MT and ²Department of Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT.

Exposure to the environmental contaminant TCDD (dioxin) causes suppressive effects on the immune system, presumably via activation of the Aryl hydrocarbon receptor (AhR). Dendritic cells (DCs), professional antigen-presenting cells in the immune system, express AhR although the level of expression depends on the maturational state of the DCs. We hypothesize that TCDD-induced AhR activation causes a loss in DC function and/or survival in unimmunized animals. C57BL/6 mice were gavaged with either vehicle or TCDD (15 µg/kg). Immune cells from the spleens, and popliteal and brachial lymph nodes (PBLNs) were harvested 7 days post-treatment, and analyzed for phenotypic biomarkers. Two distinct subpopulations of splenic DCs, the CD11c high (mature) and CD11c low (immature) cells, were identified by flow cytometry. The frequency and number of splenic CD11c high DCs was decreased in TCDD-exposed mice when compared to vehicle-treated controls. TCDD increased the expression of CD40 and CD86 on the CD11c high DCs in the spleen while their expression of CD11a and MHC class II was decreased. No significant TCDD effects were observed for the CD11c low DCs in the spleen. Loss of splenic DCs was apparently independent of Fas- or TNF-mediated apoptosis, as mice deficient for Fas, FasL or TNF receptors also exhibited a significant loss of splenic CD11c high DCs after TCDD exposure. In contrast, an increase in the number of CD11c+ cells was observed in PBLNs of TCDD-treated C57BL/6 mice. This study demonstrates the presence of a TCDD-sensitive (CD11c high) DC subpopulation in the splenic tissue of naïve mice. Studies are underway to determine if DC loss in the spleen following TCDD-exposure is attributable to enhanced apoptosis or migration. Collectively, these results suggest that TCDD may induce immune suppression in mice by disrupting DC homeostasis. Supported by NIH grants RR17670 and ES013784.

1372 ARYL HYDROCARBON RECEPTOR (AHR) IS REQUIRED FOR OPTIMAL ANTI-LISTERIA RESISTANCE.

L. Z. Shi, N. G. Faith and C. J. Czuprynski. Department of Pathobiological Sciences, University of Wisconsin-Madison, Madison, WI.

Listeriosis, caused by *Listeria monocytogenes*, is an important food-borne disease that causes considerable morbidity and a relative high mortality rate. *L. monocytogenes* is a prototypic intracellular pathogen that can multiply to great numbers within infected cells (hepatocytes and macrophages). Both innate and adaptive immune responses are important in controlling listerial infection. The aryl hydrocarbon receptor (AhR) is part of a powerful signaling system in response to xenobiotic agents such as polychlorinated hydrocarbons (PCHs) and polycyclic aromatic hydrocarbons (PAHs). There is evidence that it also regulates normal developmental and immune responses. For example, AhR activation can lead to release of TNF-α, whose beneficial role in resistance to listeriosis has been shown previously. In this study, we tested two hypotheses: (1) constitutive expression of AhR is important for resistance to listeriosis and (2) activation of AhR can enhance the killing of intracellular *L. monocytogenes*. Our data demonstrate that AhR null mice are more susceptible to listeriosis than AhR heterozygous mice when inoculated i.v. with log-phase *L. monocytogenes*. In the AhR responsive TIB73 murine hepatocyte cell line, activation of AhR by β-naphthoflavone (BNF) significantly reduced the intracellular burden of *L. monocytogenes* in infected cells. We are in the process of using siRNA for AhR to knock down AhR mRNA in TIB73 cells to further explore the role of AhR in restricting intracellular *L. monocytogenes*. The relationship of TNF-α, reactive oxygen species, and nitric oxide to AhR-mediated anti-*Listeria* resistance in vivo, and inhibition of intracellular growth of *L. monocytogenes* in vitro, are also being explored. Taken together, these data suggest an important role for the AhR in innate immunity to *L. monocytogenes* infection.

1373 GW7845, A PPAR AGONIST, INDUCES MITOCHONDRIA-DEPENDENT APOPTOSIS IN PRO/PRE-B CELLS.

J. Schlezinger, S. Bissonnette and D. H. Sherr. Environmental Health, Boston University, Boston, MA.

Apoptosis is a critical event in the deletion of lymphocytes prior to their migration to the periphery; thus pro/pre B cells also may be particularly susceptible to inappropriate apoptotic stimuli. Both malignant and normal B cells are highly susceptible

to apoptosis induced by structurally diverse peroxisome proliferator-activated receptor γ (PPARγ) agonists, including GW7845. Previously, we have shown that treatment of cultured pro/pre-B cells (BU-11) with GW7845 (40 µM) results in cytochrome c release. Here, we investigated the role of mitochondria in GW7845-induced apoptosis and the mechanisms leading to mitochondrial membrane alterations. The essential role of the intrinsic apoptotic pathway in GW7845-induced apoptosis is supported by the fact that this apoptosis was reduced significantly in APAF1 null primary pro-B cells. The effect of several permeability transition pore inhibitors on GW7845-induced mitochondrial membrane potential loss and apoptosis was tested. While bongkreik acid and atractyloside had no effect on these parameters, cyclosporin A (CsA) modestly reduced the loss of membrane potential and formation of a sub-G0/G1 population. However, CsA did not consistently prevent release of cytochrome c. Calcium played a significant role in the loss of mitochondrial membrane potential, as BAPTA, a calcium chelator that inhibits GW7845-induced apoptosis, reduced the loss to nearly background. However KN-93, an inhibitor of CaMKII that also inhibits GW7845-induced death, effected only a modest reduction in membrane potential loss. These results suggest that calcium may be initiating two separate pathways that influence the mitochondria. Finally, initial results suggest that activation and translocation of Bax is the primary mediator of cytochrome c release and the initiator of the intrinsic apoptosis pathway. Considering that PPARγ agonists are being investigated for potential chemotherapeutic use, it is important to understand the mechanisms by which they induce apoptosis in normal cells to minimize adverse effects.

1374 PLUMBAGIN-INDUCED APOPTOSIS IN LYMPHOCYTES IS MEDIATED THROUGH INCREASED REACTIVE OXYGEN SPECIES PRODUCTION AND ACTIVATION OF THE CASPASE CASCADE.

R. McKallip, C. Lombard, J. Warren, R. Ramakrishnan, P. S. Nagarkatti and M. Nagarkatti. Department Pathology, Microbiology, and Immunology, USC/SOM, Columbia, SC.

Impure extracts from plants containing plumbagin (PLB) have been shown to suppress the immune response. However, most of these claims are supported only by anecdotal evidence with few scientific reports describing the mechanism of action or the efficacy of plumbagin in the suppression of the immune response. In the current study, we tested the hypothesis that plumbagin-induced suppression of the immune response was mediated through the induction of apoptosis. Splenocytes from C57BL/6 mice cultured in the presence of 0.25 µM or greater concentrations of PLB showed significantly reduced proliferative responses to mitogens, including anti-CD3 mAbs, Concanavalin A, lipopolysaccharide and SEB in vitro. Exposure of naïve and activated splenocytes to > 0.25 µM PLB led to a significant increase in the levels of apoptosis. PLB treatment led to a significant increase in the levels of reactive oxygen species (ROS) in naïve and activated splenocytes. Furthermore, treatment with the ROS scavenger, N-acetylcysteine (NAC), prevented PLB-induced apoptosis, suggesting a role of ROS in PLB-induced apoptosis. PLB exposure led to activation of caspase-8, and caspase-9, as well as loss of mitochondrial membrane potential. PLB activation of the caspase cascade was dependent on ROS generation as treatment with NAC prevented the activation of caspase-8 and caspase-9. Finally, treatment of mice with PLB (5mg/kg) led to thymic and splenic atrophy as well as a significant suppression of the response to SEB and DNFB in vivo. Together, these results suggest that plumbagin has significant immunosuppressive properties which are mediated by the induction of apoptosis.

1375 BLOOD GENE EXPRESSION SIGNATURES PREDICT EXPOSURE LEVELS.

A. N. Heinloth¹, P. R. Bushel², J. Li², L. Huang², J. W. Chou², G. A. Boorman³, D. E. Malarkey³, C. D. Houle⁶, W. M. Sandy³, R. E. Wilson³, F. D. Rickie⁴, M. W. Russo⁷, P. B. Watkins⁷, R. W. Tennant⁵ and R. S. Paules¹. ¹ESCG, NIEHS, Research Triangle Park, NC, ²BB, NIEHS, Research Triangle Park, NC, ³NTP, NIEHS, Research Triangle Park, NC, ⁴Microarray Group, NIEHS, Research Triangle Park, NC, ⁵CBG, NIEHS, Research Triangle Park, NC, ⁶EPL, Research Triangle Park, NC and ⁷Department of Medicine, UNC, Chapel Hill, NC.

To respond to potential adverse exposures properly, health care providers need accurate indicators of exposure levels. This is particularly important in the case of acetaminophen (APAP) intoxication, the leading cause of non-viral liver failure in the U.S.

We hypothesized that gene expression patterns derived from blood cells would provide useful indicators of acute exposure levels. To test this hypothesis, we used a blood gene expression data set from rats exposed to APAP to train classifiers in two prediction algorithms and to extract patterns for prediction using a profiling algorithm. Prediction accuracy was tested on a blinded, independent rat blood test data set and ranged from 88.9 to 95.8 %. Genomic markers outperformed predictions based on traditional clinical parameters. The expression profiles of the predictor

genes from the patterns extracted from the blood exhibited remarkable (97% accuracy) trans-tissue APAP exposure prediction when liver gene expression data was used as a test set. Analysis of human samples revealed separation of APAP-intoxicated patients from control individuals based on blood expression levels of human orthologs of the rat discriminatory genes. The major biological signal in the discriminating genes was activation of an inflammatory response after exposure to toxic doses of APAP. These data and results support the hypothesis that gene expression data from peripheral blood cells can provide valuable information about exposure levels, well before liver damage is detected by classical parameters. It also supports the potential use of genomic markers in the blood as surrogates for clinical markers of potential acute liver damage.

1376 GENOMIC ANALYSIS SUGGESTS HIGHER SUSCEPTIBILITY OF CHILDREN TO AIR POLLUTION.

D. van Leeuwen¹, M. Pedersen², A. Boorsma¹, M. Kirsch-Volders³, L. Knudsen², R. Sram¹, J. van Delft¹ and J. Kleinjans¹. ¹*Health Risk Analysis and Toxicology, Maastricht University, Maastricht, Netherlands*, ²*Environmental and Occupational Health, Institute of Public Health, University of Copenhagen, Copenhagen, Denmark*, ³*Faculty of Science, Laboratory of Cell Genetics, Free University of Brussels, Brussel, Belgium* and ⁴*Institute of Experimental Medicine AS CR and Health Institute of Central Bohemia, Prague, Czech Republic*. Sponsor: H. van Loveren.

Exposure to environmental pollutants early in life is of increasing concern because of the risks it poses for development of e.g. cancer. Differences in response to and health effects of hazardous airborne exposure between children and adults have been reported, with children apparently being more susceptible. The aim of the study was to improve our understanding of differences in susceptibility to air pollution between children and adults by comparing genome-wide gene expression profiles in healthy children and their parents. Human oligonucleotide microarrays representing sequences for more than 20,000 genes were used to analyze gene expression in blood samples from 47 children and their parents inhabiting two areas in the Czech Republic with different levels of ambient air pollution. Overrepresentation of biological pathways, processes and functions was analyzed by EASE and the new tool T-profiler using either pre-selected lists of significantly differentially expressed genes or using the total dataset without pre-selection to gain a genome-wide overview of the transcriptomic response. As a phenotypic endpoint of genotoxic effects micronuclei frequencies were analyzed. Gene expressions were investigated for correlation with micronuclei frequencies in order to distract effects on pathways relevant for environmental carcinogenesis, from the whole genome response. All analysis identified defined lists of genes and/or significantly overrepresented biological pathways. More genes and pathways were responsive in children than in parents and significance of specific pathways in children but not in adults suggest differences in susceptibility to air pollution at the transcriptome level.

1377 GENE EXPRESSION PROFILING OF HUMAN BRONCHIAL EPITHELIAL CELLS EXPOSED TO SINGLE-WALLED CARBON NANOTUBES.

C. Lema¹, M. Cunningham¹, D. E. Resasco², L. Balzano³, S. R. Magnuson⁴ and M. T. Falduto⁴. ¹*Houston Advanced Research Center, The Woodlands, TX*, ²*University of Oklahoma, Norman, OK*, ³*SouthWest Nanotechnologies, Norman, OK* and ⁴*GenUs BioSystems, Inc., St. Charles, IL*.

Single-walled carbon nanotubes (SWNT) are nano-scale tubes with impressive electrical and thermal properties, which make them attractive for numerous applications. Early reports of SWNT toxicity by dermal absorption and inhalation in several mammalian species are not conclusive. In an effort to explore the potential harm of SWNT to humans, a combined systems biology and toxicogenomics approach was applied. Normal human bronchial epithelial (NHBE) cells cultures were treated *in vitro* with SWNT. Gene expression profiles were obtained at 0 and 24 hours after treatment and compared to those obtained with silica (SiO₂) and carbonyl iron (CI) as positive and negative controls respectively. Cell pellets were snap-frozen and stored at -80°C. Biotinylated cRNA probes were synthesized from total RNA isolated from the cell pellets and hybridized onto CodeLink™ microarrays containing oligomers from 19,912 unique human genes. Statistics showed high reproducibility among triplicate arrays (maximum CV=7%). Hierarchical agglomerative clustering performed from the top 100 significantly-expressed genes, as well as Principal Components Analysis (PCA), showed that SWNT and CI gene expression profiles were similar to each other but different to SiO₂. Furthermore, Integrated Bayesian Inference System (IBIS) identified several genes as potential biomarkers for exposure to SiO₂ and SWNT. Pathway and network analysis showed that SiO₂ causes perturbation of extracellular matrix remodeling and cell adhesion pathways, which included down-regulation of matrix metalloproteinases (MMP), collagen proteins, integrins, tissue plasminogen activators (PLAT), plasminogen activator inhibitors, and laminin; whereas IL-8 was up-regulated. SWNT caused down-regulation of MMP-1 and PLAT. Understanding the molecular processes leading to toxicity requires a global toxicogenomic approach, miRNA and proteomic profiling are also being investigated.

1378 EVALUATION OF THE EFFECTS OF SERIAL PHLEBOTOMY ON THE TRANSCRIPTOME OF MAJOR TISSUES AND ON THE RESPONSE TO TOXICANTS IN RATS.

E. Blomme, R. Ciurlionis, K. Marsh, J. Waring and Y. Yang. *Abbott Labs, Abbott Park, IL*.

Toxicokinetic (TK) parameters are essential for the proper toxicologic assessment of experimental compounds. Early TK studies are typically conducted in rats before any robust *in vivo* toxicologic evaluation. These studies involve collecting small volumes of blood (less than 0.5 ml) at several time points over a short period of time (typically 24 hrs). While the amount of blood collected and the timing of the collections are designed to minimize any effect on the physiological status, it is unknown how they affect sensitivity to toxicity or the transcriptome of tissues. In this study, our objective was to evaluate the impact of serial bleeding on the transcriptome of various major tissues (kidney, heart, liver, spleen) and their response to 2 well-characterized molecules, doxorubicin and cisplatin. Male Sprague-Dawley rats (n=6/group) received single intravenous injections of saline, doxorubicin (8 mg/kg) or cisplatin (4 mg/kg). In each group, 3/6 rats were serially bled by tail vein 0.25, 0.5, 1, 1.5, 2, 3, 4, 6, 9, 12 and 24 hrs after treatment. Rats were then sacrificed. Blood was collected for hematology and serum chemistry evaluation. Heart, liver, kidney, spleen, and heart were collected for histopathology and gene expression profiling with Affymetrix RAE230A arrays. Serial bleeding was associated with slight decreases of red blood cell parameters and serum total proteins, but did not result in histopathological changes or in increased sensitivity to doxorubicin and cisplatin toxicity. In addition, serial bleeding did not induce significant gene expression changes in either vehicle- or compound-treated rats when compared to their respective control groups. Overall, these results suggest that the serial bleeding procedure used in TK studies minimally affect tissue response to toxicants, and support the feasibility of gene expression studies using tissues collected from these studies.

1379 "PERCELLOME" TOXICOGENOMICS PROJECT FOR THE MECHANISM-BASED TOXICOLOGY.

J. Kanno, K. Aisaki, K. Igarashi, N. Nakatsu, S. Kitajima and Y. Kodama. *Division of Toxicology, Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan*. Sponsor: T. Inoue.

The whole genome sequence for human and mouse, and technology for monitoring whole genome expression enabled us to launch the Percellome Toxicogenomics Project for the development of the comprehensive gene cascade database/informatics by the high-precision transcriptome data.

For this project, we put a normalization method designated as "Percellome" into practical use (BMC Genomics 7:64, 2006). It generates mRNA expression values as "copy numbers per one cell" from DNA microarrays and Quantitative PCR. Thus, transcriptome data are plotted on to a common linear scale, and directly compared among experimental groups, studies, different organs, and furthermore, different platforms that adopt Percellome method (Agilent and CodeLink custom arrays).

Up to now, the time- and dose-dependent alteration of gene expression induced by a single oral exposure in mouse liver (4 time points x 4 dose levels, triplicate, 48 samples per chemical) were studied on 90 chemicals including drugs, food-related chemicals, receptor ligands, pesticides, industrial products, etc. The data is expressed in 3-D graph (X=time, Y=dose, Z=copies per cell) made of 45,000 layers of surfaces that correspond to the probe sets of the Affymetrix MOE430v2 GeneChip ("MilleFeuille" data, see <http://toxicomics.nihs.go.jp/db/> for selected data). MF data allow biologists to check the biologically plausible alterations.

Percellome Project now includes subprojects for repeated dosages, multi-organ linkages, inhalation toxicogenomics that covers exposure levels of sick building syndrome and fetus toxicogenomics for developmental toxicology as well as development of data analysis tools including unsupervised clustering method. New findings from each case and from the database will be demonstrated.

Eventually, this approach should lead to our ultimate goal of creating "virtual mouse" *in silico* in the future.

(supported by Ministry of Health Labour, and Welfare H18-Kagaku-Ippan-001, H15-Kagaku-002, H14-Toxico-001, H13-seikatsu-012, & MOE)

1380 DOSE REPOSENSE RELATIONSHIP ASSESSED BY STANDARD AND OMIC TOOLS IN A 28-DAY RAT TOXICITY STUDY WITH THE ANTIANDROGEN FLUTAMIDE.

D. Rouquié, C. Friry-Santini, M. Come, L. Elies, H. Tinwell, F. Schorsch and R. Bars. *Bayer CropScience, Sophia Antipolis, France*. Sponsor: N. Carmichael.

Since the development of the omic tools their sensitivity compared to that of more traditional tools based on gravimetry, microscopic examination or hormonal analyses has been debated. Therefore, to contribute to this discussion we have assessed

using omic and traditional tools the effects of a wide range of dose levels of the antiandrogen flutamide (FM) on male rats. Flutamide was administered to Sprague-Dawley rats at the doses of 0, 0.04, 0.2, 1, 6 and 30 mg/kg/day for 28 days. At necropsy, blood samples were collected for luteinizing hormone and testosterone measurements. The testes were collected for histopathological assessment in addition to the evaluation of gene expression changes either using full genome DNA chip or qPCR analyses. Results showed that the hormonal changes (increase in testosterone levels) and testicular lesions (Leydig cell hyperplasia) were detected from 6 mg/kg/day. The omic data (transcripts profiling) also showed changes from 6 mg/kg/day. A comparison of sensitivity and dose response effects observed between the two different approaches will be presented. Overall, these data show that, using a standard 28-day toxicity study and a well characterized adverse effect, the NOEL based on transcript profiling analyses is similar to the NOEL based on histopathological examinations.

1381 ENHANCED HEPATIC GENE EXPRESSION OF STRESS-RESPONSE FACTORS IN RATS WITH DICLOFENAC-INDUCED HEPATOTOXICITY: ROLE OF GI BACTERIAL ENDOTOXIN.

M. J. Liguori¹, X. Deng², E. Blomme¹, R. Stachlewitz¹, J. Waring¹, J. Maddox², P. Ganey² and R. Roth². ¹Department of Cellular and Molecular Toxicology, Abbott Laboratories, Abbott Park, IL and ²Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

Diclofenac (DCLF) is a widely used non-steroidal anti-inflammatory drug that has been associated with idiosyncratic hepatotoxicity. Previous studies have suggested a link between bacterial endotoxin and DCLF-induced hepatotoxicity. Liver injury from DCLF is associated with GI injury, which can increase translocation of bacterial products into the blood. To examine the relationship between gut bacteria and DCLF hepatotoxicity, male Sprague-Dawley rats were pretreated for 4 days with vehicle or with polymyxin B (150 mg/kg) and neomycin (450 mg/kg) to sterilize the gut. Rats were then given a hepatotoxic dose of DCLF (100 mg/kg) or vehicle. After 6 hrs, the livers were collected for histopathology and mRNA profiling. In contrast to the naïve gut sterilized rats, DCLF treatment induced a large number of gene expression changes and increased serum ALT activity. Gut sterilization prior to DCLF administration resulted in lowered ALT activity and decreased the number of expression changes. Transcripts uniquely regulated in rats with ALT elevations were related to cell cycle regulation, molecular chaperone activity, stress response, and DNA replication. In DCLF-treated rats, hepatic neutrophil accumulation and the regulation of several neutrophil chemotaxis genes suggested involvement of neutrophils in the mechanism of injury. The MAPK pathway, along with stress-response factors such as GADD45, HYU1, and HSP40, were over-expressed in livers from DCLF-treated rats relative to gut-sterilized, DCLF-treated rats. Interestingly, these changes are similar to those seen in livers from endotoxin-treated rats. Overall, these results are consistent with the hypothesis that intestinal translocation of bacterial endotoxin contributes to the pathogenesis of DCLF-induced hepatotoxicity. (Supported by Abbott Laboratories and NIH Grant DK061315).

1382 LONGITUDINAL TOXICOGENOMIC ANALYSIS OF TRICHLOROETHENE EXPOSURE IN LIVERS OF MRL +/- MICE.

R. Konig¹, P. Cai² and G. A. Ansari². ¹Microbiology & Immunology, University Texas Medical Branch, Galveston, TX and ²Pathology, University Texas Medical Branch, Galveston, TX.

Trichloroethene (TCE) is an industrial chemical and environmental pollutant that is associated with liver and kidney toxicity, and autoimmune diseases. Its hepatotoxic effects are mainly due to its toxic metabolites chloral hydrate, trichloroacetic acid, and dichloroacetic acid. To elucidate the mechanisms by which TCE asserts its hepato- and immunotoxic effects, we chronically exposed female MRL +/- mice, which are susceptible to develop autoimmune disorders, to a low dose of TCE in the drinking water. After 11, 24, 36, and 48 weeks, livers were excised from exposed mice and age-matched controls, and RNA was isolated. Liver gene expression was measured following hybridization of biotin-labeled antisense cRNA fragments to Affymetrix GeneChip® arrays. Data were analyzed using multiple microarray analysis software packages for computational hierarchical cluster analysis and principal component analysis. Furthermore, signaling and metabolic pathways affected by treatment with TCE were identified using Ingenuity™ Pathways Analysis and the Ingenuity™ Pathways Knowledge Database (Ingenuity, Mountain View, CA). A global functional analysis revealed that during the earlier times, changes in the cell cycle (at 12 weeks) and metabolic functions (at 12 and 24 weeks) predominated, whereas at the later times (at 36 and 48 weeks), expression of genes involved in the regulation of cancer, cell death, and the immune system homeostasis were more prominently affected. In addition, changes in cell-to-cell signaling and liver

disease occurred after prolonged TCE exposure. The gene expression data correlate well with the observed liver pathology. These results provide a mechanism for TCE-induced pathology and suggest that prolonged exposure to low doses of TCE, which are common in polluted drinking water sources, can result in hepatotoxicity and liver cancer. Our model may be important for understanding risks associated with TCE exposure in susceptible individuals.

1383 EARLY LIFE-STAGE TOXICITY OF NANOPARTICLES IN FISH.

T. Gordon¹, C. Gordon¹, N. Halzack¹, C. Chambers², C. Quan¹, L. Chen¹ and I. Wirgin¹. ¹Environmental Medicine, NYU School of Medicine, Tuxedo, NY and ²Northeast Fisheries Science Center NOAA Fisheries, Highlands, NJ.

We have studied the dose- and particle type-dependent early life-stage toxicity of nanoparticles in tomcod. Tomcod eggs were fertilized and exposed to 0.4 to 50 µg/ml carbon nanoparticles or 0.08 to 10 µg/ml carbon nanotubes. In one experiment, tomcod embryos were treated starting on day 17 after fertilization, and in the second experiment, larval-stage tomcod were treated beginning on day 3 after hatching. The test nanoparticles included carbon toner particles and the raw combustion soot material and the sludge byproduct that were obtained during the processing and purification of carbon fullerenes with metal catalysts. The surfaces of the carbon nanotubes were polyethylene glycol derivatized. Clear toxicity was observed at the highest concentrations of some but not all nanoparticles types. Significant increases in embryonic death were observed with 50 µg/ml soot and sludge nanoparticles. In comparison, neither the carbon nanotubes nor toner nanoparticles had a significant effect on embryo survival. Significant effects on survival were also observed in embryos treated with 10 µg/ml sludge, a manufacturing process waste product which would have the greatest chance of entering the ecosystem. Similar concentration-dependent effects on survival were observed in the second experiment in which 3 day-old larval stage tomcod were treated with nanoparticles. Abnormal behavior, as seen by decreased activity, was observed at concentrations as low as 2 µg/ml for the sludge nanoparticles. Other endpoints demonstrated that embryonic toxicity occurred at the lowest concentration of nanoparticles used in our experiments. A significant delay in hatching occurred in embryos treated with 0.4 µg/ml of the 3 types of carbon nanoparticles. Thus, naïve young life-stages of tomcod have proven to be sensitive monitors of chemical contamination for a variety of toxicological endpoints.

1384 AQUATIC FATE AND TOXICITY OF NANOPARTICLES: AGGLOMERATION, SEDIMENTATION AND EFFECTS ON DAPHNIA MAGNA.

K. Wiench, R. Landsiedel, S. Zok, V. Hisgen, K. Radke and B. van Ravenzwaay. Product Safety, BASF, Ludwigshafen, Germany.

The nanoparticulate inorganic pigments titanium dioxide (TiO₂) and zinc oxide (ZnO) are used in sunscreens to protect the human skin against UVB light. It has been demonstrated that these nanoparticles do not penetrate human skin. However, the possible impact on the environment and its aquatic organisms has not been well examined.

We analysed the agglomeration and sedimentation and tested the acute aquatic toxicity of TiO₂ and ZnO particles. The influence of the test medium, the dispersion method and the pH on the fate and the effects of the particles were tested. Additionally, the characteristics of the nano-scaled materials were compared to those of the micron-scaled materials.

The particle size distributions in the test dispersions were characterized by laser scattering and dynamic light scattering analysis, and sedimentation of particles was visually observed at different time points. The mass of non-sedimented particles was determined. Acute aquatic toxicity to *Daphnia magna* was tested considering the OECD Test Guideline 202.

Dispersion of the nano-powders generally leads to suspensions with agglomerated particles and sedimentation. However, agglomeration and sedimentation varied significantly depending on the choice of test media.

The acute aquatic effect of nano-TiO₂ was low and did not significantly differ from that of the micron-sized material.

The aquatic toxicity of ZnO particles largely depended on the solubilisation of Zn rather than on the particles themselves. Therefore the pH of the test medium is critical. Microscopy of the *Daphnids* revealed particles in the intestine, the filtering chamber and inside the carapax as well as adsorption to the body surface. Adsorbed and ingested particles were agglomerates rather than primary nano-scaled particles.

1385 DISTRIBUTION OF NANOPARTICLES IN THE SEE-THROUGH MEDAKA (ORYZIAS LATIPES).

S. Kashiwada. NIES, Japan, Tsukuba, Ibaraki, Japan. Sponsor: S. Kullman.

Water-suspended fluorescent nanoparticles (solid-latex solution) were used to investigate the distribution of nanoparticles in the eggs and bodies of see-through medaka (*Oryzias latipes*) because the environmental fate of manufactured nanopar-

ticles is considered an emerging environmental concern. Particles 39.4 nm to 42,000 nm in diameter were adsorbed to the chorion of medaka eggs and accumulated in the oil droplets, and 474-nm particles had the highest bioavailability to eggs. Particles 39.4 nm in diameter shifted into the yolk and gallbladder during embryonic development. Adult medaka accumulated 39.4-nm nanoparticles mainly in the gills and intestine when exposed to a 10-mg/L nanoparticle solution. Nanoparticles were also detected in the brain, testis, liver, and blood. Concentrations of nanoparticles in the blood of male and female medaka were 16.5 and 10.5 ng/mg blood protein, respectively. These results suggest that nanoparticles are capable of penetrating the blood-brain barrier and eventually will reach the brain. Salinity-dependent acute toxicity was observed in medaka eggs exposed to nanoparticles for 24 h. The bioavailability and toxicity of nanoparticles depends on environmental factors and multiple physicochemical properties. Further studies on the toxic effects of nanoparticles used in commercial products, and their environmental relevance, need to be done to define the risks and benefit of nanomaterial applications.

1386 TOXICOLOGY OF TITANIUM DIOXIDE (TiO₂) NANOPARTICLES: 1. CHARACTERIZATION AND TISSUE DISTRIBUTION IN SUBCUTANEOUSLY AND INTRAVENOUSLY INJECTED MICE.

T. Umbreit¹, J. L. Weaver², T. J. Miller², J. Zhang², R. Shah², M. A. Khan², M. E. Stratmeyer¹ and V. Tomazic-Jezic¹. ¹Center for Devices and Radiological Health, Food and Drug Administration, Rockville, MD and ²Center for Drug Evaluation and Research, Food and Drug Administration, Rockville, MD.

Medical products are beginning to use nanotechnology but efforts to ensure their safety are lagging behind. We studied TiO₂ nanoparticles (average size=4.7 nm, W740x, Degussa) in vivo. Particle sizes in media suspensions were measured by dynamic light scattering, and assessed for aggregation by light microscopy. Particles resuspended in sterile saline were injected into Balb/c female mice on days 1 and 2. Mice received either 4 subcutaneous (SC) injections in the inguinal and axillary area, or 2 intravenous (IV) injections in the tail vein. The total doses were 5600 mg/kg (SC) or 560 mg/kg (IV). Large doses were used to ensure detectability of biological responses. IV injections were well tolerated, while SC injected mice showed clinical and hematological signs of systemic inflammatory response. Necropsies were performed on day 3 and 5. Brain, liver, spleen, lymph nodes, lungs and kidney were examined macroscopically and microscopically. In the SC injected mice, most of the injected particles remained at the injection site as a solid aggregation. In the IV injected mice, lungs, liver and spleen were noticeably whitish in color, indicating presence of TiO₂ deposits. Macroscopically, all other tissues appeared normal. Histological analysis showed accumulation of TiO₂ aggregates inside macrophages in the liver, spleen and most markedly in the lungs of IV injected mice. In SC injected mice, very few or no macrophages with TiO₂ were observed in those tissues. However, hepatic vacuole formation observed in those mice may suggest hepatocellular degeneration. These results indicate that nanoparticles of TiO₂ probably aggregate immediately after SC injection inducing acute inflammation. In IV injected mice they are rapidly cleared from the circulation accumulating in lung, liver, and spleen indicating potential organ specific toxicity of TiO₂ nanoparticles.

1387 NANOSIZE TiO₂ STIMULATES REACTIVE OXYGEN SPECIES IN BRAIN MICROGLIA AND DAMAGES NEURONS, *IN VITRO*.

T. Long², J. Tajuba², P. Sama², P. Gillespie⁵, N. Saleh³, J. Parker⁴, C. Swartz², G. Lowry³ and B. Veronesi¹. ¹NHEERL/NTD/CTMB, U.S. EPA, Research Triangle Park, NC, ²School of Public Health, UNC, Chapel Hill, NC, ³Department of Civil and Environmental Engineering, Carnegie Mellon University, Pittsburgh, PA, ⁴Health Sciences, Constella Group Inc., Durham, NC and ⁵Department of Environmental Medicine, NYU, Tuxedo, NY.

This study reports that a commercially available, widely used nanosize titanium dioxide (TiO₂) product (Degussa P25), damages cultured neurons through microglia-generated reactive oxygen species (ROS) and oxidative stress (OS). Immortalized mouse brain microglia (BV2) were exposed to physicochemically characterized P25 and their release of ROS examined with fluorescent and chemiluminescent probes. Affymetrix microarray analysis on P25-exposed microglia indicated that numerous apoptotic and OS pathways were up-regulated. Immortalized rat dopaminergic (DA) neurons (N27), exposed to 2.5–40 ppm P25 for (1–72 hr), responded with early (1–48 h) increases in intracellular ATP followed by significant reductions at all tested concentrations (72 h). Initiation of apoptosis in the N27 neuron was suggested by significant increases in Caspase 3/7 activity after 24 hr exposure to P25 (>40 ppm). Direct damage to N27 neurons was indicated by significant reductions of Hoechst 33342 nuclear stain after 24 and 48 hr exposure to 20 and 40 ppm. Primary cultures, dissociated from embryonic rat striatum (containing a predominance of DA neurons), were exposed to (5–40 ppm) P25 and exam-

ined after 6, 24, and 48 hr exposure. Significant increases of nitrite, an index of reactive nitrogen species, occurred at >20 ppm exposure after 1 h (>10 ppm after 3 h). The number of immunohistochemically stained neurons in these cultures was reduced by ~32% and ~40% in response to 5 ppm after 6 and 24 hr exposure. Microscopic evidence of apoptosis was also documented. Together, these data indicate that P25 damages neurons directly, but more rapidly and at lower concentrations in complex cultures containing microglia, plausibly through OS mediated pathways.

1388 EFFECTS OF COPPER NANOPARTICLES ON VIABILITY AND FUNCTION OF PC-12 CELLS.

C. Murdock¹, K. Szczublewski¹, A. Schrand¹, D. Mattie¹, J. Schlager¹, H. Duhart², S. Ali² and S. Hussain¹. ¹AFRL/HEPB, Air Force Research Laboratory, Dayton, OH and ²Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, OH.

This investigation was designed to determine whether different nano-sized copper particles would induce dopamine (DA) depletion in a cultured neuronal phenotype, PC-12 cells. Cells were exposed to different sizes of copper nanomaterials Cu-40, 60 & 80 nm) for 24 h. The Cu particles were obtained in powder form and in sizes of 40, 60, and 80 nm particles from Nanotechnologies Inc., Austin, TX. Characterization of these particles was performed using light microscopy, electron microscopy, and photon correlation spectroscopy. Using the high illumination CytoViva system, the particles agglomerate to ~1–5 µm when dispersed in solution, which was also shown by photon correlation spectroscopy. The electron microscopy images show a non-spherical structure that is closer to a crystalline form. MTT assays and LDH assays were performed to assess cell viability and cell membrane integrity and leakage, respectively. The MTT results show marked toxicity above concentrations of 5 µg/mL for Cu 40 and Cu 60 (EC50: 8.3 µg/mL and 7.7 µg/mL, respectively) while Cu 80 showed toxicity above 10 µg/mL (EC50: 18.2 µg/mL). The LDH assay showed Cu 40 had significant leakage at concentrations of 10 µg/mL, Cu 60 had significant leakage at 7.5 µg/mL, and Cu 80 had significant leakage at 25 µg/mL. The results derived from the dopamine (DA) and its metabolites, dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) assays suggest a significant dose-dependent decrease in the levels of DA and its metabolites as a result of exposure to 5 to 50 µg/ml concentrations of Cu nanoparticles compared to control cells. Further study is required to evaluate the specific intracellular distribution of copper nanoparticles, metal dissolution rates in cells, and cellular matrices, and relevance to their size, surface area, and other physicochemical parameters.

1389 EFFECT OF ORGANIC SURFACE FUNCTIONALIZATION AND SONICATION ON SILVER NANOPARTICLE CYTOTOXICITY IN NEUROBLASTOMA CELLS.

A. Schrand², J. Stralka³, R. Teets³, D. Mattie¹, D. Goia⁴, I. Hauge¹, J. Schlager¹ and S. Hussain¹. ¹AFRL/HEPB, Air Force Research Laboratory, Dayton, OH, ²Department of Chemical and Materials Engineering, University of Dayton, Dayton, OH, ³Chemistry, United States Air Force Academy, United States Air Force Academy, CO and ⁴Center for Advanced Materials Processing, Clarkson University, Potsdam, NY.

The immense nanoparticle surface area per unit weight is an important feature for novel product development. In this study, unfunctionalized silver (Ag) NPs (Ag 25nm) and organically functionalized Ag NPs (Ag 25–30nm F) were examined with or without dispersion sonication for their effect on toxicity in mouse N2A neuroblastoma cells. The NP sizes, shapes, and completeness of dispersion in solution were characterized with light microscopy, TEM, and UV-visible spectroscopy. Using light microscopy, large agglomerates of unfunctionalized Ag 25nm NPs were clearly evident whereas organically functionalized Ag NPs were found less agglomerated. Sonication of either particle type improved overall NP dispersion. Increasing concentrations of unfunctionalized Ag 25nm led to significant reductions in cell viability at concentrations between 25–100 µg/ml. This effect was concurrent with a loss of neurite extensions, cell shrinkage, and detachment from the surface. Unfunctionalized Ag NPs sonicated for 60 s demonstrated toxicity at concentrations as low as 10 µg/ml, suggesting a size-dependent effect of Ag NPs. In contrast, N2A cells incubated with functionalized Ag25–30F NPs retained similar morphologies to control cells at concentrations from 5–50 µg/ml. Mitochondrial membrane permeability assessed by fluorescent staining was increased in cells incubated with unfunctionalized Ag 25nm. Ag25–30F NPs had little or no effect on membrane permeability. These findings were consistent with the morphological observations and cell toxicity results. Our findings demonstrate that organic surface functionalization can drastically reduce the toxic effect of Ag NPs, an effect that can remain despite sonication perturbation commonly used for NP dispersion.

1390 NEUROINFLAMMATORY RESPONSES FOLLOWING EXPOSURE TO ENGINEERED NANOMATERIALS.

K. Sriram¹, D. W. Porter¹, S. Tsuruoka², M. Endo³, A. M. Jefferson¹, M. G. Wolfarth¹, G. M. Rogers¹, V. Castranova¹ and M. I. Luster¹. ¹CDC-NIOSH, Morgantown, WV, ²Mitsui & Co., Ltd., Toyko, Japan and ³Shinshu University, Nagano, Japan.

Multi-walled carbon nanotubes (MWCNT) and fine crystalline silica are largely used in the manufacture of composites and as blasting abrasives. While the widespread application and economic benefits of manufacturing such materials are highly promising, their adverse effects on the nervous system have not been fully investigated. Populations at greatest risk for exposure are industrial workers involved in the manufacturing, handling or utilization of such materials. Here, we evaluated the potential neurotoxic effects of exposure to MWCNT (67nm diameter, 5-13µm length) and silica (<2µm) in a murine model. Exposure (by pharyngeal aspiration) of mice to MWCNT (10, 20 or 40µg/mouse) or silica (1mg/mouse) elicited neuroinflammation in discrete brain areas. Specifically, the expression of CCL2, TNFα and IL6 increased (2 to 10-fold; P<0.05) in the olfactory bulb, hippocampus and frontal cortex, within 24h following exposure. This inflammatory outburst is a consequence of microglial activation, in response to perturbation of the neuronal microenvironment and function. Silica also induced the expression of IL1α, OSM, TLR2 and FGF2, effects not observed with MWCNT at the doses tested. In addition, both MWCNT and silica induced region-selective expression of metallothioneins I and II (>2-fold, P<0.05), metal binding proteins that are regulated by inflammatory stress signals and afford protection against oxidative injury. Whether the region-specific neurotoxicity observed following pharyngeal aspiration is due to systemic responses or possible redistribution of these materials to the brain remains enigmatic. In summary, our findings indicate that exposure to engineered nano- and fine particles can elicit neuroinflammatory changes.

1391 TOXICOLOGY OF TITANIUM DIOXIDE (TiO₂) NANOPARTICLES: 2. IMMUNOLOGICAL EFFECTS IN SUBCUTANEOUSLY AND INTRAVENOUSLY INJECTED MICE.

J. Weaver¹, T. H. Umbreit², T. J. Miller¹, J. Zhang¹, M. E. Stratmeyer² and V. J. Tomazic-Jezic². ¹DAPR, CDER FDA, Silver Spring, MD and ²DB/OSL, CDRH FDA, Silver Spring, MD.

Nanoparticles that are internalized are very likely to interact with the reticuloendothelial system (RES). This will be more important with therapeutic nanoparticles that may require multiple injections in significant quantities. We evaluated effects of TiO₂ particles injected either subcutaneously (SC) or intravenously (IV) on several standard measures of the immune response. Suspensions of ~ 4.7 nm uncoated TiO₂ (W470X, Degussa) particles were injected at total doses of 5600 mg/kg (SC) or 560 mg/kg (IV) over two days. At +1 day, there was no significant change in any cell population in peripheral blood except CD8+ in SC mice. In contrast, at day +5 there was a dramatic increase in granulocytes in circulation in SC as well as proportional decreases in circulating lymphocyte percentages. Macrophage percentages were not affected. No changes were observed in any cell population in draining lymph nodes. In SC mice, there was an increase in granulocyte number in the spleen, mirroring the increase in peripheral blood. In the spleen of IV injected mice a number of macrophages containing TiO₂ aggregates were observed in the marginal zone of the white pulp, suggesting a pathway for the interaction of TiO₂ with T cells. After 3 days of culture with Con-A, an apparent lack of T-cell proliferation was seen in lymph nodes from SC but not IV injected animals. This was seen by both direct measurement of proliferation and from B-cell:T-cell ratios after culture. Cytokine analyses of the mitogen stimulated spleen and lymph node cells indicated increased production of TNF-α, IL-6 and gamma-interferon. These results indicate that the acute inflammatory response seen in SC injected mice may well have secondary effects on the immune response. These findings, along with earlier results with polystyrene nanoparticles suggest that the immune system may be especially sensitive to effects of nanoparticles.

1392 SIZE AND SURFACE COATING DIFFERENCES IN SILVER NANOPARTICLE TOXICITY AND INFLAMMATORY RESPONSE IN JURKAT CELLS.

K. Szczublewski, S. Hussain, A. Schrand and J. Schlager. AFRL/HEPB, Air Force Research Laboratory, Dayton, OH.

The use of silver nanoparticles (Ag NP) in many commercially available products for their strong antibacterial and antiviral properties has led to questions about their toxicity to mammalian cells. Our studies show that their toxicity is dependent

upon their size, concentration, and chemical surface composition. First, we examined the effect of toxicity measures due to size for uncoated Ag NPs (10, 25, and 80 nm, Nanotechnologies, Inc.) and surface coated Ag NPs (15, 30, 80nm, Clarkson University). The primary NP sizes and morphologies were visualized and characterized with scanning and transmission electron microscopy. Previous studies show a size and concentration-dependent toxicity. However, in the current studies, the coated Ag NPs were in considerably less toxic than the uncoated Ag NPs. The MTT assay of cell viability shows that surface coated functionalized particles are not toxic while unfunctionalized particles are toxic at the exposure levels and time course studied. The initiating, irritation inflammatory response using IL-2 and TNF-α production showed significant increase in non-functionalized silver particles while only marginal induction in functional particles. The results indicate that toxicity depends on the surface based on coating deactivation rather than nominal size of the nanomaterial. Other characteristics including overall dimension, surface dissolution, etc. require further studies.

1393 MANUFACTURED NANO-SIZED ALUMINA PARTICLES INDUCE ENDOTHELIAL CELL DYSFUNCTION: IMPLICATIONS IN VASCULAR DISEASE.

E. Oesterling¹, X. Arzuaga², E. Lim², L. Bachas⁴, M. Toborek^{5,3} and B. Hennig^{1,2,3,1}. ¹Toxicology, University of Kentucky, Lexington, KY, ²College of Agriculture, University of Kentucky, Lexington, KY, ³Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY, ⁴Chemistry, University of Kentucky, Lexington, KY and ⁵Surgery, University of Kentucky, Lexington, KY.

Manufactured nanoparticles (MNP) display unique physicochemical characteristics due in part to their small size and large surface area that also make them highly desirable for a number of applications. Alumina or aluminum oxide is the most abundantly produced nanosized particle. Due to the extreme potential of MNP and their increased usage, occupational and public exposure will dramatically increase in the future. Human exposure via inhalation and ingestion can lead to increased blood concentrations. The vascular endothelium is uniquely susceptible to such xenobiotics circulating through the bloodstream. Inflammation or dysfunction of the endothelial layer has been shown to be an initiating event for the development of vascular diseases. It is hypothesized that MNP will lead to increased endothelial cell dysfunction, evidenced by increased inflammatory processes. Human umbilical vein endothelial cells and primary porcine pulmonary artery endothelial cells were treated with nano-sized (~10 nm) alpha-gamma alumina particles (10-100 µg/mL). It was found that alumina significantly increased mRNA expression of vascular cellular adhesion molecule-1 (VCAM-1) and E-selectin (ELAM-1). Alumina treatment also increased VCAM-1, ELAM-1, and intracellular adhesion molecule-1 (ICAM-1) protein determined by Western blot and immunofluorescence analysis. The protein induction of VCAM-1 was inhibited by co-treatment with an NF-κB inhibitor (BAY 11-7085), suggesting that the NF-κB signaling pathway may be responsible for VCAM-1 induction. These results suggest that nano-alumina particles can lead to endothelial cell activation and dysfunction by the induction of a number of pro-atherogenic inflammatory events and that these events may be modulated through the NF-κB pathway.

1394 THE PREFERENTIAL BINDING OF HUMAN SERUM PROTEINS TO NI, AL AND DIAMOND NANOPARTICLES.

S. C. Wasdo, S. M. Roberts, D. S. Barber, K. W. Powers and M. Palazuelos. University of Florida, Gainesville, FL.

In a physiological environment, proteins rapidly accumulate on particulate material that has a charged or hydrophobic surface. A growing body of research has demonstrated that these surface-bound proteins facilitate the detection of particulate material by phagocytic cells and help determine the distribution and clearance of these materials as well as the severity of secondary immune or inflammatory responses. Identifying these bound proteins and understanding how surface properties control protein binding is essential for predicting particle induced toxicity. As a first step in this process, the identity and relative proportion of proteins bound to the surface of nickel (nominal size 50 nm), aluminum (nominal size 51 nm) and diamond (nominal size 75 nm) nanoparticles following their exposure to human serum were determined. Particle bound proteins were isolated, assayed for total protein and labeled with ¹³C containing tags using an Applied Biosystems ICAT system. Each bound protein sample was combined with an equal amount of free serum proteins that had been labeled with analogous ¹²C containing tags and these combined samples were separated on a 1-D SDS PAGE gel. Protein bands were excised, subjected to in-gel trypsin digestion and analyzed by LC MS/MS following avidin purification. By quantifying the number of equivalent peptide sequences containing ¹³C and ¹²C tags, the relative proportion of proteins bound to each particle and present in free serum was determined. Although some serum proteins such as β-2-glycoprotein and α-2-HS-glycoprotein readily accumulated on all particles, each mate-

rial displayed a characteristic ability to preferentially bind various proteins. Differential binding of proteins, however, could not be explained simply by the surface charge of the nanoparticles which underscores the need for expanded studies to identify the relevant surface properties.

1395 QUALITATIVE AND QUANTITATIVE UPTAKE OF SiO₂-COATED FLUOROPHORE NANOPARTICLES.

L. Davis¹, C. Grabinski², A. Quade¹, D. Mattie¹, J. Schlager¹ and S. Hussain¹.
¹AFRL/HEPB, Air Force Research Laboratory, Dayton, OH and ²Department of Chemical and Materials Engineering, University Dayton, Dayton, OH.

In this research, the uptake of nanoparticle-based luminescent probes was examined for biological and environmental imaging and detection applications. Organic fluorophores currently used in cell imaging decompose during imaging, resulting in photobleaching. However, rare earth ions doped inside of silica nanoparticles are stable and do not photobleach, still emitting fluorescence with intensities comparable to single organic fluorophores. Silica-coated FITC (SiO₂-FITC) and rhodamine (SiO₂-RB) nanoparticles were measured using transmission electron microscopy (TEM). Both nanoparticles are close to 100 nm in diameter and possess similar spherical morphology. Cell viability was determined using MTT assay, and results showed that the SiO₂-FITC particles significantly decrease cell viability at 100 µg/mL, while SiO₂-RB nanoparticles are not toxic at the concentrations tested (0-100 µg/mL). Fluorescence microscope images show particles agglomerated within cells and verify that washing procedures are successful in removing particles not taken up into cells. A protocol to quantify the uptake of particles into cells using this washing procedure was developed using a fluorescence microplate reader. This method allows for the determination of the critical concentration of particle uptake into the cell, in order to relate this information to cell size and toxicity.

1396 PHOSPHATIDYL SERINE ENHANCES RECOGNITION AND UPTAKE OF SINGLE-WALLED CARBON NANOTUBES BY RAT BRAIN MICROGLIAL CELLS.

Single-walled carbon nanotubes (SWCNT) are a class of nanosized materials with wide applications in industry and medicine. Inhaled SWCNT have been shown to cause a robust inflammatory and oxidative stress response in the lung and cardiovascular system. Interactions with phagocytosing cells determine SWCNT elimination or spreading into different tissues. The challenge is how to make nanotubes delivered specifically to the target site. We established that macrophages do not effectively recognize non-functionalized SWCNT but readily engulf SWCNT coated with phosphatidylserine (PS), an "eat-me" signal for phagocytes. In the brain, important immunological functions are associated with the ability of microglial cells to exert phagocytic activity. As inhaled nanoparticles have been detected in the brain we were interested to study interactions of SWCNT with microglial cells. Microglial cells were isolated from postnatal rat brains and identified with CD11 antibody. Primary cultures were obtained with 70% microglial cell population which could be activated by lipopolysaccharide (LPS) to produce NO revealed by labeling of cells with a specific fluorogenic reagent, DAF-2DA. Further we studied phagocytosis of SWCNT by microglial cells. Cells were incubated with SWCNT coated with either fluorescently labeled nitrobenzoxadiazole (NBD)-PS or NBD-phosphatidylcholine (PC) for 2h. Fluorescent microscopy was applied and revealed that NBD-PS-SWCNT were a more preferred target of recognition and uptake by microglial cells than NBD-PC-SWCNT. Control experiments were performed to confirm that NBD-phospholipids remained bound to SWCNT. Thus, similar to macrophages, microglial cells utilize PS as a signal for effective recognition and engulfment of SWCNT. Supported by NIOSH OH008282, NIH HL70755, HL70809, AHA0535365N, Human Frontier Science Program.

1397 EVALUATION OF *IN VITRO* PENETRATION OF QUANTUM DOT NANOPARTICLES INTO HUMAN SKIN.

Topical exposure to nanoparticles is becoming more of an issue due to the increased use of nanosized ingredients in consumer products and because of possible occupational and environmental exposure. Because of their small size, there is concern

about the ability of these particles to penetrate through the barrier layer of skin. *In vitro* skin absorption studies were conducted using cadmium selenide quantum dots (Qdots) as a model nanoparticle because of their relative stability and intense fluorescence. Qdots (PEG coating, maximum emission 621 nm, hydrodynamic diameter 37 nm) were synthesized and formulated into an oil-in-water emulsion, and applied to human cadaver skin assembled in diffusion cells. Initial absorption studies were conducted for 24 hr followed by examination of sections from paraffin embedded skin using a fluorescence microscope. Fluorescence from Qdots appeared to be on or in the surface layer of skin (the stratum corneum), in the opening of hair follicles or in the folds (furrows) of the skin surface. Subsequent studies with Qdot emulsion formulations were conducted for 3, 8, and 24 hr. Frozen skin sections were evaluated for location of fluorescence with a laser scanning confocal microscope (LSCM). Fluorescence in the skin appeared to be found predominately in the stratum corneum with small amounts possibly penetrating further into the upper region of the viable epidermis. Spectral analysis of the fluorescence detected by LSCM showed that most fluorescence observed in the viable epidermis and all fluorescence in the dermis was due to autofluorescence. No significant elevation of cadmium (Qdots) was observed in receptor fluid samples taken beneath the skin. It therefore appears that absorbed Qdots were found predominately in the stratum corneum and they did not penetrate through the skin.

1398 ACCUMULATION OF NANOSCALE QUANTUM DOTS IN MULTIPLE ORGANS *IN VIVO*, FOLLOWING DERMAL EXPOSURE TO DERMABRADED, BUT NOT TAPE STRIPPED OR INTACT SKH-1 MOUSE SKIN.

N. V. Gopee¹, D. W. Roberts¹, C. Cozart¹, P. H. Siitonen¹, N. J. Walker², W. Yu³, V. L. Colvin³ and P. C. Howard¹.
¹National Center for Toxicological Research, U.S. FDA, Jefferson, AR, ²National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC and ³Rice University, Houston, TX.

There are currently many cosmetics and sunscreens that contain nanoscale materials such as titanium dioxide and zinc oxide. To date the possible long-term toxicological effects of percutaneous absorption of nanoparticles have not been determined. We used nanoscale polyethylene glycol coated cadmium selenide (CdSe) core quantum dots (QD) as surrogate nanoparticles, and evaluated (a) tissue Cd distribution following intradermal administration and (b) penetration into intact, tape stripped or dermabraded in mouse skin. Female SKH-1 mice were intradermally injected with 5 µL of 19 µM QD, and following sacrifice at 24 hr, tissues were removed and analyzed for Cd content using inductively coupled plasma mass spectrometry (ICP-MS). Approximately 6% and 1% of the administered Cd dose were found in the liver and regional lymph nodes, respectively, with lesser amounts detected in the kidney, spleen, and heart. QD were visualized in the skin and lymph nodes using fluorescence microscopy. These results support the use of liver and regional draining lymph nodes as sentinel organs for assessment of the distribution after dermal exposure of QD. QD were suspended in an oil-in-water emulsion at approximately 9 µM and applied at 2 mg/cm² to the dorsal skin of mice pretreated as follows: untreated; tape-stripped to remove the stratum corneum; dermabraded. Cd was not detected by ICP-MS in sentinel organs of untreated or tape-stripped mice 24-48 hr post application; however, in dermabraded mice, approximately 1% and 0.01% of the applied QD were detected in liver and lymph nodes, respectively. These results suggest that percutaneous absorption of nanoscale materials depends on skin barrier integrity, and hence the potential hazard of topically applied nanoscale materials needs further evaluation.

1399 CELLULAR MECHANISMS OF QUANTUM DOT NANOPARTICLE UPTAKE IN PRIMARY HUMAN EPIDERMAL KERATINOCYTES.

J. P. Ryman-Rasmussen, J. E. Riviere and N. A. Monteiro-Riviere. Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

The pathway of nanomaterial uptake into cells may be an important determinant of cytotoxic potential and effects. Quantum dots (QD) 655 with cationic (PEG-amine, NH₂), anionic (carboxylic acid, COOH), and neutral (PEG) surface coatings are non-selectively taken up by primary neonatal human epidermal keratinocytes (HEK) at low concentrations, but the mechanisms of cellular uptake are unknown. The global hypothesis tested herein is that QD surface coating is the primary determinant of the magnitude and mechanisms of cellular uptake by HEK. A fluorescence microplate screen was used to quantitatively determine differences in the magnitude of uptake of 10 nM QD 655 by HEK after 24 h at 37°C. Statistical comparison revealed significant differences among all coatings, with COOH > NH₂ > PEG. Also, we investigated the temperature dependence of QD uptake by performing similar experiments at a temperature of 4°C. Uptake of all three QD

types was significantly lower at 4°C than at 37°C. A commercially available ATP-dependent bioluminescence assay confirmed that cellular ATP levels were significantly decreased at 4°C compared to 37°C for QD of all three coatings. Taken together, these data indicated that uptake for QD of all three surface coatings is energy dependent and requires active, and not passive, mechanisms of cellular transport. Co-localization of QD 655 of all three coatings with a fluorescent dextran and immunofluorescently labeled clathrin and caveolin were used in conjunction with biochemical inhibitors of clathrin assembly and caveolae formation to identify the contribution of macro- and micropinocytotic mechanisms of uptake. These results showed a clear dependence of QD uptake on surface coating, as well as the involvement of active transport mechanisms in all three cases. This is of importance for understanding mechanisms of nanoparticle cytotoxicity and cellular fate, as well as for risk assessment. (Supported by EPA-STAR Program Grant RD-83171501.)

1400 EFFECTS OF MECHANICAL FLEXION ON THE PENETRATION OF AMINO ACID-DERIVATIZED NANOPARTICLES IN SKIN.

J. G. Rouse¹, J. P. Ryman-Rasmussen¹, J. Yang², A. R. Barron² and N. A. Monteiro-Riviere^{1,2}. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and ²Department of Chemistry and The Richard E. Smalley Institute for Nanoscale Science and Technology, Rice University, Houston, TX.

In the occupational setting, activities that involve repetitive motion can intensify mechanical loads that are applied to the skin. Processes, such as constant hand movements, can alter the permeability barrier of skin and thus increase risks associated with exposure to nanoparticles. In order to investigate the relationship between mechanical stressors and nanoparticle exposure, a flexing apparatus was designed to simulate repetitive wrist motion. Dermatomed porcine skin (400µm; n=3/time point) was fixed to the flexing device and topically dosed with 33.5 mg/mL of a fullerene substituted phenylalanine derivative (Baa-(FITC)-NLS). Skin was flexed for 60 or 90 min or left unflexed (control). Percutaneous absorption was assessed using a flow-through diffusion cell system for 8 h and 24 h. After each time point, samples were bisected and either frozen or processed for transmission electron microscopy (TEM). Frozen tissues were sectioned at 20µm to visualize Baa-(FITC)-NLS penetration by confocal microscopy. TEM was used to detect the fullerene within skin at the ultrastructural level. Skin flexed for 60 and 90 min depicted dermal penetration at 8 h, whereas Baa-(FITC)-NLS did not penetrate into the dermis of unflexed skin until 24 h. TEM analysis revealed nanoparticle localization within the intercellular spaces of the stratum granulosum, suggesting that penetration of the derivatized fullerene occurs through intercellular lipid moieties. These results suggest that external factors, such as a repetitive flexing motion and the associated mechanical stressors, can influence interactions that occur between nanoparticles and skin. These results are important for risk assessment of nanoparticles because they indicate that skin is an important route of exposure. (Supported by US EPA-STAR Program Grant RD-83171501 and National Academies Keck Futures Initiative.)

1401 PHARMACOKINETICS OF SKIN DISTRIBUTION OF QUANTUM DOT NANOPARTICLES IN ISOLATED PERFUSED SKIN.

H. A. Lee^{1,2}, N. A. Monteiro-Riviere¹, A. O. Inman¹, V. L. Colvin³, W. W. Yu³ and J. E. Riviere^{1,2}. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC, ²Biomathematics Program, North Carolina State University, Raleigh, NC and ³Department of Chemistry, Center for Biological and Environmental Nanotechnology, Rice University, Houston, TX.

The disposition and pharmacokinetics of nanoparticles in tissues are crucial parameters for targeting nanotechnology-based drug delivery systems as well as defining their toxicological profile. Quantum dots (QD) are an excellent model nanomaterial since they can be synthesized with varying surface coatings that modulate disposition, as well as being amenable to quantification in tissues due to their fluorescent intensity. QD consisted of a CdSe core (8.40nm x 5.78nm) surrounded by a polyethylene glycol (PEG) coating to yield a hydrodynamic size of approximately 57nm. The maximum emission wavelength of the QD is 621nm, with a quantum yield of 54%. QD were mixed with 300 ml of media and intra-arterially infused into the isolated perfused porcine skin flap (IPPSF) for 4 hrs (dose phase). QD media was replaced with fresh media and the IPPSF perfused for an additional 4 hrs (wash-out phase). The arterial and venous perfusate was sampled and the fluorescence quantitated. A physiological-based pharmacokinetic model of QD uptake and release from skin, using continuously monitored arterial and venous QD concentrations as input, was developed based upon a model previously used to quantitate platinum distribution (J Pharm Sci 78: 550-555, 1989) in the same experimental system.

Clear arterial-venous QD extraction was observed at all doses. A dose dependent uptake of QD into skin with delayed washout was observed at higher doses. Future studies will assess the effect of differential QD surface coatings on uptake and cutaneous distribution using model kinetic parameters as endpoints. These data begin to define nanomaterial characteristics that correlate to tissue uptake and persistence. (Supported by US EPA-STAR Program Grant RD-83171501.)

1402 DISTRIBUTION OF QUANTUM DOT NANOPARTICLES IN ISOLATED PERFUSED SKIN.

N. A. Monteiro-Riviere¹, J. P. Ryman-Rasmussen¹, A. O. Inman¹, V. L. Colvin³, W. W. Yu³ and J. E. Riviere^{1,2}. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC, ²Biomathematics Program, North Carolina State University, Raleigh, NC and ³Department of Chemistry, Center for Biological and Environmental Nanotechnology, Rice University, Houston, TX.

The disposition of nanoparticles in tissues is important for developing nanotechnology-based drug delivery systems as well as defining their toxicological profile. Quantum dots (QD), nanomaterials that naturally fluoresce, can be synthesized with surface coatings that modulate disposition and are amenable to localization in skin and other tissues due to intense fluorescence. QD were synthesized with a 8.40nm x 5.78nm CdSe core and polyethylene glycol (PEG) coating. The QD have a maximum emission wavelength of 621nm and a hydrodynamic size (in water) of approximately 57nm. Flow-through diffusion cells were used to assess QD penetration through porcine skin. The isolated perfused porcine skin flap (IPPSF) was used to determine whether intra-arterially infused QD would distribute to the skin or localize in the surrounding vasculature or tissue. QD were infused into the IPPSF (6.67nM, 3.33nM, 1.67nM, or 0.83nM) for 4 hr (dose phase), followed by an additional 4 hr perfusion (wash-out phase). Upon termination of the perfusion, the IPPSF was cut into 6 segments, flash-frozen in liquid nitrogen, cryosectioned at 25µm, and imaged by confocal microscopy. The images revealed epidermal blistering caused by QD aggregation and localization within capillaries, muscle, and subcutaneous tissue. The frequency of the QD decreased with a decrease in QD concentration and from the proximal to the distal end of each IPPSF. These results indicate aggregation of infused QD in the skin vasculature with concomitant blistering of the skin. This is important for risk assessment and drug delivery, since it shows the QD can aggregate in multiple tissues and cause pathological effects. Future studies will assess the effect of differential QD surface coatings on uptake and the cutaneous distribution. (Supported by US EPA-STAR Program Grant RD-83171501.)

1403 BIOLOGICAL INTERACTION OF FUNCTIONALIZED SINGLE-WALL CARBON NANOTUBES IN HUMAN KERATINOCYTES.

L. Zhang¹, L. Zeng², A. R. Barron² and N. A. Monteiro-Riviere¹. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and ²Department of Chemistry and The Richard E. Smalley Institute for Nanoscale Science and Technology, Rice University, Houston, TX.

Carbon nanotube-based nano-vectors, especially functionalized nanotubes, have shown potential for therapeutic drug delivery. Derivatized single-wall carbon nanotubes 6-aminohexanoic acid (AHA-SWNT), are soluble in aqueous stock solutions over a wide range of physiologically relevant conditions, however, their interactions with cells and their biological compatibility of AHA-SWNT has not been explored. Human epidermal keratinocytes (HEK) were dosed with AHA-SWNT ranging in concentration from 0.0000005-0.05 mg/mL. MTT cell viability decreased significantly (p< 0.05) from 0.00005 mg/mL to 0.05 mg/mL after 24 hr. Proinflammatory cytokines IL-6, IL-8, TNF-α, IL-10 and IL-1β were assessed in HEK. Cytokine analysis did not show a significant increase in IL-6 and IL-8 in the media containing 0.00005 mg/mL of AHA-SWNT from 1 hr to 48 hr. IL-6 tended to increase in cells treated with 0.05 mg/mL of AHA-SWNT from 1 to 48 hr, while IL-8 showed a significant increase at 24 hr and 48 hr. No significant difference (p< 0.05) in TNF-α, IL-10 and IL-1β expression was noted at any time point. Transmission electron microscopy of HEK treated with 0.05 mg/mL AHA-SWNT for 24 hr depicted AHA-SWNT localized within intracytoplasmic vacuoles in HEK. Treatment with the surfactant 1% Pluronic®F127 caused dispersion of the AHA-SWNT aggregates in the culture medium leading to less toxicity. These data clearly showed that the lower concentration of 0.00005 mg/mL of AHA-SWNT maintains cell viability and induces a mild cytotoxicity, while the 0.05 mg/mL of AHA-SWNT can initiate an irritation response that was demonstrated by the IL-8 release. (Supported by US EPA-STAR Program Grant RD-83171501 and the National Academies Keck Futures Initiative.)

1404 SIZE- AND DOSE-DEPENDENT TOXICITY OF SiO₂ NANOPARTICLES IN KERATINOCYTES.

K. O. Yu¹, C. Grabinski¹, C. Carlson¹, L. Davis¹, A. Quade¹, J. Boyer¹, W. Wang², B. Gu², J. Schlager¹ and S. Hussain¹. ¹Air Force Research Laboratory, Wright-Patterson Air Force Base, OH and ²Oak Ridge National Laboratory, Oak Ridge, TN.

Although manufactured nanomaterials (NM) are becoming widely used for advancing product technology, there is a serious lack of information concerning impact on human health and the environment as large scale production, pervasive product incorporation and probable release of NM become increasingly eminent. Regarding their possible effect on cytotoxicity, and from this NM implication on human health, our main focus was to investigate eukaryotic cellular toxicity resulting from nanoparticle (NP) exposure. This study examined the cytotoxic effects of well-dispersed amorphous silica (SiO₂) in mouse keratinocytes (MK). MK were exposed over a range of dose and average size distributions with homogeneous suspension of either 35, 51, 110 and 420 nm SiO₂ at 0, 10, 50, 100 and 200 µg/mL for 24 h. Medium lactate dehydrogenase (LDH) leakage was dose- and size- dependent with the two smallest NP. Exposure of 35 and 51 nm at 200 µg/mL at 24 h resulted in 70% and 40% of LDH leakage, respectively. However, no changes were observed for both 110 and 420 nm NP for any concentration. Tetrazolium salt (MTT) reduction assays studying cell mitochondrial viability/function showed for 35 and 51 nm at high concentrations (200 µg/mL) produced significant toxicity compare to the larger 110 and 420 nm particles. Additional studies were carried out to investigate if redox potential of cells such (GSH/GSSG ratio) and mitochondria membrane potential as mechanism of SiO₂ toxicity. GSH levels of 35 nm SiO₂ at concentrations of 50, 100 and 200 µg/mL were 90, 80, and 65%, respectively. Silica nanoparticles larger than 35 nm showed no changes in GSH levels when compared with controls. Based on the results, silica NP show size- and dose-dependent toxicity.

1405 PHYSICAL CHARACTERIZATION AND DERMAL IRRITATION IN RABBITS OF TITANIUM DIOXIDE NANOPARTICLES AND NANOFIBERS.

C. Crouch¹, G. Larsen², D. Vu², E. Luxford¹, D. Gray¹, P. Haney¹, E. Spellman¹, L. Ford¹ and A. B. Astroff¹. ¹Toxicology, Midwest Research Institute, Kansas City, MO and ²LNK Chemsolutions, Lincoln, NE.

The field of nanotechnology has increased significantly in recent years, with a variety of applications ranging from enhanced paint pigmentation, to quantum dot semiconductors, to controlled release pharmaceuticals. With this rapid growth has also come the need to better understand the safety of nanomaterials, including nanoparticles (NP) and nanofibers (NF). The first objective of this study was to characterize submicron titanium dioxide (TiO₂) particles and fiber samples produced using a novel approach by LNK Chemsolutions. The TiO₂ NP and NF were characterized using energy-dispersive x-ray spectroscopy (EDS) and scanning/transmission electron microscopy (SEM/TEM). SEM/TEM analyses revealed that the NP were 1-2 µm diameter agglomerations of 10-100 nm spheres. SEM analysis showed the NF to be 0.5-5 µm lengths of 50-100 nm diameter cylindrical rods. The second objective of this study was to evaluate the local tolerance of TiO₂ NP and NF. New Zealand white rabbits (6/group) were administered 1 mL of TiO₂ NP and NF at 7.5 mg/mL, or 20 mg/mL for 6 hours/day for 14 days to a shaved dose site approximating 10% of the body surface area. A concurrent control group was administered the vehicle alone. Body weight, food consumption and clinical observations were performed throughout the study and an assessment of the dose site was performed daily. At the conclusion of the study the animals were euthanized, underwent a gross necropsy, and a sample of the dermal dose site was collected for histopathologic evaluation. There were no effects on body weight or food consumption and no edema or erythema was observed at any time during the study with either the NP or NF at either concentration. Additionally, there were no significant pathology findings of the dermal dose site. Based on these results, the nanomaterials were well tolerated over the 14-day study, at up to 20 mg/cm², the highest dose tested.

1406 SINGLE-WALLED CARBON NANOTUBES INDUCE OXIDATIVE STRESS AND INFLAMMATION IN SKIN.

A. R. Murray¹, E. Kisin¹, C. Kommineni¹, V. E. Kagan³, V. Castranova^{1,2} and A. A. Shvedova^{1,2}. ¹PPRB, NIOSH, Morgantown, WV, ²West Virginia University, Morgantown, WV and ³Department of Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.

Single-walled carbon nanotubes (SWCNT) are a novel material with unique electronic and mechanical properties. A variety of different techniques are available for the production of SWCNT; however, the most common is via the disproportionation of gaseous carbon molecules supported on catalytic iron particles (HiPco). The

SWCNT produced by this method usually contain significant amounts of iron that may act as a catalyst of oxidative stress. The skin is a prime target for SWCNT toxicity as topical exposure can result during technologic processing and use. We hypothesized that SWCNT are toxic to the skin and the toxicity is dependent on their content of iron. The major toxicity mechanisms include induction of an inflammatory response, and oxidative stress exacerbated by iron. To test this hypothesis, the effects of SWCNT were assessed *in vitro* and *in vivo*. Exposure of human keratinocytes (HaCaT) revealed cytotoxicity in cells exposed to SWCNT; partially-purified SWCNT (0.25 weight % iron) exerted lower toxicity than unpurified SWCNT (40 weight % iron). Murine epidermal cells (JB6 P+) revealed a significant dose-dependent activation of AP-1 following exposure to unpurified SWCNT while partially-purified SWCNT did not activate AP-1. NF-κB was dose-dependently activated by both unpurified and partially-purified SWCNT. *In vivo* experiments evaluated the skin of SKH-1 mice following 5 days of unpurified SWCNT exposure (2, 4, or 8 mg/kg). Depletion of glutathione, increased myeloperoxidase activity, and an increase in IL-6 levels were observed following exposure to unpurified SWCNT. Histological evaluation of the skin following SWCNT exposure revealed an increased number of mast cells and polymorphonuclear leukocytes around hair follicles of the mouse skin. These data indicate that dermal exposure to SWCNT, particularly unpurified SWCNT, can result in inflammation, oxidative stress and dermal toxicity during occupational exposures.

1407 ANTAGONISM OF THE ARYL HYDROCARBON RECEPTOR.

K. Mitchum and E. V. Hestermann. *Biology Department, Furman University, Greenville, SC.*

The aryl hydrocarbon receptor (AHR) binds to a variety of ligands and subsequently controls transcription of target genes, which mediate the toxic or carcinogenic effects of these compounds. Many AHR agonists and partial agonists are known to induce transcription; however, a pure antagonist of the AHR has not been discovered. This ideal pure antagonist would competitively inhibit the effects of a potent AHR agonist, such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Previous reports indicate that 3'-methoxy-4'-nitroflavone (MNF), 3,3'-diindolylmethane (DIM), 6-methyl-1,3,8-trichlorodibenzofuran (MCDF), α-naphthoflavone (ANF), salicylamide (SAL), and resveratrol (RES) are potential antagonists. To measure the antagonistic properties of these compounds, we performed dose-response experiments with TCDD and the potential antagonists in H1G1 mouse hepatoma cells, which stably express green fluorescent protein regulated by AHR-responsive elements. We also tested these compounds' induction of endogenous CYP1A1 and CYP1B1 mRNA expression in H1G1 cells. ANF and RES induced some expression of both the reporter and endogenous genes and did not effectively antagonize TCDD's induction of the reporter or endogenous genes. MCDF and MNF acted as partial agonists by inducing some expression and inhibiting TCDD's induction of the reporter and endogenous genes. While both DIM and SAL were effective antagonists of the reporter gene, SAL did not effectively antagonize TCDD's induction of the endogenous genes. Only DIM potentially antagonized TCDD's induction of the endogenous genes. Next, we measured the ligands' regulation of CYP1A1 and CYP1B1 mRNA expression in MCF-7 breast cancer cells. The efficacy of the compounds in the two cell types differed, suggesting the efficacy of AHR ligands could be species- and/or tissue- specific. Further research should investigate the mechanisms of the differences between the induction of endogenous and reporter genes in H1G1 cells and between the induction of the endogenous genes in H1G1 and MCF-7 cells.

1408 REGULATION OF GENE EXPRESSION BY THE ARYL HYDROCARBON RECEPTOR IN BREAST TUMOR CELL LINES.

L. Fraser and E. V. Hestermann. *Biology Department, Furman University, Greenville, SC.*

Previous reports have shown differences between estrogen receptor (ER)-positive and ER-negative breast cancer cells in regulation of gene expression by the aryl hydrocarbon receptor (AHR). We compared immortal (MCF-10F) and transformed (BP-1) ER-negative cells as well as ER-positive MCF-7 cells. While previous studies have found that AHR agonists do not induce cytochrome P450 1A1 (CYP1A1) expression in ER-negative cell lines, we found that expression of CYP1A1 and cytochrome P450 1B1 (CYP1B1) mRNAs is induced by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in MCF-10F cells, BP-1 cells, and MCF-7 cells. In contrast, 3'-methoxy-4'-nitroflavone (MNF), an AHR antagonist, does not increase mRNA expression of CYP1A1 or CYP1B1 in MCF-10F or MCF-7 cells, but it does increase CYP1A1 and CYP1B1 expression in BP-1 cells. Chromatin immunoprecipitation assays showed increased occupancy of CYP1A1 and CYP1B1 regulatory regions by AHR in both MCF-10F and BP-1 cells treated with TCDD. This increased promoter occupancy was not found in MCF-10F cells treated with MNF. We conclude that gene expression and promoter occupancy in response to AHR ligands are dependent upon differences among breast cell phenotypes that are not limited to ER status.

1409 THE ROLE OF THE ARYL HYDROCARBON RECEPTOR IN DIOXIN-INDUCED PIGMENTATION.

S. Luecke, M. Backlund and A. Rannug. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

Exposure of humans to dioxins is often manifested by alterations in the skin, mainly the development of epidermal cell hyperplasia (chloracne) and hyperpigmentation. Dioxin mediates most of its toxic effects by binding to the aryl hydrocarbon receptor (AhR), a ligand dependent transcription factor. In this study we investigated the effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on human melanocytes, the melanin producing cells of the skin. We used normal human melanocytes as an *in vitro* model system to study the effects of TCDD on pigmentation. RT-PCR revealed that melanocytes express both AhR and aryl hydrocarbon receptor nuclear translocator (ARNT). The functionality of this pathway in melanocytes was determined by studies of the expression of AhR-regulated genes. Exposure of melanocytes to TCDD resulted in a dose-dependent increase in CYP1B1 mRNA levels. Interestingly, an increase in CYP1A1 mRNA levels was not observed, although induction of CYP1A1 mRNA levels is a common response to TCDD in most cells. Melanocytes responded to TCDD (1-10nM) exposure with the activation of tyrosinase, a key enzyme in the melanogenic pathway. Tyrosinase activity was measured in an absorbance based enzyme activity assay by the formation of dopachrome after the addition of L-dopa. The tryptophan photoproduct 6-formylindolo[3,2-b]carbazole (FICZ), another high affinity ligand for the AhR, seems also to increase tyrosinase enzyme activity. AhR antagonists, such as 3'-methoxy-4'-nitroflavone and alpha-naphthoflavone, abolished the effects of TCDD on tyrosinase activation suggesting an involvement of the AhR in mediating dioxin-induced pigmentation.

In summary, the results of this study show that normal human melanocytes *in culture* respond to TCDD exposure with activation of the melanogenic enzyme tyrosinase. The activation of the melanogenic pathway by TCDD is most likely mediated via the AhR receptor.

1410 ADDRESSING AHR ACTIVATION BY PHARMACEUTICALS.

R. Ochalski¹, B. Matlock¹, A. Scally², M. Graham², S. Culp¹, M. Ribadeneira¹, A. Dudley¹, A. Ellis¹ and M. Otieno¹. ¹AstraZeneca Pharmaceuticals, Wilmington, DE and ²AstraZeneca Pharmaceuticals, Charnwood, United Kingdom.

Activation of the aryl hydrocarbon receptor (AhR) is a liability to be avoided for pharmaceuticals. The concern is to establish a threshold for toxicity for AhR activators. AhR is a transcription factor that activates several genes the most commonly studied of which is CYP1A and whose induction is used as a marker of AhR activation. The challenge for discovery toxicologists is how to assess the risk associated with AhR activation for small molecules. The aim of these studies was: (1) develop & validate *in vitro* models to detect AhR activation and (2) establish a correlation between AhR activation and toxicity *in vivo*. HepG2 cells transiently transfected with a DRE-luciferase reporter construct were used to screen > 400 pharmaceuticals. The EC50s and efficacy, expressed as % of TCDD, for benchmark compounds in this system were: TCDD (0.42-1nM, 100%), β -naphthoflavone (10 μ M, 117%), 3-methylcholanthrene (0.42 nM, 172%), and Benzantracene (6 μ M, 160%). The EC50s and efficacy for the pharmaceuticals ranged from 500nM to 10 μ M and 10 to 150% of TCDD. In addition, the small molecules that activated AhR also induced CYP1A1 mRNA in rat hepatocytes. The AhR antagonist 4-methoxy-3-nitroflavone mediated a dose-dependent inhibition of AhR activation confirming the small molecules mediate their effects via the AhR. To establish a correlation between the *in vitro* endpoints and *in vivo* toxicity, several compounds with AhR activities ranging from 10 to 102% of TCDD were dosed to rats and resulted in dose-dependent increases in CYP1A up to 75-fold after a single dose. In 2 week studies (> 7 compounds), toxicity consistent with AhR activation was observed. The compound with the highest *in vitro* efficacy (102%) had the most severe effects (CYP1A induction of 1124-fold, steatosis in the liver, elevated TSH). CYP1A induction in rat, dog, and human hepatocytes was evaluated to establish risk assessment to man. The same pattern of CYP1A induction was observed in all species demonstrating that preclinical data could be used for human risk assessment.

1411 A HIGH THROUGHPUT FLUORESCENT IMAGING BASED ASSAY FOR INDUCTION OF CYP1A1/2 - APPLICATION IN DRUG DISCOVERY.

H. J. Garside¹, N. Brown¹, M. Graham² and M. Sullivan¹. ¹ASTL, AstraZeneca, Loughborough, United Kingdom and ²Safety Assessment, AstraZeneca, Loughborough, United Kingdom.

Early identification of new chemical entities (NCE) with the potential to activate the Aromatic Hydrocarbon Receptor (AhR) is important for the reduction of compound attrition in the late stages of the drug discovery process. The activation of

the aryl hydrocarbon receptor (AhR), the key transcriptional regulator of CYP1A1/2 expression, occurs through a diverse set of chemical structures, therefore CYP1A1/2 inducers cannot easily be predicted by their chemical properties alone. Here we describe the development of an imaging based assay to assess potential of NCE to activate the AhR by quantification of CYP1A1/2 expression in the rat hepatoma cell line H4-II-E-C3 using specific antibodies. High assay throughput was achieved by the use of both 96 and 384 well culture systems, the IN Cell 3000 confocal imaging platform and automated analysis of fluorescent images using specific bespoke algorithms. Treatment of H4-II-E-C3 cells, cultured in either 96 or 384 well plates, with the prototypic CYP1A1 inducer TCDD produced a significant increase in both the total intensity of CYP1A1 expression and the number of cells within the population showing fluorescence above the basal level. This assay is able to demonstrate the efficacy and potency of AhR agonists, showing good correlation with both the activation of the AhR, as measured by receptor translocation, and transcriptional upregulation of CYP1A1 mRNA. To conclude, we have developed an automated high throughput imaging assay to allow screening of compound collections for potential CYP1A1/2 protein induction.

1412 DIFFERENTIAL RECOGNITION OF LXXLL PEPTIDE MOTIFS BY THE Q-RICH SUB-DOMAIN OF THE MOUSE AND HUMAN ARYL HYDROCARBON RECEPTOR.

C. A. Flaveny, R. K. Reen and G. H. Perdew. *The Department of Veterinary Sciences, The Pennsylvania State University, University Park, PA.*

A number of cofactors have been shown to bind to the human and mouse aryl hydrocarbon receptor transactivation domains (TAD) including the steroid receptor coactivators 1 (SRC-1), nuclear coactivators 2 (NcoA2, SRC-2), p300/CBP co-integrator protein (p/CIP) and CREB binding protein (CBP). In addition to interspecies differences in receptor-ligand binding affinity, the human and mouse AhR receptor C-terminal TADs share only 58% amino acid sequence identity. The aryl hydrocarbon receptor (AHR) has a complex transactivation domain comprising proline/serine/threonine-rich (PST) glutamine (Q-rich) and acidic amino acid residue sub-domains. We wanted to test whether the mouse AHR (mAHR) and the human AHR (hAHR) Q-rich sub-domains differentially recruit LXXLL-motif coactivators. Using Gal4 DNA binding domain (Gal4DBD) LXXLL-motif fused peptides we were able to map the critical LXXLL binding sequence of the hAHR to amino acid residues 663-688. Interestingly, increasing amounts of expressed LXXLL-motif fused Gal4DBD-peptides dramatically differed in their ability to influence the DRE-driven transactivation potential of the mAHR and hAHR in Cos-1 cells. Co-expressing increasing amounts of coactivators also differentially altered Gal4DBD mAHR Q-rich and hAHR Q-rich fusion protein activity as measured in Gal4-driven reporter assays. The Gal4DBD hAHR Q-rich fusion protein also showed relatively higher activity than the cognate mAHR sub-domain. Therefore the hAHR Q-rich domain may prove to be a more significant component in the overall transactivational activity of the human receptor compared to the same sub-domain in the mAHR. These findings suggest that the human and mouse AHR may both display differential recruitment of coactivators and hence potentially exhibit divergent regulation of specific target genes.

1413 DEVELOPMENT OF AN AHR ANTAGONIST USING PROTACS APPROACH: A POTENTIAL APPROACH FOR CHEMOPREVENTION.

D. Puppala², H. Lee¹, K. Kim² and H. Swanson¹. ¹University of Kentucky, Lexington, KY and ²University of Kentucky, Lexington, KY.

Activation of the aryl hydrocarbon receptor (AHR) leads to many adverse biological effects including tumor promotion, epithelial hyperplasia, endocrine disruption and immunodeficiency. Emerging evidence also links activation of the AHR to the development of type II diabetes. The AHR is thought to mediate its biological effects via its upregulation of a number of target genes. Agonists of the AHR includes dioxin (2, 3, 7, 8 tetrachlorodibenzo-p-dioxin) and polyhalogenated aromatic hydrocarbons found in cigarette smoke and other air pollutants. Our hypothesis is that blocking the actions of the AHR via appropriate AHR antagonists is a valid approach to be used for treatment of a number of human disease states. In the current project we have focused on the development of an AHR antagonist using the PROTACS (PROteolysis Targeting Chimeric molecules) approach. PROTACS is a novel approach of tagging small recognition sequences of a specific E3 ubiquitin ligase complex on to a known ligand for the receptor of interest (AHR) for targeting its degradation via the 26S proteasomal pathway. PROTACS contain a ligand for the AHR, a recognition sequence for the pVHL E3 ubiquitin ligase complex and a linker moiety. The initial, parent compound that serves as the AHR ligand in these studies is apigenin. Here, we demonstrate the design, efficacy and specificity of apigenin bound PROTAC molecules. The design of the apigenin-Protacs was initiated by synthesizing apigenin derivatives that retained binding to the AHR and antagonistic activity. The Apigenin-PROTACS proved to be capable of degrading

the AHR in both HepG2 (human hepatoma) and NHK (Primary human keratinocytes) cells in a time-dependent and concentration-dependent manner. These initial experiments demonstrate that the PROTAC approach can be effective in inhibiting the actions of the AHR blocking AHR-mediated effects.

1414 EFFECTS OF 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN (TCDD) ON SKIN PIGMENTATION AND ADIPOSE TISSUE HOMEOSTASIS.

A. Rannug, S. Luecke and F. Moncek. *Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.*

The overall aim of our current research is to advance the knowledge of the endogenous function of the aryl hydrocarbon receptor (AhR) and to clarify the mechanisms behind TCDD toxicity. We use in vivo and in vitro models and activate the AhR with TCDD and the suggested endogenous ligand, the tryptophan photo-product 6-formylindolo[3,2-b]carbazole (FICZ). Our hypothesis defines functions for the AhR in responses to light (adaptation and stress-responses) and in feed-back systems that regulate levels of ligands via induction of metabolizing enzymes. TCDD, because of its high lipid solubility, is concentrated in fat and in the keratinized compartment of epidermis. In humans, epidermal hyperplasia and hyperpigmentation of skin areas are the most well established dioxin related effects. In addition, disturbed lipid metabolism has been reported. We have detected that TCDD and FICZ both activate melanogenesis in primary human melanocytes via activation of the melanin producing enzyme tyrosinase. The results point to a possible function of the AhR in mechanisms that give protection against light. We also study stress-related acute effects in rat adipose tissue and primary adipocytes. Treatment of Sprague-Dawley rats with a dose of 50 µg TCDD per kg body weight led to significantly increased plasma corticosterone levels already one day post treatment. In epididymal fat from the exposed rats pronounced effects on the expression of several adipose specific genes such as leptin, adiponectin and C/EBPα were observed five days post TCDD treatment. These effects, which may be explained by reduced preadipocyte maturation, coincided with reduced plasma triglyceride and leptin levels. It must be kept in mind that this response to a high dose of TCDD on lipid metabolism contrasts with the increased triglyceride levels seen in humans with chronic low dose exposures. In conclusion, our data show that the effects seen after dioxin exposure in humans can be studied experimentally and may be related to physiologic roles of the AhR.

1415 ARYL HYDROCARBON RECEPTOR ANTAGONISTS INCREASE UV-INDUCED APOPTOSIS IN HUMAN ORAL KERATINOCYTES.

R. Wu and H. Swanson. *University of Kentucky, Lexington, KY.*

The aryl hydrocarbon receptor (AHR) is a ligand activated transcription factor that not only regulates xenobiotic metabolism, but also cell fate decisions. Our overall goal is to determine whether modulation of the AHR signaling pathway may be useful for therapeutic interventions. We have previously shown that mouse hepatoma cells lacking expression of the AHR (LA1) were more sensitive to UV-induced apoptosis than their wild-type counterpart (Hepa1c17). These results implied that the AHR may play a protective role towards apoptosis mediated by intrinsic stimuli. In this report, we have used human oral keratinocytes to: 1) determine whether the protective role of AHR is cell-type specific, 2) compare the effectiveness of different AHR antagonists in their ability to increase apoptosis susceptibility in human oral keratinocytes and 3) determine whether human oral squamous cell carcinomas may vary in their AHR expression levels. Our results indicate that AHR plays a role in conferring apoptosis susceptibility in human oral keratinocytes that is similar to that described in mouse hepatoma cells. Further, like the AHR antagonist, 3'-methoxy-4'-nitroflavone, apigenin and kaempferol are effective in increasing UV light induced apoptosis in oral keratinocytes. Finally human oral squamous cell carcinomas vary dramatically in AHR expression levels. Future experiments will determine whether the apoptotic response varies in these carcinoma cell lines in a manner that corresponds to their AHR levels and whether it is modulated upon treatment with AHR antagonists.

1416 MODIFICATION OF ARYL HYDROCARBON RECEPTOR CONTROLLED CYP1A1 TRANSCRIPTION BY PHORBOL-12-MYRISTATE-13-ACETATE.

B. D. Hollingshead, P. Ramadoss and G. H. Perdew. *Department of Veterinary and Biomedical Sciences and The Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA.*

The aryl hydrocarbon receptor (AHR) is a ligand-inducible transcription factor that regulates the expression of a battery of metabolic genes. The protein kinase C (PKC) family of serine/threonine kinases consists of a least ten members, and these proteins collectively are involved in regulating numerous biological processes. Several reports have concluded that PKC plays a role in the regulation of AHR signal transduction. Additionally, AHR transcriptional activity is modulated by the phorbol ester phorbol-12-myristate-13-acetate (PMA). The ability of PMA to en-

hance AHR activity using luciferase reporter systems is believed to be attributed to its PKC activating properties, and has been termed the "PMA effect". In contrast to reporter gene systems which exhibit enhanced expression of an AHR-driven CYP1A1 luciferase construct, we demonstrate here that ligand-induced endogenous CYP1A1 and CYP1B1 mRNA levels are greatly reduced in HepG2, HeLa, and MCF-7 cell lines when PMA (81 nM) is co-administered with the AHR ligand 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) for short time periods (2-4 h). However, when cells are exposed to TCDD for longer periods of time (24 h) CYP1A1 levels are elevated in the presence of PMA. In order to determine if the PMA-mediated decrease in CYP1A1 expression results from alterations in chromatin remodeling chromatin immunoprecipitation experiments were performed in MCF-7 cells. These studies showed that upon a 1 h co-treatment of PMA and TCDD the amount of acetylated histone-4 and RNA polymerase II is decreased at the CYP1A1 enhancer and promoter, respectively. Therefore, these studies show that the PMA-mediated decrease of AHR transcriptional activity results from the reduced amount of chromatin remodeling in response to ligand activation of the AHR. This data shows that PMA treatment causes a rapid response that inhibits TCDD-induced pre-transcriptional chromatin remodeling on the AHR-responsive gene, CYP1A1.

1417 CHARACTERIZATION OF ARNT (ARYL HYDROCARBON RECEPTOR TRANSLOCATOR) ISOFORMS FROM *MYA ARENARIA*.

R. J. Van Beneden^{1,2}, R. A. Butler¹, T. O'Toole² and L. McClellan². ¹*School of Marine Sciences, University of Maine, Orono, ME* and ²*Department of Biochemistry, Microbiology and Molecular Biology, University of Maine, Orono, ME.*

The aryl hydrocarbon receptor nuclear translocator (ARNT) is a member of the bHLH-PAS family of transcription factors. Member proteins contain well-conserved DNA binding and heterodimerization domains, although the transactivation domains show considerable sequence divergence. Vertebrate ARNT is constitutively expressed and plays a role in regulating gene expression in response to changes in cellular environment. For example, exposure to aryl hydrocarbons results in binding to another bHLH protein and ARNT dimerization partner, the AHR. A previous study revealed that some invertebrate species, including *M. arenaria*, *D. melanogaster* and *C. elegans*, have AHR homologs that apparently do not bind prototypical exogenous ligands. A single AHR gene and four distinct forms of ARNT have been identified in *M. arenaria*. All four ARNTs contain intact PAS A domains, but two have truncated PAS B domains which may influence ARNT interaction with AHR and other dimerization partners. As part of the characterization of these ARNT forms, a yeast two-hybrid system was used to test protein interaction between clam AHR and each form of ARNT. Preliminary data suggest clam AHR interacts with all forms of clam ARNT and one form interacts with human AHR. To better understand their function, tissue expression in the clam was assessed by Western blot with a pan-ARNT polyclonal antibody. Western blots indicate ARNT-A1 (72 kDa) is the predominantly expressed ARNT protein and is present in all tissues tested. ARNT-D3 protein (42 kDa) is seen in both gill and gonad tissue and ARNT-C2 (54 kDa) protein is expressed primarily in gill. ARNT-2B2 protein (45 kDa) is rarely expressed and only in gonad. Preliminary analysis has not identified a correlation between ARNT expression and gender, season or stage of gametogenesis. Since ARNT is known to be involved several vertebrate important signaling pathways, further characterization of ARNT expression may provide additional understanding of its role.

1418 INHIBITION OF ESTROGEN-MEDIATED GENE EXPRESSION RESPONSES BY DIOXIN IN THE UTERI OF C57BL/6 MICE.

D. R. Boverhof¹, J. C. Kwekel¹, L. D. Burgoon¹, K. J. Williams² and T. R. Zacharewski¹. ¹*Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI* and ²*Pathobiology & Diagnostic Investigation, Michigan State University, East Lansing, MI.*

2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) exhibits diverse antiestrogenic properties including the inhibition of estrogen-induced uterine growth and proliferation. One proposed mechanism involves the inhibition of estrogen-mediated gene expression through ER/AhR crosstalk. However, only a limited number of inhibited responses have been identified which are unlikely to fully account for all of the uterine antiestrogenic effects of TCDD. Therefore, the effects of TCDD on ethynyl estradiol (EE) mediated gene expression were investigated in the immature ovariectomized C57BL/6 uterus using cDNA microarrays with complementary physiological and histological phenotypic anchoring. Mice were gavaged with either vehicle, 3 daily doses of 10 µg/kg EE, a single dose of 30 µg/kg TCDD or a combination of EE and TCDD and sacrificed after 4, 12, 24 and 72 hours. TCDD cotreatment inhibited EE-mediated increases in uterine wet weight by 37, 23 and 45% at 12, 24 and 72 hrs, respectively. In addition, TCDD reduced EE-mediated stromal edema, hypertrophy and hyperplasia and induced marked luminal epithelial cell apoptosis. A 2 × 2 factorial microarray design was used to identify EE- and TCDD-specific gene expression responses as well as their interactive effects. Of the

2,753 uterine genes regulated by EE, only 133 were significantly modulated upon cotreatment with TCDD, indicating a gene-specific inhibitory response to TCDD. The EE-mediated induction of many genes, including trefoil factor 1 and keratin 14, were inhibited by greater than 90% upon cotreatment with TCDD. Functional annotation of these inhibited responses was associated with cell proliferation, water and ion transport, and maintenance of cellular structure and integrity. These responses correlate with the observed histological alterations and may collectively contribute to the antiestrogenic effects of TCDD on the uterus. Funded by NIH R01 ES12245

1419 SCREENING FOR ESTROGEN RECEPTOR (ER ALPHA) LIGANDS USING HIGH CONTENT NUCLEAR TRANSLOCATION ANALYSIS.

A. Dull¹, E. Martinez², G. Hager³ and J. McMahon⁴. ¹Molecular Targets Development Program, National Cancer Institute, SAIC-Frederick, Frederick, MD, ²Hamon Center for Therapeutic Oncology Research, UT Southwestern Medical Center at Dallas, Dallas, TX, ³Laboratory of Receptor Biology and Gene Expression, National Institutes of Health, Bethesda, MD and ⁴Molecular Targets Development Program, Center for Cancer Research, National Cancer Institute, Bethesda, MD.

The discovery of new drugs targeting the estrogen receptor (ER α) which would exhibit reduced incidence of adverse side effects acting selectively in different tissues is crucial for the treatment of breast cancer and for hormone replacement therapy. ER α undergoes nucleo-cytoplasmic shuttling, yet the nuclear compartment is strongly favored even in the absence of hormonal ligands. Our goal was to design an ER α whose cellular distribution would be responsive to estradiol-like ligands and to use this receptor to carry out drug screens based on nuclear translocation. To accomplish this, the N-terminus, DNA binding domain, hinge and partial ligand binding domain regions of the GR (containing the nuclear localization signal) was fused with most of the ER ligand binding domain and tagged with the green fluorescent protein (GFP). A high content imaging system was used for image acquisition and analysis of translocation dynamics. Compounds that elicited a translocation value of 85 or greater were identified as hits. We have screened 13,868 synthetic compounds and pure natural products, which produced 390 primary hit compounds, and the primary hit number was reduced to 41 compounds after filtering the hits for cytotoxic false positive results, which generated a hit rate of 0.3% for the screen. Cherry picking experiments were used to eliminate false positive fluorescent DNA-binding compounds, which further reduced the hit rate to 0.058% resulting in 8 primary hit compounds. These compounds will be further tested for ER α activity in secondary assays by the principal investigator's laboratory.

1420 CROSS-TALK BETWEEN ARYL HYDROCARBON RECEPTOR AND PREGNANE X RECEPTOR PATHWAYS.

X. Gu¹, S. Ke¹, D. Liu¹, T. Sheng² and Y. Tian¹. ¹Texas A&M University, College Station, TX and ²UTMB, GALVESTON, TX.

Pregnane X receptor (PXR) and aryl hydrocarbon receptor (AhR) are two ligand-dependent transcription factors that regulate the expressions of distinct sets of genes. Many genes regulated by PXR and AhR are important for phase I, II and III metabolic detoxification. Research on PXR-regulated gene expression has been facilitated by the identification of the regulatory module (XREM) around -7 kb of cyp3a4 genes which is mainly regulated by PXR. We have developed a HepG2 cell-based PXR-driven luciferase assay in order to analyze cyp3a4 inducers in cell culture. Interestingly, we found that rifampicin and TCDD show synergistic induction of the PXR/XREM-driven luciferase reporter gene expression. The cyp3a4 mRNA was also synergistically induced by cotreatment with TCDD and PXR ligand (rifampicin), suggesting cross-talk between PXR and AhR regulated pathways. Overexpression of AhR enhanced the synergistic activation, while small interfering RNA targeting AhR diminished the magnitude of synergistic activation in reporter gene assay. Using GST-pulldown and coimmunoprecipitation assays, we found a direct interaction between the AhR and PXR. Consistent with domain-specific interaction between AhR and PXR, AhR expression plasmids with different domain deletions showed differential trans-activities in reporter gene assay with PXR-driven CYP3A4-luc gene. These data suggested that AhR and PXR pathways crosstalk through direct interaction between AhR and PXR to regulate mutual transcription activity (Supported in part by NIEHS Grants ES09859).

1421 THE PREGNANE X RECEPTOR AND THE MAJOR HISTOCOMPATIBILITY COMPLEX CLASS II GENES.

E. Fuentes-Mattei^{1,3}, L. C. Quattrochi², P. S. Guzelian² and B. D. Jimenez^{1,3}. ¹Biochemistry, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, ²Medical Toxicology, University of Colorado Health Sciences Center, Denver, CO and ³Center for Environmental and Toxicology, University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico.

Several studies have shown that the Pregnane X Receptor (PXR) acts as a sensor to a broad range of natural and synthetic xenobiotics mediated through the induction of the detoxification enzyme CYP3A and other drug metabolizing enzymes.

Adding to this classical response, we have shown that PCN (a PXR activator in rodents) induces transcription and protein levels of Major Histocompatibility Complex class II (MHC-II) genes in primary rat hepatocytes. These findings triggered further research on the role of PXR and its activators on the regulation of genes involved in the immune response. The interest in MHC-II gene expression in disease state has recently increased within the medical community. There is data suggesting that MHC-II in non-Antigen Presenting Cells such as tumor cells can boost the immune response against itself, however, the mechanism involved in its ectopic expression is still unknown. To investigate further the molecular mechanism by which PXR and its activator rifampicin induces transcription of MHC-II genes, we performed a series of time course and dose response experiments in various cell lines. Human fibrosarcoma (HT-1080), bronchial epithelial cells (BEAS-2B) and hepatoma cells (HepG2) were treated with rifampicin and MHC-II mRNA levels evaluated. Preliminary results showed induction of HLA-DR α (2-fold) and HLA-DQB1 (5-fold) mRNAs in HT-1080 cells. The presence of human PXR1 mRNA in HT-1080 fibrosarcoma treated with rifampicin was confirmed by means of RT-PCR. HLA-DR α mRNA expression was also found to be induced in HepG2 cells treated with rifampicin. These findings support the idea of a potential involvement of PXR by enhancing transcriptional induction of MHC-II genes. This research adds a new dimension to a synchronized relationship of immune and detoxification regulation through PXR function as means of a xeno-protective mechanism.

1422 PPARB/D PROTECTS AGAINST EXPERIMENTAL COLITIS THROUGH A LIGAND-INDEPENDENT MECHANISM.

H. E. Hollingshead^{1,2}, K. Morimura⁴, M. Adachi⁴, M. J. Kennett¹, A. N. Billin³, T. M. Willson³, F. J. Gonzalez⁴ and J. M. Peters¹. ¹Department of Veterinary and Biomedical Sciences and The Center of Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA, ²Biochemistry and Molecular Biology, The Pennsylvania State University, University Park, PA, ³Nuclear Receptor Discovery Research, GlaxoSmithKline, Research Triangle Park, NC and ⁴Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.

PPAR γ and PPAR β/δ have overlapping roles in the negative regulation of genes involved in inflammatory responses. Recent reports suggest that ligand activation of PPAR γ in the epithelium of the colon protects against experimentally induced colitis in mice. Since PPAR β/δ can negatively regulate inflammation in a number of cell types, and is highly expressed in the epithelial cells of the colon, PPAR β/δ may also have a role in experimental colitis. In these studies, colitis was induced by administration of dextran sodium sulfate (DSS) to wild-type and PPAR β/δ -null mice, and a cohort of mice were treated with the PPAR β/δ specific ligand GW0742. Symptoms of disease and expression of inflammatory cytokines were examined to determine whether the absence of receptor expression and/or ligand activation of the receptor influenced the development of experimental colitis. PPAR β/δ -null mice exhibited an increased sensitivity to DSS-induced colitis, as shown by marked differences in body weight loss, colon length, colonic morphology, and increased mRNAs encoding the inflammatory markers IFN- γ , TNF- α , and IL-6 levels as compared to similarly treated wild-type mice. Although diarrhea score, bleeding score, disease activity index, and myeloperoxidase activity were not significantly increased in PPAR β/δ -null mice, there was a trend in this direction. Interestingly, these differences were not affected by PPAR β/δ ligand activation in either genotype. These studies demonstrate that PPAR β/δ expression in the colonic epithelium inhibits inflammation and protects against DSS-induced colitis via a ligand-independent mechanism. (Supported by CA89607, CA97999 and CA124533)

1423 LIGAND ACTIVATION OF PPAR-BETA INHIBITS SKIN CARCINOGENESIS.

M. T. Bility^{1,2}, M. K. Devlin^{1,2}, A. N. Billin³, T. M. Willson³ and J. M. Peters². ¹Integrative Biosciences Graduate Program, Huck Institutes for Life Sciences, The Pennsylvania State University, University Park, PA, ²Department of Veterinary and Biomedical Sciences, The Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA and ³Discovery Research, GlaxoSmithKline, Research Triangle Park, NC.

PPAR β -null mice exhibit enhanced tumorigenesis in a two stage bioassay model as compared to wild-type mice, which is likely due in part to enhanced epidermal hyperplasia and decreased apoptosis following treatment with phorbol ester. Previous work also showed that ligand activation of PPAR β induces terminal differentiation and inhibits proliferation in primary keratinocytes, and this effect does not occur in the absence of PPAR β expression. In the present studies, the effect of ligand activation of PPAR β on skin carcinogenesis was examined using both in vivo and in vitro skin carcinogenesis models. Inhibition of skin cancer was observed in wild-type mice administered GW0742, and this effect was likely the result of ligand induced

terminal differentiation. These effects were not found in similarly treated PPAR β -null mice. Ligand activation of PPAR β also inhibited cell proliferation and increased expression of mRNAs encoding terminal differentiation markers in keratinocyte cancer cell lines that represent different stages of skin carcinogenesis. These studies suggest that topical administration of PPAR β ligands is chemopreventive against chemically-induced skin cancer. (Supported by CA89607, CA97999 and CA124533)

1424 ACTIVATION OF MOUSE AND HUMAN PEROXISOME PROLIFERATOR-ACTIVATED RECEPTOR ALPHA (PPAR α) BY PERFLUOROALKYL ACIDS (PFAAS) INVESTIGATED USING A TRANS-ACTIVATION MODEL IN COS-1 CELLS.

M. Takacs and B. D. Abbott. *Reproductive Toxicology Division, U.S. EPA, NHEERL, ORD, Research Triangle Park, NC.*

The purpose of this work was to evaluate the interaction of PFAAs with PPAR α and determine the potential for activation or antagonism of the pathway. Activation of mouse and human PPAR α by perfluorobutane sulfonate (PFBS; C4), perfluorohexane sulfonate (PFHS; C6), and perfluorononanoic (PFNA; C9) was examined using a transient transfection cell assay. Cos-1 cells were transfected with either mouse or human PPAR α receptor luciferase reporter plasmid. Transfected cells were exposed to negative controls (0.1-0.8% DMSO and water), PPAR α agonist (WY14643 [10 μ M]), PPAR α specific antagonist (MK886 [20 μ M]), and freshly prepared solutions of PFBS, PFHS, PFNA (5-100 μ M). All treatments were tested both alone and in competition with MK886. Treatment induced changes in luciferase activity were measured after 24 hrs incubation. PFBS did not significantly activate mouse or human PPAR α , when compared to vehicle controls. PFHS did not significantly induce luciferase activity of the mouse PPAR α vector, but 30 μ M PFHS did significantly increase activation of the human PPAR α , although this activity was not inhibited by MK886. PFNA significantly induced mouse and human PPAR α -mediated luciferase activity at concentrations of 40-100 and 5-100 μ M PFNA, respectively, however this activity was not significantly reduced by MK886. In summary, PFNA induced activity with both mouse and human receptors while PFHS only induced activity through human PPAR α . If PFHS and PFNA induced these effects by binding to the ligand binding site of the PPARs, one would hypothesize that MK886 would compete for binding and reduce the activity. Since this did not occur, it implies another mechanism for the induction by these PFAAs. This abstract does not necessarily reflect U.S. EPA policy.

1425 PPAR β ATTENUATES HEPATOTOXICITY BY SUPPRESSING ACTIVATION OF STELLATE CELLS AND EXPRESSION OF PRO-INFLAMMATORY GENES.

W. Shan^{1,2}, E. McDevitt³, S. Ito⁴, H. Isom³, F. Gonzalez⁴ and J. Peters^{1,2}.
¹Department of Veterinary and Biomedical Sciences and Center for Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, University Park, PA, ²The Intercollege Graduate Degree Program in Genetics, The Pennsylvania State University, University Park, PA, ³Department of Microbiology and Immunology, Penn State College of Medicine, Hershey, PA and ⁴Laboratory of Metabolism, National Cancer Institute, Bethesda, MD.

Peroxisome proliferator-activated receptors (PPAR) are transcription factors that belong to the nuclear hormone receptor superfamily. PPARs can modulate target gene expression by both upregulation and repression of transcription. While the roles of PPAR α and PPAR γ are well defined, the functional role(s) of PPAR β remain largely uncertain. Previous work has shown that PPAR β is protective against carbon tetrachloride (CCl₄)-induced hepatotoxicity as indicated by elevated serum ALT and hepatic TNF α levels in the absence of PPAR β . In this study, hepatic stellate cells (HSCs) were isolated from wild-type and PPAR β -null mice and cultured in vitro. Expression of mRNA encoding PDGF β , PDGF receptor β , SMA α and collagen type1 α 1 were markedly higher in the PPAR β -null HSCs as compared to their wild-type counterparts. Western blotting confirmed the overexpression of SMA α protein in PPAR β -null HSCs. In a separate study, gene expression profiles were examined using microarray analysis of mRNA from wild-type and PPAR β -null mouse livers treated with CCl₄ revealing that a number of genes with diverse functions were differentially regulated between the two genotypes in response to CCl₄. In particular, expression of TWEAK-receptor that is regulated by TNF α and leads to NF κ B activation was greatly enhanced in PPAR β -null mice as compared to similarly treated wild-type mice. These results support the hypothesis that PPAR β protects against chemically-induced hepatotoxicity, possibly via the inhibition of hepatic stellate cell activation and repression of pro-inflammatory responses. (Supported by CA89607, CA97999 and CA124533)

1426 ROLE OF MU-OPIOID RECEPTOR IN TRAMADOL-MEDIATED ANALGESIC ACTIONS IN THE MOUSE TAIL-FLICK TEST.

X. Dai¹, C. D. Brunson¹, H. H. Loh³, I. K. Ho² and T. Ma². ¹Anesthesiology, University of Mississippi Medical Center, Jackson, MS, ²Pharmacology & Toxicology, University of Mississippi Medical Center, Jackson, MS and ³Pharmacology, University of Minnesota Medical School, Minneapolis, MN.

The mu opioid receptor plays an important role in mediating analgesic actions of a class of opioids including morphine and codeine. Tramadol, a centrally acting analgesic structurally related to codeine and morphine, consists of two enantiomers, both of which contribute to analgesic activity via different mechanisms. Tramadol has been proposed to induce analgesia via both opioid and non-opioid pathways. However, details of the mechanisms remain unclear. The purpose of this study was to determine the role of mu-opioid receptor in tramadol-induced analgesic actions using mu-opioid receptor knockout mice. Analgesic responses in the tail-flick test are expressed as the percentage maximum possible effect (% MPE) at the time point at which the greatest analgesic responses were observed for tramadol. Acute intraperitoneal administration of tramadol showed a clear dose-analgesic response relationship in the wild-type female mice with the ED50 of 69.5 mg/kg (66.4 – 72.8 mg/kg, 95% confidence intervals). However, no tramadol dose-response relationship was demonstrated in mu-opioid receptor knockout mice. A tramadol dose of 144 mg/kg, which is more than double of ED50 dose in wild-type mice, produced only % MPE value of 14.5 $\pm$ 0.7 in mu-opioid receptor knockout mice. Higher doses of tramadol caused animal death without increase in analgesic effects. The result from present study clearly indicated that mu-opioid receptor plays a critical role in tramadol-mediating analgesic actions, at least in the tail-flick test mouse model. (Supported in part by NIH grant RR-P20 RR17701)

1427 STRUCTURE ACTIVITY RELATIONSHIPS BETWEEN CAPSAICINOID ANALOGUES AND TRPV1 ACTIVATION.

K. C. Thomas, G. S. Yost and C. A. Reilly. *Department of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.*

Capsaicinoids elicit inflammatory cytokine production and cell death in cells that express the vanilloid receptor 1 (TRPV1). Cell surface and intracellular sub-populations of TRPV1 differentially regulate these responses. Activation of the intracellular pool of TRPV1 causes calcium efflux from the endoplasmic reticulum (ER). Disruption of calcium concentrations in the ER triggers a homeostatic mechanism known as the ER stress response. ER stress responses are intended to compensate for stress and promote cell survival, although prolonged stimulation of ER stress signaling causes cell death. A critical ER stress response pathway involves eukaryotic translation initiation factor 2 α kinase 3 (EIF2AK3 or PERK). This particular ER stress pathway appears to be responsible for cell death caused by ER stress-inducing agents. Induction of the pro-apoptotic gene product DNA damage inducible transcript 3 (DDIT3) is believed to cause cell death. We used synthetic variants of capsaicin and its analogue nonivamide to correlate TRPV1 receptor activation with DDIT3 expression and cell death. Capsaicinoids are composed of a 3-MeO-4-OH-benzylamide ring moiety and a hydrocarbon tail. Structural modifications to the vanilloid ring drastically reduced the ability of the capsaicinoids to stimulate TRPV1, DDIT3 gene expression, and to produce cell death. Specifically, removal, methylation or repositioning of the 4-OH group reduced DDIT3 induction and toxicity. Demethylation of the 3-MeOH group reduced toxicity in a TRPV1-over-expressing cell line, but increased toxicity in the BEAS-2B cell line suggesting a change in the mechanism of toxicity, independent of TRPV1 activation, but not DDIT3 induction. Collectively, a more thorough understanding of capsaicinoid-TRPV1 structure activity relationships will more clearly define how TRPV1 functions, how capsaicinoid variants and metabolites alter cellular function, and elucidate novel mechanisms of capsaicinoid action in cells of diverse origin.

1428 MODULATION OF EPITHELIAL CELL TUMOR NECROSIS FACTOR- α RECEPTOR RELEASE BY ANTIOXIDANTS, TNF- α AND INTERLEUKIN -1 β

S. Saperstein¹, G. S. Pryhuber^{1,2} and J. N. Finkelstein^{1,2,3}. ¹Environmental Medicine, University of Rochester, Rochester, NY, ²Pediatrics, University of Rochester, Rochester, NY and ³Radiation Oncology, University of Rochester, Rochester, NY.

Tumor necrosis factor- α (TNF- α) is a pleiotropic cytokine implicated in the pathogenesis of numerous inflammatory and fibrotic lung diseases. The two receptors for the cytokine, TNFR1 and TNFR2, exist in both membrane-bound and soluble forms, both forms capable of binding TNF- α . Our lab has investigated the solubilization or shedding patterns of the TNFRs, specifically from murine, lung type II-like, epithelial cells (MLE-15), in response to TNF- α or to another pro-inflammatory cytokine, interleukin-1 β (IL-1 β). Our results demonstrate differential

modulation of TNFR shedding by TNF- α and IL-1 β . Specifically, we observed that TNF- α inhibited while IL-1 β stimulated shedding of the TNFR1. Conversely, both cytokines enhanced the release of TNFR2. However, the mechanisms regulating this generation of soluble TNF receptors remain unclear. It is well known that both cytokines induce the formation of oxidants. To test our hypothesis that reactive oxygen species (ROS) modulate ligand-induced TNFR shedding, MLE-15 cells were exposed to TNF- α or IL-1 β in the presence or absence of the antioxidant dimethyl sulfoxide (DMSO). Effects of hydrogen peroxide and phorbol myristate acetate (PMA) were also examined as positive controls. PMA stimulated the release of both TNFRs whereas exposure of MLE-15 cells to hydrogen peroxide had minimal effects. Pretreatment with DMSO dose dependently reduced basal shedding as well as stimulant-induced release of both receptors. This reduction by DMSO was not accounted for by enhanced cell death as measured by lactate dehydrogenase assay. Further studies utilizing other antioxidants such as N-acetylcysteine (NAC) and trolox will explore the role of oxidants in TNFR shedding as our data suggests that basal, and stimulant-induced, TNFR shedding from murine lung epithelial cells involve activation of sheddases by oxidants.

1429 FENRETINIDE-INDUCED APOPTOSIS OF HUH-7 HUMAN HEPATOMA CELL IS ASSOCIATED WITH INDUCTION OF THE RAR BETA GENE.

P. Bu and Y. Wan. *Pharmacology, Toxicology and Therapeutics, the University of Kansas Medical Center, Kansas City, KS.*

Retinoids are a family of compounds related to vitamin A, which play crucial roles in vision, embryogenesis, differentiation, and antiproliferation. The goals of this study are to examine the effect and mechanism for retinoid-induced apoptosis in human hepatoma cells. A panel of 13 retinoids was screened in human hepatoma cell line Huh-7, HepG2, and Hep3B for their apoptotic effect. As a result, fenretinide [N-(4-hydroxyphenyl) retinamide], a synthetic retinoid and structure analogue of all-trans retinoic acid, showed significant apoptotic effect in Huh-7, but not in HepG2 and Hep3B, by decreasing cell number by 75% and inducing caspase-3 cleavage/activation. Further analysis using TUNEL assay revealed 20-fold increase in DNA double-strand break positive cells in fenretinide-treated Huh-7 cells. Phosphatidylserine translocation, another hallmark of apoptosis measured by flow cytometry, showed 17-fold increase in fenretinide-treated Huh-7 cells. Retinoids exert their biological effect by binding to nuclear receptors. To determine the mechanism responsible for fenretinide-induced apoptosis, mRNA level of 11 nuclear receptors, including retinoic acid receptor (RAR) alpha, beta, gamma; retinoid x receptor (RXR) alpha, beta, gamma; orphan nuclear receptors Nur77, Nurr1, Nor1; and xenobiotic sensors CAR and PXR, was quantified by real-time PCR before and after fenretinide treatment. Huh-7 cells have the highest basal mRNA level of RAR beta, RXR alpha, and Nurr1 among the three cell lines. A correlation between the induction of RAR beta mRNA level and apoptosis was noted after fenretinide treatment. At as early as 2 hours after fenretinide treatment, RAR beta mRNA level was increased, reaching 13- and 34-fold induction at 24 hours and 48 hours, respectively. In conclusion, fenretinide induces cell-type specific apoptosis in human hepatoma cells, which is associated with up-regulation of RAR beta gene expression. (NIH CA 53596 and AA14147)

1430 TRACE ELEMENTS IN COMMERCIAL INFANT FOOD.

T. Syversen, R. Meloe and L. Evje. *Department of Neuroscience, Norwegian University of Science and Technology, Trondheim, Norway.*

High growth rate and development of organ systems in childhood requires a balanced diet rich in nutrients. Low intake or low bioavailability of minerals may lead to deficiencies which may cause impairment of normal development of important body functions. The diet of many infants is based on industrial produced food and it is therefore important that the food represent an appropriate supply of trace elements.

Our study included 76 different infant products e.g. breast-milk substitute, porridges, fruit purée and dinners from Norwegian manufacturers. Samples were drawn from homogenized food product and the total concentration of major minerals, trace elements and toxic compounds were determined by High Resolution Inductively Coupled Plasma Mass Spectrometry, HR-ICP-MS. The estimated total daily intake of the minerals calcium, magnesium, sodium, zinc, iron and copper was two times or more higher than the recommended daily intake. The total daily intake of iron and zinc was higher than the tolerable upper intake level (WHO), but not considered as hazardous. None of the products contained toxic elements such as mercury, cadmium, arsenic and lead in amounts which can be considered as a health hazard for the consumer. Dinners containing fish had the highest mercury and arsenic levels, 110 $\mu\text{gAs}/100\text{g}$ and 0.60 $\mu\text{gHg}/100\text{g}$. The highest cadmium concentration was 102 $\mu\text{g}/100\text{g}$ and found in porridge.

1431 FSIS NATIONAL RESIDUE PROGRAM.

J. Vodela, C. Deyrup, P. Zervos, R. Sutton, M. O'keefe, D. Pagan-Rodriguez and H. L. Walker. *Residue Branch, USDA/FSIS, Washington DC, DC.*

The National Residue Program (NRP) is a multi-component analytical testing program for residues present in domestic and imported meat, poultry and egg products. The NRP is managed by the Food Safety and Inspection Service (FSIS), a public health regulatory agency within USDA that protects consumer health by regulating meat, poultry, and egg products. The NRP protects consumer health by detecting, identifying, and removing meat, poultry and egg products adulterated with veterinary drugs, pesticides and other chemical contaminants.

The Zoonotic Diseases and Residue Surveillance Division annually publishes the National Residue Program Sampling Plan and the Data from the testing results. In 2005, FSIS sampled and tested 17 compound classes of veterinary drugs, pesticides and environmental contaminants, comprising approximately 80 residue compounds. Under the Domestic Scheduled Sampling Plan (preliminary results) 21,472 samples were collected and analyzed. From these, sixty-two (62) chemical residue violations were found and consisted of 31 antibiotics, 10 avermectins/milbemycins, 9 sulfonamides, 6 florfenicol, 1 nitrofurantoin and 5 chlorinated hydrocarbon/chlorinated organophosphate. No residue violations were found in testing for arsenic, carbadox, nitroimidazoles, phenylbutazone, racetopamine, thyrostats, trenbolone, zeranol, chloramphenicol, beta-agonists and melengestrol acetate. The FSIS NRP, in conjunction with the EPA and FDA, plays a pivotal role in protecting consumers from violative levels of chemical residues in meat, poultry, and egg products. Furthermore, FSIS works cooperatively with state meat and poultry inspection programs to achieve mutual objectives in residue prevention and control.

1432 THE NORWEGIAN NATIONAL REPORTING SYSTEM AND REGISTER OF SEVERE ALLERGIC REACTIONS TO FOOD.

M. Lovik¹, E. Egeas², B. A. Stensby¹, C. Faeste² and E. Namork¹. ¹Department of Environmental Immunology, Norwegian Institute of Public Health, Oslo, Norway and ²Norwegian Veterinary Institute, Oslo, Norway. Sponsor: E. Dybing.

Background: The Norwegian National Reporting System and Register of Severe Allergic Reactions to Food (The Food Allergy Register) is a voluntary reporting system for medical doctors, started with Government funding in 2000. Norway has about 4 million inhabitants. The reporting system covers all first-line doctors (family and specialist practices, emergency wards, some relevant hospital departments). The aim is to collect information about the incidence of food allergy reactions, risk groups and risk situations, offending foods and follow-up by the health care system. Also, food allergen surveillance is a major goal. The Food Allergy Register: One-page reporting forms and informed consent forms are mailed to all relevant doctors at least once a year. Serum samples may be submitted for specific IgE analysis, and food samples for allergen analysis.

Results: By July 1, 2006 the number of reports was 485, with a slightly increasing trend. Two marked age peaks of food allergic reaction incidence are observed, one as expected among small children, the other among young adults age 20-35 (35% of cases). A female/male ratio of 60/40 has been found among the adult cases. Common incriminating foods are hazelnut, peanut, and shellfish, while fish allergy appears to be rare. No deaths have been reported. A number of cases with unexpected presence of allergens in commercial foods have been discovered.

Discussion: Underreporting is a problem, and the true incidence of severe allergic reactions certainly is higher than the number of reports. However, the reporting system has provided valuable information on risk groups and the most important incriminating allergens, and a number of cases of unexpected allergens in commercial foods have been detected. The value of the register increases as more cases are reported.

1433 AVOIDING PERCHLORATE EXPOSURES FROM FRESH FRUITS AND VEGETABLES: AT WHAT COSTS?

L. Barraj¹, B. Blount³, C. Sanchez⁴, R. Krieger² and C. Scrafford¹. ¹Health Sciences, Exponent, Washington, DC, ²Entomology, University of California, Riverside, CA, ³National Center for Environmental Health, CDC, Atlanta, GA and ⁴Yuma Agricultural Center, University of Arizona, Yuma, AZ.

Perchlorate residues have been detected in fruits and vegetables grown in the Colorado River Basin and in water and milk samples collected from multiple regions in the US, raising concerns about the safety of the food supply. At high doses, perchlorate can interfere with iodide uptake by the thyroid gland and disrupt its physiological functions in the body. Excessive exposures of expectant mothers may affect the fetus and newborn and result in effects such as delayed development and decreased learning capability. Since the thyroid plays a major role in proper development in addition to metabolism in children, their exposure to perchlorate is also

of potential concern. While avoidance of these foods could result in decreased perchlorate exposures, these foods are major sources of calcium, vitamins A and D, antioxidants and water-soluble vitamins. We use food consumption data from surveys conducted by USDA and CDC to compare the nutrient profile of consumers of foods that may be contaminated with perchlorate to that of non-consumers of these foods. We assess the nutritional benefits associated with consuming these foods and risk associated with avoiding them, and compare these risks to the risks of exposure to perchlorate.

1434 BALANCING AND COMMUNICATING RISKS AND BENEFITS ASSOCIATED WITH EGG CONSUMPTION – A RELATIVE RISK STUDY.

N. Tran¹, L. Barraj¹, P. Mink¹ and M. Donald². ¹*Food Safety, Nutrition and Public Health, Exponent, Washington, DC* and ²*Egg Nutrition Center, Washington, DC*. Sponsor: D. Schmitt.

The American Heart Association (AHA) and the National Cholesterol Education Program (NCEP) recommend restricting egg consumption based on the hypothesis that egg intakes will result in an increase in blood cholesterol levels, which, in turn, is associated with increased cardiovascular disease (CVD) risks. However several studies have shown that dietary cholesterol from eggs has little if any effect on plasma cholesterol or the risk for heart diseases after adjustment for other potential risk factors. Further, eggs are known to be a good source of high quality protein, B vitamins and folate, fat-soluble vitamins such as A, D, and E, and essential minerals (iodine, zinc, calcium, and iron). Eggs also contain lutein and zeaxanthin, which might be involved in the prevention of cataracts and age-related macular degeneration, and rich in choline, which may have a role in normal development of memory. Hence, wide-sweeping recommendations to restrict egg consumption to avoid CVD risk may be misguided when nutritional contribution from eggs is not considered. A relative risk study is conducted to evaluate and quantify the relative risks of CVD associated with dietary cholesterol and eggs compared to other factors including BMI, dietary, lifestyle, or drugs, etc. on cardiovascular disease and the health benefits of egg consumption. Estimates of egg contribution to dietary cholesterol and nutrition are developed based on consumption data from nationwide food consumption survey. A report card to communicate the relative risks of egg cholesterol and the nutritional benefits is explored in this paper.

1435 STRATEGIC CONSIDERATIONS IN THE DESIGN AND CONDUCT OF ANIMAL MODELS FOR ASSESSMENT OF FOOD PROTEIN ALLERGENICITY.

C. Herouet-Guicheney¹, R. Bars¹, N. G. Carmichael¹, D. Rouquie¹, R. Macdonald², I. Kimber³ and R. Dearman³. ¹*Regulatory Toxicology, Bayer CropScience, Sophia-Antipolis, France*, ²*Bayer CropScience, Calgary, AB, Canada* and ³*Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom*.

There is a recognized need for a relevant animal model for the assessment of allergenic potential of novel foods, in particular those derived from genetically modified plants. There remains some debate about the most appropriate design for such a model, and we propose here one approach based on practical and theoretical considerations. The preferred strategy is predicated on the identification of novel proteins that have allergenic properties (as judged by the ability to induce both IgG and IgE antibody), and to distinguish these from other proteins that despite being immunogenic lack allergenic potential (the ability to induce IgG, but not IgE, antibody). The recommended experimental approach is configured to provide maximum sensitivity for the purposes of hazard identification. To this end BALB/c mice are used; this strain having an atopic-like phenotype and being predisposed to mount vigorous IgE antibody responses. In order to maximise opportunity for elicitation of immune and allergic responses, and to avoid the possibility of tolerance induction associated with oral administration, exposure is systemic via intraperitoneal injection. In order to reflect accurately the inherent immunologic properties of test proteins exposure is effected in the absence of adjuvant. At various times after the initiation of exposure IgG antibody responses are measured using enzyme-linked immunosorbent assay and IgE antibody detected using passive cutaneous anaphylaxis. A detailed rationale for this experimental design, together with an analysis of performance characteristics and strengths and limitations with respect to hazard identification will be described.

1436 SAFETY EVALUATION OF A SALACIA OBLONGA EXTRACT FOR USE IN FUNCTIONAL FOODS.

S. M. Henwood², A. Flammang¹ and J. M. Mirwald². ¹*Ross Products Division Abbott Laboratories, Columbus, OH* and ²*Covance Laboratories Inc., Madison, WI*.

Salacia oblonga holds potential as a natural method to mitigate the blood glucose response for people with diabetes by inhibiting the activity of intestinal α -glucosidases. As part of a safety evaluation of novel ingredients for use in blood glucose control, the toxicity of a Salacia oblonga root extract (SOE) was evaluated in a 92-

93 day feeding study in rats using doses of 250, 1250, and 2500 mg/kg/day via oral gavage. An in vivo-in vitro rat peripheral blood lymphocyte chromosomal aberrations assay was added at termination of the subchronic rat study to examine cultured lymphocytes for possible chromosomal aberration induction. This was conducted due to a previous weak; although reproducible, positive chromosomal aberrations response in cultured peripheral blood human lymphocytes after acute in vitro treatment with SOE. No noteworthy signs of toxicity were noted in feeding or body weight, functional observational battery or motor activity. No treatment related changes were considered to be of toxicological significance. The present study results indicate that SOE was negative for the induction of chromosomal aberrations in cultured rat peripheral blood lymphocytes after 90 consecutive days of treatment with SOE. The No Observable Adverse Effect Level was determined to be 2500 mg/kg/day following oral gavage to rats for 92-93 days.

1437 NEONATAL MICE AS MODELS FOR PREMATURE INFANTS INFECTED WITH *E. SAKAZAKII*-CONTAMINATED INFANT FORMULA.

A. N. Richardson¹, S. Massengill¹ and M. A. Smith^{1,2}. ¹*Environmental Health Science, University of Georgia, Athens, GA* and ²*Center for Food Safety, University of Georgia, Griffin, GA*.

Premature or very-low-birth-weight human infants exposed to *Enterobacter sakazakii* (*E. sakazakii*) in reconstituted powdered infant formula may develop infections resulting in septicemia, necrotizing enterocolitis, meningitis, hydrocephalus, or death. Animal models are needed to estimate and understand the infectivity of *E. sakazakii* in human infants. Due to their underdeveloped central nervous system at birth, the infection of neonatal mice with *E. sakazakii* may mimic that of premature human infants. Our objective was to compare the susceptibilities of three mouse strains to *E. sakazakii* strain MNW2 by observing mortality and infectivity. Timed-pregnant dams of the CD-1, BALB/C and C57BL/6 strains were obtained, acclimatized, and allowed to give birth naturally. At postnatal day (PND) 3 or 4, the pups were orally gaged with a single dose of vehicle or 10^4 - 10^{12} colony-forming units (CFU) *E. sakazakii* strain MNW2 per ml reconstituted powdered infant formula. All pups surviving to PND 10 or 11 were sacrificed and brains, livers, and ceca excised and analyzed for the presence of *E. sakazakii*. *E. sakazakii* was isolated from 66.7%, 38.5% and 36.4% of brains, 60.0%, 30.8% and 45.4% of livers, and 26.7%, 23.1% and 18.2% of ceca from treated CD-1, BALB/C and C57BL/6 litters, respectively. No deaths occurred in any of the control groups for any mouse strain. Among the three strains, CD-1 appears to be the most sensitive demonstrating a dose-dependent response in mortality (10^{11} CFU resulted in 34.8% mortality). In C57BL/6 mice, mortality occurred only at the highest dose administered (4.2% at 10^{12} CFU). Although BALB/C mice had 19% mortality at 10^7 CFU, it was not dose-dependent. The results of this experiment suggest that the CD-1 mouse strain is the most susceptible to *E. sakazakii* infection and may serve as a potential animal model for the infection in human infants. (Funded by ILSI North America Technical Committee on Food Microbiology to MAS).

1438 SUBCHRONIC RAT FEEDING STUDY WITH GENETICALLY-MODIFIED MAIZE GRAIN FROM INSECT-PROTECTED, HERBICIDE-TOLERANT PLANTS.

L. M. Appenzeller¹, S. A. MacKenzie², L. A. Malley², N. E. Everds², K. A. Funk³ and B. Delaney¹. ¹*Pioneer Hi-Bred Int'l, Inc., Johnston, IA*, ²*DuPont Haskell Laboratories, Newark, DE* and ³*Experimental Pathology Laboratories, Inc., Herndon, VA*.

We evaluated health effects of daily consumption of a diet formulated with the combined-trait maize product DAS-Ø15Ø7-1xDAS-59122-7. 15Ø7x59122 maize provides in-plant protection from CRW and ECB larval feeding damage via expression of Bt-derived Cry34Ab1, Cry35Ab1, and Cry1F insecticidal proteins, and the *Streptomyces viridochromogenes* PAT protein confers tolerance to the herbicidal active ingredient glufosinate-ammonium. Diets conforming to Purina Mills Certified Rodent LabDiet[®] 5002 were formulated by substitution of transgenic (TG) test (15Ø7x59122), non-TG near-isogenic control, or 3 non-TG commercial reference maize grain sources at 34% (w/w). We verified TG protein presence, stability, and biological activity in the TG test diet. Young adult Crl:CD(SD) rats (12/sex/group) ate the diets for 92-94 days. Compared with rats fed the non-TG control diet, no toxicologically significant differences were observed in rats fed the 15Ø7x59122 diet with respect to body weight/gain, food consumption/efficiency, mortality, clinical signs of toxicity, or ophthalmological observations. No test diet-related effects were observed for neurobehavioral assessments, clinical pathology, organ weights, or anatomic pathology. Response variable values for animals in the test diet group fell within the range of natural variation observed for animals in the reference diet groups. Under the conditions of this study, daily consumption of a rodent diet formulated with 15Ø7x59122 maize grain caused no adverse health effects in young adult rats. We conclude that grain from the combined-trait maize product DAS-Ø15Ø7-1xDAS-59122-7 is nutritionally equivalent to and as safe as grain from non-transgenic maize.

1439 TOXICOLOGICAL ASSESSMENT OF TRANSGENIC SALMON IN A RODENT DEVELOPMENTAL STUDY.

I. Curran¹, G. Bondy¹, V. Liston¹, R. Devlin² and R. Mehta¹. ¹Toxicology Research Division, Health Canada, Ottawa, ON, Canada and ²Department of Fisheries and Oceans Canada, Vancouver, BC, Canada.

In recent years, concerns about the safety of foods derived from the application of biotechnological advances (known as genetically modified or GM foods) have re-introduced the issue of how best to determine the safety of whole foods. The current study was conducted to identify any adverse or beneficial effects due to growth-enhanced genetically modified salmon in the diet of rodents. Three modified AIN93G diets were prepared containing 20% casein protein (Diet1), 20% wild-type salmon protein (Diet2) or 20% transgenic salmon protein (Diet3). All diets were balanced for lipids (7.8%) and mineral and vitamin content. Pregnant Sprague Dawley dams (day 7 gestation; 10 per group) were brought in and immediately put on diet. The dams and subsequent pups were monitored for weight and food consumption on a weekly basis. Pups were born at day 22-23 of gestation. Pups were weaned at postnatal day (PND) 21 and maintained on the same diet as their dams until PND 28 or 80. Dams were euthanized upon weaning of the pups. No changes in dams' gestation weights or food consumption were observed between any of the diets. During lactation, dam weights were significantly greater on PND 7, 14 and 21 in Diet3 compared with Diet1. A significant increase in pup body weights was observed during the lactation period in Diet3 compared with Diet2 in male pups from PND 7 to 21 and in female pups at PND 14 and 21. No body weight differences were noted in the pups from these groups from PND 28 to PND 80, although female body weights from Diet2 and male body weights from Diet3 were significantly increased compared with Diet1 over this interval. No changes were observed in preputial separation in males, but vaginal opening in female pups was advanced by a day in both Diet2 and Diet3 compared with Diet1. The only difference between groups fed Diet3 compared with those fed Diet2 was increased body weight gain during the lactation period. These effects may be due to subtle differences in lipids and/or proteins of the fish which have yet to be determined.

1440 28-DAY ORAL (GAVAGE) TOXICITY STUDIES IN RATS OF GREEN TEA CATECHINS PREPARED FOR BEVERAGES.

C. P. Chengelis¹, J. Kirkpatrick¹, K. S. Regan¹, A. E. Radovsky¹, O. Morita², Y. Tamaki² and H. Suzuki². ¹WIL Research Laboratories, LLC, Ashland, OH and ²Kao Corporation, Haga Tochigi, Japan.

Studies have been done that suggest that tea catechins have beneficial effects when taken as a food supplement. The current studies evaluated the possible toxic effects to rats of two green tea catechin preparations for use in beverages which have different catechin monomer compositions and also a decaffeinated preparation in order to ascertain if the effects observed were due to the presence of caffeine. These green tea catechin preparations were administered orally by gavage to rats once daily at dosage levels up to 2000 mg/kg/day for 28 days. All groups consisted of 5 male and 5 female Crl:CD(SD)IGS BR rats. There were no deaths attributed to any of the green tea preparations. The clinical condition of the animals, functional observational battery and motor activity, hematology and urinalysis evaluations, organ weights, and gross necropsy findings were unaffected by any of the tea preparations. No adverse effects on serum chemistry parameters were attributed to any of the test articles. There were no effects on body weights or microscopic findings attributed to dosing with the decaffeinated preparation, whereas lower body weights were observed throughout the study in the 1000 and 2000 mg/kg/day males administered one of the catechin preparations which has a high caffeine content. The no-observed-adverse-effect level (NOAEL) for localized gastric effects was 1000 mg/kg/day based on gastric erosions at 2000 mg/kg/day. No other target organs were identified. Thus, the NOAEL for systemic toxicity following oral administration was 2000 mg/kg/day (the highest level tested) under the conditions of these studies. The changes in body weight and gastric findings observed were attributed to caffeine, as no similar findings were observed in rats dosed with the decaffeinated catechin preparation.

1441 GENOTOXICITY STUDIES ON GREEN TEA CATECHIN.

T. Kasamatsu¹, R. Ogura¹, K. Yuki¹, N. Ikeda¹, K. Saigo², C. Blackstock³, O. Morita¹ and H. Suzuki¹. ¹Safety and Environmental Research Section, Kao Corporation, Ichikai-Machi, Haga-Gun, TOCHIGI, Japan, ²Drug Safety Research Laboratories, Shin Nippon Biomedical Laboratories, Ltd., 2438 Miyounoura, Yoshida, KAGOSHIMA, Japan and ³Inveresk, Tranent, EH33 2NE, SCOTLAND, United Kingdom. Sponsor: J. Avalos.

Tea catechins have been demonstrated to give beneficial effects on health. A recent investigation indicates that ingestion of tea beverage enriched with catechins is effective on the prevention of body fat accumulation. We evaluated the genotoxic po-

tential of tea catechin preparations, namely green tea catechin, using standard genotoxicity tests. Bacterial reverse mutation assay (Ames test), the chromosomal aberration assay in cultured Chinese hamster lung cells (CHL/IU), the mouse lymphoma L5178Y/tk assay (MLA), and a bone marrow micronucleus assay in ICR CD mice were employed in the present study. Our data shows that there were no significant increases in the revertant colonies were found in the Ames test, but positive responses were observed in the in vitro chromosomal aberration assay and in vitro mouse lymphoma L5178/tk assay. However, the in vivo study demonstrated no significant increase in micronucleated erythrocytes in the bone marrow of ICR CD mice administered a high dose of the test substances up to 2,000 mg/kg. These results were comparable with those of other genotoxicity studies of tea catechins that demonstrated minimal genotoxic concern. Combined with favorable information of chemopreventive effect of tea catechins on mutagenesis and/or carcinogenesis, we conclude that there is no substantial genotoxic concern of green tea catechin under the conditions for anticipated use.

1442 EIGHT WEEKS EXPOSURE EFFECTS OF A NOVEL DIETARY SUPPLEMENT-THERMOPLUS ON SERUM BIOCHEMISTRY AND HISTOPATHOLOGY OF VITAL TARGET ORGANS OF FISHER RATS.

S. D. RAY¹, M. Parmar¹, D. Zinkovsky¹, I. Syed¹, J. Rathod¹, K. Shah¹, R. M. Hackman² and S. J. Stohs³. ¹Mol. Toxicology labs., Division of Pharmacology Scs., Long Island University, Brooklyn, NY, ²Department of Nutrition, University of California, Davis, CA and ³Res. & Dev., AdvoCare Intl., Carrollton, TX.

We have recently shown antitoxic properties (Mol. Cell. Biochem., 2006) and the safety of a caffeine and ephedra containing metabolic nutrition system (MNS-orange) in an in vivo animal model (Arch.Toxicol.79:330-340, 2005). ThermoPlus, a new dietary supplement primarily composed of *Salvia officinalis*, *Camellia sinensis*, *Paullinia cupana*, thiamine, and niacin was designed to work in conjunction with metabolic nutrition systems. The present study evaluated the safety of this novel dietary supplement-ThermoPlus (TP; AdvoCare®) on serum biochemistry and organ histopathology in Fisher 344 rats. TP is a unique combination of phytochemicals/nutraceuticals designed to provide nutritional support that helps stimulate metabolism of the body ultimately translating into more effective caloric consumption. In addition, the sage and oolong tea components are known to suppress appetite. Fisher 344 rats (adult male and female) were fed control (-TP) or TP containing (1X, 7X and 14X, 1X=daily human dose) diets and sacrificed after 2 months. Serum chemistry analysis and histopathological examination of liver, kidney, heart, brain, lung, spleen, and duodenum sections revealed that TP exposure did not adversely influence serum chemistry (proteins, lipids and carbohydrate profiles), genomic integrity of the liver and tissue architecture. Specific enzyme markers (ALT/AST: liver; CPK: heart; BUN/Creatinine for kidney) of the target organs disclosed no TP-induced toxicity. TP-exposed livers were also subjected to Western blot analysis to study its influence on the expression of the pro- and anti-cell death genes (bcl-XL and p53). Overall, TP-exposed rats were more active, and the results suggest that TP exposure produces normal serum chemistry in rats fed up to fourteen times the normal human dose and does not adversely influence any of the vital target organs [Supp. by AdvoCare®, Carrollton, TX].

1443 EFFECTS OF SYNEPHRINE AND BITTER ORANGE ON CARDIOVASCULAR AND PHYSIOLOGICAL VARIABLES IN FEMALE RATS.

P. Duffy¹, G. White¹, S. Appana¹, L. Pellicore², V. Frankos² and D. K. Hansen¹. ¹National Center for Toxicological Research, FDA, Jefferson, AR and ²Center for Food Safety and Applied Nutrition, FDA, College Park, MD.

Little is known about the adverse health effects of the dietary supplement bitter orange (B) which contains 6% synephrine (S). The purpose of this study was to determine acute physiological and cardiovascular effects of B and S in rats. Telemetric transmitters monitored temperature, motor activity, heart rate, blood pressure, and electrocardiography for 5 days in young female Sprague-Dawley rats that were gavaged once daily with the vehicle (0.25% methyl cellulose). Subsequently, rats (12/dose level) received a daily dose of B (0, 10, 50, or 100 mg synephrine/kg) or 90% S (100 mg synephrine/kg) for 6 weeks. Data were collected prior to dosing and at 0.25, 0.5, 1, 2, 4, and 6 hours after dosing with B or S. There were significant linear dose and dose*day effects for diastolic, systolic, mean, and pulse blood pressure, heart rate, activity, and QA interval at 2 or more of the time points after dosing. For all dose groups, B and S had the greatest effect on blood pressure. Compared to controls, systolic and mean blood pressure were significantly increased in the 50 and 100 mg/kg B dose groups at all time points, and pulse and diastolic pressure were increased at 4 or more time points. Pulse, mean, and systolic pressure were increased in the 10 mg/kg group at 2 or more time intervals. S caused a smaller increase in blood pressure than B at 100 mg/kg. Additionally, B decreased the QA interval in all dose groups. Both B and S had more profound effects on blood pressure than on temperature, activity, or heart rate. B significantly increased the corrected QT interval. B and S had no effect on body weight or food consump-

tion. The mortality rate for each of the three B dose groups was 8.3% with contributing factors being hypothermia, ataxia, prolonged QT intervals, and partially inverted T waves. These results suggest that both B and S may have adverse physiological effects and that B may have more significant effects on blood pressure than an equivalent dose of S.

1444 D-RIBOSE HAS NON-SIGNIFICANT TOXICITY IN BOTH SHORT AND LONG TERM SUPPLEMENTATION.

J. C. Griffiths¹ and J. A. St. Cyr². ¹Burdock Group, Vero Beach, FL and ²Bioenergy Inc., Minneapolis, MN.

D-Ribose (DR), a pentose carbohydrate, has repeatedly demonstrated its beneficial properties in replenishing cellular high energy phosphate compounds with an accompanying functional improvement following ischemic or hypoxic stressful situations without obvious significant toxicity. Food ingredients and dietary supplements (including DR) must clearly show safety-in-use. To that end, DR has been tested for toxicity in both animal and human investigations. Adult female rodent experiments analyzing both embryotoxicity and teratogenicity revealed no effects at an oral DR dose at 5% of the diet (a daily dose of ~4 gms/kg body weight/day). Findings revealed no developmental defects in the fetus, including visceral malformations or anomalies. When adult male and female rodents were fed 5% DR in the diet for 13 weeks (3.6 and 4.4 gms/kg body weight/day) in a standardized OECD Guideline 408 protocol, no abnormal measured hematological or biochemical parameters were found. Human studies have also reflected similar findings. In an acute evaluation, using escalating single oral doses of DR (0, 2, 5, 10 gms/dose) in young and older adult humans, there were no significant biochemical or purine abnormalities except for mild asymptomatic, hypoglycemia and a slight elevation in uric acid concentrations. When providing DR (20 gm/dose) for 14 days to healthy adult subjects, similar findings were also observed. There were no long-term significant changes in hematological or biochemical parameters; however, an acute elevation in uric acid and aspartate aminotransferase levels occurred at day 7 with normalization to baseline in both measurements by day 14. A clinically, asymptomatic hypoglycemia was found throughout the 14 day trial. The data from these investigations give further support for the safety of DR in both an acute and chronic setting.

1445 GENETIC TOXICOLOGY ASSESSMENT OF A NOVEL OXYGEN- COORDINATED NIACIN-BOUND CHROMIUM(III) (NBC) COMPLEX.

M. Shara¹, T. Yasmin¹, D. Bagchi^{2,1} and M. Bagchi². ¹Pharmacy Science, Creighton University, Omaha, NE and ²InterHealth USA, Benicia, CA.

Chromium (III) is a novel micronutrient essential for normal protein, fat and carbohydrate metabolism. NBC is a unique form of bioavailable chromium. We have previously assessed the acute oral toxicity, acute dermal toxicity, primary dermal and eye irritation, Ames' bacterial reverse mutation assay, mouse lymphoma test, and 90-day subchronic toxicity of NBC, and demonstrated its safety [J. Inorg. Biochem. 99 (2005) 2161-2183]. Recently, we demonstrated the long term (52-weeks) safety of NBC by administering either 0 or 25 ppm [1,000 mg elemental Cr(III) HED] doses of NBC in diet for 52 consecutive weeks to Sprague-Dawley rats (Eurotox 2006). In this study, we examined the genetic toxicology profile of NBC in a mouse micronucleus (MN) assay model, using young, healthy adult male and female Cr1:CD1(ICR) mice. NBC was administered to mice in corn oil by single dose oral gavage at doses of 1000, 2000 and 3000 mg NBC/kg body weight. Cyclophosphamide (70 mg/kg body weight) was used as a positive control. Mice were sacrificed at 24 and 48-hr post-treatment, and marrow aspirated from both femurs of each animal into a tube of fetal bovine serum. Following centrifugation, the resulting pellets were resuspended in serum. The slides were prepared from the suspensions and stained with Giemsa. A minimum of 2000 polychromatic erythrocytes (PCEs) per animal or 10,000 per treatment group were scored for micronuclei using 1000X brightfield microscopy. The number of PCEs among 500 total erythrocytes (expressed as the PCE fraction) was determined for each animal. No adverse clinical events or reduction in body weight gain were observed in the NBC treated animals. Numbers of MN-PCEs were not increased in any group treated with NBC compared to the corresponding negative control groups, while the positive control groups displayed strong increase in MN-PCEs. The results of the micronucleus test are in agreement with and further extend our previous findings with regards to the safety of NBC.

1446 ASSESSMENT OF POTENTIAL HUMAN HEALTH RISKS POSED BY BENZENE IN A COMMERCIAL BEVERAGE.

E. S. Williams¹, L. L. Ferriby¹, L. C. Haws², D. J. Paustenbach³ and M. A. Harris¹. ¹ChemRisk, Houston, TX, ²ChemRisk, Austin, TX and ³ChemRisk, San Francisco, CA.

A recent study by the Center for Food Safety and Nutrition (CFSAN) provided limited data regarding the concentration of benzene in a selection of commercial beverages. A reaction between sodium benzoate and vitamin C appears to give rise

to benzene in some drinks under certain conditions. CFSAN reported that several beverages contained levels of benzene which exceeded the EPA drinking water standard of 5 ppb. One of the beverages, Crystal Light Sunrise Classic Orange (CLSCO), was reported to have concentrations as high as 87.9 ppb, though a newer formulation registered levels <1 ppb in CFSAN testing. Due to limited testing by CFSAN, a more robust study was conducted to better characterize the levels of benzene in CLSCO. Samples of the beverage were obtained from retail outlets in the Houston Texas area, following a statistically-based sampling strategy. Three formulations were obtained during sampling: 16 oz old and new formulations, and 32 oz. formulation. Analysis of the samples revealed mean benzene concentrations of 90 ppb in 16 oz old formulation bottles, and undetectable levels in the 16 oz new formulation product. The 64 oz product was determined to contain a mean concentration of 3.38 ppb benzene, though sodium benzoate is not listed as an ingredient. Upper bound point estimates of cancer risk for exposure to these two products were calculated as 5.22×10^{-6} for teens and 2.76×10^{-7} for adults. Hazard indices for teens and adults were calculated at 0.277 and 0.0002 respectively. Monte Carlo analysis, utilizing distributions for consumption rate, benzene concentration, and body weight, resulted in a 95th percentile excess cancer risk of 7.94×10^{-6} for teens and 3.52×10^{-7} for adults. Non-cancer risk for teens and adults at the 95th percentile was estimated at 0.575 and 0.0022 respectively. These calculations indicate that cancer and non-cancer risks due to exposure to benzene in CLSCO are below levels of concern.

1447 CYTOTOXICITY OF PYRROCIDINES IN HEPG2 HEPATOCYTES AND PK15 RENAL CELLS.

S. Hsiao¹, D. T. Wicklow² and W. M. Haschek³. ¹Veterinary Diagnostic Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL, ²National Center for Agricultural Utilization Research, ARS, USDA, Peoria, IL and ³Department of Pathobiology, University of Illinois at Urbana-Champaign, Urbana, IL.

Pyrricidines are newly reported polyketide-amino acid-derived antibiotics produced by *Acremonium zeae*, a prevalent seed-borne endophyte of corn. Pyrricidines exhibits potent activity against Gram-positive bacteria, including drug resistant strains, and displayed significant activity against *Candida albicans*, as well as fumonisin and aflatoxin producing fungi. In this study, we evaluated the effect of pyrricidines in two mammalian cell lines, HepG2 cells (a cell line derived from a human hepatocellular carcinoma) and PK15 cells (a cell line derived from a normal pig kidney). The HepG2 and PK15 cells were incubated overnight to form monolayers and treated with 0 to 100 μ M of pyrrocidine A and B for 24 hours. Cytotoxicity was evaluated by the MTT assay. Pyrrocidine A and B were cytotoxic to both HepG2 and PK15 cells after 24 hours of treatment. ED₅₀ of pyrrocidine A to HepG2 cells was $0.66 \pm 0.16 \mu$ g/mL and to PK15 cells was $1.03 \pm 0.37 \mu$ g/mL. Pyrrocidine B was less potent than pyrrocidine A. ED₅₀ of pyrrocidine B to HepG2 was $15.37 \pm 4.47 \mu$ g/mL and to PK15 was $16.63 \pm 5.47 \mu$ g/mL. The cytotoxicity of pyrrocidine A to HepG2 cells was more potent than other known mycotoxins, e.g. deoxynivalenol ED₅₀ = 8.36μ g/mL, fumonisin B₁ ED₅₀ > 100 μ g/mL, zearalenone ED₅₀ > 100 μ g/mL and moniliformin ED₅₀ = 3.5 μ g/mL. A sequential morphological study using time-lapse motion photography suggested that the cell death in PK15 cells induced by pyrrocidine A was consistent with apoptosis. This is the first report of toxicity in a mammalian system. *In vivo* study are essential for risk assessment.

1448 IMMUNOTOXICITY OF NIVALENOL LACKING XENOBIOTIC METABOLISM AFTER ORAL ADMINISTRATION FOR 90-DAY IN RATS.

Y. Sugita-Konishi¹, A. Kubosaki¹, M. Aihara¹, B. Park¹, T. Tanaka², Y. Suzuki³, K. Takatori¹, M. Hirose⁴ and M. Shibutani⁴. ¹Division of Microbiology, National Institute of Health Sciences, Tokyo, Japan, ²Department of Food Chemistry, Kobe Institute of Health, Kobe, Japan, ³Department of Veterinary Science, Azabu University, Kanagawa, Japan and ⁴Division of Pathology, National Institute of Health Sciences, Tokyo, Japan.

Nivalenol (NIV), one of the trichothecene mycotoxins produced by *Fusarium* species, is an important contaminant of wheat and barley showing worldwide distribution. In the present study, we examined exposure effect of NIV through diets at doses of 0, 6.25, 25, and 100 ppm for 90 days on immune function and activities of detoxifying enzymes in the liver of male F344 rats. Examination of serum immunoglobulin levels revealed a slight increase of IgM at 100 ppm, while IgM at lower doses and IgG or IgA at any doses did not fluctuate. Flow cytometric analysis of splenic cells revealed increases of B-cell population from 25 ppm and decrease of T-cell population at 100 ppm associated with an elevation in the ratio of helper/cytotoxic T lymphocytes at 100 ppm. On the other hand, increases of

splenic NK activity against Yac-1 cells were observed in all treatment groups, while the level at 100 ppm was lower than that observed at 25 ppm. At 100 ppm, the reduction of the NK-R-P1A+ splenic cell counts was apparent. With regard to the activities of detoxifying enzymes, i.e., cytochrome P450 3A2 and 1A2, and glutathione-S-transferase isozymes, in the liver, NIV did not induce any dose-related change. Furthermore, de-epoxy form of NIV, a bacterially metabolized NIV, could not be detected in the feces or sera of administered animals. In summary, immunotoxicity of NIV was apparent from 25 ppm judging from the increase of splenic B-cell population, while increase of NK activity was apparent from 6.25 ppm as a signature of beneficial host-defense responses. Alterations in immune function by NIV were not accompanied with xenobiotic reaction in the liver as well as enterobacterial metabolism.

1449 EFFECTS OF FUSARIUM MYCOTOXINS AND THEIR MIXTURES ON CACO-2 CELLS DEATH: IMPLICATION OF P53, P21 GENES AND CASPASE-3.

E. E. Creppy¹, S. Moukha^{2,1}, J. H. Kouadio¹ and T. A. Mobio¹. ¹Toxicology, University Bordeaux 2, Bordeaux, France and ²UPR 1264 MycSA, INRA, Villenave d'Ornon, France.

We determined the implication of the p53 and p21 genes and caspase-3 activation in cell death caused either by deoxynivalenol (DON), zearalenone (ZEA), and fumonisin B1 (FB1) individually or by mixtures in the human intestinal cell line, Caco-2. The following endpoints were used: malonaldehyde production, inhibition of protein and DNA syntheses, DNA bases modifications, DNA fragmentation, and cell viability as measured by the Neutral Red (NR) and MTT tests, activity of caspase-3 and transcriptional levels of p53 and p21 genes. The reduction of cell viability results from the balance between cell proliferation and cell death triggered by either apoptosis or necrosis. In caco-2 cells which bear a mutated p53 gene, FB1 induces apoptosis in approximately 30% of cells triggered by a mechanism p53-independent and caspase-3 and p21 independent. DON and ZEA induce apoptosis in Caco-2 cells through a mechanism likely caspase-3 and p21 dependent at transcriptional level, with modulation of p53 gene without its implication in the cell death. The mixtures of mycotoxins induce caspase-3 activity in increasing order: [FB1+ZEA] < [ZEA+DON] < [FB1+DON+ZEA] < [FB1+DON] after 24h. The caspase-3 activity is increased with the mixtures of mycotoxins even though the number of cells undergoing apoptosis did not increase due to concomitant cell proliferation.

The ability of the toxins to inhibit DNA synthesis is 70%, 43% and 45% for 10 µM of ZEA, DON, and FB1, respectively. Their binary mixtures (at 10 µM each), inhibit DNA synthesis by 35%, 62%, and 65%, far less than additive effects. Surprisingly, the tertiary mixture (10 µM each) only inhibits DNA synthesis by 25% leading to cell proliferation and higher survival rate. Altogether these data suggest a potential promoter effect.

1450 INCREASED ACCUMULATION OF FUMONISIN B1, SPHINGOID BASES AND SPHINGOID BASE 1-PHOSPHATES: EXPLAINING THE DIFFERENTIAL SENSITIVITY OF RAT KIDNEY AND LIVER TO FUMONISIN TOXICITY.

R. T. Riley and K. A. Voss. *Toxicology and Mycotoxins Research Unit, USDA-ARS, Athens, GA.*

Fumonisin is a mycotoxin in maize and inhibitors of ceramide synthase a key enzyme in the de novo sphingolipid biosynthesis pathway. In liver and kidney inhibition of ceramide synthase results in a marked increase in the ceramide precursor sphinganine. This study was conducted to investigate the differential changes in sphinganine, sphingosine, sphinganine-1-phosphate and sphingosine-1-phosphate in kidney, liver, serum and heart of male Sprague-Dawley rats fed diets containing fumonisins B1, B2 and B3 at a ratio of 1.00:0.45:0.10, respectively. The total fumonisins in the diets were 1.1, 13.5 and 88.6 µg/g. Animals were killed after 1, 3, 5 and 10 days of feeding. The tissues were analyzed for sphingoid bases, sphingoid base 1-phosphates, and fumonisins B1, B2, and B3, and were microscopically examined for the presence and severity of lesions. Fumonisin B1, but not B2 or B3, was easily detected in liver, kidney and serum. There was a time- and dose-dependent increase in sphinganine in both liver and kidney that was closely correlated with the tissue concentration of fumonisin B1 and histopathologic findings. However, the sphinganine and sphingosine in kidney, but not liver, was quickly metabolized to sphinganine and sphingosine-1-phosphate. The concentration of fumonisin B1 in liver and kidney that first elicited an increase in sphinganine was similar in both tissues, however, over time, the kidney accumulated significantly more fumonisin B1 (10X) and total sphinganine (sphinganine plus sphinganine-1-phosphate).

Thus, the relative sensitivity of male Sprague-Dawley rat kidney and liver is most likely a consequence of differences in the mechanisms responsible for both fumonisin B1 uptake/clearance and sphinganine metabolism via the enzymes sphinganine kinase and sphinganine-1-phosphate lyase.

1451 FOOD CO-CONTAMINATION AND HUMAN DIETARY EXPOSURE OF AFLATOXIN B1 AND FUMONISIN B1 IN CHINA.

G. Sun^{1,2}, S. Wang², X. Hu³, J. Su⁴, Q. Cai¹, L. Tang¹, W. Gao¹ and J. Wang¹. ¹Texas Tech University, Lubbock, TX, ²Southeast University, Nanjing, China, ³CDC Chuzhou Branch, Huai'an, China and ⁴Guangxi Cancer Institute, Nanning, China.

Co-contamination of aflatoxin B1 (AFB1) and fumonisin B1 (FB1) in human dietary components was widely reported. To investigate current co-contamination status of these two mycotoxins in food and potential human dietary exposure, a cross-sectional study including food frequency surveys and food sampling were carried out in residents from 3 different areas in China. Daily food consumptions were recorded in 113 residents from different households. A total of 208 food samples, consisting of 107 corn, 29 rice, 16 wheat-flour, 17 peanut, and 39 vegetable oil were measured for AFB1 and FB1 by the ELISA. The median AFB1 levels (µg/kg) were 2.3 in corn (range, 0.4-136.8), 0.6 in rice (0.1-1.4), 0.4 in wheat-flour (0.1-0.9), 0.2 in peanut (0-0.7), and 9.1 in vegetable oil (0.2-114.4), respectively. Seventeen out of 107 (16%) corn samples had AFB1 level higher than 20 µg/kg. The median FB1 levels (mg/kg) were 1.1 in corn (range, 0-37.0), 0.2 in rice (0-0.5), and 0.2 in wheat-flour (0-0.4), respectively, but FB1 was not detectable in peanut and vegetable oil. Thirty eight out of 107 (36%) corn samples had FB1 levels higher than 2 mg/Kg. Furthermore, the high co-existence rates of AFB1 and FB1 were found in 93% corn (99/107), 93% rice (27/29), and 81% wheat-flour (13/16), respectively. Nine out of 107 (8%) corn samples had AFB1 and FB1 higher than 20 µg/kg and 2 mg/kg. Based on the dietary consumption data, the median daily intakes for AFB1 and FB1 were 1.4 (range, 0.2-49.8) µg and 187.2 (range, 30.0-10,541.6) µg. The different dietary patterns among these 3 areas resulted in the different contamination levels of AFB1 and FB1, and great variations were found in samples collected from different areas. Taken together, this study demonstrates that the high co-contamination of AFB1 and FB1 existed in food samples daily consumed by the residents in China and the potential health effect for chronic exposure to these two mycotoxins needs to be further studied. (Supported by CA94683 from NCI)

1452 THREE-MONTH INTERVENTION TRIAL WITH NOVASIL CLAY IN GHANAIS: STUDY DESIGN AND CLINICAL OUTCOMES.

E. Afrivie-Gyawu¹, N. A. Ankrah³, L. Xu², L. Tang², H. Huebner¹, D. Ofori-Adjere¹, N. M. Johnson¹, N. Sarpong¹, J. H. Williams⁴, J. S. Wang² and T. D. Phillips¹. ¹Texas A&M University, College Station, TX, ²Texas Tech University, Lubbock, TX, ³University of Ghana, Accra, Ghana and ⁴University of Georgia, Griffin, GA.

A double-blinded, placebo controlled clinical trial was conducted to investigate the safety and tolerance of dietary NovaSil (NS) in human populations in Ghana over a period of three-months. Volunteers (507 subjects, ages from 18 – 58 yrs) were clinically screened to evaluate their general health, pregnancy status, and levels of blood AFB1-Albumin adducts. Of these subjects, 177 (101 males, 76 females) were randomly assigned to 3 groups: high-dose (HD), low-dose (LD) and placebo-control (PL) groups receiving 3.0, 1.5 and 0 g NS/day in capsules. These were administered to each participant under the supervision of trained study monitors prior to meals. Blood and urine samples were collected for laboratory analysis. Physical examinations were performed monthly and follow-up was taken to record any side effects daily. Ninety-four percent of the participants (166 of 177) completed the study and compliance rate was 97.4%, 96.4%, and 98.5% for HD, LD, and PL, respectively. Mild to moderate side effects were recorded in some participants. Throughout the study duration, the total reported side effects with respect to possible complaints were 0.66%, 0.68%, and 0.48% for HD, LD, and PL, respectively. Symptoms included nausea, vomiting, diarrhea, flatulence, abdominal discomfort, heartburn and dizziness. These side effects were neither dose-dependent nor statistically significant among the three groups. Also, some participants (in all groups) reported having increased appetite in the course of the study. Overall, 99.4% of person time during the study reported no side effects. No significant differences were shown in hematology, liver and kidney function, electrolytes, and vital signs in the three groups. These findings demonstrate that NS clay for the protection of humans at high risk for aflatoxicosis is practical and economically feasible. (Supported by USAID LAG-G-00-96-90013-00).

1453 THREE-MONTH CLINICAL INTERVENTION TRIAL WITH NOVASIL CLAY IN GHANAIS: REDUCTION OF URINARY AFLATOXIN M₁ LEVELS.

N. M. Johnson¹, A. Robinson¹, N. Sarpong¹, E. Afriyie-Gyawu¹, H. Huebner¹, L. Xu², L. Tang², N. A. Ankrah³, D. Ofori-Adjei³, J. H. Williams⁴, J. S. Wang² and T. D. Phillips¹. ¹Texas A&M University, College Station, TX, ²Texas Tech University, Lubbock, TX, ³University of Ghana, Accra, Ghana and ⁴The University of Georgia, Griffin, GA.

NovaSil clay (NS) has been found to prevent aflatoxicosis in multiple animal species by decreasing toxin bioavailability from the gastrointestinal tract. A randomized, double-blinded, placebo controlled phase IIa clinical trial was conducted in 177 healthy Ghanaian volunteers who received NS clay capsules either in 1.5 g/day (low dose), 3.0 g/day (high dose), or placebo for a period of 3 months. Our objectives were to evaluate the efficacy of NS for reducing AFM₁ biomarkers of exposure in more than 600 urine samples. AFM₁ was measured by immunoaffinity-HPLC-fluorescence methods. The cleanup procedure involved acidification of urine with ammonium formate followed by dilution with deionized H₂O. Samples were passed through preparative monoclonal antibody columns followed by sequential washing steps with PBS and deionized H₂O. AF metabolites were eluted from the column with 80% MeOH then evaporated to dryness and resuspended in MeOH and ammonium formate. Fluorescence intensity was measured using HPLC. The protocol was validated, and the structure of AFM₁ was confirmed by mass spectrometry. Levels of AFM₁ in urine samples collected at baseline and 1-month after intervention did not show a statistically significant difference between the placebo group and low dose group or between the placebo group and high dose group. In urine samples collected after 3-months of the intervention, no statistically significant difference was found between the placebo group and low dose group; however, a significant decrease (up to 58%) in the median level of AFM₁ was found in the high dose group as compared to the median level in the placebo group (P=0.0391). These results suggest that intervention with NS can considerably reduce urine levels of AFM₁. (Supported by USAID LAG-G-00-96-90013-00).

1454 THREE-MONTH CLINICAL INTERVENTION TRIAL WITH NOVASIL CLAY IN GHANAIS: REDUCTION OF SERUM AFLATOXIN-ALBUMIN ADDUCT LEVELS.

P. Wang¹, Y. Tang¹, L. Xu¹, L. Tang¹, E. Afriyie-Gyawu², H. J. Huebner², N. Ankrah³, D. Ofori-Adjei³, J. H. Williams⁴, J. Wang¹ and T. D. Phillips¹. ¹Texas Tech University, Lubbock, TX, ²Texas A&M University, College Station, TX, ³University of Ghana, Accra, Ghana and ⁴The University of Georgia, Griffin, GA.

NovaSil clay (NS) provides significant protection from the adverse effects of aflatoxins (AF) in multiple animal species by decreasing bioavailability from the gastrointestinal tract. It is postulated that NS clay can be safely added to human diets to diminish exposure and health risks from AF contaminated food. To determine the safety and efficacy of NS in humans, a randomized, double-blinded, and placebo controlled phase IIa clinical trial was conducted in 177 healthy Ghanaian volunteers who received NS clay capsules either in 1.5 g/day (low dose), 3.0 g/day (high dose), or placebo for a period of 3 months. The efficacy of NS for reducing AF exposure was evaluated by measuring serum AF-albumin adducts in more than 700 serum samples collected at baseline, 1, 3, and 4 months using radioimmunoassay. Levels of serum AF-albumin adduct at baseline were comparable for the 3 treatment arms with the average 1.563±0.315, 1.505±0.322, and 1.493±0.375 pmol AF/mg albumin for the low dose, high dose, and the placebo groups, respectively. No statistical significance (P=0.345) was found among groups of the low dose (1.214±0.215 pmol AF/mg albumin), the high dose (1.168±0.244 pmol AF/mg albumin), and the placebo (1.253±0.335 pmol AF/mg albumin) in samples collected at 1 month of the trial. However, the levels of serum AF-albumin adduct in samples collected at 3 months of the trial were significantly decreased in both low dose group (0.894±0.155 pmol AF/mg albumin, P<0.0001) and high dose group (0.900±0.156 pmol AF/mg albumin, P<0.0001) compared to the levels of the placebo group (1.195±0.216 pmol AF/mg albumin). Mixed effect model analysis revealed significant dose/time interactions (P<0.001). These results suggest that the three-month intervention trial with NovaSil significantly decreased serum levels of AF-albumin adduct, a long-term biomarker for AF exposure.

1455 THREE-MONTH CLINICAL INTERVENTION TRIAL WITH NOVASIL CLAY IN GHANAIS: NO INFLUENCE ON UTILIZATION OF VITAMINS A AND E.

Z. Wang¹, L. Xu¹, H. Guan¹, X. He¹, L. Tang¹, E. Afriyie-Gyawu², H. J. Huebner², N. Ankrah³, D. Ofori-Adjei³, J. H. Williams⁴, J. Wang¹ and T. D. Phillips¹. ¹Texas Tech University, Lubbock, TX, ²Texas A&M University, College Station, TX, ³University of Ghana, Accra, Ghana and ⁴The University of Georgia, Griffin, GA.

Dietary exposure to aflatoxins (AF) decreases serum and tissue vitamins (Vit) A and E levels in addition to causing liver damage. NovaSil clay (NS) provides significant protection from the adverse effects of AF in animals. To further evaluate the influ-

ence of NS on utilization of these two vitamins in humans, levels of Vit A and E were measured by HPLC methods in 655 serum samples collected at 0, 1, and 3 months from a phase 2a clinical trial carried out in 177 healthy Ghanaian volunteers who either received NS 1.5 g/day (low dose), 3.0 g/day (high dose), or placebo for 3 months. The baseline serum levels of Vit A were comparable (P=0.8702) for groups of the placebo (2.09±0.56 µmol/L), the low dose (2.15±0.74 µmol/L), and the high dose (2.14±0.92 µmol/L). No significance was found among groups of low dose (2.28±0.85 µmol/L), high dose (2.21±0.95 µmol/L) and the placebo (2.21±0.57 µmol/L) in 1 month samples (P=0.7324). No significance was found among groups of low dose (2.22±0.87 µmol/L), high dose (2.30±0.71 µmol/L), and the placebo (2.32±0.83 µmol/L) in 3 months samples (P=0.7305). The baseline serum levels of Vit E were also comparable (P=0.6798) for groups of the placebo (16.07±4.74 µmol/L), the low dose (16.40±5.08 µmol/L), and the high dose (15.64±4.97 µmol/L). No significance was found among groups of low dose (17.9±4.99 µmol/L), high dose (17.08±4.83 µmol/L) and the placebo (17.32±4.97 µmol/L) in 1 month samples (P=0.5868). No significance was found among groups of low dose (17.03±4.71 µmol/L), high dose (17.33±4.21 µmol/L), and the placebo (18.01±6.29 µmol/L) in 3 months samples (P=0.7618). Furthermore, levels of Vit A (P=0.3665) and Vit E (P=0.1543) were not statistically significant among the treated groups and the placebo group in samples collected at 1 month post the trial. These results suggest that NS does not affect utilization of Vit A and E in humans.

1456 DETECTION OF ZERANOL AND METABOLIC ANALOGS IN MOLDY FOOD MATERIALS BY LIQUID CHROMATOGRAPHY WITH ELECTROCHEMICAL DETECTION CONTAINING SCREEN-PLATED DISPOSABLE ELECTRODES.

C. Chou¹, Y. C. Lin², W. Lee¹, C. Hung¹, W. She¹ and J. Zen³. ¹Department of Veterinary Medicine, National Chung-Hsing University, Taichung, Taiwan, ²Department of Veterinary Bioscience, Ohio State University, Columbus, OH and ³Department of Chemistry, National Chung Hsing University, Taichung, Taiwan.

Zeranol (Z) is a semisynthetic growth promoter with estrogenic activities and a naturally occurring mycotoxin metabolite. The presence of low but biologically active levels of Z and its metabolic analogs (Zs) in the diets presents a potential health risk to human consumers. Therefore, it is imperative to be able to determine trace levels of Z and Zs in the food resources. Differentiation of Z and Zs is also advantageous in distinguishing environmental contamination from Z abuse. A simple and rapid high performance liquid chromatography method with electrochemical detection using disposable carbon-plated electrodes for simultaneous determination of Z and 4 major Zs (α -zearalenol, β -zearalenol, β -zearalanol and zearalenone) was developed. With optimal amperometric conditions, the 5 compounds could be separated in 8 minutes using ammonium acetate buffer (pH 7.0) with detection limits in the 10 ppb range. Samples subjected to intentional or unintentional contamination of Z-related compounds, such as beef, pork, chicken, feed, cereal, soybean, rice and beer were analyzed after a single methanol extraction step that required no sample cleanup or derivatization process. The simplicity and reproducibility of this method has made a routine screening possible. Micrograms of Z, α -zearalenol, β -zearalenol, and/or β -zearalanol were discovered from moldy feed, cereal, soybean and rice extracts at a per gram basis, indicating high yield of these compounds from natural environment. Our results also indicated different profiles in food-derived Zs in Taiwan and suggested that rice and soybean consumption in Taiwan may be an unforeseen risk factor for diseases associated with estrogenic activities of Z and Zs.

1457 SORPTION OF ARSENIC BY FERRIHYDRITE AND MAGNETITE AND PREVENTION OF TOXICITY IN HYDRA.

J. F. Taylor, N. S. Sarpong, H. Huebner and T. D. Phillips. Veterinary Integrative Biosciences, Texas A&M, College Station, TX.

Arsenic is a toxic trace element found in groundwater due to natural and industrial processes. Exposure has been linked to cancers of the bladder, lungs, skin, kidneys, nasal passages, liver, and the prostate. Inorganic arsenic is usually found in two forms, arsenate (H₂AsO₄⁻ and HAsO₄²⁻) and arsenite (H₂AsO₃⁻ and ₂AsO₃⁻), with both forms often found together. The purpose of this research was to utilize the properties of clay minerals and iron oxides to develop enhanced composite materials for the sorption of arsenic. A variety of clay minerals and synthesized iron oxides were screened for their ability to bind As(III), as sodium arsenite, and As(V), as sodium arsenate. From this initial screening, As(III) adsorption isotherms were performed on ferrihydrite and magnetite; whereas As(V) isotherms were conducted on ferrihydrite and CP-LPHM. All isotherm data were fit to the Langmuir equation to determine adsorption capacity (Q_{max}). Ferrihydrite bound 95.93% of As(V) and 97.23% of As(III) in the screening studies and had a Q_{max} of 1.288 mol/kg for As(III) and 0.744 mol/kg for As(V). Magnetite exhibited a Q_{max} of 0.481 mol/kg

for As(III). Ferrihydrite and magnetite were combined with chitosan to make composite gel beads. Ferrihydrite was found to be a highly effective sorbent for As(III) and As(V), and magnetite was effective for As(III) removal from water. Ferrihydrite protected adult hydra at levels up to 100 times the minimal effective concentration for As(III) and could potentially be used as a dietary intervention to protect animals from As toxicity. Studies are ongoing to assess the arsenic binding ability of iron-amended-chitosan gel beads and composites. Supported by NIEHS P42 ES04917.

1458 CARRY-OVER OF FEED CONTAMINANTS TO FOOD OF ANIMAL ORIGIN: APPLICATION OF MECHANISTICALLY BASED KINETIC MODELING.

M. Zeilmaier, J. van Eijkeren, A. Sips and J. Bessemers. *National Institute for Public Health and the Environment, Bilthoven, Netherlands.*

The Netherlands

Animal feed which is accidentally poisoned or structurally polluted with environmental contaminants may lead to unwanted transfer of contaminants to domestic animals and, hence, to food of animal origin. In this context accumulation of contaminants after variable exposure scenarios, back-tracing of contaminant sources from animal food data and the determination of withdrawal periods are crucial points in maintaining food safety.

To address these issues various kinetic transfer models were developed. These kinetic models describe the transfer of dioxins and pesticides from feed/grass/soil to eggs of laying hens and milk of lactating cows, aflatoxin B1 from feed to milk of lactating cows and metals such as cadmium from feed/grass/soil to tissues of sheep and lactating cows.

Model applications comprise the back-tracing of the exposure period, the extend of internal exposure and the withdrawal period of lactating cows fed dioxin contaminated clay, the calculation of the long-term excretion of dioxins in cow's milk originating from local soil/grass intake in a heavy industrialised area, the determination of bioavailability of dioxins from soil, inclusive long-term transfer to eggs of laying hens and the determination of the exposure period needed to exceed current EU cadmium standards for the liver and the kidney in cows.

Moreover, the models served the comparison of standards in feed and animal products. For example it turned out that the current EU limit of 0.75 ng TEQ/kg feed of laying hens and the current EU residue level of 3 pg TEQ/g egg fat do not comply.

1459 MECHANISM OF ARSENITE-INDUCED CELL DEATH IS DISTINCT FROM BOTH NOCODAZOLE AND TAXOL.

B. F. Taylor and J. States. *Pharmacology and Toxicology, University of Louisville, Louisville, KY.*

Arsenite, a known mitotic disruptor, causes cell cycle arrest and cell death at anaphase. The mechanism causing mitotic arrest is highly disputed. We compared arsenite to the spindle poisons nocodazole and Taxol. Response was distinct to each drug. In TR9-7 cells, mitotic index analysis indicated an earlier peak in mitotic index during nocodazole and Taxol treatments vs. arsenite treatment. Arsenite and nocodazole displayed distinct mitotic catastrophe DNA morphology while Taxol-treated cells exhibited fragmented nuclei during cell death. Immunocytochemical analysis of α -tubulin in mitotic cells showed spindle formation in arsenite- and Taxol-treated cells but not in nocodazole-treated cells. Spindle formation in arsenite-treated cells appeared irregular and multi-polar. γ -tubulin staining show that Taxol- and nocodazole-treated mitotic cells always contained two centrosomes. In contrast, many arsenite-treated mitotic cells contained more than two centrosomes. We tested additional cell lines to examine whether arsenite sensitivity correlated with that of Taxol and nocodazole. HeLa, A375 (melanoma), and A2780 (ovarian carcinoma) cells were sensitive to all three drugs. CP70 cells, a cisplatin-resistant derivative of A2780 cells, were as sensitive to mitotic arrest inducing drugs as their parental line. A549 (lung adenocarcinoma) cells were sensitive to nocodazole and Taxol, but were resistant to arsenite. Co-treatment with BSO, a glutathione synthase inhibitor, and MK571, an MRP export pump inhibitor, sensitized A549 cells to arsenite but did not alter nocodazole or Taxol sensitivity. Carmustine, a glutathione reductase inhibitor and DNA alkylating agent, increased A549 arsenite sensitivity, but decreased both nocodazole and Taxol sensitivity suggesting that arsenite may be useful as co-treatment in order to enhance DNA damage induced apoptosis despite cells being resistant to arsenite alone. In conclusion, arsenite-induced mitotic arrest, cell death, and resistance appear to be independent of effects on tubulin polymerization. (Supported by PHS grants ES011314 and F30 ES013372.)

1460 ARSENIC TRIOXIDE INDUCES PROGRAMMED CELL DEATH IN HUMAN LEUKEMIA (HL-60) CELLS.

C. G. Yedjou and P. B. Tchounwou. *Biology, Jackson State University, Jackson, MS.*

Abstract: Although arsenic is a poison and a carcinogen, it has been used for as a medicine for thousands of years, dating back to the ancient Greeks and Romans. Recently, arsenic trioxide has been successfully used to treat all-trans retinoic acid (ATRA) resistant relapsing acute promyelocytic leukemia. Previous studies in our laboratory have showed that arsenic trioxide significantly induces cell death in HL-60 cells. However, its molecular mechanisms of action are poorly understood. In the present study, we used human leukemia (HL-60) cells as a model to investigate the in vitro effect of arsenic trioxide on cell growth inhibition and cell death mechanisms. To achieve this goal, we performed the flow cytometric analysis using annexin-V and caspase-3 kits, and DNA fragmentation. The flow cytometric assessment showed a strong dose-response relationship between arsenic trioxide exposure and early and late stage apoptosis in HL-60 cells. Upon 24 hrs of exposure, the results of annexin V/PI Staining showed that the percentages of early apoptotic cells were $1 \pm 0\%$, $11.5 \pm 0.7\%$, $19 \pm 5.7\%$, and $18 \pm 0\%$ in 0, 2, 4, 6, 8 $\mu\text{g/mL}$ of arsenic trioxide, respectively. The result of caspase-3 activity also indicated a significant increase ($p < 0.05$) of caspase 3 positive cells undergoing late apoptosis in arsenic trioxide-treated HL-60 cells. These results were further confirmed by the result of DNA laddering assay showing a clear evidence of DNA fragmentation in arsenic trioxide-treated HL-60 cells. In summary, these studies indicate that arsenic trioxide represents an apoptosis-inducing agent in HL-60 promyelocytic leukemia cells and suggest that this agent may be more broadly used for treatment of leukemias other than APL. Findings from these data indicate that the molecular mechanisms of arsenic trioxide is mediated via phosphatidylserine externalization, caspase-3 activation, and morphology changes as demonstrated by the results of flow cytometric analysis, and DNA laddering assay.

Key words: Arsenic trioxide, HL-60 cells, DNA fragmentation, annexin V, and caspase 3.

1461 ENHANCED EXPRESSION OF METALLOTHIONEIN ISOFORM 3 (MT-3) PROTEIN IN TUMOR HETEROTRANSPLANTS DERIVED FROM As^{+3} AND Cd^{+2} TRANSFORMED HUMAN UROTHELIAL CELLS.

X. Zhou, M. A. Sens, S. H. Garrett, S. Somji and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

The heavy metals arsenite and (As^{+3}) and cadmium (Cd^{+2}) are known human carcinogens and both of them have been associated with the development of bladder cancer. Previous studies from this laboratory have shown that both As^{+3} and Cd^{+2} can malignantly transform normal human urothelial cells. Furthermore, this laboratory has also demonstrated that the third isoform of the metal binding protein metallothionein (MT-3) is not expressed in the normal human bladder but its expression increases in bladder cancer. In this study, this laboratory has proposed that MT-3 might be a biomarker for the development of human bladder cancer. Immunohistochemical staining of MT-3 on archival diagnostic specimens showed that only 2 of 63 (3.17%) benign bladder specimens had even weak reactivity for the MT-3 protein. In contrast, 103 of 107 (96.26%) high grade urothelial cancers and 17 of 17 (100%) specimens of carcinoma in situ stained positive for the MT-3 protein. For low grade bladder cancer it was shown that 30 of 48 specimens (62.5%) expressed the MT-3 protein. Using a cell culture model (UROtsa), it was demonstrated that expression of the MT-3 protein was not required for malignant transformation of urothelial cells by either Cd^{+2} or As^{+3} . In contrast, it was shown that the cells transformed by Cd^{+2} and As^{+3} that did not express the MT-3 gene in cell culture, gained expression of MT-3 when grown as heterotransplants in nude mice. The gain in MT-3 expression when cells were grown as heterotransplants was also shown to occur for the MCF-7, T-47D, Hs 578t, MDA-MB-231 breast cancer and the PC-3 prostate cancer cell lines. An analysis of MT-3 mRNA and protein expression suggested that a post-transcriptional mechanism was responsible for accumulation of the MT-3 protein. The results provide strong evidence that MT-3 could be a biomarker for the development of high grade bladder cancer and that the expression of the MT-3 gene is not involved in the in vitro malignant transformation of UROtsa cells by Cd^{+2} and As^{+3} .

1462 TRANSFORMATION OF HUMAN UROTHELIAL CELLS (UROtsa) BY As^{+3} AND Cd^{+2} INDUCES THE EXPRESSION OF KERATIN 6A.

S. Somji, C. Bathula, X. Zhou, S. H. Garrett, M. A. Sens and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

This laboratory has demonstrated that both Cd^{+2} and As^{+3} can directly malignantly transform the UROtsa cell line and that the tumor heterotransplants produced from these transformed cells had histologic features consistent with human bladder

cancer. Microarray analysis of total RNA from the parental and transformed cells suggested that keratin 6a was overexpressed as a result of cell transformation. This preliminary analysis was confirmed in the present study. It was shown that the Cd²⁺ and As³⁺ transformed cells grown on serum-containing growth medium, and the derived tumor heterotransplants, all overexpressed keratin 6a mRNA and protein compared to UROtsa cells grown on serum-containing growth medium. Immunostaining of keratin 6a in tumor heterotransplants showed focal staining of the tumor cells that was localized to the cytoplasm. Focal immunostaining of keratin 6a was also found in some archival patient specimens of high grade bladder cancer, confirming translation of the results to human bladder cancer. The level of keratin 6a mRNA and protein was also found to be increased in UROtsa cells grown of serum-free growth medium and that increased expression was mediated by the epidermal growth factor (EGF) and insulin in the growth formulation. It is suggested that keratin 6a expression may be a biomarker for malignant urothelial cells that possess an activated EGF pathway that enhances cell proliferation.

1463 GENE EXPRESSION PROFILING OF HYPERKERATOTIC SKIN FROM INNER MONGOLIANS EXPOSED TO ARSENIC.

K. A. Bailey¹, Y. Xia², J. Mo³, J. L. Mumford¹ and S. Thai¹. ¹U.S. Environmental Protection Agency, Research Triangle Park, NC, ²Inner Mongolia Center for Endemic Disease Control and Research, Huhhot, Inner Mongolia, China and ³National Research Council, Washington, DC. Sponsor: D. Wolf.

Millions of people worldwide have been chronically exposed to arsenic levels in drinking water that greatly exceed the current World Health Organization's recommended limit of 10 µg/ml. The skin is a major target of arsenic toxicity, and some of the first clinical signs of chronic arsenicosis are skin abnormalities including abnormal pigmentation and hyperkeratoses (HK), which pose a high risk for cancer development. The Bayingnormen (Ba Men) region of Inner Mongolia has over 300,000 residents that have been exposed to high levels of arsenic in the drinking water for >20 years. Many of these residents have clinical symptoms of chronic arsenic exposure. To further our understanding of the mechanisms of arsenic toxicity, we examined the gene expression of arsenic-exposure-related HK from 7 Ba Men individuals (exposed to 212-950 µg/ml arsenic in drinking water) and non-lesioned skin from 4 control subjects from a nearby area (exposed to 7 µg/ml arsenic in drinking water). Gene expression profiling using Affymetrix® GeneChip Human U133 Plus 2.0 arrays was performed on RNA isolated from these samples. Over 4000 genes had differential expression in HK compared to normal skin (1-way ANOVA, p<0.05; ≥1.5-fold change in expression). The HK samples had keratin gene expression patterns characteristic of hyperproliferative skin. In addition, the altered genes in HK are consistent with proposed mechanisms of arsenic carcinogenesis. Genes that are altered in response to oxidative stress (HMOX-1, CAT, NQO1, GPX2), DNA damage (GADD45A, XPC, XRCC5, DDB2) and involved in apoptosis and cell cycle regulation were all changed in HK skin. These results suggest that arsenic-related gene expression changes in human samples are mechanistically consistent with previously observed laboratory studies of arsenic carcinogenesis and may identify useful biomarkers of arsenic exposure. [This abstract does not necessarily reflect EPA policy.]

1464 TELOMERASE AND CHRONIC ARSENIC EXPOSURE IN HUMANS.

J. Mo¹, Y. Xia², T. Wade³ and J. L. Mumford³. ¹National Research Council, Washington, DC, MD, ²Inner Mongolia Center for Endemic Disease Control and Research, Huhhot, China and ³Human Studies Division, U.S. EPA, National Health and Environmental Effects Laboratory, Research Triangle Park, NC. Sponsor: M. Madden.

Arsenic exposure has been associated with increased risk of skin, lung and bladder cancer in humans. The mechanisms of carcinogenesis are not well understood. Telomerase, a ribonucleoprotein containing human telomerase reverse transcriptase (hTERT), can extend telomeres of eukaryotic chromosomes, delay senescence and enhance cell proliferation. Telomerase activation is shown to promote tumor growth and maintain genome instability and has been suggested as biomarker for assessing cancer risk. The aim of this study is to investigate arsenic effects on hTERT gene expression. Ba Men residents in Inner Mongolia are chronically exposed to arsenic via well water and showed associated health effects, including cancer. The 324 study subjects, including equal number of males and females, have been exposed to arsenic for more than 10 years. Most subjects (76%) have been exposed to arsenic at the concentration of 0.34 to 200 µg/L and the remaining subjects exposed up to 826 µg/L. Water and whole blood samples were collected from the study subjects. RNA was isolated from the blood samples and cDNA was synthesized using reverse transcriptase. hTERT mRNA was quantified using real-time PCR and were linked to arsenic concentrations in drinking water. The results showed that levels of hTERT expression were positively associated with the concen-

trations of arsenic concentrations in drinking water (p<0.0001) after adjusting for age, sex, smoking and pesticide exposure. Among these factors, only age showed significance in affecting hTERT expression. This study provided a linkage between chronic arsenic exposure and telomerase expression in this human population and provided some insight into the mechanisms of arsenic carcinogenesis. The expression of hTERT may potentially be as a useful biomarker for assessing health effects from chronic arsenic exposure. (This abstract does not necessarily reflect U.S. EPA policy.)

1465 OXIDATIVE DNA DAMAGE INDUCED BY INORGANIC ARSENITE EXPOSURE DETECTED USING THE IMMUNO-SPIN TRAPPING METHOD.

C. Kojima¹, E. Tokar¹, D. Ramirez², R. Mason² and M. Waalkes¹. ¹LCC, NCI at NIEHS, Research Triangle Park, NC and ²LPC, NIEHS, Research Triangle Park, NC.

Inorganic arsenicals are known to be toxic and carcinogenic in humans. Chronic arsenic poisoning has occurred as a result of the consumption of high levels of inorganic arsenic-contaminated well-water. Prior work has indicated that inorganic arsenite exposure is associated with 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxo-dG) formation, a biomarker of oxidative DNA damage, possibly as a prelude to arsenite-induced genotoxicity. However, the standard method of detecting 8-oxo-dG has been questioned because of high background rates and because it cannot directly measure DNA radicals, but may instead adventitiously measure oxidation during DNA extraction and sample preparation. Thus, in this study, we investigated the ability of inorganic arsenite to induce oxidative DNA damage using immuno-spin trapping (IST). IST is based on the direct trapping of radicals with 5,5-dimethyl 1-pyrroline N-oxide (DMPO), forming stable nitron adducts, and combines the simplicity, reliability, specificity and sensitivity of spin trapping for the detection of DNA radicals. Rat epithelial liver TRL1215 cells were exposed to micromolar levels of arsenite for 24 h. Arsenite exposure induced DNA radicals in a dose-dependent manner. The values in arsenite-exposed cells were 1.5 to 2.0-fold higher than those in control cells. The addition of L-buthionine (S,R)-sulfoximine (BSO), a specific glutathione synthase inhibitor, or hydrogen peroxide (H₂O₂), as an oxidant, both increased the generation of DNA radicals induced by the arsenite exposure. DNA radical production was 40-fold higher in the presence of BSO and 3-fold higher in the presence of H₂O₂ compared to arsenite alone. These results indicate that cellular GSH plays an important role in the protection against arsenite genotoxicity and H₂O₂ may enhance this genotoxicity. In addition, long-term exposure (> 4 weeks) to submicromolar levels of arsenite caused a delayed increase in DNA radicals in a dose-dependent manner. This work may have implications in chronic arsenic poisoning in humans.

1466 POSSIBLE INTERACTIONS BETWEEN CELLULAR METHYL METABOLISM AND ADAPTIVE EFFLUX DURING CHRONIC ARSENIC EXPOSURE IN HUMAN CELLS.

J. Coppin¹, M. Webber² and M. Waalkes¹. ¹LCC, NCI at NIEHS, Research Triangle Park, NC and ²Michigan State University, East Lansing, MI.

Inorganic arsenic is a human carcinogen that targets potentially the prostate. In this work, we studied the early stages (< 16 weeks) of chronic arsenite exposure (5 µM) in the normal human prostate epithelial cell line, RWPE-1. These cells will undergo malignant transformation with 30 weeks of continuous arsenic exposure. These transformants exhibit genomic DNA hypomethylation, adaptation to arsenic toxicity and glutathione increase. Arsenic is effluxed as a triglutathione complex by the ATP Binding Cassette C1 protein (ABCC1) and increases in glutathione likely increase efflux capacity. Thus, we investigated methyl and glutathione metabolism during arsenic adaptation. The early chronic arsenic-exposed cells showed a time-dependent increase in homocysteine (Hcy) levels (1.5-fold) and in expression of S-adenosylhomocysteine hydrolase (2.5-fold) combined during the early phases, with a decrease in methionine adenosyltransferase 2A (45% reduction). Thus, it appears that S-adenosylmethionine (SAM) recycling is reduced in favor of over-production of Hcy. The expression of cystathionine β-synthase, a key enzyme in the transsulfuration pathway where cysteine is synthesized from Hcy, was markedly upregulated (1.5-fold) in arsenic exposed cells. An arsenic exposure duration-dependent increase also occurred in reduced glutathione, which was associated with an increase in expression of the genes involved in production of glutathione from cysteine, glutamate cysteine-ligase (8.0-fold) and glutathione synthetase (2.0-fold). Expression of the transport protein ABCC1 was markedly increased. These data indicate arsenic reduced SAM recycling leading to an accumulation of Hcy, possibly for increased glutathione production through the transsulfuration pathway. In combination with increased ABCC1 expression, this ultimately could lead to an increase in efflux capacity as an adaptation to arsenic intoxication. Therefore, arsenic adaptation may alter significantly cellular methyl metabolism.

1467 IN UTERO ARSENIC EXPOSURE ENHANCES SKIN SQUAMOUS CELL CARCINOMA FORMATION AND INDUCES PROLIFERATIVE LESIONS OF THE URINARY BLADDER, UTERUS AND ADRENAL IN TG.AC MICE.

M. Waalkes¹, J. Liu¹, D. Germolec², J. Ward³ and B. Diwan⁴. ¹LCC, NCI at NIEHS, Research Triangle Park, NC, ²NIEHS, Research Triangle Park, NC, ³NIAID, Bethesda, MD and ⁴BRP, SAIC-Frederick, Frederick, MD.

The carcinogenic effects of *in utero* arsenic exposure were studied in Tg.AC v-Ha-ras transgenic (Tg.AC) mice, considered a genetically pre-initiated model for skin carcinogenesis. Pregnant Tg.AC mice received drinking water containing sodium arsenite at 0 (control), 42.5 or 85 ppm arsenic from day 8 to 18 of gestation. Dams delivered normally. At weaning (4 weeks) offspring were grouped (n = 25) according to maternal dose, and topically exposed to the skin tumor promoter 12-O-tetradecanoyl phorbol-13-acetate (TPA; 2 µg/0.1 ml acetone, twice/week) from weaning until sacrifice at 40 weeks of age. Compared to control, arsenic alone did not induce skin tumors, while TPA alone produced papillomas and squamous cell carcinomas (SCC) in excess. However, combined prenatal arsenic and postnatal TPA markedly increased the tumor multiplicity (tumors/mouse) of cutaneous SCC in males (2.7-fold) and females (2.3-fold), compared to TPA alone. Prenatal arsenic prior to TPA also markedly increased (up to 10-fold) the incidence of mice with two or more skin SCC in a dose related fashion. *In utero* arsenic also induced adrenal cortical tumors in males (maximum incidence 29%) and females (26%) compared to control (0% in both) irrespective of TPA. *In utero* arsenic exposure induced urinary bladder (UB) transitional cell hyperplasia in both females (maximum incidence 33%) and males (28%), compared to control (0% in both), that appeared largely independent of TPA exposure. Two UB papillomas also occurred in arsenic treated females. Uterine cystic hyperplasia was common with early life arsenic exposure (42% maximum) compared to control (4%), and three uterine tumors (1 adenoma and 2 leiomyoma) occurred in arsenic treated females. Thus, transplacental inorganic arsenic enhanced skin SCC formation when combined with subsequent TPA in Tg.AC mice. *In utero* arsenic exposure also induced adrenal tumors and proliferative lesions of the UB and uterus.

1468 THE NITRIC OXIDE PRODRUG, V-PYRRO/NO, PROTECTS AGAINST ARSENIC TOXICITY AND APOPTOSIS AT THE CELLULAR LEVEL.

W. Qu¹, J. Liu¹, R. Fuquay¹, J. Saavedra², L. Keefe³ and M. Waalkes¹. ¹LCC, NCI at NIEHS, Research Triangle Park, NC, ²SAIC, LCC, NCI Frederick, Frederick, MD and ³LCC, NCI Frederick, Frederick, MD.

The liver is an important target tissue of arsenic. The compound O2-vinyl 1-(pyrrolidin-1-yl)diazene-1-ium-1,2 diolate (V-PYRRO/NO) is a liver-selective nitric oxide (NO) producing prodrug that is metabolized by hepatic P450 enzymes to release NO in hepatocytes. V-PYRRO/NO can protect against the toxicity of various organic hepatotoxicants *in vivo* and *in vitro* but any role in arsenic toxicity is undefined. Thus, we studied the effects of V-PYRRO/NO pretreatment on arsenic-induced toxicity and apoptosis in cultured rat liver epithelial (TRL 1215) cells. TRL 1215 cells acted upon the prodrug to release NO, producing nitrite levels in the extracellular media after 24 hours of exposure to 500 or 1000 µM V-PYRRO/NO measured at 79.0 ± 5.6 and 313.0 ± 12.9 µM, respectively, compared to control levels of 7.50 ± 0.38 µM. Cells were pretreated with V-PYRRO/NO at 500 or 1000 µM for up to 24 hours, then exposed to arsenic (as sodium arsenite) for additional 24 hours and cytotoxicity was measured. Arsenic was significantly less toxic in V-PYRRO/NO (1000 µM) pretreated cells (LC50 = 30.3 ± 2.9 µM) compared to control cells (LC50 = 20.1 ± 1.9 µM). V-PYRRO/NO alone produced a small increase in metallothionein, a metal-binding protein. However, V-PYRRO/NO pretreatment greatly enhanced arsenic induction of metallothionein. V-PYRRO/NO pretreatment markedly reduced apoptotic cell death induced by arsenic (15 µM) as measured by DNA fragmentation ELISA analysis. Activation of the c-Jun N-terminal kinase (JNK) pathway can be critical to apoptotic cell death and pretreatment of cells with V-PYRRO/NO suppressed JNK activation after arsenic exposure. Thus, the prodrug, V-PYRRO/NO, protects against the adverse effects of arsenic in liver cells in culture, including apoptotic cell death and the concurrent activation of the JNK pathway, apparently through generation of NO. The role of NO in preventing arsenic hepatotoxicity *in vivo* deserves further study.

1469 METABOLISM OF PENTAVALENT AND TRIVALENT DIMETHYLATED ARSENIC IN THE MOUSE.

M. F. Hughes¹, B. M. Adair¹, B. C. Edwards¹, D. J. Thomas¹, J. T. Creed², S. Conklin², M. Styblo³, V. Devesa³ and E. M. Kenyon¹. ¹ORD/NHEERL, U.S. EPA, Research Triangle Park, NC, ²ORD/NERL, U.S. EPA, Cincinnati, OH and ³UNC-CH, Chapel Hill, NC.

Dimethylarsinic acid (DMA(V)) is a rat bladder carcinogen after its chronic exposure in either drinking water or the diet. DMA(V) is also a major urinary metabolite of mammals exposed to inorganic arsenic. In mice, iv and po administration of

[14C]-DMA(V) results in rapid urinary excretion of unspecified [14C]. This study assessed the chemical form of the arsenicals excreted in urine by mice after exposure to DMA(V) or dimethylarsinous acid (DMA(III), iodide form), the putative reduced metabolite of DMA(V). Adult female B6C3F1 mice were administered po DMA(V) (0.6 or 60 mg As/kg) or DMA(III) (0.6 mg As/kg). Control mice were administered water. After treatment, the mice were housed for 24 h in metabolism cages for collection of urine. Two methods were used for urinary arsenic analysis. Hydride-generation atomic absorption spectrometry (HG-AAS) was used to detect for DMA(V), DMA(III) and trimethylarsine oxide (TMAO). HPLC-ICP-MS was used to analyze for dimethylthioarsinic acid (DMTA) and trimethylarsine sulfide (TMAS). All five arsenicals were detected in the urine of control and treated mice; levels of each arsenical in urine of treated mice were five times or more higher than in urine of control mice. Urinary levels of DMA(V), TMAO and DMA(III) of treated mice were in the ppm range, except for DMA(III) in the low dose DMA(V) group, which was in the ppb range. Urinary levels of DMTA and TMAS of treated mice were in the ppb range. The rank order of arsenicals detected by HG-AAS in urine of DMA(V)-treated mice was DMA(V) > TMAO > DMA(III). In urine of DMA(III)-treated and control mice, the rank order of arsenicals detected by HG-AAS was TMAO > DMA(V) > DMA(III). Similar values of DMTA and TMAS were detected in urine of each treatment group. TMAO is the predominant metabolite of pentavalent and trivalent dimethylated arsenic excreted in urine of mice, which supports the hypothesis of oxidative methylation of arsenic. (This abstract does not represent U.S. EPA policy.)

1470 CHRONIC EXPOSURE TO ARSENITE IN DRINKING WATER IMPAIRS GLUCOSE TOLERANCE IN C57BL/6 MICE.

D. S. Paul¹, F. S. Walton¹, A. Hernandez-Zavala², D. J. Thomas³ and M. Styblo^{1,2}. ¹Nutrition, University of North Carolina, Chapel Hill, NC, ²CEMALB, University of North Carolina, Chapel Hill, NC and ³NHEERL, U.S. EPA, Research Triangle Park, NC.

Chronic exposures to inorganic arsenic (iAs) have been associated with an increased prevalence of type 2 diabetes mellitus. We have shown that trivalent arsenicals inhibit insulin-stimulated glucose uptake by cultured adipocytes. The current study examines *in vivo* diabetogenic effects of iAs, in an animal model. Here, weanling male C57BL/6 mice consumed deionized water containing iAs(III) (25 or 50 ppm) or water without iAs(III) for 8 weeks. Body weight and water consumption were monitored throughout the study. At 8 weeks, intraperitoneal glucose tolerance tests were administered to all mice. Skeletal muscle, pancreas, liver, and adipose tissue were collected and analyzed for arsenic species. Mice in the 25 and 50 ppm groups consumed significantly less water than did mice in the control group. However, body weights did not differ among treatment groups. Exposure to iAs(III) resulted in impaired glucose tolerance in mice of the 50 ppm, but not 25 ppm, group. The range of concentrations of arsenic in tissues of control mice (.03 to 4.9 ng/g) were significantly lower than the range of concentrations in tissues of mice in 25 ppm (36.9 to 422.8 ng/g) or 50 ppm (120.1 to 1165.4 ng/g) groups. In general, the highest concentrations of arsenic were found in the liver, followed by skeletal muscle, pancreas, and adipose tissue. Dimethylarsenic was the predominant form of arsenic found in tissues of both control and iAs(III)-treated mice. Notably, the average total concentration of arsenic species in livers from mice in the 50 ppm group was comparable to the highest concentration of total arsenic reported in livers of residents of Bangladesh who had consumed water with much lower levels of iAs (0.22 to 2 ppm). These data suggest that the lower susceptibility of mice than humans to the diabetogenic effects of iAs reflect higher rates of clearance of iAs and its metabolites from target tissues. (This abstract does not reflect EPA policies.)

1471 IDENTIFYING CRITICAL CYSTEINE RESIDUES IN ARSENIC (+3 OXIDATION STATE) METHYLTRANSFERASE.

W. Xing¹, Z. Drobna², M. Styblo^{2,3}, B. M. Adair⁴ and D. J. Thomas⁴. ¹Curriculum in Toxicology, UNC, Chapel Hill, NC, ²Nutrition, UNC, Chapel Hill, NC, ³CEMALB, UNC, Chapel Hill, NC and ⁴PKB, ETD, U.S. EPA, Research Triangle Park, NC.

Arsenic (+3 oxidation state) methyltransferase (AS3MT) catalyzes methylation of inorganic arsenic to mono, di, and trimethylated arsenicals. Orthologous AS3MT genes in genomes ranging from simple echinoderm to human predict a protein with five conserved cysteine (C) residues. In human and rat, these are C32, C61, C85, C156, and C206. Roles of the highly conserved residues in catalysis were tested by site-directed mutagenesis in which each C was changed to a serine (S) residue. Studies with rat AS3MT (rAS3MT) found that either C156S or C206S was catalytically inactive and that C61S preferentially catalyzed monomethylation of arsenic. In contrast, human AS3MT (hAS3MT) with C61S, C156S or C206S was catalytically active, suggesting hAS3MT compensated functionally for loss of C

residues critical in rAS3MT. The hypothesis that other C residues in hAS3MT maintained activity in single mutants was tested using hAS3MT with double C to S mutants. Double mutants of conserved C residues (C61S/C156S, C61S/C206, C156S/C206S) were catalytically inactive. Double mutants of a conserved C and a non-conserved C (C156S/C334S, C206S/C334S) were inactive. Preservation of catalytic activity in single C to S mutants of hAS3MT and its loss in double C to S mutants suggests a non-conserved C (e.g., C334) in hAS3MT can provide redundancy that is lacking in rAS3MT. Redundant C residues in hAS3MT might preserve catalysis by allowing formation of disulfide bonds needed for proper protein folding or by interactions with trivalent arsenicals which are substrates for this enzyme. (This abstract does not reflect US EPA policy.)

1472 ARSENITE AND MONOMETHYLARSONOUS ACID-INDUCED SIGNAL TRANSDUCTION IN HUMAN BLADDER CELLS VIA THE PRODUCTION OF REACTIVE OXYGEN SPECIES.

K. E. Eblin, A. Hau and A. J. Gandolfi. *College of Pharmacy-Toxicology, University of Arizona, Tucson, AZ.*

Arsenicals have commonly been seen to induce ROS which can lead to DNA damage, oxidative stress, and carcinogenesis. UROtsa cells (human urothelium) were used to study the effects of arsenicals on the human bladder. Arsenite [As^{III}] and monomethylarsonous acid [MMA^{III}] induce oxidative stress, form 8-hydroxyl-2'-deoxyguanosine, and increase stress proteins in UROtsa cells after exposure to concentrations as low as 1 μM and 50 nM, respectively. This evidence implicates ROS as a plausible mechanism for the signaling alterations seen in UROtsa cells after acute arsenical exposure. MMA^{III} has been shown to increase phosphorylation of ERK 2 in the MAPK signaling cascade downstream of ErbB2. Cyclooxygenase-2 (COX-2) is induced after exposure to 50 nM MMA^{III} and 1 μM As^{III} . To determine importance of ROS in the MAPK cascade and its downstream induction of COX-2, specific ROS inhibitors were used in co-treatment for 4 hr with MMA^{III} or As^{III} and COX-2 protein levels were assessed. For 10 μM As^{III} treatment, COX-2 protein was decreased after co-treatment with DTPA (Fe chelator), superoxide dismutase (O_2^-), sodium azide (NaN_3 , $^1\text{O}_2$), and catalase (H_2O_2). For 500 nM MMA^{III} treatment, COX-2 protein was decreased after co-treatment with potassium iodide ($\bullet\text{OH}$), NaN_3 , or SOD. To determine the importance of ROS in the toxicity of arsenicals, the inhibitors were used in co-treatment with As^{III} or MMA^{III} and cell viability was assessed. The toxicity of As^{III} to UROtsa cells decreased 20% with the addition of NaN_3 , showing the importance of $^1\text{O}_2$ in arsenic-mediated signaling and toxicity. Toxicity of MMA^{III} was ameliorated by the addition of KI or NaN_3 supporting previous evidence that MMA^{III} does induce formation of $\bullet\text{OH}$ which can lead to increased levels of 8-oxo-dG. These findings support that low-level As^{III} or MMA^{III} cause cellular changes via production of specific ROS and by inhibiting ROS during treatment with arsenicals, COX-2 induction and toxicity of arsenicals can be decreased. (Supported by NIH grants ES04940, ES06694, ES07091)

1473 IN UTERO AND POSTNATAL EXPOSURE TO ARSENIC ALTERS EXTRACELLULAR MATRIX GENE EXPRESSION IN THE LUNG.

R. Lantz^{1,2}, G. Chen¹ and B. Chau¹. ¹Cell Biology and Anatomy, University of Arizona, Tucson, AZ and ²Southwest Environmental Health Science Center, University of Arizona, Tucson, AZ.

Growth and development requires the temporal and spatial coordinated expression of genes and gene products. During this critical time, *in utero* and early postnatal exposure to toxicants has the potential to affect gene expression, altering organ structure and physiological function. However, only limited attention has been paid to the effects of environmentally relevant exposures to toxicants during these critical periods of development. In this study female C57Bl/6 mice were exposed to arsenic in drinking water (0, 5, 10, 50 or 100 ppb) prior to mating. Arsenic exposure to the pregnant mothers was continued through birth of pups and until the pups were weaned. Postnatal pups were sacrificed on days 1, 7, 12 and 28 after birth and mRNA from the lungs was extracted for gene expression analysis. Gene expression levels for collagen 1a1, 1a2 and 3a1 and for elastin were determined using real time PCR. In addition, pulmonary response to methacholine challenge was carried out on 28 day old animals. Results showed a dose dependent increase in expression of collagen 1a2 on postnatal day 7 and a dose dependent increase in expression of collagen 3a1 on postnatal day 12. Arsenic-induced alterations in elastin expression were both age and dose dependent. Arsenic at these exposures did not produce any changes in expression of collagen 1a1. Pulmonary function indicated a dose dependent increase in responsiveness to methacholine challenge when expo-

sure was 10 ppb and above. These data indicate that exposure to environmentally relevant levels of arsenic during critical developmental times can lead to alterations in structural genes and in lung function.

This study is supported by NIH Center Grant P30ES006694 and SBRP Grant P42ES004940.

1474 TRANSCRIPTIONAL MECHANISMS INVOLVED IN THE MODULATION OF NQO1 GENE EXPRESSION BY ARSENITE, CADMIUM, AND CHROMIUM.

R. H. Elbekai and A. O. El-Kadi. *University of Alberta, Edmonton, AB, Canada.*

NAD(P)H:quinone oxidoreductase (Nqo1)-mediated detoxification of toxic quinones is involved in the prevention of carcinogenesis. Heavy metals alter the carcinogenicity of AhR ligands by modulating the induction of Nqo1, but the mechanism(s) remain unresolved. In this study, to decipher the molecular mechanisms involved in the alteration of Nqo1 expression, we analyzed the effect of the heavy metals As^{3+} (5 μM), Cd^{2+} (5 μM), and Cr^{6+} (25 μM) on the transcriptional activation of this gene and post-transcriptional modifications of its gene products in Hepa 1c1c7 cells. As^{3+} and Cd^{2+} induced constitutive Nqo1 activity and potentiated the induction by increasing concentrations of the AhR ligand TCDD (0.1-10 nM). On the other hand, Cr^{6+} inhibited inducible Nqo1 activity. In parallel, both As^{3+} and Cd^{2+} , but not Cr^{6+} , induced Nqo1 mRNA in a time-dependent manner and potentiated TCDD-induced Nqo1 mRNA with all concentrations of TCDD tested. Cr^{6+} , on the other hand, had no effect on the time-dependent induction of Nqo1 mRNA and completely inhibited the induction of Nqo1 mRNA with all concentrations of TCDD. The induction of Nqo1 mRNA by the heavy metals was completely inhibited with the DNA transcription inhibitor actinomycin-D, indicating a requirement for *de novo* mRNA synthesis for the induction of Nqo1 mRNA. Furthermore, the protein synthesis inhibitor, cycloheximide decreased Nqo1 mRNA induction, an effect that was partially reversed with the proteasome inhibitor MG-132, thus suggesting a role for a labile protein in the transcriptional induction of Nqo1 by heavy metals. Interestingly, the heavy metals increased Nrf2 protein expression within 0.5h after treatment, suggesting a role for this labile protein in the induction of Nqo1 expression. Surprisingly, all three metals decreased Nqo1 mRNA stability. The three metals did not alter the Nqo1 protein half-life, relinquishing the role of post-translational effects. Thus, it is apparent that heavy metals alter Nqo1 expression at the transcriptional level, possibly through a Nrf2-mediated pathway.

1475 SODIUM ARSENITE-INDUCED CELL CYCLE ALTERATIONS AND APOPTOSIS IN MELANOMA CELL LINES.

S. C. McNeely and J. States. *Pharmacology & Toxicology, University of Louisville, Louisville, KY.*

Arsenic trioxide is an efficacious chemotherapeutic used to treat acute promyelocytic leukemia. Arsenic is also undergoing clinical trials for treatment of other hematological malignancies and solid tumors. We are examining arsenic as a potential drug for the treatment of melanoma. A375 and SK-Mel-2 melanoma cell lines were sensitive to clinically achievable concentrations of arsenite. SK-Mel-3 and SK-Mel-28 cell lines were resistant to arsenite, requiring supra-physiological concentrations for toxicity. However, both resistant cell lines were sensitized to arsenite by pretreatment with buthionine sulfoximine (BSO), a glutathione synthesis inhibitor. Resistance to arsenite was also overcome by co-treatment with MK571, an inhibitor of the MRP family of transport proteins that extrude arsenic from the cell. Arsenite alone or combined with BSO or MK571 induced caspase 3 and poly(ADP-ribose) polymerase (PARP) cleavage suggesting apoptotic cell death. Apoptosis in arsenite-sensitive cell lines was associated with mitotic arrest. In A375 cells, active caspase 3 co-localized with the mitotic marker phospho-histone H3. Mitotic arrest was characterized by cyclin B stabilization. As cyclin B degradation is required for exit from mitosis, the ability of roscovitine, an inhibitor of the cyclin B/CDK1 complex, to promote mitotic exit was tested. Roscovitine decreased the mitotic index of mitotic arsenite-treated cells and abrogated PARP and caspase 3 cleavage. These data suggest that mitotic arrest or exit from an aberrant mitosis caused apoptosis in arsenite-sensitive A375 cells. In contrast, no mitotic arrest was observed in arsenite-resistant SK-Mel-3 and SK-Mel-28 cell lines treated in the presence or absence of BSO or MK571. However, GADD45 α induction suggests G2 arrest prevented mitotic arrest in the SK-Mel-3 and SK-Mel-28 cells. Although the pathway leading to cell death may differ between melanoma cell lines, the ability of arsenite to induce apoptosis in these cells merits further study of its potential use in the treatment of melanoma. (Supported by PHS grants R01ES011314 and T32ES011564.)

1476 SHIFT IN FTIR PATTERNS IN ARSENITE-EXPOSED RAT SPLENOCYTES RELATED TO RHO KINASE AND MAPK SIGNALING PATHWAY.

Arsenite has long been considered a toxic metal that can cause cancer in many organs. From our previous report, we reported that arsenite can cause vinculin and actin cytoskeleton disruption in mouse fibroblasts in a dose-dependent manner and this effect can be blocked by EGFR and PI3K inhibitors. In this study, we found that arsenite can also cause FTIR spectra pattern shift of amide bands in arsenite-exposed rat splenocytes in dose-dependent manner but this toxic effect can be completely blocked by Rho kinase and MAPK inhibitors. The toxic responses induced by arsenite related to the Rho kinase-MAPK signaling and actin cytoskeleton disruption should be further investigated.

1477 ARSENIC STIMULATES HEPATIC CAPILLARIZATION AND INCREASES SINUSOIDAL ENDOTHELIAL MEMBRANE BOUND RAC1-GTPASE *IN VIVO* AND *EX VIVO*.

A. C. Straub¹, D. B. Stolz², M. A. Ross², L. R. Klei¹ and A. Barchowsky¹.
¹Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA and ²Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA.

Arsenic (AsIII) is a naturally occurring environmental toxicant that causes a wide range of organ specific diseases and cancers in millions of people worldwide. Epidemiological evidence demonstrates that drinking water contaminated with arsenic enhances vascular remodeling in humans and contributes to the pathogenesis of liver diseases through poorly defined mechanisms. To investigate the hypothesis that AsIII targets the hepatic endothelium to initiate pathogenic change, mice were exposed to 0 or 250 ppb of AsIII in their drinking water for one, two, or five weeks. AsIII exposure did not affect the overall health of the animals, the general structure of the liver, or hepatocyte morphology. There was no change in the total tissue arsenic levels, indicating that arsenic does not accumulate in the liver at this level of exposure. However, arsenic stimulated increased sinusoidal endothelial cell (SEC) capillarization, a process by which SECs lose fenestrae and develop a basement membrane. In addition to ultrastructural demonstration of SEC defenestration and capillarization, quantitative immunofluorescence revealed increased sinusoidal PECAM-1 and laminin-1 protein expression suggesting gain of adherens junctions and a basement membrane. These effects are recapitulated in isolated SECs exposed to AsIII *ex vivo*. AsIII stimulated Rac1-GTPase localization to SEC plasma membranes *in vivo* and inhibiting Rac1 in isolated cells prevented AsIII-induced surface PECAM expression *ex vivo*. In conclusion, these data demonstrate that As(III) exposure causes functional changes SEC cell signaling for sinusoidal capillarization that may be initial events in pathogenic liver changes promoted by arsenic in drinking water. This work was supported by NIEHS grant E07373 (AB), DS (NCI CA76541) and EPA STAR Fellowship FP-91654201 (AS).

1478 SYNERGIES IN VASCULAR CELL SIGNALING STIMULATED BY CO-EXPOSURE TO ARSENIC AND ETHANOL.

L. R. Klei and A. Barchowsky. Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA.

Arsenic in the drinking water contributes to vascular diseases in millions of people worldwide through unresolved mechanisms. Further, little is known of the combined effects of co-exposures to other environmental toxicants that affect the vasculature, such as alcohol. Humans consuming alcohol may also be exposed to AsIII and these two agents share common dose-dependent angiogenic vascular effects. To investigate potential interactive mechanisms between these two agents, porcine aortic smooth muscle (SMC) or human microvascular endothelial (HMVEC) cells were exposed to a non-cytotoxic concentration of arsenite (5 μ M) in the presence or absence of 0.1% ethanol for 15 min, 1 h or 4h. Co-exposure, but not exposure to either agent alone, caused rapid increases in serine phosphorylation of PKC δ and tyrosine phosphorylation of 109 kDa protein in both SMC and HMVEC. This 109 kDa protein was identified as PYK2, which is known to regulate integrin signaling in vascular cells. Signaling synergy was also shown to be cell specific, since co-exposure increased activation of a 47 kDa Src family kinase member in HMVEC, but not SMC. In comparison, both agents equally increased membrane localization of PLC γ 1 and pro-oxidant Rac1-GTPase in both cell types with no further increase

following co-exposures. Arsenic-induced expression of the angiogenic ligand, vascular endothelial cell growth factor (VEGF) requires PKC δ activation (Soucy *et al Chem Res Toxicol* 17:555-563, 2003). Exposure of the SMC to arsenic or ethanol alone did not significantly induce VEGF, but co-exposure to the agents caused a 5-6 fold induction of VEGF mRNA levels. Thus, the effects of arsenic and ethanol on vascular cell signaling provided synergy in induction of an important vascular mitogen and remodeling factor with potential implications for pathogenic interactions between these two prevalent environmental toxicants at the level of angiogenesis.

1479 ARSENATE REDUCTION BY GLYCOGEN PHOSPHORYLASE. II. EFFECT OF ENZYME INHIBITORS.

Z. Gregus and B. Nemeti. University of Pecs, Med. School, Pecs, Hungary.

Some enzymes that catalyze phosphorolytic (or arsenolytic) cleavage of substrates can reduce arsenate (AsV) to the more toxic arsenite (AsIII) in a thiol-dependent fashion. We have shown this for purine nucleoside phosphorylase (PNP; Toxicol Sci 70:13, 2002), glyceraldehyde-3-phosphate dehydrogenase (GAPDH; Toxicol Sci 85:859, 2005) and glycogen phosphorylase (a GP; poster of Nemeti and Gregus). As inhibitors of PNP and GAPDH antagonize AsV reduction catalyzed by PNP and GAPDH, respectively, it was of interest to know whether GP inhibitors (GPI) counter reduction of AsV by GP. Therefore, we examined if GP-catalyzed AsV reduction is impaired by SH reagents as well as three groups of compounds with known GP inhibitory actions: endogenous compounds (glucose, ATP, ADP), non-specific GPIs (caffeine, quercetin), and specific GPIs (DAB, BAY U6751). The effect of these agents was tested on reduction of AsV by rabbit muscle GP in presence of glycogen (substrate), AMP (activator) and glutathione. AsIII formed in the assays from AsV was quantified by HPLC-hydride generation-atomic fluorescence spectrometry. Experiments with N-ethylmaleimide and p-chloromercuribenzoate indicated that the AsV reductase activity of GP was moderately sensitive to thiol reagents. Glucose above 5 mM and ADP or ATP at physiological levels inhibited GP-catalyzed AsV reduction. 1,4-dideoxy-1,4-iminoarabinitol (DAB; an active site GPI), BAY U6751 (an AMP site GPI), caffeine (a nucleoside site GPI) and quercetin (an unclassified GPI) all diminished reduction of AsV by GP in a concentration dependent manner. AMP at high concentration alleviated the inhibitory effect of BAY U6751 probably because BAY U6751 uses the AMP binding site. Glucose that potentiates the inhibitory effects of caffeine and BAY U6751 on the glycogenolytic activity of GP also enhanced the inhibitory effects of these GPIs on GP-catalyzed AsV reduction. Thus, GPIs inhibit not only the glycogenolytic activity of GP but also its glutathione-dependent AsV reductase activity, suggesting that the latter is coupled to glycogenolysis. (Supported by OTKA and the Hungarian Ministry of Health)

1480 REDUCTION OF ARSENATE BY GLYCOGEN PHOSPHORYLASE. I. INGREDIENTS OF THE REACTION.

B. Nemeti and Z. Gregus. University of Pecs, Med. School, Pecs, Hungary.

The environmentally prevalent arsenate (AsV) is reduced in the body to the much more toxic arsenite (AsIII). We have shown that two enzymes catalyzing phosphorolytic cleavage of their substrates, namely purine nucleoside phosphorylase (Toxicol Sci 70:13, 2002) and glyceraldehyde-3-phosphate dehydrogenase (Toxicol Sci 85:859, 2005), can reduce AsV. Another phosphorolytic enzyme that may also carry out this process is glycogen phosphorylase (GP). With inorganic phosphate (Pi), GP catalyzes the breakdown of glycogen to glucose-1-phosphate (G-1-P), but it also accepts AsV. To test the hypothesis that GP can reduce AsV, we incubated AsV with GP (the phosphorylated form) or GPb (the dephosphorylated form) purified from rabbit muscle. AsIII formed was quantified by HPLC-hydride generation-atomic fluorescence spectrometry. In the presence of AMP, glycogen, and glutathione (GSH), both GP forms reduced AsV, and AsIII formation rates linearly correlated with the enzyme and AsV concentrations. The AsV reductase activity of GP was 10-fold higher than that of GPb. However, incubation of GPb with GP kinase and ATP (that converts GPb to GP) increased AsV reduction by phosphorylase up to the rate produced by GP when incubated with ATP and GP kinase. AsV reduction by GP (like AsV reduction in rats) required the presence of GSH. It also required glycogen (a substrate for GP), and was greatly stimulated by AMP (an allosteric activator of GP) even at low micromolar concentrations. Pi, substrate for GP competing with AsV, inhibited AsIII formation moderately at physiological concentrations. G-1-P, the product of GP-catalyzed glycogenolysis, also decreased AsV reduction. In summary, GP is the third phosphorolytic enzyme identified capable of reducing AsV *in vitro* to AsIII. For AsV reductase activity of GP, the presence of GSH and glycogen is indispensable, suggesting that the reduction is linked to glycogenolysis. While its *in vivo* significance remains to be tested, further characterization of the GP-catalyzed AsV reduction is presented in the accompanying poster (Gregus and Nemeti). (Supported by OTKA and Hungarian Ministry of Health)

1481 BEHAVIORAL ASSESSMENTS OF LONG-EVANS RATS FOLLOWING A 13-WEEK SUBCHRONIC TOLUENE EXPOSURE.

T. E. Samsam, W. M. Oshiro, M. E. Gilbert and P. J. Bushnell. *U.S. EPA, Research Triangle Park, NC.*

Whereas the acute effects of volatile organic compounds (VOCs) are relatively well understood, there is some controversy regarding the potential for persistent effects following long-term exposure. The current study sought to develop an animal model of subchronic exposure to VOCs which may be used to predict effects of long-term exposure to these agents on public health. Adult, male Long-Evans rats were exposed to toluene (0, 10, 100, or 1000 ppm) 6 hr/day, 5 days/week for 13 weeks. Three cohorts of animals (N=40 per cohort) were assessed in a variety of behavioral tasks beginning 2 days after the exposure ended. Cohort 1 was tested on the elevated plus maze (EPM) and showed no differences in anxiety measures between the toluene groups. Cohort 2 was assessed for motor activity on the Figure-8 maze followed by an assessment of anxiety on the EPM. No differences in total motor activity or anxiety were seen between the toluene groups. However, indices of anxiety were significantly different from Cohort 1, presumably as a result of prior Figure-8 maze testing. Cohort 3 was tested on a trace fear conditioning task and showed no toluene-induced differences in cue learning. Conditioning to context was marginally enhanced by toluene, but with no clear dose-dependency. Training to perform a visual signal detection task to assess learning and sustained attention began in Cohort 2 12 days after the end of exposure. Acquisition of a lever-press response for food (autoshaping) was delayed in all toluene-exposed groups; all rats eventually learned the response. Learning a subsequent visual discrimination task was impaired in the 100 and 1000 ppm groups. These results indicate that subchronic exposure to toluene may cause persistent impairments in behavior. [This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.]

1482 VISUAL FUNCTION CHANGES AFTER SUBCHRONIC TOLUENE INHALATION IN LONG-EVANS RATS.

W. K. Boyes¹, L. L. Degen¹, M. Bercegeay¹, J. Mwanza², C. Pinckney³, T. E. Samsam¹, A. M. Geller¹ and P. J. Bushnell¹. ¹EPA, Research Triangle Park, NC, ²National Research Council, Washington, DC and ³Livingstone College, Salisbury, NC.

Chronic exposure to volatile organic compounds, including toluene, has been associated with visual deficits such as reduced visual contrast sensitivity or impaired color discrimination in studies of occupational or residential exposure. These reports remain controversial, however, in part due to a lack of confirmation from controlled laboratory experiments. This study examined rats following exposure to 0, 10, 100 or 1000 ppm toluene by inhalation (6 hr/d, 5 d/wk, 13 wk) as described in Bushnell et al., (SOT, 2007). The week following exposure, rats (n=10/dose group) were surgically implanted with indwelling electrodes over visual cortex. The next week, pattern elicited visual evoked potentials (VEP) were recorded over a range of visual pattern contrasts. Four weeks after exposure, rats were anesthetized, evaluated ophthalmologically, and electroretinograms (ERG) were recorded. No significant changes were observed in VEP amplitudes or contrast thresholds derived from VEP contrast-amplitude functions. There were no dose-related ophthalmologic findings. The latencies of the ERG A- and B-waves were unchanged by toluene treatment. There was, however, a significant dose x intensity interaction for the amplitudes of A- and B-waves. The amplitudes of B-waves were reduced only at stimulus luminance values higher than the apparent rod/cone break in rats treated with 1000 ppm toluene. The ERG results are consistent with a selective deficit in cone photoreceptor function following subchronic toluene exposure. These data provide experimental confirmation that repeated exposure to toluene may lead to subtle changes in visual function.

1483 SUBCHRONIC TOXICITY OF INHALED TOLUENE IN RATS: IMMUNOLOGY, CARDIAC GENE EXPRESSION, AND MARKERS OF OXIDATIVE STRESS.

P. J. Bushnell¹, P. A. Evansky¹, U. P. Kodavanti¹, R. W. Luebke¹, C. B. Copeland¹ and J. C. DeWitt². ¹U.S. EPA, Research Triangle Park, NC and ²UNC Chapel Hill, Chapel Hill, NC.

The health effects of long-term exposure to volatile organic compounds (VOCs) are poorly understood, due primarily to insufficient human exposure data and inconsistent animal models. To develop a rodent model of long-term exposure to VOCs, a sub-chronic inhalation study with multiple endpoints was conducted in rats exposed to toluene, a prevalent VOC. We report here that toluene did not affect immune function or gene expression of ion channel proteins, heme oxygenase (HO-1), or markers of oxidative stress in cardiac tissue. Effects on nervous system functions appear in separate reports. Adult male Long-Evans rats were exposed to toluene vapor at 0 ± 0, 10 ± 1.4, 97 ± 7, or 995 ± 43 ppm (mean ± SD) for 6h/d,

5 d/wk for 13 weeks. During the final week of exposure, subgroups of rats from each concentration were immunized with sheep red blood cells (SRBCs) to assess antibody synthesis; separate groups were sensitized to bovine serum albumin (BSA) to elicit delayed-type hypersensitivity (DTH) responses. Cardiac gene expression was assayed using real time PCR for HO-1, L-type calcium channel (L-Ca), KV1, connexin-40 and sodium channel protein-6 (SCP6). Activities of enzymes sensitive to inhibition by oxidative stress were also analyzed in mitochondrial and cytosolic fractions. Titers of SRBC-specific IgM and IgG antibodies and DTH responses to BSA were not affected by toluene. No consistent exposure-related changes were noted in cardiac gene expression or activity of enzymes associated with oxidative stress. These results indicate that sub-chronic inhalation of toluene in rats did not affect humoral or cellular immunity, did not change the expression of a number of genes coding for important cardiac proteins, and did not induce oxidative stress in cardiac tissue. These findings contrast with significant changes in CNS function observed in other rats in this study. This report does not reflect EPA policy.

1484 AGE-RELATED EFFECTS OF TOLUENE ON THE MOTOR ACTIVITY OF BROWN NORWAY RATS.

R. C. MacPhail, J. D. Farmer and K. A. Jarema. *Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC.*

Senescence raises many uncertainties regarding susceptibility to environmental exposures. Compromises in reserve and repair mechanisms, and alterations in metabolic capacity, may make the aging population more susceptible to environmental contaminants. Additionally, increased variability between individuals might complicate accurate assessment of susceptibility in the aging population. This study was designed to assess the relative sensitivity of aging Brown Norway (BN) rats to the behavioral effects of toluene. BN rats have been used extensively in aging research, although little is known about how they respond to environmental chemicals. BN rats were supplied by the National Institute on Aging at 4, 12 and 24 months of age (N=8 per age). The rats were tested weekly in a commercial photocell device for measuring motor activity during 30-min sessions. Toluene was administered in corn oil by gavage, 30-min prior to testing, in doses of 0, 300, 650 and 1000 mg/kg. Weekly dosing and testing continued until all rats received each treatment. Following vehicle, horizontal activity was highest in the 4-month rats and lowest in the older rats; vertical activity also decreased with age. When expressed relative to vehicle-control values, toluene produced dose-related increases in horizontal activity and decreases vertical activity. Toluene effects were most pronounced in the oldest rats. The oldest rats were, however, the heaviest and therefore received a larger amount of toluene (as mg/kg) than the younger, lighter rats. To evaluate this potential confound, all rats were given the same amount of toluene regardless of body weight. Age-related differences in sensitivity were still obtained. These results indicate advancing age may increase susceptibility to toluene.

This is an abstract of a proposed presentation; the information does not necessarily reflect Agency policy.

1485 CIRCADIAN CONTROL OF THE RAPID DEVELOPMENT OF TOLERANCE TO THE ANALGESIC ACTION OF MORPHINE AND ETHANOL IN THE RAT.

R. L. Williams¹ and K. A. Soliman². ¹DTEM, CDC/ATSDR, Atlanta, GA and ²College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Atlanta, FL. Sponsor: M. Mumtaz.

Sprague-Dawley rats weighing 180-220 g, were maintained in light of 12 hr light-dark cycle (lights on at 07:00 hr) and temperature condition of 21±1°C. In the first experiment, groups of 8 animals were injected i.p. with morphine sulfate 5 mg/kg, or saline at 06:00, 12:00, 18:00, and 24:00 hr for three consecutive days, and the degree of analgesia was assessed 30 minutes post administration by four different procedures. Pain sensitivity was measured through the use of analgesia-meter front paw and hind paw pressure base procedure, tail flick, and the hotplate methods (maintained at 55°C). The peak pain sensitivity was observed in control animals during the light phase while the minimum was observed during the dark phase. Meanwhile, there was a circadian variation in the degree of analgesia produced using each procedure. Maximum analgesia was observed during the light phase (18:00 hr) and minimum analgesia at 12:00 hr. Repeated administration of morphine during the light phase resulted in tolerance development in animals using the hot plate and tail flick methods. Animals developed tolerance using the front paw procedure at each specific hour of treatment. In the second experiment, group of 8 Sprague-Dawley rats weighing 250-350 g were injected i.p. with ethanol (3gm/kg) at 06:00, 10:00, 14:00, 18:00, 22:00, and at 02:00 hr for 2 consecutive days and the degree of analgesia was measured 30 minutes before and 30 minutes after drug administration. The repeated injection of ethanol resulted in tolerance to the analgesic response only if animals were treated during the light phase using the front and hind paw procedures. Results indicate that tolerance to the analgesic effects of morphine and ethanol is a circadian controlled phenomenon. The diurnal

fluctuation in tolerance development observed in the present investigations may be related to circadian variations in brain sensitivity to these drugs, or to diurnal fluctuation of some specific neurohormone in the brain.

1486 SEPTAL HIPPOCAMPAL NEURONAL NITRIC OXIDE SYNTHASE PLAYS A ROLE IN THE TRANSIENT COGNITIVE DECLINE INDUCED BY ETHANOL IN LONG EVANS RATS.

R. H. Khalil¹, M. A. King^{2,3} and M. R. Soliman¹. ¹College of Pharmacy, Florida A&M University, Tallahassee, FL, ²Department of Veteran Affairs, Medical Center, Gainesville, FL and ³Department of Neuroscience, University of Florida, Gainesville, FL.

The present study was conducted to evaluate the role of septal hippocampal neuronal nitric oxide synthase (nNOS) in the decline of spatial reference induced by ethanol. Male Long Evans Rats (200-250 g) were randomly divided in two groups (n=10 /group). Following a 3-day training period, the first group received a daily i.p. injection of ethanol in a dose of 3 g/kg (22.5% w/v solution in saline) for 10 consecutive days; the second group served as control and was injected i.p. with saline. Injections were performed daily at 13:00hr. One hour post injection the spatial reference memory was evaluated by measuring the latency to find the submerged platform on two separate trials, one minute apart. The same evaluation was conducted 24 hours later, immediately before the administration of the next ethanol dose. After the last evaluation, animals were sacrificed by decapitation, the septal hippocampus dissected and its nNOS levels measured by western blot. Results indicate that one hour post-injection, ethanol administration resulted in a significant increase in the time to find the platform ($P<0.0001$) as compared to controls. This impairment was consistent across testing days, indicating that no tolerance developed to acute intoxication. Spatial reference memory deficits as indicated by a significant increase in time to find the platform were also noted in ethanol-treated rats 24-hour post injection. This was mostly seen in day 3 ($p<0.0361$) and day 4 of treatment ($p<0.005$). Ethanol treatment resulted in significant increase (44%) in the levels of septal nNOS as compared to control. These findings clearly indicate that increase in septal nNOS may play an important role in the transient decline in spatial memory induced by ethanol. (Supported by VA Merit Project 0002 and NIH grant RR03020)

1487 ACQUISITION OF 8-ARM RADIAL MAZE (8ARM) TASKS DURING TREATMENT WITH SCOPOLAMINE (SCO), NICOTINE (NIC), ETHANOL (ETH), OR AMPHETAMINE (AMP).

K. L. Steinmetz, R. I. Erickson, E. B. Defensor, R. L. Garcia, D. R. Middaugh, M. Mangels and J. C. Mirsalis. *Mammalian Toxicology, SRI International, Menlo Park, CA.*

The 8ARM is used to identify potential learning and memory deficits in rodents after treatment with potentially neurotoxic therapeutics. We evaluated the utility of the 8ARM by treating adult male Sprague-Dawley rats with SCO (0.17 mpk), NIC (0.4 mpk), ETH (1500 mpk, Task 1 only) or AMP (0.125 mpk, Task 2 only) while being trained to learn one of two tasks. Both Task 1 and Task 2 are win-shift tasks, meaning the rats were rewarded for not revisiting arms. In Task 1, rats were trained to visit 6 baited of 8 arms within 5 min. In Task 2, rats were trained to visit 8 baited of 8 arms within 5 min. Evaluations included numbers and types of errors and time-to-complete (TTC). Rats treated with SCO, a muscarinic (M1) antagonist, required up to 2 min more TTC than controls and made significantly more errors. Although rats treated with NIC, a nicotinic agonist, required 20 sec less TTC, they consistently made more errors. TTC and numbers of errors made by rats treated with ETH or AMP were similar to controls throughout the study. Interestingly, rats in all groups continued to visit the unbaited arms in Task #1, thereby making the same number of reference memory errors that would be expected by chance (-1.75). To assess the effect of prior treatment on the ability to learn a new task, Task 2 rats were removed from all treatments after 5 weeks and trained to learn a new delayed non-match to position Task 3. Rats previously treated were not as proficient as controls in Week 1. By Week 3, there were no differences in performance between controls and any of the previously treated groups. This study was supported by NIAID Contract N01-AI-05417.

1488 PRELIMINARY NEUROLOGICAL AND 8 ARM RADIAL MAZE (8ARM) ASSESSMENTS AFTER TREATMENT WITH THE ANTIMALARIAL, β -ARTEETHER (β AE), TO NEONATAL AND ADULT RATS.

R. I. Erickson, K. L. Steinmetz, E. B. Defensor, D. R. Middaugh, J. Nimer and J. C. Mirsalis. *Mammalian Toxicology, SRI International, Menlo Park, CA.*

More than a million people die each year from malaria; 70% of these victims are children <5 years old. With increased drug resistance to current therapies, new treatments must be developed. Qinghaosu (artemisinin), the medicinal component

of the herb *Artemisia annua*, has been used for many centuries in Chinese traditional medicine as a treatment for fever and malaria. Since being isolated in 1971, artemisinin has shown to be potent and well-tolerated, prompting the World Health Organization to recommend that artemisinin derivatives be used in combination with other therapies to avert drug resistance. Although administered to humans (including children) without apparent toxicity, β AE given to adult rats causes severe brainstem toxicity including necrosis in the superior olive and trapezoid nucleus, regions which affect auditory, vestibular and motor functions. In our studies, adult rats treated intramuscular (i.m.) with β AE (12.5–50 mpk for 14d), did not have impaired spatial navigation in the 8ARM despite demonstrating severe gait disturbances and characteristic necrosis in brainstem nuclei. To date, nonclinical studies with artemisinins have been conducted almost exclusively in adult laboratory species which may not reflect β AE neurotoxicity potential on the developing brain. Beginning on postnatal day 7, neonatal rats (4 males and 4 females per group) were treated daily with β AE at 0, 5, 15, 30, and 90 mpk i.m. One pup (30 mpk) and 3 pups (90 mpk) died on Days 5, 5, 7, and 8, respectively. Neurobehavioral assessment on Days 1, 2, 5, 6 and 8 showed that 90 mpk impaired homing behavior. All pups receiving 90 mpk had significantly reduced weight gain and were found in moribund condition, requiring early termination of remaining pups. Surviving pups will be assessed as adults for neurological histopathology and functionality using motor activity, Functional Observational Battery, and learning and memory (8ARM). Work supported by NIAID contract N01-AI-05417.

1489 THE EVALUATION OF NEUROTOXICITY OF AN ARTIFICIAL DURA MATER CONTAINING DIBUTYLTIN IN RATS BY THE PREPULSE INHIBITION TEST AND AN OPEN FIELD TEST.

M. Tsunoda¹, Y. Inoue¹, K. Ito¹, T. Satoh¹, H. Katagiri², H. Akita³, M. Saji³, T. Yamada⁴, T. Tsuchiya⁴ and Y. Aizawa¹. ¹Preventive Medicine and Public Health, Kitasato University School of Medicine, Sagami-hara, Kanagawa, Japan, ²Public Health, Kitasato University School of Allied Health Sciences, Sagami-hara, Kanagawa, Japan, ³Physiology, Kitasato University School of Allied Health Sciences, Sagami-hara, Kanagawa, Japan and ⁴Division of Medical Devices, National Institute of Health Sciences, Tokyo, Japan.

A synthetic biodegradable artificial dura mater has recently been developed. The major components of dura mater are the co-polymers with poly-L-lactides. For the synthesis of dura mater, catalysts such as dibutyltin (DBT) are used. The effects of the artificial dura mater containing 100 ppm-DBT on the behaviors in rats after intracranial insertion were evaluated using both a prepulse inhibition (PPI) test and an open field test. Thirty rats were divided into three groups, the control, the artificial dura mater group, and the artificial dura mater containing DBT group. A circular bone of 5 mm in diameter was cut out from the cranium of each anesthetized rat. A piece of the artificial dura mater, or the artificial dura mater containing 100 ppm-DBT, was placed on the surface of the brain and covered with the bone. The control group rats underwent the same surgical operation without the insertion. After 4 weeks, PPI and open field tests were performed. In the PPI test session, four types of acoustic stimulation (a startle pulse of a burst of 120 dB, combined trials of prepulse [a burst of 70, 75, or 80 dB] followed with the pulse of 120 dB) were given to each rat in a chamber with a floor equipped with a scale. The percent of prepulse inhibition (% PPI) of a startle response at a prepulse of 80 dB (PP80), 75 dB, or 70 dB was calculated. The mean value of %PPI at PP80 in the artificial dura mater containing DBT group was significantly lower than that in the control. There were no significant differences among the groups in an open field test. The functions of cognition and learning may be impaired in the group for which the artificial dura containing 100 ppm-DBT was inserted.

1490 CIRCADIAN CONTROL OF THE RAPID DEVELOPMENT OF TOLERANCE TO THE ANALGESIC ACTION OF MORPHINE AND ETHANOL IN THE RAT.

R. L. Williams¹ and K. F. Soliman². ¹Agency for Toxic Substances and Disease Registry, Atlanta, GA and ²College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL. Sponsor: M. Sachdeva.

We have shown that the rapid development of tolerance to drugs is a phenomenon which is diurnally controlled, and we have coined the term "chronotolerance" to describe this phenomenon. The present investigations were designed to ascertain the presence of chronotolerance to morphine and ethanol in the rat. In the first experiment, four different groups of Sprague Dawley rats were injected with morphine sulfate 5 mg/kg, or saline at 06:00, 12:00, 18:00, and 24:00 hr for three consecutive days, and the degree of analgesia was assessed 30 minutes after drug administration in each animal. The results obtained indicate that animals exhibited circadian variation in their responsiveness to pain. The peak for pain sensitivity was found to occur during the light phase with a minimum sensation during the dark phase. Meanwhile, there was a circadian variation in the degree of analgesia produced

using each procedure. The results obtained also indicate that repeated injection after twenty-four hours was accompanied by a decrease in the degree of analgesia produced. It was interesting to note that the repeated administration of morphine resulted in tolerance development only if animals were treated during the light phase when assessment was made using the hot plate and tail flick methods. However, animals developed tolerance using the front paw procedure at each specific hour of treatment. In the second experiment, four different groups of male Sprague-Dawley rats were injected with ethanol (3gm/kg) at 06:00, 10:00, 14:00, 18:00, 22:00, and at 02:00 hr for 2 consecutive days, and the degree of analgesia was measured after drug administration. The repeated injection of ethanol resulted in tolerance to the analgesic response only if animals were treated during the light phase using the front and hind paw procedures. The present results indicate the presence of chronotolerance to the analgesic effects of morphine and ethanol. (Supported by NIH Grant # RR 03020)

1491 NICOTINIC-RECEPTOR BLOCKADE AND THE EFFECTS OF ANATOXIN-A ON THE MOTOR ACTIVITY OF RATS: COMPARISON WITH NICOTINE.

K. A. Jarema, J. D. Farmer and R. C. MacPhail. *Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC.*

Anatoxin-a is produced by several species of freshwater cyanobacteria and has caused numerous poisoning episodes in terrestrial and aquatic wildlife, livestock and domestic animals. Anatoxin-a is also a potent nicotinic agonist in the nervous system and at the neuromuscular junction. There has been little research on the behavioral effects of anatoxin-a, and virtually no characterization of the role of nicotinic receptors. These experiments determined the effects and interactions of anatoxin-a and selective nicotinic-receptor antagonists on the motor activity of adult male Long Evans rats. Parallel studies included nicotine. Motor activity was evaluated in a commercial photocell chamber during 20-min sessions. Each experiment included groups of 9 rats that received a dose of anatoxin-a or nicotine, a dose of a nicotinic antagonist, and their combination. Each experiment also included a vehicle-control group. Doses of anatoxin-a and nicotine were 0.6 mg/kg and 2.5 mg/kg, respectively, and were administered s.c. 5-min prior to a test session. Nicotinic antagonists included dihydro-beta-ethroidine (DHBE, 10 mg/kg) and methyllycaconitine (MLA, 10 mg/kg). MLA was given s.c. 15-min prior to testing and DHBE was given immediately before anatoxin-a or nicotine. Pretreatment with DHBE produced a transient blockade of the effect of nicotine, but did not block the effect of anatoxin-a. Pretreatment with MLA blocked the effect of anatoxin-a, but not that of nicotine. These results indicate anatoxin-a differs from nicotine in its site of action, most likely involving stimulation of alpha-7 nicotinic receptors in the nervous system.

This is an abstract of a proposed presentation; the information does not necessarily reflect Agency policy.

1492 BRAIN PGE2 CONCENTRATION IS ASSOCIATED WITH SUSCEPTIBILITY TO KAINATE-INDUCED SEIZURES.

C. D. Toscano and F. Bosetti. *National Institute on Aging/ Brain Physiology and Metabolism Section, National Institutes of Health, Bethesda, MD.*

We have previously demonstrated that genetic deletion of cyclooxygenase (COX)-2, but not COX-1, the enzymes that metabolize arachidonic acid (AA) into prostanooids, can increase susceptibility to kainic acid (KA)-induced excitotoxicity. To further understand the mechanism of this increased susceptibility, we investigated the effect of chronic pharmacological inhibition of COX-2 on KA-induced excitotoxicity. Wild type mice were placed on a diet containing 0, 1000, or 3000 ppm celecoxib, a COX-2 selective inhibitor, for six weeks. At 12 weeks of age, mice were either euthanized by focused microwave irradiation of the brain or injected intraperitoneally with 10 mg/kg KA and euthanized 24 hours after injection. Celecoxib exposure did not alter mean group body weights over the course of treatment. A dose-dependent decrease in PGE2, a major COX-2 end product, was observed in the brains of celecoxib-exposed mice and COX-2 $-/-$ mice (0 ppm = 9.2 ng/g; 1000 ppm = 7.2 ng/g (21%); 3000 ppm = 5.3 ng/g (41%); COX-2 $-/-$ = 4.4 ng/g brain weight (52%)) with no effect of celecoxib treatment or genotype on brain levels of thromboxane B2 (TXB2), a COX-1 preferential end product. Kainate-induced seizure intensity, quantified by median Racine Seizure Scale (RSS), was increased in mice with decreased brain PGE2 concentration (0 ppm RSS = 1; 1000 ppm RSS = 1; 3000 ppm RSS = 2; COX-2 $-/-$ RSS = 3; Kruskal Wallis ANOVA $p=0.008$). This inverse relationship between PGE2 concentration and seizure intensity suggests that chronic inhibition of COX-2 may decrease the production of COX end products that regulate neuronal excitability. This data confirms our previous finding that genetic deletion of COX-2 increases susceptibility to KA-induced excitotoxicity and suggests that chronic exposure to COX-2 selective inhibitors may increase susceptibility to seizures and excitotoxicity. [Supported by the NIA IRP and NIH IRTA programs].

1493 NEUROPROTECTIVE ACTIONS OF PACAP38 IN MODELS OF DOPAMINERGIC TOXICITY.

T. Guillot¹, A. Mercer², O. Zachrisson² and G. Miller¹. ¹Emory University, Atlanta, GA and ²Target Discovery, NeuroNova AB, Stockholm, Sweden.

In this study we explore the possible neuroprotective actions of PACAP38 on dopamine toxicity. PACAP38 (pituitary adenyl cyclase activating polypeptide), a relative of VIP (vasoactive intestinal peptide), has been demonstrated to release growth factors and increase neurogenesis in the subventricular zone of the lateral ventricles (Mercer et al. 2004). Furthermore, endogenous expression of PAC1, a PACAP-specific receptor, is found in the substantia nigra pars compacta and acute direct injection of PACAP38 can protect nigral neurons against 6-OHDA toxicity (Reglodi et al. 2004). In our studies, a total dose of 1 mg/kg PACAP38 was administered to C57BL/6J retired breeder male mice via subcutaneous osmotic pumps over one week. Four weeks post-treatment, PACAP38 treated mice showed a 35% increase vesicular monoamine transporter-2 (VMAT2) in the striatum, but no change in tyrosine hydroxylase (TH) or dopamine transporter (DAT). Also, at two weeks post-PACAP38, a 56% elevation in vesicular uptake velocity of dopamine was observed along with a 19% increase in VMAT2 protein. Since we have shown that mice with genetic reduction of VMAT2 are more susceptible to methamphetamine- and MPTP-induced damage (Fumagalli et al. 1997), we decided to test if PACAP38 is protective in these models. PACAP38 treatment 48 hours after MPTP attenuated some of the behavioral deficits of these mice and was able to reduce VMAT2 loss by 50%; results from methamphetamine studies are pending. While administering PACAP38 after a toxic challenge is effective, PACAP38 pretreatment may provide enhanced resistance to dopamine neurotoxins and other oxidative challenges by elevating VMAT2 levels, thus reducing intracellular dopamine quinones. Since dopamine neurons are already vulnerable due to high basal levels of oxidative stress, reducing this load by increasing VMAT2 may also prolong the survival of these neurons in an unchallenged state as well.

1494 EXERCISE PROVIDES NEUROPROTECTION AGAINST KAINIC ACID TOXICITY THROUGH INDUCTION OF THE CHEMOKINE MCP-1 IN THE HIPPOCAMPUS OF C57BL/6J MICE.

S. A. Benkovic, K. Sriram, J. P. O'Callaghan and D. B. Miller. *TMBB, CDC-NIOSH, Morgantown, WV.*

Physical exercise affords protection to neurons exposed to the excitotoxicant kainic acid (KA). We previously observed attenuation in KA-induced argyrophilia and blood-brain barrier disruption following a 14-day regimen of forced walking in male C57BL/6J mice. Here, we investigated the role of microglial activation in the hippocampus, and the production of microglial-derived factors in the protective mechanism. Mice were assigned randomly to one of four experimental groups: saline, kainic acid, exercise + saline, exercise + KA. Forced walking was achieved in a motorized exercise wheel (6 rpm, 60 min duration, 4:00 PM daily). Mice were acclimated to the wheels for three days, exercised for 14 days, and given an intraperitoneal injection of KA (25 mg/kg). Control animals were not exercised, and received a comparable injection of saline. Following a 12-hour survival, animals were sacrificed and their brains were dissected into regions for RNA extraction and analysis of microglial markers and secretory products by RT-PCR. KA treatment caused a four-fold induction in hippocampal levels of the neurotrophic factor Gdnf, and a two-fold induction in Igf-1; bdnf levels were slightly but non-significantly elevated. Microglial markers, F4/80, Iba1, Mac-1, and p67Phox were unchanged between experimental groups. KA treatment caused a 3-fold induction in IL-1 α and IL-6 levels, a 15-fold induction in Tnf- α levels, and an 8-fold induction in Mip-1 that was increased to 23-fold by exercise pretreatment. Our data suggest the protective effects of exercise against excitotoxicity may occur through modulation of the neuroinflammatory response, and may be mediated through the chemokine Mip-1. Subsequent experimentation will evaluate the protective effects of exercise in Mip-1 knockout mice.

"The findings and conclusions in this report (abstract/presentation) have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy."

1495 SUSCEPTIBILITY TO 1-BROMOPROPANE EXPOSURE AND ALTERATION OF mRNA EXPRESSION IN RATS.

F. Huang¹, S. Ichihara^{2,1}, E. Kitagawa³, S. Mizukami³, H. Iwahashi³, S. Fukunaga¹, K. Furuhashi¹, S. Banu¹, M. Iida⁴, J. Kitoh¹ and G. Ichihara¹. ¹Nagoya University Graduate School of Medicine, Nagoya, Japan, ²Mie University Life Science Research Center, Tsu, Japan, ³National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan and ⁴An-Pyo Center, Iwata, Japan.

The present study aimed to investigate the possible genes related with difference in susceptibility to 1-bromopropane (1-BP) exposure between two inbred strains of rat, F344 and Wistar Nagoya (WNA). Eighteen of 8wk old F344 or WNA male

rats were randomly divided into 2 groups of 9 each. Two groups of F344 or WNA were exposed to 1000ppm 1-BP and fresh air 8 hrs/d, 7 d/wk for 4 wks, respectively. Distal latency (DL) and motor nerve conduction velocity was measured in the rat tail. The liver was dissected out and frozen at the end of the experiment for oligo DNA microarray analysis. Another set of eighteen WNA or F344 were divided into two groups of nine and exposed to 1-BP and fresh air for 8 hrs and the liver was dissected out for the microarray analysis on acute effects of 1-BP exposure. Electrophysiological study showed a significant prolongation in the DL of tail nerve of F344 rats after 4 wk exposure compared to the control. Histopathological examination showed many scanty areas in the cytoplasm of liver cells around the central vein in the exposed F344 rats, but no change in WNA rats. Oligo DNA microarray and real time PCR showed exposure to 1-BP for 8 hrs and 4 wks upregulates mRNA expression of glutathione S-transferase, aflatoxin aldehyde reductase and epoxide hydrolase.

Although our analysis on the microarray has not shown interpretable difference related with the susceptibility between the two rat strains, the result showed consistent increase in mRNA expression of glutathione S-transferase, aldo-keto reductase and epoxide hydrolase after exposure to 1-BP at 1,000 ppm for 8 hrs and 4 wks in F344 and WNA. These genes might be related with the mechanism of 1-BP toxicity and the investigation on the polymorphism of these genes might be useful to understand the susceptibility to 1-BP exposure.

1496 NEUROPROTECTIVE EFFECTS OF SHORT REGULATORY PEPTIDES AND THEIR CYCLIC FRAGMENTS.

A. N. Petrov. *The Institute of Toxicology, ST-Petersburg, Russian Federation.* Sponsor: K. Khamidulina.

Experimental studies of short regulatory peptides and their cyclic fragments for treatment of experimental poisonings of neurotropic drugs has been conducted. One of the final stages in the chain of biological modification of some regulatory peptides involves cyclic peptides formation producing diketopiperazine ring from the residues of two C-terminal acids.

We have characterized neuroprotective effects of the following cyclic dipeptides: cAsp-Phe — cholecystokinin derivative, cLeu-Gly — oxytocin derivative, cHis-Pro — thyroliberin derivative. It was demonstrated that cLeu-Gly eliminated almost completely the short-term memory disorders in rats caused by the M-anticholinergic agent glypiline; cAsp-Phe prolonged the latent period significantly to convulsion onset and survival period in rats poisoned with corasole; cHis-Pro prevented haloperidol catalepsy in rats.

Thus, the studies showed that cHis-Pro, cLeu-Gly and cAsp-Phe have anti-cataleptic, anti-amnesic and anticonvulsant effects respectively. We suggest that some cyclic fragments of the short regulatory peptides can be used for selective impact of poisoning CNS disorders.

1497 DOPAMINERGIC AND GLIAL CELL MARKERS IN A CHRONIC MPTP NON-HUMAN PRIMATE MODEL OF PARKINSON'S DISEASE.

M. K. Chen¹, H. Kuwabara², R. J. Adams³, J. R. Brašić², J. L. McGlothlan¹, M. Alexander², A. Kumar², D. F. Wong² and T. R. Guilarte¹. ¹Env Hlth Sciences, Johns Hopkins University Baltimore, MD, ²Radiology, Johns Hopkins University Baltimore, MD and ³Comp Med., Johns Hopkins University Baltimore, MD.

The early detection of Parkinson's disease (PD) could be advantageous for the treatment and testing of drug therapies to arrest disease progression. We used positron emission tomography (PET) with radiotracers for dopaminergic neuronal and glial markers in a chronic 1-methyl-4-phenyl-1,2,3,6 tetrahydropyridine (MPTP) non-human primate model of PD. PET studies using [¹¹C]WIN35,428 for dopamine transporter (DAT), [¹¹C]DTBZ for vesicular monoamine transporter type 2 (VMAT2), and [¹¹C](R)PK11195 for peripheral benzodiazepine receptor (PBR) in glial cells were performed in baboons (n=5). MPTP was injected i.v. once/week at 0.1-0.2mg/kg for 6-7 months (m) and increased to 0.4-0.6mg/kg until the appearance of clinical signs. PET, movement and behavior were assessed at baseline, at 2, 6-7 & 9-10m after MPTP treatment. At 2m, there were significant (p<0.05) reductions of VMAT2 in caudate (46±5%) and putamen (35±5%) relative to baseline in the absence of an effect on behavior or DAT levels. Increased PBR levels were also measured in caudate (43±11%) and putamen (40±10%). After 6-7m of MPTP treatment, small but significant reductions of DAT were measured in caudate (22±8%) and putamen (17±6%) with persistent reductions of VMAT2 in caudate (46±11%) and putamen (32±8%). PBR levels were increased but did not reach statistical significance. After 9-10m of treatment, animals exhibited impairments in movement behavior and VMAT2 and DAT levels were both dramatically decreased in caudate (78±4% & 58±13%) and putamen (69±5% & 61±13%). However, PBR levels decreased to baseline values. Postmortem analysis of DAT, VMAT2 and PBR using quantitative autoradiography confirmed the PET findings. Our study

demonstrates that PBR could be a sensitive marker for early PD but lacks correlation with PD progression. Importantly, VMAT2 appears to be a more sensitive marker in the early stages of PD compared to DAT [M.J.Fox Found. and ES07062 grant to TRG]

1498 BUPRENORPHINE POTENTIATES METHAMPHETAMINE-INDUCED EXTRACELLULAR DOPAMINE RELEASE IN RAT CAUDATE-PUTAMEN.

B. Gough, S. F. Ali and Z. K. Binienda. *Neurotoxicology, FDA/NCCT, Jefferson, AR.* Sponsor: M. Paule.

Methamphetamine (METH) abuse and addiction presents a major problem in the United States. Efficacy of the adjunctive medication with buprenorphine (BUP) has been demonstrated in the treatment of opiate and cocaine dependence. Using microdialysis, the effects of dopaminergic response to a combined BUP/METH treatment in the rat caudate-putamen was examined. In vivo microdialysis and high performance liquid chromatography with electrochemical detection (HPLC-EC) were used to measure baseline and METH-stimulated striatal dopamine (DA) and its metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) levels in adult male Sprague-Dawley rats weighing between 300 and 500 g. The animals received BUP either at 1 or 10 mg/kg s.c. 10 min before METH administration at 2 mg/kg i.p. Dialysates were assayed every 20 min for 320 min following METH administration. Compared with baseline (100%), a marked 312% increase in extracellular DA within 60 min was observed in animals pretreated with BUP at 1 mg/kg and a 566% increase in extracellular DA was observed in animals pretreated with BUP at 10 mg/kg. However, DOPAC efflux did not change. This BUP potentiation in DA response indicates that BUP may be effective in the treatment of METH addiction.

1499 A TOXICITY STUDY OF QUANTUM DOTS IN MICE.

J. Geys¹, A. Nemmar¹, E. Verbeken², E. Smolders³, B. Nemery¹ and P. H. Hoet¹. ¹Laboratory of Pneumology, Unit for Lung Toxicology, K.U.Leuven, Leuven, Belgium, ²Department of Pathology, U.Z.Leuven, Leuven, Belgium and ³Laboratory of Soil and Water Management, K.U.Leuven, Leuven, Belgium.

Quantum dots are nanomaterials with numerous possible applications in medicine. Studies specially designed for toxicological assessment are few. The aim of our study was to investigate their in vivo effect and body distribution.

Type I EviTags, carboxyl or amine modified, were intravenously injected in mice. In a first experiment high doses of 100, 20 and 4 µg were used and the animals were sacrificed after one hour. In a second experiment lower doses of 4, 0.4 and 0.04 µg were administered and the mice were examined 1, 4 or 24 hours afterwards. Organs were examined with fluorescence microscopy and the cadmium content was measured for assessing the body distribution. Also blood and BAL fluid were analyzed. Ex vivo, platelet aggregation was examined in presence or absence of ADP.

After injecting 100 µg carboxyl EviTags, 3 of 4 animals died immediately. Fluorescence microscopy revealed that their lungs were filled with EviTags containing thrombi; pulmonary thrombosis was also apparent with a dose of 20 and 4 µg of EviTags. In blood, the number of platelets was decreased one hour after injecting 20 µg carboxyl EviTags; in addition, 4 hours after administering 4 µg, the percentage of neutrophils was increased, along with a relative decrease in lymphocytes. Assessing the body distribution, the quantum dots were mainly found in lung and liver. In the BAL fluid, no influx of neutrophils or lymphocytes was observed. Ex vivo, carboxyl and amine EviTags enhanced the ADP induced platelet aggregation down to 0.4 µg/ml and 15 µg/ml, respectively.

In conclusion, our study indicates that the effects of quantum dots depend on the dose and surface charge. Carboxyl EviTags are more potent than amine EviTags. This highlights the need for further investigation of the toxicity of quantum dots before they can be adopted for in vivo or clinical applications.

1500 BIOCOMPATIBILITY OF CARBON-BASED NANOMATERIALS.

C. Grabinski², K. Lafdi², J. Schlager¹ and S. Hussain¹. ¹AFRL/HEPB, Air Force Research Laboratory, Dayton, OH and ²Department of Chemical and Materials Engineering, University Dayton, Dayton, OH.

In evaluating biocompatibility of nanomaterials, defined as possessing one dimension equal to or less than 100 nm, it is important to understand how individual physicochemical parameters influence their toxicity. In this in vitro study, the cellular effect of four well-characterized carbon-based materials possessing diameters from micro- to nano- dimension was investigated using mouse keratinocytes (HEL-30) as a representative model for skin toxicity. The materials tested included conventional fibers (CF; 10 µm diameter), nanofibers (NF; 100 nm diameter), multi-

walled nanotubes (MWNT; 10 nm diameter), and single-walled nanotubes (SWNT; 1 nm diameter). CF and NF did not significantly impact cell viability. MWNT and SWNT reduced cell viability for the first 48 hours of exposure, but the cells recovered to mitochondrial function equal to control by the 72 hour time point. The mitochondrial membrane potential was unaffected by exposure to NF, MWNT, and SWNT after 24 hours. The results of this study suggest that decreasing dimension increases toxicological affects to cells. When decreasing the dimension of a material, however, the surface area and surface energy also increase. Therefore, further study is recommended to determine whether MWNT and SWNT exhibit toxicity due to dimension or the increase in one of these properties. Further studies were used to determine the toxicological effect of surface area and surface energy with constant dimension.

1501 THE EFFECT OF TITANIUM DIOXIDE NANOPARTICLES MOUSE KERATINOCYTES (HEL-30 CELLS).

L. Braydich-Stolle¹, J. Jiang², P. Biswas², J. Schlager¹ and S. Hussain¹.
¹AFRL/HEPB, Air Force Research Laboratory, Dayton, OH and ²Department of Chemical Engineering, Washington University in St. Louis, St. Louis, OH.

Titanium dioxide (TiO₂) nanoparticles are used in a wide range of products from paints to food to cosmetics and sunscreens. In order to assess the possible correlation between nanosize TiO₂ particles and toxicity, we examined the cytotoxic effect of varying sizes of TiO₂ nanoparticles on a mouse keratinocyte cell line. HEL-30 cells were continuously exposed to various sizes of TiO₂ nanoparticles (5, 10, 16, 40, 50, 72, 172, 194, or 223nm diameter particles) at concentrations ranging from 5 to 100 µg/ml. Cytoviva microscope analysis was used to visualize, and confirm, the uptake of the TiO₂ nanoparticles into the keratinocytes. Following 24, 48, or 96 hours of exposure, MTS and LDH assays were performed to assess for disruption in cell proliferation and membrane leakage, respectively. No significant effects of TiO₂ on cell proliferation were observed following a 24 h exposure at all concentrations and sizes. However, following 48 or 96 h exposures to either 50 or 100 µg/ml TiO₂, a significant decrease in cell proliferation for all sizes of TiO₂ was measured. The LDH data obtained following either 24 h or 48 h exposure found no significant increase in membrane leakage for all size particles and concentrations evaluated. Reactive oxygen species concentrations were quantified using a DCFH-DA. At 24 h post-exposure, at a concentration of 100 µg/ml, the particles that were ≥ 40 nm, showed a significant increase in the levels of oxidative stress. In contrast, there was no evidence of oxidative stress for all size particles when tested at a concentration of 10 µg/ml. Future studies are will correlate the crystallinity and structure of these particles with cytotoxic effects.

1502 THE USE OF STRUCTURE ACTIVITY RELATIONSHIPS (SAR) IN CHARACTERIZING THE TOXICOLOGICAL HAZARDS OF PLANT METABOLITES.

E. Freeman¹, R. A. Cardona¹, S. Long¹ and U. Wanner². ¹Regulatory Affairs, Chemtura Corporation, Middlebury, CT and ²Environmental Fate, Chemtura Corporation, Middlebury, CT.

Plant metabolites of the fungicide etridiazole, 5-ethoxy-3-(trichloromethyl)-1,2,4-thiadiazole, were analyzed for their potential human toxicity utilizing DEREK for Windows from Lhasa Limited, Leeds UK. The assessment of the SAR modeling results in conjunction with available toxicity data provided the basis for a useful and favorable risk assessment on the initial metabolic pathway of etridiazole in plants. This assessment involved a step wise analysis of testing and SAR data on the parent and metabolites. The parent material, etridiazole, was modeled as possibly mutagenic in vitro by DEREK; however, a substantial battery of genotoxicity testing demonstrated that etridiazole is a promoter and not a mutagenic or genotoxic compound. One of the major plant metabolites, etridiazole acid was negative for mutagenicity in a battery of in vitro and in vivo assays and also in DEREK. This metabolite was also identified in animal metabolism studies. Other metabolites (3-hydroxymethyl etridiazole, 5-hydroxyethoxy etridiazole acid and dichloro etridiazole) are unique to plant metabolism and were not characterized in in vitro or in vivo studies. The dichloro etridiazole and 5-hydroxyethoxy etridiazole acid contained structural alerts for genotoxicity and further SAR modeling was conducted using Multicase on the 5-hydroxyethoxy etridiazole acid. The overall toxicological evaluation of the plant metabolites supported a favorable safety profile for use in human risk assessment.

1503 RISK AND SYMPTOMOLOGY FROM INHALATION EXPOSURE TO SOLVENT-BASED PAINT VAPOR.

J. E. Hobden¹, R. H. Atallah¹, D. L. Sudakin² and B. J. Kelman¹. ¹Veritox, Inc., Redmond, WA and ²Veritox, Inc., Corvallis, OR.

Seven women aged 24 to 58 claimed that vapor in their indoor office following the application of acrylic sealer and fire retardant coating to an external staircase caused skin, ear, eye, gastrointestinal, joint, neurological, respiratory, and sleep problems

fatigue; headache; heart palpitations; sore throat; and cancer. The women occupied the office for an 8-hour work day before being relocated due to odor complaints. No sampling was done, but the presence of vapor was supported by odor complaints. MSDS's indicate that the volatile constituents are toluene and methyl isobutyl ketone in the sealer, and toluene, xylene, and 1,3,5 triazine, 2,4,6 triamine in the fire retardant. In order to determine what vapors were emitted, weighed paint samples were dried for 3 hours at room temperature in sealed glass vials. The resulting atmosphere was analyzed by gas chromatography/mass spectrometry. In addition to the listed constituents, methyl methacrylate (MMA), 2 hydroxy 3-methyl butanoic acid, 2-propionic acid methyl ester, and tetramethyl cyclohexane were identified from the sealer, and MMA and ethyl benzene were identified from the fire retardant. Although no significant exposure pathway could be identified, the volatile compounds detected have low odor thresholds. MMA has the lowest odor threshold (0.3 mg/m³) and has a distinctive repulsive, acrid odor. For MMA, the OSHA permissible exposure limit (PEL) is 410 mg/m³, and the proposed EPA acceptable exposure guideline level 1 (AEG-1) for an 8-hour exposure is 70 mg/m³. MMA exposure at the odor threshold for 8 hours/day would be approximately 0.07% of the OSHA PEL and approximately 0.4% of the EPA 8-hour AEG-1. The analytical results and records available for the affected individuals supported a diagnosis of mass psychogenic illness (MPI). Symptoms associated with MPI include headache, dizziness, nausea, abdominal cramps, cough, fatigue, sore throat, difficulty breathing, irritated eyes, chest pain, difficulty concentrating, nervousness, rash, and itching, and correlate well with those related by the affected individuals.

1504 COMPARISON OF ORAL ABSORPTION AND SYSTEMIC AVAILABILITY IN THE RAT.

W. Davies¹, A. D. Langford-Pollard², A. McBurney³, D. R. Hawkins², D. Kirkpatrick², P. J. Aikens², A. J. John⁴ and C. I. Smart⁴. ¹Programme Management and Consultancy, Huntingdon Life Sciences, Huntingdon, United Kingdom, ²Metabolism and Environmental Fate, Huntingdon Life Sciences, Huntingdon, United Kingdom, ³Pharmacokinetics, Huntingdon Life Sciences, Huntingdon, United Kingdom and ⁴Drug Metabolism, Huntingdon Life Sciences, Huntingdon, United Kingdom. Sponsor: S. Dean.

In the safety assessment of pesticides, EU member states now tend not to include biliary excretion in the estimation of systemic exposure via the oral route, except when liver is the main target organ. This policy may result in a more conservative risk assessment for operator exposure. This paper compares estimates of systemic availability (F), calculated from plasma AUC values derived from total radioactivity measurements after oral and intravenous dosing, with values for oral absorption obtained in biliary excretion experiments for thirteen compounds. Out of a total of 25 determinations, nine values for systemic availability were lower than those for absorption, eleven values for systemic availability were higher than those for absorption and five values for systemic availability were similar to those for absorption. The limitations of using either biliary excretion or systemic availability to assess systemic exposure are discussed.

1505 RARE ASBESTOS-INDUCED HUMAN DISEASES.

C. Siegers⁴, S. W. Weiler¹, T. Nauert², B. Schaaf³ and S. Syed Ali⁴. ¹Institute of Occupational Medicine, University of Luebeck, Luebeck, Germany, ²Industrial medicine board, State authority of health and occupational safety LGASH, Kiel, Germany, ³Clinic of Internal Medicine/pneumology, University of Luebeck, Luebeck, Germany and ⁴Institute of experimental and clinical Pharmacology and Toxicology, University of Luebeck, Luebeck, Germany.

Inhalation of Asbestos fibers can cause different adverse effects especially according the lung; where the size and diameter of the fibers is critical for their toxicity. Whilst the knowledge of the most frequent asbestos-induced diseases like lung fibrosis, pleural thickening and mesothelioma is quite common, we report on mostly unknown diseases in humans caused by asbestos. In severe cases asbestos can cause mesotheliomas, i.e. malignant tumours of the pleura or peritoneum, with a long latency period of 20-40 years.

We report on a case of a veterinary doctor who died from peritoneal mesothelioma most probably induced by Asbestos from powdered medical gloves. Talcum used in sports and medicinal gloves can contain up to 10% asbestosis fibers. It is likely that other tumors following talcum exposure are not considered as those.

Other cases of two 74 and 76-years aged men were examined after diagnosis of pericarditis constrictiva. In both cases there were longstanding occupational asbestos exposure and no concurring causes for this special disease (e.g. Tuberculosis, infectious diseases, trauma, neoplasma). Cardiac examination results were relatively normal except the diastolic filling limitation due to constriction. Both had typical findings like fibrosis, pleural plaques and round atelectasis.

Conclusions:

When pleural or cardiac changes are etiologically unclear, former asbestos exposures should be taken into account. Possibly asbestos plays a more important role in the pathogenesis of pericarditis than actually known. Even if asbestos use is banned

in many industrialized countries, ongoing use of asbestos, e. g. in automotive industries, has been reported. If there was a relevant exposition to asbestos, an occupational disease should be supposed.

1506 EVALUATION OF THE POTENTIAL EFFECTS OF VARIOUS CIGARETTE INGREDIENTS ON SELECTED BIOLOGICAL ENDPOINTS.

K. Yoshino¹, H. Nakamura¹, M. Ozaki¹, I. Ishii¹, G. W. Lulham², K. M. Lee³, R. A. Renne³, M. Hejtmancik⁴, A. J. Koester⁴ and H. Yoshimura¹. ¹Japan Tobacco Inc., Tokyo, Japan, ²JT International S.A., Geneva, Switzerland, ³Battelle Toxicology Northwest, Richland, WA and ⁴Battelle Memorial Institute, Columbus, OH.

A series of in vitro and in vivo studies was designed to evaluate the potential effects of 253 ingredients on selected biological endpoints. The studies performed included Ames assay, a neutral red cytotoxicity assay, a 30-week dermal tumor-promotion evaluation of cigarette smoke condensate with SENCAR mice, and a 13-week subchronic inhalation study of mainstream smoke with Sprague-Dawley rats. These studies utilized Reference cigarettes, manufactured with a typical commercial tobacco blend without flavoring ingredients and Test cigarettes, identical to the reference cigarette except for containing a mixture of ingredients added as they are normally used in the manufacturing process but exceeding typical application levels. 253 ingredients were divided 4 subsets of 62, 67, 61 and 63 ingredients. The overall ingredient application rates were 1.97, 2.54, 2.43 and 2.94%, respectively, of the tobacco cut filler weight. Two subsets of studies were conducted, and each subset compared 2 Test cigarettes with the Reference cigarette. Genotoxicity, cytotoxicity, dermal tumor-promotion, and inhalation toxicity studies showed no differences between cigarettes with or without ingredients. It was concluded that the addition of ingredients to cigarette does not alter biological activity of mainstream smoke or mainstream smoke condensate with regard to the parameters investigated.

1507 EVALUATION OF POTENTIAL BIOLOGICAL EFFECTS OF SODIUM ALGINATE ADDED TO CIGARETTE PAPERS.

H. Yoshimura¹, H. Nakamura¹, J. Nakai¹, K. Sumiyoshi¹, G. W. Lulham² and R. A. Renne³. ¹Japan Tobacco Inc., Tokyo, Japan, ²JT International S.A., Geneva, Switzerland and ³Battelle Toxicology Northwest, Richland, OH.

Sodium alginate is an ingredient-added to cigarette paper. A series of biological assessments, including Ames and Neutral Red assays of cigarette smoke condensate and an inhalation study of cigarette smoke, was conducted with Test cigarettes with 2 different ingredient levels on cigarette paper (T-1, T-2) compared with Reference cigarettes using conventional cigarette papers (R). In Vitro studies showed no differences between cigarettes with or without the ingredients. For inhalation study, groups of 30 rats/sex were exposed by nose-only inhalation to filtered air (Sham) or 0.06, 0.2, 0.8 mg/L WTPM of smoke for 1h/d, 5d/wk for 13wk of exposure, and 13wk of recovery. Average concentrations of WTPM and CO measured in the highest dose group were 0.806 mg/L and 615 ppm for R group, 0.799 mg/L and 693 ppm for the T-1 group, and 0.800 mg/L and 788 ppm for the T-2 group. Blood COHb concentrations were increased in a dose-related manner in all smoke-exposed groups. Both T groups had significantly greater COHb concentrations at 0.8 mg/L than those of the respective R group. Male rats exposed to all cigarette types had depressed body weight/gains compared to Sham during the exposure phase. Hyperplasia of nasal respiratory and goblet cell epithelium were present in 0.8 mg/L groups from all three cigarette types. Squamous metaplasia and hyperkeratosis were observed in the laryngeal epithelium in almost all rats exposed at 0.8 or 0.2 mg/L from all cigarette types. Exposure to 0.8 mg/L of smoke from all cigarette types induced a minimal hyperplasia in the tracheal epithelium. Statistical comparison of the incidence and severity of microscopic lesions in recovery rats indicated no differences in the severity of lesions between T-1, -2 and R groups. Complete regression from those histological lesions and body weight gain were observed after the recovery period. Inhalation studies showed no differences between cigarettes with or without the test ingredients.

1508 A TWO-GENERATION REPRODUCTIVE TOXICITY AND LACTATIONAL INHALATION-PHASE EXPOSURE STUDY OF DIMETHYL DISULFIDE IN RATS.

M. D. Nemec¹, D. T. Kirkpatrick¹, P. Sawhney¹, J. F. Knapp¹, J. Sherman¹, E. Tanchevski¹, D. A. Donahue¹, E. D. Petrucci¹ and C. H. Farr². ¹WIL Research Laboratories, LLC, Ashland, OH and ²Arkema, Inc., Philadelphia, PA.

Dimethyl disulphide (DMDS) is a promising methyl bromide replacement candidate for soil fumigation applications with zero ozone depletion potential (ODP). Methyl bromide has an ODP of 0.38 and has been classified as a Class 1 stratos-

pheric ozone depletor. Daily exposure (6 h) of 4 groups of 30 SD rats/sex to vapor atmospheres of DMDS (0, 5, 20 or 80 ppm) did not cause any adverse effects on reproduction (reproductive performance, parturition, mean numbers of implantation sites and male spermatogenic parameters) across two generations (F0/F1). No reproductive target organs were identified. At 20 and 80 ppm, systemic toxicity was apparent in deficits in body weight, body weight gain and food intake. A NOAEL for parental systemic toxicity was established at 5ppm and a NOAEL for reproductive toxicity was established at 80 ppm. However, F1 pup body weight gains were reduced across all DMDS-exposed groups without any specific correlation to exposure concentrations. In order to determine if an exposure-response relationship exists between lactational inhalational exposure and pup body weight, and to determine the critical period of lactational inhalational exposure, 4 groups of 36 female SD rats were exposed in a comparable regimen during LD 5-12, 13-20 or 5-20. While the systemic parental toxicity was replicated, no effects on pup body weights were observed. In a parallel study, 4 groups of 10 female SD rats and their pups were simultaneously exposed to DMDS (0, 2, 20 or 80 ppm) in cylindrical maternity chambers during LD 5-20. Here, an exposure concentration of 80 ppm caused maternal toxicity with an accompanying reduction in pup body weight gain, but without any indication of selective juvenile toxicity. No effects were observed at 2 and 20 ppm. Collectively, these three studies established the threshold of neonatal inhalational toxicity of DMDS, in the two-generation study, as greater than 80 ppm.

1509 N-ACETYLATION OF AROMATIC AMINE HAIR DYES ANTAGONIZES HAPTENIZATION.

C. Goebel¹, T. Sieber², O. Goettel², L. Chassot², E. Gerberick³ and P. Aeby². ¹Human Safety Assessment, Procter & Gamble Co., Wella Service GmbH, Darmstadt, Germany, ²Experimental Product Safety, Procter & Gamble Co., Wella-Cosmital SA, Marly, Switzerland and ³Central Product Safety, Procter & Gamble Co., Cincinnati, OH.

A key element in the safety assessment of cosmetic chemicals is the prediction of their sensitizing properties when applied to human skin. For aromatic amine hair dye precursors of the phenylenediamine and aminophenol type, skin metabolism may be involved in the induction of skin sensitization, since they contain amino groups capable of undergoing enzymatic metabolism in the skin.

Since N-acetylation is known as a major enzyme reaction for aromatic amines in the skin, we tested N-acetylated metabolites of p-phenylenediamine (PPD) and 4-amino-2-hydroxytoluene (AHT) for their sensitizing properties *in vitro* using our dendritic cell (DC) activation assay (Aeby et al, 2004) and *in vivo* using the Local Lymph Node Assay (LLNA).

PPD itself did not induce activation of DC cells, but induced a positive LLNA response, as expected for a known human sensitizer. Activation of DC was obtained, when PPD was pre-incubated with the strong oxidizing agent K3[Fe(CN)6] or by exposing dissolved PPD to air oxygen for 24h. Under both conditions, the potent sensitizing PPD metabolite Bandrowski's base (BB) was identified among other oxidation products, indicating that formation of BB is a possible haptenization pathway. Mono- or diacetylation of PPD did neither induce DC activation nor a positive LLNA response.

For AHT, DC activation *in vitro* was induced without pre-treatment, reflecting the positive LLNA response. N-acetylation of AHT significantly reduced DC activation. Using human skin *ex vivo* and/or a human keratinocyte cell line, we found that a substantial amount of AHT and PPD, respectively, is N-acetylated under exposure conditions mimicking the use of hair dyes. We conclude that dermal N-acetylation of aromatic amine hair dyes antagonizes their haptenization.

1510 SAFETY AND THERAPEUTIC EFFICACY OF UNDENATURED TYPE II COLLAGEN (UC-II) IN HORSES.

R. C. Gupta¹, A. Stocker¹, G. Zyrkowski¹, A. Keller¹, T. D. Canerdy¹, J. T. Goad¹, M. Bagchi² and D. Bagchi^{2,3}. ¹Toxicology, Murray State University, Murray/Hopkinsville, KY, ²InterHealth Research Center, Benicia, CA and ³Creighton University Med. Center, Omaha, NE.

Currently, millions of horses suffer from arthritis, a chronic, crippling disease that affects their daily activities, especially running. This investigation was undertaken to evaluate the effectiveness of pain reduction and safety of UC-II in arthritic horses. Arthritic horses divided into four groups (n=5-6) were treated as: Group-I (placebo), Group-II (20 mg UC-II/day), Group-III (40 mg UC-II/day), and Group-IV (80 mg UC-II/day) for a period of 150 days. Group-I horses showed no changes in arthritic condition, while those in Groups II and III showed moderate improvement. Group-IV horses receiving 80 mg UC-II/day exhibited significant and marked improvement. Reduction in overall pain was from 4.7±0.36 to 1.0±0.0 (79%); in pain upon limb manipulation from 3.4±0.20 to 1.0±0.0 (71%); and in pain after physical exertion from 3.10±0.20 to 1.0±0.0 (68%). Overall, horses were running and more playful. No significant change was noted in body weight, pulse

rate, respiration rate, and body temperature. Horses receiving placebo or UC-II revealed no change in liver (ALP, GGT, or bilirubin) or kidney (BUN or creatinine) function. These findings suggest that UC-II at 80 mg/day ameliorates signs and symptoms of arthritis and is well tolerated in arthritic horses.

1511 A 90-DAY ORAL (GAVAGE) TOXICITY STUDY OF S-111-S-WB WITH A 60-DAY RECOVERY PERIOD IN SPRAGUE DAWLEY RATS.

J. J. Mertens¹, D. W. Sved¹, G. M. Marit¹, N. R. Myers¹, P. L. Stetson¹, S. R. Murphy², B. Schmit³, M. Shinohara⁴ and C. H. Farr². ¹WIL Research Laboratories, LLC, Ashland, OH, ²Arkema, Inc., Philadelphia, PA, ³Solvay, SA, Brussels, Belgium and ⁴Asahi Glass Company, Ltd., Tokyo, Japan.

A mixture of perfluoro fatty acid ammonium salts of different carbon chain lengths (C7-C13) was administered by gavage for 90 days to CrI:CD®(SD)IGS BR rats at dosages of 0, 0.025, 0.125, and 0.6 mg/kg/day to evaluate its possible toxic effects. Males were more sensitive than females. Higher hepatic β -oxidation and liver weights indicative of mild peroxisome proliferation were present in the 0.125 mg/kg/day males and 0.6 mg/kg/day males and females. Lesions consisted of hepatocellular hypertrophy and eosinophilic foci in the 0.125 and 0.6 mg/kg/day males and hepatocellular degeneration and necrosis in the 0.6 mg/kg/day males. Other lesions consisted of ulceration, epithelial hyperplasia and acute inflammation in the duodenum and ulceration, erosion, squamous hyperplasia and chronic active inflammation in the stomach. Lower serum protein and higher bilirubin, urea nitrogen, and chloride concentrations were seen in the 0.6 mg/kg/day males and lower globulin and higher alkaline phosphatase concentrations in the 0.125 mg/kg/day males and 0.6 mg/kg/day males and females. After 2 weeks serum concentrations of pentadecafluorooctanoic acid (C8), heptadecafluoronanoic acid (C9), pentafluoroundecanoic acid (C11) and perfluorotridecanoic acid (C13) were similar at the sampling times with tmax ranging from 1-4 hrs post-dosing. After 90 days of dosing only C9 reached a steady state in the females dosed with 0.025 mg/kg/day. Serum C8 and C9 concentrations in the males were 10-fold higher than in the females, whereas C11 and C13 were similar for both genders. The main elimination for C8 was via the urine in males, C9 via the urine in females, and C11 and C13 via the feces. Elimination of C9 via the urine in males and via the feces in both genders was relatively low. Based on the results of this study the no-observed-effect-level was 0.025 mg/kg/day for the males and 0.125 mg/kg/day for the females.

1512 THE NONCLINICAL TOXICITY PROFILE OF ALEXIDINE, A DISINFECTANT FOR OPHTHALMIC USE.

M. E. Richardson¹, J. Driot², J. LePage², D. McCanna¹ and K. W. Ward¹. ¹Pre-Clinical Safety, Bausch and Lomb, Rochester, NY and ²Pre-Clinical Safety, Bausch and Lomb, Montpellier, France.

Alexidine is a biguanide disinfecting agent. A comprehensive toxicological investigation of the agent has not been published. Therefore, in these studies an evaluation of the safety profile of alexidine has been conducted. Endpoints in these evaluations include ocular safety, dermal sensitization, systemic toxicity, cardiovascular safety pharmacology, and genotoxicity potential. To evaluate the ocular effects of alexidine, an array of tests were conducted including an in vitro sodium fluorescein permeability assay, a single dose eye irritation study and a 14-day ocular safety study. A guinea pig maximization test was used to evaluate the dermal sensitization potential of alexidine. Systemic effects were evaluated in several rat and dog oral toxicity studies up to 28 days in duration while cardiovascular safety was evaluated in an in vivo conscious dog model. A battery of four assays (Ames, mouse lymphoma, chromosomal aberration, and in vivo micronucleus) was conducted to evaluate for genotoxicity potential. Alexidine demonstrated no significant effects in the ocular assays and skin sensitization model, and was negative in the genotoxicity assays. QT prolongation was not observed at very high oral doses (500 mg/kg) in the dog. Diastolic and mean arterial pressures were transiently increased in the dog at 500 mg/kg with no effects observed at the next lowest dose (100 mg/kg). The no observable adverse effect levels in the repeat dose studies were 15 mg/kg or higher with significant effects observed at 30 mg/kg or higher. In summary, these data support a favorable toxicity profile of alexidine.

1513 EVALUATION OF 4-(4-HYDROXY-4-METHYLPENTYL)-3-CYCLOHEXEN-1-CARBOXALDEHYDE (HMPCC) IN A 28-DAY ORAL SUBCHRONIC TOXICITY STUDY.

V. T. Politano and A. Api. Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.

HMPCC (4-(4-hydroxy-4-methylpentyl)-3-cyclohexen-1-carboxaldehyde) is a widely used fragrance material. A 28-day repeated dose oral subchronic toxicity study on HMPCC was conducted according to OECD Guideline 407 to evaluate

its systemic toxicity. Five rats/sex/dose were gavaged once per day for 28 days with 0, 15, 150, or 1000 mg/kg/day HMPCC in arachis (peanut) oil. Clinical signs, sensory reactivity to different stimuli, grip strength, motor activity, body weights, and food and water intake were monitored. Blood samples were drawn on day 28 for hematological and blood chemistry investigations. On day 29, all animals were euthanized and necropsied.

No effects were observed in rats treated with 15 mg/kg/day. In males treated with 150 mg/kg/day, increased albumin, decreased cholesterol, and increased liver weights were observed. Additionally, hepatocyte enlargement was observed in three males treated with 150 mg/kg/day. In females treated with 150 mg/kg/day, alkaline phosphatase was increased. Also, an increase in plasma enzymes, albumin and albumin/globulin ratio, and an increase in liver weights accompanied by centrilobular or generalized hepatocyte enlargement were observed in both sexes of the 1000 mg/kg/day group. Further, males treated with 1000 mg/kg/day showed a reduction in bodyweight gain and food consumption (Week 1 only), a reduction in plasma cholesterol, total protein and glucose, an increase in kidney weights, and centrilobular hepatocyte necrosis.

The no-observed-effect-level (NOEL) was determined to be 15 mg/kg/day. The histopathological changes observed in three males treated with 150 mg/kg/day were confined to adaptive liver changes, and as a result the no-observed-adverse-effect-level (NOAEL) was determined to be 150 mg/kg/day.

1514 EFFECTS OF PERFLUOROBUTYRATE EXPOSURE IN MICE DURING PREGNANCY.

K. P. Das¹, B. Grey¹, J. Butenhoff², S. Tanaka², D. Ehresman², D. Zehr¹ and C. Lau¹. ¹Reproductive Toxicology division, U.S. EPA, Research Triangle Park, NC and ²Medical Department, 3M, St. Paul, MN.

Perfluorobutyric acid (PFBA) is a fluorinated organic chemical found in the environment, perhaps as a contaminant of perfluoroalkyl acids (PFAA) production. Previous rodent studies from our laboratory have indicated developmental toxicity of PFAAs such as perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA). The current study examines whether similar toxicity can be extended to PFAAs with shorter carbon chains such as PFBA. PFBA/NH₄⁺ was given to timed-pregnant CD-1 mice by oral gavage daily from GD 1-17 at doses of 35, 175 and 350 mg/kg; controls received water vehicle. These doses were chosen to approximate the effective doses of PFOA, after taking into consideration the shorter half-life of PFBA (estimated at ~3 h in non-pregnant mice). At GD 17, 24 h after the previous treatment, the serum PFBA levels have declined to 3.78, 4.08 and 3.12 μ g/ml, respectively in the three treated groups. PFBA did not significantly affect maternal weight gain, number of implantations, incidence of resorptions, fetal viability, or fetus weight. Gross examination of the fetuses did not reveal any anatomical malformations. However, maternal liver weights were significantly increased in the two highest dose groups. In contrast to PFOA and PFOS, PFBA exposure during pregnancy did not adversely affect neonatal survival or postnatal growth. These data therefore suggest that, unlike PFOA and PFOS, exposure to PFBA during pregnancy in the mouse is not associated with overt developmental toxicity, perhaps in part due to the relatively short half-life of the chemical. This abstract does not necessarily reflect US EPA policy.

1515 METHYL TERTIARY BUTYL ETHER (MTBE) 14-DAY DRINKING WATER STUDY IN WISTAR RATS.

E. Bermudez¹, H. Parkinson¹ and S. J. Borghoff². ¹CIIT Centers for Health Research, Research Triangle Park, NC and ²Integrated Laboratory Services, Research Triangle Park, NC.

MTBE has been widely used as a gasoline oxygenate and identified in a variety of environmental media including groundwater. A series of studies designed to assess the potential toxicity of MTBE, administered in the drinking water, have been undertaken. In the current study, male and female Wistar rats were administered MTBE via the drinking water at concentrations of 0, 3, 7, and 15 mg/ml for 14 consecutive days. Body weights, clinical signs, and food and water consumption were monitored daily. Kidneys and testes weights were measured and blood was collected for the determination of concentrations of MTBE and its major metabolite, tertiary butyl alcohol (TBA). Additional blood analyses included hematocrit, BUN, and serum creatinine levels. Airborne concentrations of MTBE in animal room air and control cages averaged ≤ 0.2 ppm and in high dose animal cages ≤ 33 ppm throughout the study. Consumption of water was significantly reduced in treated versus control rats by approximately 20-30% and 35-39%, in males and females, respectively. There were no significant changes in body weights and food consumption. MTBE daily doses were: 371, 799, and 1624 mg/kg for males and 363, 843, and 1839 mg/kg for females. MTBE blood levels averaged ≤ 2.1 μ M, while TBA blood concentrations ranged from 38-116 μ M. Kidney weights were increased in male rats of the 15 mg/ml group. Testes weights in MTBE-treated rats were similar to control values. In summary, Wistar rats were found to tolerate MTBE in the

drinking water. Consumption of MTBE in water did not result in clear toxic effects as there were no adverse clinical observations, body weight gains and food consumption were unaffected, and there were no indications of dehydration. However, MTBE exposure resulted in increased blood concentrations of TBA, increased kidney weights in males, and BUN and hematocrit levels were depressed in females. [This study was sponsored by Shell Oil Company, Chevron USA, Inc., and ExxonMobil Corporation].

1516 A 28-DAY INHALATION
REPRODUCTIVE/DEVELOPMENTAL SCREENING
TOXICITY STUDY OF (3-
CHLOROPROPYL)TRIMETHOXSILANE IN SPRAGUE-
DAWLEY RATS.

S. D. Crofoot¹, K. P. Plotzke¹, R. Gerspach², U. Decker², K. Biedermann² and A. Marburger². ¹Dow Corning Corporation, Auburn, MI and ²RCC Ltd., Itingen, Switzerland.

The potential toxicity of (3-chloropropyl)trimethoxysilane, a high production volume chemical, was evaluated in a combined repeated-exposure toxicity study with a reproductive/developmental toxicity screening test. The study design utilized an enhanced version of a protocol in accordance with the OECD and EPA test guidelines numbers 422 and 870.3650, respectively. Neurotoxicity endpoints, including Functional Observational Battery (FOB) and Motor Activity, were performed on male and female rats. The test substance was administered six hours per day by whole-body vapor inhalation to 10 rats/sex/group at 0, 5, 25 and 100 ppm. These exposure concentrations were based on previously conducted studies in which effects were seen in the renal system, liver and adrenal glands primarily at concentrations of greater than or equal to 100 ppm. In the current study no test article-related mortalities or clinical signs were noted throughout the study. There were no effects on body weight or food consumption among the groups. No treatment-related changes were observed in any FOB or motor activity parameters. There were no macroscopic differences upon examination of organs/tissues, nor alterations in organ weights, organ-to-body weight ratios, and organ-to-brain weight ratios among the groups. Histopathologic examination of tissues and organs from control and high exposure animals demonstrated no significant microscopic findings. No effects were observed in any of the reproductive parameters evaluated. Based on the results of this study, the NOEL for (3-chloropropyl)trimethoxysilane in rats via the whole-body vapor inhalation route was considered to be 100 ppm for all evaluations: toxicological, reproductive, developmental, and neurological. (Supported by the Silicones Environmental, Health and Safety Council of North America).

1517 PERFLUORO-N-BUTYL IODIDE (PFBI) 13-WEEK NOSE-
ONLY INHALATION TOXICITY STUDY IN RATS WITH
A 4-WEEK RECOVERY PERIOD.

G. Hoffman¹, S. Gosselin¹, N. Macri¹, D. Dodd², L. Narayanan³ and D. Mattie³. ¹Huntingdon Life Sciences, East Millstone, NJ, ²CIIT-CHR, Research Triangle Park, NC and ³AFRL/HEPB, Wright-Patterson AFB, OH.

Perfluoro-n-butyl iodide (PFBI) is an environmentally acceptable (i.e., zero ozone depletion potential) replacement solvent for cleaning oxygen systems. A 90-day study was conducted in order to develop a health risk assessment. Fischer 344 rats (15 males & 10 females per group) were exposed for 6 h/day to 0 (Air Control), 500, 1500 or 5000 ppm of PFBI for 5 days/week for 13 consecutive weeks (at least 65 exposures) followed by a 4-week recovery period. Clinical observations, body weights, clinical pathology, thyroid function, organ weights and histopathology were conducted at the end of the treatment period for up to 10 animals/sex/group. Remaining animals (5 males/group) were held for a 4-week recovery period. Analytical results indicated that the PFBI test atmospheres were within 2% of target concentrations and were essentially vapor only. The target tissue following 13 weeks of daily inhalation exposure of rats to PFBI was the thyroid. The findings consisted of a minimal thyroid follicular cell hypertrophy occasionally accompanied by hyperplasia but without an increase in thyroid weight in the 500, 1500 and 5000 ppm males; only one 5000 ppm female had similar histopathological thyroid changes. At ≥500 ppm, there was also increased TSH in females and increased T3 and T4 in animals of both sexes. These effects resolved following a 4-week recovery period. Other changes were several minor clinical pathology variations at all exposure levels but with no biological significance, and a 9.4% reduction in absolute body weight in the 5000 ppm males. None of the organ weight changes were associated with histopathological correlates; these included increased kidney weights in the ≥1500 ppm females and decreased spleen weight in the 5000 ppm males. Increased adrenal weights at ≥1500 ppm (both sexes) with decreased thymic weight in the 5000 ppm males were indicative of stress while the effect on male accessory sex glands at 5000 ppm were considered secondary to decreased body weight.

1518 SAFETY AND THERAPEUTIC EFFICACY OF UC-II IN
COMBINATION WITH GLUCOSAMINE +
CHONDROITIN OR HYDROXYCITRIC ACID (HCA) +
CHROMEMATE (CM) IN ARTHRITIC DOGS.

R. C. Gupta¹, A. Peal¹, M. D'Altilio¹, M. Alvey¹, C. Simms¹, A. Curtsinger¹, T. D. Canerdy¹, J. T. Goad¹, M. Bagchi² and D. Bagchi^{2,3}. ¹Toxicology, Murray State University, Murray/Hopkinsville, KY, ²InterHealth Research Center, Benicia, CA and ³Creighton University Med. Center, Omaha, NE.

This investigation evaluated safety and therapeutic efficacy of nutraceuticals in arthritic dogs. Dogs in six groups (n=5-6) received daily treatment as follows: Group-I (placebo), Group-II (10 mg UC-II), Group-III (2,000 mg Glucosamine HCl + 1,600 mg Chondroitin Sulfate), Group-IV (UC-II + Glucosamine + Chondroitin), Group-V (1,800 mg HCA + 100 µg CM), and Group-VI (UC-II + HCA + CM). The treatment was given daily for 120 days, followed by a 30 day withdrawal. The dogs were evaluated for overall pain, pain upon limb manipulation, and exercise-associated lameness, on a monthly basis. Group-I dogs (placebo) exhibited no significant change in arthritic conditions. Following 120 day treatment, dogs in Group II, IV, and VI showed significant reductions in overall pain (62%, 57%, and 70%, respectively), pain upon limb manipulation (91%, 53%, and 67%, respectively), and exercise-associated lameness (78%, 53%, and 69%, respectively). Following a withdrawal of 30 days, all dogs (Group II-VI) experienced a relapse in pain. None of the dogs in any group showed any adverse effects or change in liver (ALT and bilirubin) or kidney (BUN and creatinine) function markers, or body weight and these supplements were well tolerated.

1519 THE RELATIONSHIP BETWEEN LOW DOSE PEANUT
EXPOSURES AND THE PERCENT OF PEANUT-
SENSITIZED AND PEANUT-ALLERGIC INDIVIDUALS
THAT REACT.

S. Assimon and P. M. Bolger. CFSAN, FDA, College Park, MD.

Determination of the percent of peanut-sensitized and peanut-allergic individuals that react to the lowest exposures of peanut is important to characterize the risk of an allergic reaction in a population. Information on the number of peanut-sensitized (determined by skin prick test and/or IgE measures) and peanut-allergic (determined by positive reactions to food challenge tests) that reacted to different levels of peanut exposure can be derived from some food challenges studies. All available published literature studies were surveyed and the percentages of these subjects that reacted at the lowest levels of peanut protein exposure, or the lowest observed adverse effect level (LOAEL), for objective symptoms within each study were estimated when possible. The nature of the relationship between the dosage level of each study LOAEL and the respective percent of peanut allergic reactors was evaluated. The resulting association exhibited a linear relationship between the dosage level of the LOAEL value expressed as peanut protein and the percent of peanut-sensitized (r= 0.75) and peanut-allergic (r=0.8) individuals that reacted to these values. The lower study LOAEL values are associated with a lower percentage of subjects reacting at these dose values. However, when the relationship between the percent of the total number of subjects within a study that reacted to a challenge at any dose level during a peanut test and the respective study LOAELs across different studies were examined, a similar relationship was not found (r=0.3). Taken together, these findings indicate that these sources of data provide reasonable estimates of the percentage of individuals that would react at the "lowest" LOAEL value identified. The percent of peanut-sensitized and peanut-allergic individuals that reacted to the objective LOAEL (2 mg peanut protein) in the study identified as "critical" from which a reference value such as a tolerable acute intake would be based were, respectively, 7.1 and 12.5 percent.

1520 NANOPARTICLE (NP) TOXICITY BY TRADITIONAL
CYTOTOXICITY AND AFFYMETRIX MICROARRAY
ASSAYS.

X. Han¹, J. N. Finkelstein^{2,1}, A. Elder¹ and G. Oberdörster¹. ¹Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY and ²Pediatrics, University of Rochester School of Medicine and Dentistry, Rochester, NY.

Nanotechnology presents many opportunities for improving human life, but it also poses potential dangers of adverse effects upon exposure. Strategies for testing biologic/toxicologic activities of NPs include the concept of ranking unknown NPs against well characterized benchmark NPs of high and low toxicity. We evaluated the cytotoxicity of TiO₂ (-20 nm, low toxicity) and of Cu (40 nm, high toxicity) as benchmarks in order to rank Ag (35 nm) and other NPs. To compare cytotoxicity of the three NPs (TiO₂, Cu, and Ag) and to decide on appropriate doses for a microarray study, lung epithelial cells (Type I like cell line R3/1) were incubated in 12-well or 6-well plates for 24 hrs with the NPs (0.5 to 40 µg/ml) for lactate dehydrogenase (LDH) and trypan blue exclusion assays. Cells were then incubated in 6-well

plates for 4 hrs with the NPs (TiO₂, 10 µg/ml; Cu, 4 µg/ml; and Ag, 0.3 µg/ml) for the array study. Results: 1. The LDH assay was not suitable for quantitative assessment of cytotoxicity of NPs due to the inactivation of LDH by the NPs. The limitation may apply to other ROS-producing toxicants. 2. Ag NPs were much more potent in causing cell death than Cu NPs, though the Cu NPs were more potent than the Ag NPs in producing ROS in other studies. So Ag NPs may exert toxic effects through other mechanisms in addition to posing oxidative stress. 3. The array study showed that more genes were differentially expressed after exposure to the Ag than Cu NPs. Many of the genes can be assigned to one or more of the following: cell cycle and apoptosis, MAPK signaling pathway, TGF-β signaling pathway, glutathione metabolism, and other oxidative stress related signaling pathways. TiO₂ NP exposure, on the other hand, led to changed expression levels of only a few genes. We suggest that Cu and TiO₂ are suitable candidates for benchmark particles. (Supported by the US DoD MURI grant FA9550-04-1-430)

1521 MAXIMUM RECOMMENDED GUIDANCE LEVELS (MRGLS) FOR ORGANOHALOGENATED IMPURITIES.

R. Millischer¹, G. Jepson² and G. Rusch³. ¹consultant, Saint Victour, France, ²Haskell Laboratory, E.I. DuPont, Newark, DE and ³Honeywell International, Morristown, NJ.

RJ Millischer¹, G. Jepson², G.M. Rusch³
1. LaMaziere, 19200 St. Victour, France 2. Haskell Laboratory, E.I. DuPont, Newark, DE. 3. Honeywell International, Morristown, NJ
Occupational Exposure Levels exist for many materials. Unless present in a blend, OELs rarely consider the presence of other substances. For blends of two or more materials that may present additive toxicity, the ACGIH's TLV Committee has published a method for estimating an OEL for the blend this is based on the following relationship:
 $Xa/OELa + Xb/OELb \dots = 1/OELblend$, where Xa is the mole fraction of "a", OELa is the OEL for "a", etc. The methodology presented in this paper has been derived for estimation of acceptable levels of impurities or contaminants in chemical products. That is levels of impurities which would not significantly impact on the OEL for the product. It is most applicable for cases where the product has a low toxicity and correspondingly high OEL while the impurity has a high toxicity and correspondingly low OEL. In this case the presence of a significant amount of the impurity could mandate a lower OEL to afford the same level of protection to those using this substance. The procedure involves first determining the OELs for the product and identified impurities either by using established OELs for these substances or when not available estimating them from OELs for similar substances. Safety factors are applied to account for additive toxicity and the potential for the impurity to fractionate. Treatment for multiple impurities, again assuming additive toxicity, is also considered. For a product with a single impurity:
The MRGL = [(Impurity OEL/safety factor x Impurity Mol. Wt)/ (product OEL x product mol. Wt.)] x 100. The calculation for multiple impurities will also be discussed.

1522 INHIBITION OF THE ADENINE NUCLEOTIDE TRANSLOCATOR BY N-ACETYL PERFLUOROOCTANE SULFONAMIDES *IN VITRO*.

T. M. O'Brien¹, P. J. Oliveira² and K. B. Wallace¹. ¹Biochemistry & Molecular Biology, Toxicology Graduate Program, University of Minnesota, Duluth, MN and ²Ctr. Neurosci. Cell. Biol., University of Coimbra, Coimbra, Portugal.

N-Alkyl perfluorooctane sulfonamides have been widely used as surfactants on fabrics and papers, fire retardants, and anti-corrosion agents, among many other commercial applications. The global distribution and environmental persistence of these compounds has generated considerable interest regarding potentially toxic effects. We have previously reported that perfluorooctanesulfonamidoacetate (FOSAA) and N-ethylperfluorooctanesulfonamidoacetate (N-EtFOSAA) induced the mitochondrial permeability transition (MPT) *in vitro*. In this study we tested the hypothesis that FOSAA and N-EtFOSAA interact with the adenine nucleotide translocator (ANT) resulting in a functional inhibition of the translocator and induction of the MPT. Respiration and membrane potential of freshly isolated liver mitochondria from Sprague-Dawley rats were measured using an oxygen electrode and a tetraphenylphosphonium-selective (TPP⁺) electrode, respectively. Mitochondrial swelling was measured spectrophotometrically. The ANT ligands bongkrekic acid (BKA) and carboxyatractylolide (cATR) inhibited uncoupling of mitochondrial respiration by 5 µM N-EtFOSAA, 30 µM FOSAA, and the positive control 5 µM oleic acid, but not FCCP induced uncoupling. ADP initiated respiration and depolarization of mitochondrial membrane potential were inhibited by cATR, FOSAA, N-EtFOSAA, and oleic acid, but not by FCCP. BKA inhibited calcium dependent mitochondrial swelling induced by FOSAA, N-EtFOSAA and oleic acid. 100 µM ADP also inhibited swelling induced by the test compounds, but cATR induced swelling was not inhibited by ADP. Results of this investigation

demonstrate that a direct interaction with the ANT by N-acetyl perfluorooctane sulfonamides results in an inhibition of ADP translocation and induction of the MPT; one or both of which may account for the metabolic dysfunction observed *in vivo*. (Supported by the 3M Co.)

1523 COMPARISON OF PHOTOTOXICITY TESTS: 3T3 NRU PT VS. MATTEK EPIDERM A 3D HUMAN EPIDERMAL SKIN MODEL.

L. Pratt, M. Fischl, A. C. Gilotti and G. L. DeGeorge. MB Research Laboratories, Spinnerstown, PA.

Currently, only the 3T3 Neutral Red Uptake Phototoxicity Test (3T3-NRU PT) has been approved as a non-animal phototoxicity test by governmental regulatory agencies. However, the 3T3-NRU PT has serious drawbacks as a model for human skin, specifically: it uses a monolayer cell culture consisting of mouse tumor cells, it is overly sensitive resulting in many false-positives, and test substances must be soluble in tissue culture media. Thus, we have developed a more relevant *in vitro* system based on a three-dimensional, differentiated human keratinocyte cultures, which can accommodate a wide range of vehicles and allow direct topical application of test substances, termed "Phototoxicity Assay in Reconstructed Skin" (PARS). Here we present a side-by-side comparison between the 3T3-NRU PT and the PARS test systems using the same Solar Simulated Light (SSL) source of UV and visible light and the 8 reference standard chemicals used for validation of the 3T3-NRU PT. The PARS test correctly predicts with 100% accuracy the phototoxic potential of all reference test substances. The concentrations of test agents needed to obtain the EC50s in the PARS MTT viability test, when compared to the Neutral Red assay in 3T3 fibroblasts, is one to two orders of magnitude higher, reflecting the thickness and complexity of a three-dimensional tissue structure. This better approximates the exposure levels of chemicals needed to induce phototoxic effect in animal tests and actual human skin. In addition, the most important practical advantage gained over the 3T3 NRU PT is that test substances can be applied topically, overcoming both the pH and solubility problems encountered when dosing via the culture media.

1524 REGULATORY REQUIREMENTS FOR *IN VITRO* SYSTEMS TO MEET PERFORMANCE STANDARDS OVER TIME AS WELL AS DURING VALIDATION.

M. Klausner, J. Kubilus, S. Aychunie, P. J. Hayden and J. Sheasgreen. MatTek Corp., Ashland, MA.

In vitro models are being proposed as alternatives to animal testing for safety evaluation of cosmetics, pharmaceuticals and consumer products. Currently available organotypic human models include dermal (EpiDerm, EpiDerm-FT), ocular (EpiOcular), ectocervical (EpiVaginal) and airway (EpiAirway). Some of these models have been, or are in the process of being, formally validated for testing of corrosivity, irritation or toxicity. However, regulatory agencies and other users also need to be reassured that the models will provide consistent, good quality data over time, not just during the validation process (K. Gupta et al., Regul Toxicol Pharmacol. 2005 Dec;43(3):219-24). Recommended guidelines include "full characterization of cells or tissues, sampling of each lot ... for performance, and regular use of controls and benchmark chemicals to provide assurance of consistency of assay performance" (A. Rispin et al. Regul Toxicol Pharmacol. 2006 Jul;45(2):97-103). The current poster summarizes the long-term reproducibility and performance of *in vitro* epidermal (EpiDerm) and ocular (EpiOcular) models against benchmark chemical treatment. Quality control of weekly batches of EpiDerm and EpiOcular was performed using the MTT assay. The exposure time needed to reduce the viability to 50% (ET-50) for Triton X-100 was determined. For EpiOcular, the yearly average ET-50 values have ranged from 20.6 minutes to 25.0 minutes. The coefficients of variation (CV) for the negative control tissue (exposed to ultrapure H₂O) have averaged under 6% for every year since 1997. In addition, the yearly average CV for all tissues has never exceeded 6.5%. For EpiDerm, the yearly average ET-50 values have ranged from 6.0 hrs to 7.5 hrs. The coefficients of variation (CV) for the negative control tissue (exposed to ultrapure H₂O) have averaged under 7.5% for every year since 1996. These results over the past 10 years of commercial production are designed to address regulatory concerns regarding performance standards over time.

1525 EVALUATION OF A NOVEL RELATIVE POTENCY APPROACH FOR AN HERBAL DIETARY SUPPLEMENT.

K. C. Findley^{1,2} and C. J. Borgert^{1,3}. ¹Applied Pharmacology and Toxicology, Inc., Gainesville, FL, ²North Florida South Georgia Veterans Health System, Gainesville, FL and ³C.E.H.T., Department Physiol. Sciences., UF Coll. Vet. Med., Gainesville, FL.

Relative potency approaches for predicting the pharmacologic and toxicologic effects of similar chemicals have been applied in diverse areas of regulatory science, including environmental toxicology, risk assessment, pesticide regulation, and in

drug efficacy and safety evaluations. Relative potency approaches assume that the chemicals to be assessed behave as if they were dilutions of a reference chemical in producing a specific biologic response, and that any differences between the assessed chemicals and the reference chemical are quantitative rather than qualitative. The validity of these assumptions directly determines whether applying a relative potency approach is valid in any particular situation. Traditionally, several criteria are evaluated to determine how well a group of chemicals conforms to the assumptions of the relative potency approach. These include that the chemicals are molecular congeners, exhibit similar patterns of metabolism and detoxification, exhibit parallel dose response curves for the specific effect of interest in the same biological assay, share the same molecular target of action, have similar mechanisms of action for the effect of interest, and exhibit dose addition for the effect of interest when combined in mixture. We used these criteria to evaluate a novel relative potency approach adopted by FDA for predicting adverse cardiac effects of herbal ephedra. We found the approach unusual in several key aspects; it employs an indirect comparison of ephedra alkaloids to the reference compound epinephrine via a surrogate reference chemical, ephedrine; it assumes quantitative similarity based on potency for qualitatively dissimilar therapeutic indications, and; it employs recommended dose ranges for the quantitative comparison rather than dose response data. We discuss the validity of this novel approach for safety evaluation and its implications for future regulatory actions involving drugs and supplements.

1526 ASSESSMENT OF DIOXIN-LIKE COMPOUNDS IN MAINSTREAM SMOKE FROM SELECTED U.S. CIGARETTE BRANDS.

C. Wilson, J. Bodnar, B. Brown, W. Morgan, R. Potts and M. Borgerding. *Research & Development, RJ Reynolds Tobacco Co., Winston-Salem, NC.*

Mainstream cigarette smoke (MS) from twelve U.S. cigarette brands was evaluated to determine concentrations of dioxins (i.e., polychlorinated dibenzo-p-dioxins, polychlorinated dibenzofurans, and dioxin-like polychlorinated biphenyls). The study included three 'tar' ranges based on Federal Trade Commission (FTC) determination: Low Yield (LY) <5.5, Medium Yield (MY) 9.6 to 12.2, and High Yield (HY) >14.5 mg/cig. Cigarettes were produced by a single manufacturer and represent the principal design features found in the U.S. market. MS was generated by a machine smoking regime (60 cc puff volume of 2 sec duration, puffs taken twice per minute) more intense than FTC or ISO standards, collected on Cambridge filters and analyzed using EPA test methods. Of the brands studied, the HY cigarettes yielded the greatest mean concentrations of World Health Organization Toxic Equivalents (WHO-TEQs) on a per cigarette basis. WHO-TEQ levels in LY cigarettes were significantly lower than for HY cigarettes ($p=0.0497$) on a yield per cigarette basis and WHO-TEQ concentrations correlated with 'tar' yield ($r=0.69$, $p=0.013$), as did concentration on a WHO-TEQ per body mass per day basis ($r=0.69$, $p=0.013$). However, on a per mg Total Particulate Matter (TPM) basis, no statistically significant relationship between 'tar' range and WHO-TEQ concentrations was observed. Concentrations for all brands tested ranged from 0.48 to 4.82 fg WHO-TEQ/mg TPM. Maximum daily exposure estimates calculated from this range (0.003 to 0.109 pg WHO-TEQ/kg bw/d) are below the current WHO Tolerable Daily Intake range of 1 to 5 pg/kg bw/d. These results do not support findings from a 2005 study in which U.S. and international cigarette brands were smoked using a less intense ISO smoking regime. In contrast, we report lower maximum TEQ concentrations, found no relationship between 'tar' ranges and TEQ concentration on a per mg TPM basis, and a positive relationship between 'tar' yield and MS dioxin concentration on a per cigarette basis.

1527 CARCINOGENS IN TOBACCO SMOKE AND QUANTITATIVE CANCER RISK.

T. Sanner. *Occup. and Environ Cancer, Inst. Cancer Research, Oslo, Norway.* Sponsor: E. Dybing.

Cigarette smoke contains more than 50 substances classified by the International Agency on Cancer Research (IARC) as known, probably or possible human carcinogen. It has been estimated that the excess cancer lifetime death risk from smoking in USA is 7.9×10^{-2} (1) The purpose of the present communication was to assess to what extent carcinogens quantified in mainstream cigarette smoke and for which quantitative data suitable for cancer risk assessment were available, could account for the cigarette smoke induced cancers. Thirteen carcinogens have been measured in mainstream cigarette smoke by the Canadian intense machine smoking regimen for which data for quantitative cancer risk exists. The data have been obtained from three different sources and the mean exposure based on a daily dose of 24 mg nicotine, which is representative for cigarette smokers in USA (2), has been calculated for the 13 substances. The lifetime cancer risk for the 13 substances was subsequently calculated by the T25 method (3) for quantitative risk characterisation of genotoxic carcinogens assuming 50-year exposure to cigarette smoke. In the calculations, no attempts were made to account for possible interactions between differ-

ent chemicals in the tobacco smoke. The 13 carcinogens could account for about 23% of the carcinogenic effects associated with smoking. PAH (with benzo(a)pyrene as indicator) represented the most important group of carcinogens accounting for nearly 75% of the carcinogenic potential identified. The four carcinogens acetaldehyde, N-nitrosomornicotine, acrylonitrile, and 1,3-butadiene accounted for about 20% of the carcinogen potential identified. The finding that the calculations could only account for 23% of the carcinogenic effect suggests synergistic interactions between the substances in the tobacco smoke and/or contributions from other carcinogens than the ones considered in the present calculations.

1528 USING DOUBLY-LABELED WATER MEASUREMENTS OF HUMAN ENERGY EXPENDITURE TO ESTIMATE INHALATION RATES.

M. Stifelman. *Office of Environmental Assessment, U.S. EPA, Region 10, Seattle, WA.*

Doubly-labeled water (DLW) data is recognized as an improvement over alternative methods to quantify human energy expenditure (e.g., calorimetry, heart-rate monitoring, and accelerometer). More accurate and representative energy expenditure data can be converted into estimates of breathing rates using equations developed by Layton. DLW methods are advantageous for several reasons: the database is robust, they are direct measures, subjects are free-living, and the observation period is longer than what is possible from staged activity measures. DLW estimates of energy expenditure can resolve differences in breathing rate estimates used for risk assessment. These estimates are currently based on short duration heart rate measures of volunteers performing staged activities or energy expenditure estimates inferred from dietary recall surveys. The range of human energy expenditure is narrow with the maximum energy expenditure not likely greater than twice the minimum. Based on DLW estimates of energy expended by physically active adults expending, 2,850 and 2,250 kcal/day, average long-term breathing rates are approximately 16 m³/day and 13 m³/day, for males and females, respectively.

1529 PHYSIOLOGICAL PARAMETERS IN HEALTHY AND DISEASED ELDERLY.

B. R. Sonawane¹, C. Thompson¹, D. Hattis², R. Tardiff³ and K. Krishan³.
¹ORD/NCEA(8623-D), U.S. Environmental Protection Agency, Washington DC, DC, ²Clark University, Worcester, MA and ³University Montréal, Montréal, QC, Canada.

The availability of a central repository of human physiological data would be useful for developing PBPK models. The objectives of this study were to collect physiological data for healthy and diseased elderly, and to populate an ACCESS database. Following an extensive literature search, 528 peer-reviewed publications were retained for evaluation. Each publication was read to identify the specific parameter evaluated as well as the experimental design/protocol, sampling method, number of samples, statistical analysis, precision/variability, and any bias. However, no re-evaluations of the reported disease state (diabetes, COPD, obesity, angina pectoris and renal disease) were attempted. Following evaluation, 155 publications were retained for inclusion in the database. From these publications, a total of 1166 data records – relating to tissue volumes, blood flow rates, metabolic parameters, tissue composition, renal clearance parameters and pulmonary clearance parameters – were retrieved and entered into the database. The data availability for the various physiological parameters was greater for the older adults (50-64 years) and young elderly (65 – 74 years) groups than for the old-old (75-84 years) and oldest-old (> 85 years) groups. The physiological parameter measurements in diseased elderly are also limited and represent a major datagap, with the exception of a mixed group containing older adults and young elderly (60 – 65 years). Another datagap across the age groups relates to tissue composition data (neutral lipid, phospholipids and protein levels). Overall, the present study has assembled available data on physiological parameters in healthy and diseased elderly along with attendant identification of the data poor parameters and age groups.

1530 HALOQUINONES, HALOGENATED FURAN DERIVATIVES, AND NITROSAMINES IDENTIFIED AS DISINFECTION BY-PRODUCTS (DBPS) OF POTENTIAL TOXICOLOGICAL CONCERN.

R. J. Bull¹ and D. A. Reckhow². ¹MoBull Consulting, Richland, WA and ²University of Massachusetts at Amherst, Amherst, MA.

Chlorinated drinking water has been epidemiologically associated with increased risk of cancer, especially in the bladder. A large number of chemicals have been identified as by-products of the disinfection of drinking water. Several by-product

classes such as the trihalomethanes and haloacetic acids have received substantial toxicological study. Although many of these have been found carcinogenic in animals, the combination of low potency as carcinogens and/or low concentrations in drinking water make them unlikely causes of the cancer risk of the magnitude suggested by epidemiology studies. To provide new direction for the resolution of this discrepancy, a strategy was developed to predict formation of novel by-products through reactions of chlorine with substructures found in natural organic matter (NOM). These potential disinfection by-products (DBPs) were examined using the QSAR program TOPKAT® to identify those chemicals of sufficient carcinogenic potency to be possible causes for the epidemiologic findings, if present. A "weight of evidence" strategy was developed to utilize the predictions of the multiple cancer models within TOPKAT and their respective training sets to identify those compounds that were most probably potent carcinogens. The likely potency of each compound was judged by predictions of the chronic LOAEL. Predictions were refined by literature review to determine whether probable modes of action would be consistent with bladder carcinogenesis. Several groups of chemicals appear to be of interest. Most prominent of these were several haloquinones, a series of halogenated furan derivatives, and nitrosamines arising from chloramine reactions with alkaloids. Most interesting, where halogen substitutions on 1,4-dibenzoquinone, compounds whose concentrations would be favored with chloramine rather than chlorine disinfection. (Supported by Awwa Research Foundation contract 2867).

1531 THE EPA MCLG FOR FLUORIDE IN DRINKING WATER: NEW RECOMMENDATIONS.

H. Limeback¹, K. M. Thiessen², R. L. Isaacson³ and W. Hirzy⁴. ¹Faculty of Dentistry, University of Toronto, Toronto, ON, Canada, ²SENES Oak Ridge, Inc., Oak Ridge, TN, ³Binghamton University, Binghamton, NY and ⁴U.S. EPA, Washington, DC. Sponsor: J. Murphy.

The U.S. EPA has set the Maximum Contaminant Level Goal (MCLG) for fluoride (F-) in drinking water at 4.0 mg/L (4000 ppb). The Mar.06 report from the National Research Council (NRC) concluded that this is not protective of human health and should be lowered. No new MCLG was recommended by the committee, nor were any benefits of F- in drinking water assessed. The MCLGs for some essential elements (e.g. Ni, Cu) have to balance the risks from adverse health effects versus the benefits. F- has been shown to be a useful agent to combat dental decay, but its mechanism is now known to be topical, not systemic (F- is not an essential element). Water fluoridation, a 60-year old policy, generally exposes entire populations to 1 mg F-/L in the drinking water. However, there are people who retain greater than normal amounts of F-, ingest more than average amounts of F- or who have a particular intolerance to chronic exposures to small amounts of F-. These people have been shown to demonstrate adverse health effects such as dental and skeletal fluorosis. The purpose of this study was to conduct a risk analysis comparison between F- and other non-essential elements (e.g. Sb, As, Be, Cd, Hg and Tl). Most MCLGs of the toxic elements are in the 0-10 ppb range. We used two different approaches: a) first calculating a reference dose (RfD) from no-observed-adverse-effect levels (NOAELs) or lowest-observed-adverse-health-effect levels (LOAELs), and deriving the MCLG from the RfD; b) the benchmark dose approach. Our results indicated that in all calculations, the new MCLG for fluoride in drinking water should be at most one tenth (0.4 mg/L) of the current MCLG of 4 mg/L, suggesting that the practice of fluoridation should be re-evaluated. 1532 TOXICITY ASSESSMENT AND DEVELOPMENT OF REGULATORY STANDARDS FOR PERCHLORATE.

T. Zewdie, C. Rowan-West, C. Smith and M. S. Hutcheson. *Office of Research and Standards, Massachusetts DEP, Boston, MA.*

In 2003, MassDEP decided to derive a drinking water standard (MCL) for perchlorate (ClO₄⁻) due to the need to protect public health from contaminated drinking water supplies and sites. As a primary mechanism of action, ClO₄⁻ interferes with iodide transport into the thyroid gland, which is essential for the synthesis of the thyroid hormones. Perturbation of thyroid function by perchlorate, especially in fetuses, neonates and developing children could result in irreversible neurotoxicity. In our evaluation, we used a weight of the evidence approach in which perchlorate toxicity data from animal and human studies were both evaluated to determine an appropriate reference dose (RfD) value and corresponding MCL. We put more weight on a human iodide uptake inhibition study performed in 2002 and identified the lowest dose in the study (0.007 mg/kg/day) as a LOAEL and calculated a chronic RfD of 7 x 10⁻⁵ mg/kg/day by applying a total uncertainty factor of a 100. This RfD equates to a health-based drinking water limit of 0.49 ppb using conventional adult exposure extrapolation, and a relative source contribution factor to account for other sources of exposure beyond that from drinking water (e.g., food, milk). In selecting a final MCL, MassDEP considers the RfD-derived limit and additional factors, including the frequency of contamination at

public water supplies in Massachusetts, analytical detection limits, treatment options, costs, and data that demonstrates that perchlorate can be introduced into drinking water from certain disinfection chemicals. To ensure the disinfection benefit is not compromised, MassDEP chose to set the MCL at a level that does not create any disincentive on the part of public water systems to introduce disinfection processes used to counter microbial contamination and associated risks to public health. The MCL of 2.0 ppb was determined to provide the best overall protection of public health, considering the benefits of disinfection, while retaining a margin of safety to account for uncertainties in the available data.

1533 EXTRAPOLATING ACROSS EXPOSURE DURATIONS: STATISTICS FROM MINIMAL RISK LEVELS (MRLS).

M. Fay and S. Chou. *CDC/ATSDR, Atlanta, GA.* Sponsor: M. Mumtaz.

ATSDR derives MRLs for hazardous substances based on available toxicological and epidemiologic information. These guidance values are estimates of the daily human exposure to a hazardous substance that is likely to be without appreciable risk of adverse noncancer health effects. They are derived when reliable and sufficient data exist to identify the target organ(s) of effect or the most sensitive health effects(s) for oral or inhalation exposures, and are categorized into acute (1-14 days), intermediate (int.; >14-364 days), and chronic (365 days and longer) exposure durations. These substance-specific health guidance values serve as screening levels for ATSDR health assessors and other responders to identify contaminants and potential health effects that may be of concern at hazardous waste sites or other exposure events. Due to a lack of sufficient information, MRLs are not always available for all durations and routes. Thus extrapolation across duration for a given route of exposure might be desired in emergency situations. They also serve as one of the few types of guidance values derived by an expert panel which address wide variations in exposure duration. We analyzed matched-pair ratios of MRLs across duration, for chemicals with more than one MRL for a given route. At this time, there are 347 MRLs offering 166 matched pairs for analysis. The median ratios for oral MRLs are: acute/chronic (acute MRL/chronic MRL) 5.0 (N=25), acute/int. 3.33 (45), and int./chronic 1.83 (32). For inhalation MRLs, median ratios are: acute/chronic 10.0 (17), acute/int. 2.86 (25), and int./chronic 2.75 (22). Additional statistics and ideas concerning extrapolation will be presented.

1534 ASSESSING THE HEALTH RISK FOLLOWING ENVIRONMENTAL EXPOSURE TO ENDOSULFAN.

M. P. Chan, S. Morisawa, A. Nakayama and M. Yoneda. *Urban and Environmental Engineering, Kyoto University, Kyoto, Kyoto, Japan.*

Endosulfan, an organochlorine (OC) insecticide that belongs to the cyclodiene group, is one of the most commonly used pesticides to control pests in vegetables, cotton and fruits. The present study was aimed to develop the PBPK model for endosulfan in rats and extrapolate to humans, to test the ability of the model to predict the pharmacokinetic behavior of endosulfan in humans. The neurotoxic risk, which utilizes the principles of PBPK modeling as well as in vitro experiments of cytotoxicity will be estimated. The PBPK model was constructed based on the pharmacokinetic data of our experiment following single oral administration of 14C-Endosulfan to male Sprague-Dawley rats. The model was verified by simulating the disposition of 14C-Endosulfan in vivo after single and multiple oral dosages and comparing simulated results with experimental results. Cytotoxic experiments on the glial and neuronal cell cultures from rat and human were used to estimate the neurotoxic risk. α -Endosulfan, β -endosulfan and endosulfan sulfate had cytotoxic effects on rat glial (C6) and neuronal (PC12) cell cultures as well as on human glial (CCF-STTG1) and neuronal (NT2) cell cultures. The effects of α -endosulfan were highly selective, with a wide range of LC50 values found in the different cultures, ranging from 11.2 μ M for CCF-STTG1 cells to 48.0 μ M for PC12 cells. In contrast, selective neurotoxicity was not so manifested in glial and neuronal cell cultures after exposure to endosulfan sulfate, as LC50 values were in the range of 10.4–21.6 μ M. CCF-STTG1 cells were more sensitive to α -endosulfan and endosulfan sulfate, whereas NT2 cells were more sensitive to β -endosulfan. Based on these experiments, there was no specific scientific evidence to prove the quantitative neurotoxic risks. However, we deduced that humans may likely develop some neurological diseases induced by endosulfan. It was known that nerve cells could not be regenerated when these cells were damaged. It is also hoped that the newly-developed PBPK model could be utilized in the human health risk assessment in the near future.

1535 A MODEL FOR ESTIMATING THE CUMULATIVE PESTICIDE EXPOSURE OF SUBJECTS IN A SECONDARY HEALTH DATABASE.

M. K. Davis and R. W. Wills. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

A challenge in designing effective epidemiological studies assessing the impact of pesticides on human health is to obtain reliable pesticide exposure and health information at an individual level. The use of secondary health databases provides a

means to access information from a large population. However, obtaining pesticide exposure history on the subjects of secondary data sources is difficult. The objective of this project was to develop a model for estimating cumulative pesticide exposure (CPE) of subjects in a secondary health database. A proxy of CPE for cases in a dataset derived from the Mississippi Cancer Registry was calculated by using the age and year at diagnosis, county of residence, and surface area and annual amounts of pesticides (based on harvested crop records) used in the county of residence. Data mining techniques including factor, correlation, and logistic regression analysis were used to measure the strength of association between CPE and the occurrence of specific types of cancer while accounting for gender, race, and age. Because pesticides are tested for lack of carcinogenicity prior to registration, no associations were expected. Among the possible 6,790 potential univariate models of association between CPE of individual pesticides and cancer type, statistically significant associations were found between 13 pesticides and the occurrence of three types of cancer. Odds ratios were generally close to 1.00 suggesting that the associations were weak. The relatively few significant associations that were determined, only 0.002%, suggest that the model is quite specific and is not likely to report many false positives. The model will be applied to other secondary health databases to determine its utility in measuring associations between pesticides and other health outcomes. (Supported by NIH P20 RR17661)

1536 ALKYL BENZENE SULFONATES RISK ASSESSMENT.

D. C. Smegal¹, T. Milano², R. Quick², C. Walls², K. Leifer³ and A. Asaad¹.
¹Health Effects Division, U.S. EPA/OPP, Washington, DC, ²Antimicrobials Division, U.S. EPA/OPP, Washington, DC and ³Registration Division, U.S. EPA/OPP, Washington, DC. Sponsor: L. Scarano.

The USEPA OPP conducted a human health risk assessment for the linear alkylbenzene sulfonates as part of pesticide tolerance reassessment required by the 1996 Food Quality Protection Act (FQPA). These antimicrobial pesticides are disinfectants and food-contact sanitizers in agricultural, food handling and commercial settings. They are also inert ingredients in pesticide formulations. The EPA selected an oral no-observable adverse effect level (NOAEL) of 50 mg/kg/day, and an inhalation NOAEL of 1 mg/m³ for use in risk assessment. The Agency applied an uncertainty factor of 100 (10X for inter- and intra-species variability) to the NOAELs, and the FQPA safety factor was removed (1X). Chronic dietary exposure was evaluated for food-contact sanitizing solutions, fruit and vegetable washes, and for inert pesticide formulations applied to agricultural crops and animals. For the inert assessment, the Agency utilized the Dietary Exposure Evaluation Model (DEEMTM) that assumed 100% of all commodities and crops were treated. Residential exposures from the inert uses for turf treatment, hard surface cleaners, and pet flea products were evaluated using the EPA's Pesticide Inert Risk Assessment Tool (PiRat), and EPA's Residential Standard Operating Procedures (SOPs). Aggregate assessments were conducted following the USEPA OPP guidance. For children, the aggregate assessment includes average dietary exposure (food and drinking water) from both the active food contact sanitizer uses and the inert uses on agricultural commodities, in addition to estimated incidental oral exposures from hard surface cleaning products as an inert ingredient. For adults, the aggregate assessment includes food and drinking water exposure from both active and inert uses and residential inhalation exposures from wiping hard surface cleaning products. The aggregate oral and inhalation risks are not of concern for adults and children, and the EPA was able to make a safety finding for the existing pesticide tolerances.

1537 PROVISIONAL ADVISORY LEVELS (PALs) DEVELOPMENT FOR DICROTOPHOS.

D. Peterson¹, F. Adeshina⁵, L. Haroun², M. Bhattacharya¹, G. Henningsen³ and D. Dorman⁴.
¹Argonne National Laboratory, Argonne, IL, ²ENVIRON International Corporation, Emeryville, CA, ³H & H Scientific Services, LLP, Evansville, IN, ⁴CIIT, Research Triangle Park, NC and ⁵U.S. EPA, Washington, DC.

Provisional Advisory Levels (PALs) that are being developed for hazardous materials by the U.S. EPA represent general public emergency exposure limits. Initial PALs correspond to different effect severity levels (PALs 1, 2, and 3) and exposure durations (24 hours, 30 days, and 2 years). Application of PAL protocols has been performed for the organophosphate pesticide dicrotophos to estimate oral (in drinking water) and inhalation exposure limits, as experimental exposure data permit. The experimental data set for dicrotophos was marginally adequate, including only animal studies. Data gaps are identified. These estimates were evaluated and approved by an Expert Consultation Panel for Provisional Advisory Levels in June 2006. PAL estimates for dicrotophos will be presented. Oral PAL values for a 24-hour exposure duration to dicrotophos are 0.58 mg/L (PAL 1), 5.8 mg/L (PAL 2), and 9.3 mg/L (PAL 3); for 30-day oral exposure duration, the value is 0.11 mg/L (PAL 1); and for 2-year oral exposure duration, the values are 0.12 mg/L (PAL 1) and 1.2 mg/L (PAL 2). Data were insufficient to derive oral PAL 2 or PAL 3 estimates for the 30-day exposure duration or a PAL 3 estimate for the 2-year exposure duration. Data were insufficient to derive inhalation PAL values for all exposure durations. Route-to-route extrapolation was suggested. The Panel identified a need to compare oral vs. inhalation data for a range of organophosphates, and then use relative

potency and available data to assess the feasibility of using route-to-route extrapolation for estimating inhalation PAL values. In the future, route-to-route extrapolation may be accepted as an approach for deriving PAL values if adequate pharmacokinetic or other data are available. (This abstract presents PAL values that are subject to change pending further review.)

1538 OPTIMAL EXPERIMENTAL DESIGNS FOR TESTING COMPLEX NONLINEAR HYPOTHESES: COMPARING THE DOSE THRESHOLDS AND ED30'S IN ADULT VS. JUVENILE RATS.

R. D. Ellis¹, C. Gennings^{1,2} and R. Carchman².
¹Biostatistics, Virginia Commonwealth University, Richmond, VA and ²Solveritas, LLC, Richmond, VA.

The 1996 Food Quality Protection Act set stringent standards to protect children from pesticide risks. To enforce these standards, the United States Environmental Protection Agency requires studies on pesticides to investigate the neurotoxicity of these chemicals. An important design strategy is to compare the dose responsiveness of adult versus juvenile rats. Of concern is that juvenile rats may be more sensitive than adult rats; here, we characterize sensitivity through the dose-threshold and ED30's. Our objective is to describe use of optimal experimental design strategies to test complex nonlinear hypotheses. Here we find the optimal design that minimizes the variance of the test statistic over dose (x) and proportion (q) of the total sample size for simultaneously testing the coincidence of the dose-thresholds and ED30's for adult versus juvenile rats. For illustration purposes we considered a single pyrethroid, Lambda-cyhalothrin. Preliminary estimates of the ED30 and dose threshold for adult Long Evans rats varying in ages from 60-66 days were taken from Wolansky et al. (ToxSci, 2005). We conjecture a 50% decrease in the dose-threshold and/or approximately a 30% decrease in the ED30 for the juvenile rats. Constrained optimal designs were found such that at least 5% of the sample is allocated to each control group. Based on the experimental range used by Wolansky, another constraint was implemented such that the maximum dose does not exceed 15mg/kg. We conclude that the optimal design for testing the hypothesis of coincidence between adult versus juvenile rats depends on (1) the preliminary assumptions about the dose-threshold and the shape of the dose response curves and (2) that the sample proportions are not equal across the dose groups.

1539 HUMAN RISK ASSESSMENT FOR CHLORPYRIFOS UTILIZING A CYP-SPECIFIC PBPK/PD MODEL.

R. J. Foxenberg, J. B. Knaak, B. P. McGarrigle and J. R. Olson. *Pharmacology and Toxicology, SUNY at Buffalo, Buffalo, NY.*

Protecting humans from the toxicological effects of organophosphorous pesticides (OPs) is dependent in part upon accurate physiologically based pharmacokinetic / pharmacodynamic (PBPK/PD) models. OP toxicity is dependent upon the balance between the formation of oxons by cytochrome P450 (CYP) catalyzed desulfuration (activation), dearylation (detoxification) by CYPs and paraoxonase (PON1), and inhibition of B-esterases by oxons. Current PBPK/PD models, which utilize single kinetic constants (Km, Vmax) for a given metabolic pathway, using rat liver microsomes, do not accurately reflect the variability in content and activity of key enzymes (CYPs, PON1) which regulate OP metabolism in humans. Simulations with chlorpyrifos have demonstrated that CYP-specific PBPK/PD models can better estimate exposure, target tissue dose and effects of chlorpyrifos in human populations by incorporating 1) kinetic parameters (Km and Vmax) for OP metabolism by specific human CYPs, 2) hepatic content of specific CYPs, 3) PON1 activity and content, and 4) serum protein binding data for OPs and metabolites into the PBPK/PD model of Timchalk et al., (2002). CYP2B6 and CYP2C19 exhibit low Km and high Vmax values for the desulfuration and dearylation of chlorpyrifos, respectively, supporting their role as the primary enzymes that regulate metabolism at low-level human exposures to chlorpyrifos. Since the hepatic levels of specific CYPs exhibit marked variability across both population and age groups, the CYP-specific PBPK/PD models should prove to be more accurate and more easily modified to address factors such as age, CYP content and genetic polymorphisms in CYP2B6, CYP2C19 and PON1 (biomarkers of susceptibility). CYP-Specific PBPK/PK models for OP pesticides, that better estimate variability in exposure, target tissue dose and effect, will be valuable tools for risk assessment efforts for chlorpyrifos and other OPs in the general population, special exposure groups, and susceptible individuals, exhibiting polymorphisms in CYPs and/or PON1. Supported by US EPA STAR grant R-83068301

1540 ASSESSMENT OF HEALTH EFFECTS RESULTING FROM POSSIBLE EMISSIONS FROM A PESTICIDE FORMULATION FACILITY.

P. Moy, J. Pierce and B. L. Finley. *ChemRisk, San Francisco, CA.*

The cyclodiene insecticides, aldrin, chlordane, and heptachlor, were widely used in the 1950s and 1960s for insect control due to their persistence in soil, resistance to degradation, retention of biological activity, and selective toxicity. Cyclodiene pesti-

cides were often prepared for sale at "formulation facilities," wherein bulk quantities of pesticides were received and repackaged into bags of various sizes. In the late 1980s, near one such facility in a rural Illinois town, it was suggested that historical cyclodiene emissions may be posing a health risk to local residents. We designed and implemented a "risk-based" sampling methodology to focus data collection on the needs of a health risk assessment. Samples of residential soils, garden vegetables, well water, and suspended particulates were collected and analyzed. A stratified sampling plan was used to permit distinction between cyclodienes associated with facility emissions vs. those associated with other sources (e.g., homeowner application and/or drift from nearby treated crops). Incremental health risks were then calculated for the "facility-related" cyclodiene concentrations in these media. Three exposure scenarios were developed ("typical", "maximum", and "minimum"), and the following exposure pathways were considered: garden vegetable and incidental soil ingestion, dermal contact with soil, and inhalation of suspended surface soil particles. The estimated incremental carcinogenic risks were 4.72×10^{-7} , 9.73×10^{-6} , and 3.75×10^{-7} for typical, maximum, and minimum exposures, respectively. The greatest contributor to total carcinogenic risk from all sources combined was found to be the result of homeowner application of cyclodienes to lawns and gardens.

1541 PROVISIONAL ADVISORY LEVELS (PALs) DEVELOPMENT FOR G-SERIES NERVE AGENTS.

A. Watson¹, E. Adeshina⁴, D. Opreko¹, L. Koller² and M. McClanahan³. ¹Oak Ridge National Laboratory, Oak Ridge, TN, ²Environmental Health and Toxicology, Corvallis, OR, ³Retired, Centers for Disease Control and Prevention, Chamblee, GA and ⁴U.S. EPA, Washington, DC.

Provisional Advisory Levels (PALs) that are being developed for hazardous materials by the U.S. EPA represent general public emergency exposure limits for 24-hour, 30-day and 2-year durations. Application of PAL protocols has been performed for chemical warfare nerve agents GA, GB, GD, GE and GF to estimate oral and inhalation/ocular exposure limits, as experimental exposure data permit. The experimental data set for agent GB was robust and included controlled human and animal studies. The remaining G-series agents were less well characterized, necessitating PAL estimation on the basis of relative potency. These estimates were evaluated and approved by the Expert Consultation Panel for Provisional Advisory Levels in August 2006.

PAL estimates for all 5 G-agents will be presented. Oral PAL values for 24-hour exposure are 0.037 mg GB/L (PAL1), 0.11 mg GB/L (PAL2), and 0.57 mg GB/L (PAL3); for 30-day oral exposure duration, values are 0.0081 mg GB/L (PAL1), 0.012 mg GB/L (PAL2), and 0.25 mg GB/L (PAL3); for 2-year oral exposure duration, the PAL1 value is 0.0020 mg GB/L. Data were insufficient to derive oral PAL 2 or PAL 3 estimates for the 2-year exposure duration.

Inhalation/Ocular PAL values for 24 hour exposure are 0.00020 mg GB/m³ (PAL1), 0.0010 mg GB/m³ (PAL2), and 0.015 mg GB/ m³ (PAL3); for 30 day inhalation/ocular exposure duration, values are 0.000018 mg GB/ m³ (PAL1) and 0.00073 mg GB/ m³ (PAL 2). Insufficient data are available to estimate a 30 day PAL3 value. For 2-year inhalation/ocular exposure duration, the PAL1 value is 0.000018 mg GB/ m³ (equivalent to PAL1 for 30 days) and the PAL2 value is 0.00016 mg GB/m³. Data were insufficient to derive an inhalation/ocular PAL 3 estimate for the 2-year exposure duration. (This abstract presents PAL values that are subject to change pending further review.)

1542 ALTERNATIVE APPROACHES FOR NONCANCER RISK ASSESSMENT OF PHOSGENE.

D. V. Singh, J. Gift, R. McGaughy and B. Sonawane. NCEA/ U.S. EPA, Washington, DC.

Phosgene is primarily used in the polyurethane industry for production of polymeric isocyanates. The majority of phosgene for industrial applications is made on site by the reaction of carbon monoxide and chlorine gas using an activated carbon analyst. Inhalation is the primary route of exposure. The noncancer risk to humans from exposure via inhalation is assessed by deriving a chronic inhalation RfC. The RfC is an estimate of daily exposure to the human population that is likely to be without appreciable risk of deleterious effect during a lifetime. The RfC was based on two inhalation subchronic studies which measured immune response and pulmonary damage. These studies used the same strain of rats with similar exposure protocols. Support for the derivation of the RfC for phosgene came from the use of three different approaches: 1) the traditional NOAEL/LOAEL approach; 2) the benchmark dose (BMD) approach; and 3) the categorical regression (cat Reg) approach for the analysis of severity-graded pulmonary damage data using the recently developed USEPA cat Reg software. The BMD approach was used to determine the RfC for phosgene because it has several advantages compared to the NOAEL/LOAEL approach: 1) it is not restricted to be set of doses used in the experiments; 2) the result is not dependent on sample size; 3) it incorporates information on statistical uncertainty. The cat Reg approach allowed the incorporation

of data on the severity of the pathological lesions, and therefore it complemented the other approaches. Conclusions from the three approaches were consistent. The BMD approach could not be used for the immune response data because it was not possible to define an adverse effect level for bacterial resistance. Use of the NOAEL/LOAEL approach for that data was consistent with the RfC derived from the lung pathology data. This paper will summarize the three approaches used in derivation of the phosgene RfC. The derivation of the RfC uses uncertainty factors to account for variation between humans, extrapolation from animals to humans, and subchronic to chronic exposure duration.

1543 PERCEIVED RISKS AND HAZARDS OF NANOTECHNOLOGY.

C. A. Hughes², S. G. Gilbert¹, H. W. Meischke³ and E. Litzler². ¹INND, Seattle, WA, ²Center for Workforce Development, University of Washington, Seattle, WA and ³Health Services, University of Washington, Seattle, WA.

Nanotechnology is the study or application of any matter at the 1-100 nanometer scale. The study objectives were to measure and evaluate differences between nanotechnologists/nanoscientists and environmental health scientists in behavior, knowledge, beliefs and attitudes relating to nano-development. This study surveyed University of Washington faculty associated with the Center for Nanotechnology and the Department of Environmental and Occupational Health Sciences. The hypotheses were that 1) environmental health scientists will perceive greater risk and greater need for nano-development regulation and public awareness than will nanotechnologists and that 2) nanotechnologists will perceive greater benefit to nano-development than will environmental health scientists. Variances in knowledge, communication, and attitudes including trust, regulation and perceived benefits and risks were examined to better understand cross-disciplinary differences. Results indicated that nanotechnologists and environmental health scientists 1) did not trust regulatory agencies to minimize risks of scientific development; 2) tended to not trust business leaders within the nanotechnology industry to minimize risks associated with nano-development; and 3) tended to think the precautionary principle is an appropriate strategy for reducing risks. The two groups tended to differ in that 4) environmental health scientists were statistically significantly more likely to believe that current regulations were insufficient, while nanotechnologists general agreed but the finding was not significant; and 5) nanotechnologists were significantly more likely to think the benefits of nano-development would outweigh the risks, while the majority of environmental health scientists only concurred. These results can be used to improve cross-disciplinary communication about nanotechnology's benefits and potential hazards, and identify appropriate levels of nano-regulation, and spark discussion about methods for nano-regulation.

1544 DEPOSITION OF INHALED NANOPARTICLES IN THE HUMAN LUNG.

O. T. Price and B. Asgharian. Division of Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC.

Increased production of industrial devices based on nanostructured materials raises the possibility of environmental and occupational human exposure with consequent adverse health effects. Nanoparticles are suspected of having increased toxicity due to their internal structure and size characteristics that elicit unique carrier transport properties. For this reason, it is important to assess the dose and distribution of inhaled nanoparticles in the human lung. A model of nanoparticle transport and deposition in the human lung was developed based on the convective and diffusive properties of nanoparticles. Local, regional, and total lung deposition was calculated by performing a mass balance on particles moving through each airway of the lung during a breathing cycle. Particle losses due to diffusive transport were found to be insignificant in the upper airways of the lung because of high airflow convection. In the deep lung, particle transport by axial diffusion was significant and deposition tended to occur more distally compared to when axial diffusion was not included in the model. However, total deposition of nanoparticles in the lung was independent of axial diffusion because of high deposition efficiency (near 100%). The nanoparticle deposition model will yield more accurate predictions of site-specific and local deposition of particles and better correlations for dose-response relationships.

1545 CARDIOVASCULAR MORTALITY AND LUNG CANCER RISK FROM DIESEL EXHAUST PARTICULATE IN CALIFORNIA.

M. A. Marty, A. G. Salmon and G. V. Alexeeff. Cal/EPA, Office of Environmental Health Hazard Assessment, Oakland, CA.

Diesel exhaust particulate (DEP) was identified as a Toxic Air Contaminant by the Air Resources Board in California in 1998 following a lengthy process that included a quantitative risk assessment based on lung cancer in occupational settings.

DEP is one component of ambient particulate matter (PM) primarily in urban settings or near major roadways. Many studies demonstrate increased risk of morbidity and mortality from cardiovascular and respiratory illness, including lung cancer, associated with ambient PM. The risk management of diesel engine exhaust has been based primarily on the estimate of cancer potency developed by the California Office of Environmental Health Hazard Assessment (OEHHA). This paper describes estimates of both cancer and noncancer risks associated with ambient diesel PM exposure utilizing measured or estimated concentrations of diesel PM statewide and near-source, and compares estimated lung cancer risk derived from relative risk estimates in epidemiological studies of chronic exposure to ambient PM with estimates based on the lung cancer potency factor developed by OEHHA. Statewide average exposures to DEP based on emissions inventories have been estimated by the California Air Resources Board to be approximately $1.5 \mu\text{g}/\text{m}^3$ considering both indoor and outdoor exposures. Outdoor average concentrations estimates range between 0.2 and $3.6 \mu\text{g}/\text{m}^3$ in California. Measured near-source and in-vehicle exposures can be much higher (up to $50 \mu\text{g}/\text{m}^3$). Statewide average exposures in California are associated with excess cancer risk of 4.5×10^{-4} and a total estimated number of lung cancer cases of about 200 per year; cardiovascular mortality risks are on the order of 6×10^{-2} for a total number of about 3800 deaths per year. Near-source exposures are associated with higher risks. Estimates of cardiovascular mortality (up to several thousand deaths per year) exceed those for lung cancer (hundred of deaths/year) by a wide margin.

1546 THE EFFECTS OF DESERT SAND (PM10) ON THE RAT AIRWAY.

E. W. Johnson, H. J. Fullenkamp, E. R. Wilfong, A. O. Olabisi and G. D. Chapman. Naval Health Research Center Detachment, Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH.

Sand storm composition varies by geographical location and may contain contaminants such as metals or microorganisms on their surfaces or within their matrix. Military personnel deployed to areas where blowing sand is a more frequent occurrence are concerned about potential health consequences from inhaling the airborne sand particles. Airborne particulate levels (PM10; PM₁₀ < 10 μm) in such regions can exceed $10,000 \mu\text{g}/\text{m}^3$, significantly higher than the recommended military exposure guideline (MEG) of $150 \mu\text{g}/\text{m}^3$. Consequently, a single exposure to desert sand (PM10) particles from a known deployed region in the Middle East was investigated for airway inflammation or injury. Male Sprague-Dawley rats (n=80/time point) were intratracheally instilled with PM10 particles suspended in sterile saline at doses of 0.84 mg/ml, 4.2 mg/ml or 12.6 mg/ml (corresponding to 1, 5 and 15 mg/Kg body weight). Positive, negative and vehicle control animals were treated with silica, titanium dioxide and sterile saline, respectively. At select times (24 hours, 3 days, 7 days and 6 months) post single exposure, the lungs were lavaged with cold phosphate buffered saline and the bronchoalveolar lavage fluid (BALF) was analyzed for markers of inflammation and injury such as lactate dehydrogenase (LDH), total protein (TP), N-acetylglucosaminidase (NAG), cytokines, cell number, type, and viability. Positive trends were observed in the concentrations of TP and LDH in the BALF of sand exposed rats (15mg) from 24 hours to 3 days post-exposure. However, at 7 days and 6 months the results were comparable to the controls. Histopathology report at 7 days showed inflammation in the lung tissues from 15 mg of sand (PM10). The inflammation was characterized by alveolitis, alveolar hyperplasia, pneumonitis, silicosis and eosinophilic infiltration in the lungs. The 6 month study is on-going.

1547 PHYSICOCHEMICAL AND CELL-BASED APPROACH FOR PREDICTING OF PHOSPHOLIPIDOSIS-INDUCING POTENTIAL IN EARLY DRUG DISCOVERY.

K. Tomizawa¹, K. Sugano², H. Yamada¹ and I. Horii¹. ¹Drug Safety Research & Development, PGRD Nagoya Laboratories, Pfizer Inc., Aichi, Japan and ²Pharmaceutical R&D, PGRD Nagoya Laboratories, Pfizer Inc., Aichi, Japan. Sponsor: M. Kurata.

Some of the principal requisites of toxicity screening methods in drug discovery are their ease to perform and high throughput, as well as the possibility to predict the occurrence of clinical events. Drug-induced phospholipidosis is defined as the excessive accumulation of phospholipids in the cytoplasm as a result of medical treatment. The accumulation of phospholipids is observed as a distinct formation of lamellar inclusion bodies by transmission electron microscopy (EM). Various physicochemical approaches to predict the phospholipidosis-inducing potential (PLIP) of drugs have been reported. The purpose of the present study was to develop a new simple physicochemical prediction method also based on lipophilicity and a charge parameter. We employed a test set of 33 compounds including 11 in-house compounds. The PLIP of the test set compounds was determined by the fluorescence-labeled lipid accumulation assay using isolated rat hepatocytes. In addition, the formation of lamellar bodies in the cytoplasm was confirmed by EM. The

usefulness of the ClogP - most basic pKa (pKa - MB) plot to the PLIP of compounds was first examined. This plot was unable to predict the PLIP of zwitterions. In order to improve its predictability, the net charge of a given molecule (NC) was introduced instead of pKa - MB, since the NC corresponds directly to the ionization state of compounds in the organelles. Compounds with high ClogP (> 1) and high NC ($1 \leq \text{NC} \leq 2$) tended to be positive. This finding was also confirmed using 30 additional validation set compounds obtained from the literature. The ClogP - NC plot differentiated positive and negative compounds with more than 98% accuracy (62/63). The method based on ClogP and NC contributes to an adequate assessment of the structure-toxicity relationship and drug design. In the assay cascade, physicochemical and cell-based approach facilitates the selection of compounds prior to the implementation of further *in vivo* studies.

1548 ACETALDEHYDE INHALATION TOXICITY APPERARS SEVER IN ALDEHYDE DEHYDROGENASE 2 KNOCKOUT MICE; : 0, 125 AND 500 PPM 24HR 2WEEKS STUDY.

T. Isse¹, T. Oyama¹, K. Matsuno², M. Muto³, I. Uchiyama⁴ and T. Kawamoto¹. ¹Environmental Health, University of Occupational and Environmental Health, Kitakyushu, Fukuoka, Japan, ²Bio-information Research Center, University of Occupational and Environmental Health, Kitakyushu, Japan, ³Endoscopy and Gastrointestinal Oncology Division, National Cancer Center Hospital East, Kashiwa, Japan and ⁴Department of Environmental Hygiene, School of Technology, Kyoto University, Kyoto, Japan.

Acetaldehyde is metabolized by aldehyde dehydrogenase 2 (ALDH2). Half of Japanese are inactive aldehyde dehydrogenase genotype (ALDH2*2/*2 and ALDH2*1/*2). ALDH2-inactive individuals were estimated to be at a higher risk of toxicity due to a higher internal exposure to acetaldehyde. However, inhalation toxicity of acetaldehyde has not been evaluated in these populations. We compare Aldh2 inactive gene targeting mice (Aldh2^{-/-}) and that of wild type mice (Aldh2^{+/+}) by 500, 125 and 0 ppm 24 hr/day 2 weeks acetaldehyde inhalation test. The average blood acetaldehyde concentration of Aldh2^{-/-} mice was higher than that of Aldh2^{+/+} mice in the acetaldehyde exposure group, observable effects by the acetaldehyde exposure on the lung and liver were not different between Aldh2^{+/+} and Aldh2^{-/-} mice. In Aldh2^{-/-} mice, the levels of (1) erosion of respiratory epithelium and the subepithelial hemorrhage in nose, (2) hemorrhage in nasal cavity, (3) degeneration of respiratory epithelium in larynx, pharynx and trachea, and (4) degeneration of dorsal skin were higher compared with Aldh2^{+/+} mice. The Aldh2^{-/-} mice expose higher level of internal acetaldehyde exposure and are more acetaldehyde-sensitive than Aldh2^{+/+} mice. In the case of the both mice have same absorption rate, same respiration and circulation status, and the blood acetaldehyde reach plateau status, one-compartment multiple dosing model figures out the risk factor of internal exposure for Aldh2^{-/-} mice is approximately 6 times higher than Aldh2^{+/+} mice. Based on this study, acetaldehyde inhalations were inferred to pose a higher risk to ALDH2-inactive human individuals.

1549 DEVELOPMENT OF TEFS FOR PCB CONGENERS BY USING AN ALTERNATE ENDPOINT - THYROID HORMONE.

J. Yang, A. G. Salmon and M. A. Marty. OEHHA, CalEPA, Oakland, CA.

PCBs are ubiquitous global toxic contaminants. Health risk assessment for these chemicals is complex; the current TEF method only covers coplanar PCBs, dibenzofurans and dioxins, without involving non-coplanar PCBs. To address this deficiency, we correlated published data for several PCB congeners on toxicity related endpoints *in vivo*, with the aim of identifying one or more readily accessible parameters which correlate with toxic responses for both dioxin-like and non dioxin-like PCB congeners. In rats fed PCBs for ninety days, the order of EROD induction was PCB 126 > PCB 77 > PCB 118 > PCB 153 > PCB 28. This is consistent with the order of thyroid toxicity, i.e., PCB 77 > PCB 118 > PCB 153 > PCB 28. These data suggest a possibility by using the thyroid toxicity endpoint as an alternative to EROD induction in developing TEFS for non-coplanar PCBs. While some PCB congeners (PCB 77 and PCB 126) increase dopamine levels in the brain, most congeners decrease the dopamine level. The toxicity order for dopamine content is inconsistent with that for EROD or thyroid hormone effects, i.e., the dopamine levels decreased in the order PCB 28 > PCB 118 > PCB 153. The estrogenic endpoint for PCB congeners is also divergent: in general, lower chlorine PCBs have estrogenic effects, whereas higher chlorine PCBs are anti-estrogenic. Crofton et al. (2005) studied thyroid hormone decreases (ED30) caused by TCDD, PCDD, TCDF, and 12 PCBs, including both dioxin-like and non dioxin-like congeners. Based on their data, the calculation of TEF-THs, referred to TCDD by using the ED30, are identical to both TEF-WHO97 and TEF-WHO05 for dioxins and dioxin-like PCBs and their correlation coefficient are $r=0.73$, $P<0.05$; and $r=0.72$, $P<0.05$, respectively. A different 90 day rat experiment *in vivo* also found significant correlations for TCDD, PCB 126 and PCB 156 between reductions in plasma total thyroxine levels and liver enzyme induction. Therefore, we

propose to use thyroid hormone reductions and thyroid histological changes, as an endpoint to generate new TEFs which address the thyrotoxic and neurotoxic effects of PCBs.

1550 MECHANISM-BASED CANCER RISK ASSESSMENT FOR 1,4-DICHLOROBENZENE.

B. E. Butterworth¹, L. Aylward² and S. M. Hays³. ¹Butterworth Consulting, Raleigh, NC, ²Summit Toxicology, LLP, Falls Church, VA and ³Summit Toxicology, LLP, Lyons, CO.

The weight of scientific evidence indicates that cancer risk assessments for 1,4-dichlorobenzene (1,4-DCB) should be based on a nongenotoxic-mitogenic mode of action, rather than the linear default assumptions used in the proposed 2006 EPA IRIS assessments. The primary driving force exerted by mitogenic carcinogens is to stimulate the growth of spontaneous precancerous lesions and predicts a threshold dose level for carcinogenic activity corresponding to doses that are insufficient to exhibit mitogenic or promotional activity. Accordingly, the appropriate risk assessment approach for 1,4-DCB is to establish a no observed adverse effect level (NOEL) for tumor induction divided by a rational uncertainty factor to estimate a human daily oral exposure below which there is unlikely to be an increased lifetime risk of cancer. Two chronic studies showing increased incidences of liver adenomas and carcinomas in mice are available for 1,4-DCB, an oral gavage bioassay with 2 dose groups and an inhalation bioassay with 3 airborne concentrations. A coherent dose-response curve exhibiting a clear threshold is obtained when the two bioassays are assessed jointly using an absorbed-dose metric. Benchmark dose modeling of the combined dose-response curve provides the basis for assessing cancer risks under both a threshold and non-threshold set of assumptions. Using the threshold approach, derived safe exposure levels via oral and inhalation routes of exposure are somewhat higher than but consistent with the RfD and RfC values proposed by IRIS. Estimated cancer slope factor and unit risk based on the combined data sets under a non-threshold set of assumptions using the combined oral and inhalation data sets are approximately 10-fold lower than the values proposed by IRIS. The default IRIS calculation estimates a 1 in 100,000 increased lifetime risk of cancer at an airborne concentration of 0.0004 ppm, 250 fold lower than a representative mechanism-based threshold model and 187,500 fold lower than the NOEL of 75 ppm.

1551 RISK ASSESSMENT FOR SITES WITH VOLATILE CONTAMINANTS IN SHALLOW GROUNDWATER.

P. Wong-Yim, T. L. Taras, B. K. Davis and M. J. Wade. *Toxic Substances Control, California Environmental Protection Agency, Sacramento, CA.*

In California, a number of hazardous waste sites are present in low-lying coastal areas with shallow groundwater (2 to 15 feet below ground surface) contaminated by volatile organic chemicals (VOCs). Shallow groundwater poses complex issues of site characterization and potential exposure pathways. In addition to potential ingestion and dermal contact through domestic water use, exposure can occur through indirect pathways. Inhalation of VOCs can occur via showering and other household uses of groundwater, following volatilization into outdoor air, and through vapor intrusion from soil or groundwater into indoor air. The vapor intrusion to indoor air pathway currently receives considerable attention in risk assessments. Exposure to VOCs from shallow groundwater can also occur via dermal contact or inhalation by construction workers and uptake of contaminated groundwater into home-grown produce consumed by residents. This paper illustrates how these issues were dealt with at specific sites in California. Risk assessment was performed at Site A for groundwater contaminated with benzene and methyl tertiary-butyl ether. A US Department of Energy model for home-grown produce predicted cancer risk as high as 3E-3 and a noncancer hazard index (HI) of 7. However, cancer risk and HI from the CalTOX model were much lower (2E-6 and 0.02, respectively), illustrating the uncertainty associated with this pathway. Excluding the food pathway, the highest cancer risk and HI were from the vapor intrusion pathway (2E-5 and 0.08, respectively). Our experience is that if significant concentrations of VOCs are present in soil or groundwater, the vapor intrusion pathway usually generates the highest cancer risk and HI. The risk assessment for Site A included an evaluation for construction workers. Although the estimated cancer risk and HI were de minimus for VOCs from groundwater in a trench scenario (3E-7 and 0.03, respectively), inhalation of VOCs from soil generated surprisingly high estimates for the outdoor air pathway (3E-6 and 52, respectively).

1552 DERIVATION OF A DRINKING WATER ACTION LEVEL FOR TRIS(MONOCHLOROPROPYL) PHOSPHATE ISOMERS.

J. Shoenfelt¹, M. H. Whittaker¹, A. Gebhart² and F. Hammer². ¹ToxServices LLC, Washington, DC and ²Underwriters Laboratories, Inc., Northbrook, IL.

Tris(monochloropropyl) phosphate isomers (TMCPs) are used in thermoset and thermoplastic materials, and for textile finishes contacting potable drinking water. TMCPs are a mixture of two isomers: tris(2-chloroisopropyl) phosphate and

tris(2-chloropropyl) phosphate. When products are evaluated to national health effects standards for use in drinking water systems, chemicals extracting from these products must be below appropriate action levels. As defined by ANSI/NSF Standard 61, a Total Allowable Concentration (TAC) is the maximum concentration of a nonregulated contaminant allowed in a public drinking water supply; a default Single Product Allowable Concentration (SPAC) is 10% of the TAC. To determine an action level for TMCPs, a health effects evaluation was performed. TMCPs are not genotoxic based on mutagenicity, cytogenicity, and cell transformation assays. The systemic toxicity of TMCPs has been investigated in subacute and subchronic studies, and in a reproduction/developmental study. Effects were reported in repeat-dose toxicity studies at doses of 481 mg/kg/day and above, and included reductions in body weight and body weight gain, increased relative and absolute liver weights, mild hepatocellular swelling and cortical tubular degeneration, and mild hyperplasia of thyroid follicular and sternal bone marrow cells. Systemic toxicity was not reported at doses up to 160 mg/kg/day. No adverse maternal or developmental effects were reported at doses up to 1000 mg/kg/day following exposure during gestation days 0-20. Collectively, available toxicity data indicate that TMCPs are without adverse health effects at concentrations up to 160 mg/kg/day. A 0.2 mg/kg/day RfD was derived using a 160 mg/kg/day NOEL from a 13-week dietary study in rats and uncertainty factors totaling 1000. A TAC of 1.1 mg/L was derived for TMCPs based on the RfD, a drinking water source contribution factor of 0.20, and a drinking water intake of 2 L/day. The SPAC is 0.11 mg/L, or 10% of the TAC.

1553 TESTING FOR ADDITIVITY IN THE LOW DOSE REGION OF AN ENVIRONMENTALLY RELEVANT MIXTURE OF 18 POLYHALOGENATED AROMATIC HYDROCARBONS.

C. Gennings^{1,2}, L. Stork³, M. DeVito⁴, B. Reeves⁵ and K. Crofton⁴. ¹Biostatistics, VCU, Richmond, VA, ²Solveritas, LLC, Richmond, VA, ³Monsanto Co., St. Louis, MO, ⁴NHEERL, U.S. EPA, Research Triangle Park, NC and ⁵Tetra Tech, Inc., Collinsville, IL.

A common default assumption in risk assessment of chemical mixtures is that the chemicals combine additively in the low dose region. Under additivity, with information from single chemical dose-response data, the risk associated with the mixture can be estimated. Our objective is to evaluate if there is sufficient evidence to claim additivity in a low dose region for the effects of an environmentally relevant mixture of 18 PHAHs on serum total thyroxine (T4). Young female rats were dosed via gavage with 18 different PHAHs [2 dioxins, 4 dibenzofurans, and 12 PCBs], for 4 consecutive days (Crofton et al, EnvHlthPersp, 2005). Serum total T4 was measured via radioimmunoassay. A mixture was custom synthesized with the ratio of chemicals based on the ratios of PHAHs found in breast milk, fish and other sources of human exposure. Following the work of Stork et al (Risk Analysis, 2006) we utilized equivalence testing methodology to test for additivity at three environmentally relevant low dose mixture groups. The ratio of predicted mean responses under additivity based on single chemical data to observed sample means at these mixture points was calculated with the corresponding 95% simultaneous confidence intervals. Two of the three confidence intervals were completely contained within predetermined additivity bounds of [0.80, 1.25]. In these two cases we conclude that there is significant evidence to claim that the T4 mean response is equivalent to that predicted from the single chemical data under additivity. In the lowest mixture dose group there is not enough evidence to claim additivity as the lower limit of the Bonferroni-corrected 95% confidence interval fell below 0.80. (This abstract does not necessarily reflect U.S. EPA policy. These data and research are not associated with Monsanto.)

1554 HEALTH RISK ASSESSMENT OF METHYL ISOBUTYL KETONE IN DRINKING WATER.

J. De France, V. S. Bhat, G. L. Ball and C. J. McLellan. *NSF International, Ann Arbor, MI.*

Acceptable levels of methyl isobutyl ketone in drinking water were determined based on Annex A of NSF/ANSI 61 (2005). Limited human but numerous animal toxicity data were identified. Subchronic gavage or inhalation exposure caused transient narcosis, liver and kidney weight increases, and renal nephropathy in rats. Two subchronic oral studies were available, but a drinking water study evaluated an insufficient number of rats, used only one dose level, and included only females. Increased liver and kidney weights and nephropathy were observed without hepatic histopathology in a standardized subchronic gavage study in rats. Increased liver weights were likely an adaptive response to metabolizing high bolus doses of methyl isobutyl ketone, while renal effects were attributed to spontaneous and/or alpha-2μ-globulin nephropathy. Since narcosis was inconsistently or transiently observed in all studies, the transient narcosis observed after gavage but not after drinking water exposure at the same dose was attributed to bolus dosing. Renal lesions in rats

and mice chronically inhaling methyl isobutyl ketone were attributed to spontaneous or alpha-2u-globulin nephropathy or were within historical ranges, thus either not considered treatment-related or relevant to humans. However, interpretation of the effects in male rats was confounded by reduced survival. The weight of genotoxicity evidence suggests that methyl isobutyl ketone is not genotoxic. According to U.S. EPA (2005) guidelines, since no epidemiological studies in humans or chronic oral data in animals were identified, the data are inadequate for an assessment of human carcinogenic potential of methyl isobutyl ketone after oral exposure. The NOAEL of 1,000 mg/kg-day, based on the lack of adverse effects in the subchronic gavage study, was used to derive the Reference Dose (RfD), since it was a standardized study and oral data are preferred, due to the lack of kinetic or metabolism data in humans to reduce route-to-route or interspecies extrapolation. The RfD of 1 mg/kg-day was used to determine the Total Allowable Concentration in drinking water of 7 mg/L.

1555 SUPPORT FOR SELECTION OF A METHAMPHETAMINE CLEANUP STANDARD IN COLORADO.

T. L. Hammon¹ and S. Griffin². ¹Colorado Department of Public Health & Environment, Denver, CO and ²U.S. EPA Region 8, Denver, CO.

Methamphetamine production for illicit use occurs in makeshift labs and is associated with the release of numerous chemicals, including methamphetamine residues. The presence of these chemicals may pose a health risk to residents who reoccupy these structures after property seizures. Several states have established technology-based cleanup standards for methamphetamine, but none have examined the health-protectiveness of these standards. In response to Colorado House Bill 04-1182, exposure intakes correlated with three technology-based standards were calculated for various groups of individuals. Exposures were assessed for a one-year old and six-year old child, as well as for a female of child-bearing age. Exposure intakes were compared to toxicity reference values developed from developmental endpoints following methamphetamine exposure from the available literature. Uncertainty factors were applied to the lowest adverse effect levels observed in these studies to arrive at the toxicity reference values. These reference values were greater than the calculated intakes from each proposed technology standard, suggesting that all of the proposed standards would be protective of human health exposure. The cost and practicality of attaining each of the proposed standards was also factored into the decision making process. In their final regulation (6 CCR 1014-3), the CDPHE selected 0.5 ug/100 cm² as their final cleanup standard for methamphetamine residues.

1556 HEALTH RISK ASSESSMENT OF 4-CHLOROBENZOTRIFLUORIDE IN DRINKING WATER.

C. J. Lee, V. S. Bhat, G. L. Ball and C. J. McLellan. NSF International, Ann Arbor, MI.

Acceptable levels of 4-chlorobenzotrifluoride in drinking water were determined based on Annex A of NSF/ANSI 61 (2005). 4-Chlorobenzotrifluoride showed minimal potential for skin or eye irritation. Results of repeated-dose systemic studies from 14 days to three months duration, whether by the oral or inhalation route, showed liver effects manifested as increased liver weight and hepatocyte hypertrophy, which were not considered adverse in the absence of changes in hematology or clinical chemistry parameters, or adverse histopathology. In some shorter-term studies, increased cholesterol and triglyceride levels were observed and considered adverse. Kidney effects related to α -2u-globulin accumulation were observed in male rats, but were not considered relevant to human health based on U.S. EPA science policy. No effects on reproduction parameters were observed in a one-generation study, and neurotoxic effects were only observed in short-term studies at very high doses. Several distribution studies indicate this chemical has a small potential to accumulate in adipose tissue. 4-Chlorobenzotrifluoride produced negative results in standard and host-mediated *Salmonella typhimurium* reverse mutation assays, and in the mouse lymphoma forward mutation assay. No evidence of damage was observed in chromosomal aberration assays in vitro or in vivo. 4-Chlorobenzotrifluoride did induce unscheduled DNA synthesis and sister chromatid exchanges. Based on mixed results in genetic toxicity assays, and on the absence of human epidemiological data or a lifetime bioassay in laboratory animals, the data are inadequate for an assessment of human carcinogenic potential. A NOAEL of 45 mg/kg-day, based on lack of adverse effects in a subchronic gavage study in weanling rats, was used to derive the Reference Dose (RfD). The RfD incorporated a total uncertainty factor of 1,000, which accounted for inter- (10x) and intraspecies (10x) extrapolation, subchronic to chronic extrapolation (3x), and database deficiencies (3x). The RfD of 0.05 mg/kg-day was used to determine the Total Allowable Concentration in drinking water of 0.3 mg/L.

1557 AN EVALUATION OF THE MODE OF ACTION INFORMATION FOR HEXACHLOROETHANE USING U.S. EPA'S 2005 GUIDELINES FOR CARCINOGEN RISK ASSESSMENT.

S. Jones¹ and J. Kim². ¹U.S. EPA, Washington, DC and ²Sciences International, Inc., Alexandria, VA.

The Integrated Risk Information System (IRIS) Program is conducting a health assessment of hexachloroethane that will apply the mode of action framework of the U.S. EPA 2005 Guidelines for Carcinogen Risk Assessment. The guidelines highlight the importance of critically evaluating toxicological and epidemiological data to characterize the mode of action information for a chemical substance in order to interpret potential cancer risk to humans. Understanding a chemical's mode of action provides insight to determine the likelihood of toxicity in humans exposed to a chemical substance. A recent evaluation of the available information for hexachloroethane identified a two-year bioassay in which renal tubule tumors were identified in F344/N male rats. The production of these tumors is frequently associated with a group of chemicals that induce alpha 2u-globulin accumulation leading to early nephrotoxicity and progressing to renal tubule tumor formation. The male rats also exhibited a range of nephrotoxic effects that are characteristic of the renal lesions observed with the protein alpha 2u-globulin-associated nephropathy. Numerous studies for hexachloroethane have demonstrated toxic effects in male rats that are commonly associated with the alpha 2u-globulin protein mechanism. However, hexachloroethane also induced similar nephrotoxic effects in animal species that are not considered characteristic of the alpha 2u-globulin-associated mode of action. Based on the framework provided in the U.S. EPA 2005 Guidelines for Carcinogen Risk Assessment, the mode of action for hexachloroethane as it relates to the alpha 2u-globulin protein mechanism has been evaluated.

1558 MUCOSAL IRRITATION OF VAPORS OF HEXANAL, ACETIC ACID AND DIOXANE IN HUMANS.

L. Ernstgård¹, A. Iregren², B. Sjögren¹ and G. Johanson¹. ¹Work Environment Toxicology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden and ²National Institute for Working Life, Stockholm, Sweden.

Chemosensory irritation of the mucous membranes is an important endpoint in the risk assessment of volatile chemicals. Information on health hazards associated with the handling of hexanal, acetic acid and 1,4-dioxane is sparse. We have performed controlled short-term chamber exposures with the intention to evaluate acute health effects of these chemicals, with emphasis on mucosal irritation. In pilot studies, the subjects where exposed to stepwise increasing levels (10 min per level) of each chemical. A questionnaire with visual analogue scales (VAS) was used for graded ratings of irritation and central nervous system symptoms. Based on these ratings, the subjects where exposed for 2 h at rest to vapors of hexanal (0, 2, and 10 ppm), acetic acid (0, 5, and 10 ppm) and 1,4-dioxane (0, and 20 ppm), respectively. In addition to the VAS ratings, effects in the airways were assessed by spirometry, nasal swelling was studied by acoustic rhinometry and nasal blocking index, blink frequency was measured by electromyography and inflammatory markers in plasma (C-reactive protein and interleukin-6) were analyzed. Exposure to 20 ppm 1,4-dioxane did not significantly affect any of the measured parameters. For hexanal, ratings of discomfort in the eyes and nose, solvent smell and headache increased significantly with exposure level. Blinking frequency was significantly increased at 10 ppm. Acetic acid caused significantly increased ratings of nasal irritation and smell at 5 and 10 ppm. No effects on pulmonary function, nasal swelling or on plasma inflammatory markers were detected in any study. In conclusion, minor effects were detected after exposure to hexanal (10 ppm) and acetic acid (10 ppm). No effects were detected for 1,4-dioxane at 20 ppm, the highest level tested.

1559 NASAL IRRITATION AND TUMORS IN RATS EXPOSED TO CHEMICALS IN DRINKING WATER MAY RESULT FROM DIRECT CONTACT WITH NASAL TISSUES.

J. K. Thomas¹, T. J. Weber¹, D. L. Stenoien¹, A. D. Woodstock¹, K. R. Minard¹, B. J. Locy², R. Clarkson², S. Sager² and R. A. Corley¹. ¹Pacific Northwest National Laboratory, Richland, WA and ²Arcadis G&M of Michigan, Southfield, MI.

Exposure to 1,4-dioxane in drinking water has lead to nasal irritation and tumors in rats in several studies at concentrations of 0.5-1.8% (5,000 to 1,800 mg/L), but not following inhalation exposures to concentrations as high as 111 ppm (400 mg/m³). It has been hypothesized that the nasal lesions likely resulted from repeated, direct contact between inspired drinking water and nasal tissues producing localized high doses and chronic irritation. Magnetic resonance imaging was initially used to determine the amount of water inspired; however, this method was useful only when

air passages were completely occluded. Therefore, a series of water soluble dyes were evaluated for their palatability and ability to stain nasal tissues with a mixture of red fluorescent dyes selected for the definitive study. Three groups of five rats each were provided with either: 1) fluorescent dye mixture plus 0.5% dioxane; 2) fluorescent dye mixture alone; or 3) control drinking water for a single night. Nasal tissues were evaluated by fluorescence microscopy the following morning. Dye-specific fluorescence, indicating a direct contact with drinking water, was observed in nasal airways of all rats exposed to the dye mixture (with and without dioxane) in the anterior third of the nose where previous studies have identified irritation and tumors following drinking water exposures. These results provide a critical linkage between nasal tissue responses and localized high doses of dioxane inspiration of drinking water and a foundation for the hypothesized cytotoxic mode of action for nasal tumors. The nasal tumors observed only in rats exposed to dioxane in drinking water is therefore of questionable relevance for humans. Furthermore, these results have implications for the assessment of any chemical that causes nasal lesions in rats when exposed via drinking water. *Sponsored by the 1,4-Dioxane Risk Management Consortium.*

1560 DEVELOPMENT OF WEIGHTED DISTRIBUTIONS OF REPS FOR DIOXIN-LIKE COMPOUNDS (DLCs).

L. Haws¹, N. Walker², M. DeVito³, L. Birnbaum³, K. Unice⁴, P. Scott⁴, M. Harris⁵, W. Farland³, B. Finley⁶ and D. Staskal¹. ¹ChemRisk, Austin, TX, ²NIEHS, Research Triangle Park, NC, ³U.S. EPA, Research Triangle Park, NC, ⁴ChemRisk, Pittsburgh, PA, ⁵ChemRisk, Houston, TX and ⁶ChemRisk, San Francisco, CA.

Potential health risks associated with exposure to mixtures of DLCs are currently assessed using a toxic equivalency factor (TEF) approach. TEFs are single point estimates of the relative potency (REP) of DLCs recommended by WHO based on underlying REP values that represent a heterogeneous data set ranging across several orders of magnitude. Recently, the WHO and NAS reviewed the TEF methodology and acknowledged the importance of better characterizing variability and uncertainty inherent in the TEFs and indicated that the use of distributions of REPs would provide a means of characterizing the variability and uncertainty inherent in the TEFs. Development of a framework to quantitatively weight studies based on quality and relevance to human health risk assessment is a central component of developing distributions of REPs for each congener. The aim of this investigation was to develop a transparent and reproducible weighting scheme, to apply it to the REP₂₀₀₄ database, and to evaluate the impact on the distributions. The consensus-based weighting scheme incorporates several different measures of study quality and relevance including REP derivation method and quality as well as endpoint. Multiple iterations and numerical scales were assessed to determine the impact on the REP distributions. This weighting scheme provides an approach for placing greater emphasis on those REP values that are believed to be more well suited for health risk assessment purposes. Application of the weighting scheme to PCB 126 and 2,3,4,7,8-PeCDF, the two most data-rich congeners, had very little impact on the overall distribution. Other congeners were also assessed. While the weighting scheme did not have a significant impact on the overall distributions, the use of such a scheme yields a more transparent, reproducible, and consistent method for deriving TEFs from the underlying REP data. This abstract does not represent USEPA policy.

1561 CANCER POTENCY ESTIMATE FOR 2, 3, 4, 7, 8-PENTACHLORODIOBENZO(P)DIOXIN (4-PECDF).

C. Kirman¹, E. Crouch², L. Aylward³, T. Simon⁴, R. Budinsky⁵, B. Landenberger⁵ and T. Long¹. ¹The Sapphire Group, Beachwood, OH, ²Cambridge Environmental Inc., Cambridge, MA, ³Summit Toxicology, Falls Church, VA, ⁴Simon Creative, Atlanta, GA and ⁵The Dow Chemical Co., Midland, MI.

A cancer slope factor was derived for 4-PeCDF using data collected from the recently published NTP bioassay in female rats. The dose-response relationship for liver tumors in rats was assessed in terms of lifetime average daily liver burden (LADLB) and body burden (LADBB), using data collected from the lifetime and stop exposure components of the bioassay. Classical pharmacokinetic (PK) and physiologically-based pharmacokinetic (PBPK) models were compared and contrasted for the purposes of characterizing tissue burdens in rats and predicting tissue burdens in humans. Variations of the multistage model, both permitting and excluding a possible threshold term (dt), were used to characterize the dose-response relationship in terms of extra risk. Probability density functions were developed for the linear term of the multistage model (q1), dt, and the dose producing a 10% increase in extra risk (ED10) to permit characterization of central tendency as well as upper and lower bounds. Information regarding the mode of action for liver tumors support a nonlinear dose-response relationship, such that the potential risks at low doses are negligible. Linear estimates of cancer potency are presented for comparison purposes. The impact of alternative decisions for each decision point in the as-

essment will be discussed. The results are compared to potency estimates based upon the WHO toxicity equivalency factor (TEF) approach for the risk assessment of dioxin-like compounds.

1562 DIVERGENT TRANSCRIPTIONAL PROFILES INDUCED BY THE AHR AGONISTS 2, 3, 7, 8-TCDD AND 2, 3, 7, 8-TCDF IN PRIMARY RAT HEPATOCYTES.

B. Gollapudi¹, R. Budinsky¹, A. Dombkowski², R. Novak², M. A. Abdelmegeed³, T. Zacharewski³, L. Burgoon³ and C. Rowlands¹. ¹The Dow Chemical Company, Midland, MI, ²Wayne State University, Detroit, MI and ³Toxicogenomic Informatics and Solutions, LLC, East Lansing, MI.

Environmental mixtures of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and structural related polychlorinated dibenzo-p-dioxins (PCDDs) and dibenzofurans (PCDFs) are regulated using the toxic equivalency factor (TEF) or relative potency (RP) approach for risk assessment. The TEF approach is based on a number of assumptions such as the effects of individual compounds are essentially additive with parallel dose response curves, which is due to identical biochemical mechanisms of action following AHR activation. In order to test this fundamental TEF assumption, primary female Sprague-Dawley rat hepatocytes were treated for 24 hours with TCDD, 2,3,4,7,8-pentachlorodibenzofuran (PeCDF) or 2,3,7,8-tetrachlorodibenzofuran (TCDF) and the induced gene array patterns were compared. TCDD altered the maximum number of genes (190) and the expression of 68 of these genes were also altered by PeCDF and TCDF. Induced genes in common between the three chemicals included Cyp1a1, Cyp1a2, and Cyp1b1 that are core members of the so called "AHR gene battery". Agglomerative hierarchical clustering (AHC) revealed two gene superclusters with one that is largely down-regulated and one that is up-regulated. In addition, AHC analysis identified that the furans (TCDF and PeCDF) clustered independent of TCDD. Similarly, Principal Components Analysis (PCA) revealed distinct clusters for the furans versus TCDD. Functional analysis identified several pathways specifically affected by TCDD and not by the furans that included glycolysis, arginine synthesis, cell survival and apoptosis, and bile acid synthesis. These results suggest that even among "TCDD-like" compounds there are significant differences in modulation of gene expression and their activation of the AHR. These results also suggest that the some of the fundamental assumptions of the TEF model for risk assessment of PCDDs and PCDFs may not be valid.

1563 TOWARDS AN INTEGRATED PHOTO SAFETY ASSESSMENT DURING DRUG DEVELOPMENT: EVALUATION OF MECHANISM-RELATED TEST APPROACHES BROADENING THE REGULATORY TEST BATTERY.

D. M. Bauer, M. Struwe, M. Trunzer, A. Mueller, U. Plappert-Helbig, P. Ulrich, H. Martus and W. Suter. *Exploratory Development, Novartis Pharma AG, Basel, Switzerland.*

Photosensitization – sunlight-induced toxicity – is a common phenomenon mediated by many natural and synthetic compounds including drug substances. For drug development there are already a few well-established test methods available (e.g. UV-VIS light absorption spectra, the in vitro 3T3 Neutral Red Uptake Phototoxicity Test and the UV Local Lymph Node Assay), which are routinely used to identify potentially photosensitizing compounds. Despite the fact that the individual test systems usually provide well-defined results, there often remain gaps in the understanding of the underlying mechanisms of phototoxicity and strategies to address those. We therefore addressed some of these shortcomings in order to identify methods providing additional insight and, in consequence, allowing for a more systematic and relevant risk assessment. Using several model substances such as lomefloxacin or chlorpromazine we generated photo safety data sets and suggest the impact and relevance of individual test results for a final phototoxicity evaluation. Along with the development of a modified alkaline Photo-Comet Assay, we first investigated in different in vitro and in vivo systems the relevance of short ultraviolet sunlight radiation (UV-B), which is cytotoxic itself and therefore often avoided in test systems. In addition, using custom-made filter sets which allow a selective UV-A and/or UV-B (only) exposure, we revealed pure UV-B effects. So far, no photogenotoxic compound was identified requiring exclusively UV-B light exposure for activation. In order to narrow the gap between absorption spectrum assessment and in vitro test results, we evaluated a general photo degradation test (using spectrophotometry and LC/MS) thereby imitating a cellular environment (PBS, prototypic reaction partners). First results indicate that fragmentation reactions could be monitored, but that specific trapping reagents might be necessary in order to cover the photo reaction mechanisms in total.

1564 PERFLUORO-N-BUTYL IODIDE (PFBI): OCCUPATIONAL HEALTH HAZARD EVALUATION.

D. E. Dodd¹, G. M. Hoffman² and D. R. Mattie³. ¹CIIT Centers for Health Research, Research Triangle Park, NC, ²Huntingdon Life Sciences, East Millstone, NJ and ³AFRL/HEPB, Wright-Patterson AFB, OH.

Perfluoro-n-butyl iodide (PFBI) is a promising alternative to CFC solvents used in aircraft maintenance operations, because it has zero ozone depletion potential and low global warming properties. To assess its health hazard potential, toxicity tests were conducted including acute (4-h), 4-week and 13-week (6 h/d, 5 d/wk) inhalation (nose-only) toxicity studies in rats, acute (10-min) inhalation cardiac sensitization study in dogs, in vitro chromosomal aberrations in human lymphocytes, and in vitro mutagenic experiments in *S. typhimurium* and *E. coli*. In the 13-week study, a separate group of male rats was assigned to a 4-week recovery. PFBI showed no mutagenic or clastogenic activity. As expected, the most sensitive tissue following repeated PFBI exposure was the thyroid. LOAELs and NOAELs were selected for the inhalation studies. Mild effects, attributed to the thyroid gland only and reversible with recovery, were considered adaptive responses, while effects external to the thyroid were considered potentially adverse. Also, the toxicity profile of trifluoriodomethane (CF₃I) was reviewed to assist with the health hazard evaluation of PFBI. A concentration of 3900 ppm PFBI was a NOAEL in the cardiac sensitization study, and this value was considered appropriate as an acute or ceiling occupational exposure level, since uncertainty factors are not generally applied to the NOAEL that results from this test. For repeated exposure, a NOAEL of 1500 ppm PFBI was selected. Following a dosimetric adjustment for daily exposure time (6 h to 8 h), uncertainty factors were applied to derive an 8-hr TWA of 40 ppm PFBI. The factors of uncertainty included animal to human extrapolation (3), interhuman variability (3), and extent of database (3). In comparison, recommended acceptable exposure limits (AELs) for CF₃I were 2000 ppm (ceiling) and 150 ppm (8-hr TWA). Uncertainty factors were less in magnitude when calculating AELs for CF₃I, because of availability of toxicokinetic and reproductive toxicity data.

1565 A RETROSPECTIVE ANALYSIS OF 12 HUMAN STUDIES WITH PESTICIDES (1992 TO 2001) TO ASSESS RBC ACHE ACTIVITY AND CLINICAL SIGNS.

J. Doherty, E. Reaves, L. Taylor and L. Scarano. U.S. EPA, Washington, DC.

Inhibition of the red blood cell (RBC) acetylcholinesterase (AChE) in humans is considered an appropriate biomarker for exposure to N-methylcarbamate (NMCs) and organophosphate (OPs) pesticides and is used in EPA's hazard assessments. Clinical signs characteristic of NMCs and OPs are expected to occur in humans only after higher levels of inhibition are attained. In this retrospective assessment, RBC AChE and clinical signs data were evaluated from 12 human studies considered to have rigorous protocols from four laboratories that assessed NMCs (3 studies) and OPs (9 studies) (some chemicals having both acute and repeat dose protocols). All laboratories used modifications of Ellman's method for AChE analysis. Clinical signs were self-reported to trained medical staff. Data from a total of 356 males and 96 females ranging in age from 18-54 years were included and nearly all were Caucasian. Mean RBC AChE control values (IU/L) ranged from 8427 ± 1039 to 12493 ± 1176 for males and from 8576 ± 556 to 12475 ± 1808 for females. Data were evaluated based on: 1) controls (111 males and 36 females); 2) dosed subjects judged to be not showing RBC AChE inhibition (204 males and 46 females); and 3) dosed subjects judged to be showing RBC AChE inhibition; i.e., consistent depression (>10%) at critical times. For each group, the variability in AChE activity over time (predosing through postdosing) was identified. RBC AChE inhibition did not exceed 50% in any study. Evidence of RBC AChE inhibition corresponding with onset of clinical signs were judged to be occurring in only two males in two studies (both with NMCs). Clinical signs from these individuals consisted of one incident each of sweating and headache. This abstract does not necessarily reflect the views or policy of the USEPA.

1566 ACUTE EXPOSURE GUIDELINE LEVELS (AEGLS) FOR CROTONALDEHYDE.

S. Milanez. Oak Ridge National Laboratory, Oak Ridge, TN.

Crotonaldehyde (>95% trans and ≤ 5% cis isomer) is a potent eye, skin, and respiratory irritant. AEGLS are airborne concentrations above which toxic effects of specified severity could occur in humans from one-time exposure for 10 min to 8 hrs: AEGL-1 (discomfort), AEGL-2 (disability), and AEGL-3 (death). AEGL-1 values were based on a study where workers exposed to 0.56 ppm for < 8 hrs had occasional minor eye irritation. An intraspecies uncertainty factor (UF) of 3 was used because eye irritation is a direct surface-contact effect not subject to pharmacokinetic variability. The resulting AEGL-1 value of 0.19 ppm was adopted for 10 min to 8 hrs because minor eye irritation is not expected to vary greatly over time. AEGL-2 values were based on a rat study where exposure to >8000 ppm-min

caused bronchiole proliferative lesions. AEGL-2 values were calculated by dividing 8000 ppm-min by 10, 30, 60, 240, or 480 min (concentration and time appeared equally important for toxicity). An interspecies UF of 10 was applied (actual exposure concentration and time were unknown and there was little supporting data), and an intraspecies UF of 3 (a greater UF yields 4 and 8-hr concentrations causing only mild irritation), yielding AEGL-2 of 27 to 0.56 ppm for 10 min to 8 hrs. AEGL-3s were derived from a rat LC₅₀ study, using calculated LC₀₁ values for 10, 30, 60, and 240 min, and scaling the 8-hr value from 240 minutes using $C^{1.2} \times t = k$. AEGL-3s of 44 to 1.5 ppm for 10 min to 8 hrs were obtained after use of an interspecies UF of 3 (LC₅₀ values for rats, mice, and guinea pigs were within a factor of 2.5), and an intraspecies UF of 3 (great human variability is unlikely given the homogeneity of the animal data, and a larger UF yields 8-hr concentrations causing only mild irritation). A preliminary cancer assessment indicated that a 10⁻⁴ excess cancer risk was associated with crotonaldehyde concentrations 25-fold greater than the toxicity-based AEGL-2 values. [This abstract presents Interim AEGL values that are subject to change pending further review.] ORNL is managed by UT-Battelle LLC for the US Department of Energy under contract DEAC0500OR22725.

1567 RISK ASSESSMENT FOR EXPOSURES TO PCBs FROM INTERIOR BUILDING SURFACES.

T. A. Lewandowski. Gradient Corporation, Seattle, WA.

As a consequence of the widespread historical use of polychlorinated biphenyls (PCBs) in industry, many older industrial sites have low level PCB contamination. We recently conducted a baseline risk assessment for an industrial property which considered health risks of low level PCB contamination on interior building surfaces. Testing revealed that wood and concrete floors in the building had low levels (<0.03 to 4 µg/sq cm) of PCBs. In many locations, these floors were covered with carpeting and padding, providing a potential barrier to exposure. In other locations, the concrete and wood floors were exposed. Air and surface dust sampling of work surfaces indicated nearly all samples were below analytical detection limits. Roller sampling of carpets also indicated no detectable PCBs. Potential worker exposure to exposed subfloors therefore constituted the only complete exposure pathway. In order to estimate baseline risks prior to any remedial activity, we evaluated potential on-site worker exposures to interior flooring using site-specific worker activity data as well as highly conservative and uncertain estimates of adult hand-to-floor and hand-to-mouth contact. We found that estimated cancer risks for a few job categories exceeded the 1E-4 cancer risk level, the typical upper bound acceptable risk for occupational scenarios. These elevated risks were due to potential worker exposures in a few high level locations. Estimated cancer risks for other job categories were in the 1E-5 and 1E-6 range. Interestingly, risk estimates developed with the OSHA PEL for PCBs as the exposure concentration were in the 1E-2 cancer risk range, clearly indicating a discrepancy between the OSHA and EPA approaches. Based on our initial work, spot remediation is being conducted to reduce average PCB concentrations to acceptable risk-based levels. Our experience in this case highlights the need for additional data to support realistic models for assessing risks of direct contact with chemicals on floors or other surfaces.

1568 CANDIDATE BENCHMARK BLOOD-LEAD AND BONE- LEAD CONCENTRATIONS.

N. Healey¹ and A. Knafla². ¹Health Canada, Sidney, BC, Canada and ²Equilibrium Environmental Inc., Calgary, AB, Canada. Sponsor: S. Safe.

The purpose of this work was to identify candidate points of departure for development of a reference blood-lead or bone-lead concentration that can be used as a measure of acceptable lead exposure. A literature review was conducted to identify the most sensitive endpoints, sub-populations and life stages of inorganic lead exposure. Because a threshold of effects was not clearly identified for key endpoints, points of departure were based on a benchmark dose approach. Exposure was quantified as a biomarker of exposure and, therefore, the potential benchmarks are expressed as blood-lead or bone-lead concentrations. Decreased intelligence in children and increased blood pressure in adults were selected as the key endpoints. Canadian population data were used to define baseline distributions of blood pressure and Coronary Heart Disease (CHD) related mortality. Gender specific linear regression coefficients relating blood-lead and bone-lead concentrations to systolic blood-pressure (SBP) were used to estimate increased rates of hypertension (SBP > 140 mm Hg) associated with lead exposure. Relationships reported in the Framingham Heart Study were used to predict the incidence of CHD related mortality associated with increased rates of hypertension. A benchmark response of a 10⁻⁵ incremental cumulative CHD related mortality risk over the age span of 35-75 years was found to be associated with an incremental increase in blood-lead of 2 µg/dL and 9 µg/dL for males and females, respectively, and an incremental increase in bone-lead of 6 µg/g for males. Adjustments to these benchmark doses to account for sensitive sub-populations may be appropriate. Increased incidence of mild men-

tal retardation (MMR) was used as the benchmark response for neurocognitive effects in children. A benchmark dose low (BMDL₁₀) of 1 µg/dL corresponding to a 10% increase in cases of MMR was estimated from a recently published pooled analysis of longitudinal studies relating children's blood-lead concentrations to IQ. This work has identified age-specific benchmark concentrations that may be used to set acceptable exposure limits for lead.

1569 CARCINOGENICITY EVALUATION OF METHYL TERT-BUTYL ETHER (MTBE).

L. A. Beyer, J. Goodman, M. Seeley, T. Slayton and B. Beck. *Gradient Corp., Cambridge, MA.*

MTBE is a gasoline additive, which has been found in ambient air and drinking water. In 1997, US EPA set levels of MTBE in drinking water to protect against taste and odor, and health effects, including cancer. In 2005 US EPA published new cancer assessment guidelines, which we used in conducting an in-depth analysis of tumors reported in rodents exposed to MTBE (i.e., leukemia/lymphoma, Leydig cell tumors (LCTs), kidney tumors, and liver tumors). We evaluated their relevance to humans, by comparing background rates to historical control rates (leukemia/lymphoma), conducting statistical analyses to take longevity into account (LCTs), using mechanistic information (kidney), and evaluating the results of genotoxicity testing.

At one laboratory, MTBE exposure was associated with excess lymphoma/leukemia in female Sprague-Dawley (S-D) rats. We identified several factors that weaken the relevance of these results: rates of lymphoma/leukemia were consistent with the historical background rate at that laboratory; there is no plausible mode of action given that MTBE is not genotoxic; the lymphoma/leukemia was found primarily in lungs (not in lymphatic tissue), and finally the excess could be a result of severe chronic respiratory disease found in the rat colony.

This laboratory also reported an increased prevalence of LCTs in treated vs. control S-D rats, but our statistical analysis (Poly-K) demonstrated that this increase was not significant when survival of control vs. treated rats was taken into account. In addition, the kidney cancer observed in rats exposed to MTBE is likely related to α 2u-globulin, a mechanism widely acknowledged to be irrelevant to humans, while liver tumors in female mice (in Chun et al., 1992) were not considered by the authors to support a carcinogenic effect.

Although positive findings were reported in animal bioassays with MTBE, they are either not reliable (i.e., leukemia/lymphoma, LCTs, liver cancer), or likely irrelevant to humans (i.e., kidney cancer). Further, MTBE is not recognized to be genotoxic. Hence, we conclude that MTBE is unlikely to be carcinogenic to humans.

1570 NOVEL PROTEOMIC APPROACH TO MAPPING SIGNALING PATHWAYS INDUCED BY SPECIFIC ISOMERS OF METHYLATED ANTHRACENES.

B. L. Upham^{1,2}, D. A. Whitten³, C. G. Wilkerson³, J. E. Trosko^{1,2} and L. Blaha^{1,2}. ¹*Pediatrics and Human Development, Michigan State University, East Lansing, MI.* ²*National Food Safety & Toxicology Center, Michigan State University, East Lansing, MI* and ³*RTSF Proteomic Core, Michigan State University, East Lansing, MI.*

Inhibition of gap junctional intercellular communication (GJIC) and activation of mitogen activated protein kinase (MAPK) are involved in tumor promotion. We previously determined that the 1-methyl but not the 2-methyl isomer of anthracene (1-MeA, 2-MeA) induced the release of arachidonic acid, inhibited GJIC and activated MAPKs using an in vitro rat liver epithelial cell model system. Inhibition of GJIC by 1-MeA is dependent on phosphatidylcholine specific phospholipase C (PC-PLC). Our current results directly measured PC-PLC and sphingomyelinase resulting in 1-MeA activating only PC-PLC, while 2-MeA had no effect on either enzyme. To provide further insight into the early upstream biochemical signaling events of 1-MeA induced inhibition of GJIC and MAPK, we demonstrate the suitability of advanced proteomics techniques. Cells were exposed to 1- or 2-MeA for 5 min and the cytoplasmic proteins were separated from those associated with membranes and then fractionated using Invitrogen ZOOM® isoelectric fractionator with pI values ranging within 1 pH unit affording greater resolution than traditional 2-D gels. Proteins affiliated with metabolism-, transcription, translation, cytoskeleton-trafficking and numerous signaling proteins were among those activated by 1-MeA as identified by mass spectrometry. Quantitative changes were further revealed by SILAC (a novel mass spectroscopy technique of Stable Isotope Labeling with Amino acids in Cell culture). Our study demonstrates advantages of recent proteomics techniques for detailed investigations of rapid and early signaling events that play an important role in tumor promotion processes such as inhibition of GJIC and activation of MAPKs. Support: NIEHS grants #R56 ES013268-01A2 and #R01 ES013268-01A2 to BLU.

1571 INVOLVEMENT OF I-KAPPA B KINASE IN ANILINE-INDUCED ACTIVATION OF TRANSCRIPTION FACTOR NF-KAPPA B IN RAT SPLEEN.

J. Wang, G. Wang and M. Khan. *Pathology, University of Texas Medical Branch, Galveston, TX.*

Aniline exposure is associated with selective toxicity to the spleen leading to a variety of sarcomas, and fibrosis appears to be an important preneoplastic lesion. Earlier we have shown that aniline exposure in rats leads to oxidative stress and overexpression of profibrogenic cytokines in the spleen. We hypothesize that aniline-induced oxidative stress leads to transcriptional upregulation of fibrogenic cytokines via activation of redox-sensitive transcription factor NF-kappaB. To determine the activation of NF-kappaB, male SD rats were treated with aniline (1 mmol/kg/day via gavage) for 7 days, an experimental condition that precedes the induction of fibrosis. NF-kappaB activation was determined in the nuclear extracts (NE) of splenocytes using an ELISA specific for NF-kappaB p65, which showed a significant increase in NF-kappaB p65 binding activity in the NE from aniline-treated rats. Also, Western blot analysis showed increased phosphorylation of p65 subunit of NF-kappaB in the aniline-treated rats. To determine if NF-kappaB activation could be mediated through I-kappaB kinase (IKK) activation, phosphorylation of IKK was studied. Splenocytes from aniline-exposed rats showed increased phosphorylation of IKK. These results show that aniline exposure leads to an activation of NF-kappaB, which could be mediated through IKK pathway. Supported by NIH ES06476.

1572 THIOREDOXIN REDUCTASE IS REQUIRED FOR MAXIMAL NF-κB-MEDIATED GENE EXPRESSION.

J. Heilman and W. H. Watson. *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

The transcription factor NFκB mediates the expression of genes involved in inflammation and cell survival. NFκB is sensitive to redox regulation at multiple levels, and thioredoxin (Trx1) plays a major role in this regulation. Although thioredoxin reductase (TR1) is responsible for maintaining Trx1 in the active form, it is not clear how inactivation of TR1 by reactive electrophiles would affect NFκB activity. In the present study, we examined NFκB activation in HeLa cells stimulated with tumor necrosis factor-α (TNF) and co-treated with either curcumin or 1-chloro-2,4-dinitrobenzene (CDNB), electrophiles known to inhibit TR1 through covalent modification of its active site. At concentrations that inhibited TR1 activity by 95%, curcumin and CDBN completely blocked TNF-induced expression of an NFκB-dependent luciferase reporter construct. To determine the mechanism by which curcumin and CDBN inhibited the NFκB pathway, we measured degradation of the inhibitory protein IκB-α by western blot, nuclear translocation of the NFκB subunits p50 and p65 by western blot of cytosolic and nuclear fractions, DNA binding activity of nuclear NFκB by gel shift analysis and subunit composition of the DNA-binding heterodimer by supershift analysis. The results showed that neither curcumin nor CDBN had any effect on these upstream processes, demonstrating that these electrophiles were not binding to known nucleophilic sites within IKK (which would have inhibited IκB-α degradation) or p50 (which would have inhibited DNA binding activity). The role of TR1 inhibition was confirmed by repeating these analyses in cells in which 95% of the TR1 protein was depleted by siRNA. TNF-induced IκB-α degradation and p50/p65 nuclear translocation were unaffected by TR1 siRNA, yet the NFκB reporter construct was inhibited by 35%. We conclude that TR1 is necessary for maximal transcriptional activity of NFκB in response to TNF, and that the toxicity of electrophiles that target TR1 may be influenced by inactivation of NFκB.

1573 SUPPRESSION OF TNF-α-INDUCED EXPRESSION OF CELL ADHESION MOLECULES BY THE COFFEE DITERPENE KAHWEOL VIA INHIBITION OF JAK2-PI3K/AKT-NF-κB ACTIVATION PATHWAY.

H. Kim^{1,2}, Y. Hwang^{1,2}, D. Kim³ and H. Jeong^{1,2}. ¹*Pharmacy, Chosun University, Kwangju, Kwangju, South Korea.* ²*Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea* and ³*Pathology, College of Oriental Medicine, Daejeon University, Daejeon, South Korea.*

Endothelial cells produce adhesion molecules after being stimulated with various inflammatory cytokines. These adhesion molecules play an important role in the development of atherosclerosis. Recent studies have highlighted the chemoprotective and anti-inflammatory effects of kahweol, a coffee-specific diterpene. This study examined the effects of kahweol on the cytokine-induced monocyte/human endothelial cell interaction, which is a crucial early event in atherosclerosis. Kahweol inhibited the adhesion of TNFα-induced monocytes to endothelial cells and suppressed the TNFα-induced protein and mRNA expression of the cell adhesion molecules, VCAM-1 and ICAM-1. Furthermore, kahweol inhibited the TNFα-induced JAK2-PI3K/Akt-NF-κB activation pathway in these cells. Overall, kahweol

has anti-inflammatory and anti-atherosclerotic activities, which occurs partly by down-regulating the pathway that affects the expression and interaction of the cell adhesion molecules on endothelial cells.

1574 PPAR γ -INDEPENDENT MECHANISMS REGULATING THE ACTIVATION OF SRC KINASE BY THIAZOLIDINEDIONES.

B. J. Dewar¹, J. Samet¹ and L. M. Graves^{1,2}. ¹Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and ²Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Thiazolidinediones (TZDs) are used clinically in the treatment of type II diabetes and are synthetic ligands for the PPAR γ , but also elicit PPAR γ -independent effects, most notably activation of MAPKs. Following ciglitazone treatment Src kinase mediates EGFR transactivation, leading to activation of the MAPK, Erk; however, mechanisms involved in Src activation by TZDs are not fully understood. In this study both ciglitazone and troglitazone, induced rapid activation of Src kinase in the rat liver epithelial cell line, GN4. We observed an increase in Src Tyr416 phosphorylation that was accompanied by dephosphorylation of Tyr527. Changes in Src phosphorylation were observed with TZD derivative compounds which lack the ability to activate the PPAR γ . Inhibition of EGFR kinase had no effect on Src activation following TZD treatment. Interestingly, inhibition of Pyk2, a calcium-dependent tyrosine kinase that has been shown to mediate Src activation and is activated in by TZD treatment, was not required for TZD-induced Src activation. However, the Src kinase inhibitor PP2, but not the inactive analogue PP3, prevented Pyk2 phosphorylation following TZD exposure. Alterations in intracellular calcium concentrations have been shown to activate both Pyk2 and Src. Intracellular calcium chelation using BAPTA-AM prevented Src Tyr416 phosphorylation but had little effect on TZD-induced Src Tyr527 phosphorylation loss. Pretreatment of cells with pervanadate, a general protein tyrosine phosphatase inhibitor completely blocked TZD-induced Src activation and Tyr527 dephosphorylation. Our data demonstrate that ciglitazone and troglitazone activate Src kinase independent of PPAR γ and EGFR leading to subsequent Pyk2 activation. Furthermore, our data suggest that TZD-induced Src autophosphorylation, an event sensitive to intracellular calcium chelation is modulated by protein tyrosine phosphatase-dependent dephosphorylation of Src Tyr527.

1575 EARLY GROWTH RESPONSE GENE 1 (EGR-1) MEDIATES DEOXYNIVALENOL-INDUCED INTERLEUKIN-8 PRODUCTION IN HUMAN INTESTINAL EPITHELIAL CELLS.

H. Yang¹, M. Lee¹ and Y. Moon^{1,2}. ¹Microbiology and Immunology, Pusan National University School of Medicine, Pusan, South Korea and ²Medical Research Institute, PNUMS, Pusan, South Korea. Sponsor: T. Jeong.

Deoxynivalenol (DON) and other trichothecene mycotoxins mediate a broad range of mucosal toxic and inflammatory effects on the human gastrointestinal tissues. The purpose of this study was to test the hypothesis that DON induces the pro-inflammatory cytokine interleukin-8 expression in human intestinal epithelial cells and that this is regulated at the level of immediate activated signaling molecule, early growth response gene 1 (EGR-1). Exposure of the human epithelial cells Intestine-407, HT-29 as well as HEK293 cells to DON markedly enhanced the production of interleukin-8 protein and mRNA. After acute exposure of human intestinal epithelial cells and mouse small intestinal tissues to DON, EGR-1 expression was markedly elevated along with extracellular, signal regulated protein kinases 1 and 2 (ERK1/2) mitogen-activated protein kinase (MAPK). ERK1/2 inhibition decreased both EGR-1 and interleukin-8 expression and promoter activity. Moreover, when EGR-1 was blocked with small interference RNA (siRNA), DON-induced interleukin-8 expression (protein and mRNA) and promoter activity were significantly suppressed in the human intestinal epithelial cells. Taken all, DON-induced EGR-1 via ERK1/2 MAPK mediated interleukin-8 production in the human intestinal epithelial cells, which provide insight into the possible general mechanism associated with mucosal toxic inflammation by trichothecene mycotoxin deoxynivalenol from food. 1576 CONSTITUTIVELY ACTIVE B-RAF COMPLEXES WITH 14-3-3 ISOFORMS AND RAF-1 IN TSC-2 NULL-CELLS.

J. D. Cohen, T. J. Monks and S. S. Lau. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

2,3,5-Tris-(glutathion-S-yl) hydroquinone (TGHQ), a hepatic metabolite of hydroquinone, is a renal carcinogen in Eker rats. Treatment of Eker rats with TGHQ results in loss of the wild-type allele of the tumor suppressor tuberous sclerosis-2 (TSC-2) in renal preneoplastic lesions and tumors. The development of these renal tumors is thought to be a consequence of disruption of the TSC-2/TSC-1 complex, which is a known inhibitor of TOR signaling. The tumor suppressor activity of TSC-2/TSC-1 may also negatively regulate the B-RAF/ERK/MAPK cascade.

TGHQ transformed cell lines from Eker rat proximal tubule cells (QTRRE cells) are null for TSC-2 and express constitutively active cytosolic B-Raf kinase, in conjugation with the constitutive phosphorylation of amino acid residues S496 and S603 (LC-MS/MS). In wild-type proximal tubule cells 14-3-3 isoforms are bound to TSC-2 at its AKT activation site. Coimmunoprecipitation revealed that within the cytosol of QTRRE cells, the active B-Raf forms a trimeric protein complex with Raf-1 and 14-3-3 isoforms β , γ , and τ . The formation of the 14-3-3/B-Raf/Raf-1 protein complex is consistent with increased ERK1/2 activity in QTRRE cells, as shown by Western blot analysis. Use of the Raf kinase inhibitor BAY 43-9006 reveals decreased activity of ERK1/2 and decreased expression of cyclin D1. Immunohistochemical analysis of tumors formed following 8-months of TGHQ treatment in Eker rats showed that cyclin D1 is overexpressed in proximal tubules surrounding tumors. Cyclin D1 is a key regulator of G1 to S phase progression in the mammalian cell cycle. Therefore, we suggest that the 14-3-3/B-Raf/Raf-1 protein complex is driving the increased expression of cyclin D1 during renal proximal tubule tumor formation. Further mechanistic studies of the 14-3-3/B-Raf/Raf-1 protein trimer may elucidate the mechanisms of proximal tubule proliferation leading to renal tumor formation. (GM39338, ES06694)

1577 REACTIVE OXYGEN SPECIES: INTEGRAL COMPONENTS OF B CELL ACTIVATION.

E. J. Romer, T. Fernando and C. E. Sulentic. *Pharmacology & Toxicology, Wright State University, Dayton, OH.*

The production of immunoglobulins (Ig) by activated B cells is a critical component of the humoral immune response. Ig production is mediated in part by a complex transcriptional regulation of the Ig heavy chain (IgH) gene. A component of this regulation involves binding of various transcription factors including the family of NF- κ B proteins to a regulatory region 3' of the IgH gene, termed the 3'IgH Regulatory Region (3'IgH RR). Activation of lymphocytes by lipopolysaccharide (LPS) has been shown to increase the production of reactive oxygen species (ROS) which are cysteine oxidizing agents known to induce tyrosine kinase activity and subsequent nuclear translocation of transcription factors. The NADPH Oxidase complex has been shown to be an intracellular source of ROS in response to LPS activation of lymphocytes. This study proposes that the production of reactive oxygen species plays a significant role in LPS-mediated Ig production in B cells perhaps by modulating the activity of the 3'IgH RR. Utilizing the CH12.LX B cell line, the increased production of ROS in response to LPS activation was detected by DCFDA fluorescence analysis. Pre-treatment with ROS scavenging molecules was found to decrease ROS levels in LPS activated cells. A transiently transfected transcriptional luciferase reporter driven by the 3'IgH RR and a variable heavy chain promoter, was utilized to show that LPS-activated B cells pre-treated with anti-oxidants decreased LPS-induced activation of the 3'IgH RR reporter construct. Pre-treatment of CH12.LX cells with NADPH Oxidase antagonists similarly decreased the activation of the 3'IgH RR reporter construct. These observations suggest that 1) the LPS-induced activation of B cells results in the production of ROS 2) the production of ROS is in part mediated by NADPH Oxidase, and 3) the production of ROS leads to the modulation of the 3'IgH RR. (Supported by the Wright State University Boonshoft School of Medicine).

1578 TRANSCRIPTIONAL RESPONSE TO OXIDATIVE STRESS IN EMBRYOS EXPOSED TO TBHQ OR TCDD.

M. E. Hahn¹, S. I. Karchner¹, D. G. Franks¹, B. R. Woodin¹, K. L. Barott¹, M. J. Cipriano² and A. G. McArthur². ¹Biology Department, Woods Hole Oceanographic Institution, Woods Hole, MA and ²Marine Biological Laboratory, Woods Hole, MA.

Oxidative stress resulting from environmental exposures has been implicated in a variety of human diseases ranging from chemical teratogenesis to cardiovascular and neurodegenerative diseases. Developing animals are especially sensitive to chemicals causing oxidative stress. The developmental expression and inducibility of anti-oxidant defenses through activation of NRF2 affects susceptibility to oxidants at these early life stages, but the embryonic response to oxidants is not well understood. The zebrafish (*Danio rerio*) is a valuable model in developmental toxicology. To assess the early response to chemical treatment occurring at different stages of development, zebrafish embryos at 1, 2, 3, 4, 5, and 6 days post fertilization (dpf) were exposed to DMSO (0.1%), TCDD (2 nM), or tBHQ (10 μ M) for 6 hr. Transcript abundance was assessed for 4 embryo pools per compound per time point by real-time qRT-PCR and microarray (Agilent 22k). Analysis by qRT-PCR showed strong (4- to 5-fold) induction of gstp1 by tBHQ as early as 1 dpf. tBHQ also induced gclc (2 dpf), but not sod1, nqo1, or cyp1a. TCDD induced cyp1a but none of the other genes. In 4-dpf embryos, microarray analysis revealed a large number of genes induced by tBHQ, including genes involved in glutathione synthesis and utilization (gstp1, gclc, gclm, ggt) as well as genes with roles in signal transduction (fos, jun, C/EBP β , cox-2) and DNA damage and stress response (hsp70, gadd45b, atf3). In contrast to results in mammals, there was no induction of sod1, nqo1, or heme oxygenases by tBHQ in these 4-dpf embryos. TCDD induced a more limited number of genes, with cyp1a and mpx being the most highly

induced. Few genes with detectable down-regulation were observed. These data show that zebrafish embryos are responsive to oxidative stress as early as 1 dpf, and that microarrays are capable of detecting altered expression of known and novel oxidant-responsive genes in whole embryos.

1579 HYPOCHLOROUS ACID ACTIVATES TRANSCRIPTION FACTOR NRF2-MEDIATED ANTIOXIDANT RESPONSE IN RAW 264.7 MACROPHAGES.

J. Pi, Q. Zhang, V. Wong, S. Collins and M. E. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Hypochlorous acid (HOCl) is a potent oxidant and important in the pathogenesis of many diseases. Transcription factor NF-E2-related factor 2 (Nrf2)-mediated antioxidant response represents a critical cellular defense mechanism that serves to maintain intracellular redox homeostasis and limit oxidative damage. In the present study, the effect of HOCl on Nrf2 activation was investigated in RAW 264.7 mouse macrophages. Exposure of RAW cells to NaOCl solution (initial concentrations up to 2 mM) resulted in a time- and dose-dependent increase in nuclear accumulation of Nrf2 and expression of Nrf2 target genes, which include NAD(P)H: quinone oxidoreductase 1 (NQO1), heme oxygenase-1, glutamate cysteine ligase (GCL) and GSH synthetase (GS), etc. Additionally, intracellular GSH, which is the prime scavenger for HOCl, decreased by 34% within the first hour of HOCl exposure. The decline was followed by a GSH rebound that surpassed the initial basal levels by up to 4 fold. This reversal in GSH levels closely correlated with the gene expression profile of GCL and GS: key enzymes in GSH synthesis. To study the mechanisms of Nrf2 activation in response to HOCl exposure, we examined the effects of several ROS scavengers and redox modifiers on the HOCl-induced Nrf2 activation. Pretreatment with cell permeable PEG-catalase (3300 U/ml), which reduces cellular H₂O₂ levels, markedly reduced expression of NQO-1 and GCL under basal and HOCl challenge conditions. A similar inhibitory effect was also observed by pretreating the cells with thiol compounds (N-acetyl-L-cysteine or GSH-monoethyl ester). These results indicate that H₂O₂ and/or depletion of intracellular reduced thiol are important for HOCl-induced Nrf2 activation. Taken together, we provide direct evidence that HOCl activates the Nrf2-mediated antioxidant response in mouse macrophages and likely underlies respiratory tract responses to chlorine which is hydrolyzed to HOCl upon absorption into tissues.

1580 KEAP1 CONFERS POST-INDUCTION REPRESSION OF AN ANTIOXIDANT RESPONSE BY ESCORTING NUCLEAR EXPORT OF NRF2.

Z. Sun, S. Zhang and D. D. Zhang. *University of Arizona, Tucson, AZ.*

The transcription factor Nrf2 has emerged as a critical factor in regulating cellular redox homeostasis. Through the antioxidant responsive element (ARE), Nrf2 regulates expression of an array of genes that encode antioxidants, detoxification enzymes, and cellular defensive proteins. Activity of Nrf2 is negatively modulated by Keap1. Recently, Keap1 has been identified as a substrate adaptor protein for a Cul3-containing E3 ubiquitin ligase. Under redox balanced conditions, Keap1 recruits Nrf2 into the multi-unit E3 ubiquitin ligase complex for ubiquitin conjugation and subsequent proteasomal degradation. Oxidative stress signal triggers activation of Nrf2 through inhibition of the Cul3-containing E3 ubiquitin ligase activity, which results in increased protein levels of Nrf2, facilitated nuclear import of Nrf2, and transcriptional activation of Nrf2-dependent genes. It is a well-accepted notion that Keap1 is a molecular switch that turns on and off the Nrf2 signaling pathway according to intracellular redox conditions. Although how the Nrf2 signaling pathway is turned on by oxidative stress is well studied, mechanisms of post-induction repression are still unclear. In this study, we have identified Keap1 as a post-induction repressor of Nrf2. When cellular redox homeostasis is reached again after oxidative stress, Keap1 translocates into the nucleus where it binds Nrf2 to dissociate Nrf2 from ARE. The Nrf2-Keap1 heterodimer is then transported out of the nucleus by the nuclear export sequence located in the Keap1 protein. Once in the cytoplasm, Keap1-Nrf2 dimer associates with the Cul3-containing E3 ubiquitin ligase, resulting in degradation of Nrf2 and inactivation of the Nrf2 signaling pathway.

1581 ARSENITE REGULATES TRANSCRIPTION FACTOR EXCHANGE AT DISTAL REGULATORY ELEMENTS OF HEME OXYGENASE-1: INTERCHANGE OF REPRESSIVE BACH1 FOR ACTIVATING NRF2.

J. F. Reichard and A. Puga. *Environmental Genetics and Molecular Toxicology, University of Cincinnati, Cincinnati, OH.*

Arsenic is a major environmental contaminant that triggers widespread alterations in gene transcription, particularly of genes regarded as part of the antioxidant response battery, such as heme oxygenase-1 (HMOX1). Increased antioxidant gene

expression mitigates oxidative damage through induction of protective enzyme systems and prevents accumulation of oxidatively modified proteins through increased expression of heat shock proteins. Nrf2 (NF-E2 related-factor 2) is well established as the transcriptional activator of antioxidant response element (ARE)-regulated genes; however, little is known regarding the function and regulation of its repressive counterpart Bach1 (BTB and CNC homolog 1). Bach1 has been characterized as a heme-sensitive repressor involved in the regulation of β -globin genes during erythroid cell differentiation through its interaction with NF-E2/Maf recognition elements; similarly, Bach1 interacts with the closely related ARE motif in cells naïve to oxidative stress. It is thought that in order for Nrf2 to bind ARE motifs, Bach1 must first be released. Here it is demonstrated that while prooxidants, such as arsenite, trigger activation of the transcription factor Nrf2, they also rapidly inactivate Bach1. In a manner opposite that of Nrf2, inactivation of Bach1 is characterized by its rapid export from the nucleus to the cytosol. In chromatin immunoprecipitation experiments, Bach1 appears to be released from multiple distal HMOX1 AREs more rapidly and at lower arsenite concentrations than are associated with Nrf2 activation. In this respect, Bach1 inactivation is a more sensitive indicator of arsenic mediated oxidative stress than is Nrf2 activation. Since Bach1 interacts with at least two types of Maf recognition elements (NF-E2 and Nrf2), these data suggest the possibility that arsenite could trigger inappropriate expression of Maf-regulated genes through inactivation of the transcriptional repressor Bach1. (Supported by NIEHS P42 ES04908 and R01 ES010807)

1582 CYANIDE INDUCED HIF-1 α ACCUMULATION LEADS TO BNIP3 ACTIVATION VIA A REDOX-MEDIATED PATHWAY.

L. Zhang, L. Li, K. Prabhakaran, X. Zhang, H. B. Leavesley, J. J. Borowitz and G. E. Isom. *Purdue University, West Lafayette, IN.*

Human exposure to cyanide continues to be a significant human toxicological problem and the response to cyanide also has served as a model to study the molecular basis of chemical-mediated neurodegeneration and selective vulnerability of the nervous system. In this study, an immortalized dopaminergic cell line, Mes23.5 was exposed to KCN to assess the extent and mode of cell death. Cyanide-treated cells exhibited a time and concentration dependent apoptotic cell death as demonstrated by the MTT assay and Hoechst 33258 staining. Cyanide induced a rapid burst of intracellular reactive oxygen species (ROS) generation, followed by p38 mitogen-activated protein kinase (MAPK) activation and accumulation of hypoxia-inducible factor-1 α (HIF-1 α). Pretreatment with antioxidants N-acetyl-L-cysteine (NAC), catalase or the p38MAPK inhibitor, SB203580 markedly attenuated p38MAPK activation and induction of HIF-1 α . This was followed by BNIP3 (Bcl-2/adonovirus E1B 19kDa interacting protein 3) upregulation at both the mRNA and protein levels. BNIP3 upregulation was reduced by HIF-1 α silencing with HIF-1 α siRNA. The role of enhanced BNIP3 levels in the cell death was determined by transiently transfecting cells with BNIP3 cDNA. Forced overexpression of BNIP3 produced mitochondrial dysfunction and a caspase-independent apoptosis. Moreover, overexpression of BNIP3 sensitized the cells to cyanide toxicity. Expression of a dominant negative BNIP3 mutant or BNIP3 siRNA knockdown significantly protected cells from cyanide. It was concluded that cyanide induced HIF-1 α accumulation via a redox-mediated pathway, followed by HIF-1 α -dependent BNIP3 transcription. The induction of BNIP3 expression then served as an initiator of mitochondrial-mediated apoptotic death. (Supported in part by NIH grant ES04140).

1583 THE HYPOXIA RESPONSE ELEMENT IN THE DEC1 PROMOTER SUPPORTS BOTH TRANSACTIVATION AND REPRESSION.

B. Yan. *Biomedical and pharmaceutical sciences, University of Rhode Island, Kingston, RI.*

DEC1 (differentially expressed in chondrocytes-1) belongs to a structurally distinct class of basic helix-loop-helix transcription factors. The expression of DEC1 is markedly increased in cells that undergo hypoxia. The proximal promoter of the DEC1 gene has two important response elements: an E-box and an HRE (hypoxia response element). The HRE supports the transactivation by hypoxia inducible factor-1 α (HIF1 α), whereas the E-box supports DEC1 autorepression. It was therefore, hypothesized that deletion of the E-box increases hypoxia response. In order to test this hypothesis, a DEC1 promoter reporter was subjected to site-directed mutagenesis to selectively disrupt the E-box. The resultant mutant reporter was tested for the responsiveness to DEC1, HIF1 α or in combination. Consistent with the hypothesis, the mutant reporter exhibited higher responsiveness to HIF1 α . Surprisingly, the mutant reporter retained the ability to respond to DEC1-autorepression. Similar repression was detected with an element reporter made of three copies of the HRE, and the repression was abolished by HIF1 α co-transfection. These findings suggest that the HRE supports both repression and activation depending on the cellular conditions (normoxic and hypoxic).

1584 EARLY GROWTH RESPONSE GENE 1 (EGR-1) VIA ERK SIGNALING PATHWAY ATTENUATES RIBOTOXIC STRESS-INDUCED CYTOTOXICITY.

Y. Moon^{1,2}, M. Lee¹ and H. Yang¹. ¹Microbiology and Immunology, Pusan National University School of Medicine, Pusan, South Korea and ²Medical Research Institute, Pusan National University School of medicine, Pusan, South Korea.
Sponsor: T. Jeong.

Endoplasmic Reticulum (ER) is the major signal transducing organelle that senses toxic insults and responds to changes of the homeostasis as a stress sentinel. Ribotoxic stress response can mediate cellular defense and repairing during the toxic insults to mucosal epithelium. The purpose of this study was to test the hypothesis that ribotoxic stresses by the translational inhibitors induce the early growth response gene product 1 (EGR-1) expression in human intestinal epithelial cells, which can play the defensive role in the gastrointestinal cytotoxicity. Exposure of the human epithelial cells Intestine-407, HT-29, HCT-116 to the translational inhibitors (cycloheximide, anisomycin and deoxynivalenol) markedly enhanced the production of EGR-1 production. Moreover, ribotoxic deoxynivalenol enhanced EGR-1 expression in the mouse small intestine. When signaling pathways were blocked with each mitogen-activated protein kinase (MAPK) inhibitors (SP600125, U0126, and SB203580), only the inhibition of extracellular, signal regulated protein kinases 1 and 2 (ERK1/2) suppressed toxin-induced EGR-1 expression. Generally, high levels of ER stresses by translational inhibitors are considered to cause the apoptotic cell death. However, suppression of EGR-1 expression by small interference RNA (siRNA) or ERK inhibition reduced the ribotoxin-induced intestinal epithelial cell death. Taken together, ribotoxic stresses enhance EGR-1 expression and ERK phosphorylation in the intestinal epithelial cells, which in turn resulted in the attenuation of the apoptotic cell death in the epithelial cells. These data provide insight into possible general mechanisms by which EGR-1 mediates the protective response to the ribotoxic stress in the gastrointestinal tract. (This work was supported by grant No. (R01-2006-000-10564-0) from the Basic Research Program of the Korea Science & Engineering Foundation.)

1585 CHRONIC ALCOHOL CONSUMPTION INDUCES TRB3 AND DISRUPTS INSULIN SIGNALING THROUGH INCREASED ER STRESS.

L. He^{1,2}, F. A. Simmen^{1,2}, M. J. Ronis^{1,3} and T. M. Badger^{1,2}. ¹Arkansas Children's Nutrition Center, Little Rock, AR, ²Physiology and Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR and ³Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR.

Prospective cohort studies have shown that chronic and excessive alcohol consumption is an important and modifiable risk factor for type 2 diabetes. Alcohol consumption alters insulin signaling, but the molecular mechanisms underlying this effect are not well understood. We previously reported that chronic and excessive alcohol intake disrupts insulin signaling via alcohol-induced TRB3 (a negative effector of Akt) in rats. In this report, we provide evidence that alcohol-induced TRB3 effects are associated with increased ER stress. ER stress in FGC4 cells was blocked by 4-phenyl butyric acid and taurine-ursodeoxycholic acid ($p < 0.05$) and this was associated with a lower alcohol-induced increase in TRB3 ($p < 0.05$). In vivo treatment with diallyl sulfide abolished hepatic ER stress ($p < 0.05$), blocked alcohol's effect on TRB3 ($p < 0.05$) and restored insulin signaling. Alcohol induced CYP2E1 and this was blocked by diallyl sulfide. Our results suggest that enhancement of ER stress is a potential mechanism by which alcohol induces TRB3 and inhibits insulin signaling. CYP2E1 may mediate this alcohol effect. Furthermore, our results may have therapeutic implications for treatment of alcohol-associated diabetes. (Supported by NIAAA008645 TMB)

1586 EFFECT OF METALLOTHIONEIN ON MATRIX METALLOPROTEINASE 2 AND 9 GENE EXPRESSION.

M. Takiguchi^{1,2}, K. Okuda¹, T. Fukuuchi¹, S. Suzuki², S. Yoshihara¹ and M. Sato². ¹Pharmaceutical Sciences, Hiroshima International University, Kure, Hiroshima, Japan and ²Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Tokushima, Japan.

Recent studies show that metallothionein (MT), a cytosolic protein in resting cells, can be translocated transiently to the cell nucleus during cell proliferation and differentiation. These results indicate that MT may be associated with nuclear functions.

We previously reported that depressions of matrix metalloproteinase (MMP) 2 gene expression and activity were observed in the immortalized MT-null fibroblast cells, suggesting MT might regulate MMP2 gene expression. In present study, to further confirm the involvement of MT in the regulation of MMP2 gene expression we studied the changes in MMP2 gene expression by using wild-type and MT-null pri-

mary mouse fibroblast. Wild-type and MT-null mouse primary fibroblasts were obtained from infant mouse skin (1 day old). The primary fibroblasts were grown to 70-80% confluence and then cells were collected and isolated total RNA for RT-PCR of MMP2. MMP2 gene expression in both of cells was same level. The result showed that MT is not essential for MMP2 gene expression in primary fibroblast. These findings directly demonstrate a cooperative interaction of MT on MMP2 gene expression with aberrant gene expression induced by SV40 large T-antigen. In addition, the involvement of MT in the regulation of MMP2 gene expression and activities was examined in wild-type and MT-null mouse liver Itoh cells. Both of cells were immortalized by SV40 large T-antigen. The results showed again that MT is not essential for MMP2 gene expression. However, the wild-type Itoh cells secreted more a 94 kDa type IV collagenase encoded by MMP9 gene than the MT-null Itoh cells. These results suggest that MT may play a different role in different cell types. (Supported by a Grant-in-aid for General Research from the Ministry of Education, Sciences, Sports and Culture of Japan.)

1587 HOW WELL DOES GENOTYPE PREDICT THE NET ACTIVITY OF ANTIOXIDANT ENZYMES IN HUMANS?

M. Bastaki¹, K. Huen², C. Chen², N. Holland², J. R. Balmes^{2,3} and I. B. Tager². ¹Environmental Studies, The Evergreen State College, Olympia, WA, ²Public Health, University of California, Berkeley, CA and ³Medicine, Pulmonary and Critical Care, University of California, San Francisco, CA.

Genetic polymorphisms are commonly used as biomarkers of genetic susceptibility, to predict response to environmental challenges. However, limited evidence is available on the impact of genetic polymorphisms upon protein function in humans. Additionally, activity of inducible enzymes, such as antioxidant, is a function not only of genetic variation but also of the concurrent exposures.

We examined the effect of genetic polymorphisms on the activity of three antioxidant enzymes: mitochondrial superoxide dismutase (MnSOD), cytosolic glutathione peroxidase (GPX1), and peroxisomal catalase, in erythrocytes of 231 healthy student volunteers. DNA from blood clot was genotyped using Taqman PCR (C47T:MnSOD and C593T:GPX1) and standard PCR (C-262T:catalase). Genotype-activity relationships were analyzed with multiple linear regression adjusted for gender and ethnicity. Median activities for MnSOD, GPX1, and catalase were 2.8 U/g Hb, 13.2 U/g Hb, and 86.3 k/g Hb, respectively, and ranged 56-fold, 6-fold, and 8-fold, respectively, between lowest and highest levels. We found that a) GPX1 activity was reduced only in males, but not females, homozygotes for the variant T GPX1 allele; b) MnSOD activity was 16% higher in females than males, and it was 39% higher in CT or TT individuals versus CC individuals, despite in vitro evidence that the TT genotype is compromised in entering into the mitochondrial matrix; and c) catalase activity was on average 18.1 k/g Hb lower for TT subjects versus CC subjects, whereas the TT variant is reported to have higher transcription factor binding properties and therefore higher expression levels. In conclusion, genetic variation can only partially explain large inter-individual variability in enzyme activity in this cohort. The net oxidant balance determined by differences in diet, environmental exposures, and additional genetic factors may account for a substantial component of this variability.

1588 IMPACT OF GENETIC VARIATION IN ACRYLAMIDE METABOLISM ON HEMOGLOBIN ADDUCT LEVELS.

S. Reutman¹, M. Butler¹, H. Vesper², W. Moorman¹, C. Toennis¹ and J. Clark¹. ¹NIOSH, CDC, Cincinnati, OH and ²NCEH, CCEH, CDC, Atlanta, GA.
Sponsor: K. Cheever.

This analysis explored contributions of genotype (genes encoding enzymes linked to acrylamide and glycidamide metabolism) and smoking on hemoglobin adduct levels of acrylamide (AA), its metabolite glycidamide (GA), and their ratio (GA/AA). Acrylamide has been shown to be genotoxic in animal studies. Human exposure occurs from diet, tobacco smoke, and occupational exposure. Blood samples from 39 consenting acrylamide industry workers with low potential risk for work contact with acrylamide were used. Variants of EPHX1 Y113H EX6+5C>T and GSTP1 I105V EX5-24A>G and gene deletions in GSTM1 and GSTT1 were identified by PCR. Hemoglobin adducts were measured by HPLC-MS/MS. Urinary cotinine was measured by immunoassay as a proxy for smoking (i.e., cotinine ≥ 200 ng/ml). Mean GA/AA ratios were calculated for dichotomized categories of EPHX1 (C/C + C/T=0.80, T/T=0.91), GSTP1 (A/G + G/G=0.88, A/A=0.87), GSTM1 (null=0.92, present=0.85), and GSTT1 (null=0.69, present=0.93). Separate linear regression models were run for log AA, GA, and GA/AA for each of these genotypes, with and without smoking adjustment. Smoking was highly significant when added to each model (p -values: 0.003 to <0.0001). EHPX1 T/T was significantly ($p=0.04$) associated with a higher GA/AA ratio after adjust-

ment for smoking. The GSTT1 null genotype was significantly associated with lowered GA/AA ratios both before ($p=0.0013$) and after ($p=0.0007$) adjustment for smoking. The GSTT1 null genotype was also significantly associated with higher AA levels, before ($P=0.02$) and after ($p=0.008$) adjustment for smoking. Genotype approached significance with AA or GA in several models. Conclusion: GSTT1 genotype appeared to affect AA levels and the GA/AA ratio, while EPHX1 Y113H affected the GA/AA ratio after adjustment for smoking. Low sample size may have limited detection of other effects. Disclaimer: The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy.

1589 ENVIRONMENTAL FACTORS AND POLYMORPHISM OF THE ENZYME GS-TRANSFERASE IN A CASE CONTROL STUDY OF ANENCEPHALY.

M. M. Sierra^{1,2}, P. J. Quintana¹, T. Dodd-Butera¹, M. P. Garcia^{1,4}, M. Ramirez Zetina^{1,3} and A. C. Batista⁴. ¹OEHS, San Diego State University, San Diego, CA, ²Microbiology, Universidad Autonoma de Baja California, Tijuana, Baja California, Mexico, ³Epidemiology, Instituto Mexicano del Seguro Social, Tijuana, Baja California, Mexico and ⁴Medicina, Centro de Estudios Universitarios Xochicalco, Tijuana, Baja California, Mexico.

Anencephaly, a type of NTD, occurs during the neurulation process as a result of failure of the neural folds in the cranial end of the neural plate to fuse and form the forebrain. This study examines the role of glutathione-S-transferase enzymes (GSTs) and environmental factors in a pilot case-control study of anencephaly at the US-Mexico border. GSTs catalyze some detoxifying reactions and may therefore affect penetration of pollutants to the fetus. Consenting obstetric patients were recruited from a hospital in Tijuana, B.C., Mex. (22 cases and 44 controls). Placentae were genotyped for GSTM1 (mu), T1 (theta) and P1 (pi) by PCR. Fathers of cases were more likely to work in a maquila (70.0% vs 42.9% of controls, $p=0.046$). Fewer mothers of cases reported having had prenatal care during the first trimester as compared to controls (52.2% of cases vs. 82.2% of controls, $p<0.01$). More mothers of cases reported being exposed to solvents during the first trimester than mothers of controls (23.8% vs. 4.9%, $p=0.026$). Cases had on average 26% lower serum folate than controls (not significant at $p=0.083$) and had resided fewer years in Tijuana (not significant at $p=0.068$). Cases and controls were not different for frequencies of GST mu and theta deletions (23.5% vs. 24.4%, GST mu, and 35.3% vs 36.6%, GST theta). GST pi genotype ile/ile was slightly higher in cases (36.8 vs. 25.6%), but this difference was not significant. In conclusion, this pilot study provides no evidence of increased frequencies of at risk GST mu, theta and pi genotypes in cases of anencephaly in a study at the US-Mexico border. However, the indications that solvent exposure and paternal occupation were associated with risk of anencephaly in this pilot study warrants further investigation.

1590 CHARACTERIZATION OF LIVER INJURY IN HUMAN HFE C282Y, Q283P, AND H63D HETEROZYGOTES USING α AND π GST QUANTITATION.

J. J. Betz¹, C. A. Mauzy¹, D. M. Todd¹, J. J. Jacobsen¹, A. G. Quade¹, M. Telford², J. P. Ruddell², J. Benjack² and N. H. Johnson¹. ¹HEPB, Applied Biotechnology, Air Force Research Laboratory, Wright-Patterson AFB, OH and ²88 DTS/SGQC, Wright-Patterson AFB, OH. Sponsor: J. Schlager.

Hemochromatosis (HH) occurs as an autosomal recessive disease of iron metabolism with the causative mutation occurring in a major histocompatibility complex class I-like gene (HFE). The Cys to Tyr change at position 282, occurs in about 10% of European descent, occurring in homozygous form in 90% of HH diagnosed patients. A HFE Q283P substitution has been shown to occur in 4-35% of HH patients, heterozygous with either C282Y, H63D, or S65C. Homozygous mutant genotypes demonstrate a disruption in regulation of iron uptake leading to iron loading in various organs and tissues, including the liver, whereas C282Y or Q283P heterozygotes show mild systemic iron deposition. New biomarkers have been developed for testing subclinical liver damage, α Glutathione-S-Transferase (α GST) and π Glutathione-S-Transferase (π GST). To examine the extent of proposed subclinical liver damage relative to HFE disease genotypes, α GST and π GST were quantified in serum and plasma (respectively) of 60 patients genotyped for C282Y, Q283P, and H63D. Samples (whole blood, serum, plasma, urine) were collected from random, anonymous individuals aged 20-45 years at Wright Patterson AFB clinical laboratory. Genotyping was accomplished with genomic DNA isolated from whole blood using standard PCR conditions and primer sets amplifying gene segments containing nt845 (C282Y), nt848 (Q283P) or nt187 (H63D). Clinical blood chemistries were analyzed on each sample (Serum alanine amino-

transferase, aspartate aminotransferase, gamma-glutamyl transferase, alkaline phosphatase, total iron, and transferrin saturation). Additionally, π GST was quantified in urine of 14 individuals chosen at random. Analysis of samples heterozygous for C282Y (or Q283P) do not suggest a statistically significant increase in π GST levels in serum or, in tested samples, in urine. Interestingly, levels of α GST were found to decrease in C283Y heterozygotes.

1591 ASSOCIATION BETWEEN POLYMORPHISMS OF HUMAN LEUCOCYTE ANTIGEN GENES WITH SUSCEPTIBILITY TO TRICHLOROETHYLENE-INDUCED ALLERGIC DERMATITIS AMONG EXPOSED WORKERS.

Y. Zheng¹, H. Li¹, Y. Dai¹, S. Leng¹, L. Li², H. Huang² and Y. Niu¹. ¹National Institute for Occupational Health and Poison Control, China CDC, Beijing, Beijing, China and ²Hospital for Occupational Diseases Control of Guangdong Province, Guangzhou, Guangdong, China. Sponsor: W. Zheng.

The aim of present study was to investigate the association between genetic polymorphisms of human leucocyte antigen, such as HLA-DQ and HLA-DRB1, with susceptibility to TCE-induced allergic dermatitis among the exposed workers. From June 1998 to March 2006, 112 cases with TCE-induced allergic dermatitis and 142 tolerant controls were recruited into the population based case-control study. The DNA sequence of HLA-DQA1 and HLA-DQB1 exon2, and HLA-DRB1 exon2 were performed by direct sequencing of polymerase chain reaction products. The frequencies distribution of allelic genotypes, SNPs and codon polymorphisms were compared, and odds ratio were calculated. There were significant differences in the frequencies of allelic genotypes of HLA-DQA1, HLA-DQB1 and HLA-DRB1 between cases and exposed controls. The frequencies of DQA1*0201,060101/0602 in cases were significantly higher than that in exposed controls (7.6% vs 3.5%, OR=2.25, 95% CI=1.01-5.02, 16.1% vs 7.0%, OR=2.53, 95% CI=1.42-4.50), while frequencies of DQA1*0103,050101/0503/0505 and DQB1*0303 in cases were significantly lower than that in exposed controls (5.8% vs 10.9%, OR=0.50, 95% CI=0.26-0.98, 8.9% vs 17.3%, OR=0.47, 95% CI=0.27-0.82, 9.8% vs 19.8%, OR=0.58, 95% CI=0.34-0.99). The frequencies of 1501,1202 and 04 in cases were significantly higher than those in controls (18.8% vs 7.7%, OR=2.75, 95% CI=1.59-4.76, 12.5% vs 6.0%, OR=2.24, 95% CI=1.19-4.21, 17.4% vs 11.3%, OR=1.66, 95% CI=1.00-2.75), while frequencies of 0301,0901,13 and 1502 in cases were significantly lower than those in controls (0.4% vs 4.6%, OR=0.09, 95% CI=0.01-0.72, 7.6% vs 13.7%, OR=0.52, 95% CI=0.28-0.94, 1.3% vs 6.7%, OR=0.189, 95% CI=0.06-0.65, 2.7% vs 8.5%, OR=0.29, 95% CI=0.12-0.74). In conclusion, the genetic polymorphisms of HLA-DQ and HLA-DRB1 might be the factors influencing the individual susceptibility to TCE-induced allergic dermatitis among exposed workers.

1592 SEARCH FOR POLYMORPHISMS IN THE GCLC, GCLM AND ALDH2 GENES VERSUS RISK OF CORONARY HEART DISEASE IN A CHINESE POPULATION.

Y. Chen¹, Z. Jiang^{1,3}, G. Zhang¹, S. Zhang², L. Jin^{1,3}, D. W. Nebert¹ and T. P. Dalton¹. ¹Department of Environmental Health, University of Cincinnati, Cincinnati, OH, ²Department of Medical Genetics, West China Medical Center, Sichuan University, Chengdu, Sichuan, China and ³Department of Genetics, Fudan University, Shanghai, China.

Coronary heart disease (CHD) is a complex trait involving the interaction of many genes plus the environment over decades of life. Reactive oxygen species (ROS) are implicated in the development of atherosclerotic plaques in CHD. Glutamate-cysteine ligase (GCL) is pivotal in synthesis of the abundant antioxidant glutathione (GSH), which protects against ROS. Single nucleotide polymorphisms (SNPs) in the 5'-UTR of the human GCLC (catalytic) and GCLM (modifier) genes have previously been reported to be independently associated with increased risk for myocardial infarction in a Japanese population. We therefore investigated the association between variants in these two genes and susceptibility to CHD in 160 cases and 156 age- and gender-matched controls in a Chinese population; 43 SNPs in the GCLC gene (transcript 47,693 bp) and 13 SNPs in the GCLM gene (transcript 22,423 bp) were chosen to cover the region between 10 kb upstream and 10 kb downstream for each gene. We also examined the Glu504Lys mutation in the ALDH2 gene (transcript 43,437 bp). Genotyping was performed using the fluorogenic 5' nuclease assay, and association was analyzed by a linear-regression model. No association was observed with GCLM. Two GCLC SNPs, rs621571 in intron 6 and rs6922238 in the 3'-UTR, and the Glu504Lys mutation in the ALDH2 gene showed p values of 0.042, 0.041 and 0.047, respectively; however, none of the three

remained significant following Bonferroni correction for multiple-testing. In conclusion, we found no correlation between polymorphisms in either *GCL* gene or the *ALDH2* gene and increased risk of CHD in this Chinese population.—

1593 THYMIDYLATE SYNTHASE POLYMORPHISM AND RISK OF NON SMALL CELL LUNG CANCER.

√É. Lima^{1,2}, V. M. Seabra², A. Coelho¹, A. Araújo¹ and R. Medeiros¹.
¹Portuguese Institute of Oncology, Oporto, Portugal and ²ISCS-Norte, Gandra, PRD, Portugal.

Lung cancer is the most common cancer in the world and the leading cause of cancer death. The non-small cell lung cancer (NSCLC) and small cell lung cancer together account for over 90% of all forms of lung cancer. The chance of developing cancer depends on both genetic and non-genetic factors. Thymidylate Synthase (TS) catalyses the final step in the synthesis of deoxythymidine monophosphate using the substrate deoxyuridine monophosphate, limiting an irreversible step in *de novo* DNA synthesis. *TS* gene promoter enhancer region contains two different polymorphisms which can influence *TS* mRNA transcriptional and translation efficiency: a polymorphic tandem repeat sequence (2R and/or 3R). It was reported that *TS* genes with the 3R sequence have a greater expression activity than those with 2R sequence suggesting that *TS* repeat sequence plays an important role in the control of *TS* protein expression thus affecting the control mechanism. It has been reported that polymorphisms in *TS* modifies the risk and the survival of some types of cancer and no previous studies are published regarding *TS* polymorphisms in NSCLC. This study was designed to evaluate the role of *TS* polymorphisms in the susceptibility to NSCLC. Tandem repeat for *TS* polymorphisms were analyzed by PCR technique in DNA obtained from peripheral blood samples of 105 patients with NSCLC and a control group of 210 healthy volunteers. Results showed absence of risk associated with the 3R/3R genotype in recessive model analysis of NSCLC patients (OR=1.39; 95% CI=0.80-2.42). In non recessive model analysis a lack of significant risk associated with 3R tandem repeat was observed. Homozygous 3R and heterozygous 2R/3R carriers had no significant risk for NSCLC when compared with homozygous 2R (OR=1.73; 95% CI=0.83-3.61; OR=1.37; 95% CI=0.70-2.72, respectively). Therefore obtained data suggests that tandem repeat *TS* polymorphism may not predispose for an increased risk for NSCLC. Further studies will be helpful to understand the role of this polymorphism in disease progression, therapeutic outcome and survival.

1594 PCB, CYP1A1 POLYMORPHISM AND RISK OF BREAST CANCER IN POSTMENOPAUSAL WOMEN.

F. Scinicariello, D. B. Moffett, H. E. Murray and B. A. Fowler. *Division Toxicology and Env.Med., ATSDR/CDC, Atlanta, GA.*

Franco Scinicariello¹, Daphne B. Moffett², H. Edward Murray¹, Bruce A. Fowler¹. 1.ATSDR, Division of Toxicology and Environmental Medicine, Atlanta, GA, USA 2.CDC/CCEHIP/NCIPC, Atlanta, GA, USA
BACKGROUND: Recent studies reported that postmenopausal women were at increased risk of breast cancer if they had a higher serum level of PCBs and the CYP1A1*2C gene. A meta-analysis was conducted to assess the association between the CYP1A1*2C gene, PCB exposure, and breast cancer and to quantify the relative risk of postmenopausal women with this genotype to develop breast cancer when exposed to PCBs.

METHODS: Meta-analyses were performed using odds ratio (OR) as the measure of effect size. Fixed effects method was used to combine data. Four studies were included in the analysis.

RESULTS: There was a statistically significant association between CYP 1A1*2C gene and the risk of breast cancer in postmenopausal women (OR = 1.46; 95% CI: 1.08, 1.96). No statistically significant association was found between high exposure to PCBs and risk of breast cancer (OR = 1.06; 95% CI: 0.88, 1.28) in postmenopausal women. Stratified analysis showed an increased risk of breast cancer (OR = 2.13; 95% CI: 1.38, 3.28) in postmenopausal women carrying the CYP1A1*2C allele and who had high PCB exposure, and no statistically significant increased risk (OR= 1.01; 95% CI: 0.66, 1.53) among women who had low PCB exposure. CONCLUSIONS: Overall, postmenopausal women carrying the CYP1A1*2C allele have 46% increased risk to have breast cancer. Moreover, carriers of CYP1A1*2C gene who had higher mean PCB serum levels had a 113 % increased odds to have breast cancer compared to women with low level of PCBs and wild type CYP1A1 gene.

CYP1A1 is a major extrahepatic component of the cytochrome P450. It contributes greatly to the toxicity of chemicals such as PAHs since it is responsible for the creation of the toxic DNA binding forms. The objective of our study was to investigate the possible role of the CYP1A1 detoxification enzyme in the incidence of various clinicopathological conditions in an isolated population group exposed to a variety of toxic factors. Our study focused on an isolated rural population in the south and east of Crete and central Peloponnese. We collected an aliquot of peripheral blood as well as relevant personal and medical history data by interviewing 492 individuals. Genomic DNA was extracted and the genotype regarding the CYP1A1*2A allele was determined by PCR RFLP. We observed 1.02% CYP1A1*2A homozygotes, 19.31% heterozygotes and 76.67% wildtype individuals. The rare CYP1A1*2A allele frequency was 0.107 and the genotype frequencies appeared in Hardy-Weinberg equilibrium. Statistical analysis of the genotypes with the personal and medical history of the individuals revealed a significant positive correlation between the CYP1A1*2A allele and the myocardial infarction was observed ($p<0.001$), as well as a significant negative correlation between this allele and miscarriages ($p=0.003$) and stillbirths ($p=0.018$). Our results show the involvement of the specific mutant allele in relation to myocardial infarction and birth outcomes. This report is a part of our ongoing population and environmental study of exposure to pesticides and assessment of its effect on public health.

1596 CLONING, EXPRESSION AND BIOCHEMICAL PROPERTIES OF CPOX4, A GENETIC VARIANT OF COPROPORPHYRINOGEN OXIDASE THAT MODIFIES THE EFFECT OF MERCURY EXPOSURE ON PORPHYRIN EXCRETION IN HUMANS.

T. Li, L. Simmonds and J. S. Woods. *Environmental Health, University of Washington, Seattle, WA.*

Coproporphyrinogen oxidase (CPOX) catalyzes the 2-step decarboxylation of coproporphyrinogen-III to protoporphyrinogen-IX in the heme biosynthetic pathway. Previously, we identified a specific polymorphism (N272H) in exon 4 of the human CPOX gene (CPOX4) and demonstrated that CPOX4 is significantly associated with a modified urinary porphyrin excretion pattern characterized by high concentrations of 4- and 5-carboxyl porphyrins as well as an atypical isocoproporphyrin in humans with low-level mercury (Hg) exposure. Here, we compared the biochemical properties of CPOX and CPOX4 to ascertain the role of CPOX4 in the etiology of this effect. Site-directed mutagenesis was performed on the wildtype CPOX cDNA (A814) to generate the CPOX4 mutant clone (C814). Wildtype and mutant CPOX cDNA-pGEX-2T constructs were expressed in *E. coli* BL21. CPOX-GST fusion proteins were purified from bacterial lysates by GSH affinity chromatography. Purified CPOX and CPOX4 were generated using thrombin to remove GST-tags. Copro'gen-III and pentacarboxy'gen-III (5dab) were incubated with purified human CPOX and CPOX4 enzymes at various concentrations, with or without Hg present. Both CPOX and CPOX4 formed proto'gen-IX from copro'gen-III or isocoproporphyrin from 5dab. However, the affinity of CPOX4 was 2-fold lower than that of CPOX using either substrate (CPOX $K_m=0.52\mu M$, $V_{max}=0.02$ pmol proto'rin-IX; CPOX4 $K_m=1.04\mu M$, $V_{max}=0.01$ pmol proto'rin-IX). Hg (0.1-1 μM) specifically inhibited the 2nd step of copro'gen-III decarboxylation (harder'gen to proto'gen-IX) in a dose dependent manner. These findings suggest that CPOX4 may be associated with impaired heme biosynthesis, which is limited further by Hg exposure. These observations are consistent with altered porphyrin excretion and potential neurotoxicity observed in humans with CPOX4 and Hg exposure (Neurotox Teratol 28:39-48,2006). Supported by ES04696, ES07033 and the Wallace Res. Fdn.

1597 GENETIC SUSCEPTIBILITY IN AUTISM.

S. E. Owens¹, M. L. Summar², J. L. Haines² and M. Aschner¹. ¹Pediatrics, Vanderbilt University, Nashville, TN and ²Center for Human Genetics Research, Vanderbilt University, Nashville, TN.

Autism is a common neurodevelopmental disorder with both genetic and environmental components. Genetic susceptibility to mercury (Hg) toxicity is recognized as a plausible explanation for autism in a subset of children. Even "safe" Hg levels

could be implicated in the etiology of autism due to genetic susceptibility that alters metabolism or intracellular compartmentalization. To identify genetic polymorphisms associated with autism that influence the extent of individual susceptibility to Hg neurotoxicity, we are conducting a thorough search for polymorphisms in four genes (MT1a, DMT1, LAT1 and MTF1) involved in Hg transport and clearance in the general population and in autistic individuals and assessing their frequency and association to the disorder. Using a sample pool of 48 unrelated individuals from both the general and autistic populations we employed Temperature Gradient Capillary Electrophoresis and Single Strand Conformation Polymorphism analysis to screen all of the exons, 5' and 3' UTR, 1kb upstream of the message start, and the exonic bordering regions for genetic variations. We have currently identified and characterized a number of polymorphisms in both MT1a and DMT1. Two of the MT1a polymorphisms are nonsynonymous, Thr to Asn at amino acid position 27, and Lys to Arg at amino acid position 51. Polymorphisms were evaluated for differences in allele frequencies using a standard chi-square analysis ($p < 0.05$). Preliminary findings failed to show association with autism. Further analysis with the TaqMan genotyping system in a larger dataset of 224 autistic samples and 224 controls is underway. Variations in MT1a, DMT1, LAT1 and MTF1 might increase susceptibility to Hg toxicity by altering the transport, binding, efflux, or tissue distribution of Hg in the body. Exposure to Hg might then act synergistically with these genetic susceptibility factors to manifest the behavioral and developmental deficits present in autism. This work was supported by grant #T32 ES007028.

1598 SOT PRESIDENTS – A PERSPECTIVE ON MIXTURES TOXICOLOGY.

M. M. Mumtaz¹ and J. E. Simmons². ¹*Division of Toxicology and Environmental Medicine, CDC/ATSDR, Atlanta, GA* and ²*NHEERL, U.S. EPA, Research Triangle Park, NC.*

Several federal agencies such as the U.S. Environmental Agency, Agency for Toxic Substances and Disease registry, National Institute of Environmental Health Sciences, National Institute of Occupational Safety and Health and others have active programs of research and methods development for chemical mixtures. Recently, enormous resources have been committed by the international community including the American Chemistry Council, Dutch government, the European Union, the SETAC, and the HESI/ILSI steering committee on chemical mixtures. Also, the SOT established a Mixtures Task Force that organized a series of meetings that led to the inauguration of the Mixtures Specialty section at the 2006 annual meeting. These activities underscore the importance of the toxicity assessment of chemical mixtures that has gradually been introduced in federal laws viz., CERCLA (1980), SARA (1986), FQPA (1996), and SDWA (1996). Often decisions regarding the influence exerted by chemical exposures on the homeostasis and the complex mechanisms operative in biological or environmental systems are based on minimal information.

This session will review (1) the nature of mixtures we encounter and historically the means that have been used to minimize their risk, (2) the evolution from default methods, through innovative experimental design to the current use of in silico methods. Three SOT past Presidents Dr. John Doull, Dr. Glenn Sipes and Dr. Linda Birnbaum will share their insights.

1599 THE USE OF DOSIMETRIC ADJUSTMENT FACTORS AND PBPK MODELING TO PROTECT INFANTS AND CHILDREN FROM INHALED ACETALDEHYDE.

K. Riveles, B. S. Winder, J. P. Brown, M. A. Marty and A. G. Salmon. *Air Toxics & Epidemiology Branch, Office of Environmental Health Hazard Assessment, CalEPA, Sacramento, CA.*

Infants and children, especially those with asthma, are potentially more sensitive to irritating organic vapors, than adults. New risk assessment methodologies including benchmark dose analysis and PBPK modeling were used to derive draft 8-hour and chronic Reference Exposure Levels (RELs) for acetaldehyde. Previous reference exposure levels for acetaldehyde were determined using the LOAEL/NOAEL (400 and 150 ppm, respectively) approach. Using the same data from Appelman et al., 1982; 1986, a benchmark dose for nasal degeneration of the olfactory epithelium (99 ppm) was generated using a continuous modeling approach. In addition, a pharmacokinetic modeling (PBPK) was applied for dosimetric interspecies extrapolation of specific nasal olfactory tissue damage rather than the standard Human Equivalent Concentration (HEC) procedure. Based on a published computational flow dynamic model to estimate mass flux across the nasal passages, a dosimetric adjustment factor (DAF) was derived by OEHHHA (DAF = 0.85), which was the ratio of this value for the rat to that for humans. The model also took into account interspecies differences in the deposition of inhaled vapors and breathing rates. Using the BMC methodology and PBPK modeling with the DAF, a revised draft chronic REL of 25 ppb and a newly defined draft 8-hr REL of 105 ppb were deter-

mined. In conjunction with the DAF, an additional interspecies toxicokinetic factor of 2 was applied. A combined intraspecies uncertainty factor of 30 was applied, reflecting intra-individual toxicokinetic variation and greater toxicodynamic susceptibility of children and asthmatics. The 8-hour RELs, if adopted, will support assessment of the health impacts on children in schools, who can be exposed for up to 8 hours. Application of the benchmark dose and PBPK techniques lowers the uncertainty associated with reference exposure levels and serve as better risk assessment models for the protection of infants and children.

1600 LONG TERM (7-MONTH) CONTINUOUS INTRAVENOUS INFUSION IN THE ALBINO RAT.

A. Patel, L. Armer, F. Edmond, N. Leroux, C. Copeman and M. Vezina. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.*

Continuous intravenous infusion via an indwelling catheter is frequently used in preclinical safety evaluation studies to mimic the proposed clinical route or to achieve higher blood drug levels than can be achieved by the defined clinical route. These studies have been conducted at our laboratory for over 20 years. Control data at our laboratory was evaluated to determine any effects of the presence of a femoral catheter and continuous intravenous infusion on the body weight gain, food intake and clinical pathology parameters over a 7 month period. A medical grade silicone-based catheter was surgically implanted under general anesthesia in the vena cava. Animals were continuously infused with saline at 0.4 mL/h for 24 hours/day over 7-months using a jacket and tether system. Body weight gains and food intake were unaffected when comparing data with historical control values for non-catheterized animals. Small differences in the clinical pathology data were observed between the catheterized and non-catheterized animals that could be associated with the presence of a foreign material.

It is concluded that in our laboratory the presence of an indwelling catheter and continuous intravenous infusion of saline at a rate of 0.4 mL/h in albino rats for up to 7 months had no adverse effects on growth compared with non-catheterized animals. Clinical pathology changes were minor and consistent with the presence of a foreign material.

1601 ESTIMATING HIGH DOSE HUMAN EQUIVALENT CONCENTRATIONS (HECS) CAN BE PROBLEMATIC EVEN WITH THE BEST PHYSIOLOGICALLY BASED PHARMACOKINETIC MODELS: METHANOL AS AN EXAMPLE.

J. L. Festa², T. B. Starr¹ and G. A. Dolan³. ¹*TBS Associates, Raleigh, NC*, ²*American Forest & Paper Association, Washington, DC* and ³*Methanol Institute, Arlington, VA.*

USEPA's procedure for establishing Reference Concentrations (RfCs) for inhaled substances typically involves determination of Human Equivalent Concentrations (HECs) corresponding to No Observed Adverse Effect Levels (NOAELs) or comparable Benchmark Doses (BMDs) developed with dose-response data for toxic endpoints evaluated in laboratory animal studies. Physiologically based pharmacokinetic (PBPK) models can facilitate this process by accounting explicitly for possible differences in 1) temporal exposure patterns, e.g., 7 hr/day vs. continuous exposure, 2) exposure route, and 3) absorption, distribution, metabolism, and elimination processes across species. However, when the most sensitive toxic endpoint (cervical rib malformations) is associated with saturation of metabolism and disproportionately high blood concentrations of the parent chemical (methanol), HEC estimation can require upward extrapolation to high airborne concentrations and/or exposure durations well beyond those for which in vivo human data are available. In such cases, the limited human data will exhibit essentially linear kinetics, and only the Vmax/Km ratio will be estimable with reasonable precision, making high dose HEC estimation problematic. To avoid this difficulty, we recommend that a Reference Increment be defined relative to the NOAEL or BMD estimate using the parent chemical's blood concentration as the dose metric, together with appropriate adjustment factors for residual pharmacokinetic uncertainty and interindividual variability. The resulting Reference Increment in blood can then be readily and accurately converted to an equivalent Reference Concentration in air using a well-calibrated and validated human PBPK model.

1602 IDENTIFICATION AND RISK ASSESSMENT OF HUMAN GENOTOXIC DRUG METABOLITES.

J. P. Bercu¹ and K. L. Dobo². ¹*Toxicology and Drug Disposition, Eli Lilly and Company, Greenfield, IN* and ²*Genetic Toxicology, Pfizer Global Research and Development, Groton, CT.*

Prior to clinical development, drug candidates are assessed in standard genotoxicity assays to identify potential genotoxic and carcinogenic hazards. Use of S9 for in vitro tests, as well as conduct of an in vivo study, allows detection of hazards related

to parent drug and metabolites. Due to the limitations of in vitro test systems, it is prudent to consider if the genetic safety of human metabolites has been adequately assessed as human ADME data becomes available during clinical development. We propose a process for identification and risk assessment of known or potential genotoxic metabolites. Human metabolites of concern are identified using a structure-based assessment, and human exposure to these concerning metabolites are estimated based on ADME excretory data. Similarly, rodent ADME data is used to estimate exposure to any concerning metabolites at the top dose intended for 2-year carcinogenicity studies. These data are submitted to a risk assessment model that determines the likelihood of not exceeding a 10⁻⁵ cancer risk from consuming a pharmaceutical with a known or suspect genotoxic metabolite. The risk assessment model is dependent on the probability that 1) a genotoxic metabolite is a human carcinogen, 2) human systemic exposure would result in a negligible cancer risk, and 3) in an oncogenicity study, animal systemic exposure to the metabolite would be high enough to cause a significant tumorigenic response in at least one animal species. A suggested process flow was developed based on results from a matrix of various clinical and nonclinical exposures. In general, if systemic exposure to the genotoxic metabolite in humans is $\leq 1.5 \mu\text{g/day}$, or in animals used in the oncogenicity study is $\geq 10 \text{ mg/kg/day}$, or there is a 1000-fold margin of safety (human exposure / animal exposure), it is unlikely that a 10⁻⁵ cancer risk will be exceeded. Based on case studies evaluated thus far, the approach seems to be a practical tool.

1603 ADDITIVITY ASSESSMENT OF TRIHALOMETHANE MIXTURES BY PROPORTIONAL RESPONSE ADDITION.

J. Simmons¹, W. Stiteler², R. C. Hertzberg³, A. McDonald¹, Y. M. Sey¹, L. K. Teuschler⁴, G. Rice¹, J. Colman⁵ and P. Durkin². ¹NHEERL/ORD, U.S. EPA, Research Triangle Park, NC, ²SERA, Fayetteville, NY, ³Emory, Atlanta, GA, ⁴NCEA/ORD, U.S. EPA, Cincinnati, OH and ⁵SRC, Syracuse, NY.

If additivity is known or assumed, the toxicity of a chemical mixture may be predicted from the dose response curves of the individual chemicals comprising the mixture. As single chemical data are abundant and mixture data sparse, mixture risk methods that utilize single chemical data are useful risk assessment tools. The present study examined, by proportional response addition, the assumption of additivity for mixtures of the four regulated trihalomethanes (THMs) that are formed during chemical disinfection of water. Under proportional response addition, the expected (predicted) effect of the mixture is a proportionally weighted sum of the responses that result from exposure to the individual components at the concentrations at which they are present in the mixture. A series of 16 experiments were conducted, including evaluation of: dose response curves for the individual THMs (chloroform, chlorodibromomethane, dibromochloromethane, bromoform); the six binary combinations of the four THMs; and, mixtures containing all 4 THMs. Female CD-1 mice were exposed by daily aqueous gavage for 14 days. Hepatotoxicity was assessed by relative liver weight and serum levels of enzymes indicative of hepatic damage (SDH, ALT, AST). A statistical approach based on comparison of expected and experimentally observed means was developed and applied to the data. Generally, the experimentally observed and the predicted mixture responses were not statistically different. As the variance in the responses increased, the ability (power) to detect departures from additivity decreased. In summary, novel proportional response addition methodology was developed and applied to evaluate the assumption of additivity for mixtures of the regulated THMs. The mixture data were supportive of a conclusion of additive joint toxicity as few statistically significant deviations from additivity were detected. (This abstract may not reflect EPA policy.)

1604 TOXICITY TESTING SCHEMA FOR THE INITIAL RISK ASSESSMENT OF FOOD CONTACT PLASTICS BASED ON THE CONCEPT OF TTC AND USAGE PROBABILISTIC FACTORS.

A. Hirose¹, Y. Yamazoe³, M. Ema¹ and Y. Kawamura². ¹Division of Risk Assessment, National Institute of Health Sciences, Tokyo, Japan, ²Division of Food Additives, National Institute of Health Sciences, Tokyo, Japan and ³Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.

The producers of food-contact plastics are responsible to ensure that their products meet the requirements on migration specified in the national registration. The migration limit of each eluting chemical should be ideally derived from the acceptable daily intake of individual chemical. However, it is not realistic to assess fully the potential risks of all chemicals. FDA and EFSA had developed the safety assessment guideline of food-contact materials prior to the application. In Japan, there are particular migration limits for the specific or general plastic products as the national standards. As for the comprehensive guidance, several industry associations introduced independently the self-guidelines like that of FDA or EFSA. Overall, the required toxicity testing schemas depending on migration levels of all guidelines are similar, except the lowest threshold of 0.5 ppb (1.5 $\mu\text{g/person}$), which is used in

FDA's. This threshold had been greatly discussed so far, however, scientific basis of higher thresholds (e.g. 50 ppb, 1 or 5 ppm) are unclear. Recently, the concept of TTC (Toxicological Threshold of Concern) have been examined and expanded for more general toxicity endpoints (Kroes et al. 2000, 2004). While, it is also important for the concept of TTC to estimate the appropriate exposure levels. Therefore, we examined the possibility for the replacement of these higher thresholds to the similar level of the TTCs, and tried to develop the modified equation for estimating the exposure levels, using the usage probabilistic factor. These works suggested that the scientifically more transparent toxicity testing schema and/or the initial risk assessment guidance could be developed.

This study was supported by the grant from the Japanese Food Safety Commission.

1605 IN VITRO PREDICTIVE MYELOTXICITY ASSESSMENT FOR NOVEL ONCOLOGY DRUGS.

M. Brughera, G. Pennella, M. Magistrelli and M. Venturi. *Preclinical Development, Nerviano Medical Sciences, Nerviano, Italy.*

It is commonly observed that at least 50% of oncology drugs, including those with a novel and target-specific mechanism of action, induce myelosuppression as the dose limiting toxicity in clinical settings. It is therefore of paramount importance to devise and validate predictive assays that would be useful to estimate the relevance of this liability in humans and derive an appropriate therapeutic index. In our laboratories, we have implemented and validated the HALO system (Hematopoietic Assay via Luminescence Output), which has recently been demonstrated to constitute a quantitative alternative to the classic clonogenic assay. This assay allows monitoring in a quantitative and precise manner and with medium throughput the effects of compounds on the hematopoietic precursor cells and therefore estimates the MTD due to neutropenia in early clinical trials. We will present the data we have obtained with a number of reference standard compounds and discuss how this assay can be used to support early candidate selection with respect to potency and animal species-specificity.

1606 CHARACTERIZATION OF SENSITIVITY OF RISK ESTIMATES TO UNCERTAINTIES ASSOCIATED WITH BIOLOGICALLY BASED MODELING OF FORMALDEHYDE CARCINOGENICITY.

Y. Yang¹, K. H. Liao¹, B. C. Allen², Y. Tan¹ and H. J. Clewell¹. ¹Center for Human Health Assessment, CIIT Centers for Health Research, Research Triangle Park, NC and ²Bruce Allen Consulting, Chapel Hill, NC.

Regulatory acceptance of a biologically based dose-response model of formaldehyde-induced rat nasal tumors (*Tox Sci* 75, 432-47) has been hindered by concerns regarding the uncertainty of risk predictions obtained with the model. To address these concerns, we developed a novel, sequential Bayesian methodology for conducting a comprehensive, quantitative sensitivity analysis of the biologically based cancer model. A hierarchical Bayesian analysis was performed using the Markov Chain Monte Carlo (MCMC) algorithm to provide a multi-step evaluation of the propagation of uncertainty from the rodent experimental data and modeling to the human extrapolation and risk estimation. The analysis provided posterior parameter distribution estimates consistent with the values used in the original model. In addition, by taking advantage of the Bayesian technique, it was possible to develop an approach to resolve a key issue regarding the choice of historical control data. The analysis demonstrated that the most crucial prediction of the modeling – the existence of a dose-dependent threshold (DDT) for formaldehyde carcinogenicity at an inhaled concentration on the order of 1 ppm in the human – is robust to uncertainties in the model and the underlying data. Most of the uncertainties investigated affect the predictions of residual risk below this threshold, rather than the existence and location of the threshold itself. Even uncertainties amounting to several orders of magnitude did not necessarily change the conclusion that risks below the DDT are negligible.

1607 REFERENCE DOSE FOR 1, 1, 2, 2-TETRACHLOROETHANE.

J. Donohue. *HECD, U.S. EPA, Washington, DC.* Sponsor: E. Ohanian.

The National Toxicology Program (NTP) published a comprehensive subchronic study of 1,1,2,2-tetrachloroethane in F-344 rats and B6C3F1 mice in 2004. As part of the evaluation of this chemical as an unregulated drinking water contaminant, the U.S. EPA Office of Water selected the data from this study to develop a reference dose (RfD) for 1,1,2,2-tetrachloroethane after examining available data from studies of oral exposure in humans and laboratory animals. Rats were found to be more sensitive than mice to the noncancer effects of this chemical. Low dose effects included increased relative liver weights, cytoplasmic vacuolization of hepatocytes, increased serum levels of alanine transaminase (ALT) and sorbitol dehydrogenase (SDH), decreases in red blood cell hematological parameters, and decreases

in sperm motility. Male animals appeared to be more sensitive to the liver effects than females. Benchmark dose modeling for dose-response identified the increased relative liver weight as the critical effect supported by the cytoplasmic hepatocyte vacuolization (7/10 animals at 20 mg/kg/day), and increased serum levels of ALT (BMDL = 29 mg/kg/day) and SDH (BMDL = 32 mg/kg/day). The RfD of 10 ug/kg/day was derived from a BMDL of 10.71 mg/kg/day using a 1000-fold uncertainty factor. [The views expressed in this abstract are those of the author and do not necessarily reflect the views or policies of the U.S. EPA.]

1608 POTENTIAL AIR CRITERIA FOR TRICHLOROETHENE (TCE) BASED ON CARCINOGENIC EFFECTS IN HUMANS AND ANIMALS.

K. G. Bogdan, G. M. Recer and J. E. Storm. *Bureau Toxic Substance Assessment, NYS Department of Health, Troy, NY.*

We derived criteria for evaluating the carcinogenic risks from low-level chronic exposures using methods consistent with US EPA guidelines. Criteria based on chronic inhalation studies in mice (liver, lung, lymphoma) and rats (kidney, testes tumors) were derived using default and PBPK-based dose metrics and linear and non-linear low-dose extrapolations. Criteria were adjusted, when appropriate, for potentially increased sensitivity of children. Recommended criteria for each cancer endpoint were selected from a larger set of potential criteria using weight-of-evidence evaluations of dose metrics and modes-of-action. Recommended risk-specific (1×10^{-6}) criteria are 0.3 ug/m³ (lymphoma, default dose metric), 1.4 ug/m³ (liver, internal dose metric), 7.8 ug/m³ (kidney, default dose metric, adjusted for potentially increased sensitivity of children), and 3100 ug/m³ (kidney, internal dose metric). Criteria based on human data were used to check the plausibility of animal-based criteria because human studies were limited by several factors, including unavoidable uncertainties in exposure estimates. Criteria were derived from a study that showed increased risks of esophageal cancer and non-Hodgkin's lymphoma among TCE workers (Hansen et al., 2001). We used an average relative risk model, two relative risk estimates (MLE or 95% UCL) for each cancer, an estimate of the mean occupational air concentration, and three estimates of mean employment duration in our derivations. For criteria based on the 95% UCL on relative risk, the median of the six estimates of the risk-specific (1×10^{-6}) criteria is 0.4 ug/m³. These criteria, criteria based on non-carcinogenic effects, and other factors (e.g., background and analytical methods) were considered in the development of a TCE guideline of 5 ug/m³.

1609 POTENTIAL AIR CRITERIA FOR TRICHLOROETHENE (TCE) BASED ON NON-CARCINOGENIC EFFECTS IN HUMANS AND ANIMALS.

T. B. Johnson, K. G. Bogdan, G. M. Recer and J. E. Storm. *Bureau of Toxic Substance Assessment, New York State Department of Health, Troy, NY.*

Because of concern about potential exposures of New York State residents to TCE in air (e.g., in indoor air through soil vapor intrusion) the New York State Department of Health (NYS DOH) derived several potential air criteria for evaluating the non-carcinogenic risks from low level chronic TCE exposures using methods consistent with US EPA guidelines. Potential criteria were derived based on human (when available) and/or animal toxicity data on central nervous system, liver and kidney toxicity, and effects on development and reproduction. Critical studies for each type of non-carcinogenic toxicity were selected, and a physiologically-based pharmacokinetic model was used to estimate internal dose metrics (from experimental air concentrations) judged to be relevant to the mode of action for the toxic endpoint reported in each study. Points of departure for low-dose and cross-species extrapolation, expressed as an internal dose metric or air concentration, were obtained using the US EPA's Benchmark Dose Software or default methods, and associated human equivalent concentrations were estimated based on reverse PBPK or Category 3 gas dosimetry. Uncertainty factors were applied according to US EPA guidance, and for some endpoints were adjusted to account for lifespan sensitivity. Recommended criteria were selected from the larger set of potential criteria based on a weight of evidence analysis. Recommended criteria were 11 ug/m³ based on central nervous system toxicity, 160 ug/m³ for both liver and kidney toxicity, 20 ug/m³ to 32 ug/m³ for reproductive toxicity, and 19 ug/m³ to 38 ug/m³ based on developmental toxicity. These criteria, along with criteria derived for carcinogenic effects and other considerations (e.g., background and analytical methods) were used to support the NYS DOH air guideline of 5 ug/m³ for TCE.

1610 ESTIMATE TRICHLOROETHYLENE CANCER SLOPE FACTORS USING A HARMONIZED PBPK MODEL.

Q. J. Zhao¹, E. Hack¹, R. Thompson², A. Maier¹ and M. Dourson¹. ¹Toxicology Excellence for Risk Assessment (TERA), Cincinnati, OH and ²Indiana Department of Environmental Management, Indianapolis, IN.

Recently, a harmonized PBPK model for TCE was developed as a joint effort organized by TERA and supported by the US Environmental Protection Agency and the Department of Defense. This harmonized PBPK model was further calibrated

with Bayesian analysis, resulting in an updated TCE PBPK model. This updated PBPK model was used to compute updated cancer slope factors for liver tumor based on mouse bioassays, and for kidney tumor based on a rat bioassay. By using the corresponding animal PBPK models, we calculated the animal internal dose metric [i.e., the area under the TCA liver concentration curve (AUC) and liver AUC for DCA in mice, and kidney AUC for DCVC in rats] corresponding to the doses administered in the bioassays. Benchmark dose-response modeling was conducted to estimate lower bounds on the effective internal doses for 10% extra risk of liver or kidney carcinogenesis (LED10). The human PBPK model was then used to estimate the human inhaled concentration and orally ingested dose of TCE that will result in the estimated LED10s for causing liver and kidney tumors in animal bioassays. Finally, the human cancer slope factors for liver and kidney tumors were calculated using linear extrapolation from the risk at the human LED10 to 0. These slope factor estimates represent the most current estimate of the risk of liver or kidney carcinogenesis in humans from TCE exposure.

1611 SPACECRAFT WATER EXPOSURES GUIDELINES FOR C1-C4 MONO-, DI-, AND TRIALKYLAMINES.

J. M. Hampton. *Texas Southern University, Houston, TX.* Sponsor: C. Obot Akata.

Spacecraft Water Exposure Guidelines for C1-C4 Mono-, Di-, and Tri-Alkylamines

The Johnson Space Toxicology Group has developed spacecraft crew exposure guidelines for target and other alkylamines found as contaminants in humidity condensate and recycled water samples obtained from shuttle spacecraft. Target alkylamines were methylamine, ethylamine, propylamine, isopropylamine, n-butylamine, dimethylamine, diethylamine, di-n-butylamine, trimethylamine, triethylamine, tripropylamine and tributylamine. The National Research Council (NRC) provides guidance to the National Aeronautics and Space Administration JSC Space Toxicology Group on development of exposure guidelines for the protection of space crews from chemical contaminants of the internal atmospheres or water systems of crew spacecraft. Spacecraft water exposure guidelines (SWEGs) are established for exposures of 1, 10, 100, and 1,000 days (d). The 1-d SWEG is intended to prevent irreversible harm and degradation in crew performance during emergencies. Longer term SWEGs are intended to prevent adverse health effects and degradation in crew performance that could result from continued exposure, and to provide guidance for exposures under normal operating conditions. In developing the SWEGs, data on the physical and chemical characteristics of the contaminants are considered, as well as observed toxic effects from oral exposures for identification of the most sensitive target organ or body system affected. Risk assessments methods established by NRC SWEG guidelines, including consideration of uncertainty factors that adjust for weaknesses of uncertainties about available data and that are specific to spaceflight, were employed to establish Acceptable Concentrations (ACs) for toxic or adverse health end points for the alkylamines. Odor thresholds were selected as the most relevant adverse health end point, and were used to establish ACs of 2mg/L (water) for the mono-alkylamines, 0.3mg/L for the di-alkylamines and 0.4 mg/L for the tri-alkylamines, each respectively applied across all designated exposure periods.

1612 REDUCING THE DEFAULT UNCERTAINTY FOR SUBCHRONIC TO CHRONIC EXPOSURE FOR THE BROMOBENZENE REFERENCE DOSE (RfD) AND REFERENCE CONCENTRATION (RFC) USING DATA FROM CHLOROBENZENE.

C. L. Smallwood. *NCEA, ORD, U.S. Environmental Protection Agency, Cincinnati, OH.* Sponsor: H. Choudhury.

Due to the limited data available for risk assessment for some chemicals uncertainty can be quite high. Bromobenzene is an example of a chemical for which no chronic studies are available. EPA is in the process of developing a Toxicological Review for bromobenzene for the Integrated Risk Information System (IRIS). In the absence of chronic toxicity data for bromobenzene, this poster explores the possibility of using data from chlorobenzene to reduce the uncertainty for the bromobenzene RfD and RFC. Animal studies identify the liver as the most sensitive target of oral and inhalation exposure to bromobenzene. Numerous mechanistic studies in animals demonstrate that hepatotoxicity is associated with the metabolites of the parent compound. Repeated dose acute studies have shown that the liver appears to develop a tolerance to bromobenzene insult. Bromobenzene and chlorobenzene exhibit striking similarities in structure, with similar Pauling electronegativities, distribution, toxicokinetic properties, and toxicity to the liver in rats and mice. Metabolic schemes for bromobenzene and chlorobenzene include cytochrome catalyzed epoxidation to reactive epoxide intermediates and subsequent formation of corresponding metabolites. Dose-response relationships for liver effects from sub-chronic and chronic exposure to chlorobenzene appear to be similar, which suggest the development of some degree of tolerance to chlorobenzene during chronic exposure. It is reasonable to expect such similarities in dose-response relationships for

subchronic and chronic exposure to bromobenzene. Therefore, the data available for chlorobenzene may help to reduce the subchronic to chronic uncertainty and support development of a chronic assessment for bromobenzene.

1613 POPULATION SCREENING LEVEL RISK ASSESSMENT OF NASAL TUMORS DUE TO NAPHTHALENE EXPOSURE.

B. H. Magee and S. Clough. *AMEC Earth & Environmental, Westford, MA.*

The National Toxicology Program (NTP) has listed naphthalene as "reasonably anticipated to be a human carcinogen." EPA Region VIII and the State of California have calculated a unit risk level of -0.04 (mg/m³)-1 using the data on neuroblastomas of the olfactory epithelium and adenomas of the respiratory epithelium in male rat. However, there is a toxicological debate regarding the relevance of the rat nasal tumor data to human health risk assessment because of physiological and biochemical differences between rats and humans. To inform this debate, this paper investigates whether there is any evidence that nasal tumors occur in workers and the general public due to their long term exposures to naphthalene in the indoor and outdoor environment. First, an evaluation of the published health effects literature of workers who were exposed to several naphthalene-containing complex mixtures (creosote, coal tar and coal tar pitch) reveals no cases of nasal tumors causally linked to naphthalene. Second, a screening level risk assessment is performed on the general population to estimate the number of nasal tumors that would be expected in the U.S. population if the unit risk value for naphthalene is as noted above. The results are that the incremental excess lifetime cancer risk for nasal tumors would be predicted to range from 8×10^{-5} for the general population not exposed to wood smoke in the home to 2×10^{-2} for people who use naphthalene moth balls in their homes. A nasal tumor burden of 12,400 nasal tumors per year is predicted. However, the observed numbers of nasal tumors each year from all causes is approximately 2,000 per year, and this includes tumors of the nasal cavity, the middle ear, and accessory organs of the nasopharynx. The observed rate of nasal neuroblastomas, a very rare tumor for this site, is even less, at about 100 per year from all causes.

1614 PROVISIONAL ADVISORY LEVELS (PALs) DEVELOPMENT FOR DIMETHYL PHOSPHITE (DMP).

L. T. Haber¹, F. Adeshina⁶, M. Dwyer², M. MacDonell³, D. Gardner⁴, G. McConnell⁵ and B. Gadagbui¹. ¹U.S. EPA, Washington, DC, ²Toxicology Excellence for Risk Assessment, Cincinnati, OH, ³Tetra Tech EM Inc., Houston, TX, ⁴Argonne National Lab., Argonne, IL, ⁵Inhalation Toxicology Association, Raleigh, NC and ⁶Toxicology Path Inc., Raleigh, NC.

Provisional Advisory Levels (PALs) that are being developed for hazardous materials by the U.S. EPA represent general public emergency exposure limits. PALs correspond to different effect severity levels (PALs 1, 2, and 3) and exposure durations (24 hours, 30 days, and 2 years). Application of PAL protocols has been performed for dimethyl phosphite (DMP), to estimate oral (in drinking water) and inhalation exposure limits, to the degree supported by the available data. In addition to being a chemical intermediate in the production of insecticides, herbicides and adhesives, DMP is used as a flame retardant, is a precursor for some chemical warfare nerve agents such as sarin, and is a degradation product of the chemically-related compound trimethyl phosphite (TMP) and some pesticides. The experimental data set for DMP was marginally adequate, including limited human data and a limited number of animal studies. Data gaps are identified. These estimates were evaluated and approved by an Expert Consultation Panel for PALs in June 2006. PAL estimates for DMP will be presented. Oral PAL values for a 24-hour exposure duration to DMP are 510 mg/L (PAL 1), 510 mg/L (PAL 2), and 750 mg/L (PAL 3); for 30-day oral exposure duration, the values are 25 mg/L (PAL 1), 25 mg/L (PAL 2), and 50 mg/L (PAL 3); and for 2-year oral exposure duration, the values are 13 mg/L (PAL 1), 25 mg/L (PAL 2), and 50 mg/L (PAL 3). Inhalation PAL values for a 24-hour exposure duration to DMP are 0.053 ppm (PAL 1) and 3.6 ppm (PAL 2); for 30-day inhalation exposure duration, the values are 0.021 ppm (PAL 1), 0.062 ppm (PAL 2), and 0.21 ppm (PAL 3). Data were insufficient to derive inhalation PAL 3 estimates for the 24-hour exposure duration or inhalation PALs 1, 2, and 3 estimates for the 2-year exposure duration. (This abstract presents PAL values that are subject to change pending further review.)

1615 ASSOCIATIONS BETWEEN ACUTE ASTHMA EXACERBATIONS AND AMBIENT SULFUR DIOXIDE EXPOSURE: POSSIBLE IMPLICATIONS FOR NATIONAL AMBIENT AIR QUALITY STANDARDS.

G. Recer¹, S. Sivanandam¹, P. L. Kinney², S. Hwang¹ and D. A. Luttinger¹. ¹Center for Environmental Health, NYS Department of Health, Troy, NY and ²School of Public Health, Columbia University, New York, NY. Sponsor: J. storm.

Sulfur dioxide (SO₂) is a respiratory irritant regulated as a criteria air pollutant under the federal Clean Air Act. We sought to compare SO₂ exposure-response relationships for acute asthma exacerbations with current SO₂ national ambient air

quality standards (NAAQS). A time-series study of ambient SO₂ (and other pollutant) levels and asthma emergency department (ED) visits in New York City (NYC) and a systematic review and meta-analysis of other time-series studies relating SO₂ levels and acute asthma exacerbations were conducted. The time series study used Poisson regression to test for effects of daily variation in 14 air pollutants measured at a roof-top monitoring station in NYC on daily asthma ED visits among residents living near the air monitoring station. Core regression models controlled for seasonality, temperature and day of week. In single-pollutant models, SO₂ was one of four pollutants (in addition to ozone, nitrogen dioxide and fine particles) that were significantly associated with asthma ED visits, with significant relative risks (RR) for increments in 24-hour mean and 1-hour daily maximum air levels. SO₂ RR estimates remained statistically significant and roughly equal in magnitude in models controlling for effects of the other significant pollutants, suggesting an independent effect of SO₂ on acute asthma exacerbations. The meta-analysis included 26 time-series data sets that met inclusion criteria for relating acute asthma hospitalizations or ED visits to ambient SO₂ levels. RRs were normalized to a fixed SO₂ increment and 16 were statistically significant. Study mean SO₂ and maximum or 95% upper bound concentrations ranged from 5–53 and 21 to 293 ug/m³, respectively. These levels are well below the current 24-hour SO₂ NAAQS (365 ug/m³).

1616 ACRYLAMIDE CARCINOGENICITY AND A MECHANISM BASED SAFETY ESTIMATE.

J. B. Schulze¹, C. Siegers³ and S. Weiler². ¹Office of the Dean, JWG University Frankfurt, Frankfurt, Germany, ²Inst. Occup. Med., University in Luebeck, Luebeck, Germany and ³Inst. Exp. Clin. Pharmacology Toxicol., University in Luebeck, Luebeck, Germany.

Acrylamide is a nongenotoxic carcinogen; It is considered a probable human carcinogen, therefore, no regulatory threshold value has been derived. Acrylamide (AA) and its metabolite glycidamide form DNA adducts, additionally AA has been shown to be clastogenic. However, animal experiments do not indicate a single target organ for acrylamide carcinogenicity and epidemiological data do not unanimously support human acrylamide carcinogenicity. Recent experiments have shown that acrylamide interferes with tubulin association. Since tubulin function is necessary for cell division, cell adhesion and growth regulation and neuronal transport, this mechanism may explain both acrylamide neurotoxicity as well as its non-specific carcinogenicity in a variety of organs. Additionally, tubulin interference explains the finding that acrylamide carcinogenicity depends on tumor promotion by e.g. TPA in animal bioassays. Assuming a toxic mechanism of action, risk assessment should be based on the derivation of a nontoxic threshold uptake rather than the current estimation of a cancer risk level of 1 / 105 (0.002 µg/kg/day) or 1 / 106 (0.0002 µg/kg/day uptake, EPA). In rat bioassays significant increases in peritesticular mesothelioma have been observed at 0.5 mg/kg/day, with possible increases in both mesothelioma and pheochromocytoma. This concentration was only marginally lower than the neurotoxic concentration of 1 mg/kg/day. For risk assessment a threshold value of 0.5 µg/kg/day is derived based on a LOAEL of 0.5 mg/kg/day and assuming safety factors of 10/10/10. There is evidence for low interspecies variability between mouse, rat and cat; additionally, the steep dose response curve for acrylamide toxicity in both in vivo and in vitro tests suggest lower safety factors. We therefore conclude that the average daily uptake of acrylamide from food estimated at 0.5–5 µg/kg/day explains the epidemiological data suggesting no or extremely low human carcinogenic potential.

1617 AN EVALUATION OF EARLY-LIFE SUSCEPTIBILITY AND EXPOSURES TO ETHYLENE OXIDE.

R. S. Kaetzel¹, M. Warner², L. M. Sweeney³, A. Duggan², M. L. Gargas³ and M. Teta¹. ¹Exponent, Bellevue, WA, ²Exponent, New York, NY, ³The Sapphire Group, Dayton, OH and ⁴Exponent, Southbury, CT.

Guidelines from the EPA state that, in the absence of chemical-specific data on childhood susceptibility, mode-of-action and other relevant studies should be used to determine age-related differences and possibly adjust potency. Relevant data exist for ethylene oxide and should be considered rather than automatically relying on defaults. Ethylene oxide is present endogenously in humans. Ethylene, a by-product of lipid peroxidation of membranes, metabolism of methionine, and metabolism by intestinal bacteria, is converted to ethylene oxide in the body. Higher levels of endogenous ethylene are not indicated in children. Currently, there are no animal toxicology or epidemiology studies that consider cancer risk of early-life exposure to exogenous ethylene oxide; however, there are data on the incidence of second cancers following exposure to other alkylating agents for the treatment of Hodgkin's disease that can be used as a surrogate. A review of these clinical epidemiological studies does not suggest greater leukemia or lymphoma risk among children, following exposure to alkylating agents. In addition, children generally tolerated doses of chemotherapeutic alkylating agents in Phase I clinical trials at least as well as adults. Furthermore, neonates and children have lower levels of

CYP2E1, the enzyme that oxidizes ethylene to ethylene oxide. Detoxification of ethylene oxide may be lower in children than adults, but the disparity is less than the assumed EPA default of 10-fold. Finally, fewer hemoglobin adducts indicate lower background ethylene oxide body burden in children.

1618 HUMAN HEALTH RISK ASSOCIATED WITH EXPOSURE TO PATHOGEN-CONTAMINATED SEDIMENTS.

D. F. Staskal¹, E. Donovan², J. Roberts², K. Unice³, B. Finley² and M. Harris⁴.
¹ChemRisk, Austin, TX, ²ChemRisk, San Francisco, CA, ³ChemRisk, Pittsburgh, PA and ⁴ChemRisk, Houston, TX.

The presence of pathogens in environmental media can severely impact the public health, particularly when contamination involves human-derived pathogens such as *E. Coli* or *Giardia*. Previous environmental assessments have reported high levels of pathogenic microorganisms in the Lower Passaic River in Newark, NJ. Many combined sewer overflows (CSOs) are present in this portion of the river and have been identified as potential sources of pathogen release into the environment. Because river sediments are reservoirs for several types of waterborne pathogens that are associated with human fecal matter, the aim of this study was to characterize the pathogenic contamination of river sediments collected from mudflats near CSOs and to assess the human health risk associated with potential exposure to the pathogen-contaminated sediments. The sediments contained several types of pathogenic bacteria including fecal coliform, *E. Coli*, fecal *Streptococcus*, *Enterococcus* and *Pseudomonas aeruginosa*, as well as protozoa, specifically *Giardia* and *Cryptosporidium*. Antibiotic resistant strains of bacteria were also found in the sediments. Risk estimates were calculated for three adult exposure scenarios: recreators, visitors and transients. The risk of contracting gastrointestinal illness following incidental ingestion of sediments from fecal coliform was >1 for all scenarios, whereas the risk of illness from fecal *Streptococcus* and *Enterococcus* was as high as 0.058 and 0.049, respectively. Risk estimates for illness associated with transient exposure to *Giardia*-contaminated sediments exceeded 1 in 100. Results suggest that incidental ingestion and/or dermal contact with pathogen-contaminated sediments near areas of CSO discharge along the Lower Passaic River were associated with a high risk of illness.

1619 PROVISIONAL ADVISORY LEVELS (PALs) DEVELOPMENT FOR TRIMETHYL PHOSPHITE (TMP).

M. MacDonnell¹, E. Adeshina⁶, M. Dwyer², L. T. Haber³, M. Finster¹, D. Gardner⁴ and G. McConnell¹.
¹Argonne National Lab., Argonne, IL, ²Tetra Tech EM Inc., Houston, TX, ³Toxicology Excellence for Risk Assessment, Cincinnati, OH, ⁴Inhalation Toxicology Association, Raleigh, NC, ⁵ToxPath Inc., Raleigh, NC and ⁶U.S. EPA, Washington, DC.

Provisional Advisory Levels (PALs) are being developed by the U.S. EPA for contaminants that may be released to drinking water or air. PALs represent exposure limits for the general public that correspond to different effect severity levels (1, 2, and 3) and exposure durations (24 hours, 30 days, and 2 years). PAL protocols have been applied to estimate both oral (drinking water) and inhalation exposure limits for trimethyl phosphite (TMP) based on available data. TMP is used to make organophosphate pesticides and flame retardants and is also a precursor for certain nerve agents. This compound converts quickly to DMP in water and air, so continuous releases were assumed to support PAL development for durations beyond one day. Data gaps are evaluated as part of the PAL development process, and the experimental data set for TMP was found to be marginally adequate, with limited human data and a limited number of animal studies. These estimates were evaluated and approved by an Expert Consultation Panel for Provisional Advisory Levels in June 2006.

PAL estimates for TMP will be presented. Oral PALs for TMP in drinking water assume an adult ingestion rate of 2 L/d. For all three exposure durations, the PAL 1 is 17 mg/L and the PAL 2 is 19 mg/L, because these are based on developmental endpoints that could result from exposure within any of the periods. For the PAL 3, the 24-hour value is 350 mg/L, and the 30-day and 2-year values are 57 mg/L. TMP data were considered insufficient to derive any 2-year PALs or a 24-hour PAL 3 (per inconsistent reporting of saturation). The inhalation PAL 1 is 0.1 ppm for both 24 hours and 30 days. For the PAL 2, the 24-hour value is 15 ppm and that for 30 days is 0.5 ppm; the value for the 30 d PAL 3 is 2.9 ppm. (This abstract presents PAL values that are subject to change pending further review.)

1620 ASSESSMENT OF CHILDREN'S EXPOSURE TO TOLUENE.

A. Javier¹, J. M. Panko¹, E. C. Shay¹, K. M. Unice¹, P. S. Price², S. Hays³ and L. Aylward⁴.
¹ChemRisk, Inc., Pittsburgh, PA, ²Linea, Inc., Portland, ME, ³Summit Toxicology, Boulder, CO and ⁴Summit Toxicology, Falls Church, VA.

Toluene was included in EPA's Voluntary Children's Chemical Evaluation Program (VCCEP) Pilot program because it has been detected in the indoor air and in human blood and milk. The objective of this study was to quantify children's expo-

sure to toluene and aggregate exposures across scenarios and pathways. A child-centered approach was used to define exposure scenarios for children's interaction with toluene, including environmental background sources and source specific exposures such as tobacco smoke and consumer products. Chronic and short-term episodic exposures were quantified in terms of typical and high-end estimates, and the contributions of various sources to overall toluene exposures were assessed. The assessment of background exposures indicated that inhalation was the primary route of exposure; accounting for 95% of the aggregate dose for all age groups, except for nursing infants of occupationally exposed mothers. For these children, 68% of their total dose was via ingestion of human milk and 32% was via inhalation. The primary source of inhalation exposures was residential indoor air. Of the chronic source specific exposures, inhalation of mainstream smoke was the primary pathway of exposure where the estimated doses were 2-5 times higher than background. Exposures to toluene from ETS and refueling vehicles did not add significantly to the aggregate exposure. A human PBPK model for toluene was used to estimate blood concentrations that would be predicted in children of various ages given the inhalation exposure concentrations for background exposures used in this assessment. The PBPK results indicated that the average and peak predicted blood values were similar to those reported recently in the literature for children. In conclusion, robust exposure data sets exist for background exposure sources of toluene, and except for the nursing infant, no unique exposure scenarios were identified for children.

1621 QUANTITATIVE DOSE-RESPONSE ASSESSMENT OF MICRONUCLEATED POLYCHROMATIC ERYTHROCYTES FROM MICE EXPOSED TO PRADOXIFLOXACIN.

T. B. Starr¹, G. M. Williams², G. M. Schmuck³ and B. Herbold³.
¹TBS Associates, Raleigh, NC, ²New York Medical College, Valhalla, NY and ³Bayer HealthCare AG, Wuppertal, Germany.

Genotoxicity endpoints have traditionally been evaluated only qualitatively (as either positive or negative), contributing primarily to the weight-of-evidence regarding an agent's mode of toxic action in risk assessments. However, many of these endpoints are remarkably sensitive, and they are amenable to quantitative dose-response evaluation on their own, provided data from a sufficient number and range of dose levels are available. Such analyses can provide information regarding the shape of the dose-response at very low doses as well as insights regarding an agent's mode of toxic action. An exemplary Benchmark Dose (BMD) analysis was undertaken of micronuclei data from two experiments in which young adult Hsd/Win:NMRI mice were exposed to a 40-fold range of doses of the veterinary drug candidate, pradofloxacin. An appropriate Benchmark Response (BMR) was first chosen to approximate a No Observable Effect Level (NOEL) for micronucleated cell (MNC) frequency among polychromatic erythrocytes (PCEs) relative to the baseline MNC frequency in unexposed animals. Statistical power calculations were employed to establish a BMR of only 1.27 additional MNC per 1,000 PCEs examined, nearly 100-fold lower than the 10% response increment typically used in BMD analyses. USEPA's Benchmark Dose software package (v. 1.3.2) was then utilized to estimate the parameters of a Weibull dose-response model as well as central (244 mg/kg) and lower 95% confidence bound (186 mg/kg) estimates of the BMD associated with the chosen BMR. The fitted dose-response model was markedly non-linear, suggesting that a threshold-based or non-linear approach to risk assessment is appropriate for pradofloxacin.

1622 COMPARISON OF TOOLS TO CALCULATE 95% UPPER CONFIDENCE LIMITS ON THE MEAN.

J. K. Tolson¹, C. J. Saranko¹, M. E. Schuck¹ and S. M. Roberts².
¹Geosyntec Consultants, Tampa, FL and ²University of Florida, Gainesville, FL.

Calculating a 95% upper confidence limit on the mean (95% UCL) for use as an exposure point concentration in risk assessment follows a two-step process. First, the data are subjected to goodness-of-fit tests to establish what type of distribution best fits the data (e.g., normal or lognormal distribution). A 95% UCL method is then selected according to the distributional characteristics of the data found in the goodness-of-fit test. A problem often encountered with environmental datasets is the existence of a number of non-detect values. The left censoring of data created by non-detect values can impose difficulties in correct assignment of distribution type and calculation of the 95% UCL. PROUCL 3, EPA software for calculation of 95% UCL values, had limited utility with datasets censored more than 15%. Due in part to this limitation, the Florida Department of Environmental Protection developed FLUCL, a software tool capable of calculating 95% UCL values from more heavily censored data. Recently, the EPA has developed PROUCL 4, which has improved capabilities with censored data. The performance of FLUCL and PROUCL 4 was compared using synthetic data sets with varying characteristics in terms of size, skewness, and censoring. Although FLUCL and PROUCL 4 can both handle

a variety of types of environmental data sets, there are differences in the way censored data are handled, distributional type is determined, and 95% UCL calculation method is selected. These differences can, in some cases, lead to substantial differences in the 95% UCL value derived. Skewness of the sample data was found to be an important factor in determining the conservatism of the 95% UCL estimates, and affected the two software tools differently. The 95% UCL software tools are a convenient means to calculate exposure point concentrations, but should not be treated as "black boxes." Existing tools have strengths and weaknesses that need to be understood in order to apply them properly in the calculation of exposure point concentrations for contaminated sites.

1623 A GLUTARALDEHYDE RISK ASSESSMENT USING BENCHMARK DOSES: DECISIONS, DECISIONS, DECISIONS!

D. A. Dankovic¹ and A. Bailer^{2,1}. ¹Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH and ²Department of Mathematics and Statistics, Miami University, Oxford, OH.

The objective of this study is to describe a quantitative risk assessment for inflammatory responses associated with glutaraldehyde exposure, using benchmark dose (BMD) methods, and to evaluate the impact of alternative assumptions on the estimated risk. These alternatives included the choice of which data set to use as a basis for BMD estimation, which toxicological endpoint(s) should be selected for extrapolation to humans, how the toxicologically-based BMDs should be scaled to humans, which statistical models in the BMD suite should be used, and how the different BMDs should be synthesized into a recommendation for human occupational exposures. Two NTP data sets were considered (13-week and 2-year), as well as RD₅₀ data. A total of 119 BMD models were fitted to various toxicological endpoints for male and female mice and rats in the two NTP studies. Within data set/endpoint combinations, different dose-response models were fit and a model-averaged BMD was obtained. BMDs based on squamous epithelial inflammation were chosen for extrapolation to humans; these ranged from 50-130 ppb in female rats and from 56-93 ppb in female mice suggesting that the BMD is not critically dependent on the choice of target species. Adjusting for 8-hr occupational exposures as opposed to 6-hr exposures in the NTP study reduces the rat BMD range to 38-98 ppb. The rat BMDs were then extrapolated to humans on the assumption of equal effects at equal exposure concentrations, regardless of species. A 32-fold uncertainty factor was applied, yielding an occupational exposure range of 1-3 ppb. This exposure range is intended to be protective against respiratory irritation due to chronic exposures to glutaraldehyde; however, it is not known whether it will also protect workers from respiratory sensitization.

Disclaimer: The findings and conclusions in this abstract have not been formally disseminated by the National Institute for Occupational Safety and Health and should not be construed to represent any agency determination or policy.

1624 DEVELOPMENT OF SHORT-TERM, SUBCHRONIC AND CHRONIC ORAL REFERENCE DOSES (RfDs) FOR MICROCYSTIN-LR.

B. Hawkins¹, H. Carlson-Lynch² and M. Odin². ¹U.S. Environmental Protection Agency, Cincinnati, OH and ²Syracuse Research Corporation, Syracuse, NY.

Microcystins are monocyclic heptapeptide toxins produced by several species of cyanobacteria (blue-green algae), including members of *Microcystis*, *Anabaena*, *Nodularia*, *Nostoc* and *Oscillatoria*. Human exposure to microcystins may occur through the consumption of contaminated drinking water, ingestion of contaminated surface water during recreational activities or through the use of blue-green algae dietary supplements. Microcystins are potent hepatotoxins, primarily due to their preferential uptake into the liver via the bile acid transport system. The primary mechanism of action of microcystins is well known and involves the inhibition of serine/threonine protein phosphatases PP1 and PP2A leading to hyperphosphorylation of cytosolic and cytoskeletal proteins and subsequent hepatocyte disruption and hepatotoxicity. Additionally, microcystins have been shown to induce a number of other cellular alterations ranging from lipid peroxidation to apoptosis. At least 80 microcystin structural variants have been identified though the most commonly detected and best studied variant is microcystin-LR. In 1999, the World Health Organization (WHO) established a provisional 'Tolerable Daily Intake' (TDI) for microcystin-LR of 4×10^{-5} mg/kg-day. New repeated-dose experimental animal toxicity data have been generated by several laboratories since the WHO provisional TDI was published in 1999. Here, following a thorough literature review and the evaluation of all available toxicity information, oral Reference Doses (RfDs) for short-term (up to 30 days), subchronic (up to 10% of the average lifespan) and chronic (up to lifetime) exposure durations were derived for microcystin-LR using current US Environmental Protection Agency methodology.

1625 COMPARATIVE ECOLOGICAL RISK ASSESSMENT FOR A NEW ALUMINUM SMELTER IN ICELAND.

P. N. Booth, J. H. Salatas, N. W. Gard and R. A. O'Boyle. *Exponent, Bellevue, WA*. Sponsor: R. Kaetzel.

Protection and maintenance of local populations and communities of plants and wildlife is gaining importance in corporate decision-making regarding industrial development. During the facility design phase for an aluminum smelter in East Iceland, it became necessary to determine if a wet (seawater) scrubber system should be installed to reduce overall sulfur dioxide emissions. In this case, predictive risk assessment was used to determine whether there would be a consequential difference in the level of risk to human and ecological receptors from constituents in air emissions from the aluminum smelter either with or without wet scrubbers. Benchmark exposure concentrations corresponding to negligible ecological risk were established for avian, mammalian, and plant receptor groups based on the toxicity literature. These benchmark exposure concentrations were then converted to concentrations in air and compared to air modeling predictions to develop risk estimates. Benchmark air concentrations were derived using plant uptake models for fluoride and PAH, and food-web modeling for birds and mammals. Spatially and temporally explicit exposure models were developed for all receptors based on predicted concentrations of constituents in air, and population-level effects were modeled for plant (lodgepole pine, heather, and mosses/lichen), bird (ptarmigan) and mammalian (wood mouse) receptors. The results of this work revealed that exposures under both scenarios are likely to be much lower than concentrations corresponding to risk thresholds and that overall risk was lower for a smelter operating without wet scrubbers. Thus, although mass loading of sulfur dioxide (and other constituents) would be reduced using wet scrubbers, corresponding risk to ecological receptors would actually be higher because of higher exposure-point concentrations in air.

1626 CANCER POTENCIES AND DAILY INTAKE LEVELS FOR SIX INDUSTRIAL CHEMICALS.

C. Reid, D. Morry, R. Zuniga, S. Hoover, M. S. Sandy and L. Zeise. *Reproductive and Cancer Hazard Assessment Branch, Office of Environmental Health Hazard Assessment, Oakland, CA*.

Cancer potencies for six carcinogens (C.I. Direct Blue 218; 2,4-hexadienal; pyridine; bromoethane; propylene glycol mono-t-butyl ether; and N-methylolacrylamide) were estimated based on data from National Toxicology Program (NTP) rodent studies. Each of these chemicals was chosen for assessment of cancer potency because they are industrial chemicals (solvents, chemical intermediates, etc.) for which exposures of workers, consumers, and/or the general population are likely to occur. Based on a review of mechanistic data, the dose-response relationship was assumed to be consistent with linearity at low dose for all six chemicals, and a linearized multistage model was used to estimate cancer potency. The cancer potency estimate corresponds to the upper 95 percent confidence bound on the linear term of the multistage model fit to the tumor response data, adjusted to account for body size differences between humans and animals. One of the chemicals (N-methylolacrylamide) induced tumors at multiple sites (liver, lung and harderian gland) in mice. In this case, cancer potency was taken to be the sum of potencies associated with the three types of tumors in the male (most sensitive sex) mouse. Because of the statistical uncertainty in individual estimates of potency for each site, the linear terms were summed statistically, using Monte Carlo techniques. The upper 95 percent confidence bound on the summed linear terms was taken as the cancer potency estimate for N-methylolacrylamide. The cancer potency estimates range from greater than 1 (mg/kg-d)-1 for pyridine down to just over 0.01 (mg/kg-d)-1 in the case of C.I. Direct Blue 218. Daily intake levels corresponding to lifetime cancer risks of one in a million vary from several micrograms per day for the least potent carcinogens down to hundredths of a microgram per day for pyridine, the most potent of these six carcinogens.

1627 VALUE OF INFORMATION APPROACH FOR DEVELOPMENT OF MODELS OF THE DEVELOPING NEOCORTX AFTER EXPOSURE TO LOW DOSE RADIATION FROM INTERNALLY DEPOSITED RADIONUCLIDES.

W. C. Griffith, N. M. DeFrank, J. M. Gohlke and E. M. Faustman. *Institute for Risk Analysis and Risk Communication, University of Washington, Seattle, WA*.

Low dose radiation exposures during particular gestational periods can result in permanent neuronal perturbations and can lead to abnormalities in behavior and mental activity. Multiple mechanisms underlie these effects including radiation-induced cell death among neuronal precursors in the proliferative regions of the neocortex. We developed a computational model based on diverse data sets to describe the extent and pattern of cell death in the neocortex and the altered patterns of mi-

gration. The model predicts the subsequent effects of cell death on neuron number at the end of neurogenesis and alterations in migration. Our results indicate that the induced death of a small fraction of neuronal precursors, dependent on the dose and time of exposure, leads to significant changes in migration and decrease in the final neuron count. The model provides a comparison of differences in absorbed dose, time of exposure, and duration of exposure. The model predicts a 1% decrease of neuronal precursor cells per cGy during the most sensitive time window of neurogenesis and about a 0.5% decrease per cGy during other times of neurogenesis. The data sets used to develop the models used single acute exposures from external sources of radiation. We have extended these models by linking to kinetic models for tritium, H-3, and Cs-137, internally deposited radionuclides commonly associated with environmental contamination. Based upon the extensions of the models we predict smaller effects from H-3 and Cs-137 than for external radiation when total doses during gestation are the same. We provide estimates for rodents and humans. Our value of information analysis indicate areas where future studies are needed to reduce variability, such as more detailed evaluation of postnatal neuron numbers. Support for this research was from Center for Child Health Risk Research, EPA RD-83170901 and NIEHS P01 ES09601, and Low Dose Program of the Department of Energy, DE-FG02-03ER63674.

1628 FUGACITY MODELING AND ESTIMATION OF SOURCE ALLOCATION FACTORS FOR DRINKING WATER CONTAMINANTS (DWCS).

K. Krishnan¹, R. Carrier², C. Totman³ and L. Ritter⁴. ¹SEST, University of Montréal, Montréal, QC, Canada, ²Health Canada, Ottawa, ON, Canada, ³Triton Environmental Consultants Ltd., Richmond, BC, Canada and ⁴University of Guelph, Guelph, ON, Canada.

Source allocation factor (SAF) or relative source contribution (RSC) refers to an estimate of the proportion of the total exposure resulting from a specific exposure source (e.g., drinking water). A default SAF of 0.2 has been used in non-cancer risk assessments of DWCS with no obvious scientific basis. Since media-specific exposure data are often unavailable, uncertain or incomplete for most DWCS, the SAFs may be developed on the basis of model-derived values. The objective of the present study was to investigate the feasibility of developing SAFs for DWCS using the fugacity modeling approach. The approach involved using an equilibrium criterion (EQC) model based on the concept of fugacity (Level 1) to predict the concentrations of DWCS in various environmental compartments and subsequently using these results to compute human exposure doses. Using n-octanol:water and water:air partition coefficients as input parameters to the EQC model, the concentrations of several volatile organic chemicals (aromatic hydrocarbons, chloroethanes, alkanes and haloalkanes) in air, water, soil and fish were generated. These results were then used in other algorithms to compute chemical concentrations in vegetable, meat and milk. SAF for each chemical was then calculated as the proportion of total dose received via drinking water and it was well within 0.2 or 20% for most volatile organic chemicals, signifying that the current SAF is generous. The fugacity model-based SAF calculations are based on physicochemical characteristics of chemicals and it may not be appropriate for chemicals which are additionally generated by water treatment or water use processes. Therefore, the model-based or physicochemical parameter-based estimations of SAF should be considered along with other data (e.g., usage pattern, exposure related to consumer products), to derive the appropriate SAF value for use in DWCS risk assessment.

1629 DEVELOPMENT OF A SCREENING FRAMEWORK FOR DATA REVIEW AND ANALYSIS TO SUPPORT THE DERIVATION OF A NEURODEVELOPMENTAL TOXICITY VALUE FOR ETHANOL.

J. Stickney¹, M. Odin¹, S. Hays² and R. Dewoskin³. ¹Syracuse Research Corp., Cincinnati, OH, ²Summit Toxicology, Lyons, CO and ³National Center for Environmental Assessment, U.S. EPA, Research Triangle Park, NC.

U.S. EPA is performing a toxicity assessment for ethanol due to its increasing use as a gasoline additive. A screening framework was developed for review and analysis of data relevant to determining a toxicity value that incorporates the extensive knowledge of ethanol pharmacokinetics and neurodevelopmental toxicity. Epidemiology data were initially used to define relevant critical effects for low to moderate exposure to ethanol (i.e., problems with attention, learning, and memory). The review of animal data focused on neurobehavioral studies or mechanistic and neuroanatomical data that relate to learning and memory deficits. An iterative process of data review and targeted literature searching was applied, and recent secondary sources were relied upon to provide an overview of the current state of knowledge. A qualitative scheme describing possible modes of action (MOA) was developed to refine the determination of critical neurodevelopmental effects based on biological plausibility and human relevance, strength and specificity of association, and dose-response and temporal concordance. Possible key events identified were apoptosis

of post-mitotic neurons, oxidative stress, disruption of growth factor signaling, and altered function of cell adhesion molecules. Medline searches were used to provide a crude measure of the weight of evidence for each key event in the MOA scheme (expressed as # of hits). Multiple-dose studies characterizing the dose-response relationship for critical effects were chosen from the literature. Quantitative models were applied for analysis of ethanol pharmacokinetics and dose-response assessment. This framework combines mechanistic understanding with quantitative simulation to support the development of a neurodevelopmental toxicity value for ethanol. (The views expressed are those of the authors and do not necessarily reflect the views or policies of the U.S. EPA).

1630 RESPIRATORY EFFECTS OF PYROTECHNICALLY DISSEMINATED TITANIUM DIOXIDE SMOKE IN SPRAGUE DAWLEY RATS.

J. S. Anthony¹, R. L. Kristovich¹, D. A. McCaskey¹, E. A. Davis¹, D. Burnett¹, B. P. Gaviola¹, K. L. Matson¹, C. L. Crouse², M. S. Horsmon² and E. C. Kimmel². ¹Edgewood Chemical Biological Center, Department of the Army, Aberdeen Proving Ground, MD and ²SAIC, Abingdon, MD. Sponsor: S. Thomson.

Recently, the U.S. Army Chemical School and PM Obscuration performed an obscuration Mission Area Analysis (MAA) to identify the current critical uses of smokes/obscurants for the military. Operational capability gaps and limitations were identified which prevent accomplishing all aspects of the mission. In response to the small through medium area screening obscuration FNA, the Family of Tactical Obscuration Devices (FOTOD) has been developed as a solution to help reduce the risks associated with this functional need. Obscuration from the enemy is needed in restrictive terrain such as urban structures (i.e. 12' x 12' x 12' rooms) or smaller confined open terrain. Rapid, short duration effects are needed to satisfy this identified gap. Other requirements are for the item to be environmentally friendly and operator safe.

The Fast Obscurent Grenade (FOG) is a bursting type grenade that fulfills this small through medium area screening obscuration need. After an analysis was performed of the currently used military obscurant payloads, titanium dioxide (TiO₂) was chosen as the safest smoke, while maintaining the necessary performance characteristics. Many studies evaluated the toxicity of inhaled titanium dioxide; however most have evaluated long exposure times (i.e. 30 minutes) at low concentrations. For the current need, elevated concentrations for short exposure times would be the predominant operational scenario. Both acute and repeat exposures are therefore possible as maneuvers are performed in confined areas and in close proximity to the dissemination source. The current study evaluated clearance of the smoke material from the respiratory system as well as other biological effects. Groups of rats were exposed for 10 minutes to high concentrations of smoke generated from the FOG. Bronchoalveolar lavage, respiratory physiology, and pathology were performed to assess the toxicity of the inhaled smoke.

1631 GEOGRAPHICAL HETEROGENEITY IN BLADDER/LUNG CANCER RISK AND ARSENIC EXPOSURE IN SOUTHWEST TAIWAN.

S. H. Lamm^{1,2}, A. Engel¹ and M. Feinleib². ¹Consultants in Epidemiology and Occupational Health, LLC, Washington, DC and ²Johns Hopkins University-Bloomberg School of Public Health, Baltimore, MD.

The bladder and lung cancer mortality data for a 42-village, six-township study in Southwest Taiwan (Wu et al., 1989) has served as the analytic base for cancer risk assessment from the ingestion of arsenic (NRC, 1999; 2001). A variety of analytic models have addressed this 42-village dataset, stressing issues of choice of comparison group, levels of stratification and aggregation, variation of arsenic levels within individual villages, population assumptions of body weight and water consumption, and additional sources of arsenic exposure. Although the earliest study of internal cancers from this area highlighted differences in risk based on water source [artesian wells] and on geography [township] (Chen et al., 1985), quantitative risk analyses have inherently assumed homogeneity in background risk for the 42-villages. Stratification by dependency has shown that increased bladder cancer mortality was limited to villages dependent upon artesian wells (Lamm et al., 2003). Further, stratification of the dataset by township has shown heterogeneity among the townships in background risk of bladder/lung cancer mortality (Lamm et al., 2006). The data from three townships show a significantly increased background risk of bladder/lung cancer mortality as calculated from regional rates. These villages show no apparent additional dose-response risk for arsenic exposure. The cause of this elevated background rate is not known and is being sought. In contrast, the other three townships show no increased background risk of bladder/lung cancer mortality. These second three townships do show a significant linear dose-response relationship with arsenic exposure that begins at 125-150 ug/L. Restriction of the analysis to villages not dependent upon artesian wells similarly shows now that the geographic heterogeneity is independent of artesian well-dependency. This analysis is consistent with modern theories of arsenic carcinogenicity.

1632 DETERMINING RISKS TO BACKGROUND ARSENIC USING A MARGIN OF EXPOSURE APPROACH.

A. S. Lewis¹, M. Eldan² and B. D. Beck¹. ¹Gradient Corporation, Cambridge, MA and ²Luxembourg-Pamol, Inc., Tel Aviv, Israel.

Inorganic arsenic (Asi) is a known human carcinogen. In certain areas of the world, where natural levels of Asi in the drinking water are extremely high (e.g., hundreds of ppbs), an association has been established between ingestion of Asi and cancer prevalence (skin, bladder and lung). Regulatory agencies use linear extrapolation to estimate Asi cancer risks; this results in risks from background exposure to Asi in food, water, and soil greater than 10⁻⁶, and, in some cases, 10⁻⁴, thus exceeding regulatory targets. However, epidemiological and mechanistic evidence strongly supports a non-linear dose response of inorganic Asi. We therefore propose a Margin of Exposure (MOE) analysis to characterize risks to background Asi exposures. For a point of departure, we use the no-effect level identified by Lamm et al. (2006). This value is based on a re-analysis of the Taiwanese data, demonstrating that the dose-response for Asi-related bladder and lung cancer has an apparent threshold, with bladder and lung cancer risk significantly increased (SMR ≥100) only at drinking water concentrations above 151 mg/L (CI: 42 to 229 mg/L). Using estimates of Taiwanese specific-weight and intake factors, we converted this drinking water level a no effect level dose of 0.013 mg/kg-day. We calculated MOEs for the US population by comparing the no effect level dose to estimates of background exposures to Asi in food, water and soil, considering distributions of intake as well as Asi concentration in the various media. We set our target MOE at 1 because the Taiwanese cohort was exposed to high Asi concentrations over a lifetime (i.e., included in utero, child and adult exposures) and, because of poor nutritional status, is likely more sensitive to Asi-related health effects than the US population. Our analysis demonstrated that typical and high end (95%ile) background exposures to Asi in food, water and soil for children and adults are well above the target MOE of 1 and do not present a toxicological concern in the US.

1633 RISK ASSESSMENT OF ESSENTIAL METALS: COPPER AS A CASE STUDY.

B. Stern. *Consulting in Health Sciences & Risk Assessment, BR Stern and Associates, Annandale, VA.*

Essential metals or trace elements (ETE) are inorganic micronutrients with specific biological functions that are indispensable for human health at all life stages. An element is identified as essential if deficiency or absence induces functional and/or structural abnormalities that are reversed by supplying the nutrient. Essential metals differ from other chemical compounds in that (1) appropriate intakes are required to maintain health and (2) complex homeostatic mechanisms have evolved to regulate absorption, excretion, distribution and storage in order to ensure a sufficient supply for performance of essential biological functions under conditions of varying intake levels. Both deficiency and excess can lead to adverse health outcomes, the dose-response curve is approximately U-shaped, and the dose-response slope is likely to be zero over a range of intake levels. Thus, approaches to risk assessment of essential metals differ fundamentally from those for conventional risk assessment. Severe or marginal ETE deficiencies are risk factors for several diseases of public health importance and can also impair reproduction, growth and development. The major challenge is to determine an "acceptable range of oral intake" (AROI) that meets nutritional requirements to prevent deficiency while simultaneously avoiding excessive intakes that can be toxic. Copper is a naturally-occurring metal that is found in all environmental media; it is also an ETE. In this case study, the hazards associated with copper excess and deficiency are summarized, a U-shaped dose-response curve is described and the AROI for copper determined. Margins of exposure are derived to determine the relative degree of human safety/risk of environmental exposures. This analysis is intended to serve as a model for characterizing the health risks of environmental metals that are also nutrients. From a public health perspective, it is important to resolve differences in methodologies and conceptual approaches between toxicologists and nutritionists in order to establish appropriate reference intake ranges for optimal health.

1634 HAZARD IDENTIFICATION AND PRELIMINARY DOSE-RESPONSE ASSESSMENT OF ORGANOTIN PLASTIC STABILIZERS FOUND IN DRINKING WATER.

J. C. Lambert¹ and J. C. Lipscomb². ¹ORISE, Cincinnati, OH and ²NCEA, ORD, U.S. EPA, Cincinnati, OH.

Organic derivatives of tin are used extensively as stabilizing agents in the manufacture of polyvinyl chloride piping for drinking water distribution systems. Leaching of these organotin compounds into drinking water may result in human exposure to mixtures of mono- and di-substituted methyl and butyl tins. Human exposure to these organotin species, irrespective of source, has been confirmed in blood and liver tissue samples. However, the toxicological significance of human exposure to

individual, or mixtures of, mono- and di-substituted methyl and butyl tins on human health remains unclear. Rodent models of oral exposure to these individual organotin species indicate multiple modes of toxic action. Specifically, organotin exposures in rats and mice suggest that the immune, central nervous, or female reproductive system and the developing fetus, may be the most sensitive targets of toxicity. Qualitative dose-response analysis suggests that toxicity in the developing fetus may be a common critical effect for the organotins of interest, and that dibutyltin may be the most potent. Candidate points of departure, using developmental toxicity as an endpoint, have been identified for future consideration in the derivation of single organotin oral reference values. However, due to the ubiquity of organotin mixtures in domestic waters, it will be imperative to develop human health risk assessments for mixtures of organotins. The most appropriate mixtures risk assessment approach will be highly dependent upon determination of mode of action. In this work, consideration of potential key events in a proposed toxic mode of action indicate that the organotins of interest induce adverse effects in fetuses independently of one another, suggesting that response addition would be an appropriate mixtures risk assessment approach. However, further mechanistic information is needed for a more informed evaluation of toxic mode of action for developmental endpoints and may lead to selection of an alternative mixtures risk assessment approach such as dose addition.

1635 RISK-RISK ASSESSMENT OF METHYLMERCURY (MEHG) EXPOSURE AND FISH CONSUMPTION.

C. D. Carrington, C. W. Murray and P. M. Bolger. *Department of Health and Human Services, U.S. FDA, College Park, MD.*

Assessment of public health risks of seafood consumption entails the quantization of the risks of exposure to environmental contaminants, like MeHg, and those associated with different levels of consumption of various fish nutrients. The estimation of risk of contaminant exposure as a matter of degree allows for the integration of other public health issues such as the nutritional benefits of fish consumption in an overall risk analysis. Estimates of seafood consumption were developed from several different sources: 1) CSFII survey (1989-91) 2) NHANES (2001-02) and 3) NMFS market share data (2002). An algorithm was constructed to account for the use of short-term consumption surveys to model long-term consumption. Variation in the types of species consumed as well as their market share and range of MeHg levels as well as the loss of water during cooking were accounted for. Dose-response relationships were developed for maternal exposure to MeHg and several different measures of neurobehavioral development that were compared by normalizing the outcomes relative to normal variation (i.e. Z-scores; $IQ = 100 + Z \cdot 15$). Dose-response relationships were also developed for potential effects of fish consumption on rates of coronary heart disease (CHD) and stroke. A variety of different consumption intervention scenarios were considered to assess the impact on these endpoints on four different U.S. subpopulations: women of childbearing age, older women, young men, and older men. The neurobehavioral models estimate that current levels of fish consumption are associated with a Z-score decrement of less than zero (i.e. there may be a benefit) to 0.01 (i.e. about 1/100th of normal variation). Fish consumption was also associated with reduction in the annual rate of both CHD and stroke by approximately 10-5 per person-year in men and women over the age of 45. Scenarios involving adjustments of seafood consumption via the selection of the species consumed or by increasing or decreasing impacted the resulting health outcomes.

1636 MARGIN OF EXPOSURE ANALYSIS FOR MTBE IN DRINKING WATER.

M. Seeley, L. A. Beyer and B. D. Beck. *Gradient Corporation, Cambridge, MA.*

MTBE is a gasoline additive used to reduce air emissions of carbon monoxide and nitrogen oxides, and can be found in drinking water at concentrations detectable by taste and odor. Although MTBE exposure is associated with development of tumors in rodents, there is a significant debate regarding the relevance to humans of the animal tumor findings. Even if the tumor findings are considered relevant in humans, the most plausible modes of action for the tumors observed in animals, as well as ample evidence that MTBE is not genotoxic, are consistent with a threshold dose response relationship. Hence, we evaluated potential cancer hazards associated with MTBE exposure using a Margin of Exposure (MOE) analysis.

We calculated the lower bound on the effective dose associated with a 10% increase in tumor incidence (LED10) for four tumor endpoints: Leydig Cell Tumors (LCTs) in male rats exposed via gavage; lymphoma/leukemia (L/L) in female rats exposed via gavage; kidney tumors in male rats exposed via inhalation; and liver tumors in female mice exposed via inhalation. We converted inhalation doses to oral doses, and converted oral doses to human equivalent doses using body weight to the ^{3/4} power.

We then converted the LED10s to drinking water equivalent levels (DWELs) assuming a time-weighted average body weight of 59 kg (6 years as a child, 24 years as an adult) and a time-weighted drinking water intake of 1.8 L/day. We calculated

MOEs from the DWELs assuming that individuals might consume drinking water with MTBE concentrations up to 100 µg/L, which is at the upper end of concentrations detected in drinking water, and also at the upper end of the taste threshold range. According to our analysis, MOEs ranged from 13,000 for L/L to 50,000 for liver tumors. Based on the magnitude of these MOEs, current concentrations of MTBE in drinking water would not present a carcinogenic hazard, regardless of whether or not MTBE is considered to be a human carcinogen.

1637 MTBE IS NOT ASSOCIATED WITH A STATISTICALLY SIGNIFICANT INCREASE IN LEYDIG CELL TUMORS IN SPRAGUE-DAWLEY RATS.

J. Goodman¹, D. Gaylor², L. A. Beyer¹, L. R. Rhomberg¹ and B. D. Beck¹.
¹Gradient Corporation, Cambridge, MA and ²Gaylor and Associates, LLC, Eureka Springs, AR.

The gasoline additive methyl tert-butyl ether (MTBE) has raised a potential human health concern because of reports of cancer in rodents. Belpoggi et al. (1995, 1997, 1998) reported an increase in Leydig cell tumors (LCTs) in Sprague-Dawley (SD) rats exposed to 1,000 (but not 250) mg/kg-day MTBE via gavage, but their statistical analyses took no account of the increased survival rate in the high-dose animals, which provides an increased opportunity for the occurrence of tumors. We re-analyzed the data using the Poly-3 method. Belpoggi et al. don't specify which rats had LCTs, so we conducted analyses for the three most extreme scenarios. In Case 1, tumors are assigned to occur in the youngest possible high-dose animals and in the oldest control and low-dose animals, resulting in the minimum dose response trend. In Case 2, tumors are assigned to occur in the youngest possible control and low-dose animals and in the oldest high-dose animals, resulting in the maximum possible dose response trend. Case 2 is not biologically plausible because any treatment-related tumors should occur in dosed animals at similar or earlier ages than in control animals. Thus, Case 3 is the maximum constrained dose-response trend that results when all tumors occur in the oldest animals in each dose group. P-values of 0.01 for pair-wise comparisons and 0.005 for trend tests of common tumors have been recommended in order to control for the overall false-positive error rate that can arise from multiple comparisons of tumor incidences in the large number of tissue/organ sites examined in chronic bioassays. Based on these significance levels, even for the biologically implausible scenario, MTBE does not cause a statistically significant increase in LCTs in SD rats. None of the recognized modes of action (MOA) for LCTs in rats is a likely MOA for MTBE, and the relevance of rat LCTs to humans is questionable. We conclude that the currently available data do not support a statistically significant association between MTBE and LCTs in rats.

1638 COMPARISON OF OBSERVED AND PREDICTED BLOOD LEAD LEVELS FOLLOWING LEAD PAINT ABATEMENT.

L. B. Wichers¹, G. L. Diamond² and J. S. Brown¹. ¹National Center for Environmental Assessment, U.S. EPA, Research Triangle Park, NC and ²Syracuse Research Corporation, Syracuse, NY.

Degradation of lead-based paint in U.S. homes built before 1978 continues to be a significant source of lead exposure for children and may result in subsequent neurological deficits. Various lead paint repair and maintenance (RM) techniques produce decreases in dust lead concentrations, but expectant reductions in children's blood lead levels (bLPb) are not similarly characterized. We compared the effects of lead paint abatement on actual and predicted bLPb in 56 children (39 M, 17 F; 2.4±1.1 yr on study admission) from urban Baltimore, MD, using a subset of publicly available data. As part of a previous EPA study on lead paint RM effectiveness, bLPb and environmental lead measurements were collected before and 6- and 12-months post-abatement. Two biokinetic models (EPA Integrated Exposure Uptake Biokinetic Model for Lead in Children, IEUBK; and O'Flaherty Model) were used to predict the effect of RM on bLPb. An average pre-RM bLPb of 13.7±7.1 µg/dL (geometric mean: 11.6±0.6 µg/dL) was observed and the dust lead concentration was 5973±10622 µg/g. For pretreatment, the IEUBK model predicted a slightly lower number of children with bLPb>10 µg/dL compared to those observed (36 vs. 41, respectively). At 6- and 12-months following RM activities, the IEUBK model predicted a greater percentage (29%) of children with bLPb <10 µg/dL. There was substantial disparity between the IEUBK and O'Flaherty model predictions (particularly when RM occurred after 2 yrs of age), which was partially attributable to differing age-specific default soil and dust ingestion rates used in the two models. In the context of using the models for predicting kinetics of bLPb changes following abrupt changes in exposure, potential contributors to the differences between model predictions and observations were evaluated. (Abstract does not represent EPA policy. This work was supported in part by an appointment to the Research Participation Program at NCEA administered by ORISE through an interagency agreement between DOE and EPA.)

1639 DEVELOPMENT OF A DRINKING WATER PUBLIC HEALTH GOAL FOR CADMIUM.

R. Sedman and R. A. Howd. *OEHA, CA EPA, Oakland, CA.*

A proposed health based drinking water criterion, or public health goal (PHG), was developed for cadmium. After an extensive literature review, renal toxicity was identified as the most sensitive toxicological endpoint. Increases in the levels of certain tubular proteins that are very sensitive indicators of the onset of renal toxicity were used to identify the onset of renal toxicity. Studies in humans showed the development of proteinuria when urinary cadmium levels exceed 2 to 5 µg/g creatinine. Proteinuria and other more severe signs of renal toxicity are not detected when cadmium levels remain at or below 1 µg/g creatinine. Thus a urinary cadmium level of 1 µg/g creatinine is considered to be equivalent to a no observed adverse effect level (NOAEL) for cadmium in humans. Toxicokinetic studies in humans were employed to estimate the long-term daily oral cadmium intake associated with urinary cadmium levels of 1 µg/g creatinine after 50 years of exposure. Humans exhibit first order elimination of cadmium, that is, the rate of urinary excretion is a function of body burden. A terminal half-life of 14 years was estimated in men based on the findings of Ellis and coworkers. With this half-life, an oral intake of cadmium of 19 µg/day would yield a urinary cadmium level of 1 µg/g creatinine after 50 years of exposure. Women are likely to be more sensitive to cadmium than men. Women have a higher body burden of cadmium, possibly related to increased oral absorption. Itai Itai disease, which is caused by cadmium, occurs principally in women. Also significant increases in mortality were observed in women but not men exposed to cadmium in rice in Japan. A PHG that is considered to be protective of women was developed based on a daily cadmium intake of 19 µg/day, an overall uncertainty factor of 50 and a relative source contribution from drinking water of 20 percent, yielding a proposed PHG of 0.04 µg/L. The current California and federal Maximum Contaminant Level is 5 µg/L.

1640 CREATING A DECISION CONTEXT FOR COMPARATIVE ANALYSIS AND CONSISTENT APPLICATION OF INHALATION DOSIMETRY MODELS IN CHILDREN'S RISK ASSESSMENT.

D. J. Crawford-Brown¹ and A. M. Jarabek^{1,2}. ¹Department Env. Sciences. Eng., UNC, Chapel Hill, NC and ²NHEERL ETD, U.S. EPA, Research Triangle Park, NC.

Estimation of risks to children from air pollutants is complicated by the lack of reliable age-specific epidemiological data. Extrapolations from adults or animals present significant challenges: (1) differences in the mode of action (MOA) due to pharmacokinetic (PK) or pharmacodynamic (PD) differences among data sources; (2) integration of data ranging from in vitro biochemical to population studies; and (3) analysis of the quality and reliability of predictions. Numerous approaches address these issues, ranging from default uncertainty factors (UF) for interspecies and intrahuman variability to use of mechanistic models. PK and PD data are being developed for different life stages in animals and biomonitoring advances may provide measurements directly in humans. While these bring MOA data to bear on extrapolations, the problem of comparing disparate models remains; e.g., one model may empirically estimate age differences at the population level while another mechanistically predicts differences at the tissue level. We propose a decision analytic framework to systematically analyze and compare model structures; evaluate data interpretation, integration, and reliability; and rationally assess the quality of resulting model predictions. It uses a conceptual model to describe the process of interest in the target context (e.g., reactive gas uptake in nasal tissue), identify key parameters from exposure to clinical effect, and determine the relevance of data, parameter values, and extrapolation premises used to support a given model structure and predictions. The framework then assesses the rationality of predictions of the process in a target context (human children), including evaluation of the strengths and weaknesses of alternative parameters and model forms, the reliability of resulting risk estimates, and key sources of residual uncertainty - the latter to aid the design of research programs targeted at increasing the accuracy of risk predictions for children. (This abstract does not reflect Agency policy.)

1641 DEVELOPMENT OF DRINKING WATER HEALTH ADVISORY FOR BORON.

S. Ramasamy¹, K. Davidson² and S. Kueberuwa¹. ¹OST/OW, U.S. EPA, Washington DC, DC and ²Oak Ridge National Laboratory, Oak Ridge, TN.

The Health Advisory (HA) Program, sponsored by the Office of Water (OW), provides information on the environmental properties, health effects, analytical methods, and treatment technologies for regulated and unregulated drinking water contaminants. HAs establish nonregulatory concentrations of drinking water contaminants at which adverse health effects are not anticipated to occur over specific exposure durations (1-day, 10-days, several years, and a lifetime). This document is an update of the previous Office of Water draft HA for boron published in

1992 to reflect more recent health and environmental effects information for boron. Boron is a nonmetallic element present in compounds such as boric acid, and its sodium salt, borax. These compounds are mostly used in glass production and to a lesser extent, in pesticides, soaps/detergents and flame retardants. Boron is found naturally in many food items. The mean dietary intake in the US ranges from 0.85 to 1.47 mg/day. The results of a mid-1980's survey of 989 public ground water systems indicate that about 81.9% of these systems had detections of boron at concentrations ≥ 0.005 mg/L. A 2004 study funded by the American Water Works Association Research Foundation (AWWARF) found that boron tends to occur at higher concentrations in ground water, as compared to surface water sources. The lifetime and longer-term HAs for adults are derived from the chronic RfD of 0.2 mg/kg/day is based on fetal bodyweight from a developmental toxicity study in rats. The revised HA document is currently being prepared for peer-review. [The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the U.S.EPA].

1642 THE NEWLY DEFINED ACCEPTANCE AND EVALUATION CRITERIA FOR THE MOUSE LYMPHOMA ASSAY AND THEIR IMPACT AND RELEVANCE.

A. Poth, S. Kunz, W. Hans-Eric and W. Voelkner. *Genetic Toxicology and Alternative Methods, RCC Ltd., Rossdorf, Germany.*

In the present study historical data from 313 mouse lymphoma studies (microwell method) performed in the years 2003-2005 at RCC were investigated in respect to the newly acceptance and evaluation criteria as defined in the workshop reports of the IWGT working group. First the defined acceptable background mutant frequencies for negative/vehicle (50-170 x 10⁻⁶) were investigated for these studies. In 23 studies either the vehicle control or the solvent control were out of the defined range where 19 studies were beyond and 4 studies below the range. Secondly our data were investigated in respect to the newly defined acceptance criteria for the positive controls (GEF, IMF300) and compared to our previously used criteria (mutation factor of 2.0). MMS, used at RCC as a positive control without S9 mix in the pulse and in the prolonged treatment, indicate that in 94 studies at least one of the newly defined criteria could not be fulfilled, even if the mutation factor of 2 was reached or exceeded.

A further investigation includes test items which were classified as genotoxic by the mutation factor approach compared to the newly defined evaluation criteria for the definition of a positive effect. In 37 out of 126 studies (29%) performed in 2005 at RCC, a positive result was obtained. 20 studies showed a positive response at pulse treatment, 17 at the prolonged treatment. In 4 studies the global evaluation factor 126 could not be reached even if the mutation factor of 2.0 was reached or exceeded (from 2.0 to 3.0).

The current presentation will discuss the impact and the relevance of the newly defined acceptance and evaluation criteria for the mouse lymphoma test based on RCC historical data and eventually a re-consideration of certain definitions.

1643 PHOTOMUTAGENICITY OF ANHYDRORETINOL AND 5, 6-EPOXYRETINYL PALMITATE IN MOUSE LYMPHOMA CELLS.

N. Mei, Q. Xia, M. M. Moore, T. Chen and P. P. Fu. *NCTR/FDA, Jefferson, AR.*

Retinyl palmitate (RP) is frequently used as an ingredient in cosmetics and other retail products. We previously reported that under UVA light irradiation, RP is readily decomposed into multiple products, including anhydroretinol (AR) and 5,6-epoxyretinyl palmitate (5,6-epoxy-RP). We also determined that combined treatment of mouse lymphoma cells with RP and UVA irradiation produced a photomutagenic effect. In this study, we evaluated the photomutagenicity of AR and 5,6-epoxy-RP, two photodecomposition products of RP, in L5178Y/Tk⁺ mouse lymphoma cells. Treatment of cells with AR or 5,6-epoxy-RP alone at 10 and 25 $\mu\text{g/mL}$ for 4 h did not show a positive mutagenic response. However, because these doses did not induce the required amount of cytotoxicity, we are unable to determine whether these two compounds are mutagenic. Treatment of cells with 1-25 $\mu\text{g/mL}$ AR or 5,6-epoxy-RP under UVA light (315-400 nm) for 30 min (1.38 mW/cm²) produced a synergistic photomutagenic effect. At 10 $\mu\text{g/mL}$ (37.3 μM) AR with UVA exposure, the mutant frequency (MF) was about 3-fold higher than that for UVA exposure alone, whereas the MF for 25 $\mu\text{g/mL}$ (46.3 μM) of 5,6-epoxy-RP+UVA was approximately 2-fold higher than that for UVA exposure alone. Compared with previous results for RP+UVA treatment, the potency of the induced phototoxicity and photomutagenicity was: AR > RP > 5,6-epoxy-RP. To elucidate the underlying photomutagenic mechanism, we examined the loss of heterozygosity (LOH) at four microsatellite loci spanning the entire chromosome 11 for mutants induced by AR or 5,6-epoxy-RP. Most mutants lost the Tk⁺ allele, and

more than 70% of the chromosome damage extended to 38 cM in chromosome length. AR+UVA induced about twice more mutants that lost all 4 microsatellite markers from the chromosome 11 carrying the Tk⁺ allele than did RP+UVA or 5,6-epoxy-RP+UVA. These results suggest that the two of RP's photodecomposition products are photomutagenic in mouse lymphoma cells causing event that affect a large segment of the chromosome.

1644 GENOTOXICITY EVALUATION OF SODIUM TUNGSTATE DIHYDRATE AND TUNGSTEN POWDER.

G. Reddy, W. C. McCain and G. J. Leach. *Directorate Toxicology, U.S. Army Center for Health promotion and preventive Medicine, Aberdeen Proving Ground, MD.*

Tungsten (W) is a naturally occurring element which has several commercial and military applications. It is also under consideration to replace lead in bullets. Tungsten has been detected in the environment (air, soil and water) at certain production facilities and Army installations. The genotoxicity data on W are limited to only a few reports. We developed genotoxicity data under extramural contract. These tests were conducted in accordance with Environmental Protection Agency's Health Effects Testing Guidelines in compliance with Good Laboratory Practice. The summary of test results of completed work will be reported here. Sodium tungstate dihydrate (STD)(99.9%) did not produce mutagenic effects at any dose up to 5000 $\mu\text{g/plate}$ in *Salmonella typhimurium* (TA98, TA100, TA1535 and TA1537) and *Escherichia coli* (WP2uvrA) tester strains with and without a metabolic activation system. Tungsten powder (TP) (APS 1-5 micron), when tested at concentration up to 5000 $\mu\text{g/plate}$, did not cause a positive increase in any these tester strains with or without metabolic activation. STD did not increase mutation frequency at levels up to 350 $\mu\text{g/mL}$ in mouse lymphoma L5178Ytk⁺ cells in the presence or absence of a metabolic activation system. TP at concentration 39.3 to 5000 $\mu\text{g/mL}$ was not cytotoxic and not mutagenic in mouse lymphoma cells with and without activation. The effect of STD or TP on in vitro chromosomal aberrations in Chinese Hamster Ovary (CHO) cells showed no effect for inducing structural chromosomal aberrations up to conc. 3500 $\mu\text{g/mL}$ and 500 $\mu\text{g/mL}$ respectively with and without activation. STD at 250, 500 and 750 mg/kg when tested in vivo in the mouse micronucleus assay was not mutagenic in mouse bone marrow. These studies reveal that STD or TP are not mutagenic in all above tests conducted. On the basis of these studies we believe that these compounds do not appear to pose genetic hazards. (Abstract does not reflect U.S. Army Policy).

1645 BIOLOGICAL SIGNIFICANCE OF DNA ADDUCTS: CORRELATION WITH OTHER ENDPOINTS OF GENOTOXICITY IN MOUSE LYMPHOMA CELLS TREATED WITH MMS AND COMPARISON OF INCREMENTS TO BACKGROUND.

A. Brink, B. Schulz, U. Lutz, W. Völkel, H. Stopper and W. Lutz. *Toxicology, University of Würzburg, Würzburg, Germany.*

The biological significance of DNA adducts as a risk factor for mutation and cancer is under debate. In view of the background DNA damage this question could be addressed quantitatively by relating increments of DNA adducts from an exogenous source to the increments measured for other endpoints of genotoxicity. Background and induced levels of four adducts, O6-methyl-2'-deoxyguanosine (O6-mdGuo) and 7-methylguanine (7-mG), 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodGuo) and 1,N6-etheno-2'-deoxyadenosine (EdAdo) were measured by LC-MS/MS in DNA isolated from large batches of L5178Y mouse lymphoma cells treated with methyl methanesulfonate (MMS) at 0, 50, 100, 200 μM concentration. In parallel, background and increments were measured in three standard assays for genotoxicity in aliquots of the same cell suspension, (i) the alkaline version of the comet assay, (ii) the micronucleus test, and (iii) the thymidine kinase tk⁺ gene mutation assay. Means and standard deviations from at least four independent replicate studies were determined for all endpoints, and increments were expressed relative to controls. Fifty μM MMS resulted in a 1.4 to 2.2-fold increase above background for the biological endpoints, whereas O6-mdGuo and 7-mG increased about 8 and 10-fold. At 100 μM MMS, the biological endpoints showed 2.8 to 4.6-fold increases, while the factors for O6-mdGuo and 7-mG were 19 and 24-fold. At 200 μM , the respective factors ranged from 4.6 to 7.4 for general genotoxicity and were 27 and 252 for the guanine methylations. No dose-related increase was observed for either 8-oxodGuo or EdAdo. Except for the sublinear dose response observed for 7-mG at high dose, linearity could not be rejected for any endpoint. For a doubling of the background measure, the required MMS concentration was about ten-fold lower for DNA methylation than for the biological endpoints. A risk assessment based on adducts may therefore result in substantial overestimation of the biological consequences.

The pregnane X receptor (PXR) regulates the metabolism of a wide range of xenobiotics and endobiotics through coordinate regulation of gene expression of phase I and phase II metabolizing enzymes. Metabolism of benzo[a]pyrene (BaP), a common environmental contaminant, can result in either detoxification or bioactivation to its genotoxic forms. The genotoxicity of BaP in a particular organism, tissue, or cell type depends on the balance between these competing metabolic pathways. To examine the role of PXR in BaP genotoxicity, a cell culture model was developed based on the well-characterized human hepatoma cell line HepG2. Constitutive expression of PXR is undetectable in HepG2 and PXR-regulated responses are lost. PXR expression was restored by stable transfection of human PXR (hPXR) expression plasmid. DNA adduct formation was measured by 32P-postlabeling of parental HepG2 cells and hPXR-enhanced HepG2 cells treated with BaP at four doses (0, 0.5, 2, 5 μ M), with or without rifampicin (5 μ M) pretreatment. BaP treatment resulted in formation of DNA adducts in a dose-dependent manner in both cell lines. The presence of transfected hPXR significantly reduced the level of adducts ($p < 0.001$). Furthermore, the prototypic PXR agonist rifampicin markedly reduced adduct levels in the hPXR-enhanced cells ($p < 0.001$). These results suggest that PXR plays an important role in protecting cells from genotoxicity induced by exposure to BaP.

1647 LEVELS OF URINARY 8-HYDROXYDEOXYGUANOSINE IN FEMALE OFFICE WORKERS WHO ARE IN MENSTRUAL AND LUTEAL PHASES.

R. Yoshida¹, Y. Ogawa¹ and Y. Mathumoto². ¹National Institute of Occupational Safety and Health, Kawasaki, Japan and ²Kitasato University, Sagami, Japan.

The natural hormone 17 β -estradiol (E2) is considered as an endogenous cancer risk factor, and one possible mechanism of carcinogenesis by E2 is induction of oxidative stress. E2 is metabolized to two catecholestrogens, 2-OHE2 and 4-OHE2, by CYP1A1 and CYP1B1, respectively. Both metabolites can contribute to metabolic redox cycling, which induces ROS and causes the formation of 8-OHdG. The levels of E2 are changed according to menstrual cycle in women. In the present study, we investigated whether the levels of urinary 8-OHdG change according to phases of menstrual cycle of young female subjects.

The subjects were female office workers at a company. Information on demographic factors, phases of menstrual cycle and lifestyle factors were obtained from self-administered questionnaires. Subjects were then classified into menstrual phase (n=21), follicular phase (n=28), luteal phase (n=36), menopause (n=2), and pregnant (n=2) groups. Urine specimens were collected in the morning and were used to measure 8-OHdG and creatinine levels. The concentration of 8-OHdG was normalized by creatinine contents. Urinary 8-OHdG levels of the subjects who were non-smokers and did not take hormone-like medicines were analyzed in this study. The results showed that urinary 8-OHdG levels were $4.16 \pm 3.20 \mu\text{g/g}$ creatinine in the luteal phase group and $3.29 \pm 1.67 \mu\text{g/g}$ creatinine in the menstrual phase group, respectively. No statistically significant difference was found between both urinary 8-OHdG levels. No menstrual cycle dependence was observed for urinary 8-OHdG levels.

1648 OXIDATIVE DNA DAMAGE AND IN VIVO MUTAGENICITY IN THE LIVERS OF GPT DELTA MICE GIVEN DICYCLANIL.

T. Umemura¹, Y. Kuroiwa¹, M. Tasaki¹, T. Okamura¹, Y. Kodama², T. Nohmi³, A. Nishikawa¹ and M. Hirose¹. ¹Division of Pathology, National Institute of Health Sciences, Tokyo, Japan, ²Division of Toxicology, National Institute of Health Sciences, Tokyo, Japan and ³Division of Genetics and Mutagenesis, National Institute of Health Sciences, Tokyo, Japan.

Dicyclanil (DC), a pyrimidine-derived insect growth regulator, is a female mouse liver carcinogen in spite of the negative results in various mutagenicity tests such as the Ames, chromosome aberration and micronucleus tests. In the present study, to explore DC-induced hepatocarcinogenesis, we examined oxidative stress and a re-

porter gene assay in the livers of male and female *gpt* delta mice given DC at a dose of 1500 ppm, a carcinogenic dose, in the diet for 13 weeks. In addition, early changes in 8-hydroxydeoxyguanosine (8-OHdG) levels were measured in the liver DNA of B6C3F1 mice, a back strain of *gpt* delta, given DC at the same dose as in the first experiment for 2 and 4 weeks. While thiobarbituric acid-reactive substances levels were not changed among the groups, 8-OHdG levels in the treated male and female *gpt* delta mice were significantly elevated as compared with the controls. In contrast to the negative outcome in the males, mutant frequencies of *gpt* in the treated females were increased with statistical significance, which were mainly due to GC:TA transversions. Four weeks exposure of DC to female mice, but not male mice was sufficient to induce 8-OHdG increment. The overall data suggested that the reporter gene assay could be a powerful tool to investigate mutagenicity of so-called non-genotoxic carcinogen. Additionally, it seemed likely that oxidative DNA damages might be implied in DC-hepatocarcinogenesis.

1649 THE SPORES OF CO-CULTIVATED ENVIRONMENTAL *STREPTOMYCES CALIFORNICUS* AND *STACHYBOTRYS CHARTARUM* INDUCE DNA DAMAGE IN RAW264.7 CELLS.

P. Penttinen^{1,2}, J. Mäki-Paakkanen¹, J. Pelkonen^{2,3} and M. Hirvonen¹.

¹Department of Environmental Health, National Public Health Institute, Kuopio, Finland, ²University of Kuopio, Kuopio, Finland and ³Kuopio University Hospital, Kuopio, Finland. Sponsor: M. Viluksela.

We have recently shown that the actinobacterium *Streptomyces californicus* and the fungus *Stachybotrys chartarum* originating from moisture damaged buildings possess both immunotoxic and immunostimulatory characteristics, which are synergistically potentiated by microbial interaction. In the present study spore-induced genotoxic potential of these microbes was investigated. Dose related differences in genotoxic and cytotoxic effects in mouse RAW264.7 macrophages were studied after 24 hrs exposure to spores of *Str. californicus* or *S. chartarum* alone, spores of the co-cultivated microbes or mixture of spores of the separately cultivated microbes. The genotoxic effect of the exposures was determined by the Comet assay and cytotoxicity was assessed by using flow cytometric methods (DNA content analysis, live gate analysis and PI exclusion test) and also the MTT test. The present results revealed that the spores of *Str. californicus* alone induced a 1.5-fold DNA damage compared to control and also extensive cytotoxicity with G2/M cell cycle arrest. Interestingly, only the spores of the co-cultivated microbes caused DNA damage, cell cycle arrest and cytotoxicity even at the low dose, and at the highest dose a 2.5-fold DNA damage compared to control was reached. Instead, the mixture of separately cultivated spores or the spores of *S. chartarum* alone did not induce DNA damage or cell cycle arrest with any tested dose although they triggered significant cytotoxicity. Our results indicate that the spores of at least some environmental microbes have genetic activity. The genotoxic capacity of the spores seems to be potentiated when the microbes are grown in the same habitat. Thus, it is possible that the genotoxicity, at least in certain exposure circumstances, may contribute to the risk of cancer.

1650 EFFECT OF BREVETOXINS 2, 3, 6, AND 9 ON CELLULAR PROLIFERATION AND INDUCTION OF DNA DAMAGE IN JURKAT E6-1 CELLS.

R. N. Murrell^{4,1}, A. J. Bourdelais², D. G. Baden^{2,3}, J. Masterson¹ and J. E. Gibson^{1,4}. ¹Pharmacology and Toxicology, ECU, Greenville, NC, ²Center for Marine Science, UNCW, Wilmington, NC, ³Chemistry, UNCW, Wilmington, NC and ⁴Environmental and Molecular Toxicology, NCSU, Raleigh, NC.

Brevetoxins (PbTx) are cyclic polyether compounds produced by several types of marine dinoflagellates (including *Karenia brevis* and *Chatonella antiqua*) during red tide events in the Gulf of Mexico, off the coasts of Florida and North Carolina. Necropsies of marine mammals killed by red tides in Florida have found inflammatory lesions in respiratory tissues with brevetoxin positive lymphocytes. Jurkat E6-1 cells, a T lymphocyte cell line, was used to examine four brevetoxins, PbTx2, 3, 6, and 9, specifically their effect on cellular proliferation and ability to induce DNA damage. Cellular Proliferation Assays determined the IC50 for PbTx2 to be 10–5.25 M, PbTx3= 10–4.5M, PbTx6=10–5M, and PbTx9= 10–4.25M. At Concentrations below 10–6M for PbTx 3, 6, and 9 and above 10–8M for PbTx2 showed increased proliferation above that of negative control. The Comet Assay was used to compare DNA damage following treatment with PbTx2, 3, and 6 at their respective IC50s. The data is given as the distributive moment, which is the percentage of DNA in the comet tail multiplied by the length between the center of the head and tail (arbitrary units). Comet Assays were performed in two groups,

PbTx2 and PbTx3 and 6. All PbTx treated samples had visible DNA damage. A t-test comparison revealed significant statistical difference for PbTx2, 3, and 6 compared with their respective negative controls. The negative control distributive moments were 15.97 (SE= 1.05) for the PbTx2 group and 26.30 (.54) for the PbTx3 and 6 group. The positive control (hydrogen peroxide, 1.75%) was 33.77 (2.62) for the PbTx2 group and 85.39 (2.15) for the PbTx3 and 6 group. PbTx2 was 27.09 (1.48), PbTx3 was 41.94 (1.91), and PbTx6 was 44.00 (2.28). Supported by the North Carolina Agromedicine Center and USDA/CSREES. PbTx was provided under NIEHS grant PO1 ES 10594.

1651 POTASSIUM DICHROMATE-INDUCED OXIDATIVE STRESS, GENOTOXICITY AND CYTOTOXICITY IN HEPG2 CELLS.

A. K. Patlolla¹, C. P. Barnes^{1,2} and P. B. Tchounwou¹. ¹Biology/Environmental Science, Jackson State University, Jackson, MS, ²Biology/Environmental Science, Jackson State University, Jackson, MS and ³Biology/STARGE 2005 student, Jackson State University, Jackson, MS.

Chromium is a widespread industrial waste. The soluble hexavalent chromium Cr (VI) is an environmental contaminant widely recognized to act as a carcinogen, mutagen and teratogen towards humans and animals. The reduction of Cr (VI) to Cr (III) results in the formation of reactive intermediates together with the oxidative tissue damage and a cascade of cellular events. However, the mechanisms of the toxic action of chromium are not completely understood. The main purpose of this study was to evaluate the occurrence of oxidative stress, genotoxicity and cytotoxicity in the human liver [HepG2] cells exposed to potassium dichromate. HepG2 cells were cultured following standard protocol and exposed to various concentrations [0 – 50 µM] of potassium dichromate. Following exposure to the toxic metal, we performed the MTT assay to assess the cytotoxicity, thiobarbituric acid test to evaluate the degree of lipid peroxidation as an indicator of oxidative stress and DNA damage evaluation using alkaline comet assay. Study results indicated that potassium dichromate is cytotoxic to HepG2 cells, showing LD50 values of 8.83 + 0.89 µg/ml, 6.76 + 0.99 µg/ml for cell mortality upon 24 and 48 hrs of exposure respectively; indicating a dose- and time-dependent response with regard to cytotoxic effect of potassium dichromate. Statistically significant increase in the concentration of malondialdehyde [MDA], an indicator of lipid peroxidation, was recorded in exposed cells [15.9 – 69.9 µM] compared to control [13 µM]. Similarly, a strong dose-response relationship (p<0.05) was also obtained with respect to potassium dichromate induced DNA fragmentation [comet assay] in HepG2 cells exposed [3.16 + 0.70 – 24.84 + 1.86 microns] to potassium dichromate than control [3.07 + 0.26]. Our results demonstrate that potassium dichromate is highly cytotoxic to HepG2 cells, and its cytotoxicity seems to be mediated by oxidative stress and DNA damage.

1652 THE CARCINOGENIC ASPECT OF POTASSIUM BROMATE GENOTOXICITY IN HUMAN LYMPHOBLASTOID TK6 CELLS.

M. Honma¹, Y. Luan^{2,1}, T. Suzuki², R. Palanisamy², Y. Takashima¹, H. Sakamoto¹, M. Sakuraba¹, T. Koizumi¹, T. Yamaguchi² and M. Hayashi¹. ¹Division of Genetics and Mutagenesis, National Institute of Health Sciences, Tokyo, Japan and ²Division of Cellular and Gene Therapy, National Institute of Health Sciences, Tokyo, Japan. Sponsor: M. Ema.

Potassium bromate (KBrO₃) is strongly carcinogenic in rodents and mutagenic in bacteria and mammalian cells in vitro. The proposed genotoxic mechanism for KBrO₃ is oxidative DNA damage. KBrO₃ can generate high yields of 8-hydroxydeoxyguanosine (8OHdG) DNA adducts, which cause GC > TA transversions in cell-free systems. In this study, we investigated the in vitro genotoxicity of KBrO₃ in human lymphoblastoid TK6 cells using the micronucleus (MN) test and the thymidine kinase (TK) gene mutation assay. In a 4-h treatment, KBrO₃ induced MN and TK mutations concentration-dependently. At the highest concentration (5mM), KBrO₃ induced MN and TK mutation frequencies that were over 30 times the background level. Molecular analysis revealed that 90% of the induced mutations were large deletions that involved loss of heterozygosity (LOH) at the TK locus. Ionizing-irradiation yielded similar mutational spectrum in our system. These results indicated that the carcinogenicity of KBrO₃ may be due to double strand breaks that lead to large deletions rather than to 8OHdG adducts that lead to GC > TA transversions, as is commonly believed. To better understand the genotoxic mechanism of KBrO₃, we analyzed gene expression profiles of TK6 cells using Affymetrix Genechip. Some genes involved in stress, apoptosis and DNA repair were up-regulated by the treatment of KBrO₃. However, we could not observe the similarity of gene expression profile in the treatment of KBrO₃ to ionizing-irradiation as well as oxidative damage inducers.

1653 AN AUTOMATED, SENSITIVE AND ROBUST VERSION OF THE FLUORESCENCE-DETECTED ALKALINE DNA UNWINDING (FADU) ASSAY FOR THE QUANTIFICATION OF DNA SINGLE-STRAND BREAKS AND DNA CROSS-LINKS IN CELLS.

A. Buerkle^{1,2,3}, M. Moreno-Villanueva¹, M. Debiak¹, T. Sindlinger¹, R. Pfeiffer^{2,3}, A. Leake², T. B. Kirkwood² and M. Mueller³. ¹Department of Biology, Molecular Toxicology Group, University of Konstanz, Konstanz, Germany, ²Department of Gerontology, SCMS, Newcastle University, Newcastle upon Tyne, United Kingdom and ³Department of Tumor Virology, German Cancer Research Center, Heidelberg, Germany.

DNA single strand breaks are among the lesions directly introduced by ionizing radiation but also represent intermediates in several DNA repair pathways. Therefore quantification of DNA strand breaks and their rate of disappearance in living cells is an important endpoint in the assessment of genotoxicity of compounds and the cells' capacity to repair DNA damage. One of the available methods, the fluorescence-detected alkaline DNA unwinding (FADU) assay, is thought to be very sensitive, yet in its original, manually performed version (Birnbom HC, Jevcak JJ, Cancer Res. 1981;41:1889-92) is technically very demanding and requires large number of cells.

In order to render this assay more convenient and reproducible, to reduce the number of cells required and to increase throughput, we established an automated version of this assay based on the use of a commercial 8-channel liquid handling device and additional modifications of the assay protocol. The automated FADU is run in a 96-well plate format. It allows detection of DNA strand breaks induced with as little as 6 cGy of X-irradiation with high reproducibility. A dose of approximately 1 Gy allows robust determination of DNA strand break repair capacity. In addition, DNA interstrand cross-linking induced by mitomycin C can also be measured as the inhibition of DNA unwinding that would result from a fixed dose of ionizing radiation.

In conclusion, the automated FADU assay is a sensitive, robust and convenient method for the quantification of DNA single-strand breaks and DNA cross-links in cells and of DNA repair.

1654 A NON-ANIMAL-BASED, HIGH-THROUGHPUT UNSCHEDULED DNA SYNTHESIS (HT-UDS) ASSAY FOR SCREENING OF GENOTOXINS.

C. A. Kirk¹, J. Tao¹, B. Bowen¹, M. J. Iatropoulos², G. M. Williams² and G. L. DeGeorge¹. ¹MB Research Laboratories, Spinnerstown, PA and ²New York Medical College, Valhalla, NY.

For over 30 years, the Unscheduled DNA Synthesis assay has been used to detect genotoxic chemicals via measurement of the incorporation of 3H-Thymidine during the repair of damaged cellular DNA. This test is often employed to more fully characterize chemical and drugs when first-tier genotoxicity tests produce conflicting results. We have developed a rapid, non-radioactive "HT-UDS" assay based on flow cytometric methods to detect nucleotide analogs incorporated into human keratinocytes, hepatocytes, embryonic chick hepatocytes and cell lines, eliminating the need for test animals (rat liver or culture of primary hepatocytes). This assay was validated with 18 known genotoxins and non-genotoxins, attaining an accuracy of 94% without the over-prediction problem of many classical mutagenicity tests (very low false-positive rate). By employing cell types of both low- and high-metabolic potential, HT-UDS allows detection of compounds that are activation-dependent, activation-independent or detoxified by bio-transformation. Other advantages of the HT-UDS include: a rapid analysis time of less than 5 days (vs. 3-4 months), decreased cost, and an automated, quantitative procedure which replaces manual or subjective scoring of films or slides. HT-UDS can also be performed on a microplate-scale, where a 1000-fold greater number of nuclei can be rapidly analyzed and multiple chemicals can be simultaneously tested. The greatly increased throughput of HT-UDS enables allows a cost-effective and rapid genotoxicity pre-screening test and is the most significant advance in the UDS method in the last decade.

1655 CYTOTOXICITY AND RADIATION SENSITIZATION WITH OXALIPLATIN IN ESOPHAGEAL ADENOCARCINOMAS.

R. R. Johnson and A. W. Blackstock. *Radiation Oncology, Wake Forest University Health Sciences, Winston-Salem, NC.* Sponsor: M. Miller.

The prevalence of esophageal adenocarcinoma in the U.S. is increasing and has a poor 5-year survival. A third generation platinum chemotherapy agent, oxaliplatin, is currently used in the treatment of colorectal cancer where it has described radiosensitizing effects. Oxaliplatin is known to form predominantly intrastrand guanine/guanine and guanine/adenine DNA adducts that block DNA replication and

transcription. We aim to determine the anti-tumor effects of oxaliplatin +/- radiation in esophageal adenocarcinomas. Clonogenic survival assays and MTT cell proliferation assays were performed in two esophageal adenocarcinoma cell lines (Seg-1 and Bic-1) treated with either 0-10 μ M oxaliplatin; 2, 4, or 6 Gy radiation; or oxaliplatin plus radiation. These assays demonstrated an increase in cell death as the oxaliplatin concentration increased and as the drug incubation time increased. The combination of oxaliplatin followed by radiation caused a further reduction in cell survival. Western blot analysis performed on the same esophageal cell lines after cells were treated with oxaliplatin and/or radiation allowed for the observation of double strand break (DSB) damage and repair through γ H2AX. Cells were harvested and lysed either immediately after treatment or after various repair times. The western results showed the combination of oxaliplatin and radiation caused more DSB than oxaliplatin alone. DSB repair appeared complete at 6 hours post-treatment. Oxaliplatin with radiation therapy is more cytotoxic to esophageal adenocarcinomas than radiation alone or oxaliplatin alone. The mechanism of this radiosensitization does not appear to be through inhibition of DSB repair, but it could possibly be through inhibition of base excision repair or nucleotide excision repair. Further experiments are needed looking at other DNA damage repair mechanisms and apoptosis.

1656 POLY ADP RIBOSE POLYMERASE ACTIVITY IN CULTURED HUMAN LUNG CELLS.

H. W. Forth¹, M. H. Ahmad¹, S. Hofmann² and A. W. Torky¹. ¹Institute of Environmental Toxicology, Martin Luther University, Franzosenweg 1a, Martin Luther University, Halle / Saale, Saxony-Anhalt, Germany and ²Clinic of Cardiothoracic Surgery, Martin Luther University, Halle / Saale, Saxony-Anhalt, Germany.

Poly (ADP-ribose) polymerase-1 (PARP-1), is included in the cellular response to DNA injury and is decisive for the final response whether the targeted cell undergoes repair or apoptosis. It is widely unknown whether PARP-1 itself is a target for modulating factors. The scope of the study was to examine the time course PARP-1 activity in normal human bronchial epithelial cells (NHBE) during a follow up period of 10 weeks in culture. We have determined whether external factors such as cigarette smoke condensate or metals will modulate PARP-1 activity in vitro. The expression PARP-1 protein was proved in normal human bronchial epithelial cells (NHBE) and tumor cell line A549 by Western Blot analysis. PARP-1 activity in normal human bronchial epithelial cells (NHBE) by H₂O₂ (100 μ M) for 5 min was measured by an immunofluorescence assay for ADP ribose polymers. In the first explants of individual donors PARP-1 activity in (NHBE) varied by a factor of 1.5-2 (n=5). PARP-1 activity was analyzed in progressive generations and passages of bronchial and peripheral lung cells for 10 weeks. The activity was almost stable for about 4 weeks. After that the activity declined till the 5th generation to 50% of the start values (n=3). Cigarette smoke condensate (CSC) 0.5 mg/L for 24 h induced PARP-1 activity in NHBE by factor 1.3 compared to controls (= basal cellular PARP activity). After H₂O₂ (100 μ M) PARP-1 activity was induced 1.4 fold and 1.8 fold by CSC (+ H₂O₂). Treatment of NHBE with copper sulfate (0.05 mM) alone did not trigger PARP-1 activity but decreased PARP-1 activity which was stimulated using H₂O₂ (0.1 mM) by 40%. Similarly mercury (II) chloride (0.03 mM) exerted no effect on PARP-1 activity and decreased the activity of PARP-1 upon co-incubation with H₂O₂ (0.1 mM) by 40%. PARP-1 expression and activity can be monitored in primary human lung cells in vitro and it is likely that PARP-1 is modulated by adaptive responses in individuals.

1657 DNA DAMAGE RESPONSE TO ESTROGEN METABOLITES.

J. A. Dalrymple¹, S. Takeda², J. A. Swenberg¹ and J. Nakamura¹. ¹Environmental Sciences and Engineering, UNC Chapel Hill, Chapel Hill, NC and ²Department of Radiation Genetics, Kyoto University, Kyoto, Japan.

DNA damage caused by estrogen metabolites is believed to be an essential process in the initiation of breast and endometrial cancers. Three pathways that are hypothesized to be the main cause of estrogen related DNA damage involve oxidative DNA lesions induced by redox cycling of estrogen metabolites, base damage directly caused by estrogen quinone metabolites, and depurination of adducted bases. In this study, we used the chicken B lymphocyte (DT40) cell line and its isogenic mutants deficient in DNA damage response genes to better understand the most biologically relevant types of DNA damage that may be responsible for the initiation of estrogen-related cancers. Using the estrogen metabolites 4-hydroxy-estradiol (4-OHE2) and 2-hydroxy-estradiol (2-OHE2), we exposed the isogenic mutants to varying metabolite concentrations by incubating the cells in the presence of the es-

trogen metabolites for ten cell replication cycles. After cultivation, XTT dye was used to measure the numbers of surviving cells. While DT 40 cells deficient in either xpa, parp-1, fen1, pol β , or pol θ were not hypersensitive to either 2-OHE2 or 4-OHE2, rev3- and msh3-deficient cells showed a marked increase in cell death when compared to wild type DT40 cells. These results provide insight about the nature of DNA damage caused by 4-OHE2 and 2-OHE2 and the subsequent cellular response. First, abasic sites induced by depurinating base adducts may not play a major role in the DNA damage response to major E2 metabolites. The mismatch repair protein Msh3 may possess a novel function related to the cellular tolerance to either bulky base damage or oxidized DNA lesions induced by E2 metabolites. Our data also suggest that translesion DNA synthesis polymerases such as Rev3 are essential for the survival of cells with stalled DNA replication forks due to lesions caused by estrogen metabolites.

1658 IN VITRO ASSESSMENT OF THE GENOTOXICITY OF BENZO-A-PYRENE USING SISTER CHROMATID EXCHANGES, HIGH FREQUENCY CELLS AND DNA SINGLE STRAND BREAKS ON HUMAN BLOOD LYMPHOCYTES.

F. Fortin^{1,3}, L. Salmi^{1,2}, C. Viau² and N. Lemieux^{1,3}. ¹Pathologie et biologie cellulaire, Université de Montréal, Montréal (Québec), QC, Canada, ²Santé environnementale et santé au travail, Université de Montréal, Montréal (Québec), QC, Canada and ³Centre de recherche, CHU Sainte-Justine, Montréal (Québec), QC, Canada.

Benzo-a-pyrene (BaP) is a polycyclic aromatic hydrocarbon compound that can induce various genotoxic effects such as sister chromatid exchanges (SCE) and DNA single strand breaks (SSBs) in humans. *In vitro* studies provide a mechanistic comprehension of those effects and of the interindividual variation observed. Some studies with occupational exposure include the measure of high frequency cells (HFC) in their analysis of the SCE assay results, but this approach is not currently used in *in vitro* studies. In our report, human cultured lymphocytes were exposed *in vitro* to three concentrations of BaP dissolved in DMSO (0.1 – 1 – 5 μ g/ml) for 24 hours. Cells were obtained from 10 subjects (5 men / 5 women) for SCE test and 4 subjects (2 men / 2 women) for electron microscopy *in situ* end labelling (EM-ISEL) assay. Cells were harvested 24 hours after the end of the exposure and assessed for SCEs increase, the rate of HFC, and SSBs using the EM-ISEL assay. An important variation was present between individuals as some subjects presented a significant increase of SCEs or SSBs starting at [BaP] 0.1 μ g/ml, while other subjects showed such an increase only at [BaP] 1 or 5 μ g/ml. This observation was unrelated to gender for SCEs, while men presented twice more SSBs than women. Analysis of our results demonstrates a significant positive correlation between the concentration of BaP and the mean SCEs number ($r=0.666$, $p<0.001$) or HFC rate ($r=0.684$, $p<0.001$). Also, a significant positive correlation is present between the mean SCEs number and the HFC rate ($r=0.758$, $p<0.001$), supporting the hypothesis that HFC represents cells being more damaged following the *in vitro* exposure to BaP. Pursuing this study on a larger number of subjects will allow us to determine the usefulness and significance of HFC and SSBs in *in vitro* studies. This work was supported by a scholarship from the FRSQ.

1659 CLASTOGENICITY OF CIGARETTE SMOKE CONDENSATE AND DNA DAMAGING AGENTS IN TWO CELL LINES BY THE IN VITRO MICRONUCLEUS ASSAY.

F. Z. Sheabar, C. Gowdy and S. Millet. Toxicology, Arista Laboratories, Richmond, VA.

V79 and CHO cell lines are routinely used in the *in vitro* micronucleus (MN) assay aimed at testing genotoxicity of chemical and physical agents. The CHO cell line is the most predominantly used cell line in genetic toxicology. However, V79 is utilized by some laboratories since the *in vitro* MN assay was initially developed using this cell line. The aim of the current study was to compare the sensitivity of these two cell lines in testing the capability of cigarette smoke condensate and 3 known DNA damaging chemical agents to induce clastogenicity/augenicity using the micronucleus bioassay. The total particulate (TPM) phase of main stream reference cigarette smoke condensate (CSC) generated under laboratory conditions using International Organization for Standardization (ISO) and Canadian Intense (CINT) conditions from KY2R4F cigarettes and 3 DNA damaging chemical agents: colchicine, cyclophosphamide and mitomycin C were utilized in the current study. Clastogenicity was examined under three various exposure terms in both cell lines. Replicate cultures of CHO and V79 cell lines in 10% fetal bovine serum in F-12 Ham and DMEM medium, respectively, were established and treated with the 3 DNA damaging chemical agents and TPM of CSC at 0-500 μ g/ml. A total of 1000

cells were analyzed for MN presence. The CSC TPM phase and the 3 tested chemicals were clastogenic in both cell lines, with one cell line being about 2-3 times more sensitive than the other in both cases. Of the 2 tested cell lines, the V79 cells was the more sensitive cell line when testing the clastogenicity of TPM from CSC. However, an opposite trend in the cell lines sensitivity was observed following treatment with the three DNA damaging chemical agents.

1660 ASSESSMENT FOR THE USE OF SALMONELLA THYPHIMURIUM STRAIN TA100 IN THE AMES II ASSAY: A VALIDATION STUDY WITH 14 COMPOUNDS.

K. Braun, A. Amberg, A. Czich, A. Jost, B. Preikschat and I. Stammberger. *Drug Safety Evaluation, sanofi-aventis, Hattersheim, Germany*. Sponsor: B. McCullough.

Originally the Ames II was developed by Xenometrix to detect only the potential of compounds to induce mutagenicity using a modified protocol with Salmonella strains TA98 (frameshift mutations) and TAMix (TA7001 – 7006, base pair substitutions). The major advantages of this screening assay are the low amount of compound needed and the higher throughput that could be achieved compared to the standard Ames assay. The Ames II using TA98 and TAMix is a well validated test system to detect mutagens. The use of TA100 in a screening Ames II mutagenicity assay in microtiter plates is of interest, since a high number of compounds are only positive in this standard Ames test strain. In the past it was not possible to use the TA100 in the Ames II due to the high number of spontaneous revertants in the control group using the microtiter plate format. With a new study protocol, developed by Xenometrix, it should now be possible to use TA100 in the Ames II assay, as the number of spontaneous revertants was reduced. Fourteen chemicals described in literature to be positive in the standard Ames tester strain TA100 and partly in TA98 or TA97 were selected to evaluate a modified Ames II protocol from Xenometrix with the Salmonella strain TA100 in the absence and presence of S9-mix. The results of the 14 compounds tested lead to the conclusion, that there are no major differences between the use of TA100 and TAMix in the Ames II to detect base pair substitution mutations. The TAMix seems to be slightly more sensitive. This might be explained by the still higher spontaneous revertant frequency of the TA100 compared to TAMix. Therefore, for weak mutagens it could be difficult to detect a clear dose dependency of a weak mutagenic effect. Based on these results, the tester strain TA100 should not be included routinely in the Ames II assay. However, on a case by case basis, compounds originating out of a chemical class known to be positive in the standard Ames TA100 should be tested in TA100 in the Ames II.

1661 FORMATION OF GENOTOXIC BY-PRODUCTS DUE TO THE REACTION OF THE SOLVENT DMSO WITH COMPOUNDS FROM DIFFERENT CHEMICAL CLASSES.

A. Amberg, K. Braun, A. Czich, A. Schnurstein, H. Kauffmann, H. Spirkel and I. Stammberger. *Drug Safety Evaluation, Sanofi-Aventis, Frankfurt, Germany*. Sponsor: B. McCullough.

DMSO is a widely used standard solvent in in vitro studies. To investigate the influence of DMSO and other solvents on genotoxicity results, we tested several compounds from different chemical classes in the Ames II assay, a liquid microtiter modification of the standard Ames plate incorporation test, by using different solvents.

As a result of these studies, the chemical classes sulfonic acid halides and carboxylic acid halides could be identified so far, which showed different results in Ames II, depending on the solvent used. Most of the compounds from both chemical classes are described in the literature (NTP database...) as genotoxic compounds or they are alerted by the in silico tool DEREK (Deductive Estimation of Risk from Existing Knowledge) to give positive genotoxicity results. Compared to our results in the Ames II, we could confirm the positive results with and without metabolic activation in the Salmonella typhimurium tester strains TAMix and TA98, when using DMSO as solvent. In contrast to these results, the same compounds were tested negative in Ames II, when using other solvents than DMSO like water or ethanol.

These results may be explained by different reactions of the compounds in the solvents. Sulfonic/carboxylic acid halides in water should completely react to the corresponding and non-genotoxic sulfonic/carboxylic acids and hydro halide acids. But when using DMSO as solvent, besides the corresponding sulfonic/carboxylic acids, dimethylsulfide halides are also formed as reaction products of DMSO. These dimethylsulfide halides are alkylating agents, which are more stable in aqueous conditions and more likely to react with DNA, resulting in a positive Ames II.

As a consequence of these results, we recommend using other solvents than DMSO to test the genotoxic potential of sulfonic acid halides and carboxylic acid halides, to avoid false positive results from DMSO reaction products, not relevant for aqueous, physiological conditions.

1662 THE AMES MPF ASSAYS: NOVEL MUTAGENICITY TESTING IN LIQUID MICROPLATE FORMAT USING S. TYPHIMURIUM TA98, TA100, TA1535 AND TA1537.

S. Flueckiger-Isler and M. Kamber. *Xenometrix AG, Allschwil, BL, Switzerland*. Sponsor: E. Zeiger.

Genetic toxicity testing has moved towards the earlier stages of drug discovery in order to identify genotoxic liabilities of new compounds in the pipeline. Because in early development many compounds are available in very small quantities, a liquid microplate version of the original Ames plate incorporation test with different S. typhimurium tester strains was developed to decrease compound consumption and to increase the through-put of the assay.

The complete Salmonella plate incorporation test includes at least 2 frameshift strains, usually TA98 and TA1537 or TA97, and at least two base-pair strains. TA100 is the most sensitive of all tester strains, but some mutagens are positive in TA1535 only.

TA98 is already successfully used in the Ames II assay, in combination with TAMix, a mixture of strains to detect base-pair mutations. TA100 with its high spontaneous reversion rate, and TA1537 or TA1535 were as yet not available in the microplate format. We were able to decrease the spontaneous reversion rate of TA100 to a level low enough to be used in the microplate format without loss of sensitivity.

The mutagenic response to 24 reference compounds was examined in the microplate format with TA98, TA100, TA1537 and TA1535, and the results were compared with published plate incorporation data. Depending on the strain tested and on the reference citation, concordance between the two assay formats was 80 - 100%. Certain mutagens exclusively reverted TA1537 or TA1535, but not TA98 or TA100, irrespective of the assay format.

These new Ames MPF tests by Xenometrix using a liquid format and 384-well microplates offer a time and cost-effective pre-regulatory alternative to the plate incorporation method. As both formats use the same Salmonella strains, results can be compared with existing data sets. The new test kits include ready-to-use media and bacteria and allow rapid screening of a large number of compounds. They consume six times less test substances and consumables than the plate incorporation method, and reduce hands-on time.

1663 EVALUATION OF A MICROAMES SCREEN THAT IS FULLY PREDICTIVE FOR THE REGULATORY SALMONELLA/E. COLI MAMMALIAN MICROsome MUTAGENICITY TEST.

M. J. Schlosser, S. G. Soelter and M. Wells. *Midwest BioResearch LLC, Evanston, IL*.

In the pharmaceutical industry there is a need for rapid genotoxicity screens that mimic regulatory assays. Predictive screens are key for assessing genotoxic risk of low-yield isolated impurities, and are important to ensure positive genotoxic responses are not found during regulatory testing, after considerable time and resources have been allocated to a drug candidate. A unique miniaturized rapid throughput version of the Ames test has been developed that requires only 10 mg. The strength of this microAmes screen is the use of regulatory Ames tester strains and classical endpoints (colonies, cytotoxicity, precipitates). To assess the robustness of this screen, 20 compounds comprising diverse mechanisms and structures, many related to pharmaceuticals, were tested with 4 regulatory accepted tester strains of Salmonella (TA97a, TA98, TA100, TA1535) and one E. coli strain (WP2uvrApKM101). Positive and negative controls were used and included compounds previously shown to yield borderline results in the full Ames test. The microAmes screen correctly predicted Ames mutagenicity in all cases and correctly predicted Ames non-mutagens except for 2 controversial compounds, oxazepam and menadione which yielded positive responses in the microAmes. Menadione was positive in WP2 without S9, while oxazepam was positive in several strains with S9 but only at concentrations where precipitates were present. In the full Ames test, menadione displays small increases in WP2 colony formation (<2 fold), whereas strong elevations are seen in the WP2-OxyR deficient strain, a variant sensitive to oxidative mutagens. Although oxazepam is negative in the full Ames test, this compound is a known in vivo mutagen, in vitro clastogen, and carcinogen. These results indicate that the microAmes not only accurately predicts the full-plate Ames assay, but is sensitive enough to detect known mutagenic compounds. The microAmes screen is therefore an extremely valuable predictive tool that can be used with high confidence to evaluate drug candidates and impurities for genotoxicity.

1664 GENOTOXICITY ASSESSMENT USING A NEW, HIGH SPECIFICITY AND HIGH SENSITIVITY HUMAN CELL ASSAY.

R. Walmsley^{1,2}, N. Billinton¹, P. W. Hastwell³, A. Knight¹ and C. Jagger¹.
¹Gentronix Ltd., Manchester, United Kingdom, ²Faculty of Life Sciences, The University of Manchester, Manchester, United Kingdom and ³Genetic Toxicology, GSK, Ware, United Kingdom.

Recent analyses of published genotoxicity and carcinogenicity assessments make rather uncomfortable reading for genetic toxicologists: a positive result from an in vitro mammalian genotoxicity test is not a very reliable indication of potential carcinogenicity. The high sensitivity of the tests is compromised by poor specificity. This over-predictivity of carcinogenicity by the current in vitro tests results in many unnecessary in vivo tests, which waste time, money and most importantly, animals. We recently described a new in vitro reporter assay for the human GADD54a gene which provides high sensitivity along with high specificity. Assays are carried out in 96 well microplates and results are simply determined after 48 hours using spectrophotometric data. That initial work with 75 tested compounds has been published (Hastwell et al 2006).

We have now assayed over 150 compounds, comprising further carcinogens and non-carcinogens, and deliberately including many examples where other in vitro mammalian genotoxicity tests have given misleading indication of carcinogenicity hazard. Data from these more recent studies as well as data collected using imaging platforms and flow cytometry will be presented that confirm high sensitivity without loss of specificity. We shall also report on trials of robustness and reproducibility, and assays performed in the presence of S9.

1665 DEVELOPMENT OF A MIROTITER PLATE VERSION OF THE YEAST DEL ASSAY AMENABLE TO HIGH-THROUGHPUT TOXICITY SCREENING OF CHEMICAL LIBRARIES.

N. Hontzeas¹, K. Hafer² and R. Schiestl^{1,3}. ¹Pathology and Laboratory Medicine, UCLA, Los Angeles, CA, ²Biomedical Physics, UCLA, Los Angeles, CA and ³Environmental Health and Radiation Oncology, UCLA, Los Angeles, CA.

Carcinogenesis can be the result of genetic instability and DNA deletions. The yeast DEL assay is a powerful molecular tool that can be used to assess the carcinogenic potential of many compounds. We have previously demonstrated that the yeast-DEL assay correctly differentiates between carcinogens and non-carcinogens. As a further development, the DEL assay has been modified into a colorimetric assay using the MTS tetrazolium compound, to allow for efficient quantification of chemical toxicity. It has been micro-scaled and can be performed in a 96 or 384-well format. Carcinogens previously characterized with the DEL plate-based assay were utilized to test the new well-based assay. Compounds included induced a range of genotoxicity from high to very low. The well-based DEL assay could readily determine the genotoxicity of the compounds; a lack of sensitivity was only discernible at extremely low genotoxic levels as determined with the plate-based DEL assay. We suggest that this new well-based version of the DEL assay can be used as an ergonomically favorable alternative to the plate-based assay to screen a large number of compounds, such as chemical libraries in a high-throughput screening (HTS) setting.

1666 THE YEAST DEL ASSAY.

Z. Sobol and R. H. Schiestl. Pathology, David Geffen School of Medicine at UCLA, Los Angeles, CA.

Genetic instability and deletions are involved in carcinogenesis. We have constructed and/or used assays (DEL assays) that select for DNA deletion events in yeast, human cells and in vivo in the mouse. DEL events in all three formats are inducible by a wide variety of carcinogens including ones, such as benzene and PCBs, that are negative in many other short-term tests. Furthermore, the yeast DEL assay correctly differentiates between carcinogen-non carcinogen structural analogs. Of 62 chemicals of known carcinogenicity status the yeast DEL assay detects 85% correctly compared to the Salmonella assay that detects only 33% correctly. More recently we have studied a variety of chemicals with the DEL assay including clastogens, alkylators, chromium(III) and Chromium(VI) and compounds that lead to oxidative damage. The DEL assays have been used to determine dose response relations and to investigate the biological activity of carcinogens. The yeast DEL assay is being further developed into a high throughput screening format and is currently used in industrial applications in attempts to identify the potential genotoxic activity of chemicals. Further validation is ongoing. We will present a review of our published

work with the DEL assay, compare other popular genotoxicity assays and discuss the mechanisms by which DNA deletions can occur. We will also present an updated correlation between the DEL assay and animal carcinogenicity data.

1667 KINETICS OF MICRONUCLEUS INDUCTION IN PERIPHERAL BLOOD OF RATS TREATED WITH DOXORUBICIN AND ETOPOSIDE FOR THE ANALYSIS OF BIOEQUIVALENCE.

C. Wiescinski, M. Woolhiser, J. Grundy, J. Beyer and B. Gollapudi. The Dow Chemical Company, Midland, MI.

Evaluation of micronucleated reticulocytes (MN-RET) in the peripheral blood compartment of the rat is gaining acceptance as a valid alternative to conventional bone marrow micronucleus test for assessing cytogenetic damage. Recent validation studies have demonstrated that the role of rat spleen in selectively eliminating MN-RET was insignificant, especially when employing a flow cytometric methodology for enumerating the MN-RET. In this study, we evaluated the bioequivalence of two topoisomerase inhibitors with differing toxicological properties by comparing the induction of MN-RET frequencies using a flow cytometric method. Male Sprague-Dawley rats (5/dose) were given a single intravenous administration of etoposide (3, 6, or 9 mg/kg) or doxorubicin (1, 2, or 4 mg/kg) and the MN-RET in peripheral blood samples were evaluated at various intervals (24, 48, and 72 h). Cyclophosphamide (CP) served as a positive control at a single oral dose of 20 mg/kg. Peripheral blood samples were analyzed using the MicroFlow® protocol developed by Litron Laboratories. Methanol-fixed cells were treated with RNase, labeled with anti-CD71 and anti-platelet flow antibodies, and stained with propidium iodide to detect micronuclei. Samples were analyzed using a Coulter® EPICS-MCL™ flow cytometer. The MN-RET incidence peaked at 48 h for all dose levels. The highest dose of doxorubicin (4 mg/kg) and the lowest dose of etoposide (3 mg/kg) induced approximately the same magnitude of MN-RET at the 48 h sampling time (approximately 19 MN-RET per 1000 RET). The positive control chemical, CP, induced the expected increase in MN-RET (12 MN-RET per 1000 RET). These data further support the utility of rat peripheral blood for monitoring the cytogenetic damage in the bone marrow.

1668 FINDING IMPORTANT RELATIONSHIPS BETWEEN BIOLOGY AND CHEMICAL STRUCTURES BASED ON HIGH QUALITY GENETIC TOXICITY DATABASES.

S. Aveston¹, P. Dierkes¹ and C. Yang². ¹SEAC, Unilever, Sharnbrook, United Kingdom and ²Leadscope, Columbus, OH. Sponsor: P. Lee.

Data mining of toxicity databases is an important step in compound screening as well as in risk assessment. Many tasks involved in the use of databases are closely tied to data mining, hence database and data mining are essential technology pairs. Toxicity databases have a special role in predictive toxicology, providing ready access to historical information throughout the workflow of discovery, development, and product safety processes in novel product development as well as in review by regulatory agencies. To provide accurate information within a hypotheses-building environment, the content of the databases needs to be rigorously modeled using standards and controlled vocabulary. The utilitarian purposes of databases widely vary, ranging from a source for (Q)SAR datasets for modelers to a basis for "read-across" for regulators. In this poster, an example of comprehensive toxicity databases based on the combination of publicly available US FDA data with that from industry partners are used to find hidden relationships in biological endpoint profiles and their relationships with chemical structural domain. Combining data from FDA and industry partners, valuable profiles between genotoxicity and their relationships with chemical structural features are presented.

1669 THE IN VITRO HUMAN PERIPHERAL BLOOD LYMPHOCYTE MICRONUCLEUS SCREEN: A COMPARISON BETWEEN WHOLE BLOOD AND ISOLATED LYMPHOCYTES.

C. S. Farabaugh, M. A. Coleman, B. J. Harris, G. P. Stojhovic, H. Murli and L. F. Stankowski. Covance Laboratories, Inc., Vienna, VA. Sponsor: B. Fisher.

A comparative study was conducted to examine differences using whole blood (WB) and isolated lymphocytes (ILs) in the human peripheral blood lymphocyte (HPBL) micronucleus (MN) assay. Venous blood was collected and lymphocytes were purified from an aliquot of each WB sample by density gradient centrifugation. Thus, a direct comparison was made for each donor sample. Two clastogens, cyclophosphamide (CP) and mitomycin C (MMC), were evaluated with and without exogenous metabolic activation (Arochlor-induced rat liver S9), respectively. Two- or 10-mL cultures (containing 2 x 10⁶ ILs or 0.6 mL WB, respectively) were

initiated (at $t = 0$ hr) in 15-mL centrifuge tubes in RPMI 1640 containing 2% phytohemagglutinin M (PHA-M), and grown at 37°C in a humidified atmosphere of 5% CO₂ in air. Cultures were treated at 24 hr with CP (3 hr +S9) or MMC (3 and 20 hr –S9), and their concurrent solvent control. Treatment was ended by centrifugation and washing, and the cultures were re-incubated. Cytochalasin B (3 µg/mL for ILs, 6 µg/mL for WB) was added at 45 hr and the cultures were harvested at 72 hr. WB slides were stained with Giemsa and May-Grunwald; IL slides were stained with acridine orange. For each culture, 400 binucleated cells were scored for the frequency of MN (%MN-BN), and 200 total cells were scored for cytotoxicity (cytochalasin B blocked proliferation index, CBPI). Significant increases in %MN-BN were observed for each compound/treatment interval in both WB and ILs ($p < 0.05$ or 0.01). However, larger increases consistently were observed in ILs, and they reached significant levels at lower concentrations than in WB. In addition, ILs had a slower cell cycle time, indicating that the purification process may have a deleterious effect on the cells. Additional studies have been performed to compare the effect of recovery time (i.e., 96-hr harvest) on MN induction and recovery, and to select a suitable aneugenic positive control.

1670 IMPROVED CYTOTOXICITY ASSESSMENT ENHANCES THE UTILITY OF A HIGH CONTENT IN VITRO MICRONUCLEUS ASSAY.

J. C. Bemis, S. M. Bryce and S. D. Dertinger. *Litron Laboratories, Rochester, NY.*

This laboratory has described a flow cytometric method for scoring *in vitro* micronuclei [Environ. Molec. Mutagen. (2006) 47:56-66]. With this method, necrotic and mid-/late-stage apoptotic cells are labeled with ethidium monoazide (EMA). Cells are washed, stripped of their cytoplasmic membranes, and incubated with a pan-nucleic acid dye. This process provides a suspension of free nuclei and micronuclei (MN) that are differentially stained relative to chromatin associated with dead/dying cells. Experiments using a larger format *in vitro* design suggest that current methods of determining cytotoxicity, such as coulter counting, may underestimate cytotoxicity. This can lead to the inclusion of overly high concentrations of test article and an increase in the occurrence of recording false positive MN. Here, we report advances to the method aimed at acquiring concomitant cytotoxicity data in order to enhance interpretation of genotoxicity data in a miniaturized format. Experiments were performed with the genotoxins methyl methanesulfonate and mitomycin C, and the cytotoxic agents dexamethasone and staurosporine. After 24 hr continuous treatment, cells were processed for flow cytometry-based measurements of relative cell count (based on "counting beads"), cell cycle, and MN incidence based on the analysis of ≥ 5000 EMA-negative nuclei per culture. Dose-dependent MN induction was observed for each of the genotoxic agents. Induction of overt toxicity, which includes both apoptotic and necrotic processes, reveals the potential for recording spuriously high MN values. Preliminary data associated with the four disparate compounds suggests that relative to simple coulter counting, flow cytometric multiparameter cytotoxicity assessments facilitate better choices in selecting top drug concentration, thereby reducing the likelihood of false positive results. Collectively, these data suggest that high content *in vitro* MN scoring benefits from multiparameter assessments of test article-induced cytotoxicity, assessments that can be achieved concurrently with the MN scoring application.

1671 FURTHER DEVELOPMENT OF A RECONSTRUCTED SKIN MICRONUCLEUS ASSAY.

R. D. Curren¹, M. Aardema², P. J. Hayden³, G. Mun¹, T. Hu², N. Wilt¹ and D. Gibson². ¹Institute for In Vitro Sciences, Inc., Gaithersburg, MD, ²Procter & Gamble Co., Cincinnati, OH and ³MatTek Corporation, Ashland, MA.

We have previously reported initial investigations of a novel micronucleus assay which utilizes a 3-dimensional human skin model – EpiDermTM – supplied by MatTek Corporation (Ashland, MA). The advantage of this *in vitro* system is that it might potentially replace second-tier animal studies (or possibly first-tier non-specific traditional *in vitro* assays) in the genotoxicity evaluation of many materials, especially cosmetics ingredients. If so, it could then satisfy the requirement for non-animal testing of cosmetics ingredients after 2009 imposed by the European Seventh Amendment to the Cosmetics Directive. An important advantage of this assay system is that materials can be applied topically to the surface of the *in vitro* human skin model in a fashion similar to probable human exposure. In addition to previously reported positive responses with mitomycin C, vinblastine sulfate, MNNG and methyl methane sulfonate, four non-genotoxins (as shown by lack of micronucleus induction activity in an *in vivo* rodent skin model) have now been shown to induce no response in the reconstituted skin model. The non-genotoxins (4-nitrophenol, 1,2 epoxydodecane, trichloroethylene, and 2-ethyl-1,3-hexanediol) were tested up to levels of approximately 50% survival. The model has been further

characterized by measuring expression of xenobiotic metabolizing enzymes. Although many enzymes were constitutively expressed, 3-methylcholanthrene and β -naphthoflavone strongly increased expression of CYP1A1 and CYP1B1, and slightly enhanced expression of CYP2C19, CYP2D6, CYP3A4 and CYP3A5. Overall, the *in vitro* model showed an enzyme expression pattern very similar to normal human skin. It appears that this model may be very useful for detecting of micronuclei induction in a structurally complex tissue of human origin.

1672 NOVEL *IN VIVO* MUTATION ASSAY BASED ON THE ENDOGENOUS PIG-A LOCUS.

S. D. Dertinger and S. M. Bryce. *Litron Laboratories, Rochester, NY.*

Conventional approaches for measuring *in vivo* gene mutation have tended to rely on either endogenous genes such as *hprt* or else transgenes. Each method has its advantages and disadvantages. A significant advance in the field of *in vivo* mutagenesis would be the development of an assay that exhibited the best characteristics of these distinct systems: compatibility with any mammal, and no cell culture requirement. The experiments described herein were designed to test the utility of an assay that relies on glycosylphosphatidylinositol (GPI) anchored protein deficiency as a phenotypic marker of mutation at the *pig-a* locus. *Pig-a* resides on the X-chromosome, and the product is essential for anchoring GPI-linked proteins to the cell surface. The experiments described herein focused on Sprague Dawley rat erythrocytes and reticulocytes, as sufficient numbers of these cells are readily available via low volume venous draws. Fluorescent staining methods that permitted the enumeration of GPI-anchor deficient mature erythrocytes or reticulocytes via flow cytometry were developed and evaluated with reconstruction experiments. Following cell handling optimization, male Sprague Dawley rats were treated on 3 occasions (every other day) with 100 mg ENU/kg/day or 40 mg DMBA/kg/day. Peripheral blood specimens were harvested at weekly intervals for 5 weeks. Reticulocytes and total erythrocyte populations were analyzed for GPI anchored protein expression based on anti-CD59 labeling or else a pan-GPI ligand (i.e., FLAER, a fluorescent derivative of proaerolysin). All DMBA- and ENU-exposed animals exhibited elevated frequencies of GPI anchor deficient cells (ranging from 82 to 344 $\times 10^{-6}$, 310 to 647 $\times 10^{-6}$, and 0 to 70 $\times 10^{-6}$ for DMBA, ENU, and vehicle control rats, respectively). The elevated frequencies observed for the genotoxicant-exposed animals were highest in the reticulocyte subpopulation, tending to peak at 4 weeks post-exposure and plateau thereafter. These preliminary data support the hypothesis that a rapid *in vivo* mutation assay can be developed around flow cytometric analysis of GPI-anchored erythrocytes.

1673 PROTECTIVE ROLE OF METALLOTHIONEIN IN BENZO[A]PYRENE-INDUCED DNA DAMAGE AND CARCINOGENESIS.

M. Takaishi¹, M. Sawada², A. Shimada², J. Suzuki³, C. Tohyama⁵, M. Satoh⁵ and H. Nagase¹. ¹Gifu Pharmaceutical University, Gifu, Gifu, Japan, ²Department of Veterinary Pathology, Tottori University, Tottori, Japan, ³Environmental Health Sciences Division, National Institute for Environmental Studies, Tsukuba, Japan, ⁴Center of Disease Biology and Integrated Medicine, Faculty of Medicine, The University of Tokyo, Tokyo, Japan and ⁵Laboratory of Pharmaceutical Health Sciences, School of Pharmacy, Aichi Gakuin University, Nagoya, Japan.

We investigated the role of metallothionein (MT) in benzo[a]pyrene (B[a]P)-induced DNA damage and forestomach carcinogenesis using MT-I/II null mice and wild-type mice. Ten-week-old male MT-I/II null mice and wild-type mice were orally treated with B[a]P 250 mg/kg and sacrificed at 6, 12, 24, 48 h after the administration. Micronucleus (MN) in the reticulocytes and 8-hydroxy-2'-deoxyguanosine (8-OHdG) in the liver were determined as indicator of DNA damage. At the 48 h after B[a]P administration, MN frequency in MT-I/II null mice was significantly increased compared with that in wild-type mice. Hepatic 8-OHdG level in MT-I/II null mice was significantly increased at 6 and 12 h after B[a]P administration, although wild-type mice were only slight changed. To study the suppressive effect of MT inducer on B[a]P-induced DNA damage, mice were subcutaneously administered ZnSO₄ once a day for 2 days and orally treated with B[a]P at 24 h after the last injection of ZnSO₄. B[a]P-induced MN frequency was reduced by ZnSO₄ pretreatment in the wild-type mice but not in the MT-I/II null mice. To study the sensitivity of MT-I/II null mice to B[a]P-induced carcinogenesis, MT-I/II null mice and wild-type mice were orally treated with B[a]P (100 mg/kg) twice a week for 4 weeks and sacrificed at 32 weeks after the last administration. Tumor incidence of MT-I/II null mice and wild-type mice was 100% and 78.6%, respectively. Tumor area of MT-I/II null mice was about 2.6 fold larger than wild-type mice. These results suggest that MT can protect B[a]P-induced DNA damage and forestomach carcinogenesis.

1674 INHIBITION OF DIHYDROOROTATE DEHYDROGENASE, AN ENZYME OF THE DE NOVO PYRIMIDINE SYNTHESIS PATHWAY, LEADS TO INDUCTION OF MICRONUCLEI BY NON-DNA REACTIVE MECHANISM VIA NUCLEOTIDE POOL IMBALANCE.

A. Czich¹, K. Braun¹, I. Stammberger¹, Z. Javvosi², M. Ouldclhkim³, V. Thybaud³ and L. Davenport². ¹*Drug Safety Evaluation, sanofi-aventis, Hattersheim, Germany*, ²*Drug Safety Evaluation, sanofi-aventis, Bridgewater, NJ* and ³*Drug Safety Evaluation, sanofi-aventis, Alfortville, France*.

Dihydroorotate dehydrogenase (DHODH) is the fourth enzyme of de novo pyrimidine synthesis, catalyzing the oxidation of dihydroorotate to orotate. The purpose of the study was to investigate the genotoxic potential of the DHODH inhibitor brequinar (IC₅₀ value ~ 100 ng/ml) and the possibility of a non-DNA reactive mechanism that could be antagonised by uridine supplementation of the test system.

In cell proliferation and DNA synthesis assays with L5178Y cells, it could be demonstrated that brequinar induced inhibition of cell proliferation, measured by BrdU incorporation. Uridine concentrations of 30 µg/mL were able to reverse cytotoxic potential of brequinar at concentrations up to 50 µg/mL. At 100 µg/mL the cytotoxicity of brequinar could not be reversed by Uridine supplementation.

The genotoxic potential of brequinar was investigated in a micronucleus assay conducted in L5178Y cells. Strong cytotoxic effects (population doubling ≤ 50 %) were observed at 49 ng/ml and above after 24 h treatment with brequinar in the absence of uridine. In parallel, the number of micronucleated cells was significantly increased at 49 and 98 ng/ml. In the presence of 30 and 100 µg/mL uridine the cytotoxicity was 1000 times less pronounced. Clear cytotoxic effects were observed only at 50 – 100 µg/mL brequinar. No induction of micronuclei was detected in the presence of Uridine even at highly cytotoxic concentrations (population doubling ~ 30%).

These results demonstrate that when the inhibition of pyrimidine synthesis is bypassed by the addition of uridine, neither cytotoxicity nor genotoxicity occurs. In conclusion, DHODH Inhibitors must be regarded as non-DNA reactive genotoxins, able to impact chromosomes via an exaggerated pharmacological activity.

1675 EVALUATION OF ALPHA-IONONE IN AN *IN VIVO* MOUSE MICRONUCLEUS TEST.

D. McGinty, A. Api and V. T. Politano. *RIFM, Woodcliff Lake, NJ*.

alpha Ionone, a widely used fragrance ingredient was tested in an *in vivo* mouse micronucleus assay to evaluate the clastogenic potential as measured by its ability to induce micronucleated polychromatic erythrocytes in mouse bone marrow. This test is a short-term *in vivo* cytogenetic assay for detecting agents that induce chromosomal breakage and spindle malfunction. In the dose range-finding phase, a dose of 1200 mg/kg was estimated to be the maximum tolerated dose. The definitive micronucleus study consisted of several groups, each containing 5 male and 5 female ICR mice. The control groups were treated with the vehicle, corn oil, or cyclophosphamide monohydrate (CP) at 50 mg/kg as the positive control. α-Ionone was also tested at dosages of 300, 600, or 1200 mg/kg. Both the test and control articles were administered at a dose volume of 20mL/kg body weight by a single intraperitoneal injection and all animals were euthanized 24 hours after treatment. Bone marrow cells (polychromatic erythrocytes, PCEs) were collected 24 and 48 hours after the treatment and examined microscopically for the presence of micronuclei. Reductions (up to 21%) in the ratio of PCEs to total erythrocytes were observed and suggest bioavailability of the test article to the bone marrow target. There was no statistically significant increase in the incidence of micronucleated polychromatic erythrocytes observed in test article treated groups relative to respective vehicle control groups. Therefore, α-Ionone as a single intraperitoneal administration at doses up to and including 1200 mg/kg did not induce a significant increase in either male or female ICR mice and may be concluded as negative in the mouse micronucleus assay.

1676 THE GENETIC TOXICITY OF DIISOCYANATES IN HUMANS AND LABORATORY ANIMALS.

E. Zeiger¹ and M. Woolhiser². ¹*Errol Zeiger Consulting, Chapel Hill, NC* and ²*The Dow Chemical Company, Midland, MI*.

Published *in vivo* genetic toxicity studies of methylene diisocyanate (MDI) and toluene diisocyanate (TDI) were reviewed to assess the potential for genotoxic effects from workplace exposures. These high production volume chemicals are used in manufacturing polyurethane foams, plastics, paints, adhesives and other products. Volunteers (previously exposed) demonstrated low levels of DNA damage in peripheral lymphocytes after MDI administration as measured by an electrophoresis method, but the Comet assay was negative. Positive results were confounded by

factors such as asthmatic responses, hypoxia, and concurrent medication in the participants. Authors speculated that immune responses and oxidative stress would have contributed to DNA damage rather than a direct interaction of isocyanate with DNA. Occupational exposure studies showed some weak cytogenetic effects, but suffered from some of the same confounders, and some effects could not be separated from other chemical exposures, including some known clastogens (e.g., benzene). Diisocyanates are reactive and there are a number of studies showing reaction with proteins at the site of exposure while producing no-to-minimal DNA binding. Studies with TDI in rodents elicited positive and negative responses for micronuclei and sister chromatid exchange, but not for aberrations, using peripheral lymphocytes. Positives were weak, sometimes non-dose related or associated with signs of toxicity, and often not reproducible. MDI yielded primarily negative micronucleus results except in one study, but this was not replicated by a different laboratory using the same protocol and rat strain. DNA adducts were at the level of detection and could not be clearly distinguished from background levels and incorporation of labeled metabolites. In summary, little confidence can be placed in the weak positive DNA fragmentation results as indication of direct DNA damage by diisocyanates. There remains insufficient evidence to conclude that MDI or TDI are genotoxic to humans *in vivo*. This review was sponsored by the International Isocyanate Institute, Inc.

1677 PELARGONIC ACID MORPHOLIDE – GENOTOXICITY AND INFLUENCE ON THE REPRODUCTIVE FUNCTION.

N. V. Lapina. *The Institute of Toxicology, St Petersburg, Russian Federation*. Sponsor: K. Khamidulina.

The aim was to appreciate the possible genotoxic effect and influence on reproductive function of pelargonic acid morpholide (PAM). Studies were performed on un-bred white rats female. Investigated object was liquid mixture which containing PAM intended for filling out self-defense gas weapons. Genotoxic effect was evaluated after an intraperitoneal administration of PAM with dose 1/100 LD₅₀ according to DNA leucocytes indexes and hematological parameters. Experiments of PAM influence study on reproductive function were performed on pregnant female rats. The animals received intragastrically the PAM containing mixture with the dose 1/20 LD₅₀ every day during all pregnancy.

Evaluation of embryotoxic effect carried out according to death of fetuses, before-implantation and post-implantation, general embryonal mortality as well length and weight fetuses. The index of chemical factors influence was a coefficient of induced embryo death.

Results: The single intraperitoneal administration of the PAM mixture resulted in increase of lymphocyte amount in peripheral blood up to 60% in 24 hours and decrease of DNA index (in 24 hours and 30 days). General embryonal mortality was increased 2.3 times, including before-implantation – 2.2 times, and post-implantation – 3.2 times. High percent age of induced death was revealed.

Conclusion: The single intraperitoneal administration of the PAM mixture with dose 1/100 LD₅₀ resulted in early genotoxic effects in female blood detectable in the 30th day after exposure that allowed assuming the presence of a prolonged genotoxic sequels. The every day intragastric administration of the PAM mixture to pregnant rat females during the whole period of pregnancy led to true disturbances of reproductive function.

1678 MUTAGENIC ACTIVITY IN THE HPRT LOCUS OF LEUKEMIA HL-60 CELLS TREATED WITH SUCCINYL ACETONE.

K. Zheng^{1,2}, K. Phouthone^{2,1} and M. Ariizumi¹. ¹*Department of Environmental and Preventive Medicine, Faculty of Medicine, University of the Ryukyus, Okinawa, Japan* and ²*Environmental and Occupational Health, University of Pittsburgh, Pittsburgh, PA*.

Succinyl acetone (SA) was initially identified in the urine of patients with tyrosinemia type 1, an autosomally recessive inherited disease. SA has been used to down-regulate the activity of myeloperoxidase (MPO) through its specific inhibition of heme biosynthesis and to investigate the biological properties of MPO in human myeloid leukemic (HL-60) cell line. The goal of this study is to evaluate the mutagenic potential of SA by determining the frequencies of somatic mutations in the hypoxanthine-guanine phosphoribosyl transferase (HPRT) reporter gene in HL-60 cells following treatment with the chemical. Treatments of HL-60 cells with 500 µM SA for 72 hours, a condition generally used to inhibit the MPO activity, resulted in a significantly increased HPRT mutant frequency (HPRT-Mf), compared with the control of untreated cells (47.25 × 10⁻⁶ versus 7.5 × 10⁻⁶, respectively, P < 0.01). Treatment of the cells with lower doses of SA also led to an increase in HPRT-Mf that is, however, significant only with 200 µM (28.67 × 10⁻⁶, p < 0.05) and not with doses lower than 100 µM (p > 0.05), compared with the control of untreated cells (7.5 × 10⁻⁶). These data show a dose-response increase in HPRT-Mf in HL-60 cells treated with SA, suggesting this chemical is mutagenic in these cells.

1679 DEVELOPMENT OF A HUMAN PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODEL FOR INORGANIC ARSENIC AND ITS MONO- AND DIMETHYLATED METABOLITES.

H. El-Masri and E. M. Kenyon. NHEERL/ETD/PKB, U.S. EPA, Research Triangle Park, NC.

A physiologically-based pharmacokinetic (PBPK) model was developed to estimate levels of arsenic and its metabolites in human tissues and urine after oral exposure to either arsenate (AsV) or arsenite (AsIII). The model consists of interconnected individual PBPK models for Asv, AsIII, monomethylarsenic acid (MMAv), and dimethylarsenic acid (DMAv). Reductions of MMAv and DMAv to their respective trivalent forms are also described in the overall model. Each submodel was constructed using flow limited compartments describing the mass balance of the chemicals in GI tract (lumen and tissue), lung, liver, kidney, muscle, skin, heart, and brain. The choice of tissues was based on physiochemical properties of the chemicals (solubility), exposure routes, and target and metabolic sites of inorganic arsenic and its metabolites. Metabolism of inorganic arsenic in liver was described as a series of reduction and oxidative methylation steps, in addition to the inhibitory influence of the metabolites on methylation. The inhibitory effects of AsIII on the methylation of MMAIII to DMA, and MMAIII on the methylation of AsIII to MMA were assumed to follow a noncompetitive mechanism. Most of the parameters used in the model were estimated from the literature. The remaining parameters were calibrated and evaluated using cumulative levels of inorganic arsenic and its metabolites in urine of exposed people. The calibrated and evaluated human PBPK model can be used, when combined with Monte-Carlo simulations, in identifying population-based distributions for some sensitive parameters (such as metabolic rate parameters differing due to genetic polymorphisms) and address the impact of these distributions on the human risks to arsenic exposure. (This abstract does not necessarily reflect EPA policy.)

1680 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR THREE DIHALOACETATES.

J. L. Matthews¹, M. R. Easterling¹, G. E. Kissling² and R. L. Melnick².
¹Constella Group, LLC, Durham, NC and ²NIEHS, Research Triangle Park, NC. Sponsor: K. Heim.

Dihaloacetates (DHAs) occur as water disinfection byproducts commonly present in public water supplies leading to widespread exposure. Dichloroacetic acid (DCA), dibromoacetic acid (DBA), and bromochloroacetic acid (BCA) are all metabolized mainly by glutathione transferase zeta (GSTzeta). A physiologically based pharmacokinetic model was developed in support of the National Toxicology Program (NTP) bioassays for DBA and BCA. A single model was developed to enhance the understanding of the kinetics of these three structurally similar dihaloacetates. The PBPK model has flow-limited compartments representing kidney, liver, stomach, and other aggregated tissues. Elimination of parent and metabolite compounds occurs through urine or biotransformation. This model examines the biotransformation of BCA, DCA, and DBA to the metabolites glyoxalate (GXA) and oxalate (OXA) in detail. GSTzeta synthesis and degradation as well as GXA and OXA production external to the metabolism of the dihaloacetates are included. Molecular interactions of GSTzeta and the DHA derivative compounds are modeled including the covalent binding of an intermediate DHA metabolite with GSTzeta which effectively inactivates the enzyme. This suicide inhibitory behavior is characteristic of the dihaloacetates. Additionally for BCA, the model allows for stereospecific treatment of the BCA(+) and BCA(-) isomers due to published evidence of toxicokinetic behavioral differences between them. Model parameters not available from the literature were fit to the DHA, GXA, and OXA data available from IV, gavage, and drinking water studies. To evaluate the accuracy of this model, predictions are measured against data not used during parameter estimation. In particular, simulations of two-week drinking water exposures followed by a subsequent gavage challenge are compared to data.

1681 A PHYSIOLOGICAL MODEL DESCRIBING TISSUE DOSIMETRY OF INHALED SULFURYL FLUORIDE AND ITS METABOLITES FLUOROSULFATE AND FLUORIDE IN RAT.

T. S. McMullin¹, M. Bartels¹, D. Markham¹ and D. Eisenbrandt². ¹Toxicology and Environmental Research and Consulting, The Dow Chemical Company, Midland, MI and ²Dow AgroSciences LLC, Indianapolis, IN.

Sulfuryl fluoride (SF) is a structural and post-harvest fumigant used to control a wide variety insect pests. SF is a key alternative to methyl bromide, a stratospheric ozone depleting substance scheduled for phaseout by the Montreal Protocol. Repeated inhalation exposures to relatively high levels of SF cause inflammation of the nasal mucosal and lower respiratory tract and reversible neurological effects in

rodents. Although the mode of action of SF-mediated neurotoxicity is not clearly understood, the metabolic profile after inhalation exposure to SF suggests that the toxicity is likely due to metabolites of SF rather than parent compound. A preliminary physiologically based pharmacokinetic (PBPK) model describes the time-course concentrations of SF and its metabolites fluorosulfate (FS) and fluoride (F) in blood/plasma, tissues and urine during and after 4-hr inhalation exposures to 30 or 300ppm SF. Systemic uptake of SF is limited by extensive deposition and/or hydrolysis along the respiratory mucosa and/or rapid hydrolysis in the blood. Parent SF is not detectable in the blood immediately following inhalation exposure. Time-course concentrations of FS in blood and urine are described in the model as dose-dependent and primarily regulated by hydrolysis to F and elimination in urine. Appearance of F in plasma occurs by hydrolysis of SF and FS and removal from plasma occurs via urinary elimination and sequestration into bone. These model descriptions are consistent with data from our laboratory indicating that SF is rapidly hydrolyzed in blood ($t_{1/2} < 3$ min) while metabolism of FS to F is estimated to occur at a rate approximately one-half that of SF to FS. This current model provides an initial framework for examining the low-dose kinetic behavior of SF and its metabolites during and following exposure to SF and extending the model description to address possible pre-systemic clearance mechanisms of SF along the respiratory mucosa.

1682 APPLICATION OF A UNIFIED PBPK MODEL TO TWO KINETICALLY DISTINCT PHTHALATE ESTERS - DBP AND DEHP.

R. A. Clewell¹, S. J. Borghoff² and M. E. Andersen³. ¹Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Research Triangle Park, NC, ²Integrated Laboratory Systems, Research Triangle Park, NC and ³Computational Biology, CIIT Centers for Health Research, Research Triangle Park, NC.

Phthalate diesters are widely used plasticizers and environmental contaminants. Human exposure occurs primarily through drinking water and food consumption. Certain phthalates, such as di-n-butyl phthalate (DBP) and di-2,4-ethylhexyl phthalate (DEHP), disrupt testosterone dependent male rat sexual development. Recently, a PBPK model was developed in the non-pregnant and pregnant rat describing serum, urine, bile and fecal data for DBP, MBP and the glucuronide and oxidative metabolites across doses, routes and life-stages. With the exception of reduced maternal UGT activity, kinetic parameters did not differ in the naive and pregnant rat. For this model to be useful for risk assessment, however, it must account for simultaneous exposure to more than one phthalate. Despite similar toxicity, DEHP and DBP have very different metabolite kinetics. To use the DBP model for DEHP, it was necessary to reduce DEHP hydrolysis in the gut (10 v. 150 mg/kg-hr) and increase the capacity for oxidative metabolism of MEHP (30 v. 1 mg/kg-hr) based on in vitro data. UGT activity (maternal and fetal) was turned off based on in vivo excretion data. These changes allow the model to describe reduced bioavailability (30 vs. 0% of diester in feces) and enterohepatic recirculation (4% vs. 30% of dose in bile), and faster clearance of the monoester. Serum MEHP kinetics were well-described after a single iv or oral MEHP (20 - 400 mg/kg) or DEHP dose (30 - 2000 mg/kg). Using the same placenta/fetal transfer parameters as DBP, the model successfully predicted maternal serum MEHP time-course data after a DEHP dose on GD 20 and amniotic fluid MEHP levels on GD 18 after 10 daily doses of 300 mg/kg DEHP (3 mg/L). This suggests that the model may be successfully applied to other phthalates using in vitro metabolism data where in vivo data is not available, thereby facilitating a more integrated risk assessment for the phthalate family.

1683 A PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR DEVELOPMENTAL EXPOSURE TO PBDE-47 IN RODENTS.

C. Emond¹, J. Raymer², E. Garner², J. J. Diliberto³, D. Staskal⁴ and L. S. Birnbaum³. ¹Environmental and Occupational Health, University of Montréal, Montréal, QC, Canada, ²RTI International, Research Triangle Park, NC, ³ORD/NHEERL, U.S. EPA, Research Triangle Park, NC and ⁴Curriculum in Toxicology, UNC, Chapel Hill, NC.

Polybrominated diphenyl ethers (PBDEs) are used commercially as additive flame retardants and have been shown to transfer into environmental compartments where they have the potential to bioaccumulate in wildlife and in people. Of the 209 PBDE congeners, approximately 5 dominate the profiles measured in humans, particularly 2,2',4,4'-tetrabromodiphenyl ether (BDE 47), demonstrating a need to understand the toxicokinetic properties associated with this class of chemicals. A small subset of the PBDES have been investigated in toxicokinetic studies; these studies have shown that binding proteins, elimination, adipose tissue mass, and placenta transfer may all play roles in the distribution of PBDEs. The aim of this work was to develop a developmental PBPK model for BDE-47 in mice and rats with the perspective of extrapolating the model to humans. The model consists of seven

compartment including liver, brain, fat, kidney, placenta/foetus, blood and rest of the body. Parameters such as tissue volumes, flow flows, and partition coefficients were extracted from previously reported studies. Optimization was performed using mouse exposure data for adult female and neonates determined in our laboratory. The optimized model was extrapolated to rats and validated using data from the literature. The model validation used experimental data from acute and subchronic exposures prior to and during gestation. The simulations predict that BDE-47 tissue concentrations in the maternal compartments are within the standard deviation of the experimental data. This PBPK model presented here is the first reported for any PBDE. This model may provide a framework for the development of a human PBPK model to predict both adult and developmental PBDE concentrations for use in risk assessments. (This abstract does not reflect Agency policy. Supported in part by EPA cooperative agreements CR830756 and DESE CT 826513.)

1684 PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELING OF INHALED MANGANESE IN RATS.

A. Nong, D. C. Dorman, H. J. Clewell and M. E. Andersen. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Manganese (Mn) is an essential element found in food, water and air. Mn-containing fuel additives introduce small amounts of Mn particulates into the atmosphere after combustion. Symptoms of central nervous system toxicity from Mn are known to occur at high concentration inhalation exposures. However, Mn is an essential element, required for normal tissue growth and function. Tissue [Mn] is closely regulated to prevent accumulation to toxic levels. The purpose of this research is to develop a pharmacokinetic model to describe the regulation of tissue [Mn] in the face of increasing concentrations of inhaled manganese. We have developed a PBPK model to describe the tissue kinetics of Mn following inhalation of Mn by rats. Each tissue compartment had shallow and deep regions to describe discrete tissue Mn stores. The PBPK model parameters were calibrated using dietary data for tissue Mn in rats following 14 days of inhalation exposure to MnSO_4 at specific doses. The steady state levels of Mn predicted by the PBPK model were tested against rat tissue measurements at dietary intakes of 2, 10 and 100 ppm of Mn. Dose dependent hepatic biliary excretion, noted in other studies, was then necessary to regulate the tissue levels of Mn in rats measured following 14 days of inhaled exposure to 0.0, 0.03, 0.3 mg Mn/m³. The hepatic controller in the model consisted of an empirical adjustment of biliary elimination rate constants of Mn based on net daily uptakes from ingestion and inhalation. At the highest inhalation exposure, the hepatic Mn controller increased the bile excretion rate constant in the PBPK model by a factor of 10 times the steady state rate. This PBPK model with the control by enhanced biliary excretion control was able to predict tissue regulated Mn levels in rats following inhalation. Multi-dose route PBPK models for Mn will provide support for the evaluation of tissue-dose based risk assessment of this essential metal.

1685 EVALUATION OF ADULT-NEONATE DIFFERENCE IN METABOLIC INTERACTIONS AMONG ALKYL BENZENES (ABS) USING A MIXTURE PBPK MODEL.

T. Adamou¹, S. Haddad² and K. Krishnan¹. ¹*SEST, University of Montréal, Montréal, QC, Canada* and ²*Université du Québec à Montréal, Montréal, QC, Canada.*

A physiologically-based pharmacokinetic (PBPK) model for mixtures of ABs (toluene (T), m-xylene (X) and ethylbenzene (E)) has previously been developed and validated in rats and humans. This PBPK model, accounting for physiological and metabolic differences between rats and humans, provided simulations of the extent of metabolic interactions among the ABs. The objective of the present study was to evaluate adult-neonate differences in metabolic interactions among ABs using this mixture PBPK model. The approach involved the substitution of physiological parameters (cardiac output, breathing rate, tissue volumes and blood flows) in the previously validated adult PBPK model while considering physicochemical parameters as age-invariant, based on available data. The maximal velocity of metabolism of ABs was computed on the basis of the hepatic CYP2E1 protein content in neonates relative to adults. For this purpose, the subject-specific data on CYP2E1 in neonates (≤ 1 month old) were obtained from published literature. The mixture PBPK model, with the physiological and metabolic data for neonates, was used to simulate the inhalation kinetics of ABs previously evaluated in adults (1-17 ppm T, 1-33 ppm X and 1-33 ppm E; 7 hr). The simulated peak venous blood concentrations (C_{max}) of ABs were greater in neonates compared to adults by a factor of <2 . However, the additional change in C_{max} during mixed exposures in neonates (upto a factor of 1.4 for a mixture of 17 ppm T + 33 ppm X + 33 ppm E; 7 hr) depended upon the subject-specific content of CYP. There was considerable interindividual variation in both neonates and adults such that the subject-specific

magnitude of metabolic interaction was primarily influenced by the CYP content as well as the relative importance of perfusion and enzyme content in the hepatic clearance of ABs. Overall, this study showed that the extent of metabolic interactions can be predicted using PBPK models as a function of hepatic enzyme content and age-dependent physiological data.

1686 PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING OF METABOLIC INHIBITION FOR INTERACTION BETWEEN TRICHLOROETHYLENE AND CHLOROFORM.

M. V. Evans¹, H. M. Yang², K. A. Yokley³, T. McDonald¹, Y. Sey¹ and J. E. Simmons¹. ¹*ORD, U.S. EPA, Research Triangle Park, NC,* ²*NIOSH, Morgantown, WV* and ³*UNC, Chapel Hill, NC.*

Trichloroethylene (TCE) and chloroform (CHCl_3) are two of the most common environmental contaminants found in water. PBPK models have been increasingly used to predict target dose in internal tissues from available environmental exposure concentrations. A closed inhalation (or gas uptake) system was used to estimate metabolic parameters using male F344 rats at different initial concentrations. Individual chemicals were first tested separately using the following initial concentrations: 100, 500, 1000, and 3000 ppm. The decrease in chamber concentration reflecting metabolism was measured for up to 6 hours. A PBPK model was then used for each individual data set to obtain the metabolic parameters describing saturable metabolism, V_{max} (maximum velocity of reaction) and K_m (affinity constant). The next set of experiments described co-exposure of different binary combinations, including 500 ppm for both chemicals, 500 ppm TCE and 10 ppm of CHCl_3 , and 500 ppm TCE with 2000 ppm CHCl_3 . PBPK modeling was used to test three types of different metabolic inhibition: competitive, uncompetitive and noncompetitive. Results of the simulations suggest that competitive inhibition gives the closest agreement between the inhalation data and the simulations, resulting in an inhibition constant (K_i) of 0.33 mg/liter, which is similar to the K_m value of 0.36 mg/liter. This interaction model was used to identify sensitive parameters for the design of future experiments. In summary, PBPK modeling results were consistent with competitive inhibition for TCE and CHCl_3 co-exposure, leading to an overall decrease in metabolism when both chemicals are present simultaneously. (This abstract does not reflect EPA policy. Research support for Karen Yokley is provided by grants EPA T829472 and EPA CT833237.)

1687 ESTABLISHING CHANGES IN METABOLISM OF CARBON TETRACHLORIDE IN THE PRESENCE OF TRICHLOROETHYLENE IN THE RAT THROUGH THE USE OF PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING.

K. A. Yokley¹, M. V. Evans² and J. E. Simmons². ¹*Curriculum in Toxicology, University of North Carolina, Chapel Hill, Durham, NC, NC* and ²*U.S. EPA, ORD-NHEERL-ETD-PKB, Research Triangle Park, NC.*

Toxicological interactions of chemicals can affect metabolism, often decreasing overall associated metabolic rates; and changes in metabolism can be evaluated through the use of mathematical models. Trichloroethylene (TCE) and carbon tetrachloride (CCl_4) are common contaminants in water and at superfund sites. A closed inhalation (or gas uptake) system was used to collect metabolic data using F344 rats at various initial concentrations of TCE and CCl_4 . The initial concentrations used for the exposures were: 25 ppm CCl_4 and 1000 ppm TCE, 25 ppm CCl_4 and 100 ppm TCE, 100 ppm CCl_4 and 500 ppm TCE, 100 ppm CCl_4 and 1000 ppm TCE, and 1000 ppm CCl_4 and 500 ppm TCE. This particular binary mixture pair is an example of metabolic synergy as opposed to the more common metabolic inhibition expected during exposure to multiple chemicals. A previously developed physiologically based pharmacokinetic (PBPK) model of carbon tetrachloride in the rat was verified to fit with gas uptake data for CCl_4 alone (with initial concentrations of 25 ppm, 100 ppm, 250 ppm, and 1000 ppm) and then used to simulate chamber concentration predictions for the aforementioned mixtures. In order to fit chamber concentration data for CCl_4 when administered with TCE, the parameter of the maximum rate of metabolism (V_{max}) was increased. An increase of 2.8 times the V_{max} value from the original model of carbon tetrachloride alone produced reasonable predictions for mixture data with higher concentrations (500 ppm or 1000 ppm) of TCE, and an increase of 1.4 times the original V_{max} worked well at predicting CCl_4 chamber concentration for mixtures with 100 ppm TCE. The increase in V_{max} suggests that metabolism of carbon tetrachloride is amplified by the presence of trichloroethylene and that this amplification is dose-dependant. (This abstract does not reflect EPA policy. Research support for Karen Yokley is provided by grants EPA T829472 and EPA CT833237.)

1688 PBPK MODELING ASSESSMENT OF THE COMPETITIVE METABOLIC INTERACTIONS FOR M-XYLENE, ETHYLBENZENE, AND A LUMPED AROMATIC FRACTION OF JP-8 JET FUEL VAPOR.

J. L. Campbell and J. W. Fisher. *Environmental Health Science, University of Georgia, Athens, GA.*

Jet Propellant 8 (JP-8), a kerosene-based jet fuel used in the military, is composed of hundreds of hydrocarbons. A PBPK model was developed to assess the metabolic interactions of JP-8 vapor on two prominent aromatic constituents of JP-8 vapor, m-xylene (XYL) and ethylbenzene (EBZ). A limited number of rats were exposed to JP-8 vapor in a Leach chamber for 4 hr to 390, 1100, or 2700 mg/m³. The chamber atmosphere was monitored during exposure with several individual hydrocarbons being quantified, including XYL, EBZ and the total hydrocarbon concentration. Blood and liver was harvested (end of exposure and 0.5 h post exposure) and analyzed by a novel headspace SPME/GC-MS method which allowed for identification and quantification of low levels of individual hydrocarbons. The PBPK model was able to describe both the single exposure data previously published for XYL and EBZ as well as the metabolic interactions between XYL, EBZ and a lumped aromatic fraction of JP-8 vapor that was estimated to be approximately 25% of the fuel vapor. Competitive inhibition of XYL and EBZ metabolism was observed for JP-8 vapor inhalation exposures of 1100 and 2700 mg/m³. Future inhalation studies with jet fuel include aerosol exposures and expansion of the PBPK models to include other hydrocarbons such as n-alkanes and upper respiratory tract dosimetry of aerosol droplets.

1689 PHYSIOLOGICALLY-BASED TOXICOKINETIC AND TOXICODYNAMIC (PBTK/TD) MODELING OF A TERNARY ORGANOPHOSPHORUS INSECTICIDE MIXTURE IN RATS: MODEL DEVELOPMENT AND VALIDATION.

J. T. Pittman and J. E. Chambers. *Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.*

A PBTK/TD model was developed, from the open literature, to predict the toxicokinetic disposition and toxicodynamic response (acetylcholinesterase inhibition) of a ternary OP insecticide mixture: chlorpyrifos (CP), methyl parathion (MP) and parathion (P). In vivo studies were conducted in adult male Sprague-Dawley rats, orally administered a CP/ MP/ P mixture (2.5, 0.5, 0.5, or 5, 1, 1 mg/kg, respectively) with selected tissues (blood, brain, diaphragm, liver, lung and skeletal muscle) collected at 30min, 4, 12 and 24hr postdosing. Low dosages were studied so the mixture did not result in significant disruption of cardiovascular function nor invalidate the model's underlying general physiological assumptions. The data were used to validate the model. The metabolites of CP (CP-oxon, 3,5,6-trichloro-2-pyridinol (TCP)), and both MP and P (their respective oxons and 4-nitrophenol), were quantified in the tissues of interest. Peak concentrations of CP were attained by 4hr in all tissues with the exception of the liver, whose peak occurred at 30min; this was supported by the model simulations. MP, P, and their respective oxons were below limits of quantitation for the lower dosage, however, were quantifiable at the higher dosage. No toxicokinetic interactions were observed. Cholinesterase inhibition in the tissues ranged from 11- 37% for the lower dosage, and 29-93% for the higher dosage group; with few exceptions, inhibition was generally additive and was also supported by the model simulations. This study demonstrates the utility of using previously developed individual PBTK/TD models and in vitro/ in vivo data from the open literature to construct reliable mixture PBTK/TD models.

1690 BAYESIAN PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC (PBPK/PD) MODELING OF MIXED ROUTE EXPOSURE OF CARBARYL.

H. J. Clewell, A. Nong and Y. Tan. *CIIT Centers for Health Research, Research Triangle Park, NC.*

Bayesian techniques enable characterizing uncertainty and variability based on prior and experimental information applicable for risk assessment of pesticides. Amongst the N-methyl carbamate family of pesticides under re-evaluation is carbaryl, a common insecticide which reversibly inhibits neuronal cholinesterase activity where the extent of knowledge is indeterminate. The objective of this work was to estimate biologically relevant doses associated with cholinesterase activity through Bayesian modeling of the carbaryl pharmacokinetics following different exposure scenarios. A physiologically-based pharmacokinetic and pharmacodynamic (PBPK/PD) model for carbaryl was developed to estimate tissue doses of carbaryl and its metabolites (1-naphthol and other hydroxylated metabolites) and particularly the cholinesterase activity in blood and brain. A Markov Chain Monte Carlo (MCMC) technique was implemented to characterize distributions of model

physiological and biochemical parameters (mean, variability, and uncertainty). Calibration of model parameters was obtained using prior literature distributions, experimental tracer data of carbaryl and its metabolites, and inhibition of cholinesterase activity measurements in rats which were exposed by dermal, oral, and intravenous routes at low and high doses ranging from 0.8 to 103 mg/kg body weight. Based on the experimental data, the converged posterior estimates of the model parameters displayed less than 0.5 fold deviations from the mean values. Monte Carlo simulations with the resulting MCMC posterior estimates and PBPK/PD model adequately predicted the tissue doses of carbaryl and 1-naphthol as well as the cholinesterase inhibition by carbaryl with an interval of confidence less than 1 fold deviation from the mean. The Bayesian PBPK/PD modeling approach developed here will serve as a prototype for developing mechanism-based risk models for other N-methyl carbamates.

1691 BAYESIAN ANALYSIS OF HUMAN TOLUENE PBPK MODEL AT STEADY-STATE.

T. Peyret and K. Krishnan. *SEST, University of Montréal, Montréal, QC, Canada.*

Bayesian statistical approaches are relevant for characterizing the population distribution of pharmacokinetic determinants and tissue dose of chemicals. Chronic inhalation exposure to volatile organic chemicals (VOCs) leads to the onset of steady-state, at which the blood and tissue concentrations of the parent chemical are constant. The steady-state blood concentration (C_{ss}) might vary among individuals as a function of the population variability of critical determinants. The objective of this study was to conduct Bayesian analysis of the inhalation pharmacokinetics of toluene using a human PBPK model at steady-state. At steady-state, the blood concentrations are influenced by alveolar ventilation rate, liver blood flow, blood:air partition coefficient and intrinsic clearance. The prior information on these input parameters for the toluene PBPK model was obtained from the literature. The algebraic equation representing the steady-state PBPK model was written in Winbugs (version 1.4; MRC and Imperial College of Science, Technology and Medicine, Cambridge, U.K.) software for conducting Markov chain Monte Carlo (MCMC) simulations. The mean and variability of C_{ss} of toluene observed in a human volunteer study (n=4) was used as a basis to create a distribution (normal) from which 16 samples were drawn using Monte Carlo approach. Based on these individual C_{ss}, MCMC simulations were conducted and the convergence of the posterior estimates of the parameters was obtained after 10000 iterations. Monte Carlo simulations were then carried out using Crystal Ball 7 (Decisioneering, Denver, CO) with the MCMC-generated posterior density estimates of input parameters. The calculated C_{ss} values compared well with the individual and population values. Overall, this study has demonstrated the feasibility of conducting MCMC simulations of C_{ss} using WinBugs, particularly during data-poor situations.

1692 STATISTICAL APPROACHES FOR EVALUATION OF PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELS.

S. Haddad¹, M. Verner¹ and K. Krishnan². ¹sciences biologiques, TOXEN, Université du Québec à Montréal, Montréal (c)al, QC, Canada and ²GRIS/TOXHUM, Université de Montréal, Montréal (c)al, QC, Canada.

PBPK model evaluation is a crucial step in its development since it ensures that the conceptual and functional representations of the real system are adequate to yield reasonable simulations in the range of its intended use. Unfortunately, the model evaluation step is often limited to a subjective analysis consisting of visually comparing simulations to experimental data. The objective of the present study was to investigate the applicability of different statistical methods for the evaluation of PBPK models. Amongst the various statistical methods, three were selected for the present study: i) the lack of fit F-test, ii) the bootstrap with bias-corrected (α) (BC α) confidence intervals, and iii) regression analysis. These tests were applied to a validated rat PBPK model for a ternary mixture of toluene, m-xylene and ethylbenzene. The lack of fit F-test doesn't seem to be an adequate statistical test because it relies on the variability of the simulations attributed to input parameters almost uniquely influenced by body weight. The regression of the error (i.e., difference between simulated and corresponding experimental data) over their sum (i.e., simulations plus corresponding experimental data) offers an adequate analysis but the assumption of residual normality on which it relies is seldom respected. The bootstrap re-sampling technique coupled with the generation of BC α confidence intervals for the error is an approach that is much more versatile than the others but necessitates a priori residual analysis in order to ensure homoscedasticity of simulated data. This study suggests that an objective evaluation of PBPK models is possible using a two step approach that combines a residual analysis with a bootstrap-BC α confidence intervals test. (SH is recipient of a research scholarship from FRSQ)

1693 MODELING THE TOXICOKINETICS OF INHALED TOLUENE IN RATS: THE IMPACT OF FEEDING STATUS, PHYSICAL ACTIVITY AND STRAIN.

E. M. Kenyon, V. Benignus, C. Eklund and P. Bushnell. *ORD/NHEERL, U.S. EPA, Research Triangle Park, NC.*

Toluene is found in petroleum-based fuels and used as a solvent in consumer products and industrial applications. The critical effects following inhalation exposure involve the brain and nervous system in both humans and experimental animals whether exposure duration is acute or chronic. The goals of this modeling effort were two-fold: (1) evaluate and explain the influence of feeding status and activity level on toluene pharmacokinetics, and (2) apply this model to the analysis of data in the published literature to explain differing toluene kinetics. Compartments in the model are lung, slowly and rapidly perfused tissue groups, fat, liver, GI tract and brain; tissue transport is blood-flow limited and metabolism occurs in the liver. Chemical-specific parameters and initial organ volumes and blood flow rates were obtained from the literature. Sensitivity analysis revealed that the most influential parameters for our experimental conditions were cardiac output, alveolar ventilation and fat volume; other parameters (e.g., partitions and metabolic rate parameters) were either well defined (multiple consistent experimental results with low variability) or relatively non-influential (e.g. organ volumes other than fat). Model-based analysis of our data and that of other investigators suggests that there is a toluene-specific effect on ventilation parameters that differs between active and sedentary rats and is dose-dependent as well. However, rats that were weight-maintained compared to free-fed rats in our studies and those of other investigators could be modeled with a single set of parameters provided that experimental data were obtained from rats exposed to toluene in whole body inhalation chambers. These results point to (1) the importance of experimental conditions and physiological status in explaining apparently conflicting kinetic data and (2) the need to match simulation conditions to experimental conditions when estimating internal doses for effects in studies that lack kinetic data. (This abstract does not necessarily reflect EPA policy.)

1694 CYP2E1 MEDIATED EXTRAHEPATIC METABOLISM IN PBPK MODELING OF LIPOPHILIC VOLATILE ORGANIC COMPOUNDS.

M. Yoon¹, M. C. Madden² and H. A. Barton³. ¹NRC Research Associateship Program, U.S. EPA, Research Triangle Park, NC, ²NHEERL, U.S. EPA, Research Triangle Park, NC and ³NCCT, U.S. EPA, Research Triangle Park, NC.

Physiologically based pharmacokinetic (PBPK) models increasingly are available for environmental chemicals and applied in risk assessments. Often a simplified representation of a real biological system is used in order to reduce uncertainties in the PBPK predictions caused by uncertainties in input parameters. Volatile organic compounds (VOCs) are important pollutants in air, soil and water. CYP2E1 metabolically activates many VOCs in animals and humans. Despite of its presence in some extrahepatic tissues, the metabolism by CYP2E1 is often described as restricted to the liver in PBPK models, unless the risk assessment requires target tissue dose metrics in extrahepatic tissue. The impact of accounting for extrahepatic metabolism (EHM) by CYP2E1 on the estimation of in vivo metabolic parameters and the prediction of dose metrics was evaluated for the lipophilic VOCs - vinyl chloride, trichloroethylene, and carbon tetrachloride. Metabolic parameters estimated from fitting gas uptake data in rats with- and without- EHM were very similar. The impact of EHM on PBPK predictions was evaluated under relevant inhalation exposure scenarios for animal toxicity studies and human risk assessment. Although small, the relative role of EHM and the differences in the predictions of dose metrics were concentration dependent with greater impact at low exposure concentrations. The extent of the impact was varied by several factors such as Km for CYP2E1, age, and species. The current study suggests PBPK modeling for VOCs that are CYP2E1 substrates is not very sensitive to a lack of accounting for EHM, implying that using simplified liver-only metabolism for PBPK modeling of lipophilic VOCs is a reasonable approach. The PBPK predictions using this assumption can be applied confidently for risk assessment, but care should be taken when applying this conclusion to VOCs that are metabolized by other enzymes (Supported by EPA-NRC #CR82879001. This abstract may not represent official EPA policy.)

1695 PHYSIOLOGICALLY BASED PHARMACOKINETIC (PBPK) MODELING IN THE ELDERLY.

C. Thompson¹, B. Sonawane¹ and K. Krishnan². ¹U.S. EPA, Washington, DC and ²University of Montréal, Montréal, QC, Canada.

PBPK models have been developed for a number of chemicals in test animal species and adult humans; however, few models have been developed to evaluate the kinetics and internal dose of chemicals in elderly. The objective of the present study was

to develop an inhalation PBPK model for a group of healthy elderly using toluene as the model substrate. The PBPK model consists of four tissues (liver, fat, slowly perfused tissues (SPT), and richly perfused tissues (RPT)) interconnected by systemic circulation. Values for cardiac output, ventilation rate, tissue volumes, and blood flows were obtained from the published literature. The partition coefficients (blood:air and tissue:blood) are the same as those used previously in an adult toluene PBPK model, since there is a lack of data suggesting significant change in tissue and blood solubility of chemicals in elderly compared to adults. The volume-normalized intrinsic clearance, obtained from the adult PBPK model, was multiplied by the liver volume in elderly, and was used along with the liver blood flow rate in elderly to compute toluene metabolism in the model. The PBPK model was used to simulate the kinetics of toluene following 7 hr exposure to 17 ppm. The simulated blood kinetic profile was compared with the experimental data collected in adult human volunteers following a similar exposure scenario. The predicted values in elderly were slightly lower than those observed in the adult male volunteers. Overall, the PBPK model developed in this study could be useful for evaluating the extent of adult-elderly differences in dose surrogates of relevance to mode of action of chemicals for risk assessment applications.

1696 PHYSIOLOGY-BASED PHARMACOKINETIC MODELING: A TOOL FOR SIMULATING PLASMA AND TISSUE CONCENTRATION-TIME CURVES OF COMPOUNDS.

P. Grossi, F. Del Bene, M. Rocchetti, M. Germani and P. Crivori. *Preliminary Development, Nerviano Medical Sciences, Nerviano, Italy. Sponsor: M. Brughera.*

Physiology-based pharmacokinetic (PBPK) modeling provides a useful tool for simulating plasma and tissue concentration-time curves for different routes of administration of compounds to humans and preclinical animal species. The present study was aimed at evaluating a PBPK model for simulating tissues and plasma concentration-time curves following different routes and schedules of administration of a compound to rodents. The first basic model, developed considering only IV administration, included a system of differential equations describing 13 tissue compartments. It required the inclusion of a minimal amount of information on the compound, obtained from in silico or in vitro investigations: octanol:water partition coefficient, ionization constant(s), fraction unbound in plasma, solubility, permeability and hepatic intrinsic clearance. Tissue partition was modeled using a set of tissue composition-based equations. Hepatic and renal clearances were obtained scaling the intrinsic clearance obtained in vitro from liver preparations, and assuming only the glomerular filtration, respectively. The model was tested comparing the predicted and the observed pharmacokinetics in plasma, after intravenous dosing, of 113 molecules synthesized as part of various discovery programs in different therapeutic areas.

Oral administration was also included by adding differential equations from an advanced compartmental absorption and transit (ACAT) model that was integrated into the PBPK model to determine the rate, extent and approximate gastrointestinal location of drug dissolution and passive absorption. Fraction absorbed, bioavailability and plasma concentration-time profiles were predicted and compared to literature data.

Multivariate analysis was used for identifying the characteristics leading to the possible risk of bias and the influence of different sources of variability using stochastic simulations.

1697 NON-INVASIVE, TELEMETRICALLY-RECORDED SURFACE ECG IN BEAGLE DOGS IN REGULATORY TOXICOLOGY STUDIES. VALIDATION WITH SUBCUTANEOUS ISOPROTERENOL.

O. Boucheix, J. Briffaux, E. Chalencon, P. Lege, S. Baudet and S. Milano. *Drug Safety Assessment, MDS Pharma Services, St Germain sur L'Arbresle, France.*

Recording of ECG in regulatory toxicology studies faces several constraints, among which predominate infrequent handling of the animals (generating stress) and recording of ECG over minutes instead of hours or days, which prevents the analysis of additional qualitative (shape of complexes, detection of arrhythmias) and quantitative data (measurement of the duration of several ECG parameters). Such constraints become critical in the evaluation of potential QT interval-prolonging properties of new chemical entities. We took advantage of our GLP validated telemetric environment to assess whether non-invasive and non-stressful investigation of ECG in freely-moving beagle dogs could be incorporated in regulatory toxicology studies. The telemetric environment consisted of an implant (DSI® Technologies, USA) and signal processing software (Notocord®, F). ECG was recorded with adhesive electrodes connected to an implant body (model

TL11M2D70-PCT), embedded in a jacket, to which the dogs had been previously accustomed. The primary objective was to assess whether this configuration could record high-quality ECG for at least 20 hours. Two dogs were subcutaneously injected with isoproterenol (0.25 mg/kg), while another 3 dogs were injected with water. The treated dogs developed marked tachycardia (up to 248 beats/min) starting 30 minutes after injection. The heart rate then stabilized about 35 beats/min above the pre-test values for the remaining duration of the recording period. No such changes were seen in control dogs. Ventricular extrasystoles developed in all isoproterenol-treated dogs and lasted for 20 hours. All ECG traces were of excellent quality and exploitable by the software. This telemetric method appears sufficiently robust to be used in regulatory toxicology studies.

1698 INVESTIGATION OF QT-INTERVAL PROLONGATION IN CONSCIOUS TELEMETERED BEAGLE DOG WITH CLASS III ANTIARRHYTHMIC DRUG.

Y. Chen, R. Padilla, S. Garthwaite and N. Rajendran. *Life Science Group, IIT Research Institute, Chicago, IL.*

Drug-induced effects on the QT-interval with the possibility of inducing fatal arrhythmias have become a new challenge for drug development and regulatory approval. The conscious telemetered Beagle dog recently became a major in vivo model for the cardiovascular safety pharmacology studies, and the duration of QT-interval has been used as the determinant of the risk of drug-induced torsades de pointes or arrhythmias (ICH S7B). However, interpretation of the QT-interval in the light of heart rate changes is often complex. The purpose of this study was to define the sensitivity of the in vivo method of safety pharmacology assessment of cardiovascular functions, and investigated a method for quantifying beat-to-beat QT-interval in a conscious free-moving telemetric canine model using an antiarrhythmic class III reference drug, d,l-sotalol. A telemetry transmitter (TL11-M2-D70-PCT) from Data Sciences International (DSI) was surgically implanted into each dog following the standard procedures. The animals' blood pressure, heart rate, ECG, body temperature and locomotor activity were simultaneously and continuously acquired by DSI OpenArt system up to 24 hours prior to and following a single bolus intravenous administration of saline (control), or d,l-sotalol at 16 mg/kg. The heart rate-adjusted QT interval (QTcB, QTcF and QTcV) was determined using the rate-correction formula in Ponemah analysis program. In addition to standard parameters an advanced beat-to-beat analysis (Tpeak-Tend duration, QT variability and P-wave duration) was performed. The d,l-sotalol induced QT prolongation was observed with maximal effects at 2-hr post dose when compared to control. Beat-to-beat variability of QT-interval was assessed from Pioncare plots (QT vs QTn-1) of 60 consecutive beats at time of maximal QT effect. In conclusion, the conscious telemetered dog has been shown a reliable pre-clinical model for detection of drug-induced ECG abnormalities.

1699 HEMODYNAMIC AND ELECTROCARDIOGRAPHIC EFFECTS OF FLECAINIDE, QUINIDINE AND MOXIFLOXACIN IN CONSCIOUS, INSTRUMENTED BEAGLE DOGS MONITORED BY TELEMETRY.

S. R. Arthur, A. K. Gupta, B. D. Car and B. Gemzik. *Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.*

Assessment of cardiovascular (CV) safety has become an integral part of nonclinical safety evaluation of all new drug candidates because several pharmaceutical products have been found to delay ventricular repolarization and increase the risk for life threatening ventricular arrhythmias. Inhibition of hERG ion channel activity is the most common mechanism of delayed ventricular repolarization by pharmaceuticals, but sodium and/or calcium ion channel effects can also result in CV liabilities. Considered with cellular electrophysiology evaluations of ventricular repolarization and ion channel activity, intact animal models allow an integrated CV assessment. We have profiled 3 cardiac ion channel inhibitors as part of a reference dataset in a canine telemetry model. Conscious, unrestrained instrumented beagle dogs (N=4) were given single oral doses of vehicle (control), or flecainide (sodium ion channel inhibitor), moxifloxacin (hERG ion channel inhibitor), or quinidine (mixed ion channel inhibitor). Parameters including heart rate, systemic blood pressure, myocardial contractility, and ECG waveform morphology and interval duration were evaluated simultaneously. Plasma drug concentrations were determined by a limited sample collection during study, and confirmed by a toxicokinetic profile in non-instrumented dogs. Flecainide at 10 mg/kg increased P wave width (≈ 10 msec), QRS (3-5 msec), and QTc (10-25 msec) intervals. Dose-related increases in heart rate, +dP/dt, and QTc (≈ 10 & 25 msec) were seen with quinidine at 10 and 25 mg/kg, with additional effects at 25 mg/kg. Moxifloxacin at 50 mg/kg increased +dP/dt (15-20%), QTc (≈ 30 msec) and heart rate. The CV changes in dogs were consistent with known ion channel profiles of these agents and reproduced their clinical effects at plasma concentrations that were within the range of their therapeutic levels. Our results demonstrate that beagle dogs can exhibit a similar sensitivity as humans and contribute to a comprehensive CV safety assessment of new drug candidates.

1700 TELEMETERED RESPIRATORY EMG/INTRAPLEURAL PRESSURE VS LIFESHIRT®: MONITORING OF BRONCHOCONSTRICTION AND VOMITING IN THE DOG.

J. Briffaux¹, O. Boucheix¹, S. Milano¹, P. Lege¹, E. Chalencon¹, M. Smyth² and A. Derchak². ¹Drug Safety Assessment, MDS Pharma Services, St Germain sur L'Arbresle, France and ²Vivometrics, Ventura, CA.

The objective of this study was as follows: a) to investigate the feasibility of non-invasive recording of respiratory muscle activity, in conscious freely-moving dogs; b) to compare the efficacy of a telemetric versus an external recording approach; c) to validate the efficacy of both approaches by triggering bronchoconstriction and emesis. Although bronchoconstriction can be measured in the dog, it is usually done in anaesthetized and instrumented animals. In addition, direct measurement of respiratory muscular activity during emesis could circumvent the unreliable and time-consuming assessment of emesis by observation of video recordings. To achieve this, inspiration was recorded by two leads of a radio transmitter implanted into the diaphragm (Dia) or into the external intercostal (EI) muscles. Expiration was recorded by two leads implanted into the rectus abdominis (RA). The intrapleural pressure (IP) was also measured, based on the method of Murphy et al. The LifeShirt® system, an ambulatory version of respiratory inductance plethysmography, consists of a shirt with embedded sensors to measure respiratory activity. Emesis was telemetrically evidenced by a series of synchronized bursts of the DIA/EI and RA, with large variations of IP. This pattern was also accurately detected by LifeShirt®. Bronchoconstriction was telemetrically evidenced by a large recruitment of the inspiratory and expiratory components, and an increase in IP. With LifeShirt®, this reflex was mainly evidenced by a decrease in the peak to mean expiratory flow relationship, and an increase in the relative tidal volume related to a change in thoracic volume. This was associated with an increase in the lung resistance invasively measured in the anesthetized dog. This study shows that both telemetry monitoring of respiratory EMG and LifeShirt® are suitable for evaluating bronchoconstriction and emesis in the dog.

1701 MET-KINASE INHIBITION DOES NOT IMPAIR RECOVERY FROM TOXICANT INDUCED ACUTE HEPATO-RENAL INJURY IN MICE.

A. K. Gupta¹, Y. Callejas¹, R. Westhouse¹, P. Marathe², J. Fargnoli³, R. M. Borzilleri⁴, B. D. Car¹ and B. Gemzik¹. ¹Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ, ²Metabolism and Pharmacokinetics, Bristol-Myers Squibb, Princeton, NJ, ³Discovery Biology, Bristol-Myers Squibb, Princeton, NJ and ⁴Oncology Chemistry, Bristol-Myers Squibb, Princeton, NJ.

Dysregulation of MET (Hepatocyte Growth Factor receptor, a cell surface receptor protein tyrosine kinase) signaling has been shown to play an important role in tumorigenesis, particularly in tumor invasion and metastasis, and is an attractive oncology therapeutic target. In addition to its established role in neoplasia, MET signaling pathways contribute to hepato-renal development and function, and in adult livers, induce mitogenesis, are cytoprotective and antifibrogenic, as well as contribute to survival functions in liver physiology. MET conditional knock-out mice exhibit impaired recovery from acute hepatocellular injury, whereas, loss of MET function is not detrimental to hepatocyte function under normal physiologic conditions. These observations suggest that a small molecule inhibitor of MET kinase may attenuate recovery from acute hepato-renal injury. We evaluated a small molecule MET kinase inhibitor, BMS-698769, in a carbon tetrachloride (CCl₄)-induced acute hepato-renal injury model in mice for its effects on recovery from toxicant-induced effects. Male Balb/C mice were given either vehicle or BMS-698769 at 100 mg/kg/day orally for 7 days, beginning 24 hours after a 50 microliters/kg i.p. dose of CCl₄. Hepatic and renal effects were monitored by serum clinical pathology and tissue histology over the 7-day period. BMS-698769 did not affect the rate or extent of recovery from CCl₄-induced hepatocellular and renal tubular toxicity when administered at a dose and plasma drug exposure that provided maximum efficacy in tumor xenograft models, and suggest a low potential for hepatic mechanism-based liabilities with the use of targeted small molecule MET kinase inhibitors.

1702 RELATIONSHIP BETWEEN DOSES THAT PRODUCE THE REINFORCING EFFECT AND GROSS BEHAVIORAL EFFECTS IN RHESUS MONKEYS - 2ND REPORT.

A. Fujiwara, Y. Wakasa, M. Iino, M. Sasaki and T. Yanagita. *Safety Pharmacology Department, Ina Research Inc., Ina-shi, Nagano-ken, Japan.* Sponsor: R. Perez.

The dose-response relationships of drugs that possess the reinforcing effect generally show inverted U-shaped curves when administered to animals by intravenous self-administration. Therefore, it is important to select appropriate dose-ranges to

assess the reinforcing effect of drugs. In the 66th annual scientific meeting of the College on Problems of Drug Dependence, it was reported that the most frequently self-administered doses of cocaine, pentazocine, pentobarbital, nicotine and caffeine were 1/8 to 1/125 of the respective minimal effective doses in gross behavioral observations following single administrations (Wakasa et al., 2004). In this study, the dose-response relationships of 2 different types of anesthetics, ketamine hydrochloride and thiopental sodium, were evaluated by gross behavioral observations following cumulative dosing and by the self-administration method. In the cumulative dosing procedure, the drugs were administered approximately 15 minutes apart and gross behavioral changes in monkeys were observed immediately and 10 minutes after each administration. In the intravenous self-administration procedure, monkeys were allowed to self-administer the drug solutions under a FR5 with time-out 1 minute schedule for 2 hours per day. The minimal effective doses in gross behavioral observations were 0.5 mg/kg with ketamine and 1 mg/kg with thiopental. The most frequently self-administered doses ranged from 0.06 to 0.125 mg/kg/infusion with ketamine and from 0.25 to 0.5 mg/kg/infusion with thiopental. These doses were 1/2 to 1/8 of the respective minimal effective doses in gross behavioral observations. Therefore, it is suggested that the reinforcing effect of ketamine and thiopental may be detected at doses less than the minimal effective doses by gross behavioral observations following cumulative dosing, as with cocaine, pentazocine, pentobarbital, nicotine and caffeine.

1703 PANCREATIC TOXICANTS DETECTED USING RINm5F CELLS.

M. McMillian¹, A. M. Leone¹, P. G. Lord¹, B. De Corte², J. R. Mabus² and E. E. Codd². ¹Johnson & Johnson, Raritan, NJ and ²Johnson & Johnson, Spring House, PA.

In the course of examining high doses of several novel compounds in rats, blood glucose elevations and pancreatic islet beta cell vacuolizations were noted after several days. These diabetes-inducing effects were reminiscent of those observed with cyproheptadine and structurally similar compounds—cyclizine, pizotyline, and azacylonol—in rats (Fischer et al, *Tox Appl Pharm* 26:288-298, 1973). The rat pancreatic RINm5F cell line, which makes and secretes insulin but has lost response to glucose, had proven an effective in vitro model to study cyproheptadine-induced diabetes (Miller et al, *J Biochem Toxicol.* 8:127-34, 1993), and we modified this model to screen compounds for pancreatic toxicity. Insulin content was determined via ELISA in cells and media, and cytotoxicity was measured via resazurin reduction. Since many drugs share structural similarities with cyproheptadine (particularly those with structures similar to 4-diphenylmethylpiperidine; Hintze et al, *Toxicology* 7:133-40, 1977), it was not surprising that several—including terfenadine, desloratidine, chlorpromazine, doxepine, clopenthixol, thietilperazine, thiothixene—produced decreases in insulin content and release in this model. Most of these drugs produced effects only at supra-therapeutic levels, or only at near cytotoxic concentrations. Possible exceptions included several antipsychotics, many linked to type II diabetes in the clinic. For example, olanzapine (3 to 30 uM) markedly decreased insulin cellular content and insulin release from RINm5F cells after 24 hours treatment with no concurrent cytotoxicity. RINm5F cells provide a simple model for screening compounds for effects on insulin content and release, and should be an early step for structural series containing diabetogenic compounds or those structurally related to 4-diphenylmethylpiperidine.

1704 APPLICATION OF THE MICROAMES SCREEN AND MULTICASE SAR FOR ASSESSING THE GENOTOXIC AND CARCINOGENIC POTENTIALS OF THE PHARMACEUTICAL IMPURITY, DIFLUOROANILINE.

M. Wells, S. G. Soelter and M. J. Schlosser. *Midwest BioResearch LLC, Evanston, IL.*

In the pharmaceutical industry, impurities from raw materials, intermediates, degradation products, synthetic reactants, and residual solvents should be assessed for genotoxic potential. Early in drug development, isolated impurities are often of insufficient quantity to fully test for genotoxicity and thus predictive screening tools become important for risk assessment. Difluoroaniline (DFA), a model impurity, was evaluated for genotoxicity by screening in the microAmes, an assay predictive for the full plate Ames test but requiring only 10 mg when used with 5 tester strains with or without an S9 metabolic activation system. DFA was also assessed for carcinogenicity using MultiCASE computer-assisted SAR coupled with ICSAS expert system. The National Toxicology Program in 1984 reported DFA to be negative in the Ames test with rat liver S9 but positive using 30% hamster S9. To understand the human relevance of this finding, DFA was evaluated in the microAmes screen using up to 30% human liver S9. The microAmes screen demonstrated DFA to be positive with hamster S9 at concentrations down to 10% and negative with rat S9 at concentrations up to 30%. DFA results using human S9 at concentrations up to 30% were also negative. These results indicate that activation of DFA by human liver S9 is more similar to rat and unlike the hamster. These results are supported by literature data indicating that hamster induced-liver microsomes have

higher rates of arylamine N-hydroxylation (activation step) and lower rates of arylamine ring-hydroxylation (detoxication step) than rat microsomes. Using MultiCASE, the overall carcinogenicity potential of DFA via ICSAS expert system was also negative. These assessments demonstrate the utility of 1) using the microAmes screen for exploring the potential genotoxicity properties of impurities, particularly when the amount of an isolated impurity is limited; and 2) employing well validated SAR databases to evaluate impurities for their carcinogenic potential.

1705 A PROPOSAL FOR REFINEMENT OF THE METHOD OF EUTHANASIA EMPLOYED IN THE MURINE LOCAL LYMPH NODE ASSAY.

A. Robertson and D. Dreher. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: *D. Everett.*

In the interests of animal welfare, and for ethical and legal reasons, methods of euthanasia employed at Covance Laboratories are intended to minimise the discomfort, pain and distress caused to animals. Whether euthanasia by carbon dioxide inhalation is humane has recently been considered. Although widely used, guidance on how it can be humanely administered is lacking.

A recent meeting to consider problems associated with CO₂ euthanasia concluded that both using chambers pre-filled with CO₂ and administering rising CO₂ concentrations posed animal welfare problems. Using chambers containing a >50% concentration of CO₂ causes pain for up to 15 seconds prior to loss of consciousness. Exposure to rising CO₂ concentrations causes stressful "air hunger".

The Murine Local Lymph Node Assay is the preferred method used in the UK to determine the potential of a chemical to cause delayed contact hypersensitivity ("skin sensitisation") by indirectly determining lymphocyte proliferation at the lymph nodes draining the sites of topical application. The assay is conducted in CBA/Ca-strain mice which are subjected to euthanasia by a rising concentration of CO₂ after six days. Incorporation of intravenously-injected 3H-methyl thymidine is then measured as disintegrations per minute (DPM) and the mean DPM values are used to calculate the Stimulation Index (SI) value for each test group.

It is considered that a refinement to this assay could be effected by the use of alternative methods of euthanasia.

Additional high dose groups which were subjected to euthanasia by exposure to Halothane(TM) have been added to studies performed with known mild-to-moderate sensitising chemicals in order to establish if the method of euthanasia affects the DPM and SI values. It was not possible to determine from these studies whether the method of euthanasia had any effect on DPM and SI values.

This poster presents the results of additional work, designed to examine whether it is possible to change the method of euthanasia and produce a refinement in the method without affecting the validity of the assay.

1706 COMPARABILITY OF *IN VITRO* HEMOCOMPATIBILITY ASSAYS WITH HUMAN AND NON-HUMAN SPECIES TO SUPPORT CANDIDATE DRUG DEVELOPMENT.

A. John-Baptiste, Q. Zong, M. Malamant, F. Sace and B. Jessen. *Research & Development, Pfizer Inc., San Diego, CA.* Sponsor: *G. Stevens.*

In vitro hemocompatibility assays have been utilized by pharmaceutical companies as a means to assess the hemolytic potential of candidate intravenous drugs prior to their use in humans. However, several disadvantages exist. First, a criterion for the determination of a compound as being hemolytic has not been universally accepted. Secondly, many blood compatibility assays require the use of large amounts of compound and vehicle formulation. Finally, extrapolations to in vivo are unclear. Three blood compatibility assays were compared in our experimental design: (1) The Dacie method utilizes serial dilutions of each test article with 0.9% physiological saline (2) The Salauze method uses ratios of test article to blood that mimic an intravenous injection immediately upon dosing and after distribution and (3) The Reed and Yalkowsky which differs from standard in vitro methods, analyzes the amount of hemoglobin in intact erythrocytes.

Known hemolytic (10% Ativan and 0.5% SDS) and non-hemolytic (10% Cremophor El and 10% Tween 80) co-solvents were used to evaluate the accuracy of each of the three methods tested. The co-solvents were selected based on published information regarding their hemolytic capability. Heparinized human blood, pooled rat and rabbit blood, and dog blood were analyzed. Our experimentation included a comparison of between analysts and between day performances of each assay. In order to accomplish this, we compared the 10% and 50% ratio, which was common for all methods, co-solvents and species. Results for Dacie and Salauze methods did not always lead to conclusions that were consistent with known properties of the co-solvents. The results from this evaluation demonstrated that the Reed and Yalkowsky method was a more accurate indicator of erythrocyte hemolysis using co-solvents reported as hemolytic. In addition, the Reed and Yalkowsky method demonstrated a higher level of reproducibility in all co-solvents evaluated for all species tested.

1707 CHROMOSOMAL INTEGRATION, IMMUNOGENICITY, AND TOXICITY OF REPEATED INTRAVENOUS INJECTION OF GENE THERAPEUTICS FOR X-CGD IN MICE.

W. S. Koh¹, Y. Lee¹, M. Lee¹, W. Choi¹, C. Joo², Y. Hong², S. Ho², S. Kim² and J. Kim². ¹Korea Institute of Toxicology, Daejeon, South Korea and ²ViroMed, Seoul, South Korea.

As a prerequisite for a human clinical trial, integration, immunogenicity and toxicity of gene therapeutics for X-CGD (murine bone marrow-derived stem cells transduced with MT-gp91 retrovirus), administered intravenously twice at an interval of two weeks at dose level of 5×10^7 cells/kg, was evaluated in C57BL/6 mice. The integration of gene therapeutics for X-CGD into host genome was evaluated by a polymerase chain reaction (PCR) assay in the reproductive tissues (testis, epididymis, seminal vesicle and prostate) 20 days after the final administration. Gene therapeutics for X-CGD was not detected in gonads in the treated groups indicating no potential of genomic integration. Immunogenicity test was performed by FACS analysis in order to investigate whether anti-gp91 antibodies are produced in sera which were collected 20 days after the final injection. No significant change in anti-gp91 antibody production was noted in sera from mice treated with gene therapeutics for X-CGD compared with sera from the vehicle control group. In the toxicity study, no treatment-related abnormalities were observed in clinical signs, body weight, food and water consumption, ophthalmologic examination and urinalysis while an increase in white blood cells and a slight decrease in albumin/globulin ratio were observed in the test substance-treated groups. The increase in both absolute and relative spleen weights was consistent with red pulp hyperplasia in the spleen noted in microscopic examination and it was considered to result from the accumulation of bone marrow-derived stem cells in the spleen.

1708 SAFETY PHARMACOLOGY EVALUATIONS ASSOCIATED WITH mRNA TARGET INHIBITION BY 2'-MOE ANTISENSE OLIGONUCLEOTIDES.

T. Kim¹, E. Park², W. Shin², J. Seo², K. Kim², E. Kim², S. Murray¹, A. A. Levin¹ and S. P. Henry¹. ¹Toxicology, ISIS Pharmaceuticals, Carlsbad, CA and ²Safety Pharmacology, Korea Institute of Toxicology, Daejeon, South Korea.

Antisense oligonucleotides (ASO) continue to make great progress as therapeutic agents and being used in clinical trials in diseases as diverse as cancer, hyperlipidemia, asthma, and diabetes. Independent of the molecular target, the toxicology profiles of ASOs tend to be qualitatively similar because of the consistency in pharmacokinetic properties from one sequence to the next. To further investigate effects on major organ systems related to chemical class and those related to the inhibition of mRNA targets on critical organ functions, the rat-specific and cross-species active ASOs were studied in rats. In the current study, four different ASOs were used to evaluate the effects of antisense inhibitors on the safety pharmacology core battery including the cardiovascular, respiratory and central nervous systems. Rats (8/group) received three doses of PBS, 50, 100 or 150 mg/kg ISIS 116847 (phosphatase and tensin homolog inhibitor, PTEN), ISIS 379804 (rat-specific apolipoprotein B inhibitor, apoB), ISIS 345198 (glucocorticoid receptor inhibitor, GCCR), or ISIS 141923 (control oligonucleotide). Treatment with the ASOs to PTEN, apoB and GCCR produced a dose-dependent and statistically significant reduction in liver PTEN (~60%), apoB (~75%) and GCCR (~50%) mRNA relative to control, respectively. However, there were no effects on the general behavior, body temperature, heart rate, blood pressure, respiratory rate, tidal volume and minute volume in the rats treated with up to total 450 mg/kg/rat antisense inhibitors. In hERG assays, there were no effects on ion current by concentrations of antisense drugs up to 150 M. There was also no evidence inhibition of the expression of PTEN, apoB and GCCR was associated with effects on critical organ functions. Collectively, these safety pharmacology data suggest that these ASOs as representatives of the chemical class do not alter the function of major organ systems.

1709 TARGET IDENTIFICATION OF DRUG INDUCED MITOCHONDRIAL TOXICITY USING MONOCLONAL ANTIBODY CAPTURE OXPHOS ACTIVITY ASSAYS.

S. Nadanaciva², A. Bernal², R. Aggeler², R. Capaldi² and Y. Will¹. ¹Drug Safety Research and Development, Pfizer, San Diego, CA and ²Mitosciences, Eugene, OR.

Mitochondrial dysfunction has been shown to be a pharmacotoxicological response to a wide variety of currently-marketed therapeutics, such as certain antiviral agents, anti-diabetic and anti-lipidemic drugs, antibiotics, analgesics and certain cancer chemotherapeutics. In order to reduce attrition due to mitochondrial toxicity, HTS applicable screens should be applied early in drug discovery and pre-clinical stages (Discovery Toxicology Paradigm). No true structure-activity relationship (SAR) has been established to date which would allow to predict the ability of a compound to induce mitochondrial toxicity. Consequently, in order to prevent new

chemical entities (NCEs) from having any possible liability, a screening paradigm needs to be in place. The goal is to establish a screen which identifies the target of inhibition, is suitable to high throughput screening (HTS) and amenable to structure-activity relationship (SAR) approaches. Here we describe five HTS applicable screens for compounds that directly inhibit complex I, II, III, IV, and V of the electron transport chain (ETC). We determined intra and assay variation and tested for specificity by using classical mitochondrial inhibitors. The HTS format of the OXPHOS Complex activity assays allowed for rapid in vitro screening of 23 drugs in parallel and for easy IC₅₀ determinations. Results show direct effects of some of these drugs on OXPHOS complexes, whereas others showed no effect. Compounds were rank-ordered according to their relative toxicities to one another and to well-known inhibitors of each complex. In summary, NCEs can easily be screened on a daily basis and the identification of mechanism can greatly assist in structure-activity-relationship (SAR) approaches.

1710 IN VITRO AND IN VIVO COMPARABILITY ASSESSMENT OF A POTENTIAL SURROGATE PRECLINICAL TOXICOLOGY MODEL.

J. A. Lansita, N. Rinaldi, J. Goyal, E. Polack, S. Ryan, S. Tangri, X. Hu, S. Harris, Q. Duong, W. McAuliffe, A. Estrellado, M. Cooper, D. Kinch, M. Lukashev, D. Hutto, M. Subramanyam, H. Gouvis and J. Clarke. Biogen Idec, Cambridge, MA.

hCBE11 is an agonist anti-Lymphotoxin-beta receptor (LTBR) monoclonal antibody developed for the treatment of solid tumors. Due to restricted species cross-reactivity, IND-enabling preclinical toxicology studies were conducted in chimpanzees. A preclinical surrogate model was evaluated for potential use in GLP chronic toxicology studies. hBHA10, another agonist monoclonal antibody to LTBR, with similar activity to hCBE11 and broader species cross-reactivity, was assessed as a potential surrogate model in the cynomolgus monkey. hBHA10 recognizes cysteine-rich domain 2 (hCBE11 recognizes domain 1) of the LTBR, and has biological activity in macaques, chimpanzees, and humans. The criteria used to assess the surrogate model focused on the pharmacological and toxicological similarities between hBHA10 and hCBE11, and also considered the technical feasibility of developing a surrogate (e.g. immunogenicity, production process). Both in vitro and in vivo assessment studies were performed comparing hBHA10 to hCBE11, which included cytokine and transcript profiling, antibody dependent cellular cytotoxicity, complement dependent cytotoxicity, pharmacokinetic comparability, tissue cross-reactivity, and in vivo cytokine induction. Using a weight of evidence approach and considering the limitations of the chimpanzee, the in vitro and in vivo assessment studies supported the potential use of hBHA10 in the cynomolgus monkey in toxicology studies.

1711 RESULTS OF LONG-TERM TOPICAL TESTS IN GÖTTINGEN MINIPIGS AND WISTAR-HAN RATS WITH TINOSORB®M.

L. E. Navarro¹ and J. R. Plautz². ¹Ciba Specialty Chemicals, High Point, NC and ²Ciba Specialty Chemicals, Basel, Switzerland.

TINOSORB®M (Bisocetrisole) is a broad spectrum sunscreen ingredient currently under review by the US FDA for addition to the OTC Sunscreen Monograph. Presently it is used as a sunscreen active in 39 countries and has over 6 years of safe global use in consumer topical sunscreen products. Previously we reported on the lack of photo(co)carcinogenic effects in hairless mice and no areas of concern based on low bio-availability by oral dosing in shorter non-clinical studies. New results from non-clinical long-term topical dosing studies in Göttingen minipigs and Wistar-Han rats are presented. Göttingen minipigs received daily topical doses applied in vehicle without occlusion for 39 weeks at 0 (vehicle), 500, 1000 & 2000 mg/kg/d. Plasma concentrations of test article were below analytic LOQ (5 ng/ml) in all groups at all time points. Systemic toxicity did not occur as evidenced by clinical signs, clinical biochemistry, and hematology. Macroscopic observations were unremarkable; microscopic examination indicated an absence of test article related changes in all organs and tissues at the systemic level; dermal changes related to the test article did not occur at the site of topical dosing. Wistar-Han rats received lifetime (104 wks) single daily topical doses of 0 (untreated), 0 (vehicle), 100, 400, & 800 mg/kg/d, in vehicle, without occlusion. Survival and growth rates were unaffected by treatment; there were no clinical signs; clinical biochemistry parameters were similar across groups; plasma concentrations of test article did not show time or dose-related increases during the study. Histopathological findings indicated the test article did not induce neoplastic changes at the dose site and systemic non-neoplastic and neoplastic changes were not rare findings or at a frequency that was related to the test article. For dermal carcinogenicity the NOEL is 800 mg/kg/d, the highest dose tested. In conclusion, TINOSORB M is a safe UV filter ingredient that can be used to make highly photostable, broad-spectrum sunscreens.

1712 RESULTS OF LONG-TERM TOPICAL TESTS IN GÖTTINGEN MINIPIGS AND WISTAR-HAN RATS WITH TINOSORB® S.

J. R. Plautz¹ and L. E. Navarro². ¹Ciba Specialty Chemicals, Basel, Switzerland and ²Ciba Specialty Chemicals, High Point, NC.

TINOSORB® S (Bemotrizinol) is a broad spectrum sunscreen ingredient currently under review by the US FDA for addition to the OTC Sunscreen Monograph. Presently it is used as an active sunscreen ingredient in 31 countries and has over 6 years of safe global use in topical sunscreen products. Previously we reported on the lack of photo(co)carcinogenic effects in hairless mice and on shorter non-clinical studies indicating no areas of concern based on low bio-availability by oral dosing. Here we present new results from non-clinical long-term topical dosing studies in Göttingen minipigs and Wistar-Han rats. Göttingen minipigs received daily topical doses applied in vehicle without occlusion for 39 weeks at 0 (vehicle), 250, 500, & 1250 mg/kg/d. Plasma concentrations of test article were below analytic LOQ (2 ng/ml) at all time points in each group during the study. Clinical biochemistry, hematological and urinalysis results were similar between all groups. Macroscopic and microscopic changes were not different in the dosed vs. control groups; dermal changes related to the test article did not occur at the site of topical dosing. Wistar-Han rats received lifetime (105 wks) topical applications in vehicle at single daily doses of 0 (untreated), 0 (vehicle), 100, 500, & 1000 mg/kg/d without occlusion. All animals showed good survival to study termination, growth within expected ranges; clinical chemistry, hematology, and urinalysis changes were not related to the test material; plasma concentrations of test article did not show time or dose-related increases during the study. Histopathological findings indicated the test article did not induce neoplastic changes at the dose site and systemic non-neoplastic and neoplastic changes were not rare findings or at a frequency that was related to the test article. For dermal carcinogenicity the NOEL is 1000 mg/kg/d, the highest dose tested. In conclusion, TINOSORB S is a safe UV filter ingredient that can be used to make highly photostable, broad-spectrum sunscreens.

1713 ULTRASONOGRAPHY QUANTIFICATION OF PROSTATE SIZE IN THE CYNOMOLGUS MONKEY.

R. Forster¹, T. P. Appelqvist¹, P. Désert¹, J. Legrand¹ and P. Kerveillant². ¹CIT, Evreux, France and ²Ultrasonography Specialist, Evreux, France.

Experimental techniques permitting the *in vivo* monitoring of the size of the prostate in large laboratory animal models can be of particular value in the development of novel therapeutic approaches to the treatment of benign prostatic hypertrophy (BPH) and prostatic cancer or in the investigation of changes in prostate size related to variations in androgen levels. Measurement of prostate size may also be a useful addition to the range of available parameters for evaluating the onset of male sexual maturity. We have used ultrasonography to obtain noninvasive measurements of the prostate size in male cynomolgus monkeys. As in man, the prostate of the cynomolgus monkey is not amenable to imaging by a ventral approach and the transrectal approach must be used. The monkeys were tranquilized with ketamine and the prostate was imaged by transrectal ultrasonography, using a IOE323 intraoperative probe coupled with an Esaote Megas CVX ultrasound system. Triplicate images were recorded digitally for each lobe of the prostate and calculated values for the volume of the right lobe, left lobe and combined volume were then estimated from measurements on these images. This work was performed in compliance with GLP (Good Laboratory Practice). Using this technique we obtained an estimate of $2.24 \pm 0.78 \text{ cm}^3$ for the (combined lobes) prostate volume of sexually mature cynomolgus monkeys with a mean body weight of 5.2 kg (n=6). We were able to perform repeated measurements on animals and to monitor and quantify prostate growth over a period of twelve months. This technique should prove to be a useful addition to current possibilities for *in vivo* monitoring of large laboratory animals.

1714 VALIDATION OF A HEAD-OUT PLETHYSMOGRAPHY MODEL FOR CONSCIOUS PULMONARY FUNCTION ASSESSMENT IN THE MOUSE: EFFECTS OF ORALLY ADMINISTERED MORPHINE.

G. P. Thomas, W. Allen, J. Morahan and C. Spainhour. Pharmacology, Calvert Laboratories, Inc., Olyphant, PA.

ICH Guidelines stipulate assessment of pulmonary function for all test agents before human use. Mouse is a small, inexpensive animal that requires smaller amount of test article for testing. Specific mechanism of action or pharmacokinetic properties may also require the use of mice in pulmonary studies. Quality of data obtained from freely moving mice using whole body plethysmography has been inadequate and many times questionable. In the present study we evaluated the effects of morphine in order to validate a head-out plethysmography model for conscious animal pulmonary function studies.

Tidal Volume, Minute Volume and Respiratory Rate were acquired in mice using DSI Dataquest Open ART & PONEMAH Physiology Platform. Morphine (40 mg/kg) and vehicle (5 mL/kg) doses were administered subcutaneously to mice. Each animal was placed in the plethysmographic chamber before and 15 min, 1, 2, 3 and 4 hours after the administration of morphine or vehicle for the measurement of pulmonary parameters. Morphine-induced changes in pulmonary parameters were statistically analyzed using Two-way repeated measures ANOVA followed by a Bonferroni Multiple Comparison Test (SigmaStat, v2.03).

Vehicle (5 mL/kg) did not induce any significant effects on respiratory rate, tidal volume or minute volume in conscious mice in this study. However, morphine (40 mg/kg) produced a significant decrease (124 ± 20.67 at 1 hour, 167 ± 30.29 at 4 hour), compared to the 285 ± 8.39 breaths per minute pre-dose value in this group. Similarly the minute volume values were significantly lower (51.5 ± 7.17 at 1 hour and 68.0 ± 13.51 at 4 hours) compared to the $109.0 \pm 7.02 \text{ mL/min}$ pre-dose value. The respiratory rate and minute volume values were significantly lower compared to the respective vehicle-group values. No significant change in tidal volume was caused by morphine in these animals. Consistency with the published data on morphine-effects on pulmonary function validates the use of this system for pulmonary function studies.

1715 UTILIZATION OF A HUMAN FACIAL SENSORY DISCOMFORT ASSAY TO EVALUATE COSMETIC FORMULATIONS.

A. H. Dang, J. W. Harbell, C. Gómez and W. Armbrister. Mary Kay Inc., Dallas, TX.

Cosmetic products are intentionally and repeatedly applied to consumers' skin and thus require a high degree of mildness. Objective clinical evaluations such as patch testing and safety in use studies are employed to identify formulations that elicit significant dermal irritation and dermal sensitization. They rely on observable damage to the skin including erythema, edema, and dryness. However, formulations that pass these stringent tests may still evoke disagreeable and unacceptable sensations. The facial sensory assay provides a measure of the sensory perception of stinging or burning caused by a topically applied product. In this study, we report the use of a modified Frosh-Kligman protocol to evaluate facial sting across classes of skin care products and to determine the influence of the preservative system in a selection of those classes. All panelists were lactic acid sensitive Asian females. The split-face study design was conducted double-blinded so that neither the panelists nor the technicians know the identity of the products. The test formulations were applied to one side of the nasolabial region and to the cheek area. Reference formulations, with extensive use experience, were applied to the contralateral side. At intervals of 0, 2.5, 5, and 10 minutes, the panelists rated the formulations for stinging or burning sensations. Moisturizers were very mild with only a small fraction of panelists responding at all. Cleansers and toners showed slightly higher values that peaked at 2.5 minutes. Masks showed the highest scores with the maximum values coming at 5 minutes. Furthermore, there was a concentration-dependent correlation between the amount of the preservative phenoxyethanol and the stinging sensation perceived by the panelists. In additional studies in the mask product, panelists rated other preservative systems to determine mildness. A formulation with diazolidinyl urea and mixed parabens received scores similar to the unpreserved formulation control. These data suggest the importance of facial sting as a tool in formulation development and overall product assessment.

1716 APPLICATION OF FLOW CYTOMETRY TO BONE MARROW EXAMINATION IN RATS: A SIMULTANEOUS MEASUREMENT OF TOTAL NUCLEATED CELL COUNTS AND CELL DIFFERENTIALS.

K. Masaaki and I. Takeshi. Drug Safety Research and Development, Pfizer Global Research and Development, Nagoya Laboratories, Pfizer Inc., Taketoyo, Aichi, Japan.

(Purpose) The bone marrow examination of drug toxicity study consists of measuring total nucleated cell counts (TNC) and differentiation of bone marrow cells. There is no method available regarding simultaneous analysis of TNC and cellular differentiation using a flow cytometry in rat bone marrow. The purpose of this study was to establish the flow-cytometric method that allows us to simultaneously measure both TNC and main cellular differentials of rat bone marrow.

(Methods) The bone marrow cells were obtained from the femur of male rats (CrI:CD(SD)), and were suspended in phosphate-buffered saline containing bovine serum. The cells were stained with CD11b/c-FITC, CD71-PE, CD3-FITC, CD45RA-PE and the anthraquinone fluorescent DNA stain (DRAQ5), and were analyzed using a flow cytometry in the presence of internal standard beads (Flow count).

(Results) The population of nucleated cells was distinguishable using DRAQ5. The TNC was calculated using the internal standard, and was well correlated with that measured by a classical method (the electrical resistance method). The nucleated

cells were further classified into myeloids and erythroids using CD11b/c-FITC and CD71-PE, respectively. In another test tube, T- and B-cells were also classified using CD3-FITC and CD45RA-PE, respectively. The ratios of cells, together with myeloid / erythroid ratio (ME), were equivalent to that obtained by a manual microscopic method as well as another flow-cytometric method (differentiation by cellular size and 2'7'-dichlorofluorescein-positive peroxidase activity). (Conclusion) The present flow cytometric method allows us to simultaneously measure not only the total nucleated cell counts but also cellular differentials of the rat bone marrow.

1717 COMPARISON OF TWO COMMON TECHNIQUES USED IN MICROAUTORADIOGRAPHY EXPERIMENTS FOLLOWING INTRAVENOUS ADMINISTRATION OF [3H]RDP58.

A. Postoyalko, B. R. Whitby, J. M. Joly and E. E. Bond. *Covance Laboratories Ltd., Harrogate, United Kingdom.* Sponsor: D. Everett.

Microautoradiography offers the advantage of determining cellular distribution of drug/metabolites by studying the distribution of radioactive markers by light microscopy. Histological evaluation of cellular distribution can then establish a mechanistic basis for pharmacological/toxicological activity.

Two microautoradiography approaches have evolved, as described by Appleton and Stumpf. Each approach administers a radioactive test substance [¹⁴C or ³H] to test animals, necropsy at selected times and harvesting the required frozen tissues. Subsequent sections are placed in contact with a photographic nuclear emulsion coated slide. Following exposure the samples are photographically processed and then histologically stained. Microscopically, the stained tissue morphology will be overlaid with silver grains; the latter denoting the presence of radioactivity in the adjacent tissue.

The principal difference between the two approaches is that for the Appleton method, the frozen section is placed in contact with frozen nuclear emulsion to minimise thawing and/or subsequent 'relocation' of radioactive material. The Stumpf method indicates that sections may be thaw mounted, as the thawing/drying processes are transient as the sections are prepared at 4µm or less and any relocation is deemed insignificant.

Due to known retention of RDP58 related material in the liver, this test substance was considered an ideal candidate for studying and comparing tissue distribution at the microscopic level using both the above methods.

Each animal received a single intravenous administration of [3H]RDP58, by tail vein injection and duplicate animals were necropsied and the livers harvested at 0.5 & 24 hours and 7 & 28 days post dose.

The results indicated few apparent differences when comparing autoradiographic evidence prepared by the methods of Appleton and Stumpf. The results indicate that the Stumpf method is technically easier and is recommended for use for establishing a mechanistic basis for pharmacological or toxicological activity.

1718 EVALUATION OF A NEW QUICK-CONNECT INTRAVENOUS INFUSION CATHETER/TETHER SYSTEM IN RATS.

A. N. Alexander, B. Saladino, N. Tripathi, N. Wood, R. Twieg, S. Walker, M. Taschwer, M. Boettcher and S. Dunn. *Toxicology, Covance Labs, Madison, WI.*

Intravenous infusion is used in preclinical toxicology studies to mimic intravenous administration in humans. Historically, small animal catheter/tether systems were comprised of a continuous indwelling femoral catheter with an external catheter tethered to an external cage-side syringe pump. This type of infusion system requires that animals be leashed to individual cages and maintenance solutions be administered continuously between dosing cycles to maintain catheter patency. This study evaluated two new quick-connect intravenous delivery systems in rats; the Strategic Applications and the AVA Biomedical system. These infusion systems offer greater flexibility in study design, allow disconnection from the tether system between dosing cycles, are less expensive to purchase, and require less time and labor. Two groups of twelve male and female rats each received Lactated Ringer's Solution, at 30 mL/kg/day. Animals were continuously infused for four cycles (four days each). To evaluate intermittent infusion, a subset of 3 animals/sex/group were disconnected from the system after the fourth dosing cycle, catheters were locked with a heparin solution, and patency reestablished. System assessment was based on the incidence of infusion line breaks, leaks, occlusions, and disconnections. Tolerability was based on clinical signs, body weights, food consumption, and clinical and anatomical pathology findings. Both systems allowed continuous and intermittent infusion. No system-related alterations in clinical signs, body weight or food consumption, clinical or anatomical pathology were observed. Infusion-associated findings were similar for both groups and were consistent with findings observed in studies using continuous catheter/tether systems. However, the AVA Biomedical system had the fewest number of catheter breaks and dosing interrup-

tions of the systems evaluated. Based on the results of this study, we adopted the use of the AVA Biomedical quick-connect catheter/tether system for intermittent and continuous infusion studies in rats.

1719 CONTINUOUS INTRAVENOUS INFUSION IN THE WEANLING BEAGLE DOG OF 50 DAYS OF AGE.

J. Perron, N. Miller, K. Murphy, K. Robinson, C. Copeman and S. Groom. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.* Sponsor: C. Banks.

Continuous intravenous infusion via an indwelling catheter is frequently used in preclinical safety evaluation studies. Previously, our laboratory has shown that continuous intravenous infusion was both feasible and well tolerated in dogs of 70 days of age. The purpose of this study was to investigate the feasibility of 28 days of continuous intravenous infusion via an indwelling femoral catheter in weanling Beagle dogs commencing at approximately 50 days of age. This age group was investigated as it could be used to evaluate products intended for use in human pediatric populations. A medical grade silastic catheter was surgically implanted under general anesthesia in the vena cava. Animals were continuously infused with saline at 1.5 mL/kg/h for 24 hours/day for 28 days using a modified jacket and tether system. Body weight gains, food intake and neurological conditions were unaffected when comparing data with control values for non-catheterized weanling dogs of the same age. Minor changes in clinical pathology were associated with the presence of a catheter.

It is concluded that, in our laboratory, continuous intravenous infusion of saline at rates of 1.5 mL/kg/h in weanling dogs approximately 50 days post partum for 28 days had no adverse effects on growth compared with non-catheterized animals. Clinical pathology changes were minor and commonly seen in catheterized animals. The experimental procedures were well tolerated and no adverse effects were observed in clinical signs, body weight or body weight gains, behavioral or neurological conditions, clinical pathology, macroscopic observations, organ weights and histopathological information of infused animals.

1720 DEVELOPMENT AND VALIDATION OF IMMUNOPHENOTYPING PROTOCOLS IN SPRAGUE DAWLEY RATS TO EVALUATE PERIPHERAL BLOOD, THYMUS AND SPLEEN LYMPHOCYTES.

S. Zhao¹, T. Childers², D. Baker¹, W. Reagan¹, T. Kawabata¹ and S. Sokolowski¹. ¹Research and Development, Pfizer, Groton, CT and ²Research and Development, Pfizer, Ann Arbor, MI.

The purpose of this study was to develop procedures for immunophenotyping rat lymphocytes, and to evaluate the assay's ability to precisely measure total T lymphocytes (CD3+), T helper/Inducer lymphocytes (CD3+4+), Cytotoxic/Suppressor T lymphocytes (CD3+8+), B lymphocytes (CD3-45RA+), NK T cells (CD3+161+), and Natural Killer cell (CD3-161+) populations in peripheral blood, thymus, and spleen. Red blood cell lysis procedures and antibodies were optimized for the study. Three antibody panels CD3PE-CD4FITC-CD8PerCP-CD45APC, CD3PE-CD45RAFITC-CD45APC, and CD161aFITC-CD3PE-CD45APC were developed to evaluate the lymphocyte subsets in naive 8-10 week old Sprague-Dawley rats by flow cytometry. Results obtained for blood (47% CD3+, 31% CD3+CD4+, 17% CD3+CD8+, 38% CD3-CD45RA+, 8% CD3- CD161a+, 0.5% CD3+CD161a+), spleen (34% CD3+, 19% CD3+CD4+, 15% CD3+CD8+, 3% CD4+CD8+, 54% CD4-CD8-, 46% CD3-CD45RA+, 4%CD3- CD161a+), and thymus (77% CD3+, 6% CD4+CD8-, 6% CD4-CD8+, 0.3% CD3- CD45RA+, 87% CD4+CD8+, 2% CD4-CD8-, 0.19% CD3- CD161a+, 1% CD3+CD161a+) were similar to those reported in the literature. Evaluation of assay precision for all parameters was acceptable with a coefficient of variation less than 10% for most parameters. Results from sample stability testing showed all stained samples to be stable for at least 24 hours. The results illustrate that new immunophenotyping protocols have been developed and validated and accurately measure lymphocyte subsets in rat tissues. Considering that new FDA and CPMP guidelines may require, under certain circumstances, immunophenotyping assays for rat peripheral blood (PB), spleen, and/or thymus, these assays have application to future regulatory studies.

1721 FEASIBILITY STUDY TO CONDUCT ANTIBODY PLAQUE-FORMING CELL (AFC) ASSAY AND SPLEEN HISTOPATHOLOGY SIMULTANEOUSLY USING FISCHER 344 RATS.

J. Thomas, C. Wiescinski and M. Woolhiser. *The Dow Chemical Company, Midland, MI.*

The assessment of a rodent's antibody response towards a T-cell dependent antigen via the AFC assay has served as a standard for some 50 years. The AFC response requires a single cell suspension of the spleen for proper representation of B cells, T

cells and antigen presenting cells, limiting the flexibility in conducting the AFC assay on standard toxicology studies without including additional animals exclusively for the spleen. This study investigated the ability to measure the AFC response to sheep red blood cells (SRBC) and evaluate spleen histopathology from the same spleen. Rats were immunized with a single injection of 2×10^8 SRBC via the lateral tail vein. On four consecutive days, designated rats received an ip injection of cyclophosphamide (CP) at 20 mg/kg. Spleens were harvested and three transverse sections approximately 2-mm thick were collected in 10% neutral buffered formalin for histopathology. The remaining spleen was homogenized to a single cell suspension and the AFC response evaluated. Histological changes in the spleen following immunization with SRBC alone, or in combination with CP treatment, were effectively evaluated using spleen sections. Rats immunized with SRBC had more germinal centers in the spleen than controls, whereas CP eliminated almost all germinal center formation. The remainder of the sectioned spleen from rats immunized with SRBC showed a mean response of 537 AFC/ 10^6 spleen cells as compared to 329 AFC/ 10^6 using whole spleens. Rats immunized with SRBC and treated with CP had a mean of 4 AFC/ 10^6 from sectioned spleens. A second study conducted to verify the robustness of the AFC response following spleen sectioning showed 186 AFC/ 10^6 in sectioned spleens as compared to 259 AFC/ 10^6 in whole spleens. These preliminary data suggest spleen histopathology and AFC response can be successfully performed simultaneously. This approach would allow for assessment of immune function via the AFC assay on standard toxicology studies without the need for additional animals.

1722 THE OPTIMIZATION OF AN ACUTE RAT MODEL TO EVALUATE EFFECTS ON INNATE IMMUNITY INDUCED BY ANTI-INFLAMMATORY AGENTS.

W. Komocsar¹, G. Burleson² and D. Wierda¹. ¹Investigative Toxicology - Immunomodulation Group, Eli Lilly & Company, Greensfield, IN and ²BRT-Burleson Research Technologies, Morrisville, NC.

Evaluation of cellular and humoral immunosuppression by pharmaceutical agents is routinely performed in targeted immunotoxicity studies and/or standard toxicology studies. A more thorough evaluation of suppression of the innate immune response requires infection with a pathogen to clearly demonstrate outcomes on host resistance. We have optimized an acute disease model using intranasal administration of *Streptococcus pneumoniae* to Lewis rats and validated effects on the pulmonary innate immune response using two anti-inflammatory agents, dexamethasone (Dex) and methylprednisolone (MP). Female Lewis rats (n of 15/group) were treated orally 2 hours prior to infection with 30, 100, and 200 mg/kg MP or 5, 15, and 30 mg/kg Dex and monitored 1, 4, and 24 hours post-infection for clearance of the *S. pneumoniae* from the lungs. To measure bacterial clearance, lung homogenates were prepared and plated, and colony counts performed. Cyclophosphamide (CY, 100mg/kg) was used as a positive immunomodulatory control by intraperitoneal administration 4 and 1 days prior to infection. Cyclophosphamide, all doses of DEX, and the 15 and 30 mg/kg doses of MP showed suppression of bacterial clearance at 24 hours, defining a relative immunosuppressive potency of DEX>CY>MP. In addition to our model in the Lewis rat, a similar suppression of the innate immune response can also be demonstrated using both the Fischer 344 and Sprague Dawley rat strains.

The relevance of this acute model to predict potential drug suppression of the innate immune response to *S. pneumoniae* is especially important given similarities of this rodent infection model with human pneumococcal pneumonia. Moreover, the ability to rank order the severity of innate immune suppression with multiple test articles in the same study make this model effective in screening potential drug candidates.

1723 EVALUATION OF VARIOUS KLH DOSING REGIMENS FOR THE CYNOMOLGUS MONKEY TDAR ASSAY.

R. Caldwell¹, M. Guirguis² and E. Kornbrust³. ¹Covance Laboratories, Madison, WI, ²Alberta Blue Cross, Edmonton, AB, Canada and ³Alta Analytical Laboratories, San Diego, CA.

The T-cell dependent antibody response (TDAR) assay is suggested to assess the immunomodulatory effects of new drugs by several regulatory agencies. The purpose of this study was to evaluate various keyhole limpet hemocyanin (KLH) dosing regimens for use in the cynomolgus monkey TDAR assay. Monkey were administered KLH by ID, IV, IM, and SC injections at various dose levels with and without FIA. Toxicology endpoints included clinical observations, clinical pathology, necropsy and histopathologic evaluations. The kinetics of the KLH antibody responses were compared using peak titers, time to peak titer, and area under the titer-time curve. No remarkable clinical observations, body weight changes, food consumption changes, clinical pathology findings, macroscopic findings, organ weight changes, or microscopic findings were associated with a particular dosing regimen. These data suggest that satellite cynomolgus monkeys are not necessary for the monkey TDAR assays during routine toxicology testing. Some animals failed to show any KLH titers, while others exhibited quantifiable predose KLH titers. No compelling differences were observed when comparing KLH responses

via different dose routes. Administration of two KLH injections produced increased antibody responses. Increasing dose levels of KLH did not produce a consistently proportional increase in kinetic parameters. Administration of KLH with FIA did not produce a remarkable change in IgM kinetics but did produce generally higher IgG, although more variable, kinetics. In general, mean maximal IgM and IgG titer values ranged from 6 to 13 days and 12 to 26 days (respectively) across all dose groups. The results of this study can be used as guidance for implementing a monkey TDAR assay using KLH. For a particular drug development program, TDAR variables should be kept constant whenever possible. Potential sources of variation include primate species, animal source, KLH dose levels and dosing regimen, serum sampling intervals, ELISA conditions, and test article interference.

1724 HUMORAL RESPONSE TO KLH AND LYMPHOCYTE SUBSET ANALYSIS IN DOGS TREATED WITH DEXAMETHASONE.

J. Descotes¹, F. Horand² and G. Ravel². ¹Poison Center, Lyon, France and ²MDS Pharma Services, St Germain s/ L'Arbresle, France.

Regulatory immunotoxicity studies are most often performed in the rat. However, the ICH S8 guideline states that the most pertinent species should be selected based on the effects observed in the standard toxicity studies. Therefore, the dog should also be considered as a relevant species for immunotoxicity investigations. In the present study, the effects of dexamethasone given by the oral route at 0.5 mg/kg/day for 28 days was tested on the humoral response against KLH and on lymphocyte subsets in 4 male and 4 female beagle dogs. The animals were immunized with KLH on days 14 and 21. Blood samples were collected before each injection and again on day 28 to determine the primary (IgM) and secondary (IgG) responses to KLH. Lymphocyte subsets (T cells, B cells, CD4+ and CD8+ T cells) were evaluated by flow cytometry before treatment, and on days 14 and 28. Dexamethasone treatment induced a 40-50% decrease in both B and T cell counts, whilst neutrophil counts were increased 30-35%. Anti-KLH IgM and IgG levels were also markedly decreased in the dexamethasone-treated dogs. These results show that the humoral response to KLH and lymphocyte subset analysis are suitable tools for the detection of immunosuppressive compounds in the dog.

1725 DELAYED-TYPE HYPERSENSITIVITY RESPONSE IN RATS CHALLENGED WITH TETANUS TOXOID (TTX) FOR IMMUNOTOXICITY EVALUATION.

Y. Takahashi, R. Imada, T. Fukuda, N. Matsuo, H. Yamatoya, T. Nakamura, H. Izumi, H. Tokado, K. Fukuzaki and R. Nagata. *Drug Safety Research Laboratories, Shin Nippon Biomedical Laboratories, Ltd., (SNBL), Kagoshima, Japan.*

[Purpose] Delayed-type hypersensitivity response is one of a battery of functional immunotoxicity tests. The purpose of this study was to assess TTx, an antigen used for delayed-type hypersensitivity response in rats; moreover, Cyclosporin (CY) suppresses delayed-type hypersensitivity response in rats challenged with TTx. [Method] CY at 0 (physiological saline), 3, 9 and 15 mg/kg/day was administered orally to 6 male and 6 female Crl:CD (SD) rats per group once daily for 4 weeks (Day 0 to 27). Rats were challenged with TTx at 1 Lf/site (10 Lf/mL, 0.1 mL/site) intradermally in the dorsal scapular region and intramuscularly in the femoral region, a total of 3 points (3 Lf/body) per sensitization, 7 and 14 days after oral administration of CY. Eleven days after final sensitization (25 days after CY administration), intradermal challenge with TTx at 0, 0.3, 1, 3 and 10 Lf/mL (10 µL/site), at 5 points in the dorsal scapular region was performed. Reaction at challenge sites was observed at 24, 48 and 72 hours after challenge. Blood was drawn at 7, 14, 21 and 25 days, and anti-TTx-specific IgM and IgG antibodies in sera were measured by ELISA. [Result] In the physiological saline and 3 mg/kg CY groups, edema scored as 1 or 2 was observed in all animals at 24, 48 and 72 hours after challenge. At 9 and 15 mg/kg of CY, the number of animals in which reaction was observed decreased. At 15 mg/kg of CY, no reaction was observed in any animal at 48 or 72 hours after challenge. At 9 and 15 mg/kg of CY, anti-TTx-specific IgM and IgG antibodies in sera were decreased at 21 days, and 21 and 25 days respectively compared with the physiological saline group. But the level of specific-IgM antibody was low. [Conclusion] In rats were sensitized twice with TTx at 3 Lf/body, induction of delayed-type hypersensitivity response and suppression by CY (9 mg/kg) were confirmed.

1726 VALIDATION OF IMMUNE FUNCTION TESTING DURING A 4-WEEK ORAL TOXICITY STUDY WITH CYCLOSPORIN.

H. Yamatoya, Y. Chizo, T. Fukuda, N. Matsuo, Y. Takahashi, T. Nakamura, H. Izumi, H. Tokado, K. Fukuzaki and R. Nagata. *Research Department 3, Shin Nippon Biomedical Laboratories, Ltd., Kagoshima, Japan.*

[Purpose] T cell Dependent Antibody Response (TDAR) using Keyhole Limpet Haemocyanin (KLH)-specific antibodies is regarded as one of the most predictive assay for immunotoxicity testing. The purposes of this study were to validate immunization of rats with KLH as a means of investigating the influence of drugs on

TDAR. [Method] Cyclosporin (CY) at 0 (physiological saline), 3, 9, and 15 mg/kg/day was administered orally (gavage) to 8 male and 8 female Crl:CD (SD) rats per group once daily for 4 weeks (Day 0 to 27), and influence on TDAR was investigated using KLH. KLH was administered subcutaneously (without adjuvant) once (2 mg/kg/body) on Day 10. KLH-specific antibodies (serum IgM and IgG) were determined by ELISA on Days 14, 17, 21, 24, and 28. Hematology, blood chemistry, gross pathology, and histopathological examinations were performed, and organs were weighed. Immunophenotyping (FACS analysis) in the peripheral blood, thymus, and spleen was also conducted. [Result] In CY groups, when compared with the physiological saline group, no significant changes were noted in body weight or organ weights (thymus, spleen, or adrenals), and no abnormalities were observed in gross pathology. In females in the 15 mg/kg CY group, a decrease in leukocyte count was noted at the end of the dosing period. In the CY groups, KLH-specific antibody production was suppressed dose-dependently in both sexes. [Conclusion] KLH-specific antibody production was suppressed by CY (9 and/or 15 mg/kg). Accordingly, it is thought that TDAR test using KLH is suitable for evaluation of immune system by investigational new drugs.

1727 EVALUATION OF DRUG-INDUCED ALTERATIONS IN LYMPHOID TISSUES BY OBJECT ORIENTED IMAGE ANALYSIS USING VIRTUAL IMAGING.

J. A. Wijsman¹, L. A. Obert¹, J. R. Piccotti², R. E. Guzman³ and R. W. Dunstan¹. ¹Investigative Pathology, Pfizer, Ann Arbor, MI, ²Investigative Toxicology, Pfizer, Ann Arbor, MI and ³Pathology, Pfizer, Ann Arbor, MI.

This work compares the quantitation of changes in B- and T-cell populations of rat lymphoid tissue obtained using Definiens eCognition software with Nanozoomer virtual images to results obtained using laser-scanning cytometry (LSC). Male Sprague-Dawley rats received intraperitoneal injections of sterile saline (vehicle) or cyclophosphamide (6 mg/kg) for 14 days to induce immunosuppression. On day 10, rats received keyhole limpet hemocyanin (KLH) (100 µg/animal) intravenously to induce a T-cell dependent antibody response. Animals were sacrificed on day 15, and spleen and thymus organ weights were recorded. Anti-KLH IgM endpoint titers were measured using an enzyme-linked immunoabsorbent assay (ELISA). Formalin-fixed, paraffin-embedded samples of spleen, thymus and mesenteric lymph node were routinely processed and stained with hematoxylin and eosin for histologic evaluation by a pathologist and fluorescent and chromogenic staining for T-cell (CD3) and B-cell (CD79a) populations for assessment with LSC and a custom Definiens ruleset respectively. Cyclophosphamide treated rats had a mean 98% decrease in anti-KLH IgM response, decreased splenic and thymus weights (30% and 25%, respectively), and histopathological evidence of lymphoid depletion in the spleen. Neither Definiens nor LSC analysis of T-cell populations revealed significant differences in the spleen or mesenteric lymph nodes in vehicle vs. treated animals. Examination of B-cell populations revealed significant decreases in the spleen (29.5 ± 3.1 vs. 10.3 ± 1.4 by LSC and 37.9 ± 3.5 vs. 16.0 ± 1.1 by Definiens) and mesenteric lymph nodes (12.9 ± 2.7 vs. 3.8 ± 0.9 by LSC and 19.8 ± 4.1 vs. 8.6 ± 1.8 by Definiens) of treated animals. In summary, image analysis of virtual images using Definiens eCognition software can be used to quantitate T- and B-cell populations in rat lymphoid tissues and these data correlate with LSC data and serologic evidence of decreased IgM.

1728 THE IMMUNOTOXICOLOGY INTER-LABORATORY PROJECT (IILP): VALIDATION OF A T CELL-DEPENDENT ANTIBODY RESPONSE (TDAR) USING KEYHOLE LIMPET HEMOCYANIN (KLH) IN RATS.

S. Spanhaak¹, M. Desmidt¹, K. Cederbrant², M. Müller³, M. Wing⁴, F. Horand⁵, F. van Och⁶, A. Romeike⁷, R. Zierz⁸ and A. Penninks⁹. ¹Johnson & Johnson PRD, Beerse, Belgium, ²AstraZeneca, Sodertälje, Sweden, ³Fraunhofer Institute, Hannover, Germany, ⁴Huntingdon Life Sciences, Huntingdon, United Kingdom, ⁵MDS Pharma, Saint Germain, France, ⁶Organon, Oss, Netherlands, ⁷Pfizer, Amboise, France, ⁸Schering, Berlin, Germany and ⁹TNO, Zeist, Netherlands. Sponsor: W. Coussement.

Aims of the IILP project are to: (1) establish a common design for a TDAR using KLH, (2) validate and test design robustness and sensitivity by inter-lab testing, (3) compare with results obtained in Plaque Forming Cell assays. Main study design, based on 4 pilot studies, included 3 treatment groups with each test compound and 2 (vehicle and a positive) control groups. Rats were treated with test compounds, cyclophosphamide (cp), azathioprine, cyclosporin A and levamisole, for 33 days and were iv immunized with KLH twice, at days 14 and 28. Serum anti-KLH-IgM/IgG titers were determined at days 19, 28 (primary KLH-IgM and IgG response, respectively) and 33 (secondary KLH-IgM and IgG response) using a standardized ELISA. Each compound was tested in the KLH assay at 4 different labs in Wistar- and at 3 different labs in SD rats and in addition once in a PFC assay.

Pilot studies indicated 300 mg KLH iv/animal provided optimal responses to cp-induced suppression. SD versus Wistar rats showed quantitatively different responses. Inter-lab comparisons showed that developed KLH specific antibody ELISAs were easily transferable with a low variability (intra-assay: <10%, inter-lab: <20%) and a high reproducibility. Initial main study results (comparison within labs) showed in general a good concordance between KLH primary IgM responses and PFC assay results. Depending on dose level immunosuppressive treatment can result in enhanced or reduced primary or secondary IgM and IgG responses. In conclusion, the developed and optimized KLH model appears to be robust with respect to inter-lab variability and reproducibility of the applied methods. Moreover intra-lab comparison shows a good concordance between primary KLH-IgM responses and PFC results.

1729 APPLICATION OF VIRTUAL MICROSCOPY AND OBJECT BASED IMAGE ANALYSIS FOR AUTOMATED DETERMINATION OF AGE-RELATED CHANGES IN THE THYMUS OF CYNOMOLGUS MACAQUES.

C. Zurenko¹, J. Wijsman¹, M. Spoor², G. Tassopoulos³, Z. Radi¹ and R. Dunstan¹. ¹Drug Safety Research and Development, Pfizer Inc., Ann Arbor, MI, ²College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, CO and ³LIFE, Definiens AG, Munich, Germany.

There has been considerable interest in the use of expanded histopathology as a primary screen for immunotoxicity assessment. To date, this assessment has primarily relied on semi-quantitative methods. In this study, we report the use of virtual microscopy and object-based image analysis to develop an automated method for quantitative assessment of thymic morphology in a non-human primate. Histologic sections of thymus from 94 male and female cynomolgus macaques were stained with hematoxylin and eosin (H&E) and trimmed at 3 micrometers. Sections were evaluated quantitatively and semi-quantitatively, related to organ, body and brain weights and analyzed based on age (young: <3 years; adult: 3-6 years; older adult: 7-15 years). For quantitative assessment, H&E stained sections were scanned on the Nanozoomer imaging platform. Definiens eCognition custom rulesets were written to 1) identify the thymus from adjacent non-thymic stromal and lymphoid tissues; 2) recognize and determine the area of the cortex; 3) recognize and determine the area of the medulla; 4) in older adult adults, compose a ruleset to quantify thymic tissue in animals with no appreciable medullary area. Semi-quantitative assessment used visual scoring by a pathologist. No appreciable differences were noted between the two methods of assessment. There was a trend for a decrease in thymic weights and ratios with increased age that was more evident in males than females. This correlated to smaller medullary and/or cortical areas. The data presented here indicate that automated phenotypic analysis of the thymus in cynomolgus macaques using conventional staining is practical, using virtual imaging and object oriented image analysis and that these results correspond to those from a pathologist.

1730 EXTENSION OF A T-DEPENDENT ANTIBODY RESPONSE MODEL IN THE RAT FOR ENHANCED PRECLINICAL IMMUNOTOXICITY ASSESSMENTS.

E. R. Gore¹, J. K. Gower¹, C. Genell¹, C. Thiele¹, F. Liu² and D. Herzyk¹. ¹Safet Assessment, GlaxoSmithKline, King of Prussia, PA and ²Statistical Sciences, GlaxoSmithKline, King of Prussia, PA.

The T-dependent antibody response (TDAR) model in the rat has recently been validated with potent immunosuppressive drugs and highly practical analytical methods. However, the utility of the model to detect mild immunosuppression and/or increased sensitivity over standard immune tests (i.e. hematology and histopathology of lymphoid organs) has not been convincingly demonstrated. Here we describe a TDAR model that combines IgM and IgG antibody measurements with *ex vivo* functional parameters (e.g. immunophenotyping, cytokine profiling, and lymphocyte proliferation) for enhanced hazard identification and characterization. Male Sprague Dawley rats were administered vehicle or cyclosporine (CsA) at a low dose of 5 mg/kg/day and a maximum tolerated dose of 20 mg/kg/day by oral gavage for 4 weeks. Immunization with keyhole limpet hemocyanin (KLH) by the intravenous route on Days 14 and 24 enabled assessment of a primary IgM and IgG (Day 19 and 24, respectively) and boosted IgG (Day 29) response. Immunophenotype analysis on peripheral blood was evaluated on Days 1, 19, 24 and 29. Splenocyte function post stimulation with KLH or Pokeweed mitogen was assessed on Day 29. Administration of CsA at 20 mg/kg/day caused significant decreases in the following: anti-KLH IgM and IgG antibodies (>90%; p<0.001); peripheral blood CD3+ T cells (40 to 50%; p<0.01); splenocyte proliferation (~70%; p<0.05); and IFN-γ, IL-4, and IL-10 production (40 to 80%; p<0.05). Rats administered 5 mg/kg/day CsA had statistically significant decreases in anti-KLH IgG antibodies (~80%; p<0.001) and CD3+ T cells (15 to 30%; p<0.05) but not anti-KLH IgM antibodies. Thus, the IgG parameter combined with immunophenotype analysis in the described TDAR model demonstrated greater sensitivity in identify-

ing mild immunosuppression caused by the low dose of CsA. *Ex vivo* functional parameters aided in the interpretation of the biological significance of immunotoxic effects observed in this model.

1731 HOST RESISTANCE STUDIES FOR COMPLIANCE WITH THE ICH-8 IMMUNOTOXICOLOGY GUIDELINE.

N. Hebert, S. Mason, C. Thompson and C. Banks. *Toxicology, Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada.* Sponsor: C. Banks.

As per the ICHS8 guideline "Immunotoxicity Studies for Human Pharmaceuticals", the evaluation of potential adverse effects of new drugs on the immune system should be incorporated into standard drug development. Host resistance assays that examine possible adverse effects due to immunosuppression in appropriate models may also be required for compliance with Regulatory Agency guidelines. Several pathogens may be used to demonstrate these effects, such as bacteria, viruses, fungi and tumor cell lines. In our laboratory, we have used several strains of mice to demonstrate deleterious effects of agents such as cyclophosphamide on the immune system. Intraperitoneal injection of 80 mg/kg cyclophosphamide for three days prior to infection in Balb/c mice with *Listeria monocytogenes* resulted in mortality, decreased body temperature and recovery of bacteria from the liver for surviving animals at necropsy. Similar results were seen in the same strain of animals following dosing with *Candida albicans* with the organism recovered from the spleen at termination. C57BL/6 mice were also treated with a B16 melanoma cell and examined for lung metastases 14 days later. Various immunostimulatory herb extracts were shown to reduce the lung colony counts by up to 40% compared with those seen in control animals. Overall, this work was considered to demonstrate the utility of host resistance assays in providing an overall assessment of immune status in relation to an animal's ability to combat an infection or tumor. These types of study are valuable as follow-on investigations to support mechanistic immunotoxicology, particularly if an effect on specific cell types has been shown for a test compound. In summary, although these studies demonstrated the versatility and utility of infectious animal models in assessment of immunological status, it should be remembered that translation to human risk assessment is more complicated, particularly due to difficulties in determining realistic infectious doses in humans.

1732 VALIDATION OF THE KLH-ASSAY AS ALTERNATIVE TO THE PFC-ASSAY: A COMPARATIVE STUDY WITH CYCLOPHOSPHAMIDE.

A. H. Penninks, J. van Bilsen, M. Brouwer, K. Junker, F. Kuper and V. Feron. *Toxicology and Applied Pharmacology, TNO Quality of Life, Zeist, Netherlands.*

For immunotoxicity testing the IgM-Plaques Forming Cell (PFC) assay using Sheep Red Blood Cells (SRBC) as antigen is regarded to be the most predictive functional assay. Because various drawbacks of this assay alternative tests like the KLH-assay, using Keyhole Limpet Hemocyanin (KLH) as antigen, are being developed. A common design for a KLH-assay was established in an Immunotoxicity Inter-Laboratory Project (IILP), using well known immunosuppressive compounds. Using cyclophosphamide (CY) the robustness and sensitivity of the KLH-assay was determined and compared with the PFC-assay. In both the KLH- and PFC study Wistar rats were exposed to 1, 3 and 10 mg cyclophosphamide/kg bw by gavage for respectively 33 and 28 days. Primary- and secondary immunization with KLH (300 µg i.v.) was performed on days 14 and 28. The KLH-specific IgM and IgG antibody responses were determined in blood at days 19, 28 and 33. In addition effects on body weight, hematology, lymphoid-organ weight and -pathology are determined. Additional control and top dose groups were included which were not immunized with KLH to assess if KLH immunization will affect routine immune histopathology. In the PFC-assay immunization with SRBC was performed on day 24 and the number of IgM-PFC in the spleen was assessed on day 28. The primary and secondary anti KLH-IgM titers were dose-dependently decreased at day 19 (significantly decreased at the 2 top dose levels) and day 33 (significantly decreased at all dose levels), respectively. At day 28 the primary anti KLH-IgG titers were still low and only significantly reduced at the top dose of CY. The secondary anti KLH-IgG titers were significantly decreased at the two top doses of CY. In the PFC-assay the number of IgM-PFC in the spleen was dose-dependently decreased which was significant at the two top doses of CY. In conclusion it was evident that the KLH and PFC-assay were equally sensitive, and that the histopathology of the lymphoid organs was not affected by KLH immunization.

1733 BONE MARROW BIOPSY IN NON-HUMAN PRIMATES: COLLECTION AND EVALUATION IN RHESUS MONKEYS.

G. Washer¹, S. Fournier¹, S. Authier^{1,2} and F. Chaurand¹. ¹LAB Research Inc., Laval, QC, Canada and ²Faculty of Veterinary Medicine, St-Hyacinthe, QC, Canada.

Examination and quantification of bone marrow cells is a valuable tool for assessment of toxicological or pharmacological effects of certain drugs, whose intended (or unintended) actions target the bone marrow. Non-terminal, serial bone marrow

collection can be used to establish a time-course of effect, and to thereby gain a better understanding of a compound's effect on progenitor cells. Our laboratory established methods to serially collect, process and evaluate bone marrow. Baseline from forty (40) untreated Rhesus monkeys is presented. Prior to collection, animals were anesthetized with an injectable. The right or left shoulder and the right or left hip were shaved and aseptically prepared. A spinal needle (Terumo, 20G, 3 1/2 inches) was inserted in the medulla of the right or left humerus and right or left femur, through the proximal epiphysis. Serial bone marrow collections were performed on each animal by alternating between left and right sides. On each biopsy occasion, a first sample of (circa 1 mL) was collected in EDTA for smear preparation while a second sample (circa 1 mL) was collected into a syringe containing circa 2 mL of culture media (RPMI1640, penicillin 50U/mL, streptomycin 50 µg/mL, 100 U/mL of DNase-1 and 90 IU/mL of preservative-free sodium heparin). Syringes with culture media were weighed pre (including the culture media) and post bone marrow collection. Samples were then transferred to sterile collection media container(s). One (1) tube was analyzed by flow cytometry after staining with CD3/CD71/CD34/CD41a antibodies. The second tube was used for automated counts of nucleated cells using a hematology analyzer. Anticoagulated bone marrow samples (unfiltered), protected against environmental temperature changes, were used for clonogenic assays (GM-CFC, CFU-E, BFU-E, MK-CFC, F-CFC). The bone marrow progenitor cells were characterized and normal values are presented. Significant inter-individual variability was noted. Serial evaluations is recommended to allow comparison of post treatment results with baseline values.

1734 EVALUATION OF THE IMMUNE SYSTEM IN RATS AND MICE ADMINISTERED AMMONIUM PERFLUOROOCTANOATE (APFO).

S. E. Loveless, D. Hoban, G. Sykes and E. E. Nancy. *DuPont Haskell Laboratory, Newark, DE.*

Few studies have evaluated immune system function following repeated exposure to APFO. Male CD rats and CD-1 mice were given doses by oral gavage ranging from 0.3 to 30 mg/kg of linear APFO for 28 days. Anti-sheep red blood cell (sRBC) IgM levels, clinical signs, body weights, food consumption, selected hematology and lipid parameters, liver weights, spleen and thymus weights and cell number, selected histopathology and serum corticosterone concentrations were evaluated. An additional group of animals was dosed with 30 mg/kg APFO for 22 (rat) or 23 (mouse) days and, following sRBC immunization, with vehicle for the remaining days prior to sacrifice on day 29. In rats no suppression of the ability to make anti-sheep RBC antibody was observed at any dose. Ten and 30 mg/kg resulted in systemic toxicity as evidenced by decreases in body weight gain (26 and 63% of control, respectively) and increases in serum corticosterone levels to 135 and 196% of control, respectively. In mice exposed to 0.3 or 1 mg/kg, no significant suppression of the ability to make anti-sheep RBC antibody was observed. At 10 and 30 mg/kg APFO, marked general toxicity and stress was observed, as evidenced by a loss in body weight of 3.8 and 6.6 g, respectively (despite a tripling of liver weight), ~230% increase in serum corticosterone, and increases in absolute numbers of blood neutrophils and monocytes with an accompanying decrease in absolute lymphocyte numbers. A number of immune-related findings occurred at 10 and 30 mg/kg that likely represent secondary responses to the systemic toxicity and stress observed at these doses: decreased IgM antibody at 10 (20% suppression) and 30 mg/kg (28% suppression); decreased spleen and thymus weights and cell numbers; microscopic depletion/atrophy of lymphoid tissue starting at 10 mg/kg in the thymus and 30 mg/kg in the spleen. In summary, no immune-related changes occurred in rats, even at doses causing significant systemic toxicity. In mice, immune-related changes occurred only at doses causing significant systemic toxicity and stress.

1735 EVALUATION OF EFFECTS OF INTRAVENOUS AND SUBCUTANEOUS ADMINISTRATION OF A CYNOMOLGUS MONKEY ANTI-IL-15 ANTIBODY IN THE CONTEXT OF REPEATED DOSE SAFETY EVALUATION.

M. Horner¹, B. Boren¹, S. Buntich¹, S. T. Wolford², R. G. Caldwell², W. Pan¹, J. Xiao¹ and J. L. Bussiere¹. ¹Amgen Inc., Thousand Oaks, CA and ²Covance Laboratories Inc., Madison, WI.

Inhibition of interleukin-15 (IL-15) is currently being evaluated for treatment of inflammatory disease. Effects of intravenous and subcutaneous administration of a cynomolgus monkey IL-15 antibody (cyIL-15 Ab) were evaluated in the context of two safety studies of 1- and 3-months duration. The purpose of these studies was to determine potential toxicity, toxicokinetics (TK), and to explore potential biomarkers of a cyIL-15 Ab, when administered weekly for 5 weeks by intravenous (IV) or subcutaneous (SC) injection or for 3 months by SC injection. In addition, recovery from test article-related effects was evaluated following a treatment-free period. For the 1-month study, five groups of monkeys (5/sex/group) were treated once weekly for five weeks at 0, 30, 60, or 150 mg/kg IV or 150 mg/kg SC. For the 3-month study, five groups of monkeys (6/sex/group) were treated once weekly for 3 months

at 0, 5, 30, or 150 mg/kg SC. Parameters evaluated included mortality, clinical signs, body weights, ECGs, ophthalmic examinations, clinical pathology, immunophenotyping, natural killer cell (NKC) activity, organ weights, gross and microscopic pathology, TK, and antibody analysis. For both studies, all animals survived to scheduled necropsy with no test article-related effects on body weights, ECGs, ophthalmic examinations, organ weights, gross pathology, or histopathology. In the 3-month study, a few animals in the test article-treated groups manifested gastrointestinal findings associated with *Shigella* infection. Test article administration produced a marked reduction in individual absolute and relative NKC values as early as one week after the first dose; this change was associated with a concomitant decrease in NKC activity. Based on these results, weekly IV or SC treatment with cyIL-15 antibody for up to 3 months in cynomolgus monkeys was fairly well tolerated, and pharmacodynamic activity of IL-15 inhibition (i.e., NKC depletion) was observed.

1736 ORAL EXPOSURE TO DISULFOTON FOR 28 DAYS BY GAVAGE PRODUCED MINIMAL IMMUNOMODULATION IN FEMALE B6C3F1 MICE.

T. L. Guo, R. D. Brown, W. Auttachoat and K. L. White, Jr. *Virginia Commonwealth University, Richmond, VA.*

Disulfoton (DST), O,O-diethyl S-[2-(ethylthio)ethyl] phosphorodithioate, is a selective, systemic organophosphate insecticide and acaricide that is effective against multiple insects. It is used to control aphids, leafhoppers, thrips, beet flies, spider mites, and coffee leaf miners. Disulfoton products are used on a wide variety of food and nonfood crops with the highest use on cotton and wheat. DST has been found to bioaccumulate in fish and other organisms. DST inhibits cholinesterase, and cholinergic muscarinic receptors have been identified on lymphocytes. In the present study, DST was administered to female B6C3F1 mice daily for 28 days by gavage at five dose levels (0.01, 0.05, 0.1, 0.5 and 1 mg/kg) in order to determine the potential effects of DST on the immune system. There were no significant changes in the terminal body weight and weights of liver, lungs, kidneys, spleen and thymus. Blood was collected from the animals by the retro-orbital route under carbon dioxide anesthesia on day 29 for hematological evaluation. The erythrocyte count, hemoglobin, hematocrit, MCV, MCH, MCHC, %reticulocytes and platelet counts were unaffected after exposure to DST. Although an increase in total leukocyte count (primarily lymphocytes and neutrophils) was observed in the 0.05 and 0.5 mg/kg-dose groups, the increase was not dose-dependent. Flow cytometric analysis suggested that a decrease in the percentage of splenic B cells at the dose level of 0.1 mg/kg; however, the absolute value was not significantly changed. Five functional assays including the spleen IgM antibody-forming cell response, spleen cell proliferative response to anti-CD3 stimulation, natural killer cell activity assay, and spleen mixed leukocyte response and cytotoxic T cell activity assay were performed. There were no biologically meaningful changes associated with any of the assays. Taken together, oral exposure to disulfoton for 28 days by gavage produced minimal immunomodulation in female B6C3F1 mice (Supported by NO1-ES-05454).

1737 LOVASTATIN, THE CHOLESTEROL LOWERING DRUG, DOES NOT ALTER IMMUNE RESPONSES IN FEMALE B6C3F1 MICE.

K. L. White, D. L. Musgrove, W. Auttachoat and T. L. Guo. *Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA.*

The statins are a class of compounds shown to be highly effective in lowering serum cholesterol levels, particularly when changes in diet and exercise prove ineffective. World wide, millions of people take one of the statin drugs, on a daily basis, in order to lower their cholesterol levels. In addition to their ability to decrease cholesterol levels, the statins have been reported to have anti-inflammatory activity which may contribute to their ability to help in reversing coronary artery disease as well as the possible prevention of heart attacks and strokes. Lovastatin (LOV) was selected, as a representative statin drug, for evaluation of its ability to modulate the immune response. Female B6C3F1 mice were administered LOV once daily for 28 days by oral gavage in a 0.5% methylcellulose vehicle. Dose levels consisted of 0.5, 2, 5, 20, and 50 mg/kg/day. On day 29, animals were evaluated for toxicological and immunological effects. In animals receiving LOV, no significant differences were observed in terminal body weights or selected organ weights, including liver, spleen, lung, thymus and kidneys at any dose level as compared to the vehicle controls. Similarly, hematological parameters and the splenic differential, as determined by flow cytometry, were unaffected. No effect was observed in functional assays used to measure humoral immunity including the antibody forming cell response to sRBC. Cell-mediated immune responses, including the MLR, CTL, and anti-CD3 mediated proliferation were also unaffected following LOV administration. In the parameters used to evaluate innate immunity, including NK cell activity and the functional activity of the mononuclear phagocyte system (MPS) there were no significant differences observed between vehicle control animals and the animals treated with any of the LOV doses. In summary, treatment with LOV for 28 days at dose levels up to 50 mg/kg/day did not result in modulation of the immune response in B6C3F1 mice. (Supported by NIEHS NO1-ES-05454)

1738 INHIBITION OF THE MURINE ALPHA 1 BETA 1 INTEGRIN DOES NOT AFFECT THE PRIMARY IMMUNE RESPONSE TO INFLUENZA IN BALB/C MICE.

K. J. Olivier¹, V. Palmer¹, F. Burleson², G. Burleson², J. Morrow¹, F. Taylor¹ and J. B. Clarke¹. ¹*Toxicology, Biogen Idec Inc., Cambridge, MA* and ²*Burelson Research Technologies Inc., Morrisville, NC.*

Preclinical development of a monoclonal antibody targeting inhibition of the alpha 1 beta 1 integrin, a member of the integrin family of cell surface molecules involved in cell-cell/ cell-matrix adhesion and communication, indicated the potential for the recrudescence of a plasmodium infection in non-human primates. Therefore, immunocompetence was tested in mice administered a hamster anti-mouse alpha 1 beta 1 integrin monoclonal antibody (HA31/8) using an influenza challenge, considered the 'gold standard' for identifying an immunotoxic effect. This model consisted of a main phase to measure viral clearance, influenza-specific IgG, cytokines, and spleen natural killer (NK) cell and cytotoxic T lymphocyte (CTL) activity, and satellite phases to measure lung NK, lung CTL, and macrophage function in the spleen and lung. Female Balb/c mice (n=50) were administered phosphate buffered saline (PBS), 0.3, 3 or 30 mg/kg mHA31/8, or 30 mg/kg P1.17 (a negative control antibody) twice weekly via intraperitoneal (IP) injection prior to viral influenza infection (Days -7 to -1) and up to 3 weeks after viral influenza infection (Days 1 to 21). Dexamethasone, a positive immunomodulatory control article, was administered (n=50) at 20 mg/kg/day orally, from Day -3 through Day 21. Animals were infected (on Day 0) with mouse-adapted influenza virus (MAIV). Necropsies for the main study groups were conducted on Days 0 (naïve animals only), 2, 6, 8, 10, and 21. Satellite phase mice were necropsied on Day 2 (lung NK and macrophage function) or Day 8 (lung CTL). Treatment with mHA31/8 did not affect mortality or spleen weight, caused only minor changes in terminal body weight, and increased lung weight. Although there were variable effects of the test article on certain cytokine levels, mHA31/8 at doses up to 30 mg/kg did not affect influenza-specific IgG levels or the clearance of influenza and was not considered to be immunotoxic.

1739 QUANTITATIVE EVALUATION OF THE TIME COURSE OF EFFECTS OF ACUTE ETHANOL ON POLY I:C INDUCED PRODUCTION OF CYTOKINES, CHEMOKINES, AND CORTICOSTERONE.

M. Glover and S. B. Pruett. *Department Cellular Biology & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Previous studies in our lab suggested a role for an ethanol-mediated stress response as a feedback mechanism in the suppressed production of one pro-inflammatory cytokine (IL-6) and the enhanced production of an anti-inflammatory cytokine (IL-10). However, these effects were only measured at one time point, so the overall effects of ethanol were not clear. The purpose of the present study was to measure both corticosterone and serum cytokine and chemokine concentrations over time, to allow calculation of the area under the concentration vs. time curves and quantitative comparisons of changes in corticosterone and changes in cytokine and chemokine production. Groups of mice (5 per group) were given no treatment (naïve), poly I:C (100 µg/mouse, I.V.), ethanol (6g/kg, oral gavage), or both, and blood samples were analyzed for corticosterone (by RIA) and cytokines and chemokines (by multiplexed bead array assay). Blood samples were taken 1, 2, 4, 6, 8, and 10 hours after administration of poly I:C and/or ethanol. Statistical analysis of the corticosterone AUCs indicate a significant increase in the poly I:C + ethanol groups versus the poly I:C or ethanol groups. Cytokine and chemokine concentrations and AUC values were calculated, and poly I:C induced readily measurable quantities of IL-1 beta, IL-12 (p40), IL-12 (p70), IL-6, IL-10, TNF-alpha, KC, CCL3, and CCL4. Concentrations of IFN-gamma and GM-CSF were near the lower limits of detection. In general, ethanol decreased the response of pro-inflammatory cytokines to stimulation by poly I:C, but increased the production of the anti-inflammatory cytokine IL-10. The time course of changes was unique for each cytokine/chemokine. Further studies will be needed to determine which of these alcohol induced effects are due to the changes in corticosterone induced by the stress response, but AUC values indicated that changes in some cytokines caused by ethanol were much greater than the slight increase in corticosterone AUC. This work was supported by NIH grant AA009505.

1740 IMMUNOTOXICITY EVALUATION OF METHOTREXATE IN RATS BY ORAL ADMINISTRATION.

R. Kawai, T. Aida, S. Komatsu, A. Muramatsu, S. Sehata, M. Teranishi, S. Manabe and T. Furukawa. *Medicinal Safety Research Laboratories, SANKYO CO., LTD., Fukuuro-shi, Shizuoka, Japan.*

Methotrexate (MTX), a folate antagonist, is widely used in the treatment of rheumatoid arthritis. Although it is a well-known immunosuppressant, its immunotoxicological profile has not been much reported. In this study, we evaluated

several immunological parameters in rats treated with MTX. MTX was intermittently given orally to male and female Crl:CD(SD) rats for 2 weeks (3 times weekly at dose levels of 0, 1, 2 or 5 mg/kg/day). The following evaluations were conducted: T-cell dependent antibody response (TDAR), serum immunoglobulin levels, lymphocyte subset analysis (on the peripheral blood, thymus, spleen and mesenteric lymph nodes), mitogen (PHA, ConA, LPS)-induced proliferation and cytokine induction on splenocytes, hematology and pathology. In the TDAR, anti- Σ RBC IgM antibody production obviously decreased. In addition, slight decreases in IgA, IgE, IgG and IgM were observed. The lymphocyte subset analysis revealed no significant changes in lymphocyte phenotypes in the peripheral blood, thymus, spleen and mesenteric lymph nodes. In the T-cell- or B-cell- mitogen response in the splenocytes, no significant changes were observed in splenocyte proliferation or in humoral immune response related cytokines (IL-4 etc.), although inflammatory cytokine production (TNF- α etc.) decreased in the highest dose group. The hematological and histopathological changes associated with the immune system were not observed in the peripheral blood, thymus, spleen and mesenteric lymph nodes. This study demonstrated that MTX decreased the humoral immune function that is complicatedly associated with several kinds of immune system cells (antigen presenting cells, T cells, B cells etc.), but it did not change the population, proliferation and response related cytokine induction potency of T-cells or B-cells. It seems likely that the immunosuppressive effect of MTX is mainly involved in inhibition to the other immune cells rather than to T-cells or B-cells. As well, the results of the analysis including other immune cells will be presented in this study.

1741 INVESTIGATING IMMUNE RESPONSES IN FEMALE BROWN NORWAY RATS GAVAGED DAILY WITH NEVIRAPINE FOR A WEEK.

M. Popovic, J. Boisclair, M. Kammüller and P. Ulrich. *Novartis AG, Basel, Switzerland.*

Nevirapine, used for the treatment of HIV infections, is associated with a significant incidence of skin rash and liver toxicity. Formerly the discovery of an animal model of nevirapine-induced skin rash in female Brown Norway rats fed with 150 mg/kg/day drug mixed in their diet has been reported, with rats developing red ears on day 7 and skin rash on day 21 of the treatment. In the current study we aimed at establishing and utilizing a new model of nevirapine-induced skin rash by gavaging and not feeding rats with the drug. We gavaged rats with either a control (0.5% methylcellulose) or commercially available nevirapine solution (75 mg/kg/day) twice a day for a week. During the treatment we regularly checked nevirapine serum concentration levels. At the end of the treatment we performed ear and liver tissue pathologies, and we analyzed rat sera, lymph nodes and splenocytes for immunological changes. Our data showed that in the rats gavaged with nevirapine drug blood concentration reached 45 μ g/ml by day three of the treatment and it subsequently subsided to 11 μ g/ml by day 7. No red ears were observed at day 7 in the nevirapine-treated rats; however, increased serum IL1 α , IL2, IL6 and IL10 levels were detected at this time point. Organ analyses showed increased liver and auricular lymph node weights as well as nodal cellularity (predominantly in T, B and macrophage cell populations) in the nevirapine-treated rats. Pathology analysis showed diffuse moderate acute inflammation in nevirapine-treated rats, characterized by prominent vessels with intravascular inflammatory cells (eosinophils) and mixed dermal infiltrate composed of polymorphonuclear and mononuclear cells. Results from our study indicate that: a) rats gavaged or fed nevirapine-diet show comparable immune response to the drug, b) gavaging rats twice per day with 75 mg/kg nevirapine induces similar immunological responses as does feeding them with 150 mg/kg and c) rats from different breeders show similar immune responses to nevirapine treatment.

1742 IMMUNOTOXICOLOGICAL ACTIVITY OF INDOOR AIR PARTICLES AND BIOAEROSOLS BEFORE AND AFTER RENOVATION OF MOISTURE DAMAGED BUILDING.

K. Huttunen, H. Rintala, A. Nevalainen and M. Hirvonen. *Department of Environmental Health, National Public Health Institute, Kuopio, Finland.* Sponsor: M. Viluksela.

Many of the building-related health problems coincide with moisture damage and mould growth within the building. This has been shown both as increased incidence of adverse health effects in moisture damaged buildings, and as a decrease in prevalence of symptoms after a thorough renovation. The aim of this study was to follow the success of repairs in two cases by analyzing the immunotoxicological activity of filter samples collected from 1) indoor air of moisture damaged building before and after renovation, 2) reference buildings and 3) outdoor air. The effects of collected bioaerosols were tested by exposing mouse macrophages (RAW264.7) for 24 hours to particle suspension extracted from the filters. Viability of the exposed cells (MTT-test) and production of inflammatory mediators (nitric oxide, IL-6 and TNF α) in cell culture medium were measured by ELISA immunoassay.

The samples collected before renovation on Case 1 were more toxic and induced higher production of inflammatory mediators in mouse macrophages compared to samples collected after the renovation. Samples from outdoor air and reference building had only minor effect, both before- and after the renovation. Instead, in Case 2 the renovation measures did not cause any evident change in before and after-samples, whereas the samples collected from the reference building induced more intense responses after renovation. The samples collected from outdoor air in Case 2 caused strikingly similar responses compared to indoor air samples. In conclusion, in the Case 1 the decrease in immunotoxicological activity of the indoor air particles coincided with the repairs. In the Case 2, the inflammogenic and toxic properties of the indoor air particles seemed to reflect the situation in outdoor air rather than changes in the indoor air. This indicates, that the adverse health effects caused by exposure to moisture and mold damaged houses are not necessarily of the same origin.

1743 KIOM-79 INHIBITS LPS-INDUCED P65 NUCLEAR TRANSLOCATION.

Y. J. Jeon¹, M. H. Li¹, J. S. Kim³ and I. Y. Chang². ¹Pharmacology, Chosun University, Kwangju, South Korea, ²Anatomy, Chosun University, Kwangju, South Korea and ³Korea Institute of Oriental Medicine, Daejeon, South Korea. Sponsor: H. Kim.

We demonstrate that KIOM-79, combined extracts obtained from *Magnolia officinalis*, *Pueraria lobata*, *Glycyrrhiza uralensis*, and *Euphorbia pekinensis*, inhibits LPS-induced expression of iNOS gene in RAW 264.7 cells. Treatment of RAW 264.7 cells with KIOM-79 inhibited LPS-stimulated nitric oxide production in a dose-related manner. Immunohisto-chemical staining of iNOS and RT-PCR analysis showed that the decrease of NO was due to the inhibition of iNOS gene expression. Immunostaining of p65, EMSA, and reporter gene assay showed that KIOM-79 inhibited NF- κ /Rel nuclear translocation, DNA binding, and transcriptional activation, respectively. Western immunoblot analysis of p38 kinase showed KIOM-79 significantly inhibited the phosphorylation of p38 kinase which is important in the regulation of iNOS gene expression. Collectively, this series of experiments indicates that KIOM inhibits iNOS gene expression by blocking NF- κ /Rel and p38 kinase signaling. Due to the critical role that NO release plays in mediating inflammatory responses, the inhibitory effects of KIOM-79 on iNOS suggest that KIOM-79 may represent a useful anti-inflammatory agent.

1744 INHIBITION OF INOS EXPRESSION BY RADICICOL IN CYTOKINE-STIMULATED PANCREATIC BETA CELLS.

K. Y. Lee² and Y. J. Jeon¹. ¹Pharmacology, Chosun University, Kwangju, South Korea and ²Korea Research Institute of Bioscience and Biotechnology, Daejeon, South Korea. Sponsor: H. Kim.

In the present study, we show that radicicol, a fungal antibiotic, produces a marked inhibition of inducible nitric oxide synthase (iNOS) transcription by the pancreatic beta cell line MIN6N-8a in response to cytokine mixture (CM: TNF- α , IFN- γ , IL-1 β). Treatment of MIN6N-8a with radicicol inhibited CM-stimulated nuclear factor- κ B/Rel (NF- κ B/Rel), which plays a critical role in the iNOS transcription, in a dose-related manner. Our data also show that the extracellular signal-regulated protein kinase-1 and 2 (ERK1/2) pathway is specifically involved in CM-induced NF- κ B/Rel activation and iNOS expression because NF- κ B/Rel DNA binding and iNOS mRNA production in the presence of a specific inhibitor of ERK1/2 pathway, PD98059, were dramatically diminished. In contrast, SB203580, a specific inhibitor of p38 had no effect on NF- κ B/Rel activation and iNOS expression. Collectively, this series of experiments indicates that radicicol inhibits iNOS gene expression by blocking ERK1/2 signaling. Due to the critical role that NO release plays in mediating destruction of pancreatic beta cells, the inhibitory effects of radicicol on iNOS suggest that this potent anti-fungal agent may represent a useful anti-diabetic agent.

1745 PANAX NOTOGINSENG ATTENUATES DENDRITIC CELL FUNCTION THROUGH INHIBITION OF NF- κ B ACTIVATION.

A. Rhule¹, J. R. Smith¹ and D. M. Shepherd^{2,1}. ¹Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT and ²Center for Environmental Health Sciences, University of Montana, Missoula, MT.

The transcription factor NF- κ B is involved in the regulation of many genes in the immune system including inflammatory cytokines. Agents that modulate NF- κ B activation are actively sought after and have great potential as novel treatments of inflammatory diseases. In this study, the natural product *Panax notoginseng* was

evaluated for its immunomodulatory effects on murine bone marrow-derived dendritic cells (BMDC). BMDC were stimulated with 1 µg/ml LPS and concurrently treated with notoginseng for 24 hours at varying concentrations ranging from 0-200 µg/ml. Notoginseng inhibited the production of the inflammatory cytokines TNF- α , IL-6 and IL-12. The expression of cell surface molecules required for the productive interaction of dendritic cells (DC) and T cells were also modulated by notoginseng. CD40 expression was decreased, while MHC class II and CD86 were unperturbed unless BMDC were pretreated with notoginseng. DC had reduced ability to phagocytose FITC-conjugated ovalbumin antigen, with variable effects on antigen-specific activation of CD4+ T cells following notoginseng treatment. Since these processes can be influenced by the transcription factor NF- κ B, the effects of notoginseng on its activation were examined. Notoginseng reduced the LPS-induced activation of NF- κ B in BMDC. Taken together, these results demonstrate that notoginseng can reduce DC activation and function presumably by altering NF- κ B activity. Supported by NIH grant RR17670 and NSF grant EPS0091995.

1746 FLAVONOID GALANGIN, BUT NOT CATECHIN OR TAXFOLIN INDUCES MITOCHONDRIAL DYSFUNCTION IN HEPG2 CELL LINE AND LEADS TO CELL DEATH.

D. J. Dorta¹, C. Curti¹ and K. B. Wallace². ¹Faculty of Pharmaceutical Sciences of Ribeirão Preto - University of São Paulo, Ribeirão Preto, SP, Brazil and ²University of Minnesota Medical School - Duluth, Duluth, MN.

Flavonoids are benzo- γ -pyrone derivatives widely distributed in the vegetable kingdom, possessing well-recognized antioxidant properties. Their fundamental structure comprises two benzene rings linked through a heterocyclic pyran or pyrone ring. The structural features favouring the antioxidant activity of these compounds are well known, however there are few studies on their toxicological potential. Objective: The study addressed aspects of mitochondrial energetics of HepG2 cells exposed to the flavonoids Galangin, Taxfolin and Catechin in context of the mitochondrial mechanisms potentially involved in the cell death. Methods: Cell viability was determined by the LIVE/DEAD assay by flow cytometry. Adenine nucleotides content was quantified by HPLC. Caspases -9 and -3 activities was quantified by measuring the cleavage of colorimetric peptides Ac-LEHD-pNA and Ac-DEVD-pNA. Apoptosis was quantified by determining the percentage of cells with nuclear morphologic changes of apoptosis detected by fluorescence microscopy of Hoechst 33342-stained fixed cells. Results: When Galangin was tested in HepG2 cells it showed a decrease in cell viability as a consequence of a decrease in the mitochondrial membrane potential and ATP levels. Catechin and Taxfolin however, did not show an effect on the mitochondria energetic process. An increase in the activity of caspases 3 and 9 exposed to Galangin was also observed, and again no effect was observed for the other two flavonoids. On the other hand, there was no statistical difference for cells with nuclear morphologic changes of apoptosis detected by fluorescence microscopy amongst all three flavonoids. Conclusions: These results suggest that galangin is the only one of the tested flavonoids that present a toxicological potential, and that changes in the mitochondrial energetics is involved in its effects, possibly leading to cell necrosis and/or apoptosis. (Financial support: Capes, FAPESP)

1747 INDUCTION OF HEME OXYGENASE-1 BY GINSENOSE RB1 INVOLVES THE ACTIVATION OF THE NRF2/ANTIOXIDANT RESPONSE ELEMENT PATHWAY.

H. Park^{1,2}, Y. Hwang^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

Ginsenosides are the most important component isolated from ginseng. Recently, most effects of Panax ginseng have been attributed to its antioxidant action. Heme oxygenase-1 (HO-1) is known as a stress-inducible protein and functions as an antioxidant enzyme. It has been shown that HO-1 is induced rapidly by a variety of chemical and physical stimuli. However, little is known about the HO-1 induction by ginsenoside and its cellular signaling events. In this work, we assessed the ability of ginsenoside Rb1 (Rb1) to up-regulate HO-1 gene expression via activation of NF-E2-related factor 2 (Nrf2) in cultured mouse Hepa-1c1c7 cells. HO-1 enzyme activity and protein expression in the cells were significantly increased by Rb1. Transfection studies using a human HO-1 ARE/EpRE reporter construct demonstrated that Rb1 activated the ARE/EpRE. Furthermore, Rb1 induced nuclear localization of the Nrf2 transcription factor. Taken together, these results demonstrate that Rb1 induced HO-1 expression through the activation of the Nrf2/ARE pathway.

1748 HEPATOPROTECTIVE POTENTIAL OF HEMIDESMUS INDICUS: ETHNOPHARMACOLOGICAL APPROACH.

G. M. Mohana Rao¹ and P. Pushpangadan^{1,2}. ¹Pharmacognosy & Ethnopharmacology, National Botanical Research Institute, Lucknow, Uttar Pradesh, India and ²Phytopharmacy, Amity Institute of Herbal & Biotech Product Development, Trivandrum, Kerala, India.

Since ancient times, plants have been an exemplary source of medicine. Various indigenous plants are known to play a vital role in the management of liver diseases but the perusal of literature reveals lack of scientific authenticity of the traditional medicine. Hemidesmus indicus, popularly known as "Anantamul" grows abundantly in most parts of the Asia. The ethanolic extract (50% v/v) of the roots of H. indicus was subjected against carbon tetrachloride (0.6 ml/kg i.p.) induced hepatic damage in Sprague dawley rats. The extract when administered to mice as a single i.p dose of 1000 mg/kg was found to be non toxic. The concentrations of AST (aspartate transferase), ALT (alanine transferase), ALP (alkaline phosphatase), total bilirubin in serum and malondialdehyde contents in liver were significantly elevated in carbon tetrachloride induced rats. Pre treatment with the extract of H. indicus roots (200 and 400 mg/kg x 7 days p.o) significantly inhibited (P<0.01) AST (aspartate transferase), ALT (alanine transferase), ALP (alkaline phosphatase) and total bilirubin levels. The liver malondialdehyde content in carbon tetrachloride rats treated with the extract was also significantly (P<0.05) inhibited. The effect of the reference drug (silymarin) on AST, ALT, ALP, total bilirubin and malondialdehyde levels were nearly similar to that of extract treated at 400 mg/kg dose. Histopathological examinations of livers challenged with carbon tetrachloride showed centrilobular necrosis, ballooning degeneration, inflammatory infiltration of lymphocytes and fatty changes. The liver sections of rats treated with the extract against CCl4 challenge showed well preserved architecture. In conclusion, the present study states that the roots of Hemidesmus indicus possess fairly good hepatoprotective activity.

1749 PROTECTIVE EFFECTS OF 3-CAFFEYOYL-4-DIHYDROCAFFEYOYL QUINIC ACID ON THE PROGRESS OF CARBON TETRACHLORIDE-INDUCED HEPATIC FIBROSIS.

Y. Chung³, J. Choi^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea and ³Division of Food Science, Chinju International University, Chinju, South Korea.

3-caffeoyl-4-dihydrocaffeoyl quinic acid (CDCQ) is a new chlorogenic acid derivative isolated from the Salicornia herbacea. The protective effects of CDCQ on the progress of acute carbon tetrachloride induced hepatic fibrosis were investigated in mice. CDCQ significantly inhibited carbon tetrachloride-induced hepatic necrosis and inflammation, as determined by serum enzymatic activities of alanine and aspartate aminotransferase and serum TNF- α levels in a dose-dependent manner. In addition, increased hepatic lipid peroxidation and fibrosis after acute carbon tetrachloride treatment were suppressed by the administration of CDCQ. CDCQ also significantly prevented the elevation of hepatic hydroxyproline and collagen content and α -smooth muscle actin expression in the liver of carbon tetrachloride intoxicated mice. These results suggest that the protective effects of CDCQ against the acute carbon tetrachloride-induced hepatic fibrosis possibly related to its ability to block both hepatic inflammation and the activation of hepatic stellate cells.

1750 PROTECTIVE EFFECTS OF PLATYCODON GRANDIFLORUM ON LIVER INJURY MEDIATED BY IMMUNE RESPONSE IN A CONCAVALIN A-INDUCED HEPATITIS MODEL.

J. Choi^{1,2}, J. Kim^{1,2}, S. Roh⁴, Y. Chung³ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea, ³Division of Food Science, Chinju International University, Chinju, South Korea and ⁴Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Chinju, South Korea.

Administration of concanavalin A (Con A) induces T cell-dependent liver failure in mice and is considered to be a model for human viral hepatitis. Platycodon grandiflorum is a traditional oriental herbal medicine that is known for its immunomodulatory and anti-tumor effects. The present study showed the protective effects of the saponins isolated from the roots of Platycodon grandiflorum A. DC (Campanulaceae), Changkil saponins (CKS), on Con A-induced hepatotoxicities and the possible protective mechanisms involved were investigated in mice. Pretreatment with CKS prior to the administration of Con A significantly prevented the increase in serum alanine aminotransferase and aspartate aminotransferase activity in a dose-dependent manner. The protective effect of CKS prior to Con A injection was associated with reduction of serum inflammatory cytokine lev-

els (TNF- α , IFN- γ , IL-6) and blockade of mRNA expressions for these cytokines. Activation of NF- κ B by Con A, which regulates TNF- α production, was inhibited in the liver of mice treated with CKS. These results suggest that the protective effects of CKS against the Con A-induced hepatotoxicity through inhibition of inflammatory cytokines-mediated immune disorders.

1751 ECHINACEA PURPUREA EXTRACTS MODULATE MURINE DENDRITIC CELL FATE AND FUNCTION.

D. M. Shepherd^{1,2}, A. Rhule², J. R. Smith², C. A. Wenner³, N. B. Cech⁴, B. Rase¹ and A. J. Pokorny². ¹CEHS, University of Montana, Missoula, MT, ²Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT, ³Department of Basic Sciences, Bastyr University, Kenmore, WA and ⁴Department of Chemistry and Biochemistry, UNC-Greensboro, Greensboro, NC.

Echinacea is a top-selling herbal remedy that purportedly acts as an immunostimulant. However, the specific effects of Echinacea on the immune system remain to be elucidated. We are focused on defining the effects of Echinacea purpurea extracts in dendritic cells (DCs)- which are centrally involved in the generation of both innate and adaptive immune responses. We hypothesize that E. purpurea extracts enhance murine bone marrow-derived DC (BMDC) activation, ultimately leading to increased immune responses. We evaluated the fate and function of DCs following exposure to E. purpurea extracts. BMDCs were exposed to extracts for 48 hours and assessed by flow cytometry. A polysaccharide-rich extract from the root of the plant increased the expression of MHC class II and CD86; whereas an alkylamide-rich leaf extract inhibited the expression of both cell surface molecules. Although both extracts promoted the production of IL-6 and TNF- α when compared to ethanol controls, a general trend towards a concentration-dependent increase (root extract) or decrease (leaf extract) in the production of both cytokines was observed following the exposure of BMDCs to E. purpurea. In a separate experiment, E. purpurea extracts from leaf, but not root, inhibited the enzymatic activity of cyclooxygenase-2, an inducible enzyme involved in inflammation. In addition, pre-treatment of BMDCs with the leaf extract of E. purpurea prior to antigen loading with OVA peptide resulted in a significant reduction in the clonal expansion of naïve, OVA peptide-specific CD4⁺ T cells when compared to the ethanol controls. Collectively, these results suggest that Echinacea has the capacity to be immunostimulatory, immunosuppressive, and/or anti-inflammatory depending on the portion of the plant utilized and how it is extracted. Supported by NIH grant RR17670 and NSF grant EPS0091995.

1752 MAST CELL MEDIATED HISTAMINE RELEASE AND PRO-INFLAMMATORY CYTOKINE PRODUCTION ARE ATTENUATED BY GALLIC ACID.

S. Kim. Pharmacology, Kyungpook National University Medical School, Daegu, South Korea.

The discovery of drugs for the treatment of inflammatory allergic diseases such as, asthma and allergic rhinitis is an important subject in human health. Gallic acid is a polyphenyl natural product from gallnut and green tea. The aim of the present study was to elucidate whether gallic acid modulates the inflammatory allergic reaction and to study its possible mechanisms of action. Gallic acid attenuated IgE-induced histamine release from mast cells by the modulation of cAMP and calcium. Gallic acid decreased the phorbol 12-myristate 13-acetate plus calcium ionophore A23187-stimulated pro-inflammatory cytokine gene expression in human mast cells. The inhibitory effect of gallic acid on the pro-inflammatory cytokine was nuclear factor- κ B and p38 mitogen-activated protein kinase dependent. In addition, gallic acid inhibited compound 48/80 or IgE-induced systemic allergic reaction. Our findings provide evidence that inhibitory effect of gallic acid on the mast cell-derived inflammatory allergic reactions, and suggest the mechanisms of action. Furthermore, in vivo and in vitro anti-allergic effect of gallic acid suggests a possible therapeutic application of this agent in inflammatory allergic diseases. This work was supported by Brain Korea 21.

1753 BREVETOXIN INDUCED-BRONCHOCONSTRICTION: CORRELATION OF STRUCTURAL DATA WITH PHARMACOLOGICAL RESPONSES.

S. Michelliza¹, H. Jacocks¹, A. William², S. Thomas¹ and D. Baden¹. ¹Center for Marine Science, UNCW, Wilmington, NC and ²Department of Research, Mount Sinai Medical Center, Miami Beach, FL.

Brevetoxins (PbTx) are potent polyether neurotoxic compounds produced by the dinoflagellate *Karenia brevis*. Inhalation of PbTx aerosolized by surf and wind induces nasal and/or tracheobronchial irritation, and pM concentrations can produce asthma-like symptoms in humans. beta-naphthoyl-PbTx, a synthetic derivative of

the natural PbTx-3 binds with high affinity ($K_i=1.2$ nM) to the neuronal voltage-sensitive sodium channels (VSSC) without increasing sodium flux, and antagonizes PbTx-induced bronchoconstriction in sheep. Thus, beta-naphthoyl-PbTx has been defined as the lead compound for investigating the mechanism by which inhaled brevetoxins induce bronchoconstriction, and by which selected derivatives reverse those effects. A series of beta-naphthoyl-PbTx analogs have been synthesized. Affinities for VSSC were determined by competitive displacement of [³H] PbTx-3 from rat brain synaptosomes. Effects on intact airways were determined by lung resistance measurements in live sheep. Extensive conformational searches were also conducted on β -naphthoyl derivatives and other analogs, as well as on the parent PbTx-2 and PbTx-3 structures to attempt to correlate structural data with pharmacological and physiological responses. Preliminary binding assays and lung resistance measurements have revealed that an ester linkage between PbTx and the synthetic functional group is necessary for maximum binding to the VSSC, and that electron withdrawing groups on the naphthoyl group induce bronchoconstriction. Additionally, conformational searches revealed that PbTx-2 and PbTx-3 have two non-degenerate ground-states. One is the traditional "staircase" conformer, the other exhibits a curved form similar to a helix. In the case of the β -naphthoyl-PbTx, the curved conformers are favored by approximately 10 kcal/mol, while the "reverse ester" derivative favors the traditional backbone conformers by approximately 6 kcal/mol over the helical forms.

1754 NATURAL AND SYNTHETIC BREVENALS: NEW THERAPEUTICS FOR MUCOCILIARY DYSFUNCTION AND CF.

D. Baden^{1,4}, W. Abraham³, A. Bourdelais^{4,1}, H. Jacocks¹, H. Fuwa², M. Ebine² and M. Sasaki². ¹Center for Marine Science, UNC Wilmington, Wilmington, NC, ²Laboratory of Biostructural Chemistry, Graduate School of Life Sciences, Tohoku University, Sendai, Japan, ³Department of Research, Mount Sinai Medical Center, Miami Beach, FL and ⁴MARBIONC, Center for Marine Science UNCW, Wilmington, NC.

Our collaborations have resulted in the complete synthesis of brevenal, a natural product from Florida red tide that stimulates mucociliary clearance and relieves many of the toxicological effects of brevetoxins produced by the red tide. Different epimer derivatives of synthetic brevenal were also produced as were several derivatives of the natural material. Experiments on all synthetic products and the natural materials were conducted in vitro in rat brain receptor bindings assays, and by observing the effects of the materials on bronchoconstriction, tracheal mucus velocity, and whole lung clearance in sheep. Synthetic compound ME-1 induced pharmacological events nearly identical with those induced by natural brevenal while the other synthetic products differed significantly. All chemicals produced significant effects following 20 breaths of a solution in the pg/mL concentration range. Further, the data suggest that the character of side chains, when reduced, confer a substantial (circa 20%) increase in bronchoconstriction. Receptor binding studies utilizing tritiated brevetoxin show a reduced displacing ability ranging from 10-100 fold when very conservative reductive or epimeric modifications are made to the molecule. All derivatives still displaced tritiated brevenal from its specific receptor site, a site allosterically-linked to the brevetoxin site. From the data collected, including spectroscopy, we conclude that brevenal stereochemistry at C-26 is *epi* to that originally published because that synthetic material most closely matches the pharmacology when compared to the natural product. We further conclude that reduction of chemical loci in either of the two side chains reduces the ability to antagonize the effects of natural brevetoxin or to confer therapeutic effects in TMV displayed by natural or synthetic brevenal.

1755 BREVETOXIN-INDUCED NEURAL INSULT IN THE RETROSPLENIAL CORTEX OF MOUSE BRAIN FOLLOWING INHALATION EXPOSURE.

T. F. Murray¹, X. Yan¹, A. P. Gómez², D. G. Baden³ and J. M. Benson². ¹Pharmacology, Creighton University School of Medicine, Omaha, NE, ²Lovelace Respiratory Research Institute, Albuquerque, NM and ³Center for Marine Science Research, University of North Carolina at Wilmington, Wilmington, NC.

Brevetoxins (Polyether breve toxins; PbTx) are polyether neurotoxins produced by the marine dinoflagellate *Karenia brevis*, an organism associated with red tide blooms in the Gulf of Mexico. Brevetoxin-3 (PbTx-3) is a major component of the array of brevetoxins found in marine aerosols. Humans exposed to aerosolized brevetoxins for short periods of time often suffer respiratory irritation whereas ingestion of contaminated shell fish produces a neurotoxic syndrome. Inasmuch as toxicokinetic studies indicate that brevetoxins distribute to the brain, it was of interest to assess the potential for aerosolized brevetoxin to produce a neurotoxic response. Female Balb/c mice were exposed nose-only for two consecutive days to

PbTx-3 aerosol, with a two hour exposure on the first day and a four hour exposure on the second day. The average PbTx-3 exposure concentration on Days 1 and 2 were $312 \pm 113 \mu\text{g}$ brevetoxin $3/\text{m}^3$ and $278 \pm 24 \mu\text{g}$ brevetoxin $3/\text{m}^3$, respectively. Coronal sections of mouse brains were evaluated for neuronal damage using both silver- and Fluoro-Jade B-staining to identify degenerating neuronal elements. PbTx-3 inhalation exposure produced neuronal degeneration in the posterior cingulate/retrosplenial cortex of mice as evidenced by silver-positive degenerating neurons in this region. No staining was found in other regions of the PbTx-3 exposed mouse brains or in brains of control, sham-exposed mice. The existence of a neurotoxic insult in PbTx-3-exposed mice was confirmed using Fluoro-Jade B to label degenerating neurons. Fluoro-Jade-positive neurons were observed in the retrosplenial cortex of PbTx-3 exposed, but not control, mice. Inhalation exposure to PbTx-3 produced a similar pattern of neurotoxicity in rat brain. These results suggest that subacute exposure to PbTx-3 for two days is sufficient to induce neuronal degeneration in a discrete region of the mouse cerebral cortex.

1756 GAMBIEROL ACTS AS A FUNCTIONAL ANTAGONIST OF NEUROTOXIN SITE 5 ON VOLTAGE-GATED SODIUM CHANNELS IN CEREBELLAR GRANULE CELLS.

K. T. LePage³, J. D. Rainier² and T. E. Murray¹. ¹Pharmacology, Creighton University, Omaha, NE, ²Chemistry, University of Utah, Salt Lake City, UT and ³Biology, Xavier University, New Orleans, LA.

The marine toxin gambierol, a polyether ladder toxin derived from the marine dinoflagellate *Gambierdiscus toxicus*, was evaluated for interaction with the voltage-gated sodium channel (VGSC) in cerebellar granule neuron cultures (CGN). At concentrations ranging from 10 nM to 10 μM gambierol alone had no effect on the intracellular Ca^{2+} concentration $[\text{Ca}^{2+}]_i$ of exposed CGN. Furthermore, there was no evidence of neurotoxicity in CGN exposed for 2h to gambierol (1 nM to 10 μM). Gambierol was however a potent inhibitor ($\text{EC}_{50} = 189 \text{ nM}$) of the elevation of $[\text{Ca}^{2+}]_i$ that accompanies exposure of CGN to brevetoxin-2 (PbTx-2). Conversely, the influx of Ca^{2+} resulting from KCl-induced membrane depolarization was not affected by gambierol. To further explore the potential interaction of gambierol with VGSC, we assessed the influence of gambierol on the neurotoxicity of PbTx-2. Gambierol reduced the PbTx-2-induced efflux of lactate dehydrogenase in exposed CGN in a concentration-dependent manner ($\text{EC}_{50} = 471 \text{ nM}$). It is noteworthy that the potencies of gambierol as an inhibitor of PbTx-2-induced Ca^{2+} influx and cytotoxicity were coincident. In agreement with a previous report, gambierol produced a concentration-dependent inhibition of the high-affinity binding of [^3H]PbTx-3 to intact rat synaptosomes. These results provide evidence for gambierol acting as a functional antagonist of neurotoxin site 5 on neuronal VGSCs.

1757 HIPPOCAMPAL C-FOS EXPRESSION AND MICROGLIA ACCUMULATION IN RATS EXPOSED TO THE MARINE TOXIN DOMOIC ACID.

A. M. Mayer¹, L. A. Carlson¹, M. T. Braddock¹, M. L. Hall¹ and P. F. McCulloch². ¹Pharmacology, Midwestern University, Downers Grove, IL and ²Physiology, Midwestern University, Downers Grove, IL.

Introduction: Domoic acid (DA) is a marine neurotoxin that may cause Amnesic Shellfish Poisoning in humans by binding to ionotropic glutamate receptors in the hippocampus, an area responsible for learning and memory processing. We investigated neuronal c-FOS expression and macrophages/microglia (BMΦ) accumulation in the hippocampus of rats treated with DA. **Hypothesis:** We hypothesized that differential behavioral responses, FOS expression and BMΦ accumulation in the CA 3 region of the hippocampus would be observed in rats injected with either DA or saline. **Methods:** Twelve rats were injected with either 2.2, 3.3 mg/kg DA or saline (control) intraperitoneally and behavioral responses were observed over a 3 hour period. A DA specific ELISA was used to quantify DA in rat serum. Neuronal FOS protein was determined by immunohistochemistry and BMΦ CD11b by immunofluorescence. **Results:** Rats receiving either 2.2 or 3.3 mg/kg DA showed significantly different behavioral responses when compared to controls which correlated with serum levels of DA: 2.2 mg/kg DA and 3.3 mg/kg DA, $>10,000 \text{ pg/ml}$ ($n=5$). A statistically significant increase in the number of CA 3 hippocampal FOS positive neurons per coronal section was observed in DA-treated rats when compared to controls: Saline, 2.9 ± 1.3 ($n=4$); 2.2 mg/kg DA, 101.5 ± 50 ($n=4$, $p<0.05$); 3.3 mg/kg DA, 220.8 ± 88.6 ($n=4$, $p<0.05$). In contrast, no difference in BMΦ accumulation was observed: mean BMΦ per 1,000 DAPI-stained nuclei; Saline, 23.7 ± 4.2 BMΦ ($n=3$); 2.2 mg/kg DA, 23.2 ± 1.1 BMΦ ($n=3$); 3.3 mg/kg DA, 26.6 ± 7.1 BMΦ ($n=3$). **Conclusions:** Our data provides partial support to our working hypothesis by demonstrating that during a 3 hour observation period, DA significantly affected rat behavioral responses and hippocampal FOS protein in a

concentration- and time-dependent manner, but did not result in changes in BMΦ accumulation. Supported by NIH (AMSM) and the Biomedical Sciences Program, College of Health Sciences, Midwestern University.

1758 THE EFFECTS OF ALOE VERA WHOLE LEAF EXTRACT ON THE GROWTH AND SHORT CHAIN FATTY ACID PRODUCTION BY *BACTEROIDES FRAGILIS*, *BIFIDOBACTERIUM INFANTIS*, AND *EUBACTERIUM LIMOSUM*.

M. Pogribna, J. P. Freeman, D. Paine, F. A. Beland and M. D. Boudreau. National Center for Toxicological Research, Food and Drug Administration, Jefferson, AR. Sponsor: B. Delclos.

The effects of changes in the environment of the gastrointestinal (G.I.) tract upon the growth and activity of gut microflora are poorly understood. Aloe vera, a popular herb and dietary supplement, is widely promoted as a prophylaxis in the treatment of intestinal disorders. Short chain fatty acids (SCFA), produced by anaerobic microflora, are the preferred energy source for the G.I. mucosa. The aim of this study was to investigate the fermentation properties of Aloe vera whole leaf extract in isolated and mixed human gut bacterial cultures. The Aloe vera extract at 0, 0.5, 1.0, 1.5, and 2.0% (wt/vol) was incubated in 24 and 48h batch culture fermentations, and bacterial growth and SCFA production were used to determine changes in populations of *B. fragilis*, *B. infantis*, and *E. limosum*. Experiments were conducted in triplicate, and SCFA production was measured by gas chromatography/mass spectrometry analyses. Results indicated that the Aloe vera extract enhanced the activity of bacteria *in vitro*. A significant linear growth response to Aloe vera supplementation was observed at 24h for each of the bacteria cultures, regardless of species or mixture. There were no significant differences in bacterial numbers among cultures at 48h with the exception of the mix, which showed a significant linear growth response. In isolated bacteria cultures, a significant positive dose response to Aloe vera supplementation was observed in the production of acetic acid by *B. infantis* and of butyric acid by *E. limosum* at 24 and 48h. Aloe vera significantly inhibited the production of propionic, iso-butyric, iso-valeric, and valeric acid in the mixed culture at 24 and 48h in a dose dependent fashion. In contrast, the production of butyric acid in the mixed culture was enhanced by Aloe vera supplementation at both time points, suggesting that Aloe vera may boost the production of butyrate in the gut. Research supported by the National Toxicology Program.

1759 POSSIBLE FALSE POSITIVE RESULTS IN THE SALMONELLA TYPHIMURIUM MUTATION ASSAY DUE TO THE PRESENCE OF HISTIDINE IN NATURAL PRODUCTS.

P. E. Kirby^{1,4}, K. J. Pant² and I. P. Lee³. ¹Genetic Toxicology, ADMET Group, Rockville, MD, ²Genetic Toxicology, InVitrogen, Gaithersburg, MD, ³Consultant, Bethesda, MD and ⁴Genetic Toxicology, ADMET Group, Rockville, MD. Sponsor: A. Li.

High and low molecular weight semi-purified fractions extracted from the mushroom *Agaricus blazei* Murril were tested for their potential to cause mutations at the histidine operon of *S. typhimurium* strains TA98, TA100, TA1535 and TA1537, and at the tryptophan operon of *Escherichia coli* strain WP2 uvrA. The extract was diluted in water and tested for toxicity to strain TA100 in a Range Finding Test at concentrations ranging from 5.0-5000 $\mu\text{g}/\text{plate}$. The tester strains were exposed to the test article in the absence of exogenous activation and in the presence of Aroclor induced rat liver S-9 plus cofactors. Toxicity was evaluated based on: 1) reversion frequency, 2) viability, and 3) integrity of the background lawn. The results of the Range Finding Test indicated that the extracts were nontoxic. However, TA100 treated with the highest extract concentration without and with activation had significant increases in revertant colonies and relative cloning efficiency as compared to the solvent controls.

Treatment of strains TA98 and TA1535 yielded similar results; a dose dependent increase in the number of revertants although the maximum increase was not always two-fold or greater than that of the solvent control plates. The most sensitive strain was TA100.

It was suspected that the natural histidine content of the mushroom might be the cause for the increase in the number of revertant colonies. Therefore, the histidine content of the extract was determined and additional assays were conducted in which control cultures for each extract concentration were treated with equivalent concentrations of histidine. These assays produced similar dose-dependent responses in both the extract treated and histidine treated cultures. Correcting for the increase in revertants due to naturally occurring histidine in the extract by subtracting the number of revertants in the corresponding control plates produced negative responses.

1760 SUBCHRONIC ORAL TOXICITY STUDY OF RHAMSAN GUM, A NATURAL FOOD POLYSACCHARIDE PRODUCED FROM SPHINGOMONAS ATCC 31961, IN RATS.

N. Imai^{1,2}, A. Hagiwara¹, K. Nabae¹, Y. Toda¹, T. Ichihara¹, S. Kitamura³, T. Omoto³, I. Asai³ and T. Shirai². ¹DIMS Institute of Medical Science, Inc., Ichinomiya, Japan, ²Department of Experimental Pathology and Tumor Biology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan and ³San-Ei Gen F.F.I., Inc., Toyonaka, Japan.

Rhamsan gum is a microbial polysaccharide belonging to the gellan family produced by *Sphingomonas* strain ATCC 31961. The material is of considerable importance, since it possesses unusually good stability under shearing pressure, superb compatibility with high salt concentrations, and excellent suspension characteristics. It has therefore found major employment as a food additive.

This study was designed to evaluate and characterize any subchronic toxicity of rhamsan gum when administered to both sexes of Sprague-Dawley rats at dietary levels of 0 (control), 0.5, 1.5, and 5.0% (10 rats/sex/group) for 90 days. During the study, the treatment had no adverse effects on clinical signs, survival, body weights and food and water consumption, or on findings of urinalysis, ophthalmology, hematology, or blood biochemistry. Examination of gross pathology and histopathology exhibited no differences of toxicological significance between control and treated rats. Increased relative cecum (filled) and cecum (empty) weights, evident in males of the 1.5% group and both sexes receiving 5.0%, were considered to be a physiological adaptation.

In conclusion, the results indicated any toxic level of rhamsan gum to be more than 5.0%, and the no-observed-adverse-effect level (NOAEL) was concluded to be 5.0% (3362 mg/kg body weights/day for males, and 4304 mg/kg body weights/day for females) from the present study.

1761 A 1-YEAR ORAL TOXICITY STUDY OF PURPLE CORN COLOR, IN CRL:CD(SD) RATS.

M. Kawabe¹, N. Imai^{1,2}, Y. Doi^{1,2}, F. Furukawa¹, Y. Tsushima³, K. Onishi³, T. Koda³ and T. Shirai². ¹DIMS Institute of Medical Science, Inc., Ichinomiya, Japan, ²Department of Experimental Pathology and Tumor Biology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan and ³San-Ei Gen F.F.I., Inc., Toyonaka, Japan.

Purple corn color (Maize morado color, PCC), extracted from the seeds of corn, *Zea mays* LINNE. is a natural food colorant used in beverages, jellies, and candies in Japan. A chronic oral toxicity study was here performed with groups of 20 male and 20 female Crl:CD(SD) rats fed the agent at dietary levels of 0, 0.5, 1.5 and 5.0 % for 1 year. Citric acid monohydrate (CA) was contained at the concentration of 2.64% in the PCC used in this study. Therefore, a CA group consisting of 10 male and 10 female rats received a dietary level of 0.14% CA (the value contained in 5.0% PCC diet) was included in this study. In the PCC treatment group, no treatment-related changes in the survival rates, body weight, food and water consumption, ophthalmology, hematology and organ weight data were observed. Regarding general conditions and gross pathology, staining of fur (5.0%, both sexes) and black feces (1.5% and 5.0%, both sexes) were noted. In addition, changes of urine coloration with dose-dependence were observed. These alterations were all considered due to the anthocyanin content. On blood chemistry determinations, phospholipid (PL) and triglyceride (TG) were significantly decreased in the 5.0% female group, but these were not considered to be toxicologically significant. Histopathological lesions observed in the dose groups were equivalent to that of the control group. Based on these results, the no-observed-adverse-effect-level (NOAEL) was judged to be 5.0% in the diet for both sexes (male; 2,689 mg/kg/day, female; 3,889 mg/kg/day) for purple corn color under the present experimental conditions.

1762 THIRTEEN WEEK TOXICITY STUDY OF INDOLE-3-CARBINOL IN B6C3F1 MICE AND FISCHER 344 RATS.

M. E. Wyde¹, N. R. Bordelon², A. Nyska³, J. Mann⁴, C. D. Hébert⁴ and J. R. Bucher¹. ¹NIEHS, Research Triangle Park, NC, ²Alcon, Fort Worth, TX, ³ILS, Inc., Research Triangle Park, NC and ⁴Southern Research Institute, Birmingham, AL.

There is substantial evidence that indole-3-carbinol (I3C), a natural component of cruciferous vegetables, can reduce the risk of certain cancers induced by several known carcinogens, but can also function as an initiator and tumor promoter. Similar to dioxin-like compounds, I3C induces hepatic cytochrome P450 1A enzymes through the Ah receptor, a process often associated with toxicity. The National Toxicology Program is currently investigating the toxicity and carcinogenicity of indole-3-carbinol in a 90-day toxicity study and forthcoming 2-year rodent bioassay. In the current study, Fischer 344 rats were exposed to up to 300 mg I3C/kg body weight and B6C3F1 mice were exposed to up to 250 mg I3C/kg body weight five days a week for 13 weeks by gavage. There were no significant treat-

ment-related effects on body weight, survival, clinical chemistry, hematology, or gross or microscopic pathology. Dose-dependent increases were observed in liver weights in male and female rats and mice. In mice, hepatic CYP 1A1 and 1A2 activities were maximally increased 2- to 4- fold. In rats, hepatic CYP 1A1 activity was dose-dependently increased with a maximal induction of 109- and 81-fold in males and females, respectively, at 300 mg/kg. Hepatic CYP 1A2 activity was also dose-dependently increased with a maximal induction of approximately 5-fold in both males and females. The magnitude of induction of CYP 1A2 activity by I3C in rats was comparable to that induced by ng/kg doses of 2,3,7,8-tetra-chlorodibenzo-p-dioxin (TCDD) in previous subchronic NTP studies in female Fischer and Sprague-Dawley rats. CYP 1A1 activity maximally induced by I3C in female rats exceeded previously observed activities induced by TCDD at doses that induced neoplastic and nonneoplastic lesions in multiple tissues at 2 years, including moderate to marked hepatotoxicity and liver tumors. Therefore, the 2-year I3C studies will provide further insight into the relationship between marked CYP 1A1 and 1A2 induction and liver tumor development in rats.

1763 MODULATION OF PROSTATE CANCER CELLS BY NATURAL "PUTATIVE" ANTI-ANDROGEN.

S. Koppula¹, R. Solipuram¹, L. Debose², K. Fontenot², A. Hurst¹ and W. Gray^{1,2}. ¹Environmental Toxicology, Southern University, Baton Rouge, LA and ²Chemistry, Southern University, Baton Rouge, LA.

Plant-derived compounds such as isoflavones, flavones, and lignans have been proposed as the cancer-protective agents in populations exhibiting low incidences of prostate disease. Plant products may contain isoflavones such as genistein with estrogenic and non-estrogenic properties that could influence both endocrine and growth-factor-signaling pathways within the prostate. Anecdotal reports suggest that Bizzy Nut may be useful for a number of medical purposes, including prevention of prostate cancer. Thus, the goal of this study is to evaluate the effect of an acetone extract of this common herbal medicine on prostate function. We examined the effect of an acetone extract of Bizzy Nut on prostate by assessing its effect on the growth of LNCaP cells, production and secretion of prostate secretory protein, androgen receptor status, and induction of androgen dependent genes. The Acetone extract of Bizzy Nut elicited a dose and time-dependent inhibition of LNCaP cells with GI50 of 50ppm. Secretion of PSA, a biomarker of prostate function, was inhibited by 2-fold within 24hr exposure to the Bizzy Nut extract. Furthermore, the acetone extract of Bizzy resulted in a down-regulation of 5 α -reductase type II in LNCaP cells. Taken together, these results suggest that Bizzy Nut may prevent prostate cancer by interfering with prostate cell growth.

1764 THE EFFECTS OF BORIC ACID ON THE ENDOPLASMIC RETICULUM IN LNCAP AND DU-145 PROSTATE CANCER CELL LINES.

K. A. Henderson¹ and C. Eckhart². ¹Molecular Toxicology IDP, UCLA, Los Angeles, CA and ²Environmental Health Sciences, UCLA, Los Angeles, CA.

The incidence of prostate cancer has increased 3% annually worldwide, and represents 33% of new male cancers, ranking second for male cancer deaths in the United States. Dietary intake and exposure to certain elements strongly influences the risk for prostate cancer. Boron has been shown to decrease prostate cancer risk in a dose dependent manner in epidemiological studies. Boron is a naturally occurring, ubiquitous, trace element that circulates in blood as boric acid. It is essential for plant growth and occurs in high levels in fruits, nuts, legumes, vegetables, and wine. Treatment with boric acid has been shown to inhibit the growth of prostate tumors in mice and proliferation of DU-145 and LNCaP prostate cancer cell lines over an 8 day period. The purpose of this study was to determine how boric acid affects DU-145 and LNCaP prostate cancer cells over 24 hours. Using a broad proteomics approach, we found that low doses of boric acid cause endoplasmic reticulum (ER) stress in DU-145 and LNCaP prostate cancer cell lines, inducing the unfolded protein response (UPR). Through 2 dimensional (2D) proteomics and western blot analysis, we have shown that the hallmarks of the UPR such as induction of chaperones BiP/GRP78, and calreticulin, as well as phosphorylation of eif2 α , occur in LNCaP and DU-145 prostate cancer cell lines. In addition, marked ultra-structural changes occur in the ER of treated cells. My future research involves determining how boric acid initiates ER stress by looking at ER calcium regulation in the presence of boric acid by using confocal microscopy. Supported by DAMP 17-03-1-0067 and TSRTF.

1765 RESVERATROL AND PICEATANNOL CYTOTOXICITY.

V. Radkar, D. Hardej, C. Lau-Cam and B. Billack. Department of Pharmaceutical Sciences, St. John's University, Jamaica, NY.

Resveratrol (3,4',5-trihydroxy-trans-stilbene) is a plant antioxidant with proven cancer-preventive, anti-proliferative and anti-inflammatory activities. The toxicity potential of resveratrol remains to be fully defined. The present study has evaluated

the *in vitro* toxicity of this compound on transformed mouse macrophages (RAW 264.7), tumor-derived human T-cells (CEM) and human epidermoid carcinoma cells (A-431). Resveratrol was found to inhibit the viability of all three cell types in a concentration-dependent manner (LC50 ranging from 12-50 μ M; 24-48hr), with T-cells being the most sensitive (~12 μ M; 48hr). Viability was assessed using an MTT-based assay. Paradoxically, while higher concentrations of resveratrol (25 and 50 μ M) inhibited the proliferation of all three cell types, a low concentration (5 μ M) stimulated the proliferation of macrophages and T-cells. Scanning electron microscopy (SEM) revealed that resveratrol induced morphological changes consistent with toxicity in both immune and skin cells (0-100 μ M; 24-48 hr). The effect of resveratrol on the cellular levels of glutathione (GSH) and on lipid peroxidation was also investigated. Treatment of macrophages and skin cells with resveratrol (0-50 μ M) resulted in a time-dependent increase in GSH while levels of thiobarbituric acid-reactive substances (TBARS) remained stable. In contrast to unstimulated macrophages, stimulation with lipopolysaccharide (LPS) and zymosan conferred significant protection against resveratrol toxicity (LC50 >50 μ M). Piceatannol (3,3',4,5'-tetrahydroxy-trans-stilbene), a major metabolite of resveratrol, was also found to be toxic to macrophages, with cell viability decreasing in a dose-dependent manner (LC50 ~ 35 μ M; 48hr). As observed with resveratrol, the cytotoxicity of piceatannol was reduced by zymosan stimulation (LC50>45 μ M). The present results demonstrate resveratrol and piceatannol to be cytotoxic. Furthermore, stimulation of macrophages with zymosan or LPS results in attenuation of resveratrol toxicity.

1766 EFFECTS OF FIVE HERBAL EXTRACTS ON CELLULAR PROLIFERATION IN CHO-K1-BH4 CELLS.

Q. Hu, D. N. Sujjavanich and J. E. Gibson. *Pharmacology and Toxicology, Brody School of Medicine at East Carolina University, Greenville, NC.*

It is commonly believed that herbal supplements are an effective way to improve health, and the dietary supplement industry is a \$30 million business in the U.S. As such, there have been countless studies performed on the therapeutic benefits and applications of various herbs and herbal extracts. However, safety evaluations on herbal products are rare. In this study, 5 commonly used herbs: chaste tree berry (*Vitex agnus-castus* L.), flaxseed (*Linum usitatissimum*), ginseng (*Panax quinquefolius*), soy bean (*Glycine max*) and wild yam (*Dioscorea villosa*), were investigated for their cytotoxic activity. Dry herbal products were ground and extracted in cell culture medium (ratio of 50mg powder/ml medium) for 24h followed by centrifugation and filter sterilization of the supernatant. Then serial dilutions were prepared and exposed to CHO-K1-BH4 cells for 48 hours in 96 well plates. The concentration of the tested herb extract that suppressed the cell numbers by 50% in comparison to the untreated controls was determined (IC50) and used as an index of cytotoxic activity. CHO-K1-BH4 cells were seeded at a density of 4×10^4 cells/ml for 24 hrs before treatment. Then, the culture medium was replaced with a new medium containing the tested extract with different concentrations and incubated at 37°C for 48 hours. The medium without extract was used as the untreated control and ethanol with different concentrations correspondingly served as positive control. A minimum of two independent assays was performed with each herb in duplicate for each concentration. The results showed that the IC50 of ethanol was 1.41%, wild yam 0.69%, ginseng 4.29%, chaste tree berry 6.62%, flaxseed and soy bean >10%, the maximum test concentration. This suggested wild yam had a greater inhibitory effect on cell proliferation than other tested herbs in the present experiment.

1767 CHEMOPREVENTIVE EFFECTS OF CITRUS AURAPTENE IN N-METHYLNITROSOUREA INDUCED RAT MAMMARY CARCINOGENESIS.

H. E. Kleiner^{1,3}, P. Krishnan^{1,3} and J. McLarty^{2,3}. ¹Pharmacology, Toxicology & Neuroscience, Louisiana State University-Health Sciences Center, Shreveport, LA, ²Medicine, Louisiana State University-Health Sciences Center, Shreveport, LA and ³Feist-Weiller Cancer Center, Shreveport, LA.

Auraptene, a citrus coumarin derivative, has been studied for its chemopreventive effects in rodent models of skin, tongue, esophagus and colon carcinogenesis. We investigated the chemopreventive effect of auraptene in N-methylnitrosourea (MNU)-induced mammary carcinogenesis in female Sprague-Dawley rats. At 42 days of age the rats were divided into 4 groups of 24-26 each and were fed a test diet as follows. Groups 1 and 2 were fed Teklad (powdered diet) only. Groups 3 and 4 received auraptene (200 ppm and 500 ppm, respectively) mixed in the test diet for the duration of the study. At 50 days of age Groups 2-4 received an intraperitoneal injection of MNU (50 mg/kg body weight in sterile acidified saline). Group 1 received vehicle only. The rats were palpated for tumors twice a week starting at 3 weeks after MNU administration. Rats were weighed once a week. At the end of 16 weeks, the average percentage of rats with palpable mammary tumors (incidence, means $\pm$ SE) in Group 2 (Teklad/MNU) was 84.6 ± 7.2 , and the average number

of palpable mammary tumors per rat (e.g., multiplicity, means $\pm$ SE) in Group 2 was 1.96 ± 0.28 . In Group 3 (auraptene 200 ppm/MNU) incidence and multiplicity were 73.1 ± 9.0 and 1.65 ± 0.28 , respectively. In Group 4, incidence and multiplicity were reduced to 50 ± 10 and 1.33 ± 0.38 , respectively. There were no palpable tumors in Group 1 (vehicle only). Trend analysis confirmed a dose-dependent effect of auraptene. There was a mild but significant decrease in body weight gain in all the MNU-treated rats compared to the saline control (Group 1). However, there were no differences in body weights between Groups 2-4. These results point to the potential chemopreventive effects of auraptene in mammary carcinogenesis. Further studies are required to understand the mechanism of action of auraptene. (Supported by 1K22CA102005-01A2)

1768 POLYPHENOLIC FRACTION OF PHYLLANTHUS MADERASPATENSIS AMELIORATES CHEMOTHERAPY-INDUCED NEPHROTOXICITY AND GENOTOXICITY.

P. Bommu, N. Moola Joghee, C. Moola Joghee Nanjan and S. Bhojraj. *TIFAC CORE in Herbal Drugs, J.S.S College of Pharmacy, Ootacamund, Tamilnadu, India.*

The polyphenolic fraction of *Phyllanthus maderaspatensis* (PPM) was studied on cisplatin and induced nephrotoxicity and genotoxicity in Swiss albino mice. The treatment of mice with different doses of PPM (50 and 100 mg/kg body weight) for seven days before the administration of a single i.p. dose of cisplatin (5mg/kg), exhibited significant chemoprotective activity. The single dose of cisplatin significantly elevated the levels of blood urea nitrogen, serum creatinine, and the kidney to body weight ratio, but pretreatment with PPM (100mg/kg/day) for seven days significantly attenuated the cisplatin induced nephrotoxicity. The frequency of micronucleated polychromatic erythrocytes (MNPCEs) in the bone marrow were determined at 24 h after the administration of cisplatin. After administration of cisplatin, the frequency of MNPCEs distinctly increased. In mice treated with PPM before cisplatin application, there is a decrease in the number of MNPCEs, when compared to mice injected with only cisplatin. PPM showed a marked free radical scavenging effect in the kidney, indicating its antioxidative property. Quercetin, one of the active compound in the PPM was identified and quantified with HPLC. The results suggest that PPM has a protective effect against cisplatin induced toxicity through its antioxidant property.

1769 THE EFFECT OF TWO COMMONLY USED HERBAL SUPPLEMENTS, GLYCINE MAX (SOY) AND LINUM USITATISSIMUM (FLAXSEED) ON RNA ISOLATION IN HEPG2 CELLS.

D. N. Sujjavanich¹ and J. E. Gibson^{1,2}. ¹Biology, East Carolina University, Greenville, NC and ²Pharmacology and Toxicology, Brody School of Medicine at East Carolina University, Greenville, NC.

The herbal supplement industry has been growing over the last twenty years; however, the safety assessment of these products is still in its infancy. There are several herbs marketed towards women for relief of menopausal symptoms. Soy and Flaxseed are predominant in this group of herbs. The objective of this study was to monitor the effect of these herbs, in unprocessed form, on RNA isolation from cells treated *in vitro*. HepG2 cells were grown in a maintenance media of MEM (with Earle's and nonessential amino acids without L-glutamine) and 10% Fetal Bovine Serum, supplemented with L-glutamine, Sodium Pyruvate, Nystatin, and Penicillin/Streptomycin. 7.134×10^7 cells were plated for Negative, PGE₂, Soy and Flaxseed treatments in 6 well plates, with 3 wells dedicated to each. Extracts of soy and flaxseed were made using the maintenance media solution at the concentration of 50 mg finely milled herb powder per 1 mL HepG2 maintenance media; the suspensions were put in a shaker for 24 hours before they were filter sterilized. 10% v/v extract/media was used for both herbs, and treatment time in a 37°C incubator was 48 hours. The cells were then isolated and subjected to a Bio-Rad™ AquaPure® RNA Isolation kit. A NanoDrop® 1000 was used for quantification of the resulting RNA. The treatments did have an effect on amount of RNA isolated. All treatments showed comparable 260/280 ratios. The soy showed a 48.6% increase whereas the flaxseed showed a 162.4% increase over untreated cells. These findings demonstrate that herbal supplements do affect RNA isolation in this cell line.

1770 ANALYTICAL METHOD DEVELOPMENT AND METHOD VALIDATION FOR THE QUANTITATION OF BETA-MYRCENE IN FISCHER 344N RAT PLASMA.

P. J. Schebler¹, R. L. Mathias¹, A. Y. Shan¹, A. P. Clark¹, R. K. Harris¹, J. W. Algaier¹, B. Jayaram² and C. S. Smith². ¹Product Sciences Division, Midwest Research Institute, Kansas City, MO and ²Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.

The monoterpene, β -myrcene, is found in essential oils isolated from the small tree *Xylopia Aromatica*, lemon grass and other plants. Because of its use in food products, cosmetics and perfumes, β -myrcene is under toxicological evaluation by the

NIEHS. In this work, a gas chromatographic method using flame ionization detection (GC/FID) was developed and validated for the analysis of β -myrcene in F344 rat plasma. An eight-point spiked standard curve was prepared in Fischer 344N male rat plasma, the β -myrcene concentration ranged from -0.06 to -51 $\mu\text{g/mL}$. To prepare each spiked standard, proteins were precipitated using acetonitrile followed by extraction with 400 μL of hexane containing 1-undecene as the internal standard. The analysis method was linear (correlation coefficient > 0.999), accurate (%RE of -18.7 to 12.0), and precise ($\leq 11.1\%$ RSD). The within-day variability and instrument drift was minimal with precision of 11.1% RSD for the low concentration spiked matrix standard. Between-day variability, evaluated by comparing precision of each validation day ($\leq 11.1\%$), met criteria of $\leq 15\%$ RSD. The mean percent recovery was 74.9 to 91.1% relative to the corresponding solvent standards and β -myrcene was not detected in any control blanks. The experimental limit of quantitation (ELOQ) was -0.06 $\mu\text{g/mL}$, with a limit of detection (LOD) of 0.01329 $\mu\text{g/mL}$ and a limit of quantitation (LOQ) at 0.0443 $\mu\text{g/mL}$. A short stability study evaluated three β -myrcene concentrations at -0.2 $\mu\text{g/mL}$, -2 $\mu\text{g/mL}$, and -20 $\mu\text{g/mL}$ β -myrcene in male rat plasma. After short-term storage under ambient, refrigerated (-5 $^{\circ}\text{C}$) and freezer (-20 $^{\circ}\text{C}$ with 3 freeze/thaw cycles) conditions, the percent recoveries ranged from: 60.9 to 74.0% ; 91.5 to 105.0% ; and 98.7 to 109.8% , respectively. The method was cross validated and shown to be transferable to Fischer 344N female rat plasma over a concentration range of -0.06 to -50 $\mu\text{g/mL}$ β -myrcene in matrix.

1771 NATURALLY OCCURRING SMALL MOLECULE INHIBITOR FOR INDUCIBLE NITRIC OXIDE SYNTHASE AND CYCLOOXYGENASE-2 EXPRESSION MEDIATED THROUGH THE DOWN-REGULATION OF NF- κ B, AP-1, AND JNK IN LPS-STIMULATED RAW264.7 CELLS.

S. Yea^{1,2}, C. Choi^{1,2}, K. Park^{1,2}, J. Lee^{1,2} and K. Liu³. ¹Department of Biochemistry, College of Medicine, Inje University, Busan, South Korea, ²Biohealth Product Research Center, Inje University, Busan, South Korea and ³Department of Pharmacology, College of Medicine, Inje University, Busan, South Korea. Sponsor: H. Kim.

In the present study, we investigated the effect of the plant-derived small molecules on inducible nitric oxide synthase (iNOS) and cyclooxygenase-2 (COX-2) expression in RAW264.7 murine macrophages stimulated with lipopolysaccharide (LPS). Of the small molecules tested, IMB-112 from *Petroselinum sativum* markedly inhibited production of nitric oxide and prostaglandins, which were found to be correlated with decreases in the protein synthesis and mRNA expression of iNOS and COX-2, respectively. To further characterize the inhibitory mechanism of IMB-112 at the transcriptional level, we examined the DNA binding and transcriptional activity of NF- κ B and AP-1. We found that IMB-112 inhibited NF- κ B- and AP-1-dependent transcriptional activities as well as DNA binding activities of both transcription factors. IMB-112 also suppressed the phosphorylation of c-Jun N-terminal kinase (JNK). These results suggest that IMB-112, a naturally occurring small molecule derived from plant source, inhibits iNOS and COX-2 expression mediated through the down-regulation of NF- κ B, AP-1, and JNK signaling pathway, which may explain its potential for immune modulation. Supported by a grant from MOCIE and ITEP through the BPRC of Inje University.

1772 INHIBITION OF T-CELL PROLIFERATION AND IL-2 EXPRESSION BY PLANT-DERIVED NATURALLY OCCURRING SMALL MOLECULE IMB-112 IS MEDIATED THROUGH THE DOWN-REGULATION OF NF- κ B AND AP-1.

J. Lee^{1,2}, K. Park^{1,2}, C. Choi^{1,2}, D. Seog¹, Y. Park¹ and S. Yea^{1,2}. ¹Department of Biochemistry, College of Medicine, Inje University, Busan, South Korea and ²Biohealth Product Research Center, Inje University, Busan, South Korea. Sponsor: H. Kim.

In the present study, we show the effect of IMB-112, a naturally occurring small molecule derived from *Petroselinum sativum*, on T-cell function. IMB-112 produced an inhibition of concanavalin A (ConA)-induced lymphoproliferation in B6C3F1 mouse splenocytes. In light of the fact that IL-2 is responsible for the clonal expansion of T-cells, effect of IMB-112 on IL-2 expression was determined using ELISA and real-time RT-PCR. Mouse splenocytes and EL-4 T-cells exhibited IL-2 gene expression in response to ConA or phorbol-12-myristate-13-acetate (PMA) plus ionomycin (Io), which were inhibited by IMB-112 in a dose-dependent manner. No effect was observed on the treatment with IMB-111, a structural analogue to IMB-112. Electrophoretic mobility shift assay was performed to evaluate the effect of IMB-112 on binding activity of transcription factors for IL-2 gene expression in PMA/Io-stimulated EL-4 cells, and IMB-112 decreased the binding activity of NF- κ B and AP-1. These results suggest that the IMB-112 has the poten-

tial for immune modulation, which is due to the inhibition of NF- κ B- and AP-1-mediated IL-2 expression. Supported by a grant from MOCIE and ITEP through the BPRC of Inje University.

1773 PLANT-DERIVED SMALL MOLECULE INHIBITORS FOR T-CELL PROLIFERATION AND INTERLEUKIN-2 EXPRESSION MEDIATED THROUGH THE DOWN-REGULATION OF NF-AT, NF- κ B, AND ERK1/2.

K. Park^{1,2}, J. Lee^{1,2}, C. Choi^{1,2}, D. Seog¹, Y. Park¹ and S. Yea^{1,2}. ¹Department of Biochemistry, College of Medicine, Inje University, Busan, South Korea and ²Biohealth Product Research Center, Inje University, Busan, South Korea. Sponsor: H. Kim.

In the present study, we investigated the effect of plant-derived small molecules, IMB-104 and its analogue IMB-105, on T-cell function. IMB-104 and IMB-105 from *Syzygium aromaticum* produced inhibition of concanavalin A (ConA)-induced lymphoproliferation in B6C3F1 mouse splenocytes. In light of the fact that IL-2 is responsible for the clonal expansion of T-cells, effect of IMB-104 and IMB-105 on IL-2 expression was determined. Phorbol-12-myristate-13-acetate (PMA) plus ionomycin (Io) as well as ConA induced IL-2 mRNA expression and protein secretion in mouse splenocytes, thymocytes, and EL-4 T-cells, which were inhibited by IMB-104 and IMB-105 as determined by real-time RT-PCR and ELISA, respectively. Electrophoretic mobility shift assay was performed to evaluate the effect of the small molecules on binding activity of transcription factors for IL-2 gene expression. IMB-104 and IMB-105 decreased the binding activities of NF-AT and NF- κ B in PMA/Io-stimulated EL-4 cells. No effect was observed on the binding activity of AP-1 or Oct. Western blot analysis showed that IMB-104 and IMB-105 decreased the phosphorylation of ERK1/2 as well as the protein levels of NF-AT and NF- κ B p65 in nucleus. These results suggest that IMB-104 and IMB-105, naturally occurring plant-derived small molecules, inhibit IL-2 expression mediated through the down-regulation of NF-AT, NF- κ B, and ERK1/2 signaling pathway, which may explain their potential for immune modulation. Supported by a grant from MOCIE and ITEP through the BPRC of Inje University.

1774 PROTECTIVE EFFECTS OF THE SAPONINS DERIVED FROM ROOTS OF PLATYCODON GRANDIFLORUM ON THE CADMIUM-INDUCED CYTOTOXICITY.

S. Hwang^{1,2}, H. Jeong^{1,2} and H. Kim^{1,2}. ¹Pharmacy, Chosun University, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

Cadmium is a ubiquitous toxic metal which is toxic to humans. Cadmium-induced cytotoxicity has been implicated in reactive oxygen species (ROS) generation due to the depletion of glutathione and protein-bound sulfhydryl groups, demonstrated in experiments involving several antioxidants and antioxidant enzymes. In this study, the effects of saponins isolated from the roots of *Platycodon grandiflorum* A. DC (Campanulaceae), Changkil saponins (CKS), on the cadmium-induced cytotoxicity were investigated in human hepatoma cell line HepG2 cells. Pretreatment with CKS significantly inhibited cadmium-induced cellular toxicity, suggesting that CKS might protect cells against cadmium toxicity by inducing the synthesis of a certain protein or proteins. The synthesis of metallothionein, a protein that is known to reduce the toxicity of heavy metals, was induced by CKS. Furthermore, CKS significantly inhibited the cadmium-induced production of intracellular ROS. These results suggested that CKS might reduce cadmium toxicity by promoting the synthesis of metallothionein that protect cells against the toxic effects of cadmium.

1775 IDENTIFICATION AND INTERPRETATION OF TREATMENT-RELATED EFFECTS IN DEVELOPMENTAL NEUROTOXICITY TESTING.

L. P. Sheets¹, R. W. Tyl², A. Moretto³, K. M. Crofton⁴, V. C. Moser⁴, T. J. Sobotka⁵ and J. W. Fitzpatrick⁶. ¹Toxicology, Bayer CropScience LP, Stilwell, KS, ²RTI International, Research Triangle Park, NC, ³University of Padua, Padua, Italy, ⁴NTD, NHEERL/EPA, Research Triangle Park, NC, ⁵FDA/CFSAN, Laurel, MD and ⁶ILSI Research Foundation/RSI, Washington, DC.

Expert working groups were convened by ILSI Research Foundation/Risk Science Institute to assess the knowledge and experience gained from the implementation of the USEPA Developmental Neurotoxicity Guideline (OPPTS 870.6300) and to provide guidance for future use. Manuscripts were prepared in public health protection, use of positive controls, understanding normal variability, appropriate statistical techniques, and data interpretation. This paper presents the key findings

that provide a framework for the integration of the available information to properly interpret the results of DNT studies. The reliable detection, measurement and interpretation of treatment-related effects depend on appropriate study design and execution, using scientifically established methodologies, with appropriate controls to assist with interpretation. Statistical analysis should be optimized for the specific endpoints in advance, analyzing results across time and functional domains, as far as possible. The findings should be interpreted in light of available information from historical and positive controls, maternal and offspring systemic toxicity and other relevant data from the study, using "weight of evidence" principles to aid the assessment of the biological significance of statistically significant differences from concurrent controls. Case studies are used to illustrate the application of these principles. This work was supported by USEPA Cooperative Agreements X-82916701 (OPPT) and R-83049601 (OPP) and the ILSI/RF Risk Science Institute. This abstract does not necessarily represent EPA policy.

1776 EVALUATION AND INTERPRETATION OF NEURODEVELOPMENTAL ENDPOINTS FOR HUMAN HEALTH RISK ASSESSMENT – POSITIVE CONTROL STUDIES, NORMAL VARIABILITY, AND STATISTICAL ISSUES.

K. M. Crofton², K. C. Raffaele³, R. R. Holson⁴, V. C. Moser², J. A. Foss⁵ and J. W. Fitzpatrick¹. ¹Risk Science Institute, ILSI Research Foundation, Washington, DC, ²NTD/NHEERL, U.S. EPA, Research Triangle Park, NC, ³OPP, U.S. EPA, Washington, DC, ⁴Department of Psychology, New Mexico Tech, Socorro, NM and ⁵Charles River Laboratories, Horsham, PA.

ILSI Research Foundation/Risk Science Institute convened an expert working group to assess the lessons learned from the implementation of the EPA Developmental Neurotoxicity (DNT) Guideline and provide guidance for future use. The group prepared manuscripts in five areas: public health protection, use of positive controls, understanding normal variability, appropriate statistical techniques, and data interpretation. This poster will present the results from the positive control, variability, and statistical reports. Positive control data are instrumental in evaluating laboratory proficiency in detecting chemical-induced changes in measured endpoints. This review is a practical guide for the selection, use, and interpretation of positive control studies in DNT. To evaluate data quality and interpret results of treatment, normal levels of variability in measured parameters must be understood. This report presents a framework for investigators and regulators to use in comparing achieved versus expected levels of variability in DNT study data, as well as a discussion of factors contributing to inappropriate levels of variability. Appropriate statistical analyses of the behavioral data collected in DNT studies are imperative, including attention to within-litter correlations, gender and repeated testing as factors, and approaches specific for the different data types. This report presents a discussion of statistical approaches and makes general recommendations. This work is supported by EPA Cooperative Agreements X-82916701 (OPPT) and R-83049601 (OPP) and the ILSI/RF Risk Science Institute. This abstract does not necessarily represent EPA policy.

1777 ADMINISTRATION OF 3, 3'-IMINODIPROPIONITRILE (IDPN) IN JUVENILE RATS: EVALUATION AS A POSITIVE CONTROL FOR THE MOTOR ACTIVITY TEST IN THE DEVELOPMENTAL NEUROTOXICITY STUDY (DNT) AND STATISTICAL CHARACTERIZATION OF EFFECTS.

J. F. Barnett¹, J. A. Foss¹, L. Freshwater² and A. M. Hoberman¹. ¹Preclinical Services, Charles River Laboratories, Horsham, PA and ²BioSTAT Consultants, Inc., Portage, MI.

Positive control data are a required component of DNT studies submitted to the USEPA. Administration of IDPN on postnatal days (PNDs) 5, 6 and 7 (day of birth = PND 0) has been shown to induce dyskinesia and hyperactivity that persists into adulthood (Crofton KM et al. *Neurotoxicol Teratol* 1993;15:117-29), and in this study the effects of that dosage regimen were evaluated using a different means of measuring motor activity and alternative statistical analyses. IDPN, or the saline vehicle alone, was administered intraperitoneally at dosages of 0, 75, 150, 225 or 300 mg/kg/day (10 mL/kg) to one Crl:CD(SD) rat/sex in each of 15 litters. On PNDs 13, 17, 21 and 60 the rats were transported to a separate testing area and the number of movements and time spent in movement were monitored for six 10-minute intervals using individual passive infrared sensors on a cage rack. These data were evaluated using separate repeated measures analyses of variance (ANOVA) for each sex and postnatal day. A second, comprehensive approach evaluated dose-related trends in a RANOVA model that included both sexes and all sessions. Approximately 10% and 30% of the rats at 225 and 300 mg/kg, respectively, died prior to scheduled necropsy. Body weights at PND 71 were reduced 7.4, 7.6, 14 and 32% in the male rats at 75, 150, 225 and 300 mg/kg, and the corresponding

reductions in the female rats were 7.0, 7.2, 14 and 30%. The IDPN treatment affected motor activity at every age except PND 14. Both statistical approaches identified significant increases in activity at 300 mg/kg on PNDs 18, 21 and 60 as well as the increases at 225 mg/kg on PND 18; however, the analysis that included both sexes and evaluated dose-related trends also identified significantly increased activity at 150 mg/kg on PND 18.

1778 A RETROSPECTIVE REVIEW OF THE USE OF THE DEVELOPMENTAL NEUROTOXICITY STUDY IN PESTICIDE RISK ASSESSMENTS.

J. Rowland¹, S. L. Makris², K. Raffaele¹, K. Schumacher¹ and L. Scarano¹. ¹OPP/HED, U.S. EPA, Washington, DC and ²ORD/NCEA, U.S. EPA, Washington, DC.

As of August 2006, guideline developmental neurotoxicity (DNT) studies (OPPTS 870.6300) for 68 pesticide active ingredients had been submitted by registrants to the US Environmental Protection Agency (US EPA) Office of Pesticide Programs (OPP) in support of product registration. These studies, conducted in rats, include detailed neurobehavioral and neuropathological assessments, following in utero and postnatal exposures to pesticide chemicals. OPP assesses risk for various routes and durations of human exposure to pesticide chemicals. To determine the influence of DNT studies in OPP risk assessment decisions, NOAELs and LOAELs from the DNT studies (maternal and offspring) were compared to the doses and endpoints used in the most recently published OPP risk assessments. The impact or potential impact of the DNT study on those risk assessments was determined. Of the submitted studies, reviews were available for 58 pesticide chemicals. For 8 of those 58, the DNT study was selected as the hazard value for regulatory purposes in at least one exposure scenario. For 18/58, the review indicates potential regulatory impact since these studies were received after the current regulatory decisions had been finalized. (This abstract does not necessarily reflect the policy of the US Environmental Protection Agency.)

1779 ASSESSMENT OF CHEMICAL EFFECTS ON NEURONAL DIFFERENTIATION USING THE ARRAYSCANTM HIGH CONTENT SCREENING SYSTEM.

N. M. Radio, T. M. Freudenrich, K. M. Crofton, T. J. Shafer and W. R. Mundy. *Neurotoxicology, U.S. EPA, Research Triangle Park, NC.*

The development of alternative methods for toxicity testing is driven by the need for scientifically valid data that can be obtained in a rapid and cost-efficient manner. In vitro systems provide a model in which chemical effects on cellular events can be examined using techniques that are amenable to high-throughput analysis. We used the new technology of high content screening (HCS) to examine the effect of chemicals on differentiation and neurite outgrowth in Neuroscreen-1 cells (NS-1, a PC12 cell clone). HCS was performed using the Cellomics ArrayScan VTITM, an automated epifluorescence microscope and image analysis system using cells in a microtiter plate format. To establish the parameters for differentiation, NS-1 cells were grown on a 96-well plate in the absence (negative control) or presence (positive control) of increasing concentrations of nerve growth factor (NGF). Morphological measures indicative of NS-1 cell differentiation and growth (cell size, neurite elaboration, neurite length) were assessed after fixation and staining for Hoechst (nucleus) and beta-tubulin (cell body and neurites). Treatment with NGF caused a concentration-related increase in cell body area, average number of neurites per cell, and neurite length. Maximal effects of NGF occurred at 30-100 ng/ml. Differentiation of NS-1 cells induced by NGF was observable at 48 hr and reached maximum at 72 hr. All subsequent studies used 100 ng/ml NGF to induce differentiation and included non-NGF treated wells as negative controls. NGF-treated cells were exposed to chemicals 2 hr after plating, and differentiation was assessed 72 or 96 hr later. DMSO (vehicle) did not effect differentiation at a concentration of 0.1%. A MAP kinase inhibitor (U0126) and a PKC inhibitor (Bis I) both inhibited differentiation at concentrations that were not cytotoxic. These studies demonstrate the utility of HCS to assess chemical effects on neuronal differentiation and growth in an in vitro model. (This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.)

1780 DEVELOPMENT OF AN *IN VITRO* ES-D3 STEM CELL ASSAY FOR QUANTITATIVE DEVELOPMENTAL NEUROTOXICITY TESTING.

J. Lammers¹, L. Hondebrinck¹, J. van Burgsteden¹, A. Freidig¹, A. Seiler², H. Vijverberg³, R. Westerink³, A. Wolterbeek³ and D. de Groot¹. ¹TNO Quality of Life, Zeist, Netherlands, ²Federal Institute for Risk Assessment, ZEBET, Berlin, Germany and ³Institute for Risk Assessment (IRAS), Utrecht University, Utrecht, Netherlands. Sponsor: V. Feron.

Effects of chemicals on any developmental process like proliferation, migration, differentiation or apoptosis will likely have neurotoxic consequences for the CNS as an organ. In search for an in vitro screening test for developmental neurotoxicity we

have developed an assay in which ES-D3 stem cells differentiate into neurons, astrocytes and oligodendrocytes. We hypothesize that the in vitro neuronal development from stem cells mimics the in vivo differentiation to such extent that chemicals that interfere with any process in in vivo neuronal development also interfere with the neuronal development in this in vitro system. To improve the assay, variations were made 1) in culturing embryonic bodies in order to achieve uniform and reproducible embryonic bodies, 2) in the transfer from Petri dish to flask inducing cell migration, 3) in cell numbers replated prior to differentiation and 4) in additions to promote differentiation after replating. As an endpoint in the assay, immunohistochemical staining is used to distinguish different cell types in the culture. Treatment of the test system with the thyroid hormone T3 leads to an increase in oligodendrocytes. However, quantitative analysis of results needs further effort in order to overcome misinterpretation of observed differences in cell-ratios. For that purpose, the use of the computer aided stereological toolbox (CAST) system in in vivo developmental neurotoxicity testing and the translation to its possible use in quantification of in vitro results is explained. Further validation should be done by testing a selection of chemicals for their effects on individual developmental processes in relation to a shift in neuronal cell types arising after occurrence of these effects.

1781 USING ZEBRAFISH TO SCREEN FOR NEUROBEHAVIORAL TOXICITY.

D. T. Cerutti¹, Z. Bencan², E. Linney³ and E. D. Levin^{2,1}. ¹Department of Psychology, Duke University, Durham, NC, ²Department of Psychiatry, Duke University Med. Ctr, Durham, NC and ³Department of Molecular Biology and Genetics, Duke University, Durham, NC.

Zebrafish models can help in toxicant discovery with high through-put, low-cost assays. Neurobehavioral function can be efficiently and reliably determined in zebrafish with appropriate test methods. These can complement classic mammalian models of toxicant effects on behavioral function including learning and memory as well as locomotor activity and stress response. In addition, molecular mechanisms of the drug and toxicant effects can be effectively studied in zebrafish with the wide variety of mutants available. We have developed tests of learning and memory, stress response and locomotor activity for zebrafish, which are sensitive to drug and toxicant effects, which resemble those seen in classic rodent assays. Nicotine in adults improves both learning and memory in zebrafish much as in rats. Developmental exposure to the organophosphate pesticide chlorpyrifos impairs learning in zebrafish as it has been found in rats. Anxiolytic effects of nicotine have been documented in studies with rodents and humans. We have documented a similar effect in adult zebrafish with nicotine significantly reducing the diving response that zebrafish show in novel environments. This is at the same dose that we earlier found to significantly improve learning and memory. Zebrafish models can usefully complement mammalian investigations by providing a high through-put front-end to the investigatory sequence to triage the chemicals for further testing. In addition, molecular tools and reporter techniques for continuous visualization of the developmental process can help determine mechanisms of toxicity. The development of a neurobehavioral test battery for zebrafish will bring these advantages to bear for functional neurotoxicity. Zebrafish can provide useful starting points for the full characterization of toxicity with classical mammalian models. (Supported by the Duke University Superfund Basic Research Center ES010356).

1782 LOW LEVEL ORGANIC MERCURY EXPOSURE DISRUPTS OLIGODENDROCYTE PRECURSOR CELL FUNCTION.

T. Dong¹, Z. Li¹, L. Opanashuk² and M. Noble¹. ¹Biomed. Genetics, University of Rochester, Rochester, NY and ²Environment Med., University of Rochester, Rochester, NY.

Methylmercury (MeHg) and thimerosal (THIM) (an ethylmercury derivative) are two major sources of human organic mercury exposure. Although the developing central nervous system (CNS) is a primary target of organic mercury toxicity, there is limited information regarding whether MeHg or THIM interferes with neural precursor cell function. During CNS development, oligodendrocyte-type-2-astrocyte precursor cells or oligodendrocyte progenitor cells (O-2A/OPC), undergo self-renewal and differentiation. Both intracellular redox status and platelet-derived growth factor (PDGF)-AA regulate O-2A/OPCs maturation. This study tested the hypothesis that organic Hg disrupts O-2A/OPCs function by interfering with PDGF-mediated signaling pathways. Therefore, experiments determined whether MeHg or THIM exposure, at environmentally relevant levels, impacted survival, proliferation, and intracellular signaling in O-2A/OPCs both in vitro and in vivo. Cell survival assays showed that O-2A/OPCs are extremely sensitive to nanomolar (nM) levels of MeHg or THIM. Sublethal MeHg or THIM concentrations (20-30nM) also compromised O-2A/OPCs self-renewal and differentiation by altering cellular redox status. These observations were accompanied by a downregulation of

the PDGF signaling pathway and reduced PDGF receptor α (PDGFR α) expression in O-2A/OPCs following exposure in vitro. Furthermore, N-acetyl-L-cysteine, a glutathione precursor, protected O-2A/OPCs from MeHg or THIM toxicity. Additional results showed that perinatal exposure to low levels of MeHg or THIM reduced O-2A/OPC division in postnatal SJL mice. PDGFR α expression was also decreased in multiple CNS regions. The adverse effects of organic Hg exposure were dependent upon mouse strain, since CBA mice were less sensitive. These findings suggest that developmental exposure to low levels of organic Hg may interfere with myelination in the CNS. Moreover, impaired O-2A/OPC development following organic Hg exposure could depend upon gene environment interactions. Supported by NIH RO1 ES 012708 & P30 ES 01247.

1783 METHYLMERCURY (MEHG) INDUCED CELL CYCLE ARREST AND APOPTOSIS IN NEURAL PRECURSORS ARE PREVENTED BY CASPASE INHIBITION.

K. B. Sokolowski¹, A. Falluel-Morel², X. Zhou² and E. DiCicco-Bloom². ¹Joint Graduate Program in Toxicology, Rutgers, Ocean, NJ and ²Department of Neuroscience and Cell Biology, UMDNJ, Piscataway, NJ.

Recent studies show that MeHg, a neurotoxicant, inhibits DNA synthesis in hippocampus of newborn rat pups (Burke et al, 2006). Mechanistic studies in cerebral cortical precursor neurons in culture suggested that initial inhibition depends on a blockade in cell cycle progression, whereas later reductions were consequent to apoptosis. Further, inhibition of DNA synthesis and S phase entry were accompanied by reduced levels of cyclin E, a cell cycle regulator required for G1/S phase transition. Since the apoptosis-associated caspases cleave proteins, including cyclin E, we examined the role of the enzymes by blocking their activity using the pan-caspase inhibitor, Z-VAD-FMK (R&D System).

Primary cultures of S-D E14.5 cortical precursors were incubated in defined medium or medium containing 1.5uM MeHg with or without 60uM Z-VAD for 24h and assessed for [3H]thymidine incorporation, protein levels, and cell numbers. MeHg reduced DNA synthesis by 27%. In the presence of the Z-VAD, MeHg reduced DNA synthesis by only 9%, suggesting that caspase activity contributes to inhibition of DNA synthesis. The inhibitor alone had no effect. In addition, while cyclin E levels were reduced by 40% after MeHg exposure, the Z-VAD virtually prevented cyclin E degradation. Finally, MeHg also induced mild cell loss, reducing numbers by 12%, an effect partially reversed by Z-VAD at 24h.

These data indicate that MeHg exposure reduces DNA synthesis, cyclin E levels and neuronal numbers after 24h, and that a pan-caspase inhibitor protects against these losses. Results further suggest that activation of the caspase cascade contributes to both cell loss as well as cell cycle arrest. Specifically, caspases may not only initiate cell death but also block the G1/S phase transition through degradation of cyclin E. Further studies at earlier timepoints will clarify relationships between caspase activation and inhibition of DNA synthesis. Support: NIH: ES07148, ES11256; USEPA R829391; FRM SPE2006.

1784 GESTATIONAL LEAD EXPOSURE (GLE) INCREASES CELL PROLIFERATION AND NEUROGENESIS IN THE DEVELOPING MOUSE RETINA.

A. Giddabasappa¹, W. Xiao¹, J. E. Johnson¹, R. Hamilton¹, S. Chaney¹, A. Swaroop² and D. A. Fox¹. ¹University Houston, Houston, TX and ²University Michigan, Ann Arbor, MI.

Postnatal lead exposure decreases the scotopic electroretinogram (sERG) a- (rod photoreceptors) and b-wave (bipolar cells) in man and rodents and produces rod-selective apoptosis. In contrast, GLE increases these sERG amplitudes in children, monkeys and rodents. To determine the molecular mechanism underlying these novel supernormal ERGs, a murine model of GLE was established. Adult retinas from control and GLE mice were immunostained with molecular markers for different retinal cells and retinal immunoblots were run. To assess kinetics of retinal cell proliferation, developing retinas were immunostained for cell cycle markers (BrdU & phosphohistone 3 [PH3]) and apoptotic cells. Retinal sections were examined by light or confocal microscopy and stereological techniques determined cell counts. Affymetrix mouse genome microarrays were run with developing retinas from control and GLE mice. Real-time PCR validated the results. In adult mice, GLE produced a dose-dependent selective increase in rods and bipolar cells as horizontal, amacrine, ganglion and Müller glial cells counts were unchanged. Immunoblots confirmed these results. In retinas from GLE mice, BrdU- and PH3-positive cell numbers increased, retinal progenitor cell (RPC) proliferation was prolonged, and developmental apoptosis decreased. Microarray data analysis followed by functional classification revealed that genes associated with cell cycle and cell fate determination were up-regulated in GLE mice. Thus, GLE in mice produced a

novel phenotype characterized by an increased proliferation and genesis of late-born neurons, but not glial cells. The persistent increase of these neurons likely produces the lead-induced supernormal ERGs. Upregulation of cell growth genes appears to underlie the increased/prolonged RPC proliferation and rod/bipolar cell neurogenesis. These findings have relevance for retinal development and the permanent cognitive and behavioral deficits observed in GLE children. NIH Grants ES012482, EY007551, EY007024, EY11115 and Sramek Foundation.

1785 DIFFERENTIAL SUSCEPTIBILITY OF ROD PHOTORECEPTOR SYNAPTIC AND NON-SYNAPTIC MITOCHONDRIA TO LEAD EXPOSURE: NEUROPROTECTION BY BCL-XL OVEREXPRESSION.

D. A. Fox¹, G. A. Perkins², J. E. Johnson¹, A. Dixit² and M. H. Ellisman².
¹University Houston, Houston, TX and ²University California, San Diego, CA.

Rod inner segment (RIS) mitochondria are considered primary target sites of action during inherited and chemical-induced retinal degenerations. To date, rod synaptic terminal (spherule) mitochondria have not been examined. To determine and compare the long-term effects of low-level postnatal lead (Pb) exposure on RIS and rod spherule mitochondria, we used wild-type and transgenic mice overexpressing Bcl-xL in photoreceptors (Tg). Newborn C57BL/6 mice were raised by dams drinking water (Con) or Pb solution throughout lactation. Immunocytochemistry and confocal microscopy, electron microscopy (EM) and three-dimensional electron tomography (ET) studies used adult retinas from all four groups: Con, Tg, Pb and Tg+Pb. Molecular markers of mitochondrial compartments revealed retinal lamination and cellular localization of mitochondria. Bcl-xL localized to RIS and rod spherule mitochondria. Each rod spherule had one large mitochondrion compared to ~5/RIS cross section. Pb induced mitochondrial swelling and decreased crista/mitochondria volume, crista/mitochondria surface area and crista junction size. In contrast, the same Pb exposure did not alter these measures in RIS mitochondria, although it increased contact sites and activated a cytochrome c-caspase apoptotic cascade. Bcl-xL prevented the Pb-induced alterations in RIS mitochondria. In contrast, persistent Pb-induced structural and substructural alterations remained in the rod spherule mitochondria of Tg+Pb mice. These results reveal the importance of compartmental analysis/differences between RIS and rod spherule mitochondria and in their differential sensitivity to divalent cation-induced overload. These findings have relevance for exocytosis/endocytosis, cell injury, neuroprotection and visual function. They also expand lead's retinal sites of action and demonstrate the importance of retinal compartmental analysis and their relation to therapies for mitochondrially-mediated retinal degenerations. NIH Grants RR04050, ES10337, ES012482, EY007551.

1786 KETAMINE-INDUCED OXIDATIVE STRESS AND DNA REPAIR IN MONKEY FRONTAL CORTICAL CULTURE DURING DEVELOPMENT.

C. Wang, N. Sadovova, X. Zou, A. C. Scallet, H. E. Charlotte, T. A. Patterson, J. P. Hanig, M. G. Paule and W. Slikker. Division of Neurotoxicology, national center for Toxicological Research, Jefferson, AR.

This study was designed to determine whether ketamine-induced neuronal cell death correlates with oxidative DNA damage and altered DNA repair system. Frontal cortical cultures were incubated for 24 hrs with 10 μ M ketamine or normal culture medium (control). After washout of ketamine, cultures were kept in serum and glutamate-containing medium for 2, 6 and 24 hrs. In this study, 8-oxoguanine, a modification of guanine induced by endogenous and exogenous reactive oxygen species (ROS) to nucleic acids, was used as a biomarker for oxidative DNA damage. Antibody to human 8-oxoguanine DNA glycosylase (hOGG1) that catalyzes the removal of the 8-oxoG through cleavage of the DNA phosphodiester bond, was applied to explore the potential regulatory DNA repair systems. Immunostaining data indicate that 8-oxoguanine in both neurons and glia was primarily localized in the nucleus and mitochondria. Ketamine administration remarkably upregulated 8-oxoguanine expression and withdrawal time-dependently decreased hOGG1 expression that is responsible for repair of oxidative DNA damage. Meanwhile, ketamine (10 μ M) caused a marked reduction in immunostaining for PSA-NCAM, a substantial increase of lactate dehydrogenase (LDH) release, increased TUNEL-positive cells, and a reduction in mitochondrial metabolism of 3-[4,5-Dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT). Western analysis showed that co-administration of NR1 antisense oligonucleotide prevent the synthesis of NMDA NR1 subunit protein and effectively block the neurotoxic effects induced by ketamine. These data suggest that Ketamine-induced neurotoxic effect is associated with an up-regulation of NMDA receptor function. ROS have been associated with ketamine-induced oxidative DNA damage as indicated by increased 8-oxoguanine expression and decrease DNA repair enzyme (hOGG1) expression in developing monkey. Supported by FDA/NCTR E-7189, and NICHD.

1787 MATERNAL-FETAL DISTRIBUTION OF PCB 153 VERSUS PCB 169 IN CYP1A2(-/-) KNOCKOUT COMPARED WITH CYP1A2(+/+) WILD-TYPE MICE.

C. P. Curran¹, T. P. Dalton¹, M. T. Williams², C. V. Vorhees² and D. W. Nebert¹. ¹Environmental Health, University of Cincinnati, Cincinnati, OH and ²Neurology, Cincinnati Children's Research Foundation, Cincinnati, OH.

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that occur in complex mixtures, with dozens of individual congeners identifiable in common food products. PCBs cause CNS damage, immunosuppression, endocrine disruption, and cancer in lab animals. Human exposures are well documented, based on samples taken from blood, breast milk, and tissues from stillborn infants. Children exposed in utero and via mother's milk are known to be at highest risk for PCB-induced neurotoxicity. Previously this lab has demonstrated the critical importance of maternal liver CYP1A2 levels in protecting fetuses from prenatal exposure to TCDD (dioxin); CYP1A2 appears to act as a "sink" to sequester planar TCDD. We have extended this work by comparing Cyp1a2(-/-) knockout with Cyp1a2(+/+) wild-type mice, following in utero exposure to an environmentally relevant mixture of eight PCB congeners spiked with either ¹⁴C-labeled PCB 153 or the PCB 169 isomer. PCB 153 is a non-planar hexachlorobiphenyl unable to bind the aryl hydrocarbon receptor (AHR); PCB 169 is a planar isomer with high affinity for the AHR. Pregnant dams were given a single gavage dose at gestational day 10 (GD10), and tissues were harvested at GD18. There were no significant differences in the distribution of PCB 153 from dams to fetuses; highest levels were found in dam adipose tissue followed by dam mammary tissue. In contrast, liver levels of PCB 169 were >5 times higher in Cyp1a2(+/+) dams than Cyp1a2(-/-) dams (p < 0.001), and fetuses carried by Cyp1a2(-/-) dams had PCB 169 levels 54% higher than fetuses carried by Cyp1a2(+/+) dams (p < 0.01). Our findings further support the role of maternal hepatic CYP1A2 levels in protecting the developing embryo/fetus by sequestering planar hydrophobic environmental toxicants in the maternal liver.—Supported, in part, by NIH grants P30 ES006096, T32 DK059803, and R01 ES014403.

1788 DEVELOPMENTAL EXPOSURE TO POLYCHLORINATED BIPHENYLS REDUCES INFARCT SIZE IN THE ADULT RAT FOLLOWING ISCHEMIC STROKE.

D. Yang¹, S. Dziennis², N. J. Alkayed², P. D. Hurn² and P. J. Lein¹. ¹Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR and ²Anesthesiology and Peri-Operative Medicine, OHSU, Portland, OR.

Stroke outcome is a sexually dimorphic response and there is evidence suggesting that sexual dimorphism in stroke is shaped by exposure to sex steroids during development of the brain. Polychlorinated biphenyls (PCBs) are environmental contaminants that have been identified as endocrine disruptors, and experimental evidence suggests that PCBs interfere with sexual differentiation of the brain. Moreover, PCBs have been linked to increased incidence of risk factors associated with stroke such as vascular disease and a recent epidemiological study reported a positive association between PCB exposure and increased stroke incidence. Thus we tested the hypothesis that developmental exposure to PCBs would alter stroke outcome in adults in a sex-specific manner. Female Wistar rats were dosed daily with vehicle or Aroclor 1254 (0.1 mg/kg or 1 mg/kg) beginning 2 weeks prior to conception and continuing throughout gestation and lactation. Exposure to the pups ended upon weaning at postnatal day 21. At 8-10 weeks of age, male and female adult rats that had been exposed to PCBs developmentally were subjected to 2-hour middle cerebral artery occlusion (MCAO), followed by 22 hours of reperfusion. Body and head temperatures, blood gases and laser-Doppler cortical perfusion were monitored during MCAO and early reperfusion, and infarct size was measured by TTC staining. Unexpectedly, developmental exposure to Aroclor 1254 significantly decreased striatal infarct in both males and females at 1 mg/kg and 0.1mg/kg respectively. A similar trend, which was not statistically significant, was observed with cortical infarcts. We conclude that PCB exposure during development alters the brain's susceptibility to stroke in adult life in a brain region specific manner, and that males and females may exhibit differential sensitivity. This work supported by the NIH grants ES010338 (PJL), HD40936 (PJL), NS49210 (PDH) and NS33668 (PDH).

1789 EFFECTS OF DEVELOPMENTAL EXPOSURE TO CHLORPYRIFOS OR METHYL PARATHION ON BRAIN-DERIVED NEUROTROPHIC FACTOR EXPRESSION DURING SPATIAL MEMORY FORMATION.

F. O. Johnson, R. L. Carr and J. E. Chambers. Center For Environmental Science, Mississippi State University, Starkville, MS.

Brian-derived neurotrophic (BDNF) is a member of the neurotrophin family whose expression is believed to be necessary for spatial memory formation. In the present study, we investigated the involvement of BDNF mRNA expression in

working and reference memory formation following developmental exposure to methyl parathion or chlorpyrifos in rats. The 12-arm radial maze was used to assess working and reference memory. Working memory was assessed using the total number of accurate choices within the first eight arm visits and entries to repeat. On the final day of training in the 12-arm radial maze, males exposed to the medium and high dosage regimen of methyl parathion (MPS) reduce significantly ($p < 0.05$), the total number of accurate choices within first eight arms visits. In contrast, entries to repeat and reference memory was not significantly affected by either chlorpyrifos or methyl parathion exposure for both males and females. To assess the involvement of BDNF mRNA expression in working and reference memory formation, the hippocampus of male and female rats were dissected 30-minutes post radial arm maze training. The radial arm maze training paradigms significantly ($p < 0.05$) increase the expression of BDNF mRNA expression in control male and females when compared to naive controls. However, the exposure of males to the CPS medium and high dose regimen, decrease significantly ($p < 0.05$), the expression of BDNF mRNA hippocampal expression. This reduction of BDNF gene expression due to treatment resulted in the impairment in working memory formation. Interestingly, females exposed developmentally to CPS or MPS resulted in a significant ($p < 0.05$) reduction in hippocampal BDNF mRNA gene expression at all exposure levels but these reductions did not correlate significantly with impairment in memory formation. Finally, these data seem to suggest that developmental exposure to CPS or MPS impair BDNF mRNA expression and these impairments sex-selectively correlated to working memory formation.

1790 SHIPPING STRESS DURING PREGNANCY AFFECTS THE NEUROTOXIC EFFECTS AFTER PRENATAL EXPOSURE TO VALPROATE.

T. Ogawa¹, M. Kuwagata^{1,2} and S. Shioda¹. ¹Anatomy I, Showa University School of Medicine, Tokyo, Japan and ²Toxicology, Hatano Research Institute, FDSC, Kanagawa, Japan.

Developmental neurotoxicity tests are important to protect the pediatric brain from chemically-induced tragedies. Prenatal stress is well known to affect the development of the central nervous system. However, numerous developmental neurotoxicity studies published recently have used pregnant rodents purchased from a breeder. The pregnant rodents purchased definitely sustain shipping stress. In the present study, we investigated the effect of shipping stress on the neurotoxicity induced by valproate (VPA) exposure (a proposed rat model of autism). Two groups of pregnant rats, purchased (P) and mated at our animal facility (M), were established. These rats were exposed to VPA (800 mg/kg) orally on gestation day (GD) 9 or 11 (VPAE9 or VPAE11), and the fetal brain was observed on embryonic day 14 by serotonin and TuJ1 (a marker of immature neurons) immunohistochemical staining. Fetal brains were carefully observed using serial coronal and sagittal sections. The VPA exposure affected the number of dead fetuses and fetal body weight only in the P group. Development of the serotonin nervous system was not affected by VPA. VPA on both exposure days induced an altered structure in the thalamus, which was rounder with an enlarged third ventricle, and diminished development of TuJ1 positive neurites in the cerebral cortex. The size of the forebrain was also affected by VPA. Two factor ANOVA analysis demonstrated that the P group was much more sensitive to these toxic effects. The findings of this study strongly suggest that purchasing pregnant rats or mating rats at the test facility is a very important issue in risk assessment. (Supported in part by a grant for Long-range Research Initiative from the Japan Chemical Industry Association).

1791 CONCURRENT EXPOSURE TO PERFLUOROOCTANE SULFONATE (PFOS) AND RESTRAINT STRESS DURING PREGNANCY IN MICE: NEUROBEHAVIORAL EFFECTS ON THE OFFSPRING.

T. Colomina^{1,2}, S. Fuentes^{1,2}, P. Vicens^{1,2} and J. L. Domingo². ¹Psychobiology, Rovira i Virgili University, Reus, Spain and ²Toxicology & Environment Health, Rovira i Virgili University, Reus, Spain.

Perfluorooctane sulfonate (PFOS) is an organic persistent pollutant used in a great variety of commercial products. Concern about this chemical is due to its detection in human tissues and wildlife samples on a global scale. Studies performed in mammals show that PFOS exposure can cause adverse effects on adults. However, only few studies have provided information concerning the effects of PFOS on development. Data on the development of the offspring after weaning are particularly scarce. On the other hand, several investigations have demonstrated that stress can enhance the developmental toxicity of some chemicals. The aim of this study was to assess the combined effects of maternal restraint stress and PFOS on the behavior of the offspring of mice at three months of age. Thirty-four plug positive females were divided in two groups). Animals were given by gavage 0 and 6 mg PFOS/kg/day on gestation Days 12-18. One-half of the animals in each group was subjected to restraint stress (30 min/session, three sessions per day) during the same period. At

three months, mice were evaluated for general activity in an open-field, and for learning and memory in a water maze task. The group prenatally exposed to PFOS and restraint presented a reduced mobility in the open-field, whereas the group exposed to restraint performed a greater number of rearings. In the water maze, an interaction between sex and restraint was observed. Delayed task learning was detected in females prenatally exposed to PFOS and restraint. An overall effect of restraint was observed in mice on retention of the task, suggesting a better retention in restrained animals. Corticosterone levels were lower in animals prenatally exposed to restraint. The current results suggest that prenatal PFOS exposure induced long lasting effects in mice. Interactive effects between PFOS and maternal stress were also observed.

1792 HIGHLY BROMINATED DIPHENYL ETHERS (PBDE 209) INTERACT WITH THE PERFLUOROOCTANOIC ACID (PFOA) DURING NEONATAL BRAIN DEVELOPMENT TO ENHANCE DEVELOPMENTAL NEUROBEHAVIOURAL DEFECTS.

N. Johansson, A. Fredriksson and P. Eriksson. Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden.

Polybrominated diphenyl ethers (PBDEs) and perfluorinated compounds (PFCs) have been identified as emerging classes of persistent environmental compounds, present in humans as well as wildlife. A concern is that these compounds are present at a higher level in the children compared to the mother's and grandmother's generation. PBDEs are used in large quantities as flame-retardant in polymers, especially in electric appliances. PFCs are found in consumer applications such as stain resistant treatment coatings for clothing fabrics, carpets, as well as foam fire extinguishers. We have earlier reported that neonatal exposure to PBDE 209 on PND 3 cause developmental neurotoxic effects, but not when exposed on PND 10. Neonatal exposure to PFOA causes developmental neurotoxic effects when given on PND 10 to mice. The present study was carried out to see whether PBDE 209 and PFOA interact during neonatal brain development to enhance neurobehavioural defects. Neonatal mice, 3 and 10 days of age (PND 3/PND 10), were orally exposed to PBDE 209 (1.4 or 8.0 $\mu\text{mol/kg bw}$), PFOA (1.4 or 8.0 $\mu\text{mol/kg bw}$), co-exposed to PBDE 209 and PFOA, or a vehicle (20 % fat emulsion). Neonatal exposure to single oral dose of PBDE 209 on PND 3 and a single oral dose of PFOA on PND 10 caused impaired spontaneous behaviour in 2- and 4-month-old mice, an effect significantly different from single exposure to PBDE 209 or PFOA. Furthermore, neonatal exposure to PFOA on PND 10, but not on PND 3, significantly impaired spontaneous behaviour in 2- and 4-month-old mice. There was no interaction between PBDE 209 and PFOA when both compounds were given on PND 3. This study suggests that highly brominated diphenyl ethers interact with perfluorinated compounds (PFOA). At low doses of these compounds enhance developmental neurobehavioural defects when present during a critical phase of neonatal brain development.

1793 NEONATAL DEVELOPMENTAL NEUROTOXICITY OF DECABROMINATED DIPHENYL ETHER, PBDE 209: A SUMMARY.

H. Viberg, A. Fredriksson, N. Johansson and P. Eriksson. Department Environmental Toxicology, Uppsala University, Uppsala, Sweden.

Polybrominated diphenyl ethers (PBDEs) are flame-retardants used in order to reduce the risk of fire. PBDEs have been found to increase in the environment and in human mother's milk. In recent studies we have seen that neonatal exposure to several congeners of PBDEs (PBDE 47, 99, 153, 183, 203, 206, and 209), can cause permanent neurotoxic effects in mice and/or rats. Here follows a summary of the neonatal developmental neurotoxic effects of the decabrominated diphenyl ether, PBDE 209, the only PBDE congener still in use.

Study 1: Male mice were exposed to 2.22 or 20.1 mg PBDE 209/kg b.wt. on PND 3, 10 or 19 and tested in a spontaneous behaviour test at different ages. Exposure to 20.1 mg PBDE 209/kg b.wt. on PND 3 induced irreversible behavioural effects that got worse with age.

Study 2: Male mice, exposed to 1.34 to 20.1 mg PBDE 209/kg b.wt. on PND 3 showed significantly impaired spontaneous motor behaviour as adults. Animals exposed to PBDE 209 showed opposite reaction to the cholinergic agent nicotine, compared to the controls. These effects were dose-response related.

Study 3: Male rats, exposed to 6.7 or 20.1 mg PBDE 209/kg b.wt. on PND 3 showed significantly impaired spontaneous motor behaviour as adults. This effect was dose-response related. Animals exposed to 20.1 mg/kg b.wt. showed opposite reaction to the cholinergic agent nicotine compared to the controls.

Study 4: Male mice, exposed to 20.1 mg PBDE 209/kg b.wt. on PND 3 showed significant changes in the three structurally and functionally important proteins BDNF, CaMKII and GAP-43 in the brain 7 days after exposure to PBDE 209.

In conclusion, neonatal exposure to PBDE 209, during a restricted period of brain development, induces behavioural derangements in adult mice and rats, effects that are dose-response dependent and get worse with age. In addition, PBDE 209 affects the cholinergic system in both mice and rats. PBDE 209 also affects levels of BDNF, CaMKII and GAP-43 in the neonatal brain. These studies indicate that PBDE 209 has to be metabolized to exert its neurotoxic effects.

1794 POTENTIATION OF METHAMPHETAMINE NEUROTOXICITY IN ADULT RATS FOLLOWING POSTNATAL EXPOSURE TO DELTAMETHRIN.

J. R. Richardson^{1,2} and J. Mathew^{1,2}. ¹*Environmental and Occupational Medicine, UMDNJ/RWJMS, Piscataway, NJ* and ²*EOHSI, UMDNJ/RWJMS/Rutgers, Piscataway, NJ*.

Methamphetamine (METH) abuse has become a serious public health issue in the United States. In addition to its addictive properties, METH has been demonstrated to be acutely toxic to both dopaminergic and serotonergic neurons. There is evidence in the human population and in animal studies that there are a number of modifying factors that influence the severity of METH's neurotoxicity. Among these factors is age (younger animals less susceptible than older), gender (males more susceptible than females), and potentially genetic differences that influence the outcome of METH exposure. However, little attention has focused on potential environmental factors that may influence the neurotoxicity of METH. Here, we demonstrate that exposure to the pyrethroid pesticide deltamethrin (DM) during postnatal development potentiates the neurotoxicity of METH administered in adulthood. Rats were administered corn oil (control) or DM (0.1 mg/kg) every day from postnatal day (PND) 1-21. Following weaning on PND22, rats were aged to adulthood (12 weeks of age) and then administered either saline or 4x5 mg/kg METH every two hours. Two days following the last injection, the striatum was dissected from these animals and assayed for dopamine (DA) and serotonin (5HT) by HPLC. METH exposure reduced striatal DA by 42% and 45% in control males and females, respectively. Reduction of DA by METH was greater in DM males (62%), with no potentiation observed in DM females (45%). METH reduced 5HT levels by 34% and 41% in control males and females. No potentiation of 5HT reduction was observed in DM males (34%) or females (44%). These data suggest that environmental exposures during development may render the dopamine system more susceptible to neurotoxic damage by METH in adulthood. Additionally, these data suggest that males are more sensitive to the potentiation of METH neurotoxicity following developmental exposure to deltamethrin. Supported in part by NIH R21ES013828 (JRR)

1795 GESTATIONAL POLYCYCLIC/HALOGENATED AROMATIC HYDROCARBON EXPOSURE EFFECTS ON HIPPOCAMPAL AND SOMATOSENSORY PLASTICITY MECHANISMS.

D. B. Hood¹, L. Woods², L. Brown¹, S. Johnson¹ and F. F. Ebner². ¹*Division of Neurobiology and Neurotoxicology, Meharry Medical College, Nashville, TN* and ²*Department of Psychology, Vanderbilt University, Nashville, TN*.

To characterize the impact of gestational exposure to Benzo(a)Pyrene [B(a)P] and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on hippocampal and cortical plasticity mechanisms; pregnant Long Evans rats were exposed to either sub-acute doses of B(a)P (100ug/m³) on gestation day 14-17 (GD) and/or to a single oral dose of TCDD (700ng/kg BW) on GD15. When F1 generation animals reached maturity, long-term potentiation (LTP) was measured from the hippocampus and neuronal activity was recorded from neurons in the whisker representation of SI (barrel) cortex. LTP was significantly reduced as was spontaneous/evoked activity of cortical neurons in environmental contaminant-exposed F1 generation animals when compared to controls. To mechanistically ascertain the basis of environmental contaminant induced plasticity perturbations, total RNA from F1 animals was analyzed to determine mRNA profiles for molecules that are important for synaptic plasticity. Ionotropic glutamate receptor subunits were profiled for developmental mRNA and protein expression levels in offspring control and exposed rats using semi-quantitative PCR, western analysis and fluorescence microscopy. The results of the molecular studies revealed a significant down-regulation in the temporal developmental expression of glutamate receptor (NMDA and AMPA) subunits in the hippocampus and SI cortex. The results also demonstrate that exposed offspring animals present with deficiencies in behaviors that depend on normal hippocampal and cortical function and predict that deficits in behaviors will be present throughout life. The results from these studies suggest that gestational exposure results in plasticity deficits mediated through down-regulation of developmental glutamate receptor subunit expression and function at a time when excitatory synapses are being formed for the first time in the developing central nervous system. [Supported by NS041071 and 1S11ES014156].

1796 CORRELATION BETWEEN THE EVALUATION OF CORTICAL PLATE FORMATION AND HYPERACTIVITY INDUCED BY PRENATAL BRDU EXPOSURE IN RATS.

M. Kuwagata^{1,2}, T. Ogawa², S. Shioda² and T. Nagata¹. ¹*Toxicology, Hatano Research Institute, Hadano, Japan* and ²*Anatomy I, Showa University, School of Medicine, Tokyo, Japan*.

Developmental neurotoxicity (DNT) tests have been developed to protect against developmental disorders in humans. In the current DNT guidelines, treatment covers a long period from prenatal to postnatal, so that the critical period of DNT has not been evaluated to date.

We reported that a genotoxic agent, 5-bromo-2'-deoxyuridine (BrdU) induced hyperactivity when 50 mg/kg of BrdU was administered intraperitoneally to rats on gestational day (GD) 9 to 15. In this study, the critical period for induction of hyperactivity by prenatal BrdU exposure was evaluated, and the relationship between findings obtained from fetal brain and postnatal behavioral abnormality (hyperactivity) was investigated. BrdU treatment was administered on GD9-10, GD11-13, or GD14-15, and behavior in the offspring and GD16 fetal brains were examined. In the GD 9-10 treated group, locomotion in the open field was not changed. In the GD11-13 and GD14-15 treated groups, locomotion was significantly increased but was less than that of GD 9-15 treated group (GD11-13 < GD14-15 < GD9-15). On examination of GD16 fetal brain, dysgenesis of the cortical plate was observed in the GD11-13 and GD14-15 (and GD9-15) treated groups, and grades were consistent with the induction of hyperactivity. Anti-BrdU immunoreactive cells were observed in sub- and cortical- plates in these groups, indicating that BrdU exposure timing, which induced hyperactivity coincided with cortical plate formation.

Thus, the critical period of hyperactivity induced by BrdU was estimated to begin after closure of the neural tube and continuing for a relatively long period. The findings in fetal brain (abnormal cortical plate) reflected the grade of hyperactivity in the offspring, suggesting that observations of the cortical plate in the fetal brain can be one of the useful endpoints supporting postnatal DNT test.

1797 THE EFFECTS OF LOW DOSE PTU ON ENDPOINTS OF THYROID HORMONE ACTION IN THE DEVELOPING BRAIN.

D. S. Sharlin¹, D. P. Tighe¹, M. E. Gilbert² and R. Zoeller¹. ¹*Biology Department, University of Massachusetts, Amherst, MA* and ²*Neurotoxicology Division, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC*.

Thyroid hormone (TH) is essential for normal brain development. Therefore, there is concern that any factor that reduces TH levels may permanently alter brain development. As part of an EPA Cooperative Agreement, the goal of this work was to characterize the degree to which circulating TH levels must decline to alter endpoints of TH action in the developing brain. We induced graded decreases in serum TH levels in timed pregnant rats by exposure to the goitrogen propylthiouracil (PTU; 0, 1, 2, and 3ppm). Measures of TH action included RC3 expression in the hippocampus and cingulate cortex, and the oligodendrocyte to astrocyte ratio in the corpus callosum (CC) and anterior commissure (AC). To characterize potential adaptive responses to TH insufficiency, we measured the expression of the deiodinase enzymes (D2 and D3), and the TH transporters MCT8 and OATP14 in the hippocampus. The results presented here are focused on postnatal day 15, a time when TH levels are at their peak during development. We report that PTU treatment induced a dose-dependent decrease in serum T4 levels. In addition, we observed a dose-dependent decrease in the oligodendrocyte to astrocyte ratio in the both the AC and CC. Two additional points are worth noting regarding this TH endpoint. Interestingly, we found that the dose of PTU necessary to significantly reduce T4 levels (1ppm), was less than the dose necessary to measure an altered glial ratio (2ppm) and second, the CC was more sensitive than the AC to TH insufficiency. These data will be evaluated from the perspective of finding the degree to which TH levels must decline before adverse effects result and, in addition, to identify adaptive mechanisms that may account for differences in the shape of the dose response observed between individual endpoints of TH action and different thyroid toxicants. This work is supported by an EPA STAR predoctoral fellowship (FP916424 to DSS) and an EPA STAR Grant (RD-83213701-0 to RTZ). Does not reflect US EPA policy.

1798 THYROID HORMONE INSUFFICIENCY AND BRAIN DEVELOPMENT - EXAMINING NEUROTOXICITY AT LOW LEVELS OF HORMONE DISRUPTION.

M. E. Gilbert¹, M. Taylor², D. Sharlin³, W. Anderson¹, D. Ferguson² and R. T. Zoeller³. ¹*U.S. EPA, Research Triangle Pk, NC*, ²*Georgia, Athens, GA* and ³*U Massachusetts, Amherst, MA*.

Thyroid hormone (TH) deficiencies during development produce deleterious effects on brain structure and function. The degree to which TH must be perturbed to induce neurotoxicity remains unclear. The present study was conducted as part

of a Cooperative Agreement between US EPA, U Georgia, and U Massachusetts to define dose-response relationships between low level TH reductions induced by the goitrogen propylthiouracil (PTU) and brain dysfunction. Pregnant rats were administered PTU via the drinking water (0, 1, 2, 3ppm) from gestational day (GD) 6 until weaning of pups on postnatal (PN) day 23. Maternal weight gain was similar across dose groups. Pup weights were similar from birth to PN15, with a slight decrease in the 3ppm dose group on PN21. Eye opening was delayed by 3ppm PTU. Modest reductions in dam T4 levels were observed, with no change in T3 detected at any dose. Pups displayed dose-dependent reductions in T4 between PN4-22, with modest reductions in T3 limited to the high dose group. TH returned to control values by PN127. Cognitive function was assessed in adults using 2 fear conditioning (FC) paradigms. Trace FC was induced in male offspring by presenting a neutral stimulus (light/tone) paired 30s later (trace interval) with mild foot-shock. To increase task difficulty, a 2nd FC paradigm incorporated a flashing light randomly presented throughout training (Distract FC). Conditioning to context in trace FC was enhanced at 1 and 2ppm dose levels, with no effect at the high dose. Cue learning was impaired in the 3ppm dose group. Deficits were observed in Distract FC in context and cue learning at the high dose. Context learning in female offspring in Distract FC was impaired at all dose levels. These findings reveal learning deficits at low levels of TH insufficiency, potential gender differences in susceptibility, and the power of postnatal serum T4 levels to predict alterations in some but not all toxicological and functional endpoints. (Does not reflect US EPA policy)

1799 AMPHETAMINE EXPOSURE DURING THE BRAIN GROWTH SPURT PRODUCES BEHAVIORAL MODIFICATIONS IN ADOLESCENT RATS.

A. M. Smith and W. A. Chen. *Neuroscience & Experimental Therapeutics, Texas A&M Health Science Center College of Medicine, College Station, TX.* Sponsor: *S. Meier.*

Prenatal exposure to amphetamine has been shown to interfere with behavioral development in the affected offspring. This study was to examine whether exposure to d-amphetamine sulfate (AMPH) during the most dynamic brain growth spurt altered behavior during both adolescence and adulthood. Pups were intragastrically administered a milk formula containing 5, 15 or 25 mg/kg/day of AMPH from postnatal day (PD) 4-9. Additionally, an intubation control (IC; 0 mg/kg/day AMPH) and a normal control (SC; no experimental manipulation) were employed. Animals received two intubations each day spaced two hours apart, with each intubation consisting of half the daily dose. Pups were raised by dams until weaning on PD 21. On PD 24, offspring were subjected to open-field behavioral testing with 2 trials/day from PD 24-27. On PD 60, behavioral testing of the Morris water maze began. Each animal was given 5 daily training trials for six consecutive days with one probe trial occurring at the end of the sixth day, and another probe trial taking place 24 hr later. Results from these two behavioral tests revealed a main effect of AMPH in the open-field behavioral test, with animals in the AMPH 25 group having significantly lower levels of activity. However, while animals did learn to find the escape platform in the Morris water maze test, there were no changes in behavioral performance as a result of AMPH exposure. Since neonatal AMPH exposure altered the behavior of animals in the behavioral test employed during their adolescence (open-field) and not during adulthood (Morris water maze), these findings suggest that neonatal AMPH-induced alterations in behavior may be either transient in nature or behavioral task specific. (Supported by NIH grant DA018809)

1800 DEVELOPMENTAL EXPOSURE TO AMMONIUM PERCHLORATE ALTERS RUNNING WHEEL ACTIVITY AND BALANCE BEAM PERFORMANCE IN RATS.

J. J. Widholm and C. B. Reed. *Psychology, College of Charleston, Charleston, SC.* Sponsor: *S. Schantz.*

Ammonium perchlorate (AP) is a major chemical component in solid rocket fuels and fireworks and is reliably detected in soil and water throughout the U.S. Currently, the effects of developmental AP exposure on neurobehavioral function are largely unknown. The current experiment is part of a larger project designed to assess the ability of developmental AP exposure to alter neurobehavioral function and learning ability in rats. Female Long Evans rats (n=22 and n=20 for AP-exposed and control rats, respectively) were dosed daily with 0 or 30 mg/kg of AP (99.8% purity, Sigma-Aldrich, Milwaukee, WI) beginning 17 days prior to mating and continuing throughout the weaning of the offspring. One male and one female were randomly selected from each successful litter (n=15 and n=16 for AP-exposed and control litters, respectively) and began testing on the neurobehavioral test battery on postnatal day 70. The neurobehavioral battery included an assessment of spontaneous wheel running, balance beam performance, and open field locomotor activity. For spontaneous wheel running, a sex-specific effect was evident in which the AP-exposed females emitted significantly more wheel revolutions than the control females while the AP-exposed males were unaffected. Performance on the bal-

ance beam was also affected by developmental AP exposure with the AP-exposed rats slipping off the balance beam more rapidly than the non-exposed controls. Open field activity testing did not reveal an effect of AP exposure. The results of the current study indicate that developmental exposure to 30 mg/kg/day of AP is capable of increasing activity and altering balance beam performance in the exposed offspring. The effect on the balance beam could be an effect of AP on balance but could also be an artifact of elevated activity while on the balance beam, thus placing the rats at greater risk of slipping off. Lastly, the running wheel data suggest that females may be more susceptible than males to the neurobehavioral effects of developmental AP exposure.

1801 DEVELOPMENTAL NEUROBEHAVIOURAL EFFECTS AFTER CO-EXPOSURE TO GAMMA-RADIATION AND METHYL MERCURY DURING A CRITICAL PHASE OF NEONATAL BRAIN DEVELOPMENT IN MICE.

C. Fischer¹, S. Bergman², A. Fredriksson¹, B. Stenelöw³ and P. Eriksson¹.
¹Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden,
²Vattenfall Power Consultant AB, Stockholm, Sweden and ³Division of Biomedical Radiation Sciences, Rudbeck Laboratory, Uppsala University, Uppsala, Sweden.

In our environment mammals (including humans) are exposed to different types of ionizing radiation as well as persistent and nonpersistent chemicals. It is known that ionizing radiation, as well as methyl mercury, can give rise to neurotoxicological and neurobehavioural effects in mammals and that developmental neurotoxic effects can be seen after exposure during gestation. There is a lack of knowledge concerning effects and consequences from low-dose exposure during critical phases of perinatal and/or neonatal brain development and the combination of ionizing radiation and environmental chemicals. A recent study has also indicated that low doses of ionising radiation to the human brain during infancy influence cognitive ability in adulthood. Neonatal NMRI male mice, 10 days of age, were exposed to a single oral dose of MeHg (0.40 mg/kg bw). Four hours after the MeHg exposure the mice were irradiated with 60Co gamma radiation (The Svedberg Laboratory, Uppsala University). Mice were irradiated in plastic dishes with a surface dose-rate of around 0.070 Gy/min. The mice were irradiated at the doses of 0.2 and 0.5 Gy, respectively, given at one occasion. The animals were subjected to spontaneous behaviour test at ages of 2- and 4-months, and water maze test at an age of 5 months. Neither the single dose of MeHg (0.4 mg/kg bw) nor the radiation dose of 0.2 Gy affected the spontaneous behavior, but the co-exposure to external gamma radiation and MeHg caused developmental neurotoxic effects. The effects were also dose-response and time-response related. The study shows that co-exposure to ionising radiation and MeHg can interact and significantly enhance developmental neurotoxic effects, manifested as disrupted spontaneous behaviour, lack of habituation, and impaired learning and memory functions.

1802 TITLE: THE EFFECT OF CHRONIC ORAL ACRYLAMIDE EXPOSURE ON INCREMENTAL REPEATED ACQUISITION (LEARNING) PERFORMANCE IN FISCHER 344 RATS.

M. G. Paule, S. A. Ferguson and J. Garey. *Division of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR.*

Acrylamide (ACR) is a known neurotoxicant routinely found in our diet. At relatively high levels of exposure, it has been shown in rats and humans to produce effects on the nervous system. The possibility that chronic dietary exposure to ACR might produce effects on learning is a question of current concern. This research evaluated the effects of daily exposure to ACR beginning prenatally from gestation day 6 and continuing throughout the rats' lifespan. Plug-positive Fischer 344 dams (8-10 dams per treatment group) were gavaged daily with 0, 0.1, 0.3, 1.0 or 5.0 mg/kg/day ACR. On postnatal days (PNDs) 1-22, pups were gavaged with the same dose their dam had received. On PND 22, pups were weaned and pair-housed with a same-sex littermate with exposure continuing via drinking water. One male and one female pup per litter was behaviorally tested in an operant chamber for incremental repeated acquisition (IRA) performance beginning at approximately six weeks of age. Rats performing this task must learn a new sequence of lever presses each test day. Rats receive food pellets for correct responses. Over 28 testing sessions (from ~PNDs 36-140), a significant treatment effect was found on percent task completed (PTC), with Tukey's posthoc test (P<0.05) indicating a significantly lower PTC for the 5.0 mg/kg/day group compared to controls. No treatment effects were found for response accuracy (P=0.07) and response rate (P=0.07). For each of these measures, a significant effect of session was observed (P < 0.0001) demonstrating that performance improved overall through the 28 sessions, regardless of treatment group. The results suggest that chronic exposure to ACR can adversely affect learning performance albeit at only the highest exposure tested. Supported by ORISE (JG) and NTP 224-93-0001.

1803 CARDIOVASCULAR EFFECTS OF INHALED ULTRAFINE (NANO) PARTICLES IN HUMAN VOLUNTEERS.

E. Cassee¹ and R. Devlin². ¹Centre for Environmental Health Research, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands and ²Human Studies Division, EPA, Research Triangle Park, NC.

Particulate matter (PM) is any material that exists as solid or liquid droplets in the atmosphere that are less than 10 microns. PM may be in the form of fly ash, soot, dust, fog, fumes etc. Sources of particulate matter include traffic and power plants. Although PM is currently regulated by the mass concentration in ambient air, particles in the nanometer size range, also known as ultrafines, hardly contribute to the total mass. Yet, these ultrafine particles are of major concern because they will penetrate deep into the lung, are likely to escape normal defense mechanism and may end up in the systemic circulation. In addition, nanoparticles are also found to be translocated to the brain through the olfactory nerve system. Technologies that allow inhalation exposure to this complex mixture of gases and particles have now been applied by the scientific community for several years. In addition controlled studies with for instance diesel soot or carbon particles have been performed. Many different biological endpoints have been investigated to determine whether or not PM can cause health effects at levels that are not unheard of in real life.

This session aims to present:

- (a) different approaches used to study ultrafine PM health effects in humans to understand the epidemiological observations.
- (b) the potential biological mechanisms by which ambient nano-sized PM may lead to pulmonary and also cardiovascular effects.
- (c) the representativeness of the health endpoints in experimental particulate matter studies in relation to the epidemiological observations (premature death, exacerbation of respiratory diseases)

This session will narrow the gap between exposure, toxicology and epidemiology.

This abstract does not necessarily reflect RIVM or EPA policy.

1804 HUMAN CLINICAL STUDIES OF ELEMENTAL CARBON ULTRAFINE PARTICLE INHALATION: EFFECTS ON VASCULAR FUNCTION.

M. W. Frampton, M. J. Utell and G. Oberdörster. *Medicine & Environmental Medicine, University of Rochester, Rochester, NY.*

Ultrafine particles (UFP) may contribute to the cardiovascular effects of exposure to particulate air pollution, in part because of their relatively efficient alveolar deposition, potential to enter the pulmonary vascular space, and ability to deliver reactive molecular species as part of their surface chemistry. We have tested the hypothesis that inhalation of elemental carbon ultrafine particles alters cardiovascular homeostasis in healthy and compromised human subjects. Inhalation of ultrafine carbon particles (25 to 50 µg/m³, count median diameter ~27 nm) for 2 hours, with intermittent exercise, caused alterations in peripheral blood leukocyte phenotype consistent with increased transit time through the pulmonary circulation, reduced diffusing capacity for carbon monoxide (DLCO), and blunted increases in flow-mediated vasodilatation in the forearm. These findings suggest that short-term inhalation of ultrafine carbon particles alters vascular function, both systemically and in the lung. Data from these human clinical studies of exposure to air pollutants help to elucidate the mechanisms responsible for pollutant health effects, and assist in establishing rational air quality standards.

1805 BIOLOGICAL RESPONSES OF HEALTHY HUMAN VOLUNTEERS FOLLOWING EXPOSURE TO CONCENTRATED AMBIENT COARSE, FINE, AND ULTRAFINE PARTICLES.

R. Devlin¹, J. Samet¹, D. Graff¹, A. Ghio¹ and W. Cascio². ¹Human Studies Division, EPA, Research Triangle Park, NC and ²Department of Medicine, East Carolina School of Medicine, Greenville, NC.

Particle size has been implicated by epidemiological and toxicological studies as an important determinant of the toxicity of ambient particulate matter (PM). In an effort to characterize the cardiovascular, hematological and pulmonary effects of different PM size fractions in humans, we have conducted controlled human exposures of normal volunteers to ultrafine, fine, and coarse fraction PM concentrated from ambient air in Chapel Hill, NC. Healthy non-smoking male and female subjects between the ages of 18 and 35 participated in these studies. Exposures were undertaken with the use of particle concentrators fitted with size-selective outlets. These devices are capable of generating concentration factors between 10- and 20-fold over ambient levels. Lung function was assessed and bronchoalveolar lavage performed to measure lung inflammation and injury. Holter monitoring was used to characterize changes in heart rate variability and repolarization. Blood was obtained to characterize inflammation, acute phase response, and changes in clotting/coagulation factors. The design of these studies permits direct comparison of

the effects of concentrated ambient PM as a function of particle size. The results of these studies show reveal modest size fraction-dependent effects of concentrated PM exposure on cardiovascular, pulmonary and hematological parameters in normal adult human subjects. These findings have relevant implications for the design of future controlled exposure studies and the role of particle size fraction in the adverse health effects of PM exposure in humans. This abstract does not necessarily reflect EPA policy.

1806 THE EFFECTS OF COMBUSTION DERIVED NANOPARTICULATE ON VASCULAR AND ENDOGENOUS FIBRINOLYTIC FUNCTION IN MAN.

N. L. Mills¹, F. R. Cassee², D. E. Newby¹ and K. Donaldson³. ¹Centre for Cardiovascular Sciences, University of Edinburgh, Edinburgh, United Kingdom, ²Centre for Environmental Health Research, National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands and ³Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom.

Increased exposure to particulate air pollution PM is a risk factor for death and hospitalization with cardiovascular disease. It has been suggested that the nanoparticulate component of PM is capable of translocating into the circulation with the potential for direct effects on the vasculature. This paper will focus on recent findings from inhalation exposures to filtered and unfiltered diesel engine exhaust, nano-sized carbon black and ambient fine+ultrafine particles in healthy non-smoking volunteers. The effects of exposure on vascular and endothelial function, endogenous fibrinolysis and ex vivo thrombosis were assessed. At levels encountered in an urban environment, inhalation of dilute diesel exhaust impairs two important and complementary aspects of vascular function in humans: the regulation of vascular tone and endogenous fibrinolysis. These important findings provide a potential mechanism that links air pollution to the pathogenesis of atherothrombosis and acute myocardial infarction.

1807 DO CLINICAL FINDINGS WITH PARTICLE EXPOSURES (INCLUDING AMBIENT PM FRACTIONS, CARBON, AND DIESEL EXHAUST) EXPLAIN EPIDEMIOLOGICAL RESULTS?

H. Gong¹ and F. R. Cassee². ¹Medicine & Preventive Medicine, Rancho Los Amigos/USC, Downey, CA and ²Centre for Environmental Health Research, National Institute for Public Health and the Environment, Bilthoven, Netherlands.

During the past decade, acute adverse health effects of particulate matter (PM) pollution have been evaluated by:

- (a) epidemiologic time series studies of daily morbidity and mortality;
- (b) short-term observational epidemiologic studies of volunteer panels;
- (c) controlled exposures of lab animal or human volunteer subjects to artificially generated pollutant particles;
- (d) partly controlled exposures of subjects to concentrated ambient particles (CAPs) with differing size ranges (coarse, fine, ultrafine) and composition; and
- (e) field exposures of human volunteers with well characterized PM sources and monitored ambient emissions.

Current air quality standards are primarily based on epidemiologic (mostly time series) studies, which find adverse biological and clinical effects in a variety of urban PM environments. This research has found considerable evidence that combustion-derived PM elicits health effects, most notably systemic inflammation and cardiovascular morbidity and mortality. Mechanistic pathways have been explored in animal toxicology and human clinical studies. The results from these disciplines have been enlightening and yet not fully corroborative, consistent, or concordant with those from epidemiological studies. Nonetheless, further research may reveal missing links and ultimately show that multiple pathways exist, perhaps determined by different ambient PM modes (ultrafine, fine, and coarse), mixtures with different PM sizes and/or copollutant gases, and by susceptibility characteristics of the exposed population. Gaps in our knowledge should foster healthy skepticism and further scientific investigation.

1808 INTRODUCTION: CURRENT ISSUES IN DEVELOPMENTAL TOXICOLOGY.

S. L. Makris. *ORD/NCEA, U.S. EPA, Washington, DC.*

The maturing field of developmental immunotoxicology (DIT) is an area of interest and concern for children's health risk assessment. A strong body of evidence has demonstrated that the developing immune system is more susceptible to some chemicals (including some drugs and environmental contaminants) than the adult immune system, and that toxicant exposure during critical periods of immune system development can result in an adverse response that is quantitatively or qualitatively different from the adult response. Treatment-related effects can be morphological and/or functional, can exhibit evidence of greater severity or persistence following developmental exposures, and may be observed near the time of exposure

or expressed later in life. Recent research in the area of developmental immunotoxicity, the focus of this symposium, covers a broad range of immunotoxicological responses including hypersensitivity, autoimmunity, and immunosuppression following developmental exposures to chemical toxicants. Studies that consider critical processes and interactions in the developing immune system, explore alternative animal models, and characterize differential DIT responses and susceptible life stages/populations, contribute information that will be useful in developing a regulatory testing paradigm (i.e., DIT study protocol and test strategy) for characterizing immunotoxic hazard and potential risk to children from chemical exposures.

1809 AUTONOMIC AND NEUROENDOCRINE CROSS-TALK WITH THE IMMUNE SYSTEM: RELEVANCE TO EARLY LIFE EXPERIENCES, CHRONIC DISEASE, AND AGING.

D. L. Beller. *Pathology & Human Anatomy, Loma Linda University School of Medicine, Loma Linda, CA*. Sponsor: S. Makris.

Bi-directional communication exists between the nervous and immune systems. Both the hypothalamo-pituitary-target organ systems and the autonomic nervous system are major sources of neural-immune signaling, while cytokines act as signaling molecules for immune-neural signaling. Sympathetic nervous system (SNS) activation of the immune system via beta-adrenergic receptor (AR) stimulation can alter functional activities of neutrophils, antigen-presenting cells, T and B lymphocytes, and natural killer (NK) cells. In vitro and in vivo studies examining the role of SNS and AR signaling in immune regulation after immune challenge and under disease conditions suggest that the SNS can: (1) limit the magnitude of acute and chronic inflammatory responses; (2) promote Th2-driven antibody (Ab) response; (3) enhance cell-mediated responses; and (4) differentially affect Ab responses. In contrast, exposure to stressors or agents that activate the SNS (increasing circulating catecholamines) reduces T cell responses, anti-viral immune reactivity, and NK cell activity, reflecting the importance of the SNS in maintaining immune homeostasis. Similarly, hypothalamo-pituitary-adrenal cortical (HPA) activation modulates the immune system to eliminate pathogens and restore homeostasis. Studies have shown that HPA and SNS dysregulation affects severity and expression of viral and bacterial infections, wound healing, autoimmune reactivity, tumor growth, proliferation and spread, and immune senescence. During development, environmental stimuli can influence the maturation of stress pathways that modulate immune function with long term functional consequences. Because the SNS and neuroendocrine systems play an important role in numerous adult diseases, early life stressors affecting SNS and neuroendocrine development may contribute to the etiology of common disorders, such as obesity, hypertension, insulin resistance, and host resistance to infectious diseases, cancer and autoimmunity.

1810 AIR POLLUTANT EXPOSURE DURING PREGNANCY INCREASES NEONATAL SUSCEPTIBILITY TO ASTHMA.

L. Kobzik. *Environmental Health, Harvard School of Public Health, Boston, MA*. Sponsor: S. Makris.

In utero exposure to environmental agents can cause significant abnormalities in the developing immune system, but the mechanisms remain poorly understood. Asthma exemplifies the need for new models to study how environmental exposures in utero may alter immune responses. Epidemiologic and experimental data indicate that air pollution components, e.g., diesel exhaust particles (DEP), can promote allergic responses. We have adapted a previously developed mouse model of the maternal transmission of asthma risk to study exposure to air pollutants during pregnancy. The key finding is that baby mice show increased susceptibility to asthma after exposure of normal pregnant mice to diesel exhaust particles or aerosols of residual oil fly ash (ROFA) leachates. The increased susceptibility is manifest as allergic airway inflammation and airway hyper-responsiveness in response to aerosolized allergen (OVA, ovalbumin), after a suboptimal sensitization protocol that has minimal effects in normal baby mice. The potential of this model for evaluation of environmental exposures and for analysis of immune mechanisms will be discussed.

1811 DEVELOPMENTAL EXPOSURE TO TCDD INCREASES AUTOREACTIVE T CELLS IN SPLEEN OF C57BL/6 MICE AND IN LYMPH NODES OF SNF1 MICE AT 24 WEEKS OF AGE, AND CAUSES OTHER CHANGES CONSISTENT WITH INCREASED RISK OF AUTOIMMUNE DISEASE.

S. Holladay, R. Gogal, A. Mustafa and R. Kerr. *Biomedical Sciences and Pathobiology, Virginia Tech, Blacksburg, VA*.

Developmental exposure of autoimmune-predisposed SNF1 mice to TCDD induces and exacerbates postnatal autoimmune lupus-like nephritis. Mechanisms that may singly or collectively underlie this environmental chemical effect on immune development were examined in these TCDD-insensitive SNF1 mice as well as

TCDD-sensitive C57BL/6 mice, exposed to vehicle or TCDD by maternal oral gavage on day 12 of gestation. In C57BL/6 mice, developmental TCDD exposure resulted in increased spleen cellularity in females but not males at 24 weeks of age. Numbers and percentages of CD4-CD8+ T cells, and of T cells expressing autoreactive CD4+ Vβ17a+ and CD3+ Vβ3+ TcR were significantly increased in both genders. Peripheral lymph nodes were hypocellular with histopathologic evidence of increased apoptosis. In the SNF1 mice, spleen weight was increased in males but not females at 24 weeks of age, such that the male spleen became equivalent in weight to the females. In these mice, the female spleen is normally significantly larger than the male, and females display more severe autoimmune disease and earlier lesions than males. Autoreactive CD4+ Vβ17a+ and CD3+ Vβ3+ TcR were not increased in SNF1 spleens at 24 weeks of age. However percentage expression of CD4+ Vβ17a+ T cells was increased by 70% and 110% in peripheral lymph nodes of TCDD-exposed males and females, respectively, compared to vehicle-exposed mice. Males, but not females, also showed increased lymph node expression of CD3+ Vβ3+ T cells, to 2.6 times percentages in vehicle-exposed mice. In both strains of mice, impaired deletion of autoreactive T cells was therefore suggested, as evidenced by increased peripheral numbers of these cells, and may relate to exacerbated postnatal autoimmune disease in the predisposed SNF1 mice. Supported by NIH R21-PAR-03-121.

1812 DEVELOPMENTAL IMMUNOTOXICOLOGY (DIT) AND LATER LIFE IMMUNE DYSFUNCTION.

R. R. Dietert. *Microbiology and Immunology, Cornell University, Ithaca, NY*.

The perinatal period of development is a time of key immune maturational events in the offspring. Additionally, it is a period of dramatic shifts in functional capabilities and balance within the immune system. In fact, exquisitely timed changes in fetal immune balance near birth are important for successful pregnancy maintenance and may influence parturition itself. In the fetus, certain immune capacities such as Th1-driven allogeneic responses need to be suppressed to avoid fetal-maternal rejection and miscarriage. However, for the neonate a significantly different immune balance, including enhanced dendritic cell maturation with Th-1 promotion, is needed to effectively meet postnatal disease challenges. Not surprisingly, many early-life immune maturational events are either exclusive to this period of development or have significantly different ramifications when they occur later in life. Given these life-stage associated differences in immune maturation, it is not surprising that a fully-matured immune system is an ineffective surrogate to model potential DIT risk. Results to date from DIT studies indicate that the developing immune system is far more sensitive to xenobiotic-induced immunotoxicity than that of the adult. This presentation will consider: 1) the immune developmental windows sensitive to immunotoxicants based on current data; 2) the types of errors encountered when adult-exposure modeling of DIT is employed; 3) the predisposition of the perinatal system for specific types of xenobiotic-induced immune dysfunction as related to risk of later life disease and 4) the benefits of DIT screening in safety assessment.

1813 DEVELOPMENTAL IMMUNOTOXICOLOGY AND RISK ASSESSMENT.

Y. G. Yang. *Office of Pesticides Program, U.S. EPA, Washington, DC*. Sponsor: S. Makris.

Recent research has demonstrated that the developing immune system is more susceptible to exposure of environmental chemicals and drugs than the fully mature immune system. There is a concern that immunotoxicity studies conducted exclusively in young adult animals would not detect this greater susceptibility. Several scientific workshops and roundtable discussions have been held to discuss a variety of aspects for developmental immunotoxicology assessment, including appropriate testing endpoints, methodologies and the evolving state of the science. This presentation will include an analysis of the current state of immunotoxicology testing for pesticides and other environmental chemicals, and a discussion of current policy and practice regarding the potential use of developmental immunotoxicity test data in risk assessment. (*Disclaimer: This presentation does not necessarily reflect the view or policies of the U.S. Environmental Protection Agency.)

1814 DEVELOPMENTS IN EXPOSURE-BASED QUANTITATIVE RISK ASSESSMENT (QRA) FOR INDUCTION OF DERMAL SENSITIZATION FOR FRAGRANCE INGREDIENTS.

A. Api¹ and P. M. McNamee². ¹Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ and ²Procter & Gamble Company, Egham Surrey, United Kingdom.

Some of the chemicals in common use today may have the potential to cause dermal sensitization. However, the fact that a chemical is a skin sensitizer does not mean it cannot be formulated into consumer products at safe levels. This is also the

case for fragrance ingredients. Based on the chemical, cellular and molecular understanding of dermal sensitization, it is possible to conduct an exposure-based quantitative risk assessment (QRA) to determine safe levels of fragrance ingredients in different consumer product types. Key steps of the quantitative risk assessment process are determination of known safe benchmarks; application of sensitization assessment factors and calculation of consumer exposure through normal product use. Using these parameters, an acceptable exposure level (AEL) can be calculated and compared with the consumer exposure level (CEL). The ratio of the AEL to CEL must be favorable to support the safe use of the skin sensitizer. This ratio must be calculated for the skin sensitizer in each product type. This symposium provides an overall picture of how a recently developed exposure-based QRA approach is being newly applied to fragrance ingredients. Within the overall theme, each presentation addresses a specific element of this risk assessment methodology with the last presentation providing examples of implementing this QRA approach for induction of dermal sensitization to fragrance ingredients.

1815 AN INTRODUCTION TO QRA FOR INDUCTION OF DERMAL SENSITIZATION FOR FRAGRANCE INGREDIENTS.

P. A. Cadby. *Firmenich SA, 1211 Geneva 8, Switzerland.* Sponsor: A. Api.

Since the 1960s, the fragrance industry has attempted to manage the risks of Type IV allergy to fragrance materials. Due to the paucity of reliable data on allergic reactions following the use of different types of perfumed articles, risk assessment has been typically based on predictive testing, most often on human subjects, to determine the potency of different substances in inducing allergic states. Earlier risk assessments by industry were based on the belief that passive absorption through the skin makes the concentration of a particular allergen on the skin the determinant metric of exposure. More recent evidence shows that this is not the case. Within certain limits, the quantity per surface area is a better measure of exposure. Furthermore, other factors previously ignored in risk assessment of fragrance materials must also be considered. These include the condition of the skin and body-region, the presence of other irritants, of other factors that increase penetration and residence time on the skin. For this reason, a new approach has been used for the risk assessment of fragrance allergens in different types of consumer products. A quantitative risk assessment (QRA) approach has been developed based on exposure and these other factors.

1816 TOOLS FOR THE IDENTIFICATION OF A MATERIAL AS A DERMAL SENSITIZER.

G. Gerberick. *Procter & Gamble, Cincinnati, OH.*

Different methods are available to identify a material as a dermal sensitizer. The different methods including their strengths and limitations will be described in this presentation. Since it is extremely important to understand allergenic potency in risk assessment, the recently approved LLNA will also be reviewed in terms of its ability to predict allergen potency in humans. Possible impact of future method developments e.g. in vitro assays will also be reviewed.

1817 THE IMPORTANCE OF USING DOSE/UNIT AREA AS THE DOSE METRIC IN QRA FOR INDUCTION OF SKIN SENSITIZATION.

I. Kimber. *Central Toxicology Laboratory, Syngenta, Cheshire, United Kingdom.*

Skin sensitization is acquired following topical exposure of inherently susceptible subjects to an amount of chemical allergen necessary to induce a cutaneous immune response of sufficient vigor, and of the appropriate quality. Of pivotal importance in the induction of skin sensitization are the roles played by cutaneous dendritic cells, and in particular epidermal Langerhans cells (LC). These cells are responsible for the recognition, internalization, processing, and subsequent presentation to T lymphocytes of allergen encountered at skin surfaces. There is now compelling evidence, deriving from both clinical and experimental studies, that the important exposure metric in the acquisition of skin sensitization is the dose of chemical per unit area of skin, rather than the total delivered dose. Thus, for instance, when a fixed amount of chemical allergen (2,4-dinitrochlorobenzene) was administered topically to human volunteers, then the effectiveness of sensitization was found to decrease as the area of skin over which the chemical was applied increased. The relationship between dose per unit area and the effectiveness of sensitization applies under most circumstances of exposure, although when chemical is administered over a very small area then total dose assumes greater importance. It is assumed that the relationship between the acquisition of sensitization and the dose of chemical per unit area of skin surface is a reflection of the requirements for inter-

action of allergen with epidermal LC. Specifically, it is proposed that the amount of allergen displayed per presenting cell directly influences the effectiveness with which T lymphocytes will be activated, and the vigor of the cutaneous immune response.

1818 THE PRINCIPLES OF QRA FOR INDUCTION OF DERMAL SENSITIZATION FOR FRAGRANCE INGREDIENTS.

P. M. McNamee. *Procter & Gamble Company, Egham Surrey, United Kingdom.* Sponsor: A. Api.

This presentation describes the principles of an exposure-based QRA for induction of dermal sensitization as applied to fragrance ingredients. It specifically addresses the elements of this exposure-based risk assessment approach that are unique to the induction of dermal sensitization, while being consistent with the principles of general toxicology risk assessment. The key steps of the QRA process: 1) determination of benchmarks (No Expected Sensitization Induction Level or NESIL); 2) application of sensitization assessment factors (SAF); 3) calculation of consumer exposure (CE) through product; 4) calculation of an acceptable exposure level (AEL) 5) comparison with the consumer exposure level (CEL) and 6) comparison of the AEL to CEL and the impact of the AEL to CEL ratio are described for fragrance ingredients.

1819 APPLICATION OF QRA FOR INDUCTION OF DERMAL SENSITIZATION OF FRAGRANCE INGREDIENTS.

A. Api. *Research Institute for Fragrance Materials, Inc., Woodcliff Lake, NJ.*

Using the principles of quantitative risk assessment for dermal sensitization, it is possible to determine acceptable exposure levels for fragrance materials in a variety of consumer products. No Expected Sensitization Induction Levels or NESILs for a group of fragrance allergens, categorized in potency classes, were based on a weight of evidence approach, which considers all data including guinea pig, mice (LLNA) and human predictive tests. In addition, sensitization assessment factors specific for fragrance materials in the Research Institute for Fragrance Materials, Inc., (RIFM) scientific program, were determined in different product types and supported by scientific data. Examples will be presented using fragrance ingredients in various consumer product types.

1820 THE SAFETY ASSESSMENT OF IMPROVED FOOD AND FEED CROPS DEVELOPED WITH GENE SUPPRESSION TECHNOLOGY.

B. G. Hammond. *Product Safety Center, Monsanto Company, St. Louis, MO.*

RNA interference (RNAi) has allowed agricultural researchers to develop new crop varieties such as Flavr Savr tomatoes, high amylose potatoes and even blue roses. RNAi is a promising tool for development of other new and improved plant varieties using agricultural biotechnology. Suppression of endogenous plant gene expression by RNAi is achieved through the introduction of a construct that produces double stranded RNA (dsRNA) in the plant. Plant RNAi machinery converts this larger dsRNA to 19-24 base pair small interfering RNAs (siRNAs). These siRNA molecules subsequently target complementary mRNA molecules for nuclease degradation, resulting in gene suppression. To date, there has been limited discussion in public scientific forums regarding appropriate safety assessment considerations for products derived using this technology. The speakers in this symposium will address topics to foster greater understanding of the use of this technology and of the safety considerations for products derived using this technology. The opening presentation will focus on the mechanisms of RNAi and on manufacture and chemical modification of synthetic siRNA molecules for in vivo use, from a leading commercial siRNA supplier. In the second presentation, the use of siRNA to treat human disease and the relevant safety considerations for siRNA use in therapeutics will be addressed by a representative of a leading company specializing in siRNA-based therapeutics. The third presentation will include a discussion of the function of RNAi in plants, applications of gene suppression technology in agricultural biotechnology, and possible applications for RNAi in future development of improved plant varieties. The closing talk will present a safety assessment strategy for using RNAi in agricultural products, building upon the current understanding of gene suppression in animals and plants, coupled to what has been learned both in human pharmaceutical applications and in the safety assessment of agricultural products derived using modern biotechnology.

1821 THE BIOCHEMISTRY OF RNA INTERFERENCE (RNAi): IMPACT ON DESIGN, SYNTHESIS, AND MODIFICATION OF RNA DUPLEXES FOR *IN VITRO* AND *IN VIVO* USE.

M. Behlke. *Molecular Genetics and Biophysics, Integrated DNA Technologies, Inc., Coralville, IA.* Sponsor: B. Hammond.

RNA interference (RNAi) is an evolutionarily conserved pathway present in organisms ranging from plants to humans, in which double-stranded RNA (dsRNA) triggers a series of biochemical events culminating in sequence-specific suppression of gene expression. Within "RNAi", related but distinct biochemical pathways exist which target different steps of gene expression. MicroRNAs (miRNAs) comprise an endogenous gene-regulatory network which suppresses protein translation in the cytoplasm. Small interfering RNAs (siRNAs) direct mRNA degradation in the cytoplasm and may also be capable of suppressing transcription in the nucleus, either directly or via chromatin remodeling. Knowledge of RNAi biochemistry can be used to guide intelligent design of experiments, protocols and reagents. For the degradative RNAi pathway, long dsRNAs are cleaved by the RNase-III class endoribonuclease Dicer into 21-23 base duplexes having 2-base 3'-overhangs. These species, called siRNAs, enter the RNA Induced Silencing Complex (RISC) and serve as a sequence-specific guide to target degradation of complementary mRNA species. Synthetic siRNAs can be used as an experimental tool to selectively reduce expression of targeted genes. In addition to utility in research applications, several siRNA drugs are already undergoing clinical trials as therapeutic agents. As drugs, nucleic acids (both antisense oligos and siRNAs) can be administered by a variety of routes including IV, IP, SQ, intrathecal, direct local injection, or as a topical cream; oral bioavailability is generally poor. Chemical modification of the siRNA can confer nuclease stability and improve pharmacodynamic properties. Building upon historical work done in the area of antisense therapeutics, the medicinal chemistry of therapeutic siRNAs is already advanced and a number of effective chemical modification strategies have been described.

1822 SAFETY CONSIDERATIONS FOR THE USE OF SIRNA IN THE PHARMACEUTICAL INDUSTRY: DEVELOPMENT OF AN SIRNA FOR THE TREATMENT OF VIRAL HEPATITIS.

J. Lockridge, D. V. Morrissey, C. Vargeese and B. Polisky. *Sirna Therapeutics, Inc., Boulder, CO.*

Development of siRNAs as therapeutic agents will require improvements in not only the stability of siRNAs but also in the efficiency and specificity of tissue-targeted delivery in vivo. Considerable progress has been made in developing chemical modifications for synthetic siRNAs that provide resistance to nuclease degradation and are also compatible with proper recognition and function of the siRNA by cellular RNAi protein machinery. However, efficient delivery modalities will likely be needed in addition to stabilization chemistry in order to fully realize the therapeutic potential of siRNAs. A method for lipid nanoparticle (LNP)-mediated delivery of stabilized siRNA has been developed and initially characterized in animal models for HBV. Significant reduction of viral titer has been observed with this formulation at therapeutically relevant doses that correlate with improvements in pharmacokinetics. Both in vitro and in vivo models have been used to assess the toxicity profile and target organ toxicity of this LNP-formulated siRNA. The findings from this preclinical siRNA antiviral program will be used to discuss potential safety considerations for administering siRNA systemically to humans.

1823 THE USE OF GENE SUPPRESSION TECHNOLOGY TO DEVELOP IMPROVED CROPS.

W. Parrott. *Crop and Soil Sciences, University of Georgia, Athens, GA.* Sponsor: B. Hammond.

Gene suppression technology has been used successfully in agriculture since before WWII, long before its practitioners knew the biological basis of this phenomenon. The discovery that fruit trees could be protected from severe viral infection by intentional inoculation with a milder strain of the virus led to development of plants genetically engineered to express viral genes that confer resistance to the target virus. Recent investigations into the basis behind transgene-mediated virus resistance led to the discovery that plants possess a gene-silencing mechanism triggered by presence of double-stranded RNA. This phenomenon is now known as RNA interference (RNAi). The discovery of RNAi provided a unifying concept in plant genetics, and explained everything from developmental pathways, such as organ differentiation, to pigmentation patterns in flowers and seeds. Not only does RNAi

explain natural phenomena, it also explains the apparently random gene silencing patterns that were identified in various engineered plants, and clarifies why both over-expression and antisense expression of genes leads to silencing. In hindsight, biotech products such as the FlavrSavr tomato, and virus-resistant squash and papaya are examples crops that utilize RNAi technology. The advent of RNAi technology is timely and provides an effective means to overcome the lack of homologous recombination in plants, which has hindered previous efforts at gene suppression in plants. Now that the RNA-based gene silencing mechanism is well understood, it is possible to design vectors that readily generate double-stranded RNA that silence the target gene when engineered into plants. This approach is proving effective at achieving pest resistance, including resistance to viruses and nematodes. The use of RNAi also can alter composition of plant products, such as oil and protein, to enhance their nutritional quality or tailor them for specialty purposes. For example, silencing of genes involved in production of linolenic acid results in increased content of oleic acid. Thus, RNAi will be a key technology for future development of improved agricultural products.

1824 SAFETY ASSESSMENT STRATEGY FOR FOOD AND FEED FROM BIOTECHNOLOGY-DERIVED CROPS DEVELOPED USING GENE SUPPRESSION TECHNOLOGY.

J. Petrick. *Product Safety Center, Monsanto Company, St. Louis, MO.*

RNA interference (RNAi) is an endogenous process mediating transcriptional and translational silencing in plants and animals. Plant breeders are using RNAi to develop new plant varieties that have improved nutritional properties or enhanced pest or viral resistance. A safety assessment approach is proposed that ensures new crop varieties developed using RNAi are safe to consume. This strategy includes: (1) Establishing a history of safe consumption: Plants possess endogenous dsRNA-mediated gene-silencing mechanisms, and thus, small interfering RNAs (siRNAs) and other dsRNAs are widely consumed in the diet. These endogenous small dsRNAs will be identified in plants to demonstrate their presence in the food/feed. (2) Assessing the potential digestibility of siRNAs and dsRNAs in simulated digestive fluids containing nucleases will be confirmed experimentally. Based on available literature, siRNAs and dsRNAs are likely to be readily digested by endogenous nucleases. (3) Confirmatory animal studies will test whether oral administration of naked siRNAs or food containing dsRNAs or siRNAs exerts any adverse effects. Existing animal studies show that effective intravenous or intraperitoneal administration of naked siRNAs requires large doses and may require carrier agents or stabilizing modifications. This observation indicates that naked siRNAs in food or feed are unlikely to be orally active. The dietary exposure of laboratory animals to dsRNA or siRNA will be considerably in excess of potential human exposure levels, thus providing a large margin of safety. (4) The absence of unintended changes in food/feed will be tested using comprehensive agronomic assessment and compositional analyses for key nutrients and antinutrients, if present. In light of the specificity of RNAi, the proposed lack of oral activity of siRNA and dsRNA, and the history of safe RNA consumption, this adaptation of the current safety assessment paradigm for biotechnology-derived food and feed crops is considered suitable for evaluation of those crops produced using gene suppression technology.

1825 TARGET-BASED TOXICITY OF NOVEL PHARMACEUTICAL AGENTS.

G. H. Cantor¹ and P. J. Ciaccio². ¹Discovery Toxicology, Bristol-Myers Squibb Co., Princeton, NJ and ²Safety Assessment U.S., AstraZeneca Pharmaceuticals LP, Wilmington, DE.

The toxicity of a pharmaceutical compound can be due to its interactions with an unanticipated molecule in the body (off-target) or the direct consequence of inhibiting or stimulating the molecular target (target-based). Target-based toxicities are especially likely when the target has many roles in multiple tissues. In some situations, target-based toxicity can be accepted as an unpleasant but inevitable side effect of a life-saving drug, but in other situations, target-based toxicity is unacceptable. In those cases, early recognition of target-based toxicity enables a company to avoid further investment in a program that cannot achieve success. This early recognition enables pharmaceutical companies to focus on more viable therapeutic targets and increase the likelihood of success to market. In other cases, target-based toxicity can be specific only to particular preclinical species and is not relevant to human toxicity. A variety of approaches have been used to identify target-based toxicity and to put issues into an appropriate risk-assessment perspective. This session will explore these approaches and give a flavor of how scientists are integrating such approaches at earlier phases of drug discovery and development.

1826 USE OF TRANSGENICS, KNOCKOUTS, AND CONDITIONAL KNOCKOUTS IN TARGET DISCOVERY AND VALIDATION.

E. J. Galbreath. *Discovery Biology Research and Clinical Investigation, Lilly Research Laboratories, Indianapolis, IN.* Sponsor: G. Cantor.

Each completed genome provides vast sequence and variation data that pharmaceutical discovery research is actively translating into functional biologic assessments. The ultimate goal is to understand the therapeutic potential of gene function and validate targets in the context of the whole animal. Strategies to elucidate function include genetic overexpression of proteins of interest, elimination or knock-down of target expression and tissue-specific or time-course regulatory control of gene expression. This overview will review the more common approaches and provide examples of how in vivo research of gene function and target validation has led to new understanding of gene function in the whole animal, including the potential for exuberant pharmacology and identification of potential detrimental effects.

1827 MECHANISM-BASED HEPATOTOXICITY OF TUMOR NECROSIS FACTOR α (TNF α) CONVERTING ENZYME INHIBITORS.

L. Lehman-McKeeman. *Discovery Toxicology, Bristol-Myers Squibb, Princeton, NJ.*

TNF α is an important mediator of inflammatory diseases, and numerous agents have been developed to neutralize its activity or suppress its production. Chemical inhibitors of TNF α converting enzyme (TACE) reduce the processing and release of mature TNF α and are effective in animal models of inflammatory diseases. However, TACE inhibitors were also hepatotoxic in several species, producing early liver lesions manifested as intra-sinusoidal aggregates of mononuclear cells that progressed to large mononuclear cell aggregates, Kupffer cell hypertrophy and hyperplasia and hepatocellular necrosis. To evaluate the mechanisms underlying the development of lesions, studies were carried out to determine whether hepatotoxicity was caused by unique properties of the compounds, by unexpected off-target effects or by untoward effects associated with TACE inhibition. Results indicated that adverse effects in liver were directly associated with TACE inhibition. Evidence for mechanism-based toxicity included: (1) elimination of gut-derived endotoxin did not reduce the severity of hepatotoxicity suggesting that toxic effects were observed in the absence of an endogenous signal for hepatic TNF α secretion, and (2) inactive enantiomers of TACE inhibitors were not hepatotoxic. The uncleaved, transmembrane proTNF α is biologically active, and may accumulate when TACE is inhibited. Furthermore hepatotoxicity was reported in transgenic mice engineered to overexpress the TNF-R2 receptor, which is also a substrate for TACE. Studies conducted to determine whether hepatic levels of pro-TNF α and/or TNF receptors increased during TACE inhibition indicated that proTNF α increased to 4-times control, whereas TNF-R2 increased approximately 2-fold over control levels. Collectively, these studies demonstrate that the hepatotoxicity of TACE inhibition is a mechanism-based effect resulting from decreased shedding of the TACE substrates proTNF α and TNF-R2. These studies also provide a general experimental strategy for determining whether toxicity is directly related to the mechanism of drug action.

1828 ANGIOGENIC INHIBITORS: TARGET-RELATED EFFECTS AND RISK ASSESSMENT USING A MULTISYSTEM PHYSIOLOGIC APPROACH.

R. A. Westhouse. *Discovery Toxicology, Bristol-Myers Squibb Co., Princeton, NJ.* Sponsor: G. Cantor.

Because angiogenesis plays a significant role in the pathogenesis of numerous diseases, such as cancer, wet macular degeneration and inflammation, the inhibition of this process is commonly considered a lucrative therapeutic target. Angiogenesis is a critical factor for a number of normal physiologic processes, such as wound healing, endochondral ossification related to bone growth, estrous cycling, and fetal development. The inhibition of angiogenesis will directly impact these processes. A number of angiogenic inhibitors, either already marketed or in development, target the vascular endothelial growth factor (VEGF) pathway by various mechanisms (antibodies to the receptor or ligand, small molecule receptor tyrosine kinase inhibitors, ligand traps, etc). Angiogenic inhibitors acting through the VEGF pathway, regardless of the specific interventional mechanism, have been confirmed to affect these processes and also cause VEGF target specific effects, such as hypertension, in nonclinical and clinical studies. A multisystem physiology-based mechanistic approach was used to associate various findings in preclinical models for the purpose of a broad-based robust risk assessment and management. This type of risk assessment for VEGF inhibitors has revealed the utility of using one of these target-related effects, specifically, hemodynamic changes, as an indicator of pharmacodynamic effect and as a surrogate biomarker for efficacy in clinical studies. The use of

these biomarkers in clinical development allowed critical decisions to be made early, instead of having to rely on time to tumor progression data, which would come much later in time.

1829 ANDROGEN DEPENDENT MAMMARY GLAND VIRILISM IN RATS GIVEN THE SELECTIVE ESTROGEN RECEPTOR MODULATOR LY2066948 HYDROCHLORIDE.

D. G. Rudmann¹, I. R. Cohen³, M. R. Robbins³, D. E. Coutant² and J. W. Henck⁴. ¹Pathology, Eli Lilly and Co., Greenfield, IN, ²Drug Disposition, Eli Lilly and Co., Greenfield, IN, ³Investigative Toxicology, Eli Lilly and Co., Greenfield, IN and ⁴Nonclinical Safety Assessment, Eli Lilly and Co., Greenfield, IN.

In the rat, male and female mammary glands exhibit striking morphologic differences that can be altered secondary to disruption of the normal hormonal milieu. Mammary glands from female rats given the Selective Estrogen Receptor Modulator (SERM) LY2066948 hydrochloride (LY2066948) for one month had morphologic alterations characterized by intralobular ducts and alveoli lined by multiple layers of vacuolated, hypertrophied epithelial cells. This altered mammary gland ductal and alveolar morphology in SERM-treated female rats resembled the morphology of these structures in the normal male rat mammary gland. We will describe investigative studies that demonstrated the mechanism and species-specific nature of these changes and will discuss how these data impacted the nonclinical risk assessment of the mammary gland finding in rats.

1830 INTRODUCTION TO TOXICOGENOMICS IS A TEAM SPORT.

G. A. Boorman. *Environmental Toxicology Program, National Institute of Environmental Health Sciences (NIEHS), Research Triangle Park, NC.*

There is increasing use of toxicogenomic studies by research groups in academic, government, pharmaceutical and chemical settings. Toxicogenomic data is beginning to be submitted in support of product development to government regulatory agencies. Geneticists, molecular biologists and bioinformaticists often conduct the studies but toxicologists and pathologists are often approached to become involved with study interpretation. While the amount of data generated by these studies is massive, toxicologists and pathologists are crucial in putting the genomic data in context. Toxicologists and pathologists can make their results more assessable to the bioinformaticists by transforming the diagnoses into a digital format. They also need to effectively communicate the importance and significance of the toxicological data endpoints. The most effective toxicogenomic studies utilize the expertise of toxicologists and pathologists in formulating the research question, study design, selection of appropriate animal models, animal care issues, nutrition, tissue and data collection all of which can have significant impact on the resulting data. Toxicogenomics is a team sport that to be successful requires the active participation of pathologists and toxicologists.

1831 VISUALIZATION OF HISTOPATHOLOGICAL DATA ENHANCES BIOLOGICAL INSIGHT AND INTERPRETATION.

E. K. Lobenhofer. *Investigational Genomics, Cogenics, a Division of Clinical Data, Morrisville, NC.* Sponsor: G. Boorman.

Gene expression profiling, metabolomic screens, and other high-dimensional methods have become an integral part of many biological investigations. To facilitate interpretation of these data, it is important to have detailed phenotypic data – including histopathology – to which these data can be associated, or “anchored”. However, as the amount of phenotypic data increases, associations within and across these data can be difficult to visualize and interpret. We have developed an approach for categorizing and clustering biologically related histopathological diagnoses to facilitate their visualization, thereby increasing the possibility of identifying associations and facilitating the comparison with other data streams. To demonstrate the utility of this approach, a case study will be presented in which histopathological data generated as part of a standardized toxicogenomics compendium study was used to categorize and compile histopathological diagnoses in order to develop visualizations that facilitate biological insight that were further supported by gene expression profiling data.

1832 INTERPRETATION OF TOXICOGENOMICS DATA AND CONFOUNDING VARIABLES, WITH SPECIAL REFERENCE TO FASTING AND THE HEPATIC TRANSCRIPTOME.

K. T. Morgan and Z. Jayyosi. *Drug Safety Evaluation, Sanofi-Aventis, Bridgewater, NJ.*

The liver plays a central role in many aspects of whole-body physiology, including regulation of energy metabolism, immune and endocrine functions. Toxicogenomics (TGx) studies, with their large-scale view of the hepatic transcriptome(s), provide an opportunity to explore many aspects of liver physiology and pathophysiology. A transcriptome is 'considered to be the entire population of mRNA transcripts in a cell or cell population at a given moment in time.' A whole-liver TGx study provides a measure of a mixture of such transcriptomes, each present in proportion to the population size of their cell type of origin. Cell type is but one of many confounding variables in hepatic TGx studies. Others include sexual cycles, strain and age of animals and their husbandry, circadian rhythms, inter-individual animal variation, the presence of pathophysiological events in extra-hepatic sites, and pharmacologic action of test articles. Fasting has the potential to influence a large proportion of TGx studies because (a) fasting is often selected in toxicology study protocols, (b) toxic responses to high doses of test articles can cause test subjects to go off of their food, and (c) a broad range of hepatic functions are altered during the fasting state. Thoughtful examination of TGx data, with due consideration of confounding variables, can generate a rich source of insights for the design of critical follow-up studies.

1833 DIFFERENTIAL RESPONSE OF THE LEFT AND MEDIAN LIVER LOBES TO TOXIC CHALLENGE.

R. Irwin¹, G. A. Boorman², J. S. Parker³ and E. K. Lobenhofer⁴. ¹NIEHS, Durham, NC, ²NIEHS, Durham, NC, ³Constella Group, Durham, NC and ⁴Congenic, Durham, NC.

Although the liver in most species of mammals is composed of four separate lobes, it is generally assumed that the lobes are functionally equivalent. However several liver disorders exhibit a distinct lobe preference, including Wilson's disease (right lobe), progression of cirrhosis (right lobe), and iron storage disease (left lobe), suggesting that lobes may respond differentially to the challenge posed by these diseases. We hypothesized that functional heterogeneity among lobes might be revealed in their response to a toxic challenge. To explore this possibility we examined the gene expression profiles of the left and median lobes of male F344 rats administered toxic and non toxic doses of acetaminophen. Using a variety of analytical tools we find significant time and dose related differences in the response of the left and median lobes to acetaminophen exposure.

1834 PATTERNS OF DIFFERENTIAL GENE EXPRESSION IN LIVER FOLLOWING HEPATOTOXICANT EXPOSURE.

K. E. Gerrish and R. S. Paules. *NIEHS, Research Triangle Park, NC.*

Our studies are designed to gain insight into mechanisms of liver injury or disease and to link gene expression alterations to specific parameters of well-defined indices of injury and disease. One central component of this research strategy is the concept of phenotypic anchoring in which alterations in gene expression are correlated with specific adverse effects of environmental stresses defined by conventional parameters of toxicity and pathology. To accomplish this task, we have utilized classical hepatotoxicants at multiple doses and times of treatment in order to study the biological responses to these agents. Clinical chemistry and histopathological analysis indicated a dose and time-dependent increase in hepatotoxicity. Analyses of differentially expressed genes suggest that many biological pathways play a critical role in regulating the liver's response to these agents. These include processes that disrupt normal liver function as well as those that promote cellular survival in response to stress. Results suggest that translational and transcriptional programs known to regulate bile acid homeostasis, drug metabolism and the unfolded protein response, play an important role in the liver's response to xenobiotic exposure. In summary, gene expression measurements in liver have the potential to yield a comprehensive insight into cellular pathways that are activated following exposure to hepatotoxicants.

1835 KIM-1, CLUSTERIN AND HO-1 AS POTENTIAL BIOMARKERS FOR NEPHROTOXICITY TESTING IN VITRO.

E. Rached, W. Dekant and A. Mally. *Department of Toxicology, University of Würzburg, Würzburg, Germany.*

The kidney is one of the main targets of xenobiotic induced toxicity, but early detection of renal damage is often difficult. Recently, several novel biomarkers of nephrotoxicity have been identified in vivo by transcription profiling, including

heme oxygenase-1 (HO-1), clusterin, and kidney injury molecule-1 (KIM-1). Changes in the expression of these markers were frequently observed before nephrotoxicity was evident by traditional endpoints, suggesting that they may serve as sensitive endpoints for nephrotoxicity detection in vivo. However, it is not known if these cellular marker molecules may also be useful for detection of nephrotoxic effects in vitro.

The aim of this study was to determine if changes in the expression of HO-1, clusterin and KIM-1 occur in proximal tubule cell cultures in response to sub-lethal concentrations of model nephrotoxins. Normal rat kidney epithelial cells (NRK-52E) were treated with CdCl₂, cisplatin, KBrO₃, and ochratoxin A (OTA) for 24-48h, and expression of HO-1, clusterin and KIM-1 was analyzed by qRT-PCR and immunoblotting. Treatment with CdCl₂ or KBrO₃ for 24 and 48h resulted in concentration-dependent increase in HO-1, whereas even cytotoxic concentrations of OTA and cisplatin had little or no effect. Expression of clusterin was induced following treatment with 5 µM cisplatin for 48h, but inconsistent changes were observed by immunoblotting and qRT-PCR in response to CdCl₂, KBrO₃ and OTA. Although KIM-1 was previously shown to be up-regulated in various models of nephrotoxicity in vivo, modulation of kim-1 gene expression was only observed after treatment with cytotoxic concentrations of CdCl₂, OTA, and KBrO₃ in NRK-52E cells, indicating that KIM-1 may not be a sensitive marker in vitro.

In summary, altered expression of HO-1 and clusterin, but not of KIM-1, was detected in NRK-52E cells treated with non-cytotoxic concentrations of model nephrotoxins. However, responses varied between compounds and may, therefore, depend on the mechanism of toxicity.

This work was supported by the European Union 6th RTD Framework Programme and RCC Ltd.

1836 EVALUATION OF KIDNEY TOXICITY BIOMARKERS IN HUMAN KIDNEY CELLS.

M. Sonee, A. Hannay, K. Abele and L. G. Peter. *Mechanistic Toxicology, GPCD, Johnson & Johnson PRD, Raritan, NJ. Sponsor: S. Sawant.*

Renal toxicity is one of the common side effects that can occur on administration of pharmaceutical agents. Traditional markers of nephrotoxicity, like BUN and Creatinine, are not very sensitive and are expressed when two-thirds of the kidney is damaged. The goal of this study was to evaluate the expression of four more recently discovered nephrotoxicity biomarkers, clusterin, alpha-GST, osteopontin and neutrophil gelatinase-associated lipocalin (NGAL) in human proximal tubular kidney (HK2) cells. In this study, cisplatin was selected as the model nephrotoxin while transplatin was selected as negative control. The cells were treated with various concentrations of the toxin ranging from 0-150 mM. After 24hrs, ATP levels were measured in control and treated cells as an indicator of cytotoxicity while expression of biomarkers was measured using ELISA assays using commercially available kits. Dose dependent cytotoxicity was seen in HK2 cells with cisplatin while transplatin treated cells did not exhibit toxicity at any concentration in the dosing range. In cisplatin-treated cells, an increase in NGAL, osteopontin, alpha GST and clusterin was noted at concentrations lower than when significant cytotoxicity was observed. This indicates that these biomarkers can be used as early biomarkers of kidney toxicity in HK2 cells. On the other hand, the levels of the four biomarkers remain unchanged at all concentrations in transplatin-treated cells, corroborating that non-nephrotoxic compounds do not induce these biomarkers in HK2 cells. Further studies have shown that NGAL levels were increased in cells treated with other nephrotoxins like amphotericin B, cyclosporin A and puromycin at concentrations lower than needed to achieve significant cytotoxicity. The results imply that in an in vitro kidney cell model, these biomarkers provide a sensitive and predictive assessment of cytotoxicity and can be used for screening compounds early in drug development for potential proximal tubular toxicity.

1837 EVALUATION OF NOVEL BIOMARKERS OF NEPHROTOXICITY IN RATS TREATED WITH CISPLATIN.

J. Gautier¹, L. Mylecraine², B. Riefke³, V. Guilpin⁴, N. Barlow⁴, J. Walter³, T. Gury¹, V. Baker⁵, D. Hoffman⁶, T. Steger-Hartmann³, E. Harpur⁵ and S. Pettit⁷. ¹sanofi-aventis, Paris, France, ²Berlex, Inc., Montville, NJ, ³Shering AG, Berlin, Germany, ⁴sanofi-aventis, Malvern, PA, ⁵sanofi-aventis, Alnwick, United Kingdom, ⁶sanofi-aventis, Bridgewater, NJ and ⁷HESI Biomarkers Committee, Washington, DC.

Cisplatin is an anticancer agent that induces renal proximal tubule lesions in rats. Studies were conducted in Sprague-Dawley (SD) and Han-Wistar (HW) rats to evaluate the utility of novel preclinical biomarkers of nephrotoxicity with this compound. Groups of 10 males were given a single intraperitoneal injection of 0.3, 1 and 3 mg/kg cisplatin and were sacrificed at Days 2, 3 and 5. The novel biomarkers GSTα (for tubular proximal lesions), GSTμ (for tubular distal lesions), clusterin (for general kidney lesions) and RPA-1 (for papilla/collecting ducts lesions) were

measured in urines using enzyme immunoassays. Histologically, degeneration and necrosis of the S3 segment of the renal proximal tubule were observed with 1 and 3 mg/kg cisplatin at Day 2 (HW), Day 3 (both strains) and Day 5 (both strains). Serum creatinine and BUN were significantly increased with 3 mg/kg cisplatin in SD rats (1.7 and 1.6-fold controls, respectively) and HW rats (2.5 and 3.5-fold, respectively) at Day 5 only. The novel biomarker GST α was clearly increased at Day 3 and Day 5 in SD rats (2.9 and 3.6-fold, respectively) and HW rats (3.1 and 20-fold, respectively) given 3 mg/kg. Clusterin was strongly increased at Day 5 in SD rats (4.5-fold) and HW rats (23-fold) given 3 mg/kg. An increase of clusterin was also observed at Day 3 in SD rats treated with 3 mg/kg cisplatin (2.2-fold) and at Day 5 in HW rats given 1 mg/kg (3.2-fold). These results suggest that GST α and clusterin are more sensitive than the traditional biomarkers tested. The novel urinary biomarkers GST μ and RPA-1 were increased at Day 5 in SD rats (1.8 and 1.5-fold, respectively) and HW rats (2.6-fold for both) given 3 mg/kg, and RPA-1 was increased at Day 3 in SD rats at this dose (2.6-fold). These changes may indicate concomitant damage of the distal tubules and/or the collecting ducts.

1838 EVALUATION OF NOVEL BIOMARKERS OF NEPHROTOXICITY IN RATS TREATED WITH GENTAMICIN.

D. I. Bounous¹, D. M. Westcott¹, D. M. Dambach¹ and H. Nephrotoxicity Working Group². ¹Bristol-Myers Squibb, Princeton, NJ and ²HESI, Washington, DC. Sponsor: S. Pettit.

As part of HESI Nephrotoxicity Biomarker Initiative, male Sprague Dawley rats (n=10-20/group) were treated orally for 7 or 14 days with a proximal tubular toxicant, gentamicin sulfate, at doses of 0, 5, 25, 50 or 100 mg/kg/day. Urine collected after 3, 7 and 14 days of dosing was analyzed for traditional biomarkers and by EIA for α - and μ -GST (proximal and distal tubule injury markers, respectively), clusterin (general renal injury marker) and RPA-1 (renal papillary antigen-1; collecting duct injury marker). Clinical pathology and histopathology assessments were performed on a set of control and high dose rats dosed for 7 days and for all groups after 8-14 days (10 moribund high dose animals euthanized after 8 and 10 days of dosing). Moderate to severe proximal tubular necrosis and regeneration were significant changes in high dose rats after 7, 8, or 10 days. Dose-dependent proximal tubular necrosis, regeneration and tubulointerstitial nephritis were significant changes in the 5, 25 and 50 mg/kg groups after 14 days. Increases in RPA-1 and clusterin excretion were first detected at day 3 in high dose rats and at day 7 in other groups. At day 3 urine NAG (N-acetyl glucosaminidase) activity, urine protein, granular casts were increased in high-dose rats, and at day 7 in 50 mg/kg group. Increases in excretion of α -GST and μ -GST were first detected at day 7 in 50 and 100 mg/kg groups. Excretion of α -GST in 5 and 25 mg/kg groups increased by day 14, but excretion in 50 mg/kg group was less at day 14, likely due to severe necrosis with loss of tubules in these rats. Urinary μ -GST peaked on day 14 in 5, 25, 50 mg/kg groups and was highest on day 10 in surviving high-dose rats. Serum BUN and creatinine were increased at day 7 in high dose rats and at day 14 in only 50 mg/kg group. In summary, tubular injury had associated increases in both traditional (protein, casts, NAG) and novel biomarkers (clusterin, RPA) at 3 days. Additional study is needed to define the relationship between increases in RPA, clusterin, NAG and chronology of morphologic injury.

1839 EVALUATION OF NOVEL MARKERS OF NEPHROTOXICITY IN A RATS TREATED WITH NPAA.

G. R. Betton¹, D. T. Davies¹, T. Lambert², D. Ennulat², S. Gould¹ and C. HESI Biomarkers³. ¹AstraZeneca, Macclesfield, Cheshire, United Kingdom, ²GlaxoSmithKline, King of Prussia, PA and ³HESI, Washington, DC. Sponsor: S. Pettit.

As part of the ILSI-HESI nephrotoxicity initiative, Han Wistar (HW) and Sprague Dawley (SD) rats (n=15/group) were treated orally for 14 days with N-phenylanthranilic acid (NPAA) at toxic (350-500mg/kg/day, mkd) and non-toxic (50mkd) doses. Urine collected overnight on days 4, 8 and 15 was analysed for standard markers and by EIA for α - and μ -GST (for proximal and distal tubule, respectively), clusterin (general renal injury marker) and RPA-1 (renal papillary antigen-1, for collecting duct injury). Papillary necrosis occurred in 8/15 HW and all high dose SD rats on day 15 and in a subset of high dose HW and SD rats on day 8. Other findings included cortical tubular degeneration and/or basophilia, localized by immunohistochemistry to cortical collecting duct, distal tubule and thick ascending limb. Rats given 50 mkd NPAA had no treatment-related findings. Standard urinalysis was generally unremarkable. Paradoxical decreases in α - and μ -GST excretion (61-74%) occurred in both strains. RPA-1 and clusterin were maximally increased in HW and SD rats on day 4 or 8 and were decreasing on Day 15, with the largest increases in both RPA-1 (24.8 fold) and clusterin (12.4 fold) in HW rats. Clusterin increases were greatest in HW rats with full necrosis and were highly variable in SD rats with papillary necrosis. In the NPAA model, degenerative

changes affecting the collecting duct in both cortex and papilla commence on day 7, and only a proportion of animals progress to full papillary necrosis with irreversible loss of the papillary tip. RPA-1 increases were observed prior to necrosis from day 4 onwards in both rats with full papillary necrosis and those with earlier pathologies. As RPA-1 is a specific collecting duct marker, early (day 4) appearance of RPA-1 in the urine prior to full papillary necrosis supports its utility in early collecting duct injury.

1840 A HESI EVALUATION OF NOVEL BIOMARKERS OF NEPHROTOXICITY.

E. Harpur², D. Hoffman³, S. Beushausen⁴, A. Roche⁵ and S. D. Pettit¹. ¹HESI Biomarkers Committee, Washington, DC, ²sanofi-aventis, Alnwick, United Kingdom, ³sanofi-aventis, Bridgewater, NJ, ⁴Pfizer, St. Louis, MO and ⁵Biotrin International, Dublin, Ireland.

This work was conducted as part of a HESI collaborative program with the goal of evaluating new bridging biomarkers (BMs) of toxicity in order to establish their scientific and regulatory acceptance. There is agreement among industrial, academic and regulatory professionals on the need to develop better renal BMs that can report toxicity before the occurrence of irreversible damage, or that can help monitor low-grade nephrotoxicity in the clinic. Better understanding of the pathophysiology of nephrotoxic processes, combined with information arising from studies using 'omic-based approaches, has led to the identification of promising new BMs. Following adequate validation, these have the potential to serve as sensitive, site-specific BMs of nephrotoxicity with application in both the preclinical and clinical setting. Four candidate BMs were selected by the HESI consortium to enter the experimental program of acute and chronic rodent studies using region-specific kidney toxicants. These 4 novel BMs are: α - and μ -GST, localized in the proximal and distal tubules respectively, renal papillary antigen-1 (RPA-1), specific to the collecting duct, and clusterin, which is more generally distributed in the nephron. Enzyme immunoassays (EIAs) were either available (the GSTs) or were developed and their performance characteristics assessed (RPA-1 and clusterin). Six laboratories have contributed to the analytical validation of the EIAs that included assessment of linearity, recovery, repeatability (intra-run precision), intermediate precision (intra-lab precision) and reproducibility (inter-lab precision). The assays performed very well with respect to linearity ($r^2 > 0.98$) and recovery (90 – 110%). The acceptance criteria for repeatability and intermediate precision were pre-set at < 25% and were generally <10%. It is concluded that the EIAs for these BMs are fit for use in biological qualification studies.

1841 NEPHROTOXICITY BIOMARKER DEVELOPMENT: SUCCESSFUL TRANSFER FROM A DISCOVERY PLATFORM TO A SCREENING PLATFORM, I.E. MICROARRAY TO MULTIPLEX.

G. Vansant¹, K. Oades¹, P. Nordone², C. Afshari², F. Ferre¹ and S. Thukral². ¹Althea Technologies, San Diego, CA and ²Comparative Biology and Safety Sciences, Amgen, Inc., Thousand Oaks, CA.

Microarrays have successfully been utilized in the area of biomarker discovery providing useful tools to probe the whole genome during this phase of the biomarker development process. Once putative biomarker(s) are identified, there is a need for a higher throughput platform to determine the expression level of these genes in multiple samples. Currently low complexity real time assays are developed for each biomarker and used to monitor the gene expression of each biomarker separately. This is not optimum because of the cost of each individual assay, as well as the large sample requirement for multiple reactions, may provide significant hurdles. We have addressed these challenges by developing a multiplex RT-PCR assay incorporating genes that may be candidate biomarkers of nephrotoxicity and re-screening the samples that were used in the initial discovery process.

Rats were treated with model nephrotoxicants mercuric chloride, 2-bromoethylamine, and puromycin at two different doses, and tissue samples were collected 1, 3, and 7 days post dosing. Gene expression profiles were generated from kidney RNA using rat microarrays and analyzed in conjunction with histopathology. A set of potential biomarkers showing a time and dose response with respect to the proximal progression of proximal tubular toxicity were identified. A subset of these genes, were selected to be included in a multiplex assay to confirm concordance of data generated from the two platforms and to develop an assay to screen samples for monitoring the expression of nephrotoxicity biomarkers (Thukral et al., 2005). Data generated from the RT-PCR assay correlated to microarray data which in turn was reflective of the pathology seen at each time point. In summary, microarray discoveries can be successfully transferred to a higher throughput gene expression platform for sample analysis and evaluation.

1842 QUALIFICATION OF BIOMARKERS FOR REGULATORY DECISION MAKING – A KIDNEY SAFETY BIOMARKER PROJECT.

F. Dieterle, F. Staedtler, O. Grenet, A. Cordier, E. Perentes, D. Roth, A. Mahl, R. Papoian, P. Grass, M. Kammüller, F. Legay, D. Wahl, J. Vonderscher, S. Chibout and G. Maurer. *Novartis, Basel, Switzerland.*

In drug development, the use of early, sensitive and reliable predictors of safety and efficacy is primordial. In the last years, several "Exploratory Biomarkers" have been identified by a number of groups. It is expected that some of them can become appropriate for regulatory decisions as "Probable Valid Biomarkers" or "Known Valid Biomarkers" after submission to and approval by regulatory authorities.

Following a Cooperative Research and Development Agreement (CRADA), the FDA and Novartis initiated a collaboration to qualify kidney safety biomarkers for preclinical use and further clinical applications. The lessons learned and the process map proposed in this project will support the development of a draft guidance.

Here we present the results and milestones on the way to regulatory approval of up to 14 biomarkers for monitoring kidney safety in rats, such as:

- Selection of appropriate model compounds to cover different compartments of the target organ(s) and identification of specific biomarkers to monitor different modes of toxicity
- Design of toxicity studies in rats for 8 nephrotoxicants and 2 hepatotoxicants
- Evaluation of toxicity by standard methods including in-life observations, clinical biochemistry and histopathology
- Validation of RT-PCR low density arrays for the quantification of the biomarkers on a gene expressions level in kidney, liver and blood samples
- Development and validation of multiplexed protein assay panels to quantify the biomarkers on a protein level in urine, plasma and organ homogenates
- Statistical data mining focusing on diagnostic predictivity of markers and signatures versus histopathology and clinical biochemistry

The sensitivity and specificity of these biomarkers and signatures thereof in urine, blood and tissue will be presented discussed, and compared to the current gold standards of kidney function/toxicity (i.e. histopathology, creatinine, BUN). Finally, the status of this prototype submission will be communicated with respect to regulatory approval.

1843 4-HYDROXY ESTRADIOL-INDUCED ROS MEDIATED ACTIVATION OF CELL CYCLE GENES, CDC2 AND ITS REGULATORS CDC25C AND PRC1, CONTROLS CELL TRANSFORMATION.

K. Triff, Q. Fely and D. Roy. *Environmental & Occupational Health, Florida Int'l University, Miami, FL.*

There is considerable experimental and epidemiological evidence that 4-hydroxy estradiol (4-OH-E2), a catechol metabolite of 17 β estradiol (E2) plays a critical role in breast carcinogenesis; however, this effect cannot be fully accounted for by the mitogenic effects induced by estrogenic stimulation of its cognate receptor (ER). We have recently shown that reactive oxygen species (ROS) are involved in the regulation of E2 induced growth of breast cancer cells. In this study we have investigated whether 4-OH-E2-induced ROS through activation of nrf1-1 signaling is involved in the transformation of normal breast epithelial cells to malignant cells. Using a normal cell line (MCF-10A) that develop preneoplastic foci in response to 4-OH-E2, we measured the effects of this metabolite on nrf-1 interaction with cell cycle genes by ChIP assay and the expression of cell cycle genes cdc25c, cdc2, nrf-1 and prc1 by real time RT-PCR. After exposure of 8h following two 48 hrs treatments with 4-OH-E2; we observed an approximately 1.14, 1.55, 1.57, 1.81 and 1.0 fold increase in the expression of prc1, cdc2, nrf-1, cdc25c, and TFAM respectively. Overexpression of MnSOD markedly decreased 4OHE2 induced cdc2(-.45), cdc25c(-.86), and TFAM(-.39) expression compared to normal cells. Overexpression of catalase also decreased 4-OH-E2-induced expression of prc1(-.50), cdc2(-.39), and nrf1(-0.4). We further examined whether nrf-1 interacts with potential binding sites that regulate transcription of target cell cycle genes cdc2, cdc25, and prc1 in cells exposed to 4-OH-E2. We found a greater rate of nrf-1 binding to chromatin in cells exposed to 4-OH-E2 compared to unexposed cells. In conclusion, these results indicate distinct altered expression of cell cycle genes following exposure to 4-OH-E2. We postulate that 4-OH-E2-induced ROS through nrf-1 mediated transcriptional activation of cell cycle genes, cdc2 and its regulators cdc25C (critical for mitotic entry) and prc1, controls 4-OH-E2-induced cell transformation. Supported by DoD grant BC051097.

1844 ACTIVATION OF PI3K/AKT SIGNALING PATHWAY IS INVOLVED IN 4-HYDROXY-ESTRADIOL-INDUCED CELL TRANSFORMATION.

V. O. Okoh. *Environmental and Occupational Health, Florida International University, Miami, FL.* Sponsor: D. Roy.

The involvement of estrogen in the etiology of human breast cancer is supported by a large body of epidemiologic and experimental evidence. However, the mechanisms by which estrogen initiate or stimulate the progression of cancer remain the subject of a long-standing controversy, because we have not been able to resolve whether estrogen or their metabolites are procarcinogenic. Thus, in order to obtain novel and reliable insights into dysregulation of signaling networks associated with breast carcinogenesis, we have recently developed an in vitro model for estrogen-induced cellular transformation. The ER alpha negative, normal human breast epithelial MCF-10A cells when exposed to 17 beta estradiol (E2) or 4-hydroxyestradiol (4-OH-E2) produced increased reactive oxygen species formation, DNA synthesis and cell transformation. When these cells were pre-treated with ebselen, N-actylcystine or catalase before 4-hydroxy-estrogen exposure, reactive oxygen species, DNA synthesis and cell transformation were abrogated. In addition, treatment of cells with LY294002, a PI3K inhibitor, prevented AKT phosphorylation and cell transformation. In conclusion, the exposure of 4-OH-E2 or E2 to normal human breast epithelial MCF-10A cells produced transformed phenotypes. The 4-OH-E2-induced cell transformation was attenuated by the antioxidants. Overexpression of catalase and MnSOD also reduced the extent of 4-OH-E2-dependent increased cell transformation and AKT activation. Taken together, these data indicate that 4-OH-E2-induced ROS activate the AKT pathway in MCF-10A cells, which, in turn, supports the growth of anchorage independent cells. Supported by DoD grant BC051097.

1845 RESVERATROL PREVENTS THE FORMATION OF DEPURINATING DNA ADDUCTS AND NEOPLASTIC TRANSFORMATION IN HUMAN BREAST EPITHELIAL CELLS.

F. Lu. *Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE.*

Prolonged exposure to estrogen is a major known risk factor for breast cancer. Specific estrogen metabolites may contribute to estrogen carcinogenicity. Genotoxicity is caused by cytochrome P450 (CYP)-mediated oxidation of estrogens to quinones that react with DNA to form depurinating DNA adducts and initiate cancer. CYP1B1 favors quinone formation by catalyzing estrogen 4-hydroxylation, whereas Quinone reductase (NQO1) catalyzes the reduction of quinones back to catechol estrogen (CE). Resveratrol has anti-cancer effects in diverse in vitro and in vivo systems. TCDD and estradiol (E₂) induce CYP1B1 expression through the AhR. Resveratrol is an AhR antagonist that decreases the CYP expression, whereas it induces NQO1 expression. We hypothesize that resveratrol may prevent estrogen genotoxicity and neoplastic transformation via blocking the formation of CEs and DNA adducts.

We used MCF-10A cells to investigate the chemopreventive effect of resveratrol in breast cancer initiation. The profile of estrogen metabolites and DNA adducts in resveratrol-treated cells co-treated with TCDD and/or E₂ was analyzed by HPLC. The expression and activity of CYP1B1 and NQO1 were determined by immunoblotting and HPLC, respectively. The anti-transformation effects of resveratrol were determined by an anchorage-independent growth assay. Resveratrol induced apoptosis in a dose-dependent fashion in both normal and tumor cells. Resveratrol (25 μ M) completely blocked the formation of DNA adducts in MCF-10A cells treated with E₂ or TCDD plus E₂. Resveratrol suppressed TCDD and/or E₂-induced cell transformation by decreasing E₂ metabolism and preventing DNA adduct formation. We conclude that TCDD induction of CYP1B1, enhancing estrogen metabolism and formation of DNA adducts, plays a major role in breast cancer initiation, and resveratrol acts as a potential chemopreventive against estrogen-induced breast cancer by blocking multiple sites of the estrogen genotoxicity pathway (Supported by U.S.P.H.S grant P01 CA49210).

1846 POTENTIAL SYNERGISM OF P-GLYCOPROTEIN MODULATING PHYTOCHEMICALS AND TAXANES IN SUPPRESSION OF POLYCYCLIC AROMATIC HYDROCARBON INDUCED MAMMARY DNA ADDUCTS AND TUMORS.

S. R. Kondraganti, L. Wang, W. Jiang, K. Muthiah and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Each year breast cancer is diagnosed in 910,000 women worldwide, and 376,000 women die from the disease. Polycyclic aromatic hydrocarbons (PAHs) are commonly found in our environment and appear to be carcinogenic by genotoxic mechanisms. Some of these mimic the properties of estrogen and it has been proposed that they may exert a hormonal influence on breast cancer.

Drug metabolizing enzymes (DMEs) play central roles in the metabolism, elimination and/or detoxification of xenobiotics. P-glycoprotein (P-gp), Pregnane X receptor (PXR), and CYP3A4 are associated with multi drug resistance (MDR) in breast cancer chemotherapy. Taxanes are among the most unique, and successful, chemotherapeutic agents used for the treatment of breast and ovarian cancer. Taxanes induce CYP3A by activating PXR-mediated transcription and enhance P-gp mediated drug clearance in human mammary tumor cells. The abundant and inexpensive chemopreventive dietary phytochemicals are being explored as P-gp modulators for the reversal of MDR to breast cancer chemotherapeutic drugs.

In the present study, we evaluated the effects of PAHs and chemopreventive dietary phytochemicals on the function of P-gp and reversal of multidrug resistance induced by taxanes. We also assessed the effects of dietary phytochemicals and drugs, alone or in combination, on Cyp3a11 and PXR activities, and studied the mechanism of regulation using transgenic mice. Chemotherapeutic drugs, paclitaxel and docetaxel induced hepatic CYP3A11 mRNA in female mice compared to controls. The mammary P-gp expression was elevated in mice treated with paclitaxel and docetaxel compared to controls. Administration of dietary chemopreventive phytochemicals inhibited the P-gp expression significantly showing a potential to reverse multi drug resistance.

These studies will help to develop rational strategies for the combination drug development for the successful chemotherapy of environmental and hormonal induced human breast cancer.

1847 ALTERED DIFFERENTIATION AND ACTIVATION OF GROWTH FACTOR SIGNALING PATHWAYS IN 2D AND 3D CULTURES OF PRIMARY HUMAN MAMMARY EPITHELIAL CELLS (HMEC) PRODUCED BY ENVIRONMENTAL POLYCYCLIC AROMATIC HYDROCARBONS (PAHS).

S. W. Burchiel, I. Ivnitiski-Steel, F. Lauer, T. Thompson and L. Hudson. *College of Pharmacy, University of New Mexico, Albuquerque, NM.*

There is great interest in determining mechanisms by which environmental agents contribute to the increasing incidence of human breast cancer. Benzo(a)pyrene (BaP) is a complete carcinogen that is present in emissions from the burning of fossil fuels, woodsmoke, tobacco smoke, and in the diet where it is associated with charcoal-broiled foods. BaP exerts important genotoxic and non-genotoxic actions, but its mechanism of tumor promotion is poorly understood. Recent work in the PI's lab has shown that BaP exerts novel actions on the epidermal growth factor receptor (EGFR) and insulin-like growth factor (IGF) signaling pathways. Metabolites of BaP, most notably BaP-quinones (BPQs), stimulate cell proliferation through an oxidant stress and redox-cycling mechanism [Burdick, et al (2003) *Cancer Res* 63, 7825-7833]. Stimulation of cell proliferation and inhibition of apoptosis are both important non-genotoxic mechanisms of tumor promotion and progression. We have found using mRNA arrays that BPQs activate AhR and anti-oxidant response element (ARE) associated pathways in MCF-10A cells. Studies performed in the human mammary epithelial cell line MCF-10A were further validated in primary cultures of normal human mammary epithelial cells (HMEC). In 3D cultures of HMEC, we found that low concentrations (.01-.1 μ M BPQs) produce: 1) an increase in acinar size, 2) a loss of cell-cell junctions with a decrease in β -catenin expression, and 3) a decrease in expression of E-cadherin. These results suggest that BPQs may induce an epithelial mesenchymal transition (EMT). In addition, we have detected an increase in the expression of CXCR4 in these normal HMEC. Thus, treatment of primary HMEC in 3D cultures with BPQs produces changes in surface markers that are associated with breast cancer phenotypes. Supported by NIEHS RO1 ES-07259 and P30 ES-012072

1848 OVEREXPRESSION OF LIPOCALIN 2 IN COP RAT MAMMARY GLAND AND ITS RELATIONSHIP WITH DIFFERENTIAL GENETIC SUSCEPTIBILITY TO MAMMARY CARCINOGENESIS BETWEEN COP AND F344 RAT.

X. Ren^{1,2}, R. Sullivan², K. A. Serikawa³, R. Bumgarner³ and H. Zarbl^{2,1}. ¹Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, ²Division of Human Biology and Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA and ³Department of Microbiology and Center for Expression Arrays, University of Washington, Seattle, WA.

Rat strains differ dramatically in their susceptibility to mammary carcinogenesis following exposures to chemical, hormones or ionizing radiation. The H-ras oncogene, activated by a G→A transition at the codon12, is found in the majority of NMU-induced rat mammary carcinomas, as well as some spontaneous mammary tumors. This mutation event was thought to be the most important initiating event during the development of rat mammary carcinogenesis. However, although H-ras

mutation was also found in Copenhagen (Cop) rat, Cop rats are completely resistant to mammary carcinogenesis. Further study showed the resistance of the Cop rat to mammary carcinogenesis is not due to a defect in initiation but rather appears to be due to suppression of the growth of preneoplastic cell. In the current study, we compared the transcriptomes in mammary tissue from the resistant Cop rat and the susceptible Fischer 344 (F344) rat at different time points following exposure to a single, carcinogenic dose of NMU. Among the genes differentially expressed between Cop and F344 rat strains, the steady state levels of Lipocalin-2 (Lcn2) mRNA levels were 30 to 70-fold higher in Cop rat mammary gland vs. in F344 rat. Our further study showed that highly expressed Lcn2 could inhibit Ras-transformed cell independent growth by regulation of the Erk 1 and 2 phosphorylation. It suggests that Lipocalin2 is a mammary tumor suppressor that, highly expressed Lcn2 in Cop rat contributed, at least in part, to the genetic resistance of the Cop strain to mammary carcinogenesis by suppressing the growth of preneoplastic cells that carries the activated NMU induced H-ras oncogene. (This study was supported by grants U19-ES-011387 & P30-ES-07033 from the NIH/NIEHS.)

1849 MOLECULAR BIOMARKERS OF MAMMARY CANCER IN THE ACI RAT: A MODEL FOR CHEMOPREVENTION.

P. E. Thomas¹, K. R. Reuhl¹, I. Yang¹, B. Buckley¹, W. Cohick¹, T. Cornwell¹ and M. A. Gallo². ¹Rutgers U, Piscataway, NJ and ²UMDNJ-Robt Wood Johnson Med. Sch., Piscataway, NJ.

The ACI rat is susceptible to mammary cancer induction by estradiol (E2) and is an outstanding model of estrogen receptor positive (ER+) human breast cancer (BC). Potential biomarkers for ER+ BC were identified by differential proteomic and genomic expression in E2-induced tumors compared to normal mammary tissues. Rats were implanted with 2 mg E2 pellets sc., for up to 46 wks resulting in 70% tumor incidence. Utilizing an 8K rat oligo library DNA microarray, 7137 genes were detected: 610 genes showed a 2-fold increase and 487 genes a 2-fold decrease (tumor vs. normal). Ten of 19 genes representing the Luminal type A of human BC were detected. Six of these 10 (GATA6, ER α , protein tyrosine phosphatase 4a1, COX, neuregulin 1, GST-mu1) exhibited at least 2-fold changes up or down. DNA-microarray results were supported by proteomic analysis from 2-D gels. 60+ spots were significantly different between normal and tumor tissues. Selected spots were identified by LC-MS/MS after trypsin digestion. 12 of 26 proteins identified are associated with human cancers. Five were upregulated in tumor samples: glutamate dehydrogenase, chloride intracellular channel 1, cytokeratin19 and nucleolar phosphoprotein B23.1; seven were downregulated: transaldolase 1, β -galactoside-binding lectin, heart-type Fatty Acid Binding Protein (hFABP), GDP-dissociation inhibitor, glycosylation dependent CAM1, annexinV, tropomyosin 1 and calreticulin. Cytokeratin 19 (CK 19), whose human ortholog (CK18) is upregulated in the ER+, Luminal type A human BC, was increased 26-fold in ACI tumors. We also found a marked suppression of hFABP, a postulated tumor suppressor gene down-regulated in some human BC. These results are the first reported expression analysis for E2-induced ACI mammary tumors. The constellation of CK19 and GATA-6 up-regulation along with hFABP down-regulation in breast tumors is a biomarker for the detection of BC. (Supported by CINJ Breast Cancer Research Program Award, Rutgers Busch Award and NIEHS ES05022)

1850 A NOVEL MECHANISM FOR THE CHEMOPROTECTION OF TCDD FOR BREAST CANCER.

E. L. Hsu^{1,2,3}, D. Y. Yoon^{2,3}, H. Choi^{1,2,3} and O. Hankinson^{1,2,3}. ¹Molecular Toxicology, UCLA, Los Angeles, CA, ²Jonsson Comprehensive Cancer Center, UCLA, Los Angeles, CA and ³Pathology and Laboratory Medicine, UCLA, Los Angeles, CA.

Although it is causative for many types of cancers, experimental and epidemiological evidence suggest that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) may in fact protect against breast cancer. The mechanism(s) for this protection remain unclear, although an anti-estrogen effect has been implicated. In an attempt to further elucidate this mechanism, we performed a microarray experiment in order to identify genes that were modulated in MCF-7 breast cancer cells upon TCDD treatment. We found that TCDD down-regulated the G-protein coupled receptor, CXCR4, as well as its unique chemokine ligand, CXCL12. The interaction between CXCR4 and CXCL12 is known to play a central role in the metastasis of breast cancer. Organs to which breast cancers preferentially metastasize, namely the lung, liver, and bone, secrete high levels of CXCL12, which binds to CXCR4 expressed on the primary cancer cells. This subsequently stimulates the invasive properties of the primary tumor cells and attracts them to the preferred organ sites of metastases. Utilizing an in vitro chemotaxis assay, we demonstrate that TCDD inhibits the migration of MCF-7 cells towards a CXCL12 gradient. Additionally, we show that TCDD inhibits the inductive effects of estradiol on CXCL12. As the CXCR4/CXCL12 axis is also implicated in the progression of numerous other

types of cancer, we screened several cancer cell lines for a similar response to TCDD and found that CXCR4 and CXCL12 are indeed modulated in some of these lines. Finally, we demonstrate that 3,3'-diindolylmethane (DIM), a selective aryl hydrocarbon modulator (SAHRM) and nontoxic AHR ligand currently in clinical trials for the treatment of breast cancer, down-regulates CXCR4 and CXCL12 in a dose-dependent manner. We therefore propose that TCDD protects against breast cancer metastasis via down-regulation of the chemokine CXCL12 and its receptor CXCR4. Further, other less toxic ligands for the AHR (ShARMs) may exert their protective effects by a similar mechanism.

1851 THE EFFECT OF REPEATED LOW LEVEL SARIN EXPOSURE ON BRAIN MUSCARINIC RECEPTOR SITES IN F344 RATS.

R. Henderson¹, E. Barr¹, M. Sopori¹, M. Basile² and D. Mash². ¹Lovelace Respiratory Research Institute, Albuquerque, NM and ²University of Miami, Miami, FL.

The objective of the study was to address whether Gulf War veterans returning from duties in a hot desert region where low levels of nerve gas might have been present during destruction of munitions, could have suffered persistent adverse health effects. In earlier studies, we reported that 5 days of exposure of F344 rats to low levels of sarin gas resulted in alterations in muscarinic receptor sites in the brain. This report is on the effects of continuing those exposure for 10 days to determine if the effects were enhanced or if adaptation occurred. F344 male rats were exposed nose-only for 60 min/day to 0.2 or 0.4 mg/m³ sarin for 5 days/wk for 2 weeks under normal or heat-stressed conditions. The levels of sarin represent 1/20th and 1/10th, respectively, of the expected LC50 for rats. The heat stress was sufficient to raise the core temperature of the rats by 1 degree C. Control rats were exposed to vehicle under the same conditions as the sarin-exposed rats. Brains of the rats were observed 30 days after the end of the exposures to look for persistent changes. The findings confirmed our earlier results following 5 days of exposure and showed an enhanced response. The M1 receptor sites were decreased in a dose-dependent manner in all areas of the brain tested (frontal cortex, olfactory region, hippocampus and striatum). In contrast to the 5-day studies, these changes occurred under both normal and heat-stress conditions. There was little change in the M2 receptor site densities with the exception of an increase in sites in the frontal cortex at the higher exposure level under heat stress condition. As in the earlier studies, the M3 receptor sites were increased only when the exposures were done under heat stress conditions. These findings demonstrate that the rat model of sarin exposure is an important first step in identifying brain systems involved in the development of persistent effects following subclinical sarin exposures. 1852 GENOMIC ANALYSIS OF RAT BRAIN FOLLOWING EXPOSURE TO SOMAN.

J. F. Dillman¹, C. S. Phillips¹, D. M. Fath², C. P. Tompkins², T. A. Hamilton² and R. K. Kan². ¹Cell and Molecular Biology, USAMRICD, Aberdeen Proving Ground, MD and ²Comparative Pathology, USAMRICD, Aberdeen Proving Ground, MD.

Soman (O-Pinacolyl methylphosphonofluoridate) is a potent neurotoxicant. Acute exposure to soman causes profound inhibition of the critical enzyme acetylcholinesterase, resulting in excessive levels of the neurotransmitter acetylcholine. Excessive acetylcholine levels cause convulsions, seizures, and respiratory distress which are fatal without treatment. We performed gene expression profiling of rat hippocampus following soman exposure to gain greater insight into the mechanism of neurodegeneration following soman poisoning. Male Sprague-Dawley rats were pretreated with oxime HI-6 (125 mg/kg, ip) 30 min prior to challenge with soman (1.6xLD50 or 180 ug/kg, sc). One minute after soman challenge, animals were treated with atropine methyl nitrate (2.0 mg/kg, im). Hippocampal tissue was harvested 1, 3, 6, 12, 24, 48, 72, 96, and 168 hr post exposure. RNA was extracted from the hippocampal tissue and used to generate oligonucleotide microarray probes for gene expression profiling using Affymetrix Rat 230 2.0 microarrays. Principal component analysis of the gene expression data revealed a progressive alteration in gene expression profiles beginning at 1 hr post exposure and continuing through 24 hr post exposure. At 48 hr to 168 hr post exposure, the gene expression profiles clustered nearer to controls, but did not completely return to control profiles. Based on the principal component analysis, analysis of variance was used to identify the genes most significantly changed as a result of variation over time and soman exposure. These genes were rank ordered by p-value and categorized using gene ontology-based algorithms into molecular functions and biological processes significantly affected by soman poisoning, which include immune response, metabolic activity, and cell cycle regulation. These data provide important insights into the molecular pathways involved in soman-induced neuropathology.

1853 MICROARRAY ANALYSIS OF MURINE GENE UPREGULATION AFTER CUTANEOUS SULFUR MUSTARD EXPOSURE.

Y. Chang¹, P. M. Zito¹, R. A. Hahn¹, C. L. Sabourin², R. P. Casillas², M. K. Gordon¹ and D. R. Gerecke¹. ¹Pharmacology & Toxicology, EOHHS, Rutgers University, Piscataway, NJ and ²Battelle Biomedical Research Center, Columbus, OH.

Skin exposure to sulfur mustard [bis-(2-chloroethyl)-sulfide; SM] results in characteristic blister formation in the exposed skin. Skin from mice exposed to a high level (0.08 mg) of SM was collected at early (6, 12, and 24 h post exposure) or late (72 and 168 h post exposure) time intervals, the RNA isolated, and analyzed for gene expression analysis by the Affymetrix Murine high-density oligonucleotide array (46K genes and ESTs). Expression of greater than 1000 genes was upregulated greater than 2-fold in SM-exposed tissue compared to control skin for a minimum of one of the five timepoints. Data was organized into three major groups based on cluster analysis: 1) those with a 2-fold increase in early genes that stayed upregulated; 2) those with a 2-fold increase in early genes that became down-regulated in the late timepoints; and 3) those with a 2-fold increase in late genes only. Group 1 was mostly cytokines, growth factors, and transcription factors. Group 2 was mainly families of cellular activators, and cellular regulators. Families included eukaryotic translation factors, MAP kinases, prostaglandins, nuclear receptors, ribosomal proteins, and zinc finger proteins. Group 3 contained families of genes involved in inflammatory and immune responses including the cathepsins, various CD antigens, interleukin receptors, lymphocyte antigens, toll-like receptors, TNF superfamily members and individual inflammation inducing genes such as caspase 1 and TGF- α and TGF- β 1. Selected genes were analyzed by quantitative PCR to verify our observations. Histopathology of tissue sections furthermore supported the data. The results provide a further understanding to cutaneous SM exposure and enable diagnostic markers and therapeutic targets to be identified for treating exposure to SM.

1854 ESTIMATING MIOTIC, SEVERE AND LETHAL TOXIC EFFECTS IN GOTTINGEN MINIPIGS FOLLOWING INHALATION, INTRAVENOUS AND SUBCUTANEOUS EXPOSURES TO VX.

S. W. Hulet¹, D. R. Sommerville¹, R. B. Crosier¹, K. L. Matson¹, C. L. Crouse², J. A. Scotto¹, D. B. Miller¹, B. J. Benton¹, J. R. Jarvis², B. I. Gaviola¹, D. C. Burnett¹, R. J. Mioduszewski¹ and S. A. Thomson¹. ¹Toxicology, U.S. Army ECBC, Aberdeen Proving Grounds, MD and ²SAIC, Abingdon, MD.

Constriction of the pupils (miosis) is often identified as the first noticeable sign of exposure to vapor nerve agents. In rats, VX vapor has been shown to be more potent at causing pupil constriction than GB or GF (VX>GB>GF). We have previously identified that the miotic potencies of GB and GF are roughly equal in minipigs. In the current studies sexually mature male Gottingen minipigs were exposed to various concentrations of VX vapor in order to determine the effective concentrations (ECT50s) for pupil constriction over exposure durations of 10, 60 and 180 minutes. Initial studies show that in minipigs VX is less potent than either GB or GF at causing pupil constriction. In practical terms the concentrations of VX vapor that elicit pupil constriction are much closer to concentrations that result in severely toxic or lethal signs than are seen for either GB or GF vapors. Additionally, male Gottingen minipigs were exposed to liquid VX via intravenous (IV) or subcutaneous (SC) injections. Signs of nerve agent exposure were classified as lethal, severe, or moderate. Maximum likelihood estimation using a probit model was used to calculate the median effective (severe effects) and lethal doses (LD50) for IV and SC exposures. For intravenously injected VX, the LD50 was 11.8 μ g/kg (9.7 – 14.5 μ g/kg) and the ED50 (severe) was 6.6 μ g/kg (4.8 – 9.0 μ g/kg). For subcutaneously injected VX, the LD50 was 16.1 μ g/kg (12.9 – 19.9 μ g/kg) and the ED50 (severe) was 12.8 μ g/kg (10.1 – 16.2 μ g/kg).

1855 DIFFERENTIAL BRAIN ACETYLCHOLINESTERASE INHIBITION FOLLOWING MICROINSTILLATION INHALATION EXPOSURE TO SOMAN IN GUINEA PIGS.

M. P. Nambiar¹, N. T. Le¹, N. A. Wajda¹, T. S. Moran², R. K. Gordon¹, B. P. Doctor¹ and A. M. Sciuto². ¹Biochemical Pharmacology, Walter Reed Army Institute of Research, Silver Spring, MD and ²Analytical Toxicology, U.S. Army Medical Research Institute of Chemical Defense, Edgewood, MD.

We assessed acetylcholinesterase activity following inhalation exposure to the chemical warfare nerve agent soman (GD) in different brain regions of guinea pigs. Guinea pigs were exposed to GD by a newly developed microinstillation inhalation exposure technique. This technique delivers aerosol with a particle size less than 2 microns and bypasses the degradation of GD by carboxylesterase present in the airway of guinea pigs. The technique mimics human inhalation exposure. Guinea pigs

were exposed to GD, 0.3LC₅₀ at a rate of 40 pulses/min during inspiration for 4 min. Since the animals exposed to GD die 10-15 min after exposure, methyl atropine nitrate (2.5 mg/ml) was delivered immediately after GD exposure, (40 pulses/min, 1 min). Treatment with methyl atropine nitrate, which does not cross the blood brain barrier, restored the respiration of the animals. The animals were euthanized 24 h after exposure and the brain removed and placed immediately on ice. Different regions of the brain were dissected, and the samples were suspended in 7-volumes of tissue protein extraction reagent (T-PER) (wt/vol), and homogenized on ice using an Omni microhomogenizer. The supernatant was separated after centrifugation and assayed for cholinesterase activity and protein levels. Acetylcholinesterase was specifically assayed by samples incubating with tetraiso-propyl pyrophosphoramidate (iso-OMPA, specific BChE inhibitor). In brain from guinea pigs 24 h after GD exposure, there was a significant inhibition of AChE in the cortex ($p=0.034$). Other regions exhibited less inhibition than cortex. These data suggest that AChE in the cortex is inhibited more due to the soman induced aging of the enzyme and poor blood circulation to the deeper areas of the large cortex. In other brain regions, AChE inhibition was lower probably due to quicker recovery and higher vasculature and blood circulation.

1856 CORRELATION OF VAPOROUS VX EXPOSURE WITH BIOMARKERS AND EFFECTS BY MEANS OF A PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC MODEL (PBPK/PD).

J. Gearhart¹, E. Merrill¹, P. Robinson¹, E. Jakubowski², J. McGuire², R. Evans², S. Hulet², R. Mioduszewski² and S. Thomson². ¹AFRL/HEPB, Dayton, OH and ²U.S. Army ECBC, Edgewood, MD.

A challenge in the use of animal studies of chemical warfare nerve agent (CWNA) toxicology is extrapolation of the results to risk estimates of human response. Most mechanistic animal studies with CWNAs have been at near lethal to supra-lethal doses, by dosing routes (i.e. subcutaneous, intramuscular) that are less applicable to likely human exposure scenarios (i.e. inhalation, dermal), and in animal models that may be compromised (atropine pretreatment). A previously developed PBPK/PD model for GB (sarin) that allows the quantitative extrapolation of exposure effects in one species and dose route, to other species by other dose routes, was parameterized to simulate the kinetics and the dynamic effects of VX vapor exposure in the Gottingen minipig. Biomarkers of VX exposure simulated were the fluoride ion regenerated VX G-analog (VX-G) in red blood cells, blood plasma and tissues (Jakubowski 2006), as well as dynamic effects like miosis. The PBPK/PD model was used to simulate agent exposure profiles from serial blood samples taken before, during, and after whole body VX vapor exposures of Gottingen minipigs. Simulation of these VX biomarker data were compared to those available in the literature for other species. The apparent species differences in response were addressed with regards to the different PK profiles of VX. Simulation of VX in the present PBPK/PD model, initially using parameters from GB simulations of multiple dose routes and levels of dose, required decreasing the plasma enzymatic hydrolysis parameters by 7x, while increasing the affinity of VX for the lipid tissues to 4x that of sarin. The model simulations were also used to explain the differences in VX-G kinetics versus that of the freely extractable VX found in the plasma. Previously published in vivo and in vitro estimates of VX hydrolysis were confirmed as a necessary model parameter requiring adjustment to reproduce VX pharmacokinetics and pharmacodynamics in the minipig.

1857 PRALIDOXIME INDUCES A SUSTAINED CHOLINESTERASE REACTIVATION BUT ONLY TRANSIENT NORMALIZATION OF PARAOXON-INDUCED RESPIRATORY DISTRESS.

F. J. Baud^{2,1}, P. Houze², C. Monier² and P. Risede². ¹Medical and Toxicology Intensive Care Unit, AP-HP University Paris 7, Paris, France and ²UMR 7157, INSERM U705, Paris, France. Sponsor: G. Isom.

Objective: The efficiency of oximes in organophosphate poisoning is a matter of debate. In rats poisoned with paraoxon (PO), we studied the effects of pralidoxime (PX) methylsulfate on respiratory distress and blood cholinesterase (ChE) activities. Methods: we tested in whole blood in vitro the efficiency of various PX concentrations to reactivate PO-induced ChE inhibition. Male Sprague-Dawley rats were treated with PX (base: 10, 25, 50 mg.Kg-1) using IV and IM routes to assess the dosage regimen providing plasma PX > 4 mg/l during the longest period of time. PO (0.215 mg.Kg-1 i.e. 50% LD50) was administered subcutaneously. Rats were treated with PX 30 min post injection of PO. Respiratory function was assessed using whole body plethysmography. ChE activities were measured in whole blood. Results are expressed as mean $\pm$ SEM. Statistical analysis used Student's t test and ANOVA tests with $p < 0.05$. Results: The 50 mg.Kg-1 IM dose resulted in plasma PX concentrations > 4 mg.L-1 during 35 min post infusion. PO induced an in-

crease in total time, expiratory time and tidal volume, and a decrease in respiratory rate. In the same time, whole blood ChE activities were decreased to 40% of the basal value. Thirty minutes after PO administration, PX (50 mg.Kg-1, IM) induced: 1-) a fast, total and prolonged ChE reactivation (> 180 min), 2-) a rapid (< 5 min), complete but only transient (< 30 min) reversal of PO-induced respiratory effects. Discussion : A 50 % LD50 of PO induced respiratory distress and decrease in ChE activity. A single dose of PX rapidly corrected both effects which were dependent on PX concentrations. Thereafter, normalization was sustained for ChE activity but only transient for respiratory distress. Our data suggest that ChE reactivation is a necessary but not sufficient condition for the antidotal effect of PX. ChE reactivation cannot be used alone to assess the antidotal efficiency of oximes.

1858 MEDICAL COUNTERMEASURES USING ATROPINE IN COMBINATION WITH OTHER DRUGS FOR VX INHALATION EXPOSURE ACUTE RESPIRATORY TOXICITY, AND LUNG INJURY.

M. P. Nambiar^{1,3}, N. A. Wajda¹, A. M. Katos^{1,2}, P. E. Rezk¹, T. S. Moran², R. K. Gordon¹, B. P. Doctor¹ and A. M. Sciuto². ¹Biochemical Pharmacology, Walter Reed Army Institute of Research, Silver Spring, MD, ²Analytical Toxicology, U.S. Army Medical Research Institute of Chemical Defense, Edgewood, MD and ³Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD.

The efficacy of atropine, administered in combination with other drugs (dexamethasone, N-acetylcysteine, Syk antisense oligonucleotides, surfactant and liquivent), was evaluated against lung injury and respiratory toxicity caused by VX exposure. Guinea pigs were exposed to saline or 27 mg/m³ VX for 4 min using a microinstillation inhalation exposure technique. Exposure to this dose of VX resulted in a 24 h survival rate of 52%. A significant increase in bronchoalveolar lavage (BAL) protein, total cell number, and cell death were observed in the VX-exposed animals compared to the saline controls. Surprisingly, direct pulmonary treatment via instillation 2 minutes post-exposure with pulmonary therapeutics did not increase the survival rate of VX-exposed animals. VX-induced viscous mucous secretions were exacerbated by the aerosolized treatments leading to further blocking of the airway. To overcome this effect, we developed a strategy to combine the individual treatments with atropine. Atropine inhibits muscarinic stimulation and markedly reduced the copious airway secretion following vx exposure. When atropine methyl bromide, which acts peripherally and does not penetrate the blood brain barrier, was administered in conjunction with the other pulmonary treatments the result was 100% survival of VX-exposed animals at 24 h. Atropine treatment in combination with pulmonary therapeutics dexamethasone and antisense Syk also reduced the VX-induced increase in bronchoalveolar lavage protein levels, cell number, and cell death. These results demonstrate that post-exposure nasal treatment with atropine in combination with pulmonary therapeutics inhibits mucous secretion for survival and also protect against lung injury and respiratory toxicity from inhalation exposure to VX.

1859 FETAL MOUSE PHTHALATE EXPOSURE SHOWS THAT GONOCYTE MULTINUCLEATION IS NOT ASSOCIATED WITH DECREASED TESTICULAR STEROIDOGENESIS.

K. Gaido¹, J. B. Hensley¹, D. Liu¹, D. G. Wallace¹, S. Borghoff², K. J. Johnson¹, S. J. Hall³ and K. Boekelheide³. ¹CIIT Centers for Health Research, Research Triangle park, NC, ²Integrated Laboratory Systems, Research Triangle park, NC and ³Brown University, Providence, RI.

The rat has been explored in detail for its in utero susceptibility to male reproductive tract malformation following phthalate exposure. Few other species have been studied in detail. We investigated the response of the fetal mouse testis to phthalate exposure and compared these results with those previously obtained from the rat. Initial experiments using a variety of phthalate congeners (monobutyl phthalate, di-(n-butyl) phthalate, or mono(2-ethylhexyl) phthalate) and exposure paradigms did not reduce fetal mouse testis testosterone levels. Pharmacokinetic data after a single 500 mg/kg DBP exposure on mouse gestation day (gd) 18 demonstrated that the concentrations and kinetics of the active metabolite (MBP) in fetal and maternal plasma were similar to the rat. After a single 500 mg/kg or multiple day 250 mg/kg fetal mouse DBP exposure, rapid and dynamic changes in testis gene expression were observed, including induction of immediate early genes. Unlike the rat, expression of genes involved in cholesterol homeostasis and steroidogenesis were not decreased. Similar to the rat however, a 250 or 500 mg DBP/kg/day mouse exposure from gd 16 through 18 significantly increased seminiferous cord diameter, the number of multinucleated gonocytes per cord, and the number of nuclei per multinucleated gonocyte. Together, these results demonstrate that fetal mouse and rat phthalate exposure both induce immediate early gene expression and disrupt of seminiferous cord development. This response in the mouse occurs without a measurable decrease in testicular steroidogenesis, suggesting that altered seminiferous cord formation is not mechanistically linked to lowered steroidogenesis.

1860 IDENTIFICATION OF REGION-SPECIFIC GENE EXPRESSION CHANGES AND SIGNALLING PATHWAYS AFFECTED BY DI(2-ETHYLHEXYL)PHTHALATE (DEHP) IN FETAL RAT TESTES.

S. M. Plummer¹, R. M. Sharpe² and C. R. Elcombe¹. ¹CXR Biosciences Ltd., Dundee, United Kingdom and ²MRC Human Reproductive Sciences Unit, Edinburgh, United Kingdom.

Previous studies have shown di(2-ethylhexyl)phthalate (DEHP) to elicit a testicular dysgenesis in rats following in utero exposure. This study was performed in order to identify signalling pathways associated with DEHP-induced testicular dysgenesis and to determine the region-specificity of the gene expression alterations. Pregnant Wistar rats were administered DEHP (500 mg/Kg body weight daily by gavage) from gestation day (GD) 12 to GD 19. At GD 19, fetal testes were harvested and interstitial (INT) and tubular (CHORD) regions isolated by laser capture microdissection. RNA was prepared from the isolated INT and CHORD cells and high density microarray analysis (Agilent rat whole genome array) performed. Comparison of the INT and CHORD signature gene lists ($p < 0.01$) identified genes that were uniquely or commonly regulated by DEHP in the two regions. In the INT region down-regulation of genes involved in sterol and fatty acid biosynthesis and steroidogenesis was seen (eg. hydroxymethylglutaryl coenzyme A reductase and synthase, farnesyl diphosphate synthase, isopentenyl diphosphate delta isomerase, mevalonate decarboxylase, CYP17, scavenger receptor class B member 1). Several genes that are regulated by insulin like growth factor 1 (IGF1) such as cathepsin D, solute carrier family 2 member 1, and ribosomal protein S6 kinase, were also uniquely down-regulated in the INT (Leydig cell region), correlating with repression of IGF1 in this region. By contrast, genes involved in regulation of androgen and estrogen receptors were strongly represented in the CHORD 'unique' signature gene list. These results indicate that DEHP-induced testicular dysgenesis involves region- and cell type-specific effects on a number of genes, many of which are involved in sterol biosynthesis and steroidogenesis. The Phthalate Esters Panel of the American Chemistry Council funded this study

1861 STRUCTURE ACTIVITY RELATIONSHIP OF PHTHALATE ESTERS TO INHIBITED FETAL TESTICULAR TESTOSTERONE PRODUCTION IN THE SPRAGUE DAWLEY RAT.

K. L. Howdeshell, J. Furr, C. R. Lambright, V. S. Wilson and L. Gray. Reproductive Toxicology Division, U.S. EPA, Research Triangle Park, NC.

Several of the phthalate esters (widely used as plasticizers of polyvinyl chloride and other applications) have been shown to inhibit fetal testicular testosterone (T) production and *Ins3* mRNA in the laboratory rat. The current study was designed to define the dose response of 7 individual phthalates with respect to their impact on fetal T production. Time-pregnant Sprague Dawley female rats were administered oral doses from gestation day (GD) 8 through 18 with a broad dose range (25-900 mg/kg/d) of the following phthalates: benzyl butyl phthalate, BBP; dibutyl phthalate, DBP; diisobutyl phthalate, DiBP; diisooctyl phthalate, DiHP; dipentyl phthalate, DPP; diethyl phthalate, DEP; and di-n-heptyl phthalate, DnHP. On GD18, fetal testes were collected and incubated ex vivo for fetal T production. We report that fetal T production was suppressed by phthalates with monoester metabolites of 4 to 6 carbons in the ortho position, whereas those with longer or shorter side chains (or in the para-position) were inactive. BBP, DBP and DiBP were of similar potency to the known reproductive toxicant diethylhexyl phthalate (DEHP). DiHP and DPP were 2-fold and 5-fold more potent than DEHP, respectively. As expected based on structure, a range of 100 to 900 mg/kg/d DEP and DnHP did not significantly reduce fetal T production. The same phthalates that inhibited fetal T production also caused mid-pregnancy fetal loss, albeit at higher dose levels. The fetal resorptions are consistent with previously reported phthalate-induced suppression of progesterone during pregnancy. In conclusion, the ability of phthalates to suppress fetal T production is determined by their monoester metabolite structure and the SAR of our study was the same as that reported in pubertal male rats. We plan to use the relative potency data of the bioactive phthalates to design mixture studies measuring the effects of phthalate mixtures on fetal T production and *Ins3* gene expression. (This abstract does not necessarily reflect EPA policy.)

1862 CUMULATIVE REPRODUCTIVE EFFECTS OF IN UTERO ADMINISTRATION OF MIXTURES OF ANTIANDROGENS IN MALE SD RATS: SYNERGY OR ADDITIVITY?

L. E. Gray, J. Furr, V. S. Wilson, A. K. Hotchkiss, K. Howdeshell and C. Rider. ORD, NHEERL, RTD, EB, U.S. EPA, RTP, NC.

In 1996 the USEPA was charged under the FQPA to consider the cumulative effects of chemicals in their risk assessments. Our studies were conducted to provide a framework for assessing the cumulative effects of antiandrogens. Toxicants were

administered individually or as mixtures to rats on GD 14-18 and the development of the male offspring evaluated. Data were analyzed to determine if the chemicals behaved in a response- or dose-additive fashion. When seven antiandrogenic chemicals were combined at doses that individually produce little or no hypospadias or epididymal agenesis 100% of the male offspring were malformed (vinclozolin (V-15 mg/kg/d), procymidone (P-15 mg/kg/d), linuron (L-20 mg/kg/d), prochloraz (PZ-35 mg/kg/d) and three phthalate esters (DBP, DEHP, and BBP-150 mg/kg/d/phthalate)). Dose addition was the only model that accurately predicted the malformations induced by this complex mixture. When pairs of chemicals that act via similar and dissimilar mechanisms of action were combined, we found that dose addition was the appropriate model to predict hypospadias and other malformations. For example, mixtures of androgen receptor antagonists with phthalates that reduce fetal testosterone produced effects consistent with dose- but not response- additivity. Individually, the chemicals induced low rates of hypospadias P (1.5%), and L, BBP and DBP (0%) as compared to L plus BBP (56%) or P plus DBP (49%). The observation that dose- but not response-addition accurately predicts the effects of chemical mixtures that act via diverse mechanisms suggests that synergistic interactions may commonly occur among chemicals that disrupt the same signaling pathway at different molecular sites during sexual differentiation. This abstract does not necessarily reflect EPA policy.

1863 THE GENOMIC RESPONSE OF ISHIKAWA CELLS TO 17 α -ETHYNYL ESTRADIOL AND BISPHENOL A: A POTENTIAL ALTERNATIVE TO ANIMAL TESTING FOR ESTROGENS.

J. M. Naciff, Z. S. Khambatta, R. G. Thomason, G. J. Carr, J. P. Tiesman and G. P. Daston. Central Product Safety, Procter & Gamble Company, Cincinnati, OH.

The establishment of in vitro systems to determine the potential estrogenic activity of chemicals of interest is indispensable in order to develop reliable high-throughput screening assays and to minimize animal testing studies for this mode of action. With this goal in mind, we have determined the genomic response of the Ishikawa cells to estrogen exposure in a time and dose dependent manner, using two estrogen receptor agonists: 17 α -ethynyl estradiol (EE) and bisphenol A (BPA). The concentrations tested were: 1pM, 100pM, 10nM, and 1 μ M, for EE and 1nM, 100nM, 10 μ M and 100 μ M for BPA. The time points were 8, 24 and 48h. The transcript profiles were evaluated using Affymetrix Human Genome U133plus2.0 arrays. The analysis of the data indicates that the genomic response of the Ishikawa cells to a potent and a weak ER agonist exposure is time and dose dependent, following a pattern of a monotonic response for both parameters. Similar characteristics of the genomic response are elicited by EE and BPA in an in vivo model (the juvenile rat uterus). We determined by statistical analysis of the two experiments separately, that more than 1200 genes changed their expression by exposure to EE or BPA. Further, the change in the expression of 389 genes is identical in the direction of the change, although the magnitude of the change of some genes is different in the Ishikawa cells exposed to these two ER agonists. Using the annotation available for the genes responding to EE and BPA, we determined that the response of the Ishikawa cells involves cellular processes relevant for cell proliferation, differentiation and tissue remodeling. Many of these genes are also involved in organogenesis in the rat uterus, a process that is also affected by exposure to potent estrogens. These data indicate that the Ishikawa cells are capable of mounting a proper estrogenic response and they seem to offer a robust in vitro system to evaluate the potential estrogenicity of chemicals of interest.

1864 ROLE OF THE ESTROGEN RECEPTOR IN THE DIETHYLSTILBESTROL-INDUCED DISRUPTION OF THE EXPRESSION OF WNT5A AND WNT7A IN HUMAN ENDOMETRIAL (ISHIKAWA) CELLS.

L. Lehmann, J. Wagner and M. Metzler. Department of Chemistry and Life Sciences, University of Karlsruhe, Karlsruhe, Germany.

Genes of the WNT family are involved in signal transduction cascades important for development and carcinogenesis. WNT5A is supposed to be an upstream regulator of WNT7A expression in a signaling pathway that transmits information among stromal and epithelial cells of the endometrium. Disruption of this pathway is associated with morphological abnormalities of the female reproductive tract, and mice treated neonatally or in utero with the trans-placental acting carcinogen diethylstilbestrol (DES) show the same abnormalities, whereas estrogen receptor (ER) α knockout mice are insensitive towards DES.

The aim of the present study was to determine the influence of the synthetic estrogen DES on the mRNA expression of WNT5A and WNT7A in a human endometrial adenocarcinoma cell line (Ishikawa cells) by reverse transcription/competitive PCR. The role of the ER was examined by (i) the determination of the mRNA expression and the enzyme activity of the alkaline phosphatase (ALP), which is regulated by the ER in Ishikawa cells, (ii) the use of the ER antagonist ICI 182,780 (ICI), and (iii) silencing of the ER α by RNA interference using siRNA.

After treatment of Ishikawa cells with DES at concentrations that stimulated the expression of the ALP for 6-48 h, a significant decrease in the mRNA levels of WNT7A was observed reaching maximum reduction after 24 h. DES-induced reduction of WNT7A mRNA levels was prevented by the ER antagonist ICI as well as by knock down of ERalpha by RNA interference. After treatment with DES for 24 h and longer, mRNA levels of WNT5A correlated with those of WNT7A; however, there were pronounced differences after treatment periods of 6 h and less. In conclusion, when challenged with DES, the Ishikawa cell line reacts similar to the endometrial epithelium of mice exposed to DES in utero or neonatally, thus providing a powerful tool for the investigation of endocrine disrupting of the female reproductive tract.

1865 INVOLVEMENT OF THE C-KIT SIGNALING PATHWAY IN 4-VINYLCYCLOHEXENE DIEPOXIDE-INDUCED FOLLICLE LOSS IN RAT WHOLE OVARIAN CULTURES.

S. M. Fernandez, H. L. Brooks and P. B. Hoyer. *Physiology, University of Arizona, Tucson, AZ.*

The occupational chemical, 4-vinylcyclohexene diepoxide (VCD), selectively destroys small pre-antral (primordial and primary) ovarian follicles after repeated daily dosing of postnatal day (PND) 28 rats and following *in vitro* exposure of PND4 rat ovaries in culture. From previous studies, expression of the tyrosine kinase receptor, c-Kit, in ovarian cultures was reduced ($p < 0.05$) by VCD exposure in ovarian mRNA (0.45 ± 0.31 relative to control; $n=4$) and protein ($78.64 \pm 0.91\%$ of control; $n=3$). Interactions between c-Kit and its ligand, Kit Ligand (KL), play a crucial role in primordial follicle recruitment and follicle survival. Additionally, growth and differentiation factor-9 (GDF-9) and bone morphogenetic protein-4 (BMP-4), also play important roles in folliculogenesis. Therefore, the current study was designed to investigate a possible role of KL, GDF-9, and BMP-4 in VCD-induced ovarian follicle loss. Ovaries from PND4 Fischer 344 rats were excised and cultured in control or VCD-containing (30 μ M) medium with or without KL (25, 50, 100 ng/ml), GDF-9 (50, 100, 200 ng/ml), and BMP-4 (50, 100, 200 ng/ml). Following incubation (8d), ovaries were collected and prepared for histological evaluation. When co-incubated with VCD, KL at 50 and 100 ng/ml prevented ($p < 0.05$) VCD-induced small pre-antral follicle loss (Primordial: VCD 225 ± 31 ; 50 ng/ml KL+VCD 341 ± 33 ; 100 ng/ml KL+VCD 342 ± 28 follicles counted/ovary; Primary: VCD 39 ± 6 ; 50 ng/ml KL+VCD 65 ± 6 ; 100 ng/ml KL+VCD 76 ± 5 follicles counted/ovary; $n=8-9$). Conversely, GDF-9 and BMP-4 had no effect on VCD-induced follicle loss. These data support that ovarian c-Kit/Kit Ligand signaling is disrupted by VCD, and likely plays a role in the mechanism by which VCD induces ovarian small pre-antral follicle loss. Whereas, two other signaling pathways associated with small pre-antral follicle survival/recruitment (GDF-9, BMP-4) appear to not be involved. (ES09246 and Center Grant 06694)

1866 IN VITRO EFFECTS OF COMMERCIAL HEXABROMOCYCLODODECANE (HBCD) AND ITS INDIVIDUAL STEREO-ISOMERS ON AROMATASE ACTIVITY.

R. F. Canton and M. van den Berg. *Institute for Risk Assessment Sciences, IRAS, Utrecht, Netherlands.*

Hexabromocyclododecane (HBCD) is a brominated aliphatic cyclic hydrocarbon used as flame retardant in polystyrene foam and textile coating. The commercial HBCD mixture contains 3 stereo-isomers (α , β and γ). Several recent environmental studies indicated a sharp increase in HBCD concentrations from 2001 onwards, possibly due to an increase in production.

During the last years, we focused in our laboratory on environmentally relevant brominated flame retardants BFRs including HBCD and their possible effects on sex steroidogenesis. Aromatase (CYP19) is one of the key enzyme in the pathway. In the present study, the human H295R adrenocortical carcinoma cell line has been used to assess the effects of HBCD on aromatase activity. Concentrations of HBCD ranged from 0.01 to 100 μ M. Aromatase was measured using the tritiated water-release assay. Inhibition of aromatase activity was only found after a 24h exposure although with cytotoxic effects above 10 μ M, while IC50 values for the reference compound 4-hydroxyandrostendione was 0.3 μ M.

The inhibitory properties of HBCD, commercial mixture and individual stereo-isomers were then further studied using microsomes of human placenta for possible interaction with aromatase enzyme. Concentrations of commercial HBCD and its stereo-isomers ranged from 0.04 to 400 μ M. All compounds showed aromatase inhibition with IC50 values around 5 μ M, 50 times higher than the IC50 of the reference compound 4-hydroxyandrostendione (80 nM). Based on concentrations used in these *in vitro* experiments and those observed in humans and wildlife a preliminary risk assessment was done for the relevance under environmental conditions.

1867 THE PHOSPHOINOSITIDE 3-KINASE RELATED KINASE HSMG1 ACTIVATES AN EARLY GENOTOXIC STRESS RESPONSE TO HYPEROXIA.

S. Gehen¹ and M. A. O'Reilly². ¹Environmental Medicine, University of Rochester, Rochester, NY and ²Pediatrics, University of Rochester, Rochester, NY. Sponsor: C. Johnston.

While clinically important, hyperoxic ventilation results in the production of reactive oxygen species which damage macromolecules and promote cell death. Prolonged exposure to hyperoxia has also been used as a model to study signaling pathways activated by chronic exposure to pro-oxidants. In response to genotoxic stress caused by hyperoxia, the p53-dependent expression of p21 inhibits proliferation and protects against cell death. Given the importance of p53-mediated expression of p21 in promoting cell survival, this study examines activation of this pathway in hyperoxia. Our laboratory has demonstrated a role for the wortmannin-sensitive phosphoinositide 3-kinase related kinases (PIKKs) in regulating hyperoxia-dependent phosphorylation of p53 on Ser15, a critical site in activating p53 in response to damage. Here, genetic and pharmacologic approaches were utilized to examine the contribution of PIKK family members in stimulating the p53 pathway in hyperoxia. To explore the role of the PIKK ATM in regulating this pathway, ATM wild-type or deficient lymphoblasts were treated with hyperoxia for various lengths of time. Interestingly, ATM was not required for Ser15 phosphorylation at early time points in hyperoxia and activation of p53 was abrogated by wortmannin treatment in both wild-type and ATM-deficient cells. In human adenocarcinoma A549 cells exposed to hyperoxia, siRNA targeting of the newly identified PIKK hSMG1 but not ATR reduced p53 phosphorylation relative to control treated cells demonstrating that hSMG1 contributes to p53 activation in hyperoxia. In addition, siRNA knockdown of ATM in A549 cells resulted in the loss of Ser15 phosphorylation only after 48 hours of hyperoxia while targeting of hSMG1 attenuated the p53 response at earlier time-points. These results suggest that hSMG1 activates an early damage or redox-sensitive p53 response to hyperoxia and indicate that hSMG1 may play a pivotal role in regulating checkpoints and other pathways that determine cellular outcome to genotoxic stress.

1868 ARSENIC INDUCES APOPTOSIS BY INCREASING PHOSPHORYLATION OF LCK AND FYN IN MOUSE LYMPHOCYTES.

L. Vega and G. A. Soto-Peña. *Toxicology, CINVESTAV, Mexico D. F., Mexico.* Sponsor: L. Del Razo.

Arsenic is a widely distributed human carcinogen with various toxic mechanisms that interferes with DNA repair enzymes, microtubule and cytoskeletal assembly. Arsenic can produce chromosomal aberrations, cell cycle delay and differential toxicity depending on the gender and on the cell type evaluated. It has been reported that arsenic presents a differential toxicity on cell type regarding the immune system. We postulate that this differential toxicity is related with the capacity of arsenic to induce apoptosis and cell cycle arrest on T helper cells by increasing the phosphorylation rate of several molecules on the signal transduction pathway of interleukin 2 receptor-mediated activation such as lck and fyn.

In order to elucidate the possible mechanism by which arsenic can induce apoptosis in immune cells, we determine the effects of sodium arsenite on lck and fyn phosphorylation status and the induction of apoptosis on male C57BL/6N mouse spleen cells *in vivo* and *in vitro*. Animal studies were carried out in accordance with the Society's criteria for the care and use of animals in research. Animals were exposed orally to arsenic for 15 days and sacrificed by CO2 inhalation. Spleens were collected and cells were washed and incubated with a mitogen (Concanavalin A or antiCD3/CD28 antibodies). The proliferative response, as tritiated thymidin incorporation, and IL-2, IL-4 and IL-10 secretion by ELISA-sandwich, were evaluated as activation parameters. The phosphorylation of lck and fyn was evaluated by flowcytometry as well as the viability, necrosis and apoptosis rate. This same parameters were evaluated in spleen cells *in vitro* with different exposure times.

Arsenic exposure and *in vitro* treatment increased phosphorylation of lck and fyn in a dose- and time-dependent manner in spleen cells, this effect was also observed on mitogen-stimulated cells. Arsenic exposure also caused an increase in apoptotic cells and an inhibition on cell proliferation and IL-2 secretion, both effects probably due to the induction of phosphorylation of lck and fyn.

1869 MODULATION OF LPS-INDUCED CYTOKINE AND TISSUE FACTOR EXPRESSION IN MACROPHAGES BY THE PI3K-AKT PATHWAY.

J. P. Luyendyk, M. Tencati, T. Holscher and N. Mackman. *Department of Immunology, Scripps Research Institute, La Jolla, CA.*

Lipopolysaccharide (LPS) stimulation of monocytes/macrophages activates various intracellular signaling pathways, including the mitogen-activated protein kinases (MAPKs; e.g., ERK1/2) and the phosphatidylinositol-3-kinase (PI3K)-Akt path-

way. In addition, LPS induces the expression of a variety of genes, such as the cytokines TNF α , IL-6 and IL-10, as well as tissue factor (TF), the principal activator of blood coagulation. At present, the role of the PI3K-Akt pathway in the regulation of LPS-induced gene expression is controversial. The activation of Class IA PI3K requires both a 110kD catalytic subunit (α , β , or δ) and a 85kD regulatory subunit (α or β). PI3K generates PIP3, a lipid second messenger required for the activation of Akt. PIP3 levels are counterbalanced by the phosphatase PTEN. We tested the hypothesis that activation of PI3K-Akt signaling modulates LPS induction of cytokines and TF in peritoneal macrophages (PMs). First, we determined the effect of genetically reducing PI3K activity on LPS induction of cytokines and TF expression using PMs from p85 $\alpha^{-/-}$ mice. LPS activation of Akt was reduced and ERK1/2 activation was enhanced in PMs from p85 $\alpha^{-/-}$ mice compared with PMs from wild type mice. These p85 α -deficient PMs exhibited enhanced LPS induction of IL-6, TNF α and TF, whereas expression of the anti-inflammatory cytokine, IL-10, was reduced. Next, we determined the effect of genetically increasing Akt activity on LPS induction of cytokine and TF expression using PMs from PTEN^{fllox/lox}/LysMCre mice. LPS-stimulated Akt activity was enhanced in PTEN^{fllox/lox} PMs, whereas LPS activation of ERK1/2 was reduced. This change in intracellular signaling was associated with reduced LPS induction of IL-6, TNF α and TF expression and increased expression of IL-10 in PTEN^{fllox/lox} PMs. Taken together, our results suggest that the PI3K-Akt pathway inhibits proinflammatory gene expression in macrophages by inhibiting LPS activation of MAPKs, but is required for IL-10 expression.

1870 DIFFERENTIAL REGULATION OF CYP1A1 AND MUC GENE EXPRESSION BY TCDD IN HUMAN AIRWAY EPITHELIAL CELLS.

Y. Lee, S. Song, D. Wu, M. M. Chang, M. Denison and R. Wu. *UC Davis, Davis, CA.*

RATIONALE: 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) has been identified to be one of the most potent toxicant in the environment. It has been shown that TCDD is associated with chronic obstructive pulmonary disease, although the exact mechanism is still unknown. **METHODS:** Primary human tracheobronchial epithelial (TBE) cells and HBE1 cell line were cultured under the air-liquid interface condition and treated with various amounts of TCDD and vehicle (DMSO). For EGFR and MAPK pathway inhibitor studies, the inhibitor was added 30 min prior to the TCDD treatment. At various times after the treatment, cultures were harvested for RNA isolation. Quantitative real-time PCR was used to quantify the levels of CYP1A1, MUC5B, MUC5AC and control genes (b-actin and GAPDH). **RESULTS:** We have observed a 3 to 6 fold stimulation of CYP1A1, MUC5B, and MUC5AC messages in these human TBE cells after 24 hrs treatment. The stimulation was time- and dose-dependent on TCDD. Inhibitor studies have showed that TCDD-induced CYP1A1 was JNK inhibitor sensitive, but insensitive to inhibitors of the other two MAPK pathways, ERK and p38, and EGFR signaling pathways. In contrast, TCDD-induced MUC5B and MUC5AC expressions were both sensitive to the ERK and p38 inhibitors and the inhibitor of EGFR signaling, but insensitive to the JNK inhibitor. **CONCLUSION:** We have demonstrated that TCDD is a potent inducer for MUC gene expression, a clinic hallmark associated with the pathogenesis of COPD. The inhibitor studies suggest that TCDD induces the expression of MUC5AC and MUC5B, not through conventional aryl-hydrocarbon receptor, but through EGFR, ERK and p38 MAPK pathways.

1871 REDUCTIONS IN THE LEVEL OF AHR PROTEIN IN CELLS LINES HAS A DRAMATIC IMPACT ON AHR-MEDIATED GENE REGULATION.

R. S. Pollenz. *Cell Biology, Microbiology and Molecular Biology, University of South Florida, Tampa, FL.*

The Ah receptor (AHR) is rapidly degraded both in vivo and in vitro following binding to halogenated aromatic hydrocarbons (HAH) typified by 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). Since several studies have shown that the overall level of endogenous AHR in cells and tissues from different species can vary over an order of magnitude, it was of interest to evaluate the impact of reducing the level of endogenous AHR on AHR-mediated gene regulation in cell culture lines derived from mouse or human tissues. It was also of interest to evaluate whether there would be differences in the level of gene regulation when different ligands were utilized. Mouse Hepa-1 and human retinal epithelial cells (hRPE) were used for these studies. Both cell lines are responsive to AHR ligands and induce endogenous CYP1A1. To quantitatively reduce the level of endogenous AHR in the cells, siRNA transfection was used. This method could consistently achieve >90% transfection of the cell populations and by using graded levels of siRNA, the level of endogenous AHR could be reduced from 30-95%. The results show that reduction in the level of AHR has a profound impact on the dose-response curve for the induction of endogenous CYP1A1. In Hepa-1 cells, a reduction of as little as 30% of the

AHR level shifted the dose-response curve for TCDD induction of CYP1A1 to the right and reduced the overall magnitude of the response. At 70% AHR reduction, the EC50 for TCDD was increased by an order of magnitude and the maximal level of CYP1A1 induction was reduced by >80%. The changes in dose-response were even more profound when less potent AHR ligands were used, and modest reductions in the level of AHR resulted in complete loss of CYP1A1 induction in some cases. Collectively, these studies suggest that modulation of the level of AHR protein can have a dramatic impact on the magnitude of AHR-mediated gene regulation and suggest that the concept of "spare receptors" may not hold for the AHR signaling pathway. Supported by ES10991.

1872 CROSSTALK BETWEEN THE AHR AND WNT SIGNALING PATHWAYS DURING TISSUE REGENERATION.

L. K. Mathew^{1,2,3}, E. A. Andreassen^{1,2,3} and R. L. Tanguay^{1,2,3}. ¹*Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR*, ²*EHSC, Oregon State University, Corvallis, OR* and ³*MFBS, Oregon State University, Corvallis, OR*.

Inhibition of early life stage zebrafish caudal fin regeneration by aryl hydrocarbon receptor (AHR) activation has been developed as an in vivo platform to define the cross talk between AHR and other molecular signaling pathways. Using antisense repression approach, we have previously identified that AHR2 and ARNT1 are necessary and sufficient for TCDD to impair regenerative growth. Global gene expression analysis performed using RNA isolated from the regenerating tissue obtained from the control or TCDD exposed larvae revealed that a cluster of genes involved in extracellular matrix remodeling, cell migration and cell adhesion were misregulated by AHR activation. Using pathway analysis, we identified more than 20 Wnt target genes differentially expressed in regenerating tissue suggesting misregulation of Wnt signaling by AHR activation. Distinctively, R-Spondin 1, a novel ligand for the Wnt receptor was one of the most highly TCDD-induced genes at all the time points analyzed. Since R-Spondin-1 is an upstream modulator of Wnt signaling, we proposed that AHR-dependent misregulation of R-Spondin-1 may dictate the downstream gene expression changes that collectively result in impaired extracellular matrix remodeling and cellular migration. If the induction of R-Spondin 1 is required for TCDD to block regenerative growth, antisense repression of R-Spondin 1 should permit regeneration even in the presence of TCDD. In support of this hypothesis, partial suppression of R-Spondin1 using splice blocking morpholinos abrogated the TCDD-dependent block of regeneration, suggesting that inappropriate induction of R-Spondin 1 is required for TCDD to impair regeneration. These studies for the first time identify functional cross talk between Wnt and AHR signal transduction pathways and indicate the power of zebrafish model to discover and define molecular pathways that regulate complex in vivo biological responses. Supported by NIEHS grants ES10820, ES00210, and #ES03850.

1873 INHIBITION OF BLADDER CANCER CELL GROWTH BY GLYCYRRHETINIC ACID DERIVATIVES.

G. Chadalapaka¹, S. Chintharlapalli², S. Papineni², I. Jutoori¹ and S. Safe^{1,2}. ¹*Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX* and ²*Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.*

Bladder cancer incidence has been increasing and, even after chemotherapy with highly cytotoxic drugs, the prognosis for disease-free survival in most patients is only 1 to 2 years. 2-Cyano-3,11-dioxo-18 β -oleana-1,12-dienoic acid (CDODA) and its methyl ester (CDODA-Me) are synthetic analogs derived from glycyrrhetic acid (GA), a triterpenoid natural product found in licorice. While GA and several unsubstituted analogs exhibited minimal cytotoxicity to Ku7 and 253J-BV bladder cancer cells, IC50 values for growth inhibition by CDODA were < 5 μ M (both cell lines) and, by CDODA-Me, were 1.0 and < 0.5 μ M, respectively. Both cell lines were used as models for investigating the effects of CDODA-Me, the most active analog, on inducing growth inhibitory and proapoptotic pathways in bladder cancer cells. CDODA-Me activated peroxisome proliferator activated receptor γ (PPAR- γ) in transactivation assays; however, most of the responses induced by CDODA-Me were not inhibited by PPAR γ antagonists. CDODA-Me did not induce expression of p21 or p27 whereas cyclin D1 expression was downregulated in both cell lines. The tumor suppressor gene caveolin-1, which is induced in colon cancer cells by PPAR γ agonists, was decreased in 253J-BV cells treated with 0.1-1.0 μ M CDODA-Me and the high constitutive expression of caveolin-1 in this cell line was totally suppressed in cells treated with 1.0 μ M CDODA-Me. In contrast, there was neither induction nor suppression of caveolin-1 in Ku7 cell lines. CDODA-Me also induced the proapoptotic nonsteroidal anti-inflammatory drug activated gene-1 (NAG-1) and caspase-dependent PARP cleavage in both cell lines, and downregulation vascular endothelial growth factor (VEGF) was also observed. The mechanisms associated with these proapoptotic/antiangiogenic effects of CDODA-Me in bladder cancer cells is currently being investigated. (Supported by NCI CA112337)

1874 GLYCYRRHETINIC ACID DERIVATIVE INHIBIT PANCREATIC CANCER CELL GROWTH THROUGH ACTIVATION OF MULTIPLE PATHWAYS.

I. Jutooru¹, S. Chintharlapalli², S. Papineni², G. Chadalapaka¹ and S. Safe^{1,2}
¹Veterinary Physiology & Pharmacology, Texas A&M University, College Station, TX and ²Institute of Biosciences & Technology, Texas A&M Health Science Center, Houston, TX.

Glycyrrhetic acid (GA), a triterpenoid found as a glycoside conjugate in licorice, exhibits a broad spectrum of therapeutic properties. GA exhibited minimal cytotoxicity to pancreatic cancer cells. The IC₅₀ values for inhibition of Panc1 pancreatic cancer cell growth by a synthetic derivative 3,11-dioxo-18 β -oleana-1,12-dienoic acid (DODA) and its methyl ester (DODA-Me) were >40 and >15 μ M, respectively. In contrast, IC₅₀ values for 2-cyano-3,11-dioxo-18 β -oleana-1,12-dienoic acid (CDODA) and its methyl ester (CDODA-Me) were 2.5 and 1.0 μ M in Panc1 and 5.0 and 1.0 μ M in Panc28 cells, respectively. The growth inhibitory effects of CDODA and CDODA-Me were paralleled by their proapoptotic activity which included activation of caspase-dependent PARP cleavage. We also observed that both CDODA-Me and CDODA, but not DODA or DODA-Me, activated peroxisome proliferator-activated receptor γ (PPAR γ) in pancreatic cancer cells transfected with a PPAR γ -GAL4 chimera and a pGAL4-Luc construct which contains 5 yeast GAL4 response elements linked to luciferase. Using the more potent CDODA-Me as a model, the proapoptotic and growth inhibitory effects and the role of PPAR γ in mediating these responses was further investigated. CDODA-Me induced p21 and p27 and downregulated cyclin D1 protein expression in Panc28 cells; however, cotreatment with PPAR γ antagonists did not affect these responses. We also observed that CDODA-Me affected additional receptor-independent responses associated with apoptosis and these included induction of glucose related protein 78 (endoplasmic reticulum stress), non-steroidal anti-inflammatory drug activated gene-1 (NAG-1), and activating transcription factor 3 (ATF3). This study has identified a novel cytotoxic triterpenoid acid (CDODA) derived from GA that activates PPAR γ and induces a diverse spectrum of receptor-independent proapoptotic and growth inhibitory pathways. (Supported by NCI CA112337)

1875 CAN A SINGLE EXPERIMENTAL MODEL PREDICT THE RESPIRATORY SENSITIZATION POTENTIAL OF CHEMICALS AND PROTEINS?

J. Hotchkiss. *Respiratory Toxicology, The Dow Chemical Company, Midland, MI.*

The prevalence of asthma in the United States appears to have substantially increased during the past two decades. While progress has been made in the control of asthma, complete remission is uncommon. One potential control strategy, therefore, is to minimize exposure to xenobiotics with the potential to induce allergy and asthma. Implicit in the concept of reducing exposure is the ability to identify the proteins and chemicals with the potential to induce asthma and airway hyperreactivity in humans. The development of animal models of asthma has paralleled our interest in and our understanding of the pathogenesis of the human disease. Each model has its strengths and weaknesses and many were developed to examine specific aspects of the human disease by exploiting unique characteristics of the experimental species. This roundtable will examine current in vitro and in vivo experimental models in light of their ability to identify chemicals and proteins with the potential to induce asthma and respiratory sensitization in humans. The goal of the roundtable is to identify the key attributes that a robust, predictive, experimental model of respiratory sensitization must have and use this framework to evaluate current models, identify knowledge gaps, and propose a path forward to a consistent, predictive testing strategy. This roundtable should be of interest to experimental respiratory- and immuno-toxicologists investigating asthma and respiratory sensitization induced by chemicals and proteins as well as individuals involved with pharmaceutical, agrochemical, and biotechnology development, human risk assessment, and product regulation and registration.

1876 K-12 EDUCATION: INVESTING IN THE FUTURE OF TOXICOLOGY.

S. C. Fitzpatrick¹ and D. Cragin². ¹Office of the Commissioner, FDA, Rockville, MD and ²Merck, Whitehouse Station, NJ.

Today's young students face a world of increasing global competition. To maintain the US pre-eminence in science, scientific organizations such as the Society of Toxicology must foster innovation in K-12 science. Experienced scientists wish to get involved in enhancing opportunities for young students to actively participate in toxicology but often they don't know where to begin. This symposium will focus on the many opportunities and resources available for toxicologists to enable them to make a difference in our future generation of scientists by introducing them to the exciting world of toxicology.

1877 THE IMPORTANCE OF K-12 ACTIVITIES TO THE FUTURE OF SOT.

K. Wallace. *University of Minnesota, Duluth, MN.*

SOT's goals is to be the leading global force in enhancing human, animal, and environmental health through the science of toxicology. To help achieve this goal, SOT must look at new and creative ways to enhance opportunities for young students to actively participate in toxicology. Engaging students early in their K-12 years will help recruit talented students into the field of toxicology.

1878 OUTSOURCING, OFFSHORING, AND OCCUPATIONS IN A GLOBAL ECONOMY: THE CASE FOR IMPROVING K-12 SCIENCE EDUCATION.

B. Fuchs. *National Institutes of Health, Bethesda, MD.* Sponsor: S. Fitzpatrick.

To remain competitive in the 21st century, science education will become increasingly important to America. International surveys show that middle school and high school students in America rank near the bottom in terms of math and science knowledge. Yet, the creation of new scientists and engineers is key to the future growth of the American economy. Motivating middle school and high students to become scientists will help meet this need.

1879 PLANNING K-12 OUTREACH EVENTS - 'NUTS AND BOLTS' OF WHAT YOU CAN DO.

S. Wild. *Amgen, Inc., Thousand Oaks, CA.*

The K-12 committee will share its experiences in planning a K-12 Outreach Event with practical tips, lessons learned, and ideas for future outreach. The committee will share experiences from the 2006 SOT "Paracelsus Explores the Genome: Toxicology Advances Health" and provide information on partnering with existing institutions, utilizing their expertise, and planning a successful event.

1880 TIPS FOR KEEPING YOU COOL IN A K-12 CLASS: DO, DON'TS, AND TOOLS.

S. Gilbert. *Institute of Neurotoxicology & Neurological Disorders, Seattle, WA.*

Volunteering to share your knowledge of toxicology with K-12 students is one of the personally most rewarding endeavors we can do and it serves to increase science education. Obviously there are different requirements depending on the grade level but all the students want to hear what it is like to be a scientist. It is important to check with the teacher on how to fit your material into the topics they are covering. This presentation will cover some practical do and don'ts in K-12 teaching and review some useful tools.

1881 INTRODUCTION.

T. T. Kawabata. *Pfizer Research and Development, Groton, CT.*

You've completed your post-doctoral training and landed your first job. After many dedicated years in graduate school and as a post-doctoral fellow, you now have the scientific knowledge and technical skills needed to get the job done and you are ready to hit the ground running. However, there are many other important skills you need to learn. Whether your new job is in academia, government or industry, you just can't focus on the science. You need to be aware of the many planning and people skills needed to be successful in your new job.

1882 PLANNING FOR SUCCESS AND CAREER SATISFACTION.

H. M. Mehendale. *Department of Toxicology, University of Louisiana at Monroe, Monroe, LA.*

Regardless of whether one chooses a career in the private sector, academia or government, planning and preparing for success and career satisfaction must begin very early. First, you need to identify your strengths, weaknesses, likes and dislikes in order to plan your career path and to assess the skills that need to be developed. For example, if you like to work with and develop people, you may direct your career toward management or as a research advisor. Secondly, one needs to consider the

practical aspects of career choices. Should one specialize in a specific area or be broader for greater flexibility and employability? Should you stay with one employer or move between them? Personal factors such as geography, work-life balance and salary should also be taken into consideration. Third, when developing these plans, it is important to seek advice from others. This includes networking with colleagues and working with mentors. Finally, changes that alter your career path are to be expected. Those with personal resilience and flexibility will be able spot opportunities, recharge, and develop necessary new skills, thereby maintaining a high level of career satisfaction and employability.

1883 THE IMPORTANCE OF PEOPLE AND LEADERSHIP SKILLS IN CAREER SUCCESS.

W. D. Pennie. *Drug Safety Research and Development, Pfizer Research and Development, Groton, CT.* Sponsor: T. Kawabata.

To be successful in your career you must develop skills to lead and work with people in many different situations. For many people, the development of these skills are pushed aside for higher priority issues. However, they soon encounter difficult situations with their staff, colleagues and supervisors that they are not equipped to handle. One of the most important skills that should be a key focus is effective communication. This involves developing listening and interactive approaches. A good understanding of individual and cultural differences will help increase collaborations. One must also learn how to assert yourself in certain situations and be able to resolve conflicts. These techniques will be very important when working in teams and facilitating meetings throughout your career. Leadership of technical staff and projects should also be a key development area for all scientists throughout their career. A good leader provides vision and goals, energizes the team, knows how to best utilize each individuals abilities and is willing to change the status quo when needed. It is not true that certain people are just born with these skills, these skills can be developed and must be reinforced throughout your career.

1884 CHEMICAL MIXTURES: IS THE 'PROBLEM' SOLVABLE?

J. Simmons. *NHEERL/ORD, U.S. EPA, Research Triangle Park, NC.*

The potential human health risk(s) associated with exposure to multiple chemicals, either concurrently or sequentially, has been an open question for many years. Solving the mixtures problem is of considerable importance as there are economic costs of assuming increased risk due to chemical mixtures when none exists and human health costs of assuming no increased risk if, in fact, such risk exists. Historically, advances in understanding mixtures has been limited by a variety of factors, including the astronomical number of combinations of chemicals and the inability to conduct the extremely large experiments required by traditional full-factorial designs for mixtures of several chemicals. Progress has been made with regard to experimental designs that require fewer dose groups, detection of departure from dose- and response- additivity, and methods for analyzing and modeling mixture response. This Roundtable will address whether recent advances have given us the necessary tools and the knowledge base needed to 'solve' the mixtures problem. The purpose is to bring together experts to examine important questions whose answers will advance our understanding of the potential human health risk posed by exposure to mixtures and recent advances in knowledge gained by use of techniques, methods and models developed and applied over the past decades. The objective is open discussion aimed at stimulating thinking in this very important area of science. (This abstract may not reflect EPA policy.)

1885 HOW DO WE EVALUATE AND IMPROVE NONMECHANISTIC MIXTURE RISK FORMULAS?

R. Hertzberg. *Consultant, Atlanta, GA.* Sponsor: J. Simmons.

Formulas for mixture risk assessment in use by regulatory agencies and related groups based on the mixture component chemicals are conceptually simple and require few data resources. For example, both the standard and interaction-based hazard index formulas of the U.S. EPA are roughly based on the classical formula of dose addition. Attempts to support dose addition with biological arguments such as Finney's concept of simple similar action have advanced the understanding of mixture risk formulas only to a limited degree. This presentation will examine quantitative methods for direct evaluation of existing risk formulas that involve tight definitions, bounding simplifications, statistical applications with nested mixture data, and comparison with more biologically based mixture models.

1886 HOW CAN PHARMACOKINETIC AND PHARMACODYNAMIC MODELING BE USED TO UNDERSTAND OBSERVED INTERACTIONS?

N. J. Waker. *NTP, NIEHS, Research Triangle Park, NC.*

The dioxin Toxic Equivalency Factor (TEF) approach is currently used worldwide for assessing and managing the risks posed by exposure to mixtures of polychlorinated dibenzodioxins (PCDDs), dibenzofurans (PCDFs) and biphenyls (PCBs). While the TEF approach is only applied to dioxin-like PCBs (non-ortho and mono ortho substituted PCBs), previous studies have shown the potential for interactions between different classes of PCBs for nonneoplastic responses. Analyses from studies conducted by the National Toxicology Program evaluating dose additivity of effects for dioxins and interactions between dioxin-like and nondioxin-like PCBs for carcinogenic responses support the TEF methodology for additive risk when based on administered dose. Given the use by the USEPA of body burden as a dose metric for dioxin like compounds, there is a need to evaluate this approach using internal dose metrics. Using tissue data from the NTP studies we have developed an integrated pharmacokinetic and pharmacodynamic model for dioxin like compounds for the assessment of the relative potency of these compounds using different internal dose metrics.

1887 ARE GENOMIC DATA USEFUL FOR UNDERSTANDING CHEMICAL INTERACTIONS IN TOXICITY STUDIES?

J. Groten. *TNO, Zeist, Netherlands.* Sponsor: J. Simmons.

In the area of combination toxicology, toxicogenomics enables the study of the combinatorial effects of chemicals at the molecular level without a priori knowledge on the possible mechanisms of action. Although the number of published toxicogenomics studies on single compounds outweighs that on chemical mixtures or combined exposures, the first studies on complex chemical mixtures using genomics approaches have appeared in the literature. This talk summarizes results of studies with mixtures of chemicals to compare toxicity end-points or biomarkers in laboratory animals making use of a systems toxicology approach. One of the research projects deals with hazard identification and risk assessment of a quaternary mixture of pollutants (methyl mercury, lead, benzene, and trichloroethylene). PBPK-models of the four individual compounds are used to translate the dosing regime in experimental animals and this modeling approach will be used to distinguish interactions at the toxicokinetic level from interactions at the toxicodynamic level and to compare conventional toxicological assessment with toxicogenomic parameters.

1888 IS CHEMICAL MIXTURE TOXICOLOGY PREDICTABLE?

R. S. Yang. *Colorado State University, Colorado Springs, CO.*

Predicting the toxicity of chemical mixtures is one of the most important issues facing toxicologists today. This issue is significant because there are not enough resources to keep on conducting toxicity testing on the single chemicals in commerce, let alone chemical mixtures. Further, the number of deaths due to adverse drug reactions from multiple drug treatments is alarmingly high and we currently have limited means to deal with it. Developed and advanced in our laboratory, biochemical reaction network modeling, and its possible integration with physiologically based pharmacokinetic modeling, provides a ray of hope in helping us to address the complex issue of toxicity prediction. This presentation will briefly outline our approach, the progress, and future perspective.

1889 IMPLICATIONS OF JOINT TOXICITY AND RISK ASSESSMENT TO PUBLIC HEALTH.

M. Mumtaz. *Division of Toxicology and Environmental Medicine, ATSDR, Atlanta, GA.*

Ideally, toxicity assessments must represent summation and conclusion of all available epidemiological, experimental, animal and human data of a chemical or its mixtures and the potential risk such exposures pose to the public. Qualitative, and if data lend themselves, quantitative conclusions are made through the process of exposure assessment, hazard identification, dose response assessment, leading to risk characterization. In turn, such conclusions serve as the basis of decision making for controlling releases of contaminants in the environment. This process has served well for the protection of general populations. However, because of lack of data, certain uncertainties are part of these toxicity estimates. Apart from these known uncertainties, a major challenge is to address the issue of susceptible populations that are age, body burden or polymorphisms dependent. A renewed interest

in the process of hormesis and the role of tissue repair/injury pose additional challenges to this practice of toxicology. We have to prioritize research to diminish the uncertainties and increase the accuracy in such toxicity estimates. The evaluation of these processes and their role at low level exposures will be discussed in this talk.

1890 UROPORPHYRIN ACCUMULATION IN MOUSE LIVER EXPRESSING EITHER MOUSE OR HUMAN CYP1A2: RELATIONSHIP OF CYP1A2 LEVELS TO HUMAN PORPHYRIA CUTANEA TARDA.

N. A. DRAGIN¹, N. Gorman², P. R. Sinclair², D. W. Nebert¹ and T. P. Dalton¹.
¹Environmental Health, University of Cincinnati, Cincinnati, OH and ²VA Medical center, Dartmouth, White River Junction, VT.

Polychlorinated biphenyls (PCBs) are ubiquitous environmental contaminants that cause cancer, immunosuppression, and act as endocrine disruptors. PCB-induced CYP1A2 results in inhibition of uroporphyrinogen decarboxylase and oxidation of uroporphyrinogen to uroporphyrin (URO); the result is an increased rate of URO formation (uroporphyria) and hepatic tumors in laboratory animals. In mice, CYP1A2 is absolutely required for developing uroporphyria; *Cyp1a2*(-/-) knockout mice treated with PCBs, polycyclic aromatic hydrocarbons, or dioxin never show any detectable URO accumulation in the liver, blood or urine. Humans show >60-fold genetic differences in liver basal CYP1A2; however, the involvement of CYP1A2 in clinical uroporphyria (porphyria cutanea tarda) is unclear. We compared two BAC-transgenic mouse lines, carrying hCYP1A2 and hCYP1A1 in the absence of mCYP1A2 [*hCYP1A1_1A2/mCyp1a2*(-/-)] or carrying hCYP1A2 and hCYP1A1 in the absence of mCYP1A1 [*hCYP1A1_1A2/mCyp1a1*(-/-)], with wild-type mice [*mCyp1*(+/+)]. We induced uroporphyria by pretreatment with Fe-dextran, a 75 µg/kg PCB126 injection, and 5-aminolevulinic acid in the drinking water for 4 and 8 weeks. The *mCyp1*(+/+) and *hCYP1A1_1A2/mCyp1a1*(-/-) mice accumulated URO at 4 and 8 weeks, whereas *hCYP1A1_1A2/mCyp1a2*(-/-) showed no detectable URO levels at 4 or 8 weeks. On the other hand, hepatic acetanilide 4-hydroxylase activity and hCYP1A2 mRNA and protein were 1.5- to 2-fold higher in *hCYP1A1_1A2/mCyp1a2*(-/-) than in *hCYP1A1_1A2/mCyp1a1*(-/-) mice. We conclude that, in the absence of mouse CYP1A2, human CYP1A2 appears to be normally expressed yet, in the protocol used here, did not support URO accumulation. —Supported in part by NIH grants R01 ES008147, R01 ES014403, and P30 ES06096; and Dept of Veteran's Affairs.

1891 TRANSGENIC MICE OVEREXPRESSING THE HUMAN CYTOCHROMES P450 (CYP)1A1 OR 1A2 GENE PROMOTERS DISPLAY ENHANCED SUSCEPTIBILITIES TO HYPEROXIC LUNG INJURY *IN VIVO*.

B. Moorthy¹, L. Wang¹, R. Barrios², X. Couroucli¹ and W. Jiang¹. ¹Pediatrics, Baylor College of Medicine, Houston, TX and ²Pathology, The Methodist Hospital, Houston, TX.

Supplemental oxygen therapy is often required for the treatment of infants having pulmonary insufficiency. However oxygen therapy contributes to bronchopulmonary dysplasia (BPD) in infants. Recent studies have suggested a role for cytochrome P450 (CYP)1A enzymes in hyperoxic lung injury in rodents. Here, we tested the hypotheses that (i) induction of CYP1A1/1A2 expression by hyperoxia *in vivo* is mediated by transcriptional activation of the corresponding genes; and (ii) transgenic overexpression of CYP1A1 or 1A2 gene promoters in mice would alter their susceptibility to oxygen-mediated lung injury *in vivo*. Twelve week-old male wild type (WT) (CD-1) or transgenic mice expressing the human CYP1A1 (CYP1A1-luc) or 1A2 (CYP1A2-luc) gene promoters and the reporter luciferase gene were exposed to hyperoxia (greater than 95% O₂) or room air for 24-72 h. Luciferase expression was determined *in vivo* by bioluminescent imaging. Endogenous pulmonary and hepatic CYP1A1/1A2 enzyme activities, apoprotein contents, and mRNA levels were also determined. The CYP1A2-luc as well as CYP1A1-luc mice were more susceptible to lung damage than similarly exposed WT animals, with 1A2-luc mice being the most sensitive. Forty-eight hours of hyperoxia caused significant (2-4-fold) increases in luciferase expression in the CYP1A1-luc and CYP1A2-luc animals, compared to WT animals. Luciferase induction declined by 72 h. The transgenic animals were refractory to induction of endogenous CYP1A1/1A2 expression by hyperoxia. Our results indicate that induction of CYP1A1/1A2 expression by hyperoxia *in vivo* is mediated by transcriptional activation of the corresponding genes. The lack of induction of endogenous CYP1A1/1A2 by hyperoxia in the CYP1A1-luc and 1A2-luc mice may have contributed to the increased susceptibilities of these mice to hyperoxic lung injury, suggesting that these enzymes play protective roles against oxygen-mediated injuries. (Supported by NIH grant ES009132 and HL070921.)

1892 CYTOCHROME P450 1 GENE EXPRESSION IN ZEBRAFISH, *DANIO RERIO* ADULTS AND EMBRYOS.

E. E. Jönsson, B. R. Woodin, J. V. Goldstone and J. J. Stegeman. *Biology, WHOI, Woods Hole, MA.* Sponsor: M. Hahn.

Effects of planar halogenated AH receptor agonists (e.g., non-ortho-substituted polychlorinated biphenyls - PCBs; polychlorinated dibenzo-*p*-dioxins) largely involve AHR regulated genes. Fish exhibit greater sensitivities to developmental defects caused by these chemicals than do mammals, which may involve differences in expression of multiple *CYP1* genes (*CYP1A*, *1B1*, *1C1*, and *1C2*). We cloned *CYP1C2* and examined expression of the *CYP1* complement in zebrafish, *Danio rerio*. Cloned *CYP1C2* exhibits a 78% amino acid identity with zebrafish *CYP1C1* and has several dioxin response elements in the proximal promoter region. Adult and embryonic (8 hpf) zebrafish were exposed to 100 nM 3,3',4,4',5-PCB (PCB126) or 20 ppm acetone (vehicle control) for 24 h and then held in clean water for 24 and 48 h, respectively. The *CYP1* genes were expressed in control embryos and in all examined organs (eye, gill, heart, liver, kidney, brain, gut, and gonads) in control adults. The highest basal expressions in adults were observed in liver (*CYP1A*) and in heart and eye (*CYP1B1*, *1C1*, and *1C2*). PCB126 induced *CYP1A* in all organs, *CYP1B1* in eye, gill, heart, liver, kidney, and brain, and *CYP1C1* in eye, gill, heart, liver, and kidney, whereas *CYP1C2* was not induced significantly in any organ examined. In embryos (80 hpf) both *CYP1C1* and *1C2* tended to have a higher basal expression than *CYP1A* and *CYP1B1*, and all four genes were strongly induced by PCB126. The results indicate that the two *CYP1C* genes are AHR regulated. Patterns of *CYP1C* expression suggest that these genes play roles in zebrafish during their whole lifespan, as both genes were present in embryo controls and in all organs examined in control fish. The two genes may have distinctive functions, however, as *CYP1C1* was induced by PCB126 in several organs, while *CYP1C2* was not induced in any adult organ. Furthermore, the difference in inducibility of *CYP1C2* in embryos and adults suggests that *CYP1C2* may play different roles in embryonic and adult fish. (The Swedish Research Council Formas; NIH P42-ES07381; EPA R827102; NIH 1 F32 ES012794)

1893 COMPARISON OF *IN VITRO* PHASE I AND II METABOLIC ACTIVITY ASSAYS BETWEEN RAINBOW TROUT (*ONCORHYNCHUS MYKISS*) AND HUMAN HEPATIC MICROSOMES AND S9 FRACTIONS.

K. M. Johanning¹, J. Stover¹, W. Jason¹, L. Easterwood¹, C. Black¹, L. Schultz², J. Hill¹ and J. Sahi¹. ¹CellDirect Inc., Austin, TX and ²Battelle Pacific Northwest National Lab., Sequim, WA.

Phase I (e.g. cytochrome P450-mediated oxidation and demethylation) and Phase II (e.g. sulfotransferase and UDP glucuronosyltransferase) drug metabolizing enzymes mediate the biotransformation of xenobiotics in both mammalian and aquatic species (i.e. fish). Assessment of the bioaccumulation of environmental contaminants can be achieved utilizing metabolism in model organisms such as rainbow trout. Metabolic turnover can be predicted by *in vitro* assays with isolated liver fractions. However, metabolic enzymes in trout liver are not well characterized. The goal of this study is to compare Phase I and II drug metabolizing activities in liver microsomes and S9 fractions from rainbow trout (*Oncorhynchus mykiss*) and humans. Microsomes and S9 fractions were prepared from both isogenic and hatchery-reared rainbow trout livers (age: two years) using standard protocols. The human liver subcellular fractions were pooled from 15 donors. Phase I drug metabolizing enzymes were measured for EROD (ethoxresorfin deethylase) and testosterone hydroxylation activities and Phase II drug metabolizing enzyme activities were measured for sulfotransferase (ST) and UDP glucuronosyltransferase (UGT). The incubations were performed at pH 7.8 and 25 °C, conditions which are optimal for *in vitro* metabolic activity for trout liver fractions. Metabolic activities for isogenic and hatchery-reared trout liver fractions showed similar activities which were lower (>2 fold) than corresponding human activities. These results will aid in the development of standard conditions for assessment of *in vitro* metabolism in trout and in the application of trout metabolic activities for the assessment of bioaccumulation potential of environmental compounds.

1894 GENETIC MAP OF THE CYTOCHROME P4501A5 GENE ASSOCIATED WITH AFLATOXIN B1 HYPERSENSITIVITY IN THE TURKEY (MELEAGRIS GALLOPAVO).

R. A. Coulombe¹ and K. M. Reed². ¹Department of Veterinary Sciences and Graduate Toxicology Program, Utah State University, Logan, UT and ²Department of Veterinary and Biomedical Sciences, University of Minnesota, St. Paul, MN.

Turkeys are the most susceptible animals to the toxic effects of the mycotoxin aflatoxin B1 (AFB1). This was graphically demonstrated by "Turkey X Disease" which caused widespread deaths of turkeys and other poultry throughout Europe in the

1960s, later shown to be caused by AFB1-contaminated feed. For toxicity, AFB1 requires metabolic activation by hepatic cytochromes P450 (CYP) which convert it to the reactive and electrophilic intermediate, the AFB1-8,9-epoxide (AFBO), which then binds to DNA and other critical macromolecules. We recently cloned CYP1A5 from turkey liver, the heterologously-expressed protein from which had high AFB1 bioactivation activity (high V_{max} , low K_m), which is inhibited by prototype CYP1A inhibitors, and by phenolic antioxidants. This supports our previous work showing that the mechanism of aflatoxicosis chemoprevention in turkeys by dietary antioxidants is by inhibition of the hepatic form of this enzyme. Comparative genomic approaches were used to selectively amplify and sequence the introns and 3' flanking region of CYP1A5. The architecture of CYP1A5 was found to be equivalent to human CYP1A1 with seven exons of 38, 858, 127, 90, 124, 87 and 307 bp, respectively, and six introns. A single nucleotide polymorphism in the 3' untranslated region (UTR) was used to genetically map CYP1A5 to turkey linkage group M16 (equivalent to chicken chromosome 10). The results of this study provide the framework for identifying allelic variants of this important CYP gene in poultry, and may represent a useful strategy to identifying AFB1-resistance traits in poultry.

1895 BRAIN CYTOCHROME P450 ISOFORMS EXPRESSION IN RATS EXPOSED TO DDT.

H. Osorio-Alonso¹, L. M. Lopez-Gonzalez² and A. Sierra-Santoyo². ¹Nephrology, Instituto Nacional de Cardiología Ignacio Chavez, Mexico City, D.F., Mexico and ²Toxicology Section, CINVESTAV-IPN, Mexico City, D.F., Mexico.

DDT is an endocrine disruptor and a cytochrome P-450 (CYP) inducer. CYP-dependent metabolism is regulated by age, gender and tissue. Information about the effect of DDT on expression CYP isoforms in extrahepatic tissues is limited. The objective of this study was to determine the effect of DDT on CYP isoforms levels in rat brain. Wistar adult male rats (200±20 g) were administered with single oral doses of DDT technical grade (0.1, 1, 5, 10 and 100 mg/kg) dissolved in corn oil. Animals were sacrificed 24 h later and brain removed and processed to obtain microsomes. CYP1A1, 2B, 2A, 2C11, 2E1, 3A2 and 4A1 were assessed by Western blot analysis. DDT produced a biphasic dose-dependent response in brain CYP levels. An inductive effect in the majority of the isoforms was observed in the range of 0.1 to 5 mg/kg. At the lowest dose of DDT (0.1 mg/kg) the maximum inductive effect (70%) was detected in CYP1A1, 2A and 4A1 levels. CYP2B, 2E1 and 3A2 levels increased in a dose-dependent manner and the maximum effect was at 5 mg/kg (2-fold). On the contrary, at 10 and 100 mg DDT/kg CYP isoforms expression levels drastically decreased, representing less than 40% of levels in the non-treated group. CYP2C11 levels decreased dose-dependent in a manner at all DDT doses. These results indicate that exposure to single DDT doses may modify brain metabolism of xenobiotics and endogenous substrates, and that such effects on CYP expression are dose-dependent. They also suggest that the selective effect on brain CYP expression may represent an endocrine disruption mechanism.

1896 MODIFICATION OF CYTOCHROME P450 3A4 METABOLISM OF NAPHTHALENE AND 17 β -ESTRADIOL BY ORGANOPHOSPHORUS COMPOUNDS.

T. M. Cho, R. L. Rose and E. Hodgson. *Environmental & Molecular Toxicology*, North Carolina State University, Raleigh, NC.

Cytochrome P450 (CYP) 3A4 is the most abundant monooxygenase in human liver and small intestine, and is the primary contributor to the phase I metabolism of both endogenous and exogenous substrates. Due to its abundance and broad spectrum of metabolic activity, CYP3A4 frequently causes a significant impact on the bioavailability of clinical drugs, thus a modification of the metabolic activity of the enzyme by inhibitors or activators may affect the safety and efficacy of such drugs or the toxicity of other xenobiotics. In the current studies, we examined the metabolic modification of CYP3A4 metabolism of naphthalene and 17 β -estradiol (E_2) by chlorpyrifos-oxon (CPO) and chlorpyrifos (CPS). CYP3A4 metabolism of naphthalene was significantly activated by preincubation of the enzyme with CPO, in a dose-dependent manner. V_{max} and K_m for naphthalene metabolism by CYP3A4 were significantly increased and decreased, respectively as the concentration of CPO preincubated with the isoform was increased, indicating that CPO bound to the enzyme appears to facilitate the binding of naphthalene to CYP3A4. This activation was independent of cytochrome b_5 , indicating that the metabolic activation was probably facilitated by conformational changes of the enzyme rather than stimulation of electron transfer from cytochrome b_5 . The CYP3A4 metabolism of E_2 was significantly inhibited by CPS in a concentration- and time-dependent manner. The inactivation rate constant (k_{inact}) and the inhibitor concentration required for half-maximal rate of inactivation (K_i) were 0.3 min⁻¹ and 4.9 μ M, respectively. This irreversible inhibition of E_2 metabolism by CYP3A4 is believed to be due to the sulfur atom released from CPS during CPO formation. These studies

support the hypothesis that the binding site of CYP3A4 can hold multiple substrates and that the metabolic activity of the enzyme can be modified by the first molecule bound to the enzyme.

1897 EFFECTS OF PUERARIA MIRIFICA SUBCHRONIC EXPOSURE ON HEPATIC CYTOCHROME P450 IN RATS FED WITH NORMAL- AND HIGH CHOLESTEROL DIET.

S. Lawanprasert¹, L. Phivthong-ngam², S. Srichairat³, N. Niwattisaiwong¹, K. Charoenkul¹ and C. Chaichantipyuth¹. ¹Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, Thailand, ²Faculty of Medicine, Srinakharinwirot University, Bangkok, Thailand and ³Faculty of Veterinary Sciences, Chulalongkorn University, Bangkok, Thailand. Sponsor: L. Robertson.

Pueraria mirifica Airy Shaw and Suvatabandhu, known locally as White Kwao Keur, is a plant in family Leguminosae. In this study, effects of P.mirifica on hepatic cytochrome P450 (CYP) were investigated in male Wistar rats. Rats were randomly divided into four treatment groups as following: normal diet-fed group; normal diet-fed supplemented with P.mirifica group; high cholesterol diet-fed group; high cholesterol diet-fed supplemented with P.mirifica group. Each group comprised 10 rats. P.mirifica was administered orally at a dosage of 100 mg/kg/day for 90 consecutive days. At the end of the treatment, animals were anesthetized. Microsomes were prepared from the livers for enzyme assays. The results showed that P.mirifica significantly inhibited CYP2B1&2B2 in either normal diet or high cholesterol diet-fed rats. Its inhibitory effect of CYP1A2 and CYP2E1 was found only in normal diet-fed rats. No effect of P.mirifica was found on CYP1A1 and CYP3A. Inhibitory effects of P.mirifica on CYP2B1&2B2 and CYP2E1 were also found in the in vitro study. Inhibitory effects of P.mirifica on CYP1A2, CYP2B1&2B2 and CYP2E1 indicated a beneficial potential of this plant regarding the chemical-induced carcinogenesis while providing a possible potential information of this plant regarding drug-drug interaction with other medicines that are metabolized by these CYPs. Effects of P.mirifica at various doses as well as the mechanism of these effects should be further investigated. Effects of P.mirifica on human CYP should also be explored.

1898 CYP2E1 KNOCKOUT MICE ARE PROTECTED FROM THIOACETAMIDE-INDUCED LIVER INJURY.

J. Chilakapati¹, M. C. Korrapati¹, J. R. Latendresse² and H. M. Mehendale¹. ¹Toxicology, The University of Louisiana at Monroe, Monroe, LA and ²Pathology Associates International, NCTR, Jefferson, AR.

Thioacetamide (TA), a model hepatotoxicant, is bioactivated to TA sulfoxide (TASO), and further to the highly reactive sulf dioxide (TASO₂), that initiates hepatic necrosis by covalent binding. Although the mechanism by which TA initiates liver injury has been well understood, the specific enzymes responsible for the bioactivation of TA in rats had not been identified for a long time. Studies by Wang et al. (2001) using specific CYP2E1 inducer, isoniazid, and inhibitor diallyl sulfide, suggested a major involvement of CYP2E1 in TA bioactivation. The objective of the current study was to further investigate the role of CYP2E1 in TA bioactivation. We employed male cyp2e1 knockout mice (KO) in a 129SV background for this purpose. Liver injury was assessed over a time course (0 to 48 h) in wild type (WT) and cyp2e1 KO mice after administration of a LD100 dose (500 mg TA/kg dose, ip) in WT mice. The cyp2e1 KO mice were completely protected from TA liver injury as assessed by ALT, AST and liver histopathology when compared with the WT mice. The cyp2e1 KO mice exhibited neither initiation nor progression of any liver injury. As expected, the WT mice (Cyp2e1^{+/+}) showed marked liver injury leading to liver failure and mortality. These findings provide confirming evidence in support of previous conclusions that CYP2E1 is the enzyme responsible for bioactivation of TA.

1899 MECHANISMS OF ETHANOL-MEDIATED INDUCTION OF THE RENAL 1, 25-DIHYDROXYVITAMIN D3-24-HYDROXYLASE (CYP24A1).

K. Shankar^{1,3}, X. Liu^{1,3}, T. M. Badger^{2,3,1} and M. J. Ronis^{1,3}. ¹Department Pharmacology & Toxicology, University of Arkansas for Med. Sciences., Little Rock, AR, ²Department Physiology & Biophysics, University of Arkansas for Med. Sciences, Little Rock, AR and ³Arkansas Children's Nutrition Center, Little Rock, AR.

Chronic ethanol (EtOH) consumption via total enteral nutrition leads to the disruption of vitamin D3 (VD) homeostasis. Serum levels of 1,25-(OH)₂VD are in part regulated by the 1,25-(OH)₂VD-24-hydroxylase (CYP24A1) which mediates its conversion into inactive calcitriol. EtOH consumption induced the mRNA, protein and gene transcription (hnRNA) of CYP24A1. In the present work, we explore the underlying mechanisms of how EtOH mediates the induction of

CYP24A1 using *in vitro* systems. Dose (50 – 100 mM EtOH) and time-course (0–48 h) studies with rat primary renal proximal tubule cells (RPTC) revealed ~6-fold induction of the CYP24A1 mRNA levels at 24 h with 50 mM EtOH. Both hnRNA and protein levels of CYP24A1 were also increased following EtOH treatment. Induction of CYP24A1 was only partially blocked by 4-methyl pyrazole suggesting that at least part of the induction may be directly mediated by EtOH. However, CYP24A1 induction by EtOH was completely abolished by cycloheximide suggesting the requirement of new protein synthesis. Further, we investigated the roles of specific MAP kinases in EtOH mediated induction of CYP24A1. Both p38 MAPK inhibitor (SB203580) and MEK1 inhibitor (U0126) but not the MAPKK inhibitor (PD98059) completely mitigated EtOH effects on CYP24A1. EtOH treatment also increased production of reactive oxygen species (ROS) in RPTCs and treatment of cells with different doses of H₂O₂ also led to induction (4 to 10-fold) of CYP24A1 mRNA. Finally, we examined the influence of EtOH on VD mediated induction of CYP24A1. We observed dramatic synergism in the induction of CYP24A1 (~125-fold) with co-treatment with VD and EtOH that themselves only caused 6 and 10-fold induction of the enzyme, respectively. In conclusion, our data show a novel regulation of CYP24A1 by EtOH presumably via increased p38 MAPK activation subsequent to EtOH-induced ROS production. Supported in part by R01AA012928 to MJJR.

1900 INHIBITION OF THE HUMAN METABOLISM OF FIPRONIL AND NONANE BY CHLORPYRIFOS.

H. Joo, K. Choi, R. L. Rose and E. Hodgson. *Toxicology, North Carolina State University, Raleigh, NC.*

Based on our previous studies, it has been established that chlorpyrifos (CPS), fipronil and n-nonane can all be metabolized by human liver microsomes (HLM) and a number of cytochrome P450 (CYP) isoforms. However, metabolic interactions between these three substrates have not been described. In this study the effect of either co-incubation or pre-incubation of CPS with either n-nonane or fipronil was investigated. In both co- and pre-incubation experiments CPS significantly inhibited the metabolism of n-nonane or fipronil by HLM although CPS inhibited the metabolism of fipronil more effectively than that of n-nonane. CPS significantly inhibited the metabolism of fipronil by CYP3A4 as well as the metabolism of n-nonane by CYP2B6. In both cases pre-incubation with CPS caused greater inhibition than co-incubation, suggesting that the inhibition is mechanism based.

1901 EFFECT OF CYTOCHROME P450 INHIBITOR 1-AMINOBENZOTRIAZOLE (ABT) ON THE PHARMACOKINETICS OF NIMODIPINE IN MALE SPRAGUE-DAWLEY RATS.

B. Chanas, K. Cook, C. Gambino and V. Ong. *Memory Pharmaceuticals Corp., Montvale, NJ.*

The purpose of this study was to evaluate the effect of broad spectrum and isozyme specific cytochrome P450 (CYP) inhibition on the pharmacokinetic parameters of nimodipine in male Sprague-Dawley rats. Nimodipine (NIM) is an L-type calcium channel antagonist known to undergo CYP-mediated oxidative metabolism in rat, presumably via isozymes CYP3A and CYP2D. Pretreatment with 50 mg/kg po ABT 2 hr prior to administering 10 mg/kg po NIM to fasted male Sprague-Dawley rats resulted in a greater than 200-fold increase in AUC_{0-24 hr} and 50-fold increase in C_{max} compared with sham pretreatment + NIM. Pretreatment with selective CYP3A inhibitors ketoconazole and bergamottin produced a more modest increase in AUC_{0-24 hr} (2-4 fold) and C_{max} (2-fold) of NIM. Pretreatment with 50 mg/kg po ABT 24 hr prior to and concurrent with 10 mg/kg po NIM to fed male Sprague-Dawley rats resulted in a greater than 40-fold increase in AUC_{0-24 hr} and 10-fold increase in C_{max} compared with sham pretreatment + NIM. ABT pharmacokinetic parameters were consistent with previously published reports and were not altered by NIM co-administration. Pre-dose and concurrent ABT treatments were also shown to significantly increase NIM in brain tissue concentration 24 hr post-administration. These data suggest that this model can be used to increase plasma exposure in pharmacokinetic and drug safety assessment studies of other dihydropyridines that undergo extensive CYP-mediated metabolism in rodents.

1902 TESTOSTERONE HYDROXYLASES IN EVALUATING INDUCTION OF CYTOCHROME P450 ISOENZYMES BY PERMETHRIN.

M. R. Martínez-Larrañaga, M. J. Díaz, V. Caballero, M. A. Martínez, J. del Pino, M. Martínez, I. Ares, I. Nieto and A. Anadón. *Department of Toxicology and Pharmacology, Faculty of Veterinary Medicine, Complutense University, Madrid, Spain.*

Pyrethroid insecticides are potent neurotoxicants to both insects and mammals. Although their acute neurotoxicity has been well characterized, information regarding the potential interaction with liver drug-metabolizing enzymes of this class of

compounds is limited. In this work, the effect of the pyrethroid Type I permethrin on hepatic cytochrome P-450 (CYP) activities was investigated. Steroid hydroxylase reactions, particularly reactions utilizing testosterone as substrate, have proved useful in characterizing the individual catalytic capacity of CYP. Testosterone hydroxylation at the 2 α -, 16 α -, 6 β -, 7 α -, and 16 β - positions was chosen as marker for CYP2C11, CYP3A1/2, CYP2A/2 and CYP2B1/2 activity. Groups of 6 male Wistar rats weighing 200 g were deprived of food for 6 h before the single daily oral dose of permethrin (180 mg/kg for 6 days). Permethrin- and corn oil-treated animals were killed 24 h after the last dose by cervical dislocation and decapitation. The livers were removed, individually homogenized and microsomal pellets prepared and stored at -90C prior to use. The microsomal hydroxylation of testosterone was determined as described (1). Testosterone metabolites were analyzed by HPLC assay utilizing a reverse phase column and a mobile phase consisting of a methanol:water:acetonitrile gradient. Column effluents were monitored at 254 nm. Metabolites were quantitated by comparison of their peak areas with those of reference standards. Permethrin induced some members of CYP2C, CYP3A, CYP2A and CYP2B subfamilies. Permethrin treatment resulted in an increase in the formation of 2 α -hydroxytestosterone (37%, p<0.01), 6 β -hydroxytestosterone (103%, p<0.05), 7 α -hydroxytestosterone (327%, p<0.001) and 16 β -hydroxytestosterone (176%, p<0.001). Further studies of the oxidative metabolism of pyrethroid insecticides can strengthen the scientific basis for risk decisions. (1) Wood, AW et al. (1983) J. Biol. Chem. 258(14), 8839-8847.

1903 SUPPRESSION OF 3-METHYLCHOLANTHRENE-INDUCED CYP1A1 EXPRESSION BY 1-FURAN-2-YL-3-PYRIDIN-2-YL-PROPENONE IN MOUSE HEPA-1C1C7 CELLS.

H. Hee^{1,2}, T. Jeong³, E. Lee³ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea and ³College of Pharmacy, Yeungnam University, Kyungsan, South Korea.

1-Furan-2-yl-3-pyridin-2-yl-propenone (FPP-3) is a chemically synthesized novel propenone compound with anti-inflammatory activities, without showing any ulcerogenic effects. In the present study, we investigated the effect of FPP-3 on 3-methylcholanthrene (3-MC)-inducible cytochrome P450 (CYP) 1A1 gene expression in mouse hepatoma Hepa-1c1c7 cells. 3-MC-induced CYP1A1-specific 7-ethoxyresorufin O-deethylase (EROD) activity and CYP1A1 mRNA level were markedly reduced in the concomitant treatment of 3-MC and FPP-3 in a dose dependent manner. A transient transfection assay using dioxin-response element (DRE)-linked luciferase revealed that FPP-3 reduced transformation of the aryl hydrocarbon receptor (AhR) to a form capable of specifically binding to the DRE sequence in the promoter of the CYP1A1 gene. These results suggest the down regulation of the CYP1A1 gene expression by FPP-3 in Hepa-1c1c7 cells might be antagonism of the DRE binding potential of nuclear AhR.

1904 EXPRESSION OF HEPATIC CYP2E1, CYP1A1/2 AND CYP2B1/2 PROTEIN IN DEVELOPING SPRAGUE DAWLEY RATS.

B. McPhail, S. Muralidhara and J. V. Bruckner. *PBS/Interdisciplinary Toxicology, University of Georgia, Athens, GA.*

Cytochrome P450s (CYP450s) are Phase I enzymes that metabolize endogenous as well as exogenous compounds. They play a key role in the metabolic activation of a number of potentially carcinogenic halocarbons such as trichloroethylene, methylene chloride and perchloroethylene. The ontogeny of a number of CYP450 isozymes has been recently delineated in human liver. There is relatively little such information about immature rats, a primary animal model for infants and children. The overall objective of our project has been to characterize the ontogeny of several toxicologically-relevant CYP450 isozymes (CYP1A1/2, CYP2B1/2 and CYP2E1) in Sprague-Dawley (S-D) rats. Previous data from our laboratory generally indicates an age-dependent increase in the activity of CYP2E1, CYP2B1/2 and CYP1A1/2 in unsexed preweanling S-D rats. We did see a decrease in CYP2E1 activity after 10 days of age, and peak CYP1A1/2 and CYP2B1/2 activity prior to adulthood. The aim of the current study was to determine whether the increase and decrease in CYP450 activities coincided with changes in protein expression through the use of the Western blot technique. A Fotodyne Inc. instrument and software were used to attain the protein images, while Kodak 1D Image Analysis system was used to quantify the protein. Liver microsomes were prepared from naïve rats on days 5, 10, 15, 21, 30, 40, 50, 60 and 90 after birth. Day 5, 10 and 15 samples were pooled and analyzed as single samples. Day 21-60 samples were sexed and day 90 males were used as the adult. Primary antibodies to CYP2E1, CYP1A1/2 and CYP2B1/2, along with the appropriate secondary antibody, were used to quantify 10 μ g of microsomal sample from each animal. The expression of CYP2E1, CYP1A1/2 and CYP2B1/2 protein levels followed a pattern very similar to the ac-

tivities measured previously. Characterizing the maturation of hepatic CYP450 isozymes in rats may prove useful in assessing their applicability as models for children in the investigation of halocarbons and other xenobiotics which undergo metabolic activation.

1905 CYP3A4, CYP2B6 AND CYP1A2 mRNA INDUCTION IN RAT, PIG, AND HUMAN HEPATOCYTES.

C. Healan-Greenberg, J. F. Waring and E. Blomme. *Cellular, Molecular and Exploratory Toxicology, Abbott Laboratories, Abbott Park, IL.*

The induction of drug metabolizing enzymes by xenobiotics can lead to drug-drug interactions, autoinduction, and toxicity. Traditional pre-clinical animal studies are generally not sufficient to determine the induction potential of a new compound, as induction effects are often species-specific. Consequently, in vitro assays in primary human hepatocytes are currently used to assess clinical induction potential. Human hepatocytes are quite expensive and often difficult to obtain, however, so an alternative cell type that is predictive of human induction would be advantageous for early screening of compounds. In this study, we treated rat, human and Gottingen minipig hepatocytes with a variety of human CYP3A4, CYP2B6, and CYP1A2 inducing and non-inducing compounds, and we compared the inductive responses to each compound in all cell types. We found that rat hepatocytes respond differently to inducers of CYP3A4 and CYP2B6 than pig or human hepatocytes, but responded similarly to CYP1A2 inducers. Pig hepatocytes, however, responded to inducers of all three enzymes in a very similar manner to human hepatocytes. These data suggest that pig hepatocytes may be useful in early screening for induction potential, and the Gottingen minipig may be a useful species for predicting clinical induction potential.

1906 TEMPORAL CHARACTERIZATION OF CYP1A2, 2B6 AND 3A4 INDUCTION IN PRIMARY CULTURES OF HUMAN HEPATOCYTES BY RT-PCR, ENZYME ACTIVITY AND WESTERN BLOT.

Y. Weng, D. Stresser and G. Zhang. *BD Biosciences Discovery Labware, Woburn, MA.*

Cytochrome P450 (CYP) induction potential of drug candidates is commonly assessed during drug discovery and development. Recent guidance from the FDA recommends the exposure time of test article for in vitro induction experiments with primary cultured hepatocytes to be 2 to 3 days. In this study, we evaluated the time course for the induction of CYP1A2, CYP2B6 and CYP3A4 by prototypical inducers in human hepatocytes with three endpoints: 1) enzyme catalytic activity, 2) protein expression by Western blotting and 3) mRNA expression by real time RT-PCR. These enzymes were chosen as they are regulated by distinct but overlapping mechanisms involving nuclear receptors Ahr, CAR and PXR. Hepatocytes from two donor livers were treated with 20 μ M β -naphthoflavone (BNF), 2 mM Phenobarbital (PB) or 20 μ M rifampicin (RIF). At each time point (6, 24, 48 and 72 hours) catalytic activity of CYP1A2, CYP2B6 and CYP3A4 was determined in situ by measuring acetamidophenol, nirvanol and 6 β -hydroxytestosterone formation from corresponding probe substrates. The hepatocytes were then lysed and homogenate was prepared for Western blotting assays. In addition, replicate plates were used for preparation of RNA for real time RT-PCR analysis. The results showed that mRNA expression for all three enzymes was induced as early as 6 hours. The fold induction for CYP1A2, CYP2B6 and CYP3A4 mRNA averaged from these two donors were 6.9 (9.3 and 4.4), 14 (21 and 7.4) and 7.5 (2 and 13), respectively. The mRNA induction increased further with exposure time and was maximal at 48 or 72 hours. Induction of catalytic activity and protein of each enzyme was not observed at 6 hours but a robust induction response was found for each enzyme at 24 hours and subsequent time points. In conclusion, the mRNA expression was the most sensitive measure of induction and as expected provided the earliest indicator of response. Exposure time for optimal sensitivity of CYP induction potential for these three enzymes was 48 to 72 hours in the two donors tested.

1907 EFFECTS OF DIELDRIN AND PHENOBARBITAL ON THE SPATIAL DISTRIBUTION OF CYP2B1/2 MESSENGER RNA WITHIN THE LIVER ACINUS.

M. Dail, S. C. Burgess and J. E. Chambers. *Center for Environmental Health, Mississippi State, Mississippi State, MS.*

Traditionally the liver has been considered a homogeneous, well-mixed organ. The literature, however, suggests that cytochrome P450 is differentially distributed within the hepatocytes lining the sinusoids of the liver acini and that this distribution is altered by various xenobiotics. The mRNA levels of CYP2B1/2 within the liver acinus were compared following treatment of rats with two P450 inducers, phenobarbital or dieldrin (a persistent organochlorine insecticide). Adult male Sprague Dawley-derived rats were treated with either i.p. phenobarbital in saline at

80mg/kg/day for 5 days or dieldrin in corn oil p.o. at 2.5 mg/kg/day for 13 days. Control rats received i.p. saline or p.o. corn oil for the same length of time. Laser capture microdissection (LCM) and real-time reverse transcriptase duplex-PCR (QPCR) were used to measure the CYP2B1/2 mRNA produced in bands of hepatocytes isolated from 3 different locations along the path of blood flow from the hepatic portal vein (periportal area) to the central vein (centrilobular area). Mean QPCR critical threshold (CT) differences and fold changes were determined. All LCM band samples showed significant increases in CYP2B1/2 mRNA following treatment. Dieldrin increased CYP2B1/2 mRNA values as blood flows through the acinus from the periportal region (320 fold increase) to the midzonal (538 fold increase) to the centrilobular region (1,418 fold increase). A different pattern resulted following phenobarbital exposure where the largest increase was present in the midzonal area (4,973 fold increase) with lower expression in both the periportal (1,031 fold increase) and the centrilobular areas (1,136 fold increase). These results reinforce the concept of a highly variable liver microenvironment in which CYP2B1/2 expression changes both temporally and spatially in response to different xenobiotics. 1908 PHENOBARBITAL EFFECTS ON GENE EXPRESSION IN HUMAN HEPARG CELLS.

C. Lambert¹, C. Spire¹, M. Renaud¹, A. Platel¹, A. Guillouzo² and N. Claude¹. ¹Drug Safety, SERVIER, GIDY, France and ²U620, INSERM, Rennes, France.

The effects of phenobarbital were studied in the human hepatoma cell line, HepaRG. When maintained at confluence, this cell line differentiates into both biliary-like cells and hepatocyte-like cells and these latter become able to express many phase I and phase II enzymes, influx and efflux transporters. Therefore, this cell line could be considered as a relevant model for *in vitro* drug metabolism and toxicity studies. Differentiated HepaRG cells were treated with phenobarbital at 8 mM for 20h through 4 different experiments (intra- and inter-laboratory reiterations). Their functional capacity was investigated using 22k or 44k AgilentTM whole human genome microarrays (two-color). The cytotoxicity levels varied from 53% to 79% between experiments. Data sets were analysed using Feature ExtractionTM 8.5 and ResolverTM 6.0 (Rosetta Biosoftware) to build Venn diagrams and unsupervised clustering with a dose-related effect. These studies allowed to identify a reproducible set of about 1200 signature genes (p-values $\leq 4.5 \times 10^{-7}$) in response to phenobarbital treatment on 22k microarrays. This gene set included about 50% up-regulated and 30% down-regulated genes showing at least a 2-fold change. Approximately 90% of this gene set was retrieved on the 44k microarrays. Major networks hold the scales between proliferation, cell growth and apoptosis (Ingenuity Pathway AnalysisTM). Our results showed the interest of gene expression profile analysis for elucidating mechanism of action of phenobarbital in human liver cells.

1909 PERSISTENT INDUCTION OF HEPATIC CYP1A1 AND 1A2 GENE EXPRESSION BY 3-METHYLCHOLANTHRENE IS MEDIATED BY SUSTAINED TRANSCRIPTIONAL ACTIVATION OF THE CORRESPONDING PROMOTERS.

W. Jiang, L. Wang, I. Fazili, S. Kondraganti and B. Moorthy. *Pediatrics, Baylor College of Medicine, Houston, TX.*

Humans are constantly exposed to polycyclic aromatic hydrocarbons (PAHs), many of which are carcinogens. Cytochrome P4501A (CYP1A) enzymes play important roles in the activation of PAHs such as 3-methylcholanthrene (MC) to genotoxic metabolites, which could in turn lead to carcinogenesis. We reported earlier that exposure of rats to MC leads to persistent induction of hepatic microsomal cytochrome P450 (CYP)1A enzymes for up to 45 days (B. Moorthy, J. Pharmacol. Exp. Ther, 294: 313-322, 2000). In this study, we tested the hypothesis that persistent induction of CYP1A1 and 1A2 gene expression by MC is mediated by sustained transcriptional activation of the corresponding promoters. Twelve week-old female wild type (WT) (CD-1) or transgenic mice expressing the human CYP1A1 (CYP1A1-luc) or 1A2 (CYP1A2-luc) gene promoters and the reporter luciferase gene were treated with MC (100 μ mol/kg, i.p.), once daily for 4 days, and luciferase expression was determined in vivo by bioluminescent imaging of the mice at 1, 8, 15, and 28 days after the last treatment. Endogenous expression of CYP1A1 and 1A2 catalytic activities, apoprotein contents and mRNA levels was also determined in the liver tissues. MC elicited a 12- and 7-fold augmentation in luciferase expression in the CYP1A1-luc and 1A2-luc mice, respectively at the 1 day time point, compared to vehicle treated controls. This induction persisted for up to 28 days. On the other hand, MC caused only a modest induction in the endogenous expression of CYP1A1 and 1A2 in the 1A1-luc and 1A2-luc mice, respectively. These results support the hypothesis that persistent induction of CYP1A1 and 1A2 by MC is mediated by sustained transcriptional activation of the corresponding gene promoters. Future studies on the detailed mechanisms of persistent induction of CYP1A by MC could lead to the development of rational strategies in the prevention and/or treatment of humans cancers induced by PAHs. (Supported by NIH grant ES009132.)

1910 CHROMIUM INTERFERES WITH THE EPIGENETIC REGULATION OF BENZO[A]PYRENE-INDUCIBLE EXPRESSION OF MOUSE CYP1A1 GENE IN HEPA-1 CELLS.

M. Schnekenburger, L. Peng and A. Puga. *Environmental Health, University of Cincinnati, Cincinnati, OH.*

Carcinogenic metals, such as chromium (Cr), and polycyclic aromatic hydrocarbons (PAH), such as benzo[a]pyrene (B[a]P), co-exist naturally and may lead to multiple adverse health effects. In mouse hepatoma Hepa-1 cells, Cr affects the B[a]P-inducible expression of numerous genes including Ah receptor (AHR)-dependent CYP1A1 activation, due to the inhibition of both the release of histone deacetylase (HDAC) 1 and the recruitment of p300 to the CYP1A1 promoter. Concomitantly, binding of the AHR to the xenobiotic response elements is unaffected by Cr. Since change in histone modifications is a major event in the critical steps of chromatin structure remodeling necessary for gene transactivation, we tested the hypothesis that Cr interferes with the epigenetic control of B[a]P-induced CYP1A1 gene expression. We performed chromatin immunoprecipitation assays with cells treated with B[a]P in the presence or absence of Cr to compare the profile of histone modifications at the CYP1A1 promoter. Our results show that Cr leads to an inhibition of B[a]P-induced histone 3 (H3) S10 phosphorylation, H3K4 tri-methylation, and both H3 and H4 acetylation. Furthermore, sodium butyrate and 5-aza-2'-deoxycytidine (azaC) decreased Cr repression of CYP1A1 induction by B[a]P. However, these treatments did not affect the constitutive and inducible expression level of CYP1A1. In addition, we found that DNA methyl transferase (DNMT) 1 is associated with HDAC1 on the CYP1A1 promoter. Although, no DNA methylation was detected in the CYP1A1 promoter CpG island, azaC is able to reduce the association of DNMT1 and HDAC1 on the promoter. These data helps develop an understanding of the molecular mechanisms underlying the toxicity associated with environmental mixtures. Supported by NIEHS grants P30 ES06096, 2R01 ES06273 and 1R01 ES10807.

1911 EFFECTS OF HISTONE ACETHYLATION AND DNA METHYLATION ON THE mRNA EXPRESSIONS OF CYP1A AND 3A IN HEPG2 CELLS.

A. Miyajima-Tabata, S. Ozawa, S. Ishida and K. Nakazawa. *Division of Pharmacology, National Institute of Health Sciences, Tokyo, Japan.* Sponsor: M. Ema.

The human cytochrome P450 (CYP) plays a key role in metabolizing various endogenous compounds and xenobiotics including therapeutic drugs, and CYP enzymes exhibit inter-individual variation at the activity level. Single nucleotide polymorphisms (SNPs) of CYP genes have been analyzed but only few SNPs have been associated with observed inter-individual differences. Nuclear receptor pathways have been reported to participate in the regulation of CYP enzymes. Roles of other regulating factors, however, have been suggested, which ultimately result in the inter-individual variation of CYP expression. In this study, effects of inhibitors of histone deacetylation and DNA methylation on the constitutive and induced CYP 1A and 3A mRNA levels were studied using HepG2 cells.

Cells were pretreated with trichostatin A (TSA) or 5-aza-2'-deoxycytidine (AzaC) and then treated with or without CYP inducers, omeprazole (OME) or rifampicin (RIF). The mRNA expression levels of CYP1A1, 1A2, 3A4, 3A5 and their related receptors, arylhydrocarbon receptor (AHR), pregnane X receptor (PXR) were measured by the real-time reverse-transcription polymerase chain reaction method (RT-PCR) with specific TaqMan probes.

TSA increased the constitutively expressed levels of CYP1A2 and 3A4 by 5- and 11-fold, respectively. Much more remarkable increase was observed in the induced expression levels of CYP1A2 and 3A4 by 22- and 13-fold. Similar results were observed in the case of AzaC. On the other hand, AHR and PXR expressions were changed no more than 2 fold with TSA and AzaC. These results show that TSA and AzaC influenced the constitutive and induced expressions of CYP1A and 3A. The inhibitions of histone deacetylation and DNA methylation seemed to affect the constitutive expression more profoundly than induction of CYP3A4 gene in HepG2 cells.

1912 REGULATION OF TRANSCRIPTIONAL ACTIVITY OF HUMAN PREGNANE X RECEPTOR BY HISTONE METHYLTRANSFERASE PRMT1.

Y. Xie¹, X. Gu¹, S. Ke¹, D. Liu¹, M. Bedford² and Y. Tian¹. ¹Veterinary Physiology and Pharmacology, College of Veterinary Medicine, TAMU, College Station, TX and ²Department of Carcinogenesis, University of Texas M.D. Anderson Cancer Center, Smithville, TX.

Histone modification is an important mechanism for the epigenetic regulation of gene expression. Protein arginine methyltransferase 1 (PRMT1), which methylates arginine 3 at the N-terminal tail of histone H4, has recently been shown to play an

important role in the functions of nuclear/steroid receptors. The pregnane X receptor (PXR) regulates the expression of a set of genes involved in phase I, II xenobiotic/drug metabolism as well as transporters. Cytochrome P450 3A4 (cyp3a4) is regulated by PXR at transcriptional level and is responsible for the first pass biotransformation of over 50% prescription and non-prescription drugs. Using coimmunoprecipitation/Western analysis with Flag-tagged human PXR, we have found that PRMT1 associated with PXR complex in human hepatoma (HepG2) cell line. The immunoprecipitated complex contained methyltransferase(s) that specifically methylated arginine 3 of histone H4 as determined by N-terminal sequencing analysis, suggesting PRMT1 may be the primary methylating enzyme. Using GST-pulldown and mammalian two hybrid assays, we found that PRMT1 interacts with PXR directly. Using the chromatin immunoprecipitation (ChIP) assay, we detected a ligand (rifampicin)-dependent, transient recruitment of PRMT1 to cyp3a4 regulatory regions concomitant with methylation of arginine 3 in histone H4. Histone methylation by PRMT1 is a critical step for subsequent histone modifications (e.g. acetylation). Our results suggest that PRMT1 plays important roles in regulating PXR-mediated gene expression (Supported in part by NIEHS Grant ES09859, ES09106 and American Heart Association Grant 0355131Y).

1913 CCR4-NOT COMPLEX REGULATES THE TRANSCRIPTIONAL ACTIVITY OF PREGNANE X RECEPTOR.

D. Liu, N. Eagleton, X. Gu, Y. Xie, S. Ke and Y. Tian. *Department of Veterinary Physiology and Pharmacology, Texas A&M University, College Station, TX.*

Pregnane X receptor (PXR) is an orphan nuclear receptor that regulates the metabolism and disposition of various xenobiotics and endobiotics. PXR has been considered as the xeno-sensor because of its remarkable ability to bind a wide range of structurally diverse ligands and coordinately regulate the Phase I and Phase II drug metabolizing enzymes as well as the "Phase III" transporters. PXR plays an important role in drug-drug interactions, adverse drug responses, cholestatic liver diseases, and colon cancer. In order to understand the mechanisms of transcriptional regulation of PXR, we performed yeast two-hybrid screening to identify the interactive proteins in human liver cDNA library, using PXR ligand binding domain as a bait. More than one million independent clones were screened; the known PXR interactive partners were among the positive clones, including NcoR2 and RXR β . One positive clone was a partial cDNA of CNOT2 (amino acids 183-540). CNOT2 is a component of Ccr4-NOT which is multi-subunit protein complex highly conserved from yeast to human. Ccr4-NOT complex plays critical roles in various aspects of transcriptional regulation, including initiation, and mRNA degradation. Using mammalian two-hybrid assay in CV-1 cells and GST-pulldown assay, we confirmed the direct interaction between PXR and CNOT2. In HepG2 cells, overexpression of CNOT2 suppressed the PXR-regulated luciferase reporter gene activity. These preliminary results strongly suggest that Ccr4-NOT complex regulates the transcriptional activity of PXR. (Supported in part by NIEHS Grants ES09859).

1914 RETINOIDS ACTIVATE THE RXR/RXR AND RXR/VDR-MEDIATED PATHWAY AND INDUCE CYP3A4 IN HEPG2 CELLS.

K. Wang, S. Chen and Y. Y. Wan. *The University of Kansas Medical Center, Kansas City, KS.*

Retinoids are frequently used as food supplements or as drugs to treat cancer or dermatological diseases. Retinoids exert their effects through retinoic acid receptor (RAR) and retinoid x receptor (RXR). 1 α , 25-dihydroxyvitamin D3 (D3), can activate RXR/vitamin D receptor (VDR) heterodimers and regulate transcription of hepatic cytochrome P450 3A4 (CYP3A4). However, the role of retinoids in regulation of CYP3A4 through the RXR/VDR signaling pathway is currently unknown. We therefore tested a panel of retinoids as potential ligands for RXR/VDR, using transient transfection assay. Cells were co-transfected with reporter, tk-(3A4)3-Luc, which contains RXR/SXR binding site (ER6) of CYP3A4 promoter, and expression plasmids. In CV-1 cells, of 13 retinoids screened, 9-cis-retinoic acid (9-cis RA) and all-trans-retinoic acid (all-trans RA) activated reporter tk-(3A4)3-Luc (3-fold induction). In HepG2 cells, 7 out of 13 retinoids activated reporter activity, among them, 9-cis-retinal (9.8-fold), 9-cis RA (23.9-fold), and all-trans RA (5.1-fold) showed the highest level of induction. To discern whether the retinoid mediated tk-(3A4)3-Luc induction occurs via RXR homodimers or RXR/VDR heterodimers, a mutant RXR α (Tyr402) expression plasmid with impaired VDR heterodimerization capability and enhanced homodimerization capability was employed for transfection. The results suggest that retinoic acids activate both RXR α homodimers and RXR α /VDR heterodimers and induce tk-(3A4)3-Luc. Among the three RXR isoforms (α , β , and γ), the β isoform was less effective than α or γ in inducing tk-(3A4)3-Luc. The induction of reporter luciferase activity by 9-cis-RA was dose-dependent and low dose (0.1 μ M) 9-cis RA induced reporter activity.

Neither additive nor synergistic effects were noted when retinoids and D3 were used simultaneously. Furthermore, 9-cis RA and all-trans RA induced CYP3A4 activity by 2.9- and 2.6-fold, respectively, in HepG2 cells. In conclusion, certain retinoids, 9-cis RA and all-trans RA, can induce CYP3A4 activity through the RXR/RXR and RXR/VDR-mediated pathway in HepG2 cells.

1915 INDUCTION OF CYP3A4, PXR AND RXR ALPHA BY SODIUM ARSENITE AND DIMETHYL ARSENIC IN THE SMALL INTESTINE OF A CYP3A4 TRANSGENIC MICE.

G. Elizondo, I. M. Medina-Diaz, E. Estrada-Muñiz and L. Vega. *Toxicology, CINVESTAV, Mexico, DF, Mexico*. Sponsor: A. Albores.

Inorganic arsenicals are widely distributed in the environment. Exposure of humans, experimental animals, and cultured cells to arsenic results in a variety of health effects, including cancer. Changes in the liver morphology, and a decrease on cytochrome P-450 (CYP) content have been reported in rats treated with sodium arsenite. Moreover, it has been shown that arsenite decreases induction of CYP1A1, 1A2, 2B1 and 3A23 in cell cultures. These effects may modify the metabolism of several compounds, thus affecting human health. CYP3A4, the predominant CYP expressed in human liver and intestine, contributes to the metabolism of approximately half of the drugs in clinical use today. CYP3A4 catalyzes the 6 beta-hydroxylation of a number of steroid hormones, and is involved in the bioactivation of environmental pro-carcinogens. In the present study we determined the effect of sodium arsenite and dimethyl arsenic on CYP3A4 expression as well as on PXR, RXR alpha, and C/EBP beta expression, all of them involved in the activation of CYP3A4 transcription. Transgenic mice expressing intestinal CYP3A4 were treated with a single dose of 0.05, 0.5, or 5 mg per kg body weight of sodium arsenite or 0.05 mg per kg body weight of dimethyl arsenic. Twenty four h later animals were sacrificed by cervical dislocation and the small intestine of the mice were removed. CYP3A4, PXR, RXR alpha, and C/EBP beta mRNA levels were evaluated by Real Time PCR. Our results indicate that both, sodium arsenite and dimethyl arsenic increase CYP3A4, PXR, and RXR alpha mRNA levels whereas no effect was observed in C/EBP beta transcript levels. In conclusion, the present study revealed that sodium arsenite and dimethyl arsenic increase CYP3A4 levels by inducing PXR and RXR alpha transcription, and suggest that arsenic compounds may induce other genes that are under PXR and RXR alpha regulation.

1916 BROMINATED FLAME RETARDANTS AS INDUCERS OF CYTOCHROME P450 3A.

Y. Fery¹, S. Germer¹, S. O. Mueller² and D. Schrenk¹. ¹*Food chemistry and environmental toxicology, University of Kaiserslautern, Kaiserslautern, Germany* and ²*Merck KGaA, Institute of Toxicology, Molecular Toxicology, D-64293 Darmstadt, Germany*.

Brominated flame retardants (BFRs) are added to plastics, textiles and electronic equipments to reduce the risk of fire. The group of BFRs comprises, e.g., polybrominated diphenyl ethers (PBDEs), hexabromocyclododecane (HBCD), tetrabromobisphenol A (TBBPA) and polybrominated biphenyls (PBBs). Many of these substances are persistent and lipophilic, and accumulate in the environment, in wildlife, and humans. Some BFRs have been shown to be active as endocrine disrupters, and to exert developmental toxicity. The induction of drug metabolism may play a role in such effects.

In this study HBCD and a cleaned-up commercial PBDE mixture ('Pentamix') mainly containing BDE 99 (2,2',4,4',5-pentabromo-DE) were used. A previous study in rats has shown induction of hepatic CYP3A after treatment with HBCD and Pentamix. In rat hepatocytes in primary culture, both compounds also induced CYP3A mRNA and protein. Furthermore, reporter gene expression in H4IIE (rat) and HepG2 (human) hepatoma cells, transiently transfected with an XREM-driven reporter gene construct was also increased significantly. Co-transfection of the human pregnane-X-receptor (PXR) further enhanced the response in HepG2 cells. In summary, our findings demonstrate that HBCD and Pentamix have the potential to induce CYP3A, a group of key enzymes in drug metabolism of humans and rodents. Thus these compounds may cause adverse effects by affecting the metabolism of exogenous and endogenous substrates.

1917 GLUCOCORTICOID REGULATION OF PXR INFLUENCES CYP3A4 INDUCTION BY DEHP AND THE METABOLITE MEHP

B. W. Cooper and A. D. Wallace. *Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC*.

Di (2-ethylhexyl) phthalate (DEHP) is a widely used phthalate ester plasticizer found in polyvinyl chloride medical devices. High level DEHP exposure to hospital patients occurs as it leaches from medical tubing, blood bags and IV fluid bags.

Phthalates such as DEHP are ubiquitous environmental contaminants that act as developmental and reproductive toxicants. DEHP is rapidly metabolized to mono (2-ethylhexyl) phthalate (MEHP). DEHP and MEHP are ligands for the pregnane X receptor (PXR), a key regulator of xenobiotic metabolism, and induce CYP3A4 (3A4) which is known to metabolize pharmaceuticals and endogenous steroids. The magnitude of CYP3A induction by phthalates may be dependent on PXR protein levels. PXR expression has been shown to be regulated by glucocorticoids and many hospital patients exposed to DEHP are also administered glucocorticoids. The purpose of these studies was to examine the effects of glucocorticoid and phthalate co-exposure on 3A4 expression. The rat liver cell line H4IIE-C3 was transiently transfected with a CYP3A4-luciferase reporter and treated with dexamethasone (Dex) and 10 µM DEHP. CYP3A4 promoter activity was highly induced by DEHP and Dex co-administration over either agent alone. This induction was abrogated by administration of the glucocorticoid receptor (GR) antagonist RU486, suggesting a critical role for GR. Similar effects were observed with MEHP treatment. Western blots of H4IIE-C3 cells demonstrated a dose dependent induction of PXR in response to Dex. To examine the effect of Dex on PXR protein in a human model system, western blot analysis was performed on Dex treated primary human hepatocytes and revealed a Dex dose-dependent increase in PXR expression. Dex and DEHP or MEHP co-treated hepatocytes demonstrated a synergistic induction of 3A4 protein expression. These data suggest that PXR is regulated by glucocorticoids and induction of PXR protein contributes to synergistic induction of 3A4 expression in response to DEHP or the metabolite MEHP.

1918 REGULATION OF CONSTITUTIVE ANDROSTANE RECEPTOR (CAR) BY SILENCING MEDIATOR OF RETINOID AND THYROID RECEPTORS (SMRT).

T. Li, J. Sonoda, R. R. Nofsinger, M. R. Downes and R. M. Evans. *Gene Expression Laboratory, The Salk Institute for Biological Studies, La Jolla, CA*.

Nuclear receptors (NRs) are ligand-activated transcription factors regulating metabolism, development, reproduction, and other biological processes. The NR constitutive androstane receptor (CAR) is expressed predominantly in the liver and its activity is induced by a number of xenobiotics and endogenous chemicals, resulting in activation of the hepatic drug clearance pathway that consists of cytochrome P450 enzymes, conjugating enzymes, and drug transporters. In this study, we find that the over expression of the NR corepressor silencing mediator of retinoid and thyroid receptors (SMRT) inhibits CAR transactivation of the CYP2B promoter. Using in vitro and in vivo assays, we show that the interaction between the ligand-binding domain of CAR and SMRT is dependent upon a few critical amino acid residues in the SMRT nuclear receptor-interaction domain (RID). Most importantly, we found that a mouse strain harboring point mutations in the SMRT RID shows increased expression of CAR target genes. As a result, the mutant mice have a higher level of drug metabolism when challenged with multiple chemicals. Taken together, we propose that SMRT is a key regulator of hepatic drug metabolism.

1919 RETINOIC ACID REGULATION OF THE PULMONARY EXPRESSED CYTOCHROME P450 2S1.

A. M. Rowland, S. N. Cutler and G. S. Yost. *Pharmacology and Toxicology, University of Utah, Salt Lake City, UT*.

Cytochrome P450 2S1 is one of the few P450 enzymes that exhibit both selective expression in extrahepatic tissues, including the lung, and constitutive expression throughout development of the fetus. Although there is conflicting evidence in the literature as to the nature of its substrate(s), the fact that this enzyme is highly conserved indicates that it may play an important metabolic role. Previous studies have demonstrated CYP2S1 induction by all-trans retinoic acid in human skin biopsies. Retinoic acid (RA) is an important signaling molecule, derived from the metabolism of Vitamin A (retinol). RA signaling plays an important role in development by regulating cell growth, differentiation and proliferation in numerous cell types including the lung. Deregulation of RA signaling has been implicated in tumorigenesis. The CYP2S1 promoter contains a number of potential Retinoic Acid Response Element (RARE) half-sites. Using CYP2S1 promoter luciferase constructs and real-time PCR, we wanted to determine 1) which promoter regions are important for the lung-selective expression of CYP2S1 by comparing human lung aveolar A549 with human liver HepG2 cells, and 2) determine whether retinoic acid induces CYP2S1 expression in A549 cells. Results from these studies showed that A549 cells supported a robust (125-fold) enhancement of reporter gene activity and RA significantly induced both reporter luciferase activity and CYP2S1 transcription. The human liver HepG2 cells only moderately (25-fold) supported luciferase activity and RA did not induce the promoter-driven reporter gene. This research was supported by NIH grant #HL60143.

1920 ALTERNATIVE PROMOTERS DETERMINE TISSUE-SPECIFIC EXPRESSION PROFILES OF HUMAN MICROSOMAL EPOXIDE HYDROLASE (EPHX1).

X. Yang^{1,2}, S. Liang¹ and C. J. Omiecinski¹. ¹Center for Molecular Toxicology and Carcinogenesis, Penn State University, University Park, PA and ²Interdisciplinary Program in Genetics, Penn State University, University Park, PA.

Microsomal epoxide hydrolase (EPHX1) catalyzes hydration reactions that determine the cellular disposition of reactive epoxide derivatives derived from xenobiotic exposures. Whereas the previously defined human EPHX1 exon 1 sequence, E1, is derived from a gene promoter immediately proximal to exon 2 of the EPHX1 coding region. Remarkably, the E1 promoter directs expression only in the liver. We have identified an alternative EPHX1 promoter that is localized ~18.5 kb upstream of exon 2. Northern hybridizations demonstrated that the E1b promoter functions as the primary driver of EPHX1 expression in human extrahepatic tissues. Using a rolling circle amplification-RACE technique, together with EST database analyses, we have identified 2 distinct EPHX1 transcripts in extrahepatic tissues and cell lines that are derived from the E1b promoter region. We term the transcripts E1b and E1b'. The E1b transcript includes a noncoding 46 bp exon 1 in its 5'-untranslated region. In contrast, the length of the E1b' 5'-UTR is extended, and includes 2 upstream AUG codons together with high GC content. Analyses of the human E1b gene promoter region indicated the presence of multiple transposable elements, including Alu repetitive elements of the AluSp, AluSx, AluJo and AluYa5 classifications. The AluYa5 elements are relatively recent in evolutionary history, and their presence in the EPHX1 promoter was associated with significant reduction in EPHX1 transcriptional activity following transfection experiments conducted in transformed human cell lines derived from multiple tissues, including kidney 293A, lung A549, hepatoma HepG2, and breast cancer MCF7. Further investigations are underway to assess the regulatory features of this promoter that direct its transcriptional activity in human tissues.

1921 ACQUIRED ANDROGEN INDEPENDENCE DURING CADMIUM-INDUCED MALIGNANT TRANSFORMATION OF HUMAN PROSTATE EPITHELIAL CELLS.

L. Benbrahim-Tallaa¹, L. Jie¹, M. Webber² and M. Waalkes¹. ¹NCI at NIEHS, Research Triangle Park, NC and ²Michigan State University, East Lansing, MI.

Early human prostate cancer (PCa) is typically androgen-dependent but can progress to an aggressive androgen-independent (AI) state that is frequently lethal. AI growth often involves changes in the androgen receptor (AR). Cadmium (Cd) is a possible prostate carcinogen potentially linked to aggressive PCa. Thus, acquisition of AI growth was studied in normal prostate epithelial RWPE-1 cells malignant transformed by chronic low-level Cd exposure (CTPE cells). CTPE cells were hyperproliferative compared to control, and androgens or antiandrogens had little effect on this proliferation. Prostate specific antigen (PSA) was markedly increased while the tumor suppressor gene *p27* was reduced in CTPE cells, changes typical in AI PCa. AR levels were similar in control and CTPE cells but androgen actually induced less AR-related gene expression in CTPE cells. Thus, this AI growth is unrelated to changes in AR levels or sensitivity. AI growth can involve estrogen signaling via the estrogen receptor (ER). In fact, after exposure to estradiol (E2) CTPE cell proliferation greatly increased while control cells showed little response. ER α transcript was elevated in CTPE cells, while ER β transcript was distinctly lower. Antiestrogen treatment nearly abolished E2-induced CTPE cell growth. CTPE cells had increased 5 α -aromatase (5 α -A), which metabolizes testosterone to estrogen. Disruption of IGF signaling is frequently found in AI PCa and IGF expression is frequently controlled by estrogen. Although basal levels were similar, E2 markedly (6.5-fold) increased in IGF-1 in CTPE cells but not in control, indicating IGF-1 is a key factor in E2-induced CTPE cell proliferation. Thus, Cd-induced malignant transformation of human prostate cells precipitates AI growth, unrelated to AR expression or activity. Increased ER and 5 α -A expression and IGF-1 responsiveness suggests estrogen signaling may be critical to Cd-induced acquired AI growth, which fortifies their emerging role in PCa development and progression.

1922 EUKARYOTIC TRANSLATION ELONGATION FACTOR 18 OVEREXPRESSING CELLS ARE RESISTANT TO CADMIUM-INDUCED TOXICITY AND APOPTOSIS.

S. Othumpangat, C. Umbright and P. Joseph. Toxicology and Molecular biology, NIOSH, Morgantown, WV.

The role of Eukaryotic translation elongation factor 18 (eEF18) in cadmium-induced cytotoxicity and apoptosis was investigated. Transgenic cell line overexpressing the eEF18 gene were generated by transfecting HeLa cells with the expression vector pcDNA 3.1 containing human eEF18 cDNA. Stable transfectant cell line was developed using blasticidin (5mg/mL medium). Expression of eEF18 in the

transgenic cell line was determined by real-time PCR and Western blot analysis. Cell line exhibiting 2 fold (eEF184) and 3 fold (eEF1811) increases in eEF18 expression were developed. The vector alone transfected cell line served as the control. The transgenic cell line exhibited enhanced cell proliferation, overexpression of eEF18, eIF4E and eEF2 genes compared with the control cell line. Cadmium-induced cytotoxicity was significantly lower in the eEF18 overexpressing cell line compared with the control. Cadmium induced apoptosis was also studied using the control and eEF18 overexpressing cell lines. The eEF18 overexpressing cell line exhibited significantly higher resistance to cadmium-induced apoptosis compared with the control cell line. Real-time PCR analysis of eEF18 overexpressing cell line exposed to cadmium showed significant induction of anti-apoptotic genes like Bcl-2, with a concurrent decrease in the expression of the pro-apoptotic gene, p53 compared with the control cell line. In summary, the eEF18 gene overexpressing cell line exhibited significant resistance to cadmium-induced cytotoxicity and apoptosis.

1923 TOXICOGENOMIC ANALYSIS OF CADMIUM RESPONSIVE TRANSCRIPTION IN CAENORHABDITIS ELEGANS REVEALS NOVEL GENES AND PATHWAYS INVOLVED IN HEAVY METAL RESISTANCE.

Y. Cui¹, W. A. Boyd², S. J. McBride¹ and J. H. Freedman^{1,2}. ¹Nicholas School of the Environment and Earth Sciences, Duke University, Durham, NC and ²Laboratory of Molecular Toxicology, ETP, DIR, NIEHS, Research Triangle Park, NC.

The transition metal cadmium is a known human carcinogen, and exposure to this metal is associated with a variety of human diseases. Although individuals are continuously exposed to this metal, pathologic effects are prevented by intracellular defense and repair systems. In the present study, we used *C. elegans* as a model system to identify (a) genes that are induced by a sub-lethal level of cadmium; (b) biological pathways and functions that are affected by cadmium, and (c) genes that are induced by cadmium to protect nematodes against metal toxicity. The global transcriptional changes after 4h and 24h exposure to a sub-lethal concentration of cadmium (100 μ M) were measured using *C. elegans* whole genome arrays. Gene ontology analysis indicated that *C. elegans* metabolism and transport pathways were significantly enriched with differentially expressed genes following both 4h and 24h exposure, while proteolysis and fatty acid metabolism pathways were affected only in 24h exposure. The relationship between cadmium-induced expression changes and protection against cadmium toxicity was investigated by quantifying growth and reproduction after RNA interference. We identified a list of cadmium-inducible genes that were related to cadmium sensitivity in *C. elegans* and many of them have catalytic or binding activities. Protein interaction analysis also revealed that *kel-8*, which is a signaling molecule expressed in neurons, was required in the defense response against cadmium toxicity. Further, the protective effect of *kel-8* depends on normal function of *mek-1*, suggesting that a novel pathway is involved in the metal response. We are also applying the information obtained from *C. elegans* to the mammalian system by studying the homologue of a novel cadmium-responsive *C. elegans* gene in human HEPG2 cells.

1924 LOSS OF GLUTAMATE-CYSTEINE LIGASE MODIFIER SUBUNIT SENSITIZES MICE TO CHRONIC CADMIUM TOXICITY.

S. N. Schneider, B. Wang, D. W. Nebert and T. P. Dalton. Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.

High concentrations of Cd cause toxicity in several organs including liver, lung, bone and kidney. Reduced glutathione (GSH) is one of the cell's major defenses against oxidative stress and has also been shown to possess a protective role against Cd damage, acting as a "first line of defense" in both animals and cultured cells. Glutamate-cysteine ligase modifier subunit (GCLM) has the overall effect of increasing the efficiency of GSH synthesis. *Gclm*(-/-) knockout mice generated in our laboratory show GSH levels that are 15% (liver) and 25-30% (kidney) of that in *Gclm*(+/+) wild-type littermates. Numerous studies have demonstrated Cd as being a toxic metal that causes oxidative stress. Cd toxicity, in the context of chronic GSH depletion, has not been studied-most likely because of complications in interpreting data from animals chronically treated with chemicals that deplete GSH, such as buthionine sulfoximine. To examine the role of chronic GSH depletion in chronic Cd toxicity, we compared *Gclm*(-/-) mice and WT littermates. The effects of repeated subcutaneous injections (6 per week) of CdCl₂ at a dose of 10 μ mol/kg vs isotonic saline (0.9% NaCl) given to both genotypes were compared. This dose of Cd is not acutely lethal, even to sensitive strains. All mice were given 1 mL of water by gavage once a week, urine was collected for 2 h in metabolic cages, and blood collected via saphenous vein. Increases in weight loss, plasma ALT and AST, blood urea nitrogen, and urinary *N*-acetyl- β -D-glucosaminidase (NAG), suggesting liver and kidney failure preceding mortality, occurred in both genotypes. Fifty percent mortality with CdCl₂ treatment occurred in 28 days for *Gclm*(-/-) mice vs 40 days

for WT littermates. No mortality was observed in saline-treated groups. The lower GSH levels present in *Gclm*(*-/-*) mice led to a dramatic sensitization of the animal to chronic Cd toxicity, suggesting that the protective role of GSH is important not only in acute Cd toxicity but also in chronic Cd toxicity. **Supported in part by NIH grants R01 ES012463 and R01 ES010416**

1925 THE MOLECULAR CHARACTERIZATION OF A CADMIUM INDUCIBLE TRANSFORMER-2-LIKE PROTEIN FROM THE NEMATODE CAENORHABDITIS ELEGANS.

B. E. Tvermoes^{1,2}, Y. Cui^{1,2}, W. Boyd¹, D. Snyder¹ and J. H. Freedman^{1,2}.
¹LMT, NIEHS, Research Triangle Park, NC and ²Nicholas School of the Environment, Duke, Durham, NC.

Cadmium is a known human carcinogen and was recently ranked number eight on the hazardous substance priority list. It is not completely clear how cadmium can affect signaling pathways to induce specific changes in gene expression. The underlying mechanisms that modulate cellular response to metal exposure are highly conserved. To understand and describe more fully the molecular basis for cadmium response in *Caenorhabditis elegans*, whole genome analysis was used to identify genes responsive to cadmium exposure. In this analysis, we identified a novel gene, F08F8.5, whose transcript level showed a 7.1-fold induction after 24 hr exposure to cadmium. The amino acid sequence for F08F8.5 has a 50% identity to a transformer-2-like serine/arginine-rich protein. Quantitative real time PCR was used to further quantify the response of F08F8.5 to cadmium and seven other metals. Heat shock was also examined to assess the effects of a more general stressor on F08F8.5 transcript levels. The strongest induction of F08F8.5 occurred from treatment with cadmium, followed by copper. Heat shock did not result in an increase in the mRNA abundance of F08F8.5, indicating F08F8.5 is a metal-specific responsive gene, with cadmium being the strongest inducer. Transgenic *C. elegans* containing promoter-GFP fusions of F08F8.5 were generated. Constitutive expression of the F08F8.5 promoter was observed in the AWA sensory neurons. Cadmium treatment resulted in the rapid synthesis of detectable levels of GFP expression in the intestine and pharynx; where as copper exposure resulted in high levels of GFP only in the pharynx. We are also conducting RNAi screens to gain a better understanding of the biological relevance of F08F8.5 in mediating a response to cadmium exposure in *C. elegans*. The identification and characterization of cadmium-responsive genes will facilitate an understanding of how cadmium exposure results in specific cellular responses.

1926 CHARACTERIZATION OF ZIP14: MEMBER OF THE VERY ANCIENT SOLUTE-CARRIER-39 (SLC39) METAL-TRANSPORTER FAMILY.

K. Girijashanker, L. He, T. P. Dalton, J. M. Reed, C. Ma, E. L. Kendig, M. Soleimani and D. W. Nebert. Medical Center, University of Cincinnati, Cincinnati, OH.

Our lab [PNAS 2005; 102: 3401] has shown that the mouse *Slc39a8* gene, encoding the ZIP8 metal transporter, is responsible for Cd-induced testicular necrosis. Sensitive inbred strains have much greater ZIP8 mRNA and protein accumulation in endothelial cells of the testis vasculature than resistant strains, leading to higher Cd uptake and damage. ZIP8-containing cells in culture show >10-fold increased Cd uptake and >30-fold risk of Cd-induced cell death than control cells. The endogenous function of ZIP8 is that of a Mn/HCO₃⁻ (perhaps also Zn/HCO₃⁻) co-transporter and highly expressed in testis, kidney and lung. All 14 *SLC39* family members (mouse, human) encode for Zrt-like Irt-like Proteins (ZIP), which possess a characteristic ZIP domain by which divalent metals influx across membranes. These very ancient transporters exist in prokaryotes, yeast, plants and all animals. The gene having greatest evolutionary relatedness to mouse *Slc39a8* is *Slc39a14* (similar number of amino acids; highest percent identity). We found two functional isoforms of ZIP14, due to alternative splicing of exons 4: ZIP14A, ZIP14B. We generated stable retrovirally-infected ZIP14A and ZIP14B cDNA into mouse fetal fibroblast (MFF) cultures to make rvZIP14A and ZIP14B cell lines. We established that ZIP14A and 14B, just like ZIP8, are rogue Cd transporters showing a pH optimum of 7.5, temperature optimum of 37 °C, and inhibition by CN⁻. Both also require HCO₃⁻ and, like ZIP8, are Mn, Zn and Cd/HCO₃⁻ co-transporters. Consistent with their "influx" role, ZIP14 proteins are located on the plasma membrane of MFF cells, as demonstrated by Western blot and immunofluorescence microscopy, and are located on the apical side of polarized MDCK epithelial cells, implicating important roles in Cd uptake and disposition. We found that Zn is much more effective in preventing Cd uptake by rvZIP14A or rvZIP14B cells, compared with that by rvZIP8 cells.—**Supported in part by NIH grants R01 ES010416, R01 ES012463, and P30 ES06096.**

1927 MODULATION OF PROTEIN EXPRESSION IN RAT KIDNEY PROXIMAL TUBULAR EPITHELIAL CELLS BY CADMIUM.

B. T. Madhavan. BPS, University of Rhode Island, Kingston, RI.

Renal impairment is the main toxic effect observed upon chronic cadmium (Cd) exposure and proximal tubular epithelial cells are the primary target. We hypothesized that Cd induced cytotoxicity in these cells may involve a changes in expression of certain biologically important proteins. Therefore, the present study was designed to elucidate protein expression in a normal rat kidney epithelial cell line, NRK-52E. The cells were incubated with 5, 10, 15, or 20 µM CdCl₂ for 6, 12, 18, or 24 h. At the conclusion of the exposure, soluble proteins were extracted and separated by two-dimensional polyacrylamide gel electrophoresis. With the aid of PD-Quest software, a total of ten protein spots exhibiting changes in their expression patterns were identified. Nine of these proteins were under-expressed and only one was over-expressed. The approximate molecular weights and isoelectric points (PI) of these proteins were determined by using proteins of known molecular weight and PI. The expression of three protein spots (39 kD, PI 5.3; 36 kD, PI 5.4; 21 kD, PI 6.2) was suppressed after exposure to 5 µM Cd for 6 h and of one (40 kD, PI 5.4) after 12 h exposure. The fifth protein spot (47 kD, PI 6.9) did not show any decrease in staining intensity until the Cd concentration was increased to 10 µM and the cells were exposed for 12 h. Protein spots six (51 kD, PI 6.7) and seven (50 kD, PI 6.3) were under-expressed after 12 h exposure to 15 µM Cd. As the concentration of Cd was raised to 20 µM, protein spots eight (36 kD, PI 4.9) and nine (26 kD, PI 5.2) were under-expressed following 12 and 24 h exposures, respectively. In contrast, protein spot ten (9 kD, PI 4.6) increased in intensity in a concentration- and time-dependent manner. In summary, exposure to Cd causes changes in the expression patterns of specific proteins. Further identification of these proteins may give us more insights into their roles in the Cd-induced renal toxicity.

1928 RAPID ACTIVATION OF ERK1/2 AND AKT IN HUMAN BREAST CANCER CELLS BY CADMIUM: ROLE OF MEMBRANE ESTROGEN RECEPTOR ALPHA.

Z. Liu and Z. Shaikh. College of Pharmacy, University of Rhode Island, Kingston, RI.

Cadmium (Cd), an estrogen disruptor, can rapidly induce a variety of signaling events including the activation of ERK1/2 and AKT. In this study, the involvement of membrane estrogen receptor alpha (ERα) in these events was evaluated in three human breast cancer cell lines (MCF-7, MDA-MB-231, and SKBR-3) following exposure to Cd. In the MCF-7 cells, that express both ERα and ERβ, exposure to 10 µM Cd caused maximum activation of ERK1/2 within 2.5 min and the level of phosphorylated ERK1/2 gradually decreased during the next 60 min. Cd also triggered a gradual increase and sustained activation of AKT during this period. These activation patterns of Cd were similar to those exhibited by the MCF-7 cells in response to 17β-estradiol. A transient phosphorylation of ERα was also observed within 2.5 min of Cd exposure. In contrast to the MCF-7 cells, Cd was unable to induce rapid activation of either ERK1/2 or AKT in MDA-MB-231 cells that express only ERβ. Similarly, in SKBR-3 cells, that express neither ERα nor ERβ, while Cd induced a transient activation of ERK1/2 at 7.5 min, it failed to induce activation of AKT. Next, an estrogen receptor antagonist, ICI 182780, was utilized to investigate the role of membrane ERα in Cd-induced rapid signaling. This specific receptor antagonist did not prevent the Cd-induced activation of ERK1/2 and AKT. Moreover, their activation was not blocked by knockdown of ERα expression by siRNA. We conclude from these observations that Cd induces rapid signaling in the MCF-7 human breast cancer cells through mechanisms that do not seem to require membrane ERα.

(Z.L. received support from RI-INBRE grant # P20RR016457 from NCRR, NIH)

1929 THE PROTECTIVE EFFECTS OF LYCOPENE ON CADMIUM INDUCED GENE EXPRESSION AND LIPID PEROXIDATION IN RATS.

L. Tang¹, T. Jin² and J. Wang¹. ¹Texas Tech University, Lubbock, TX and ²Fudan University, Shanghai, China.

It has been demonstrated that changes in the expression of c-fos, c-jun, bcl-2 and MT-I genes occurred in rats exposed to cadmium to cause carcinogenesis in testes and ventral prostate. To study the protective effect of lycopene on cadmium induced gene expression and lipid peroxidation, Male Wistar rats were divided into three groups and were pretreated by gavage with lycopene doses of 0, 6, or 30 mg/kg body weight (bw) for three weeks. These animals were further divided into a total of 9 subgroups and were given a single (s.c.) injection of CdCl₂ doses of 0, 2, 5 µmol/kg bw. Animals were then sacrificed 5 days after the treatment. RNA was made

from testes and prostate tissues using a Trizol kit from Gibco. Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) analysis for gene expression was performed using an Access kit from Promega. Lycopene concentrations at blood and tissues were quantitated by HPLC. Lycopene pretreatment significantly reduced cadmium-induced mRNA expression of *c-fos* and *c-jun* in the testes and ventral prostate as compared to the cadmium treated control, but the expressions of *bcl-2* and *MT-I* mRNA were not affected. Lycopene pretreatment inhibited cadmium induced lipid peroxidation in blood, testes and prostate. Formation of lipid peroxide (LPO) was reduced up to 45.31% in 30 mg/kg lycopene pretreated group (33.02 nmol/g) as compared to 5 μ mol/kg CdCl₂ treated control group (60.38 nmol/g, $p < 0.05$). Averaged lycopene concentrations were 0.38 μ mol/L in blood, 47.61 nmol/g in the liver, 0.49 nmol/g in the testes, and 0.25 nmol/g in the prostate tissue after 3-week pretreatment with 30 mg/kg lycopene. These results supported epidemiological findings that a lower risk of prostate cancer was found in men frequently consuming tomato products and may contribute to the understanding of the protective effects of lycopene against cadmium-induced toxic effects.

1930 THE CRITICAL ROLE OF THE CELLULAR THIOL HOMEOSTASIS IN CADMIUM PERTURBATION OF THE LUNG EXTRACELLULAR MATRIX.

Y. Zhao¹, S. Gao¹, L. Chou², P. Toselli¹, P. Stone¹ and W. Li¹. ¹Biochemistry, Boston University School of Medicine, Boston, MA and ²Microbiology, Boston University School of Medicine, Boston, MA.

Cadmium (Cd) enhances levels of cellular thiols providing the first defense line against heavy metal toxicity. Lysyl oxidase (LO), a copper (Cu)-dependent enzyme secreted by fibrogenic cells, stabilizes the lung extracellular matrix (ECM) by crosslinking of collagen and elastin. As shown here, CdCl₂ (0-6 μ M) exposure to rat lung fibroblasts (RFL6) for 24 h induced upregulation of metallothionein (MT) and glutathione (GSH), two metal scavenging agents, and gamma-glutamylcysteine synthetase (γ -GCS), a key enzyme for GSH biosynthesis, which was associated with downregulation of LO at the mRNA, protein and catalytic levels. To gain insight into the possible role of cellular thiol homeostasis in LO regulation, we further assessed effects of elevated levels of cellular thiols on LO expression at mRNA levels. Interestingly, increased cellular MT induced by scrape loading and elevated levels of cellular GSH by treatment of cells with GSH monoethyl ester (GME), a GSH delivery system, both significantly inhibited the expression of LO mRNAs. Notably, downregulation of LO in Cd treated cells was closely accompanied by inhibition of the synthesis of collagen type I, a major component of the lung ECM. Furthermore, using rats repeatedly instilled with CdCl₂ (30 μ g, once a week) intratracheally as an animal model, we demonstrated that Cd exposure induced a biphasic response in the lung LO activity and collagen synthesis, i.e., an initial increase (at 2 weeks) followed by a steady decrease (at 4-6 weeks) upon long-term exposure. However, the lung MT levels increased almost linearly over the 6-week exposure and emphysematous lesions were found. In view of regulatory effects of cellular thiols on the metabolism of essential metals such as Cu, a cofactor of LO, these results suggest that upregulation of cellular thiols as an important cellular event plays a critical role in LO regulation. This may be a potential mechanism for Cd-induced lung injury (Supported by NIH grant R01-ES11340).

1931 ROLE OF METALLOTHIONEIN(I, II, III) IN CADMIUM-TRANSFER FROM UTERUS-PLACENTA TO FETUS.

H. Ohta¹, Y. Ohkawa¹, Y. Nakamura¹, K. Ohba¹, K. Nakazato² and K. Suzuki². ¹Department Environ. Occup. Health & Toxicol, School of Allied Health Sciences, Kitasato University, Sagami-hara, Japan and ²Department Pathol. School of Health Sciences, Gunma University, Maebashi, Japan.

The role of metallothionein(MT) for maternal to fetal and to new born rat of cadmium(Cd) transfer was investigated.

Mother rats were given Cd orally(1,2,5 mgCd/kg).Immunohistochemical localization and protein and gene expression of iso-MT(I,II,III) in the uterus and placenta were determined. Cd accumulation and MT concentration increased in uterus and placenta, and in intestine, kidney and stomach milk of offspring rats.

MT level in placenta increased depending on increase of Cd level, but the increased MT protein level in uterus depending on the increase of Cd accumulation was not found.

An increased gene expression of iso-MT (I, II, and III) were found in uterus of 2 and 5mgCd/kg group, but MT protein induction corresponding to gene expression of iso-MT-III was not found in uterus. It was suggested that iso-MT-III may not participate actively for the Cd transfer from mother to fetus in comparison with the cases of MT-I and MT-II. Because of more Cd was accumulated into liver rather than that in kidney of new born rats, it was suggested that Cd in fetus was transported or leaked from uterus and placenta by the form of non-MT-Cd. As meaning the dysfunction of placenta, the immunohistochemical staining showed the atrophy of syncytiotrophoblast cells and decreased positive-stain of MT in placenta tissues of 2 and 5 mgCd/kg groups depending to increasing Cd dose.

From these results, it was considered that MT is participating to trap Cd in uterus and placenta to protect Cd transport to fetus, but for trace amount of Cd to leak by dysfunction of syncytiotrophoblast cell into fetus.

(This study was supported by several research grants from the Japan Public Health Association, Health Sciences Research Grant on Environmental Health and Kitasato University PRG).

1932 RESISTANCE OF METALLOTHIONEIN TO PROTEOLYTIC DIGESTION AS A PROBE OF THE METAL BINDING STATUS OF THIONEINS: A LIQUID CHROMATOGRAPHY AND TANDEM MASS SPECTROMETRY ANALYSIS.

R. Wang, D. A. Sens, S. H. Garrett, S. Somji, M. A. Sens and X. Lu. *Pathology, University of North Dakota, Grand Forks, ND.*

Proteomics typically involves proteolytic digestion followed by mass spectrometric analysis of proteins. The metal binding protein, Metallothioneins (MTs) were observed to be resistant to proteolytic digestion by trypsin, the commonly used proteolytic agent in proteomics. The resistance of MT to tryptic digestion was further investigated using a model thionein, MT-3, which is a thionein fully saturated with 7 transition metals. It was shown that fully metal saturated MT-3 was completely resistant to proteolytic digestion. In contrast, metal free thionein-3, apoMT3 or MT3 fully depleted of metals with EDTA, was able to undergo complete digestion. When thionein-3 containing less than 4 metal ions was treated with trypsin, the thionein-3 was digested but displayed primarily peptides resulting from missed cleavages. When thionein-3 bound to either 4 or 5 metal ions was treated with trypsin, digestion occurred only at the hinged regions of the protein (Lysine 26, 31 and 32) located between the C-terminal α -domain and N-terminal β -domain. Trypsin was unable to digest thionein-3 once it was bound with 6 or more metal ions. A mechanism to explain these observations would be that the cleavage sites in thionein are located next to, or within one amino acid of, the conserved cysteine residues rendering these sites inaccessible to the relatively larger trypsin molecule (>20 kDa) due to space hinderance. In addition, when metal saturated, MT3 is folded into a compact and rigorous structure, shielding the cleavage sites from trypsin. This study demonstrated that proteolytic digestion followed by LC-MS/MS is a fast and sensitive method to distinguish among metal free, partially metal-bound, and metal-saturated thioneins. The combination of proteolytic digestion and LC-MS/MS analysis was able to identify thioneins as well as provide information regarding metal binding status of the molecule.

1933 UNAMBIGUOUS IDENTIFICATION OF METALLOTHIONEIN ISOFORMS BY NANO-FLOW LIQUID CHROMATOGRAPHY AND TANDEM MASS SPECTROMETRY: APPLICATION TO RABBIT LIVER AND HUMAN PROSTATE EPITHELIAL CELLS.

X. Lu, R. Wang, A. Albrecht, S. H. Garrett, S. Somji, M. A. Sens and D. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

Metallothioneins (MTs) are a family of low molecular weight, cysteine-rich metal binding proteins, whose sequences are highly conserved. There are six MT members in rabbits and more than ten in humans; the homology of protein sequence is greater than 90% among human or rabbit MT members. These proteins play an important role in the homeostasis of essential metals such as Zn⁺² or Cu⁺² during growth and development as well as in the detoxification of heavy metals such as Cd⁺² and Hg⁺², rendering the MTs important mediators and attenuators of heavy metal-induced. One of the major difficulties is to unambiguously identify individual MTs involved in a specific biological process. In this report, we described an automated proteomic method based on nano-flow liquid chromatography and tandem mass spectrometry using a high resolution quadrupole time-of-flight mass spectrometer. The method integrated top-down and bottom-up proteomic approaches where the individual MTs were identified by their unique full-length protein sequences as well as their accurate masses (mass accuracy < 50 ppm). The applicability of the method was first demonstrated by the analysis of commercial MT preparations from rabbit liver. Three MTs were identified including MT-1A, MT-2D and MT-2E, majority of which were N-terminal acetylated with a minor amount in unmodified (native) forms. The method was further applied to MT crude fractions prepared from cultured RWPE cells, a human prostate epithelial cell line. Six human MTs were identified and are currently under further investigation. The results were consistent with independent RT-PCR experiments which detected the expression of 1E, 1X and 2A isoforms in RWPE cells. The current proteomic method is advantageous in its abilities of profiling MT protein isoforms with high speed and characterizing the post-translation modifications of MTs.

1934 INDUCTION OF METALLOTHIONEIN IN OREOCHROMIS MOSSAMBICUS EXPOSED TO CADMIUM STRESS.

U. A. Rani and S. P. Basha. *Zoology, SV University, Tirupati, AP, India.* Sponsor: C. Chetty.

Metals are known to induce oxidative stress in aquatic organisms. To date numerous studies have implicated metallothionein (MT) formation in the: a) detoxification of heavy metals, b) regulation of metal-distribution and c) the tissue damage due to generation of reactive oxygen species (ROS). MT is an ubiquitous, cysteine-rich metal binding protein and its synthesis is induced by cadmium (Cd) mediated-oxidative stress, glucocorticoids and anticancer agents. In the present study, the MT in liver, kidney, brain, gill and muscle of the edible fish *Oreochromis mossambicus* (Tilapia) exposed to Cd (5mg/l) for 30 days was quantified by cadmium-saturation method. The induction of MT was in the order of kidney (97.3 µg/g) > liver (63.5 µg/g) > gill (17.2 µg/g) > brain (7.4 µg/g) > muscle (6.8 µg/g). The data show that the Cd-concentration as determined by the DEAE cellulose ion exchange chromatography was higher in kidney (11.4 ppm) followed by liver (6.6 ppm), gill (2.8 ppm), brain (2.3 ppm) and muscle (1.98 ppm). The relative migration of MT protein was measured as 0.67 for liver, kidney, gill and muscle suggesting a molecular weight of 10-12 KD whereas for brain it was found to be 0.7 suggesting 10 KD. In general, the purification of brain MT protein showed the same elution pattern as that of hepatic and renal MTs. The present study suggests that the occurrence of MT-III protein in brain of piscine model could be a growth-inhibitor factor similar to the one reported in mammalian brain.

1935 VERY LOW DOSE MERCURY MODULATES CYTOKINE SECRETION BY HUMAN PERIPHERAL BLOOD MONONUCLEAR CELLS *IN VITRO* WITHOUT CHANGING CELL POPULATIONS.

R. M. Gardner, J. Nyland, S. Evans and E. K. Silbergeld. *Environmental Health Sciences, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Mercury (Hg) is implicated as an immunotoxicant by studies in humans, animals, and in vitro cell culture systems. However, most studies have been conducted with exposures in the micromolar range, far above that found in blood under environmental exposure situations. To investigate Hg's immunotoxic effects under more environmentally relevant conditions, we investigated immune function in primary cultures of human peripheral blood mononuclear cells (PBMCs) exposed to a concentration of HgCl₂ up to 200 nM (which roughly corresponds to a whole blood concentration of 50 µg/L, at the upper range of occupationally exposed and fish eating populations). These concentrations, well below those in the published literature, do not induce overt cytotoxicity (as measured by MTT and trypan blue exclusion assays). Parameters of immune function were measured in the presence and absence of 50 ng/ml LPS to model Hg's effects on both resting and activated immune system. Cells were harvested after 48 hours in culture and immediately stained for flow cytometry. Cell culture supernatants were analyzed by ELISA for cytokine concentrations. In PBMCs from both male and female volunteers, dose-dependent increases in both TNFα and IL-6 were observed, while no changes were observed in IFNγ levels. These changes in cytokine production were detectable under conditions where no changes were detected in cell populations as measured by flow cytometry (CD19+ B cells, CD11b+ NK cells and monocytes, and CD3+/CD4+ or CD3+/CD8+ T cells and CD4+/CD8+ T cell ratios). Additionally, there were no changes in markers of activation (CD25, CD80, CD86, CD69) for any of the subpopulations studied over the dose range of Hg used. This study shows that Hg can exert significant effects on cytokine production at levels that are both non-cytotoxic and environmentally relevant, indicating that Hg effects at low concentrations are likely reflective of changes in signal transduction pathways rather than in cell viability or subsets.

1936 AN INTEGRATED FUNCTIONAL GENOMICS APPROACH TO ASSESS THE EFFECTS OF DIETARY EXPOSURE TO METHYLMERCURY AND SELENIUM IN JUVENILE AND ADULT MICE.

A. Lundebye¹, K. Ingvaldsen¹, C. Glover¹, D. Zheng², G. Sales² and C. Hogstrand^{2,1}. ¹NIFES, Bergen, Hordaland, Norway and ²Nutritional Sciences Research Division, Kings College London, London, United Kingdom. Sponsor: T. Syversen.

Seafood is a good source of nutrition, yet may also be a route of exposure to contaminants such as methylmercury (MeHg). Epidemiological studies implicate the consumption of MeHg-contaminated seafood with effects on the nervous system, particularly during development. Micronutrients normally found in high levels in seafood, such as selenium have been shown to modify the toxicity of methylmercury. Selenium counteracts the toxic effects of methylmercury, possibly due to the

formation of stable adducts. A study was conducted to establish the importance of MeHg speciation, and identify the mechanisms of MeHg toxicity in a murine model. Female mice were fed MeHg (as either MeHgCl or MeHgCys) and in a separate study MeHgCys and/or selenium before mating, during gestation, and for two weeks following parturition. Neurobehavioural indices such as stress/anxiety response, reflex behaviour and locomotion were monitored in pups. Behavioural impacts were also determined in adult mice. An increased latency to movement in an elevated plus maze in MeHgCl- but not MeHgCys-exposed adults were discerned. Brains of these pups were then subjected to microarray analysis to monitor changes in gene expression. Results highlighted perturbations in a number of biological functions, befitting the widespread toxic effects of methylmercury noted in more restricted studies. Of note were alterations in genes relating to cell cycle control, cell signalling, calcium metabolism, cell adhesion, apoptosis, and oxidative stress. A number of genes were also identified that are associated with neural degenerative disorders such as Alzheimer's disease, suggesting that mechanisms of neural impairment may be conserved, independent of the causative agent. The 5 mg kg⁻¹ methylmercurycysteine treatment induced the greatest number of significantly differentially expressed genes, contrary to expectations based on previous literature findings of lowered toxicity of this methylmercury species.

1937 NON-LINEAR EFFECTS OF METHYLMERCURY ON PRIMARY RAT CORTEX ASTROCYTES AND NEURONS: ROLE OF GRP78 AND GRP94.

R. Lu¹, Z. Yin¹, H. Jiang¹, G. C. Jiang¹, J. Cai² and M. Aschner¹. ¹Pediatric Toxicology, Vanderbilt University, Nashville, TN and ²Ophthalmology and Visual Sciences, Vanderbilt University, Nashville, TN.

Methylmercury (MeHg) is a well-known environmental neurotoxicant. It has been suggested that MeHg exerts its neurotoxicity via the generation of reactive oxygen species and depletion of intracellular thiols. While preferentially accumulating in astrocytes, neurons are significantly more sensitive to MeHg's effects. However, the patterns and underlying mechanisms of low-level effects of MeHg in astrocytes and neurons remain unclear. Due to the crucial roles of endoplasmic reticulum (ER) chaperone proteins in protein folding, refolding and trafficking, the objective of this work was to define the differential vulnerability of astrocytes and neurons to low-level MeHg exposure with emphasis on the effects of GRP78 and GRP94, markers of ER. Primary cortical cultures of astrocytes and neurons were exposed for 0.5, 1, 2, 6, 12 and 24 hrs to 10⁻¹⁷ to 10⁻⁴ M MeHg. Cellular viability and cytotoxicity were determined by MTT and LDH leakage assays. The expression levels of GRP78 and GRP94 were assessed by western blotting. MeHg (>10⁻⁴ M) was toxic to both astrocytes and neurons at all time points. However, at lower concentrations (10⁻¹³-10⁻⁷ M MeHg), an opposite trend associated with cell protection, namely increased cellular viability (~120% of controls; p<0.05), was noted. Neurons and astrocytes exhibited a similar pattern of GRP78 and GRP94 protein expression levels. Significant induction of these proteins was noted at low-level (10⁻¹⁶-10⁻¹⁰ M) MeHg exposure, and inhibition was associated with exposures to high-levels (10⁻⁷-10⁻⁴ M) of MeHg at 6, 12 and 24 h. Our results demonstrate that MeHg induces non-linear effects in astrocytes and neurons potentially via the induction and inhibition of ER stress proteins. Accordingly, the role of ER stress signal pathways in MeHg neurotoxicity represents a fruitful area for future study (Acknowledgement: This work supported by Public Health Service of National Institute of Health Grant NIEHS ES07331).

1938 INVESTIGATION OF CADMIUM-INDUCED OXIDATIVE STRESS AND CHANGES IN RUNX2 mRNA EXPRESSION IN THE HUMAN OSTEOBLAST-LIKE CELL LINE, SAOS-2.

L. M. Hunt, J. J. Rodriguez Reyes, M. B. Wells and S. J. Heggland. *Biology, Albertson College of Idaho, Caldwell, ID.*

The heavy metal cadmium is an environmental and occupational toxin. Notable sources include electronic waste and cigarettes. Human exposure to cadmium has been associated with the development of bone diseases including osteoporosis, but the mechanisms by which cadmium exerts a direct effect on bone are unclear. Oxidative stress has been implied in the pathogenesis of osteoporosis, therefore one possibility is that cadmium induces oxidative stress in Saos-2 cells. Furthermore, we explore whether cadmium-induced oxidative damage leads to a decrease in the osteoblast transcriptional factor, RUNX2. This transcriptional factor is a key modulator of osteoblastogenesis and has been reported to play a protective role against osteoporosis in postmenopausal women. We hypothesize that cadmium exposure induces oxidative stress which leads to a decrease in RUNX2 mRNA expression. Saos-2 cells were treated with or without 10 µM CdCl₂ for 0-24 hours. Oxidative stress induced by CdCl₂ was assessed by measuring glutathione (GSH) depletion. RUNX2 mRNA expression was determined by RT-PCR. Cadmium exposure induced oxidative stress, in part, by a depletion of the antioxidant GSH. Ongoing oxidative stress experiments are evaluating reactive oxygen species formation and lipid

peroxidation. Exposure to CdCl₂ also resulted in a significant decrease in RUNX2 mRNA expression, about 40% at 6 and 12 hours, compared to untreated controls. To show that cadmium-induced oxidative damage occurs upstream from changes in RUNX2 expression, cells will be pretreated with antioxidants to control the level of oxidative stress. We predict antioxidants will prevent cadmium-induced decrease in RUNX2 expression. This study will provide insight into the mechanisms underlying cadmium-induced alterations in bone function.

1939 A N-TERMINAL MUTANT FORM OF MT-3 AFFECTS THE GROWTH RATE, VECTORIAL ACTIVE TRANSPORT AND EXPRESSION OF CADHERIN MOLECULES IN MCF-7 BREAST CANCER CELLS.

C. Bathula, S. H. Garrett, S. Sonji, D. A. Sens and M. A. Sens. *Pathology, University of North Dakota, Grand Forks, ND.*

The metallothioneins (MT) are well-known for their role as metal-binding proteins and for their protective effects against heavy metal induced toxicity. MT-3 possesses neuronal growth inhibitory activity, a characteristic feature not shared by any other member of the MT family. Previous studies from this laboratory have shown that MT-3 can inhibit the growth of the PC-3 prostate cancer cell line or the MCF-7 and Hs578T breast cancer cell lines. Furthermore, studies from this laboratory also suggested that MT-3 might have a role in cell differentiation. This was suggested by studies which demonstrated that the stable expression of MT-3 restored active vectorial ion transport to a proximal tubule cell line that had lost this differentiated function. Active vectorial ion transport was monitored by the formation of out-of-focus areas of the cell monolayer known as domes, a hallmark of cultured renal epithelial cells that retain the in situ property of vectorial active transport. In the present study, a site directed mutant of MT-3 was generated in an attempt to determine which epitope of the MT-3 protein was responsible for the growth inhibition noted when MCF-7 cells were stably transfected with the MT-3 gene. The MT-3 mutant possessed alteration in the beta domain of the protein, specifically, proline 7 and 9 were mutated to threonines. Transfection of the MT-3 mutant into MCF-7 cells abolished the growth inhibitory activity of the protein. Furthermore, the cells formed domes in culture indicating a gain-of-function for the differentiated property of vectorial active ion transport. It was also demonstrated that these cells expressed high levels of E-cadherin compared to the parent MCF cells as well as the MCF cells expressing the MT-3 gene, suggesting that MT-3 may be involved in the regulation of junctional molecules.

1940 MOLECULAR AND TOXICOLOGICAL RESPONSES TO MERCURIALS IN C. ELEGANS.

M. K. McElwee^{1,2}, W. A. Boyd¹ and J. H. Freedman^{1,2}. ¹Laboratory of Molecular Toxicology, NIEHS, NIH, DHHS, Research Triangle Park, NC and ²Nicholas School of the Environment and Earth Sciences, Duke University, Durham, NC.

Humans are typically exposed to three different species of mercury: inorganic, methyl and the mercury-containing compound thimerosal. While these compounds are toxic, their mechanisms of toxicity are poorly understood. We hypothesize that different mercurial species modulate the activity of unique and overlapping intracellular signal transduction pathways to affect transcription. Using the nematode *C. elegans*, we have investigated the mechanisms of toxicity of these compounds. After determining an equitoxic dose for each compound, microarrays were run to determine changes in gene expression resulting from mercury exposure. Bioinformatics analysis was then used to predict which signaling pathways are affected by the different mercury species. To assess the potential roles of these pathways, siRNA used to knock-down genes of interest, and *C. elegans* was subsequently exposed to the different mercurials to test for a mercury-sensitive or mercury-resistant phenotype. The localization and induction of novel genes will be investigated by integrating GFP-tagged genes into *C. elegans*. Through this combination of toxicology, bioinformatics and molecular biology techniques, we hope to elucidate the mechanisms by which the different mercurials exert their respective toxicities.

1941 DOSE RESPONSE EFFECTS OF MUTANT KI-RASG12C IN MOUSE LUNG.

S. T. Dance¹, H. S. Floyd², J. E. Moore¹, L. J. Mosley¹, N. D. Kock¹ and M. S. Miller¹. ¹Wake Forest University, Winston Salem, NC and ²NC State, Raleigh, NC.

Our laboratory has developed a bitransgenic mouse lung tumor model that, upon treatment with 500ug/ml of doxycycline (DOX) for 12 months, allows for the maximal expression of the human Ki-rasG12C allele in the lung, resulting in the development of benign focal hyperplasias and adenomas. We determined if different levels of mutant RAS expression would influence the phenotype of the lung le-

sions. Treatment with 25 and 100ug/ml of DOX resulted in dose-dependent increases in tumor multiplicity. At the 500ug/ml dose, all of the lesions were <1mm; however, in mice that received the lower doses of DOX, there was a significant number of lung lesions that were ≥1mm, with some reaching up to 4mm in size. Interestingly, there was a dose-dependent difference in the morphology of the proliferative lesions. The 25 and 500ug/ml treated bitransgenic mice exhibited hyperplasias and relatively benign adenomas, whereas the 100ug/ml treated mice also exhibited more severe, high grade adenomas with atypical features of AC. Immunohistochemical analysis of signaling pathways suggested similarities and differences in the expression and/or phosphorylation of specific signaling molecules. Increased expression of p19ARF, along with the concomitant activation of the p53 pathway, was only seen at the 500ug/ml dose. Elevated levels of Ki-67 staining were found at all 3 levels of transgene expression. Interestingly, increased caspase-3 activity was noted at the 25 and 100, but not the 500ug/ml, dose. Increased expression of survivin was seen at the 100ug/ml and 500ug/ml doses but not at the 25ug/ml dose. Using a phospho-specific antibody, we found an increase in phosphorylated JNK at the 25ug/ml dose, but not at the two higher doses. Our results suggest that the molecular alterations driving tumorigenesis may differ at different levels of transgene expression, and this should be taken into consideration when inducible transgene systems are utilized to promote tumorigenesis in mouse models. (Supported by NCI grant CA91909)

1942 SILICA CARCINOGENICITY IN A SUSCEPTIBLE MOUSE MODEL.

M. R. Gwinn¹, L. A. Battelli², M. Wolfarth², S. S. Leonard², L. M. Sargent², A. F. Hubbs², M. L. Kashon² and V. Vallyathan². ¹NCEA, EPA, Washington, DC and ²HELD, NIOSH, Morgantown, WV.

In 1997 IARC classified crystalline silica as a Group I human carcinogen despite disagreements in the scientific community related to the lack of a mouse model for silica-induced carcinogenicity. Since mutations of the p53 tumor suppressor gene are the most frequently observed genetic changes in human and animal cancers, this study was designed with mice deficient in p53 to evaluate the potential carcinogenicity of crystalline silica. Specifically, these experiments examined the effects of pharyngeal aspiration of freshly fractured silica (0 or 2mg) on various biochemical, molecular and genomic changes and incidence of preneoplastic lesions in the lungs of wildtype, heterozygous and homozygous mice after 2 and 6 months. Analysis performed on bronchoalveolar lavage fluid markers (albumin, lactate dehydrogenase), cells (differential cell counts, apoptosis, cell cycle analysis), and lung tissue (microarray, DNA damage) have shown differences related to exposure in various markers of toxicology and oxidative stress. Histopathologic alterations associated with silica exposure included alveolar epithelial cell hyperplasia, peribronchiolar bronchiolization and lipoproteinosis in the lungs of silica-exposed animals. Microarray analysis demonstrated alterations in genes related to cell cycle control, DNA damage repair and apoptosis, consistent with alterations seen in the cellular analysis. Preliminary microarray analysis also suggests a variation in activated signaling pathways in the wild-type animals as compared to the heterozygous animals. The data described here shows an effect of p53 status on response to silica exposure as early as 2 months following the initial exposure. This susceptible mouse model may provide insights into the critical role of p53 in silica-induced lung injury. The findings and conclusions of this abstract are those of the authors and do not necessarily represent the views of the National Institute for Occupational Safety and Health.

1943 USE OF GENETICALLY MODIFIED C3B6F1 TRP53(+/-) P53 HAPLOINSUFFICIENT MICE FOR SHORT-TERM CANCER BIOASSAYS OF ANTIRETROVIRAL (ARV) DRUGS.

J. E. Leakey¹, F. W. Lee¹, S. M. Lewis¹, G. R. Olson², J. K. Dunnick³ and W. T. Allaben¹. ¹OSC, NCTR, Jefferson, AR, ²TPI, Jefferson Laboratories, Jefferson, AR and ³NTP, NIEHS, Research Triangle Park, NC.

The advent of ARV drugs revolutionized the treatment of HIV/AIDS and has allowed pregnant HIV-positive women to give birth to uninfected babies. However, ARV therapy is not without side-effects and as new ARV drugs become available it is necessary to test them in combination with existing drugs. The ARV, zidovudine (AZT) is genotoxic in fetal mice and monkeys and carcinogenic in mice. We assessed a new C3B6F1 trp53(+/-) (designated C3B6-trp53tm1Brd[N12]F1) p53 haploinsufficient, genetically modified mouse model for use in short-term cancer bioassays. These mice are produced by mating Taconic C3H females with C57Bl6(N12)trp53(-/-) males. They were dosed with 0, 80, 160, 240 mg/kg/day AZT, by gavage in aqueous methylcellulose/ polysorbate 80 (0.2/0.1%), transplacentally (via maternal gavage) from GD12 to GD18 then postnatally from PND1 until 45 weeks old. The dose and dose volume was reduced to 50% from PND1-10 to reduce acute toxicity. During the initial postnatal period (PND1- PND28), survival was >95% and >82% for the control and dosed groups respectively. The AZT treatment produced only small (<10%) reductions in body weight gain. AZT at all 3 concentrations increased blood reticulocyte micronuclei formation at PND1, 10 and 28. AZT treatment did not significantly reduce hepatic mitochondrial gene ex-

pression or increase serum lactate levels, but did increase liver tumor incidence at 45 weeks in male mice: Incidence of hepatocellular adenoma plus carcinoma was 3/27 (12.5%), 3/27 (13.6%), 6/27 (22.2%) & 9/27 (33.3%) in the 0, 80, 160, 240 mg/kg/day dose groups respectively. Thus, unlike previous p53(+/-) mouse models which use a C57Bl6 background, this mouse model develops liver tumors within a 45 week period and has a similar tumor type profile to the B6C3F1 mouse. The C3B6F1 trp53(+/-) mouse may therefore be a good model for evaluating cancer risk of ARV drugs.

1944 APPLICATIONS AND UTILITY OF THE ACCELERATED CANCER BIOASSAY (ACB).

M. J. Iatropoulos and G. M. Williams. *New York Medical College, Valhalla, NY.*

The ACB is a versatile mechanistic initiation/promotion chronic toxicity and carcinogenicity bioassay designed to assess potential carcinogenic activity of a test substance (TS) in 6 critical organs and tissues of rodents in which human carcinogens are active, i.e. liver, lung, kidney, urinary bladder, stomach and mammary gland.

ACB is capable of identifying both putative genotoxic initiators and epigenetic carcinogens (promoters). The standard protocol involves 2 segments; a first in which the TS is administered as an initiator at an appropriate high dose for 16 weeks, followed by promoters for the target organs, and a second segment in which the test substance is administered in a promotion segment for 24 weeks after administration for 16 weeks of an initiator for the target organs. The TS is also given alone for 40 weeks. Thus, the effects of the TS are compared to those of 6 standard initiating agents and 6 standard promoting agents. Variations to the standard protocol can also be made to accommodate mechanistic needs, and other known toxicokinetic data. Age and gender considerations are also included. Post mortem markers to monitor tissue proliferation and differentiation, as well as during life markers measuring temperature and endocrine endpoints, are also routinely utilized.

Five chemically diverse TSs have been tested: (1) BAY12-9566 (BAY), a substituted 4-biarylbutyric acid, a matrix metalloproteinase (MMP) inhibitor (MMPi); (2) moxifloxacin (MOX), a novel bacterial gyrase-inhibitor fluoroquinolone antibiotic; (3) nifurtimox (NFX), a 5-nitrofurant derivative used in the treatment of American trypanosomiasis; (4) phentolamine (PHEN), an alpha-adrenergic receptor antagonist; and (5) Wingstay 100 (W100), a diaryl-p-phenylenediamine rubber antioxidant/antioxidant. We report that all 5 did not demonstrate carcinogenicity, although NFX is genotoxic. Rather, all 5 reduced initiator-induced or promoter-induced neoplasia or even spontaneous neoplasia. Thus, the utility and versatility of ACB is presented and discussed.

1945 A SHORT-TERM *IN VIVO* ASSAY FOR THE PREDICTION AND MECHANISTIC ASSESSMENT OF NON-GENOTOXIC HEPATOCARCINOGENS.

M. R. Fielden, R. Brennan and J. Gollub. *Iconix Biosciences, Inc., Mountain View, CA.*

Shorter term alternatives to the two year rodent bioassay for identifying carcinogenic chemicals would facilitate significant cost savings for development of therapeutics and speed the identification of potentially carcinogenic chemicals. However, existing short term assays demonstrate performance that renders them unsuitable for regulatory approval, and their utility as hazard identification tools for early stage screening is also in doubt. Using a 5 day repeat dose *in vivo* test in rats, a gene expression signature was derived using a training set of 100 structurally and mechanistically diverse non-genotoxic hepatocarcinogens and non-hepatocarcinogens. The multi-gene signature was then independently validated on 47 additional chemicals with resultant sensitivity and specificity of 85%. Alternate tests for hepatocarcinogenicity were evaluated for comparison, including liver weight, hepatocellular hypertrophy, hepatic injury and putative gene-based biomarkers such as cytochrome P450 genes, Tsc-22 and alpha2-macroglobulin. In contrast to these and other putative gene biomarkers, our signature was more accurate in predicting non-genotoxic hepatocarcinogens. Additionally, unlike existing tests, an understanding of potential modes of action for carcinogenicity can be derived through comparison of the signature profile of test chemicals to hepatocarcinogens of known mechanism. This was exemplified by the association of chloroform with the known carcinogens methapyrilene and thioacetamide, the association of beta-naphthoflavone with known carcinogenic P450 inducers, and diethylstilbestrol with hormonal carcinogens. This signature is not only more accurate than current methods, but also facilitates the identification of mechanism of action to aid in the assessment of human cancer risk.

1946 PRENATAL AND NEONATAL MICE ARE MORE SENSITIVE TO MUTAGENICITY OF CARCINOGENS THAN ADULTS.

T. Chen, N. Mei, M. M. Moore and R. H. Heflich. *NCTR/FDA, Jefferson, AR.*

The incidence of childhood cancer is increasing and recent evidence suggests an association between childhood cancer and environmental exposure to genotoxins. Genotoxic carcinogens generally induce more tumors in neonate mice than in

adults. To investigate the age-dependent mutagenic sensitivity to genotoxic carcinogens, neonatal and adult Big Blue mice were treated with three different genotoxic carcinogens, N-ethyl-N-nitrosourea (ENU), 4-aminobiphenyl (4-ABP) and aflatoxin B1 (AFB1). Liver samples from the ENU, 4-ABP and AFB1 treatments and brain samples from the ENU treatment were assayed for cII mutant frequency (MF). All three compounds resulted in much higher MFs from the neonatal treatment than from the adult treatment. ENU, a direct-acting mutagen, resulted in 3-fold and 4-fold higher MFs in neonates than in adults for brain and liver, respectively, while treatment with 4-ABP and AFB1, which are activated to genotoxic derivatives in the liver, produced 4-fold and 13-fold higher MFs in neonates than in adults. Molecular analysis of the mutants indicated that the higher MFs from the neonates treated with genotoxic carcinogens were not the result of clonal expansion and that the mutational spectra from the treated mice were, to a certain extent, age-dependent. The mutagenicity results indicate that the neonatal period is a life stage when some tissues are very sensitive to mutation induction by genotoxic carcinogens and that mutation is an important rate-limiting factor for age-related carcinogenesis.

1947 PRODUCTION OF GALL BLADDER AGENESIS, LIVER PRENEOPLASIA AND GENOTOXICITY IN TURKEY FETUSES ADMINISTERED DIETHYLNITROSAMINE.

K. D. Brunnemann¹, D. J. Smart¹, H. G. Enzmann², M. J. Iatropoulos¹ and G. M. Williams¹. ¹Pathology, New York Medical College, Valhalla, NY and ²Federal Institute for Drugs and Medical Devices, Bonn, Germany.

The *in ovo* carcinogenicity assay (IOCA) was used to examine the morphological changes in fetal turkey livers caused by the carcinogen diethylnitrosamine (DEN). Fertilized turkey eggs were divided into 3 groups: untreated control (UC), vehicle control (VC) and DEN-treated. At day 0, the eggs of the DEN group were injected with 4 mg/egg (50mg/kg) of DEN dissolved in 0.2 ml water. All eggs were allowed to incubate at 37°C and 60 % humidity for 24 days. The fetal livers were collected and processed for histopathological evaluation (H&E staining) and cell isolation for culture and comet analysis of DNA damage. Typical survival rates were 82 % for the UC, 50 % for the VC and 16 – 40 % for the DEN-treated fetuses. The fetal body weights in the DEN-treated group were about 10 % lower than in the UC, while the liver weights were similar in both groups. All DEN-treated fetuses exhibited absence of the gall bladder and the livers of these fetuses frequently were of greenish color.

All liver samples from both UC and VC groups demonstrated normal microscopic architecture reflecting their age. In the DEN group, there was hepatocellular cytomegaly, karyomegaly, anisokaryosis and assumption of a glandular pattern of the 2-cell thick plates. Microscopically, the agenesis of the gall bladder was accompanied by agenesis of the common bile duct and the 2 lobular ducts. Hepatocellular altered (basophilic) foci (FAH) were present in livers of most DEN-treated fetuses, resembling preneoplastic lesions of adult rat livers. An *ex vivo* model of cultured fetal turkey hepatocytes was also developed to study the morphology and growth regulation of initiated cells. Preliminary data reveal the presence of megalocytes (immunofluorescence) and increased levels of DEN-induced DNA damage (comet assay). The IOCA is a rapid and inexpensive short-term bioassay.

1948 HIGH INORGANIC PHOSPHATE STIMULATES LUNG TUMORIGENESIS THROUGH AKT PATHWAY IN K-RAS NULL MICE.

H. Jin, C. Xu and M. Cho. *Toxicology, College of Veterinary Medicine, Seoul National University, Seoul, South Korea.*

Inorganic phosphate (Pi) plays a key role in diverse physiological functions. Most studies for Pi have been focused mainly on bone, because the bone is the major organ affected by Pi. Regulation of Pi balance is accomplished by the family members of sodium-dependent inorganic phosphate transporters (NPTs), which regulate entrance into the cellular membrane. The NPT2b is one of the NPT family, and expressed in lung, thus, suggesting that Pi may play an important role in lung homeostasis. In this study, we examined the effects of dietary high Pi on lung cancer development. Ten K-ras null mice were randomly allocated to two groups; one group fed normal diet containing 0.5% Pi, and other group fed high Pi (1%). The experiment period was four weeks. The serum Pi level was increased by high Pi diet; however, the serum calcium concentration remained unchanged. Dietary high Pi diet caused a significantly increase NPT-2b expression in lung of K-ras null mouse. Dietary high Pi stimulated lung cancer proliferation through increasing cyclin D3, CDK2 and PCNA expression. Additionally, the dietary high Pi decreased tumor suppressor gene PTEN and CTMP expression; and increased Akt phosphorylation at Ser473. High Pi increased the Akt-mediated cell signals including mTOR, 4EBP1 and p70S6K expression. Taken together our results indicate that dietary high Pi possibly stimulates the lung tumorigenesis in K-ras null mouse. Supported by KOSEF

1949 COMPLEX MIXTURES ALTER BENZO[A]PYRENE AND DIBENZO[A, L]PYRENE-INDUCED CARCINOGENESIS.

L. Courter and W. M. Baird. *Environmental and Molecular Toxicology*, Oregon State University, Corvallis, OR.

The primary source of human exposure to the carcinogenic polycyclic aromatic hydrocarbons (PAHs) benzo[a]pyrene (B[a]P) and dibenzo[a,l]pyrene (DB[a,l]P) is through environmental complex mixtures, such as urban dust particulate matter (UDPM) and diesel exhaust (DE). To understand the influence of these complex mixtures on the carcinogenic potency of B[a]P and DB[a,l]P, we used both *in vivo* (SENCA mice) and *in vitro* (human breast epithelial cells) analyses on exposure to appropriate concentrations of PAH plus UDPM or DE. Results from the tumor initiation-promotion assay revealed not only decreased tumor formation but also a significant delay in the onset of tumors upon co-exposure to UDPM or DE plus PAH, compared to PAH alone. Tumor initiation results correlated with cytochrome P450 (CYP) enzyme activity, CYP1A1 protein expression and PAH-DNA adducts. *In vitro* experimentation indicated that UDPM and DE decreased the carcinogenic potency of B[a]P and DB[a,l]P by inhibition of CYP metabolic capacity and PAH-DNA adduct formation. Further, expression of aldo-ketoreductase (AKR) 1A1, 1C1, 1C2, and 1C3 genes were significantly upregulated (> 2-fold change) upon co-exposure to either mixture plus B[a]P or DB[a,l]P. Increased DNA strand breaks and oxidative damage, as measured by the presence of 8-oxo-dG, were also detected following exposure to PAH plus UDPM or DE, compared to PAH treatment alone. These findings suggest that complex mixtures alter the carcinogenic potency of PAH by inhibition of CYP metabolism and upregulation of the competing AKR1 metabolic pathway. In addition, the results from this study emphasize the need for in-depth assessments of mixtures, rather than individual compounds, in order to better predict human cancer risk.

1950 VALIDATION OF A HIGH THROUGHPUT GAP-JUNCTIONAL INTERCELLULAR COMMUNICATION (GJIC) ASSAY USING CIGARETTE SMOKE CONDENSATES.

H. Lammerich and D. Weisensee. *Cell Biology, PHILIP MORRIS Research Laboratories GmbH, Cologne, Germany*. Sponsor: E. Roemer.

Cigarette smoke condensate (CSC) is known to inhibit cell communication in a dose-dependent manner. We developed and evaluated a new high throughput GJIC assay for reproducible dose response, accuracy, and precision. An automated fluorescent microscope (ArrayScan®, Cellomics), the rat liver epithelial cell line WB-F344, and CSC from the 2R4F Kentucky reference cigarette and two single-to-bacco cigarettes (i.e., Bright and Burley) were utilized in the evaluation. Experimental: Cells were stained with the fluorescent dye Calcein. Stained cells were pipetted to unstained cells of the same type and incubated for 3 h with the test substance or solvent control (0.5% DMSO). After establishing the connexin channels, the transfer of the fluorescent dye to neighboring cells within 3 h was determined and expressed as "% stained cells" as a measure of gap-junctional intercellular communication. Phorbol-12-myristate-13-acetate (TPA), a well known inhibitor of GJIC, was used as a control. Results: The assay showed a reproducible dose response. The repeatability and reproducibility for the 2R4F were 3.7% and 6.9%, respectively; the minimal detectable difference was 5.7 µg/ml. The EC50 value for TPA was 0.34 ng/ml, which is in the range reported in the literature for other GJIC assay designs. The EC50 values for CSC from the three cigarette types were 45 µg/ml for Bright, 51 µg/ml for the 2R4F, which is a mixture of Bright and Burley tobacco, and 58 µg/ml for Burley, which had a shallower slope than the other two cigarette types. Conclusion: This cell-based assay can determine the GJIC-inhibitory activity of CSC, and meets ISO criteria for precision and accuracy. The assay can also discriminate between different CSCs, as reflected by the EC50 values for the three cigarette types. In conclusion, this screening assay is an adequate tool to determine GJIC, which has been proposed to play a role in tumor promotion.

1951 DEVELOPMENT OF AN ASSAY SYSTEM FOR SIMPLE AND EASY DETERMINATION OF CELL DIFFERENTIATION IN WELL-DIFFERENTIATED HUMAN COLON CANCER CELLS.

Y. Nakamura¹, Y. Nakayama¹, E. Park¹, K. Sato¹, B. L. Upham², C. Chang² and J. E. Trosko². ¹Food Science, Kyoto Prefectural University, Kyoto, Japan and ²Pediatrics and Human Development, Michigan State University, Lansing, MI.

Well-differentiated types of colon carcinoma account for 52.5% of the total number of colon cancer patients. However, very few *in vitro* studies have been performed with a well-differentiated colon cancer cell type, because the well-differentiated type of cells are generally difficult to culture *in vitro*. The goal of this study was to develop an assay system for a simple and easy determination of cell differentia-

tion in a well-differentiated human colon cancer cell type. Confluent RCM-1 cells (well-differentiated human colon cancer cells) spontaneously form some ducts resembling microvilli structures in plastic culture dish. When RCM-1 cells seeded in a 96-multi-well plate were cultured with kaempferol (a flavonoid mainly distributed in onion and broccoli) as an inducer of cell differentiation, duct formation was accelerated in the number and the size. Alkaline phosphatase activity, which is an early stage marker in cell differentiation, also increased. It is suggested that the real-time morphological observation of the duct formation can substitute for the alkaline phosphatase activity as an indication for differentiation. We thus developed the simple assay system that made possible speedy assessment for many samples in cell differentiation. Using this morphological differentiation assay, two well-differentiated human colon cancer cells (RCM-1 cells and KNC cells) were cultured to survey their potential involvement in differentiation. Forskolin accelerated the duct formation in RCM-1 cells, and AG490 changed the cell morphology in KNC cells. Thus, increasing intracellular cAMP and inhibition of Stat3 phosphorylation might be involved in the differentiation of RCM-1 cells and KNC cells, respectively. U0126 and wortmannin had no effects on either cell line. cAMP and Stat3 appeared to be involved in kaempferol-induced differentiation of RCM-1 and KNC cells, respectively.

1952 EVALUATION OF THE CYTOTOXICITY OF DRINKING WATER DISINFECTION BYPRODUCTS (DBPS): TRIHALOMETHANES (THMs), HALONITROMETHANES (HNMs), AND HALOACETIC ACIDS (HAAs) IN NORMAL HUMAN COLON CELLS.

C. P. Jones¹, A. Khamdy², K. Sawyer², S. Vong³, M. Moyer⁴ and A. DeAngelo¹. ¹NHEERL, U.S. EPA, Research Triangle Park, NC, ²Biology Department, North Carolina A&T University, Greensboro, NC, ³Shaw University, Raleigh, NC and ⁴InCell Corporation, San Antonio, TX.

Epidemiological studies have linked the consumption of chlorinated surface waters to an increased risk of colorectal cancer. THMs and HAAs were found to increase cancer in laboratory animals, but no toxicity studies exist for the recently identified HNMs. Normal Human colonocytes (NCM-460) were plated at 7000 cells/well and incubated for 24 hours at 37°C/5% CO₂ after which the cells were exposed to THMs, HNMs, or HAAs at concentrations of 1.00E-07 M - 3.0E-03 M for 72-96 hours. Cell density was quantified using a crystal violet staining procedure. The concentration of a chemical that induced a 50% inhibition of cell growth (IC50) when compared to the untreated cells was calculated. The HNM IC50 ranged between 1.30E-05 - 1.0E-4 M. Only tribromo-methane and dibromochloromethane of the THM series exhibited cytotoxicity (~3.0E-03 M). Enzymatic analysis demonstrated that NCM460 cells possessed GSTT-1 and CYP2E1 activity similar to that measured in the large intestine and suggests a capability to activate THMs to cytotoxic intermediates. Prior treatment of the HNMs and THMs with human microsome preparations did not alter their cytotoxicity. The IC50 for the HAAs ranged between 1.48E-05 M - 3.41E-03 M. In general, the order of cytotoxicity was HNMs>HAAs>THMs. Within a series, the cytotoxicity increased with the degree of bromination and decreased with increasing molecular weight. The study demonstrated a cytotoxic response of NCM460 cells to DBPs similar to that of non-human mammalian cells (Plewa, MJ et al., Environ. Sci. Technol. 2004, 38, 62-68) and suggests that they might prove useful in determining a mechanistic potential for the carcinogenicity of unregulated DBPs. (This abstract has been reviewed and approved by the Environmental Protection Agency and does not necessarily reflect the views of the Agency)

1953 SIGNIFICANCE OF INFLAMMATION-ASSOCIATED REGENERATIVE MUCOSA CHARACTERIZED BY PANETH CELL METAPLASIA AND β -CATENIN ACCUMULATION IN THE ONSET OF COLORECTAL CARCINOGENESIS IN RATS INITIATED WITH 1, 2-DIMETHYLHYDRAZINE.

T. Imai, M. Hasumura, Y. Cho, Y. Ota, S. Takami and M. Hirose. *National Institute of Health Sciences, Tokyo, Japan*. Sponsor: A. Nishikawa.

It is known that a short-term dextran sodium sulfate (DSS) treatment strongly promotes colorectal tumor development in rats initiated with 1,2-dimethylhydrazine (DMH). In the present study, to clarify mechanisms for the DSS-associated tumor promotion, a time-course study for histopathological and immunohistochemical analyses and β -catenin gene mutations in colorectal mucosa at early stages of this model were conducted. F344 males were given three subcutaneous injections of DMH (40 mg/kg body weight) in a week, followed by free access to drinking water containing 1% DSS for a week. At 1 to 8 weeks after the DSS treatment, rats were euthanized and colorectal samples were collected. At week 1, the colorectal mucosa showed extensive loss of crypts/erosion along with significant inflammatory cell infiltration. Reactive hyperplasia was frequently accompanied in the neighboring mu-

cosa. At weeks 4 to 8, the pronounced inflammatory and hyperplastic lesions were mended, and regenerative mucosa with architectural alteration of crypts without significant cellular atypia were frequently observed. The regenerative mucosa was partly characterized by with Paneth cell metaplasia and altered subcellular localization of β -catenin along with some interstitial inflammatory cell infiltration. Dysplastic foci were frequently found in the regions with Paneth cell metaplasia, and adenomas/carcinomas also arose at this time point. Point mutations mainly in codons 34 and 41 of β -catenin gene were detected in the six of 27 samples of regenerative mucosa with Paneth cell metaplasia and four of 9 dysplastic foci/adenomas/carcinomas. These findings indicate that cell proliferation/inflammation-associated regenerative mucosa with Paneth cell metaplasia and alteration in APC/ β -catenin/Tcf signal transduction pathway is possibly involved in the acceleration of colorectal carcinogenesis in this DMH-DSS rat model.

1954 OCHRATOXIN A CARCINOGENICITY: TIME- AND DOSE-DEPENDENT INCREASE IN RENAL CELL PROLIFERATION IN MALE F344 RATS.

E. Rached¹, G. C. Hard², K. Blumbach³, K. Weber³, R. Draheim³, U. Steger⁴, W. Dekant¹ and A. Mally¹. ¹Department of Toxicology, University of Würzburg, Würzburg, Germany, ²NTP Archives, Research Triangle Park, NC, ³RCC Ltd., Itingen/Ettenhofen, Switzerland and ⁴Department of Surgery, University of Würzburg, Würzburg, Germany.

The mycotoxin ochratoxin A (OTA) is one of the most potent renal carcinogens studied by the NTP to date. Male rats are most susceptible to OTA nephrotoxicity and carcinogenicity and chronic administration of OTA (70 and 210 μ g/kg b.w.) for two years has been shown to induce high incidences of adenomas and carcinomas. In contrast, treatment with a lower dose of 21 μ g/kg b.w. did not result in increased tumor rates. Since the mechanism of tumor formation by OTA is still largely unknown, this study was conducted to determine if sustained stimulation of renal cell proliferation may contribute to OTA carcinogenicity.

Male F344 rats were treated with OTA for up to 13 weeks under conditions of the NTP bioassay. Bromodeoxyuridine (BrdU) was administered via osmotic pumps implanted 7 days prior to necropsy and cell proliferation was quantified using BrdU immunohistochemistry. No signs of nephrotoxicity were evident by clinical chemistry, but relative kidney weight was significantly reduced in the mid and high dose group. Repeated administration of OTA at doses of 70 and 210 μ g/kg b.w. led to a marked dose- and time-dependent increase in renal cell proliferation. The pattern of labeling consisted of scattered individual or clusters of P3 tubules with multiple nuclei labeled, spreading from the medullary rays into the outer stripe of the outer medulla, with a clear increase related to time and dose. No significant effects were evident in the low dose group (21 μ g/kg b.w.) or in the liver, which is not a target for OTA carcinogenicity.

In summary, results from this study indicate that stimulation of cell proliferation may play an important role in OTA carcinogenicity. The apparent correlation between enhanced cell turnover and tumor formation induced by OTA provides further evidence for an epigenetic, thresholded mechanism.

1955 HIGHER UPTAKE, CYTOTOXICITY, AND CELL TRANSFORMING ABILITY OF NICKEL SUBSULFIDE COMPARED TO NICKEL SULFATE IN C3H/10T1/2 MOUSE EMBRYO CELLS.

D. C. Castillo¹, M. Mathur¹, K. Vander Wall¹, J. J. Chen¹, R. Verma¹ and J. R. Landolph^{1,2,3}. ¹Department of Mol. Microbiol./Immuno., University of Southern Calif., Los Angeles, CA, ²Department of Path., University of Southern Calif., Los Angeles, CA and ³Department of Pharmacology/Pharmacology Sciences., University of Southern Calif., Los Angeles, CA.

Different nickel compounds have different carcinogenic potentials. To determine why nickel subsulfide (Ni3S2) was carcinogenic in animals and nickel sulfate (NiSO4) was not, we measured their cellular uptakes, cytotoxicities, and abilities to induce morphological transformation in cultured C3H/10T1/2 (10T1/2) mouse embryo cells. Ni3S2 (NiPERA, mean particle diam., 8.4 μ m) was phagocytosed into 10T1/2 cells at concentrations of 0.25 - 1.0 μ g/ml (60% of cells had phagocytic vesicles with Ni3S2 particles at 1 μ g/ml), and nickel ions were detected in the cytoplasm and nuclei of cells (Newport Green fluorescence method). Ni3S2 (48 hr exposure) induced strong, dose-dependent cytotoxicity in 10T1/2 cells (LC50 = 1.0 μ g/ml), and a linear, dose-dependent yield of morphologically transformed foci (slope = 3.2 foci/20 dishes/ μ g/ml compd.). NiSO4 hexahydrate (Sigma Chem. Co.) was not phagocytosed by 10T1/2 cells but did enter the cytoplasm and nucleus of cells, but only at high concentrations, 50 - 100 μ g/ml, and induced a dose-dependent but weak cytotoxicity (LC50 value = 50 μ g/ml). NiSO4 induced weak morphological transformation in three of four experiments, only at high concentrations, 25 - 100 μ g/ml (slope = 0.011 foci/20 dishes/ μ g/ml compd., p = 0.053). We

conclude: 1) Ni3S2 is a 50-fold stronger cytotoxin and at least a 291-fold stronger cell transforming agent than NiSO4 because Ni3S2 is taken up by cells at 0.25 - 1.0 μ g/ml, whereas NiSO4 is only taken up into cells at 50 - 100 μ g/ml; 2) NiSO4 is a weak cell transforming agent, only at much higher concentrations than nickel subsulfide (50 - 100 μ g/ml); and 3) the in vitro cell transforming activities of Ni3S2 and NiSO4, are consistent with the strong carcinogenicity of Ni3S2 and lack of carcinogenicity of NiSO4, by the inhalation route in rats. Supported by Contract from NiPERA to J. Landolph.

1956 GENE EXPRESSION ANALYSIS OF METAL-IMPLANTED LEG MUSCLE.

E. J. Perkins⁴, D. Bannon¹, J. F. Dillman², L. E. Roszell¹, C. S. Phillips², W. Bao³ and R. D. Wolfinger³. ¹Directorate of Toxicology, Center for Health Promotion and Preventive Medicine, U.S. Army, APG, Aberdeen, MD, ²Cell and Molecular Biology Branch, Medical Research Institute for Chemical Defense, U.S. Army, Aberdeen Proving Ground, MD, ³SAS Institute, Inc., Cary, NC and ⁴Environmental Genomics and Genetics Team, Environmental Laboratory, Engineer Research and Development Center, U.S. Army, Vicksburg, MS.

Rhabdomyosarcoma is a rare childhood muscle cancer with an incidence of less than 1 per million per year and a poor prognosis, depending on the subtype. Though naturally-occurring rhabdomyosarcoma is rare, a similar disease has been shown to be highly penetrant in animals implanted with the transition metals nickel and cobalt, as well as nickel containing alloys. The applicability of this model to the human disease has not been investigated. In this work, microarray analysis was used to examine gene expression in rats implanted with rhabdomyosarcoma inducing alloys to see if gene expression could be linked with either mode of action or mechanism. Tissue samples surrounding implanted pellets were taken at necropsy for 1 and 3 month exposures; and from tumors (at 7 months) and tissue proximal to the tumor that appeared normal. Samples were flash frozen in liquid nitrogen. RNA was extracted from the tissue and used to generate oligonucleotide microarray probes for gene expression profiling using Affymetrix Rat 230 2.0 arrays. Results were analyzed using JMP Genomics and Genesifter, using PCA, ANOVA, and KEGG Pathways. The 1 and 3 month samples showed an immunologic response which was not evident in the tumors or control tissue. On the other hand the tumors showed cell cycle deregulation compared to normal tissue. These preliminary results represent the first analysis of gene expression in this type of model, and further work is proposed to examine the fundamental mechanism of this metal-induced sarcoma using selected time points on the pathway to tumor formation.

1957 FOLATE DEFICIENCY ENHANCES ARSENIC EFFECTS ON EXPRESSION OF GENES INVOLVED IN EPIDERMAL DIFFERENTIATION.

G. Nelson¹, G. Ahlborn¹, D. Delker¹, K. Kitchin¹, T. O'Brien², Y. Chen², M. Kohan¹, B. Roop¹, W. Ward¹ and J. Allen¹. ¹U.S. Environmental Protection Agency, Research Triangle Park, NC and ²The Lankenau Institute for Medical Research, Wynnewood, PA.

Chronic arsenic exposure in humans is associated with cancers of the skin, lung, and bladder. There is evidence that folate deficiency may increase susceptibility to arsenic's effects, including arsenic-induced skin lesions. K6/ODC mice develop skin tumors when exposed to 10 ppm sodium arsenite for 5 months. In the current study, K6/ODC mice maintained on either a folate-deficient or a folate-sufficient diet were exposed to 0, 1, or 10 ppm sodium arsenite in the drinking water for 30 days. Total RNA was isolated from skin samples and gene expression analyzed using Affymetrix Mouse 430 2.0 GeneChips. Data from 24 samples, with four mice in each of the six treatment groups, were RMA normalized and analyzed by two-way ANOVA using GeneSpringTM. Top gene ontology (GO) categories for genes responding significantly to both arsenic treatment and folate deficiency include DNA metabolism, DNA replication, sulfur metabolism and epithelial cell differentiation. For these genes, folate deficiency magnifies the response to arsenic treatment. In particular, expression of markers of epidermal differentiation such as loricrin, small proline rich proteins, and involucrin was significantly reduced by arsenic in the folate-sufficient animals, and reduced further or at a lower arsenic dose in the folate-deficient animals. In addition, several genes involved in epidermal cell growth were up-regulated by arsenic treatment, but folate status did not consistently affect their expression. The suppressive effect of arsenic on epidermal differentiation marker expression in cultured human keratinocytes has been reported in the literature. This may point to a mechanism of neoplasia in which the cells are blocked from achieving the normal state of differentiation and remain capable of proliferation. Our *in vivo* results suggest that dietary folate deficiency may exacerbate this effect. *This abstract does not necessarily reflect EPA policy.*

1958 CENTROSOMAL AMPLIFICATION AND ANEUPLOIDY IN CULTURED HAMSTER CELLS EXPOSED TO ZIDOVUDINE (AZT).

O. A. Olivero¹, J. M. Ming¹, Y. Ward², C. Semino-Mora³, E. J. Robinson¹, J. P. Borojerdi¹, C. Cooch¹, B. J. Taylor¹ and M. C. Poirier¹. ¹CDI, National Cancer Institute, Bethesda, MD, ²Cell and Cancer Biology Branch, National Cancer Institute, NIH, Bethesda, MD and ³USHS, Bethesda, MD.

Alterations in chromosome number, or aneuploidy, play a pivotal role in malignant transformation, although it has not been established if they are the cause or the consequence of malignancy. The centrosome, an organelle that consists of two orthogonally-placed centrioles immersed in a matrix of proteins, directs chromosomal migration by a complex process of tubulin-chromatin binding. Here, alterations in these proteins, as well as centrosomal amplification, were explored in Chinese Hamster Ovary (CHO) cells exposed to 0, 200, 400 or 800 μ M AZT for 24 hours. Centrosomes, identified by a pericentrin antibody, and centromeric positive micronuclei, stained using a CREST antibody, were quantified in 500-1000 cells from each of three separate exposures. In addition, cell replication, but not centrosome replication, was arrested by hydroxyurea (HU), and genomic instability and aneuploidy were analyzed by immunofluorescence and confocal microscopy. Centrosomal amplification, evidenced by the percentage of cells containing ≥ 2 centrosomal positive bodies, occurred in 7.0, 10.5, 9.3, and 14.5% of cells exposed to 0, 200, 400 or 800 μ M AZT + 2mM HU, respectively. In parallel cultures, electron microscopy (EM) confirmed an increase in the number of centrosomes, and high resolution images revealed centrosomal fragmentation and electron-dense pericentriolar satellites. Centromeric positive micronuclei were analyzed in CHO cells exposed to 0, 200, 400 or 800 μ M AZT, and the percentage of 25 micronuclei with centromeric positive signals was 10, 8.0, 9.5, and 18.0% respectively. Therefore, genomic instability, driven by AZT genotoxicity and clastogenicity as well as alterations in proteins involved in centrosomal activation, may contribute to the carcinogenic potency of this compound.

1959 LINGERING OIL AND SEA OTTERS: DETECTION OF DNA ADDUCTS AS A BIOMARKER OF PAH EXPOSURE.

B. Mahadevan¹, T. Rianprakaisang¹, V. LaRonge¹, B. Ballachey², P. Snyder³ and W. M. Baird¹. ¹Environmental & Molecular Toxicology, Oregon State University, Corvallis, OR, ²United States Geological Survey, Anchorage, AK and ³Department of Veterinary Pathobiology, Purdue University, West Lafayette, IN.

Lingering oil from the Exxon Valdez oil spill has been known to persist in intertidal habitats in western Prince William Sound, particularly in bays and passages where oiling was most severe in 1989. Some of the strongest evidence of continuing effects of lingering oil spill comes from long term monitoring of sea otter populations and their exposure to polycyclic aromatic hydrocarbons (PAH). Sea otter population recovery remained incomplete as of 2003-2004 and individual sea otters continued to exhibit elevated levels of the cytochrome P450 1A biomarker in areas with greatest quantities of lingering oil. In order to understand the biological effects on individual animals, we used the detection of DNA adducts as a biomarker for PAH exposure. DNA was isolated from sea otter peripheral blood mononuclear cell (PBMC) samples collected from 1996-2005, including samples from otters recaptured in two different years, and subjected to DNA adduct analysis by 33P postlabeling and HPLC. Several of the archived samples revealed the formation of DNA adducts with a major adduct peak eluting at the same retention time as benzo[a]pyrene DNA adducts. The total DNA adducts formed ranged from 0.1-0.8 pmol/mg of DNA. Although there were no significant differences in DNA binding between samples from different years, low but detectable DNA adducts were exhibited by PBMC from several animals. The results from this study suggest that there may be biological effects of lingering oil on sea otters and that measurement of DNA adducts may be a strong indicator of deleterious effects from PAH exposure.

1960 REPLICATION OF N²-ETHYLDEOXYGUANOSINE DNA ADDUCTS IN HUMAN CELLS.

D. C. Upton¹, X. Wang¹, P. Blans², F. W. Perrino¹, J. C. Fishbein² and S. A. Akman¹. ¹Wake Forest University Health Sciences, Winston-Salem, NC and ²University of Maryland - Baltimore County, Baltimore, MD. Sponsor: M. Miller.

The association between alcohol and the risk of cancer is well documented, but the exact mechanism of alcohol-related carcinogenesis is unknown. Ethanol is predominantly converted to acetaldehyde in vivo, which can react with DNA to form stable exocyclic alkylamino DNA adducts. The primary adduct formed by this reaction can be converted to N²-ethyldeoxyguanosine (N²-ethylGuo). In vitro, N²-ethylGuo blocks a variety of replicative DNA polymerases. Single chemically synthesized N²-ethylGuo or O⁶-ethyldeoxyguanosine (O⁶-ethylGuo) adducts were placed site specifically in the suppressor tRNA gene of the mutation reporting shuttle plasmid pLSX and replicated in human embryonic kidney 293 (HEK293)

cells. N²-ethylGuo and O⁶-ethylGuo were both minimally mutagenic in double stranded pLSX replicated in HEK293 cells. When deoxyuridines were placed on the complementary strand at 5' and 3' positions flanking the adduct, 5-fold ($p = 0.02$) and 22-fold ($p = 0.00006$) enhancements of the N²-ethylGuo and O⁶-ethylGuo-induced mutant fractions were seen in HEK293 cells, respectively. In the HEK293 cells, the mutation spectrum generated by N²-ethylGuo consisted of 65% single base deletions, 25% adduct site-targeted transversions, and 18% transversions at the site of the adduct, in contrast to the exclusive production of adduct site-targeted transitions by O⁶-ethylGuo. The yield of progeny plasmids after replication in HEK293 cells was reduced by the presence of N²-ethylGuo in parental plasmids with or without deoxyuridine to 39% ($p = 0.005$) or 19% ($p = 0.0004$), respectively. Taken together, these data indicate that N²-ethylGuo is a mutagenic DNA lesion, and that N²-ethylGuo in DNA exerts its principal biological activity by blocking translation DNA synthesis in human cells, resulting in either failure of replication or frameshift deletion mutations.

1961 DNA DAMAGE RESPONSE TO NAPHTHALENE METABOLITES IN DT40 MUTANT CELLS.

A. M. Luke¹, S. Takeda², J. A. Swenberg^{1,3} and J. Nakamura³. ¹Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, ²Department of Radiation Genetics, Kyoto University, Kyoto, Japan and ³Department of Environmental Science and Engineering, University of North Carolina, Chapel Hill, NC.

Naphthalene is a ubiquitous environmental pollutant that has been associated with carcinogenesis in laboratory animals and humans. Reactive quinonoid and quinone intermediates, formed by biotransformation, may have a role in the mechanism of action of naphthalene toxicity. Three possible mechanisms by which the naphthalene metabolites cause deleterious mutations have been proposed: oxidative stress, abasic sites and bulky adducts. To better understand DNA damage response to the metabolites, we have used a series of isogenic DT40 cells deficient in the DNA damage response genes. Wild-type (wt) and mutant DT40 cell lines were exposed to 1,2-naphthalenediol (NCAT), 1,2-naphthoquinone (1,2-NQ), 1,4-naphthalenediol (NHQ) or 1,4-naphthoquinone (1,4-NQ) for ten cell replication cycles. Cell survival was determined by the XTT-based cell proliferation assay at the end of cultivation. The impact on the cell survival of the naphthalene metabolites in the wild-type (wt) DT40 cells was ranked in decreasing order as NHQ=1,4-NQ>NCAT=1,2-NQ. In contrast, the DNA damage response deficient cell lines displayed stronger sensitivity to the NHQ over 1,4-NQ. Cell survival in the mutant cell lines treated with NHQ was ranked as *msh3>fancd2>xpa=parp1>rev3>fen1>atm>brca1>blm>brca2>po1>chk1=wt=wrn*. Cell death of 1,4-NQ in the same mutant cell lines was ranked as *fen1>brca1>fancd2>msh3>parp1>po1>brca2>rev3>po1>atm>wt=blm>xpa>chk1>wrn*. These results showed a distinct difference among the mutant cell lines in response to the 1,4 metabolites suggesting that exposure to NHQ and 1,4-NQ elicit different DNA damage responses. These DNA damage response data suggest that bulky adducts or oxidative DNA lesions, but not abasic sites, appear to play important roles in the DNA damage response to NHQ and 1,4-NQ. (Supported in part by P42-ES05948 and P30-ES10126 from the NIH; 5T32ES007126-22 and 5T32CA72319-08 from the NIEHS.)

1962 DNA DAMAGE RESPONSE TO FORMALDEHYDE AND ACROLEIN.

J. R. Ridpath¹, S. Takeda², J. A. Swenberg¹ and J. Nakamura¹. ¹Environmental Sciences and Engineering, UNC-Chapel Hill, Chapel Hill, NC and ²Department of Radiation Genetics, Kyoto University, Kyoto, Japan.

This project has been undertaken to better understand cellular processes that respond to environmental and endogenous exposure to aldehydes. To date, we have focused on formaldehyde (FA) and acrolein (ACR) and the impact of each on excision repair processes, namely, mismatch repair (MMR), nucleotide excision repair (NER) and base excision repair (BER). Previous experiments have implied that NER may be the primary process that repairs DNA-protein cross-links (DPC) caused by FA, but the relative contributions of NER, MMR, and BER have not been characterized. DT40 cells utilized in this study provide a powerful system with advantages over either yeast or murine cells. There are a multitude of isogenic DT40 cell lines available which have been used primarily for genetic studies; however, we are aware of only limited use of these cells for studying cellular effects of environmental and endogenous toxins. To better understand the DNA damage response to FA and ACR, we have used a panel of isogenic DT40 cells deficient in the excision repair genes *po1*, *fen1*, *parp1*, *xpa* and *msh3*. Our results show that cells deficient in *xpa* (NER), *msh3* (MMR) and *parp1* mutants are exquisitely sensitive to FA. *Po1* (BER) showed moderate sensitivity to FA while *fen1* (BER) exhibited none. Thus, it is strongly suggested that FA-induced damage is repaired by both NER and MMR pathways. Parp1 has been reported to be an important protein in several DNA repair pathways (BER, SSBR, perhaps homologous recombination

(HR) mediated double strand break repair). The hypersensitivity of *parp1* mutants along with moderate sensitivity of *poβ* mutants may imply a function of BER in DPC repair as well as in HR-mediated repair and translesion DNA synthesis. ACR exposure also resulted in strong sensitivity in *msh3*, and with moderate sensitivity in *xpa*, *fen1*, and *parp1* mutants indicating the importance of NER, MMR and BER. (This research was supported in part by P42-ES05948, ES11746, P30-CA16086, and P30-ES10126 from the National Institutes of Health.)

1963 THE ROLE OF HEMATOTOXICITY IN CHEMICALLY INDUCED ACUTE MYELOID LEUKEMIA.

D. Pyatt^{1,2}, S. Hays¹, L. Alyward¹, P. Kerzic³ and C. Berger^{4,5}. ¹Summit Toxicology, Lafayette, CO, ²Schools of Pharmacy and Medicine, University of Colorado, Denver, CO, ³John Hopkins University, Baltimore, MD, ⁴Applied Pharmacology and Toxicology, Inc., Gainesville, FL and ⁵C.E.H.T., Department Physiol. Sciences., University of Florida College of Veterinary Medicine and Toxicology, Gainesville, FL.

The vast majority of acute myelogenous leukemias (AML) are de novo, having no known cause. However, AML has also been reported following high dose exposure to benzene, certain classes of cytotoxic chemotherapy or ionizing radiation (s-AML). The cell of origin for AML and s-AML is believed to be a myeloid committed hematopoietic progenitor cell (HPC), historically found only in the bone marrow; thus, s-AML has traditionally been thought to require bone marrow toxicity. However, recent data reveal a small population of HPCs circulating in peripheral blood (pHPC), suggesting that s-AML could theoretically arise from a pHPC that is transformed in the periphery and migrates back into the bone marrow for subsequent proliferation and manifestation of AML. If true, chemicals (even those that lack systemic distribution following exposure, e.g. formaldehyde) could cause s-AML without bone marrow toxicity. We have evaluated the published literature to test these mutually exclusive hypotheses: 1) s-AML arises in bone marrow secondary to obligate bone marrow toxicity/involvement; and 2) s-AML arises in the peripheral circulation from a damaged pHPC. Literature was evaluated according to minimal criteria for establishing scientific evidence: a) measurements have been authentically identified and are stable within a known rate of experimental error; b) extraneous factors that could affect the measurements have been adequately controlled; c) the stable measurements have been independently replicated. Based on these criteria, there is considerable scientific evidence in support of hypothesis 1. However, data to support hypothesis 2 is lacking or falls short of constituting scientific evidence. Accordingly, peripheral transformation in the absence of bone marrow toxicity is not currently supportable based on existing scientific evidence.

1964 CAN INHALED FORMALDEHYDE RESULT IN HEMATOPOIETIC MALIGNANCIES?

B. Golden³ and D. Pyatt^{1,2}. ¹Summit Toxicology, Lafayette, CO, ²Schools of Pharmacy and Medicine, University of Colorado, Denver, CO and ³ToxLogic, Potomac, MD.

This poster specifically addresses the hypothesis that formaldehyde exposure is a potential etiological agent in the development of human hematopoietic malignancies. Proponents of this hypothesis have advanced the position that formaldehyde is a potential risk factor in the development of acute and chronic myeloid leukemia, Hodgkin's and non-Hodgkin's lymphoma (NHL), multiple myeloma and acute and chronic lymphocytic leukemia. If true, this would establish formaldehyde as an unprecedented hematopoietic toxicant as no single agent has ever been shown to increase the risks of all of these discrete diseases (including high dose benzene exposure, ionizing radiation exposure and myelotoxic doses of chemotherapeutic agents). Epidemiological evidence for the hematopoietic toxicity and carcinogenicity of formaldehyde is weak. As a result, attempts have been made to supplement the lack of strong epidemiological support with biological plausibility arguments. One hypothesized mechanism includes the potential for NHL to arise following formaldehyde exposure to susceptible cells located in the Nasal Associated Lymphoid Tissue (NALT). Experimental studies have demonstrated that blood concentrations of formaldehyde change very little following inhalation exposure to relatively high concentrations. Therefore, formaldehyde induced transformation must occur in peripheral lymphoid tissue and cannot be dependent upon systemic distribution. There is currently no evidence that chemically induced transformation of lymphoid tissue in the NALT can occur. Moreover, endogenous production of formaldehyde results in blood concentrations far greater than those resulting from occupational exposures. Therefore, it is difficult to understand how slight increases in blood levels of formaldehyde following inhalation could result in such an extraordinarily potent hematopoietic toxicant. The biological evidence pertaining to this hypothesis is discussed, particularly regarding NALT tissue as a potential target for chemical transformation.

1965 CYTOTOXICITY AND CYP MODULATION IN DELTAMETHRIN AND PERMETHRIN TREATED HUMAN HEPATOCYTES.

P. C. Das¹, E. Hodgson¹, Y. Cao¹, N. Cherrington² and R. L. Rose¹. ¹Toxicology, North Carolina State University, Raleigh, NC and ²College of Pharmacy, University of Arizona, Tucson, AZ.

Deltamethrin and permethrin are widely used in agriculture, public health and military deployments. Their toxicity is mediated by interference with nerve membrane sodium channels, GABA-receptor ionophore complexes and neurotransmitters. In this study the potential of deltamethrin and permethrin for cytotoxicity and induction of CYP isoforms in human hepatocytes was evaluated. Permethrin and deltamethrin showed dose-dependent effects on adenylate kinase activity in HepG2 cells, in which 50 and 100 μ M, respectively, induced ~3- and 5-fold, with no further increase above 200 μ M. Permethrin and deltamethrin likewise induced adenylate kinase in human hepatocytes. Approximately 3-fold induction was noted at 200 μ M deltamethrin and ~4-fold induction was noted at 100 μ M permethrin. Cytotoxicity was noted in HepG2 cells after 48 to 72 h exposure to 100 and 200 μ M deltamethrin [15-25%] or permethrin [15-20%]. Dose-dependent induction of caspase-3/7 by deltamethrin was initiated at 12.5 μ M and peaked at 100 to 200 μ M after 72 h. Permethrin showed induction of caspase-3/7 at 3.125 μ M, peaking at 100 μ M reaching a plateau at 200 μ M after 72 h. Maximal induction was ~2.5 fold by either pyrethroid. Actinomycin D induced caspase-3/7 ~5-7 fold whereas Z-DEVD-FMK completely abrogated the deltamethrin and permethrin induced caspase-3/7 activity. At 100 μ M deltamethrin 2-3 fold induction of CYP1A1 and CYP2B6 mRNA was noted while ~25-fold induction of CYP3A4 mRNA was noted. Permethrin-mediated CYP induction was much less potent, up to 4-fold or less for CYP1A1, CYP3A4, CYP3A5, CYP2B6, and CYP2A6. However, the variability in CYP mRNA induction was extensive making the induction potential of deltamethrin and permethrin difficult to evaluate. Overall, either pyrethroid showed mild induction of major CYPs but also caused cytotoxicity in human hepatocytes.

1966 METABOLISM OF CHLORPYRIFOS BY HUMAN HEPATOCYTES.

K. Choi, E. Hodgson, H. Joo and R. L. Rose. Toxicology, North Carolina State University, Raleigh, NC.

The metabolism of chlorpyrifos (CPS) by human hepatocytes was investigated using LC-MS/MS. Cytochrome P450 (CYP)-dependent and phase II-related products were determined following incubation with CPS. The CYP-related products, 3, 5, 6-trichloro-2-pyridinol (TCP), diethyl thiophosphate (DETP) and dealkylated CPS were found. Diethyl phosphate (DEP) was not identified due to its high polarity and lack of retention with the chromatographic conditions employed. Phase II-related conjugates, including O- and S-glucuronides as well as glutathione (GSH)-derived metabolites were determined in CPS-treated human hepatocytes. CPS-SG and mono-O-deethyl CPS-SG, probable key intermediates of the GSH conjugation pathway were detected. CPS is likely to be biotransformed in the hepatocytes through four different pathways: dearylation (I), dealkylation (II), glucuronidation (III) and GSH conjugation (IV). However, chlorpyrifos oxon (CPO) was not found using either LC-MS/MS or HPLC-UV. Even though human liver CYP isoforms are known to activate CPS to CPO, these results suggest that human liver plays an important role in detoxification, rather than activation, of CPS.

1967 DIFFERENTIAL EXPRESSION OF RETINOIC ACID BIOSYNTHETIC AND METABOLISM GENES IN LIVERS FROM MICE TREATED WITH HEPATOTUMORIGENIC AND NON-HEPATOTUMORIGENIC CONAZOLES.

P. Chen, W. T. Padgett, T. Moore, S. D. Hester, S. Thai, W. Winnik and S. Nesnow. Environmental Carcinogenesis Division, U.S. EPA, Research Triangle Park, NC. Sponsor: D. Wolf.

Conazoles are fungicides used in crop protection and as pharmaceuticals. Triadimefon and propiconazole are hepatotumorigenic in mice, while myclobutanil is not. Previous toxicogenomic studies suggest that alteration of the retinoic acid metabolism pathway may play a key event in conazole-induced hepatotumorigenesis. We have used quantitative real-time polymerase chain reaction (qRT-PCR) to examine the expression of specific genes associated with the biosynthesis, and metabolism of all trans retinoic acid (RA) in the livers from male CD-1 mice (3 per group). The mice were exposed to triadimefon (1800 ppm), propiconazole (2500 ppm) or myclobutanil (2000 ppm) in the feed for 4, 30 or 90 days. The genes examined were RA biosynthesis genes *Bcmo1* (β -carotene 15, 15'-monooxygenase), *Aox1* (aldehyde oxidase), *Rdh9* (retinol dehydrogenase), and *Alldh1a7* (aldehyde dehydrogenase); the RA catabolism gene *CYP26a1* (retinoic acid hydroxylase); and the retinol transport and storage gene, *Lrat* (lecithin-retinol acyltransferase). *CYP26a1* mRNA had increased expression by all three conazoles at the 4 and 30

day exposure times. Triadimefon induced the greatest mRNA expression of *CYP26a1* at each time point (e.g. 9.6-, 11.6- and 2.1-fold induction vs. controls at day 4, 30 and 90, respectively). *Aldh1a1* was upregulated, and *Bcmo1*, *Rdh9*, and *Lrat* were down regulated by all three conazoles at selected time points. *Aox1* was unaffected by conazole treatment. Overall, the transcriptional activities of *Bcmo1*, *Rdh9*, and *Lrat* were correlated with temporal *CYP26a1* expression for triadimefon and propiconazole. The induction of *CYP26a1* and the associated down regulation of several RA biosynthesis genes and *Lrat* suggest that RA levels may be reduced in hepatic tissues by these conazoles. The consistent alteration of this pathway by the tumorigenic conazoles suggests that it might be a necessary event in conazole-induced hepatotumorigenesis. (This abstract does not reflect U.S. EPA Policy)

1968 O, P-DDT ENHANCES VASCULAR ENDOTHELIAL GROWTH FACTOR EXPRESSION THROUGH THE ACTIVATION OF HIF-1 α

K. Gyun^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea and ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea.

Dichlorodiphenyltrichloroethane (DDT) is used as an insecticide and prevents many people in the tropical zone from devastating malaria. On the other hand, a number of reports have indicated that it may act as an endocrine disruptor and also has possible carcinogenic effects. VEGF, a hypoxia-inducible endothelial cell mitogen, has been characterized as a potent vascular permeability critical factor in vasculogenesis and angiogenesis. In the present study, we investigated o,p-DDT activates HIF-1 α leading to VEGF expression in the human endothelial-like ECV304 cell line. o,p-DDT treatment increased the stability and activity of HIF-1 α protein. The expression of HIF-1 α by o,p-DDT was correlated with the activation of HIF-1 α DNA binding activity and the transactivation of a HIF-1 α -dependent VEGF reporter gene. o,p-DDT induced the phosphorylation of phosphatidylinositol 3-kinase (PI3K) and ERK in the regulation of HIF-1 α activation. These results demonstrate that o,p-DDT regulates HIF-1 α action through a PI3K and ERK dependent pathway, resulting in increased VEGF expression.

1969 UP-REGULATION OF MATRIX METALLOPROTEINASE-2 EXPRESSION BY O, P-DDT.

H. Hong^{3,2,1}, H. Kim^{1,2}, J. Choi^{1,2} and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteinaceous Materials, Chosun University, Kwangju, South Korea and ³Biology, Honam University, Kwangju, South Korea.

Dichlorodiphenyltrichloroethane (DDT) is used as an insecticide and prevents many people in the tropical zone from devastating malaria. On the other hand, a number of reports have indicated that it may act as an endocrine disruptor and also has possible carcinogenic effects. In the present study, we investigated the effect of o,p-DDT on the expression of matrix metalloproteinase-2 (MMP-2) in human fibrosarcoma HT-1080 cells. o,p-DDT dose dependently increased MMP-2 mRNA and stimulated MMP-2 activity using reverse transcription-polymerase chain reaction and zymography assay, respectively. Transient transfection experiments also showed that o,p-DDT increased in MMP-2 promoter activity. MMP-2 secreted as a proenzyme, and activated by membrane-type 1 MMP (MT1-MMP). o,p-DDT treatment also increased the MT1-MMP expression. Taken together, these results demonstrate that o,p-DDT can stimulate the production of MMP-2 through the up-regulation of MT1-MMP expression in human fibrosarcoma HT1080 cells, which play an important cause of tumor-promotion.

1970 A PHYSIOLOGICALLY BASED PHARMACOKINETIC/PHARMACODYNAMIC (PBPK/PD) MODEL FOR ESTIMATION OF CUMULATIVE RISK FROM EXPOSURE TO THREE N-METHYL CARBAMATES: CARBARYL, ALDICARB, AND CARBOFURAN.

X. Zhang¹, M. S. Okino², J. B. Knaak³, A. M. Tsang¹, F. W. Power², J. Xue⁴, L. S. Harrison¹, C. B. Thompson¹ and C. C. Dary². ¹General Dynamics Information Technology, Henderson, NV, ²NERL, U.S. EPA, Las Vegas, NV, ³Department of Pharmacology and Toxicology, University at Buffalo, Buffalo, NY and ⁴NERL, U.S. EPA, Research Triangle Park, NC.

A Physiologically Based Pharmacokinetic/Pharmacodynamic (PBPK/PD) model was developed using the Exposure Related Dose Estimating Model (ERDEM) system to estimate cumulative risk resulting from exposure to three N-methyl carbamate insecticides: carbaryl, aldicarb, and carbofuran. The three-chemical model parameters were derived from previous single-chemical models which were optimized

against controlled-study rat and human (where available) data. The model includes Michaelis-Menten metabolism kinetics and equations for possible metabolic interaction among the chemicals. Acetylcholinesterase (AChE) inhibition was described by competing bimolecular inhibition processes. Exposure to the three chemicals through the dietary pathway was based on outputs from the Stochastic Human Exposure Dose Simulation (SHEDS) model. Simulations from the cumulative PBPK model produced distributions of resulting concentrations of urinary biomarkers. These distributions were then compared with the available urinary biomarker concentration distributions from CDC's Third National Health and Nutrition Examination Survey, NHANES III. The cumulative model was also used to predict the distribution on red blood cell AChE activity. The simulated results from this human cumulative PBPK/PD model in ERDEM provide a good framework for future human risk assessment.

Although this work was reviewed by EPA and approved for publication, it may not necessarily reflect official Agency policy.

1971 BIOMONITORING AND ENVIRONMENTAL MONITORING FOLLOWING INDOOR USE OF PYRETHROID PESTICIDES.

J. J. Keenan¹, X. Zhang¹, R. S. Gold², G. Leng³ and R. I. Krieger¹. ¹University of California, Riverside, Riverside, CA, ²Brigham Young University-Hawaii, Laie, HI and ³Bayer Industry Services, Leverkusen, Germany.

Pyrethroid products are extensively used in residential pest management. Twenty families that used indoor pesticides were recruited from 5 states by word-of-mouth. Pyrethroid foggers and crack and crevice ("perimeter") sprays were included. Families included 46 children (< 12 years old) and 54 teens/adults (≥ 12). Commercially available indoor fogger (Raid Deep ReachTM Fogger) with 1.7 % cypermethrin and commercially available crack and crevice spray (Air DevilTM HPX) with 0.1 % cypermethrin active ingredient were utilized. These families were biomonitoring for at least 8 days by either 24-hour, a.m./p.m., or a.m. sampling strategies. Total $\mu\text{g/kg}$ pyrethroid equivalents following crack and crevice treatment were 1.5 ± 1.1 and 0.55 ± 0.21 $\mu\text{g/kg}$ for children and teens/adults after 8 days, respectively. Total $\mu\text{g/kg}$ pyrethroid equivalents following fogging were 11 ± 8.3 and 2.6 ± 1.65 for children and teens/adults after 8 days, respectively. Back-calculated exposures below known LOAELs and regulatory NOAELs for cypermethrin indicate about a 4-fold greater urine elimination of biomarkers by children than teens/adults. Deposition pattern, air level, total surface pesticide, and transferable surface residue from several common indoor surfaces were monitored after pesticide use. Following fogger use, floor, wall, and ceiling deposition coupons accounted for 75.0, 15.5, and 9.40 %, respectively, of the pyrethroid pesticide released while less than 0.01% was found in air. Transferability testing from several different flooring materials including wood, tile, carpet, and linoleum combined with floor plans for several of the residences involved in biomonitoring will be used for determination of the relationship between flooring materials and exposure in children and adults. Biomonitoring in conjunction with in-depth environmental monitoring could prove invaluable in characterizing indoor exposure.

1972 EFFECTS OF TYROSINAEMIA ON SELECTED ORGANS IN RATS.

O. J. Blanck¹, M. Dreist², G. Semino¹, E. B. Shipp¹, F. Schorsch¹, B. A. Mallyon¹ and B. Stahl¹. ¹Bayer CropScience, Sophia Antipolis, France and ²Bayer CropScience, Monheim, Germany.

The compound 2-(2-Nitro-4-trifluoromethylbenzoyl)-cyclohexane-1,3-dione (NTBC) is a potent inhibitor of 4-hydroxyphenylpyruvate dioxygenase (HPPDase), a key enzyme in mammalian tyrosine catabolism. In 28- and 90-day studies, we examined the effect of NTBC, administered alone or co-administered with diet enriched with 2% tyrosine, on plasma tyrosine concentration and on histopathological findings in selected organs in the rat. Co-administration of a low dose of NTBC (10 or 20 $\mu\text{g/kg}$ bw/day) with dietary tyrosine allowed maximal induction of tyrosinemia. In both studies, 2% dietary tyrosine increased plasma tyrosine concentrations only moderately over controls (by 4-fold in the 28-day study, by 7-fold in the 90-day study, with a plateau reached on day 1 or 2 and a decrease thereafter). Administration of NTBC alone also increased plasma tyrosine (by 3-fold only on day 28 at 10 $\mu\text{g/kg/day}$; by approximately 12-fold from day 1 to 90 at 20 $\mu\text{g/kg/day}$). Co-administration of NTBC and 2% dietary tyrosine had a much greater effect on plasma tyrosine concentrations (26-fold from day 21 up to day 28, as much as 43-fold at day 4 and decreased thereafter in the 90-day study) than did either treatment alone. Ophthalmological and histopathological examination revealed the expected increased incidence of corneal opacities and ocular histopathological findings only in the groups co-administered NTBC and tyrosine, where plasma tyrosine generally exceeded the known threshold value for corneal effects. In

animals co-administered tyrosine and NTBC for 28 or 90 days, or NTBC for 90 days, organ weight increases and histopathological findings were observed in the presumed target organs (kidney, liver, pancreas, thyroid). There were no effects observed in animals administered either tyrosine alone for either duration or NTBC alone for 28 days. From these data it is clear that histopathological findings observed in target organs after HPPDase inhibition are secondary to increased plasma tyrosine concentrations, and are not primary effects of the inhibition itself.

1973 EFFECT OF TYROSINEMIA ON PREGNANCY AND EMBRYO-FETAL DEVELOPMENT IN THE RAT.

P. Kennel, G. Semino, E. B. Shipp, S. Wason, B. A. Mallyon and B. Stahl. *Bayer CropScience, Sophia Antipolis, France.*

The relationship between increased plasma tyrosine concentrations, due to maternal 4-hydroxyphenylpyruvate dioxygenase (HPPDase) inhibition, and potential effects on embryo-fetal development was investigated in the rat. Tyrosinaemia in pregnant rats was induced by a co-administration of NTBC [2-(2-nitro-4-trifluoromethylbenzoyl)-1,3-cyclohexanedione] at 10 µg/kg/day by gavage from gestation day (GD) 6 to 20 and tyrosine at 2% (w/w) in the diet from GD 6 to 21. NTBC is a triketone molecule which acts by inhibiting the HPPDase enzyme, i.e. the second step of the tyrosine catabolism in mammals. Co-administration of a low dose of NTBC with dietary tyrosine allowed maximal induction of tyrosinaemia. Similar groups of pregnant rats were co-administered 1) vehicle plus untreated diet, 2) NTBC plus untreated diet, or 3) vehicle alone plus 2% dietary tyrosine. The results of this study showed that tyrosinaemia was much more pronounced in the group where NTBC and tyrosine were co-administered: plasma tyrosine concentrations at necropsy were increased by 63-fold in pregnant rats co-administered NTBC plus tyrosine, by 5-fold in the group administered dietary tyrosine only, and by 8-fold in the group treated with NTBC alone. Tyrosinaemia as a result of co-administration of NTBC and dietary tyrosine produced minimal maternal toxicity in the form of slightly reduced mean food consumption, in association with a slight reduction of mean body weight gain and macroscopic findings (a few cases of mottled kidney and minimal corneal opacity). Fetal findings, induced by tyrosinaemia and observed only in the NTBC plus tyrosine co-treatment group, consisted principally of a generalized delay in ossification noted at the skeletal fetal examination, together with a higher incidence of short 14th rib and of extra ossification points on the 14th thoracic vertebra. In association, a reduction of mean fetal body weight of 7% was noted at cesarean section. In conclusion, a marked increase in plasma tyrosine concentration in pregnant rats induced a generalized delay in fetal skeletal ossification.

1974 IN VITRO METABOLISM OF TYROSINE IN VARIOUS SPECIES AFTER HPPDASE INHIBITION BY NTBC.

M. Totis, G. Semino, E. B. Shipp, B. A. Mallyon and B. Stahl. *Bayer CropScience, Sophia Antipolis, France.*

The substance 2-(2-Nitro-4-trifluoromethylbenzoyl)-cyclohexane-1,3-dione (NTBC), a potent inhibitor of the 4-hydroxyphenyl pyruvate dioxygenase (HPPDase) enzyme, was incubated with Liverbeads™ from rat, dog, rabbit, mouse and human, to determine the ability of these species to metabolize cellular tyrosine via a substitute enzymatic pathway producing hydroxylated metabolites including 4-hydroxyphenyl lactic acid (HPLA). The ability to produce such metabolites in vivo under HPPDase inhibition allows the reduction of plasma tyrosine concentrations to near-physiological levels and avoidance of the biological consequences of HPPDase inhibitor-induced tyrosinemia. In vitro measurement of HPLA production in the presence of an HPPDase inhibitor allows ranking of several species with regard to their ability to use an alternative pathway for tyrosine catabolism. Liverbeads™ contain hepatocytes in a 3-dimensional alginate matrix and were selected for their availability in all desired species. Liverbeads™ from all species were incubated in one of four conditions: 1) basal (tyrosine-free HBSS buffer), 2) basal + 100 mg/L tyrosine, 3) basal + 30 µM NTBC, or 4) basal + 100 mg/L tyrosine + 30 µM NTBC. Concentration of HPLA in the medium was measured by HPLC with fluorimetric detection at 0, 2, and 4 hours of incubation. In the rat, dog, and rabbit, HPLA was only produced in the basal + tyrosine + NTBC incubation, at low amounts and at late timepoints only. Mouse Liverbeads™ produced HPLA in all incubations and at all timepoints, with increasing production over time. Human Liverbeads™ produced HPLA in incubations with tyrosine, with NTBC, or with both tyrosine and NTBC. These results allowed us to classify the tested species into two main groups: 1) rabbit, dog, and rat, in which the alternative pathway of HPLA production is very inefficient under either physiological or stressed conditions; and 2) human and mouse, which efficiently produce HPLA via the alternative pathway. This ability to hydroxylate tyrosine prevents the toxicological consequences of HPPDase inhibition *in vivo*.

1975 LIVER-SPECIFIC EFFECTS OF CYPROCONAZOLE, A TRIAZOLE FUNGICIDE, ARE DEPENDENT UPON THE CAR NUCLEAR RECEPTOR.

R. C. Pepper¹, G. Milburn², J. Wright², J. Dow², R. Currie², J. Harris², J. Davis³, T. Pastoor¹ and I. Rusyn⁴. ¹Global Human Safety, Syngenta Crop Protection, Inc., Greensboro, NC, ²Central Toxicology Laboratory, Syngenta Ltd., Macclesfield, United Kingdom, ³Integrated Laboratory Systems, Inc., Research Triangle Park, NC and ⁴Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC.

Cyproconazole is a triazole fungicide that causes liver tumors in mice at dose levels of 100 and 200 ppm via a non-genotoxic mode of action. Cyproconazole-induced enzyme induction and other phenotypic changes to the liver resemble those of phenobarbital, a known agonist of constitutive androstane receptor (CAR). *Car*-null and wild type (C3H/HeNClrBR background) male mice were administered cyproconazole (200 or 450 ppm) or phenobarbital (850 ppm) in the diet for up to 7 days. In wild type mice, 200 ppm of cyproconazole caused liver hypertrophy, increases in liver weight and cell proliferation, single cell necrosis and fat vacuolation – effects generally similar to those caused by 850 ppm of phenobarbital. The higher dose (450 ppm) of cyproconazole caused similar liver changes, but was also accompanied by liver damage as evidenced by large increases in serum transaminases. Induction of both mRNA and protein levels for *Cyp2b10* (187-258 fold) and mRNA for *Gadd45β* (2-7 fold) was observed in cyproconazole- and phenobarbital-treated wild type mice. *Gadd45β* is an anti-apoptotic gene that is also associated with stimulation of S-phase and cell proliferation. Coumarin 7-hydroxylase activity, a marker of *Cyp2a5*, was also increased by cyproconazole and phenobarbital. In *Car*-null mice, the effects noted with either cyproconazole or phenobarbital were absent or greatly diminished. These experiments demonstrate that the short-term liver effects of cyproconazole in mice are CAR nuclear receptor-dependent and similar to those of phenobarbital, a known non-genotoxic rodent liver carcinogen.

1976 THE TYPE II PYRETHROID PESTICIDE ESFENVALERATE LOWERS SERUM ESTRADIOL AND DELAYS ONSET OF PUBERTY.

M. Pine. *Veterinary Integrative Biosciences, Texas A&M University, College Station, TX.* Sponsor: K. Donnelly.

Concern has risen that alterations in the reproductive system by exposure to endocrine disruptive chemicals such as pesticides may be adversely impacting human reproduction. Organochlorine pesticides, such as p,p'-dichlorodiphenyl trichloroethane (DDT) have been reported to possess estrogenic activity; while exposure to organophosphates such as chlorpyrifos have been associated with altered thyroid function in humans. Because exposure to these pesticides may be affecting the endocrine system, less toxic alternatives, such as synthetic pyrethroids, are increasing in usage. Pyrethroids are used worldwide to control both agricultural and household pests, and exposure is occurring in children as well as adults as evidenced by metabolites found in urine from the general population. Even though pyrethroids have been considered relatively safe, recent in vitro studies have indicated that they too may be estrogenic. Therefore, we wanted to determine the effects of juvenile exposure to a type II pyrethroid, esfenvalerate (® Asana), on puberty-related hormones and the onset of female puberty.

To assess pubertal effects, female Sprague Dawley rats were gavaged once daily from postnatal day 22 until vaginal opening (VO) with esfenvalerate (ESF) at 12, 8, and 5 mg/kg. Controls received corn oil. Animals treated with ESF showed a delay ($p < 0.05$) in age at VO for all doses administered as compared to controls. A second group of rats was gavaged once daily from day 22 until day 30 with the 5.0 mg/kg dose, and serum levels of estradiol (E2) and luteinizing hormone (LH) were measured by radioimmunoassay. E2 levels were found to be two times lower in the pesticide treated animals ($p < 0.05$) while LH levels were the same in both groups. This data would indicate that the pesticide is not acting as an environmental estrogen. While the mechanism for how ESF caused a decrease in E2 is unknown, a direct effect on the ovary seems plausible. Also, the fact that lowered serum E2 should cause an increase in serum LH suggests a potential deficit at the hypothalamic-pituitary level as well.

1977 INHIBITION OF HUMAN RECOMBINANT ACETYLCHOLINESTERASE BY CHLORPYRIFOS OXON OR METHYL PARAOXON DISPLAYS CONCENTRATION-DEPENDENT KINETICS.

R. Kaushik and L. G. Sultatos. *Pharmacology and Physiology, UMD- New Jersey Medical School, Newark, NJ.*

The capacity of the anticholinesterase organophosphates to inhibit acetylcholinesterase is often quantified by the inhibitory constant k_i . In the current study, the k_s for both chlorpyrifos oxon (*O,O*-diethyl *O*-(3,5,6-trichloro-2-pyridyl) phosphate) and methyl paraoxon (*O,O*-dimethyl *O*-(4-nitrophenyl) phosphate) towards

human recombinant acetylcholinesterase changed as a function of inhibitor concentrations below 100 nM. For example, at 37° the k_i for 100 nM chlorpyrifos oxon was 2.95 nM⁻¹h⁻¹, while that for 2.5 nM chlorpyrifos oxon was 270.72 nM⁻¹h⁻¹. Similarly the k_i for 100 nM methyl paraoxon was 0.07 nM⁻¹h⁻¹, while that for 2.5 nM was 8.24 nM⁻¹h⁻¹. These results indicate that the interactions of acetylcholinesterase with chlorpyrifos oxon or methyl paraoxon cannot be adequately described by simple Michaelis-Menten kinetics. Co-incubation of chlorpyrifos oxon and *p*-nitrophenyl acetate with acetylcholinesterase gave a K_d and k_2 for chlorpyrifos oxon of 126.69 nM and 13.93 h⁻¹, respectively. Interestingly, co-incubation of chlorpyrifos oxon and acetylthiocholine with acetylcholinesterase resulted in a reduced K_p compared to that determined with *p*-nitrophenol acetate. Acetylthiocholine and acetylcholine are known to be ligands for the peripheral anionic binding site on acetylcholinesterase, and their occupation of this site might alter the binding affinity of the enzyme for chlorpyrifos oxon. These data suggest that the inhibitory capacity of chlorpyrifos oxon towards acetylcholinesterase *in vivo* might continually change depending on oxon levels, as well as acetylcholine levels. (Supported by Grant ES012648 from NIEHS)

1978 PHARMACOKINETICS AND MILK TRANSFER OF A SINGLE ORAL DOSE OF CHLORPYRIFOS IN LACTATING RATS.

A. A. Abdel-Rahman, G. M. Blumenthal and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

Although chlorpyrifos has been banned as a household insecticide in the US, its ongoing use on golf courses and other settings may continue to expose potentially sensitive individuals such as pregnant or lactating women. In this study, the pharmacokinetics and milk transfer of a single oral 5.0 mg (7 uCi)/kg dose of ring-labeled [¹⁴C]chlorpyrifos were investigated in lactating Sprague-Dawley rats 6 days after delivery. Three dams and five pups per dam were sacrificed at 2, 4, 8, 12, 18, 24, 36, 48, 72, and 96 hr after dosing. Milk was also collected from the breast of each dam for each time point. Radioactivity and 3,5,6-trichloropyridinol (TCP) were determined using scintillation counting and high performance liquid chromatography (HPLC), respectively. Both were detected in all tissues and milk at 2 h after dosing. The peak concentration of radioactivity in maternal plasma was 3.3 ug chlorpyrifos equivalents/ml at 2 hr, in milk 1.6 ug chlorpyrifos equivalents/ml at 4 hr, in pups 0.15 ug chlorpyrifos equivalents/g at 8 hr, and in pup plasma 0.15 ug chlorpyrifos equivalents/ml at 8 hr. No chlorpyrifos was detected in milk, pups, or pup plasma. TCP was detected by HPLC to be the only identified metabolite in milk, pups, and pup plasma. The maximum concentration of TCP detected in maternal plasma was 3.2 ug/ml at 2 hr, in milk 0.38 ug/ml at 4 hr, in pups 1.2 ug/g at 8 hr, and in pup plasma 0.04 ug/ml at 8 hr. Pharmacokinetic analysis best described radioactivity and TCP as disappearing biexponentially from maternal plasma with terminal half-lives of 26 and 29 hr, respectively. Radioactivity and TCP disappeared mono-exponentially from milk, pups, and pup plasma with half-lives of 29 and 50 hr in milk, 15 and 15 hr in pups, and 25 and 15 hr in pup plasma, respectively. The results indicate that maternal metabolism of chlorpyrifos is rapid resulting mainly in TCP, and that distribution of TCP to pups and pup plasma is rapid, while elimination of TCP is prolonged.

1979 ENDOSULFAN-ALPHA INDUCES CYP2B6 AND CYP3A4 BY ACTIVATING THE PREGNANE X RECEPTOR (PXR).

R. C. Casabar^{1,2}, P. C. Das¹, G. DeKrey³, C. S. Gardiner³, E. Hodgson¹, R. L. Rose¹ and A. D. Wallace¹. ¹Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC, ²Air Force Research Laboratory, Wright-Patterson AFB, OH and ³Department of Biological Sciences, University of Northern Colorado, Greeley, CO.

Endosulfan is a widely used organochlorine pesticide that has been shown to have endocrine disrupting activity in animal studies. Our previous work determined that endosulfan-alpha is metabolized by cytochrome P450 (CYP) 2B6 and 3A4. We postulated that endosulfan's endocrine disrupting properties may be due to its ability to activate PXR and/or the constitutive androstane receptor (CAR) to induce CYP2B6 and 3A4, which results in increased testosterone metabolism. CYP induction was explored by transient transfection assays in HepG2 cells using CYP2B6 or 3A4 reporter plasmids concomitant with human PXR (hPXR) or mouse CAR (mCAR) expression plasmids. Endosulfan-alpha at 10 μM induced CYP3A4 and CYP2B6 promoter activities by 11- and 16-fold, respectively, in the presence of hPXR. With mCAR, endosulfan-alpha induced the CYP2B6 promoter by only 3-fold over control. Human hepatocytes were treated with endosulfan-alpha and western blots of S9 fractions showed a dose-dependent induction of CYP2B6 protein, but induction of 3A4 protein was only observed at higher doses. CYP activity was measured by testosterone metabolism assay using the same S9 samples and results showed an increase in testosterone hydroxylation, although only at higher

doses of endosulfan-alpha. To investigate the ability of endosulfan to regulate CYP3A *in vivo*, sleep time studies were done using the anesthetic tribromoethanol (TBE) in PXR null and PXR humanized male mice. We found that endosulfan-alpha induces CYP3A metabolism of TBE via PXR. The ability of endosulfan-alpha to induce key CYP enzymes and enhance testosterone metabolism may be an important mechanism by which endosulfan affects endocrine homeostasis and causes reproductive toxicity.

1980 METABOLISM OF PYRETHROID PESTICIDES BY RAT AND HUMAN CYP450S AND SERUM.

S. J. Godin¹, M. F. Hughes², M. K. Ross³ and M. J. DeVito². ¹Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC, ²ORD, NHEERL, ETD, PKB, U.S. EPA, Research Triangle Park, NC and ³CEHS, Mississippi State University, Mississippi State, MS.

Pyrethroids are neurotoxic pesticides in which the parent chemical acts via the modulation of nerve axon ion channels. Both the pharmacokinetic and pharmacodynamic behavior of pyrethroids plays a role in their toxicity. The phase I biotransformation of pyrethroids occurs via cytochrome P450 mediated oxidation or esterase hydrolysis. Deltamethrin and esfenvalerate are type II pyrethroid pesticides, which are metabolized primarily by oxidative metabolism in rat liver microsomes. In human liver microsomes, esfenvalerate is also metabolized primarily by oxidative metabolism. In contrast, deltamethrin is metabolized almost entirely by hydrolysis in human liver microsomes. This research aims to determine which cytochrome P450 enzymes are responsible for the metabolism of deltamethrin and esfenvalerate in rat and human liver microsomes. In addition, this research examined the hydrolysis of deltamethrin and esfenvalerate in rat and human serum. Initial studies indicate that rat CYPs 1A1, 2C6, 2C11, and 3A2 metabolize both deltamethrin and esfenvalerate. Deltamethrin was metabolized most rapidly by 2C6 followed by 2C11>1A1> and 3A2. Esfenvalerate was metabolized most rapidly by 3A2 followed by 2C6>2C11> and 1A1. Esfenvalerate was also metabolized by human CYP2C9 while deltamethrin was not metabolized significantly by any human P450s. The hydrolysis of pyrethroids occurs primarily via carboxylesterase. Rat serum, which contains carboxylesterases, metabolized both deltamethrin (15.33 ± 3.24 pmoles/min/mL) and esfenvalerate (9.97 ± 2.94 pmoles/min/mL). Human serum however, which does not contain significant amounts of carboxylesterase, did not metabolize either deltamethrin or esfenvalerate. These species differences in the liver, P450, and serum metabolism of deltamethrin and esfenvalerate may influence extrapolation of exposure-dose relationships between species. 1981 EFFECT OF INDUCTION AND INHIBITION OF CYP3A4/7 ON ALACHLOR CYTOTOXICITY IN HEPG2 CELLS.

S. R. Miranda and S. A. Meyer. *Toxicology, University of Louisiana-Monroe, Monroe, LA.*

Alachlor (2-chloro-2',6'-diethyl-N-(methoxymethyl)-acetanilide) is cytotoxic to human hepatoblastoma HepG2s, a cell line that expresses constitutive CYP3A7 and dexamethasone (DEX)-inducible CYP3A4 and CYP3A7. CYP3A4 catalyzes alachlor N-dealkylation to 2-chloro-N-(2,6-diethylphenyl)acetamide (CDEPA), precursor of 2,6-diethylbenzoquinoneimine, putative reactive metabolite for rat nasal carcinogenicity. We have observed time- and dose-dependent alachlor cytotoxicity in HepG2 cells (EC50 ~ 500 μM and 264 ± 17 μM at 6 and 24 h, respectively) as assessed by LDH leakage. We thus hypothesized that alachlor cytotoxicity was mediated by CYP3A4 and would be increased with dexamethasone (DEX), reported by others to induce CYP3A4 mRNA in HepG2 cells (Krusekopf et al. 2003. Eur. J. Pharmacol. 466:7-12). Although DEX pretreatment (25 μM, 48 h) did not alter CYP3A4 enzyme activity, it significantly increased CYP3A7-catalyzed luciferin 6' benzylether O-debenzylation. However, DEX had no effect on alachlor toxicity. Further, CYP3A4/7 inhibitor triacetyloleandomycin (100 μM) did not prevent, but rather potentiated, alachlor cytotoxicity. In agreement, the alachlor metabolite, CDEPA was less toxic than parent alachlor. Since HepG2 CYP3A4 activity was unaffected by DEX pretreatment, studies were done in DPX-2 cells, a HepG2 derivative engineered to overexpress pregnane-X receptor (Puracyp, Inc. Carlsbad, CA) that exhibits rifampicin (RIF) induction of endogenous CYP3A4. Alachlor cytotoxicity in these cells, measured as loss of ATP, occurred over a concentration range equivalent to that in HepG2 cells. CYP3A4 activity of DPX-2 cells treated with RIF (10 μM, 48 h) was twice that of untreated cells, but RIF did not increase alachlor toxicity. These results do not support metabolic activation of alachlor to a cytotoxic product by either CYP3A4 or CYP3A7. Support: Johnston Science Foundation and Louisiana Board of Regents.

1982 MECHANISM OF TRIFLURALIN INDUCED THYROID TUMOR IN RATS.

S. A. Saghir, G. D. Charles, M. J. Bartels, L. L. Kan, M. D. Dryzga, K. A. Brzak and A. J. Clark. *Toxicology & Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.*

Groups of 15 male F344 rats were exposed to control, trifluralin-fortified (6500 ppm) diet, or gavaged with phenobarbital (PB; 75 mg/kg/day) for 2 weeks. Ten rats/group were sacrificed, sera analyzed for T3, T4 and TSH and liver analyzed for selected T4-specific UGTs gene expression and enzyme level. Bile was collected from 5 rats/group for 2 h by terminal surgery and analyzed for free and conjugated T3 and T4. Serum T3 and T4 were decreased by 17 and 90% and TSH increased by 37% in trifluralin treated rats. The sera TSH level was increased by PB with little impact on T3 and T4. Both compounds induced mRNA expression of selected hepatic UGTs (up to 6.4-fold for trifluralin and 58-fold for PB) and total UGT enzyme activity (2-3 fold). The bile flow (g/h/kg) was 14 and 105% higher resulting in 20 and 86% increase in total bile collected in 2 h from PB and trifluralin-treated rats, respectively than the controls. Elimination of the total T4 in bile remained unchanged between control and PB-treated rats (42±11 and 41±5 ng) and more than doubled (86±19 ng) in trifluralin treated rats. Trifluralin treatment caused a 216% increase in biliary elimination of conjugated T4 and a 38% decrease in free T4 elimination. Biliary elimination of conjugated T3 in trifluralin-treated rats was 63% higher than in control, whereas remained unchanged in PB-treated rats. Decreases in serum T3 and T4 were due to enhanced peripheral metabolism and increased bile flow that resulted in a compensatory increase in TSH synthesis and secretion. These data suggest that high levels of TSH with chronic exposure to trifluralin would exert a continuous stimulation of thyroid gland leading to cellular hypertrophy and proliferation predisposing to the development of follicular cell tumors. Such TSH-mediated promotion of thyroid tumors has little relevance to humans since human thyroid follicular cells are less susceptible to TSH stimulation, in addition to the presence of high-affinity T4 binding protein (TBG) to modulate any dramatic decreases in T4 levels observed in F344 rats.

1983 90-DAY SUBCHRONIC ORAL TOXICITY OF SS-220I IN RATS.

J. T. Houpt, G. J. Leach, H. I. Paulus, L. C. Crouse, M. L. Thompson, M. W. Michie and R. B. Lee. *Directorate of Toxicology, U.S. Army Center for Health Promotion and Preventive Medicine, Aberdeen Proving Ground, MD.*

A 90-day subchronic toxicity study was conducted to determine the oral toxicity of the candidate insect repellent SS-220i (CAS# 77251-47-9). Entomological studies have demonstrated SS-220i to be at least as effective or better than N,N-diethyl-m-toluamide (DEET) in repelling various species of mosquitoes and biting flies. The entomological data supports continued development of SS-220i as a topical insect repellent. Information generated from this study, along with results from other laboratory animal toxicity studies, will be utilized to predict the potential risk to human health upon exposure to this compound. SS-220i was administered via the oral route to young adult Sprague-Dawley rats five days per week for ninety days at dose levels of 0, 100, 500, 750 or 1000 mg/kg/d. The subchronic 90-day oral study indicated that oral exposure to SS-220i produced systemic toxicity in rats at the 500, 750, and 1000 milligram per kilogram (mg/kg/d) dose groups, manifested as gastric changes, blood changes, morbidity, seizure activity, ataxia, lethargy and differences in body weights. These observations were not reported in all dose groups or sexes, but none of these observations were noted in the control and 100 mg/kg dose groups. The possible target organs identified from the 90-day oral study for SS-220i were the stomach, nervous system, blood (possible anemia), and liver. Female rats appeared to be more susceptible to the effects of SS-220i than males. This study shows that the No-Observed-Adverse-Effect-Level (NOAEL) for subchronic oral exposure to SS-220i for 90-days is 100 mg/kg/d. The views expressed in this paper are those of the authors and do not necessarily reflect the views and policies of the U.S. Army. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

1984 COMMUNICATING PESTICIDE RISKS TO AGRICULTURAL WORKERS.

D. D. Petersen^{1,2}. ¹Research & Development, U.S. EPA, Cincinnati, OH and ²Biology and Chemical Technology, University of Cincinnati, Cincinnati, OH.

Abstract: The goals of the US EPA pesticide worker safety program are to protect human health and the environment by ensuring the competency of pesticide applicators, to minimize pesticide exposure to occupational pesticide users and agricultural field workers, to assure use of pesticides, and to engage health care providers in improving the recognition and management of pesticide poisonings. The worker safety program includes statutory requirements, regulations and label requirements.

To augment these components, US EPA uses education, outreach and training, guidance documents, partnerships, compliance assistance and capacity building, and oversight of implementing agencies.

A new hazard communication pilot study was undertaken to identify the best ways to communicate pesticide risk with agricultural workers. In many areas, most agricultural workers are native spanish speakers, and literacy rates can be low. Effectively communicating the risks of various pesticide exposures can be challenging. We developed and tested a variety of color-coded, icon-based tools for communicating PPE use, potential symptoms of over-exposure and actions workers could take to avoid pesticide exposures. The symbols were tested with agricultural workers in both Florida and California in the spring of 2006. A hazard training program was developed based upon the best-rated symbols, and again the training program was evaluated in focus groups in Florida and California agricultural workers during 2006. Through research, and stakeholder review, US EPA has identified gaps in the framework of the agricultural worker protection regulations. These gaps compromise US EPA's ability to ensure the safe use of pesticides and the protection of pesticide exposed agricultural workers. To reduce risk, ensure competency, promote consistency, and raise the standards of the federal program to those of many states, regulatory amendments are necessary. These studies identify risk communication tools that can be used to help fill these gaps.

1985 ORGANOCHLORINE EXPOSURE DURING FIRST TRIMESTER OF PREGNANCY AND ITS EFFECT ON ANOGENITAL DISTANCE IN MEXICAN CHILDREN. PRELIMINARY FINDINGS.

M. Zepeda^{3,2}, L. Torres-Sanchez², L. López-Carrillo², J. Belkind², R. Garcia¹ and M. E. Cebrián¹. ¹Toxicology, Cinvestav, Mexico City, D.F. Mexico, ²CISPR, INSP, Cuernavaca, Morelos, Mexico and ³Mount Sinai International Training Program for Minority Students, Mount Sinai School of Medicine, New York, NY.

DDE is considered an antiandrogenic compound. In rodents, prenatal DDE exposure has been shown to reduce anogenital distance in male progeny. In humans, DDE exposure has been linked to alterations in semen quality, pre-term birth and fetal loss. Our aim was to evaluate the impact of DDE, DDT, and HCH prenatal exposure on anogenital distance (AGD), a potential marker for androgenic fetal function. We conducted a cross-sectional study in a sample (n=76/382 births) pertaining to an ongoing cohort study evaluating the effects of organochlorine pesticides (OCP) on children neurodevelopment. Serum samples from the mothers were obtained during the first trimester of pregnancy to determine OCP by electron capture gas-liquid chromatography. We used the anal position index (API) as an indicator of AGD. We measured the distance between the center of the anus and the coccyx [anococcygeal distance (AC)] and the distance between the center of the anus and the posterior base of the scrotum for boys and the fourchette for girls [perineal distance (PA)]. We added AC and PA to calculate the coccyx-scrotum (CS) and coccyx-fourchette (CF) distances. The API was calculated as the PA to CS ratio for boys and PA to CF for girls (Reisner et al., 1984). Multivariate analysis showed that maternal DDE serum levels at first trimester of pregnancy were associated with a significant reduction of API ($\beta=-0.015$; $p=0.04$) in boys, suggesting the presence of antiandrogenic effects. No significant associations were observed in girls. Further studies in larger populations are needed to confirm this finding and to validate API as a marker of antiandrogenic effects. 1986 PRELIMINARY ASSESSMENT OF BENZENE'S NEUROTOXIC POTENTIAL FROM CHRONIC OCCUPATIONAL EXPOSURE USING AUTOANTIBODIES.

H. A. El-Fawal¹, A. M. Moussa², N. M. El-Fawal¹ and M. Y. Shamy². ¹Neurotoxicology Laboratory, Mercy College, Dobbs Ferry, NY and ²Institute of Public Health, University of Alexandria, Alexandria, Egypt. Sponsor: J. O'Callaghan.

Benzene's acute neurotoxicity, carcinogenicity and hematotoxicity are documented. However, few studies have investigated the neurotoxic potential of chronic exposures, although some suggest central-peripheral neuropathy. Furthermore, reports suggest that benzene's potential neurocytotoxicity may be due to its metabolites. Recent reports indicate an increase in autoantibodies (AuAb) to several proteins as a result of occupational exposure to benzene. Previously, AuAb to nervous system (NS) proteins have been detected following exposures to heavy metals, pesticides and volatile organic compounds. In the present preliminary study, detection of serum AuAb, using ELISA, to neuronal proteins: the neurofilament triplet (NF) and glial proteins (glial fibrillary acidic protein: GFAP, and myelin basic protein: MBP) were used as indices of nervous system insult in workers occupationally-exposed (7±1 years) to benzene (BZ) in a refinery (n=40; 20 females and 20 males; 25

mg/m³±7) compared to demographically and socioeconomically-matched reference (R) workers in a food processing plant (n=60; 30 females and 30 males). Urinary phenol (UPh; µg/g creatinine), a marker of exposure, was significantly (p<0.01) higher in BZ than in R (65±2 and 8±1, respectively). More than 50% of BZ had IgG and IgM AuAb titers (ng/ml) to NF68, NF160 and NF200 compared to 13% of R (Z=3.2; p≤0.01). Mean titer levels were significantly (p≤0.01) higher in the BZ population. There was no statistical difference in either immunoglobulin to GFAP, although a higher percentage of BZ had titers. IgG to MBP were significantly (p≤0.01) higher in BZ than in R. A comparison based on gender also indicated a significant difference based on exposure. A comparison between exposed females and males indicated differences in only IgM to NF 160 and GFAP. These findings suggest that the neurotoxicity of chronic exposure to benzene warrants further study and that AuAb detection may be used in monitoring potential neurotoxic effects.

1987 EFFECTS OF VISUAL CONTRAST SENSITIVITY IN WORKERS EXPOSED TO STYRENE.

M. Ma¹, R. Kishi¹, Y. Saijio¹, Y. Gong¹, F. Sata¹, T. Taga¹ and T. Kawai².
¹Department of Public Health, Hokkaido University School of Medicine, Sapporo, Hokkaido, Japan and ²Osaka Occupational Health Service Center, Osaka, Japan.

Several studies have shown that styrene has ophthalmotoxic properties. Visual contrast sensitivity (CS) loss has been observed among workers exposed to organic solvent mixtures and styrene. Little attention has been paid to the relation between biological exposure index and CS loss. The present study aimed to (1) assess the relationship between urinary metabolites and CS loss and (2) examine visual function in relation to cumulative styrene exposure. CS was measured for 165 male workers exposed to styrene in four fiberglass and reinforced plastics factories (length of exposure>3 years) and 125 male non-exposed workers and college students using the Vistech MCT 8000 chart. All subjects were asked to complete questionnaire in which the items concerned their work history, occupational exposure or non-occupational solvent exposure, lifestyle habits, drug use and anamnesis. The personal styrene exposure in the air and end shift urinary mandelic acid (MA) and phenylglyoxylic acid (PGA) were measured, and the individual cumulative exposure index (CEI) was calculated. The results showed a significant reduction in CS at in styrene-exposed workers compared to the controls (p<0.001), after adjusting age, alcohol and smoking consumption. There was a significant effect of urinary MA+PGA level, with workers in high and medium concentration (>=200mg/g creatinine) group compared to low concentration group and controls at different spatial frequencies. With respect to CEI, there was a significant reduction in CS in 12 cycles per degree in high group workers than those in low group. The results suggest that urinary MA plus PGA less than 400 mg/g creatinine in long term exposure to styrene might lead to CS loss and CS loss might appear with increase of CEI.

1988 EXPOSURE-RESPONSE ANALYSIS FOR BERYLLIUM SENSITIZATION AND CHRONIC BERYLLIUM DISEASE AMONG WORKERS IN A BERYLLIUM METAL MACHINING PLANT.

K. Unice¹, A. K. Madl¹, J. Brown¹, M. E. Kolanz² and M. S. Kent². ¹ChemRisk, Inc., San Francisco, CA and ²Brush Wellman Inc., Cleveland, OH.

The current Occupational Exposure Limit (OEL) for beryllium has been in place for more than 50 years and was believed to be protective against chronic beryllium disease (CBD) until studies in the 1990s identified beryllium sensitization (BeS) and subclinical CBD in the absence of physical symptoms. Inconsistent sampling and exposure assessment methodologies have often prevented the characterization of a clear exposure-response relationship for BeS and CBD. Industrial hygiene (3,831 personal lapel and 616 general area samples) and health surveillance data from a beryllium machining facility provided an opportunity to reconstruct worker exposures prior to the ascertainment of BeS or the diagnosis of CBD. Airborne beryllium concentrations for different job titles were evaluated, historical trends of beryllium levels were compared for pre- and post-engineering control measures, and mean and upper bound exposure estimates were developed for workers identified as beryllium sensitized or diagnosed with subclinical or clinical CBD. Four methods were used to reconstruct historical exposures of each worker: industrial hygiene data were pooled by year, job title, era of engineering controls, and the complete work history (life-time weighted average) prior to diagnosis. Results showed that exposure metrics based on shorter averaging times (i.e., year versus complete work history) better represented the upper bound worker exposures which could have contributed to the development of BeS or CBD. It was observed that all beryllium sensitized and CBD workers were likely exposed to beryllium concentrations greater than 0.2 µg/m³ (95th percentile) and 90% were exposed to concentrations greater than 0.4 µg/m³ (95th percentile) within a given year of their work history.

Based on this analysis, it would appear that BeS and CBD generally occurred as a result of exposures greater than 0.4 µg/m³ and that maintaining exposures below 0.2 µg/m³ 95% of the time may prevent BeS and CBD in the workplace.

1989 PHARMACOKINETIC MODEL FOR ASSESSMENT OF LEUKEMIA RISK ASSOCIATED WITH DERMAL EXPOSURE TO CYCLOPHOSPHAMIDE AMONG NURSES.

W. Fransman¹, H. Kager¹, T. Meijster^{1,2}, D. Heederik¹, H. Kromhout¹ and B. Blaauboer¹. ¹Division Toxicology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands and ²Department Food & Chemical Risk Analysis, TNO Quality of Life, Zeist, Netherlands.

Cyclophosphamide (CP) is a human carcinogen. Oncology nurses are exposed to CP during daily work. This study aimed at assessing the leukemia risk of occupational exposure to CP in nurses.

Task-based dermal exposure intensities for oncology nurses were used to calculate dermal exposure levels to CP. Also, a worst-case exposure scenario was made using the maximum frequency for each task and the maximum intensity of exposure. Internal CP doses were estimated applying a PBPK model to assess the delivered dose for CP and its active metabolites, phosphoramidate mustard and acrolein, in bone marrow. This dose was related to epidemiological information from a longitudinal study with CP-treated patients using linear extrapolation from high to low dose to estimate the risk of leukemia for oncology nurses after 40 y occupational exposure to CP.

The cumulative phosphoramidate mustard and acrolein amounts in bone marrow were simulated to be 12.3 nmol for an average oncology nurse after 40 y occupational dermal exposure. The worst-case scenario with maximum task frequencies resulted in cumulative amounts of metabolites in bone marrow of 1.83 µmol.

Epidemiological data from a cohort of 111 ovarian cancer patients with a total CP dose of 46.35 grams over a 12 m period showed a cumulative risk for leukemia of 11.1% after a ten year period. This administered dose was inserted into the PBPK model as a monthly administration of 14.78 mmol CP into the blood compartment, which resulted in a cumulative dose of CP active metabolites in bone marrow of 5.02 mmol, after 12 m.

Based on this model the risk of developing leukemia for nurses exposed to CP via the skin of hands for 40 y, was estimated to be 0.3 per million oncology nurses. This risk estimate could potentially increase to a maximum of 40 per million oncology nurses for nurses with the maximum exposure frequency and intensity for all tasks (worst-case scenario).

1990 EPIDEMIOLOGICAL INVESTIGATION OF CANCER RATES WITHIN A TWO MILE RADIUS OF VERMICULITE ORE PROCESSING SITES IN UTAH.

W. Ball and S. LeFevre. *Environmental Epidemiology Program, Utah Department of Health, Salt Lake City, UT.*

Vermiculite ore from Libby, Montana contained high levels of amphibole asbestos and asbestiform fibers and has been associated with asbestos related disease among Libby residents. Human exposure to the contaminated vermiculite has possibly occurred in communities throughout the United States located near facilities that received vermiculite ore from the Libby mine. A major source of exposure to asbestos is from exfoliation of the ore at exfoliation facilities. The U.S.E.P.A. identified two former exfoliation facilities in Salt Lake City, Utah, which operated from 1941-1987.

The Utah Department of Health investigated the incidence of asbestos-related cancers and asbestos related mortality in a two-mile radius around these sites for the following time periods: 1973-79, 1980-85, 1986-90, 1991-95, and 1996-2000. Cancer data were obtained from the Utah Cancer Registry. Mortality data were obtained from the Office of Vital Records for the same population group.

Cancer incidence and mortality rates in the two-mile radius study area for all asbestos-related cancers combined, cancer of the respiratory system and intrathoracic organs, and cancer of the lung and bronchus were significantly elevated during the time periods analyzed.

Rates for mesothelioma and asbestosis, diseases directly related to asbestos exposure, were not elevated in the study area. This suggests that exposure from the vermiculite processing facilities likely were not a significant contributing factor to the increased rates observed in other asbestos related cancers and diseases in the study area.

Factors that must be considered in the development and etiology of cancers, but that could not be evaluated in this investigation, include latency period, population migration, personal habits, diet, occupational exposures, and familial history of cancer. These issues limit the conclusions that can be drawn from this investigation. Additional research is needed to address the impact of these risk factors on the elevated rates of respiratory cancers in the study area.

1991 META-ANALYSIS OF ASBESTOS-RELATED DISEASE AMONG SKILLED CRAFTSMEN IN VARIOUS OCCUPATIONAL SETTINGS.

P. Chapman¹, P. R. Williams¹, J. Kuykendall¹ and D. Paustenbach². ¹*ChemRisk, Boulder, CO* and ²*ChemRisk, San Francisco, CA.*

A number of epidemiology studies have evaluated the risk of asbestos-related disease for different categories of workers who were potentially exposed to asbestos in non-manufacturing occupations over time. In this presentation, we provide an extensive review of the available literature on this topic, and present the methodology and key findings of a meta-analysis of asbestos-related disease among skilled craftsmen in various occupational settings. Our initial review of the literature included over 100 published and unpublished studies that were identified during various search efforts. Studies were included in a meta-analysis based on an evaluation of study and control populations, source of mortality data, diagnostic methods, exposure classifications, time period of exposure, latency period, and possible confounders. The different crafts evaluated were insulators, pipefitters and plumbers, boilermakers, carpenters, electricians, laborers, millwrights, sheet metal workers, and welders. Separate analyses were also performed for study setting (shipyard vs. non-shipyard) and disease outcome (mesothelioma vs. lung cancer). The results of each analysis yielded relative risk (RR) estimates and 95% confidence limits. Our findings indicated that, not surprisingly, the greatest risk of asbestos-related disease was historically observed among workers with the most potential for asbestos exposure, such as insulators or crafts employed in Naval shipyards, and workers with the longest duration of exposure. Elevated relative risks were also observed for some other crafts in non-manufacturing occupations, such as in the construction industry, where sprayed asbestos or insulation removal activities often occurred. Despite some limitations, the results of this analysis were generally consistent with prior estimates of asbestos exposure for various craftsmen in different occupational settings.

1992 CHARACTERIZATION OF RISKS TO WELDERS DUE TO EXPOSURES TO ASBESTOS IN WELDING ROD FLUX.

B. L. Finley and J. Pierce. *ChemRisk, San Francisco, CA.*

Due to its unique chemical properties, chrysotile asbestos was formerly incorporated into a wide variety of products, including the outer covering, or "flux" of certain classifications of general arc welding electrodes. The purpose of this analysis was to review the historical exposure and epidemiology information relevant to asbestos in welding rods and assess whether mild steel welders are at increased risk of developing asbestos-related diseases as a result of welding rod use. We found that studies that have attempted to measure airborne asbestos directly in welding rod fumes found no measurable fibers; this is likely due to the fact that the fibers degrade at the high temperatures present in the welding arc. In addition, "worst-case" use simulation studies, specifically intended to generate airborne flux particles, reported that airborne concentrations were undetectable or very low. The airborne concentrations generated were always below the current OSHA permissible exposure limit (0.1 f/cc TWA), and the lifetime doses associated with "worst-case" use were found to be far below plausible thresholds for mesothelioma and lung cancer. The epidemiology literature is complicated by the fact welders often experienced significant "bystander" exposure to amphibole-containing insulation. We have reviewed over 65 studies of asbestos-related disease that either specifically examined welders or included welding as a job category. Of these, roughly 40% concluded that welders are not at an increased risk of developing mesothelioma or lung cancer; approximately 60% concluded that there is an increased risk of one or both diseases. Of these latter studies, 1). there was almost always clear evidence of significant insulation exposure, and 2). none of the authors attributed the disease to exposures to asbestos in welding rod flux. We conclude that the weight of evidence indicates that welders were not historically at risk of developing asbestos-related diseases as a result of welding rod use.

1993 CATEGORIZATION OF ASSOCIATIONS BETWEEN EXPOSURE TO THE HERBICIDES USED IN VIETNAM OR THEIR CONTAMINANTS AND HEALTH OUTCOMES.

J. A. Cohen and M. B. Paxton. *The National Academies, Washington, DC.* Sponsor: *M. Catlin.*

Between 1962 and 1971, United States military forces sprayed herbicides over Vietnam. Because of ongoing uncertainty about the long-term health effects on Vietnam veterans of the herbicides sprayed, Congress passed the Agent Orange Act of 1991. That legislation directed the Secretary of Veterans Affairs to request the National Academy of Sciences, a non-profit organization that provides independent, objective advice on scientific issues, to perform a comprehensive review and evaluation of scientific and medical information regarding the health effects of ex-

posure to Agent Orange, other herbicides used in Vietnam, and the various chemical components of those herbicides, including dioxin. The first comprehensive review was published in 1994 and biennial updates have integrated all subsequent relevant peer-reviewed information. In assessing the evidence for an association of exposure to the herbicides or their components with a health outcome, the committee responsible for the report reviews the available literature and categorize the evidence as 1) sufficient for an association; 2) suggestive of an association; 3) inadequate or insufficient to determine whether an association exists; or 4) suggestive of NO association. In addition, conclusions regarding the biological plausibility of the health effects and the risk to Vietnam veterans are made. The latest of reports, Veterans and Agent Orange: Update 2006, will be released in March 2007. The assessments in the reports are used by the Department of Veterans Affairs to make policy decisions regarding compensation to veterans for service-related illnesses. The methods used by the committee, as well its most recent conclusions, will be discussed.

1994 CHILDHOOD CANCER AND PESTICIDES: POSSIBLE GENE-ENVIRONMENT INTERACTIONS.

O. Soldin^{1,2,3}, C. A. Loffredo¹, P. G. Shields¹, D. Barr⁴, N. Luban⁵, A. Shad¹ and D. Nelson⁶. ¹*Oncology, Georgetown University Medical Center, Washington, DC,* ²*Medicine, Georgetown University Medical Center, Washington, DC,* ³*Center for Sex Differences, Georgetown University Medical Center, Washington, DC,* ⁴*Centers for Disease Control and Prevention, Atlanta, GA,* ⁵*Children's National Medical Center, (CNMC), George Washington University, Washington, DC* and ⁶*Pediatrics, Georgetown University, Washington, DC.*

Introduction: Growing evidence supports the association between pesticide exposure and pediatric acute lymphoblastic leukemia (ALL). Studies of the association of pesticides with ALL have been limited by ecological study designs, reliance on self-reported exposures, and lack of biological measurements.

Study Question: Does the interaction between environmental factors (pesticides) and genetic polymorphisms lead to childhood cancer.

Methods: Genomic DNA was extracted and SNP analysis conducted for GPX1, COMT, PON1, GSTM1 and GSTT1. Urine specimens were analyzed for pesticide content using Tandem Mass Spectrometry.

Results: Metabolites of organophosphorus pesticides (OP) had elevated levels in cases compared to controls. Overall, for most compounds these correlations were not statistically significant. Genetic polymorphisms in several genes for xenobiotic metabolizing enzymes indicated that cases were more likely to be impaired in their ability to detoxify OP relative to controls. The odds ratios for the three PON1 genotypes increase with the increase in the number of copies of mutant gene. For mothers the OR for GG vs. AG is 2.08 [95% CI: (0.41, 11.79); p=0.51], while the OR for GG vs. AA is 4.58 [(0.81, 28.31); p=0.10], indicating a trend of increasing risk with increasing number of copies of the A allele. The trends in the OR for children were similar: OR for GG vs. AG is 1.41 [95% CI: (0.21, 11.08); p>0.99] while OR for GG vs. AA is 3.33 [(0.32, 37.60); p=0.48].

Conclusions: The results of this pilot study suggest that cancer cases were more likely to be impaired in their ability to detoxify OP relative to controls.

1995 FAMILIAL INTERSTITIAL PNEUMONIA (FIP) IS PHENOTYPICALLY AND GENETICALLY HETEROGENEOUS.

A. Wise^{1,2}, M. P. Steele^{1,2}, M. C. Speer¹, J. E. Loyd³, K. K. Brown^{4,5}, A. Herron¹, L. H. Burch¹, M. I. Schwarz^{4,5} and D. A. Schwartz^{1,2}. ¹*National Institute of Environmental Health Sciences, Research Triangle Park, NC,* ²*Duke University, Durham, NC,* ³*Vanderbilt University School of Medicine, Nashville, TN,* ⁴*National Jewish Medical and Research Center, Denver, CO* and ⁵*University of Colorado Health Sciences Center, Denver, CO.* Sponsor: *J. Freedman.*

The Idiopathic Interstitial Pneumonias (IIPs) are complex conditions, with limited treatment options and unknown etiology. A whole genome microsatellite screen for Familial Interstitial Pneumonia (FIP, the familial form of IIP), revealed multiple linkage peaks on chr 10 with a maximum LOD score of 2.1. To determine if either phenotypic classification or environmental exposures could better define the linkage peaks, ordered subset analysis (OSA) was conducted. In the presence of genetic heterogeneity, OSA uses family level covariate data to define a more homogeneous subset of families that maximize linkage. The 83 families were divided into 2 phenotypic classifications: 40 homogeneous families where all cases were diagnosed with the idiopathic pulmonary fibrosis type of IIP and 43 heterogeneous families where more than one type of IIP was observed within each family. Smoking (proportion of cases that ever smoked in a family) and age of onset (average age of diagnosis for cases in a family, and youngest age of diagnosis in a family) were also investigated as covariates using OSA. On chr 10, an early age of onset was found to increase evidence for linkage amongst all families (LOD 2.1 to 3.2) and the homogeneous families (LOD 1.9 to 3.7, p=0.01 at the more centromeric peak), while cigarette smoking was found to be suggestive of an increase in linkage amongst all

families (LOD 1.0 to 3.0) and heterogeneous families (LOD 1.8 to 2.1 at the more telemeric peak). Thus, it appears that different phenotypic classifications and environmental risk factors maximize linkage in distinct regions of chr 10. It is therefore likely that multiple genetic risk factors play a role in FIP, with both environmental and phenotypic classifications distinguishing more homogeneous sub-groups.

1996 BLOOD GROUP TYPE B IS ASSOCIATED WITH HIGH BLOOD LEAD LEVELS IN CHILDREN WITH CHRONIC EXPOSURE.

Children chronically exposed to environmental lead are at risk of suffering severe adverse health effects. The aim of this study was to assess a possible association between blood group type (as a marker of susceptibility) and blood lead concentrations (PbB) above 10mg/dL, value considered as indicative of lead poisoning. The study was conducted in Torreón, Coahuila, Mexico, a city where lead contamination in soil, dust and air around a smelter site has resulted in increased lead body burden in scholar children, living in the vicinity of the major smelter complex of Latin America. We examined PbB in 233 children, 5-7 years old, and determined their blood group type. Blood group type O was the most common type (153 [66.2%] children) followed by types A (24.2%), B (8.2%) and AB (1.3%). Median PbB was 8.39 µg/dL in children with blood group type A, 9.6 µg/dL in children with blood group type O, 10.6 µg/dL in children with blood group type AB and 12.4 µg/dL in children with blood group type B. In univariate analysis higher risks of PbB above 10 µg/dL were observed in children with blood group type B (OR=3.33; P=0.03) and blood group type O (OR=1.87; P=0.05), in male children (Odds Ratio 1.58; P=0.08) and in children living closer to the smelter complex (OR=13.8; P=0.000). After controlling for gender and vicinity to the smelter complex, children with blood group type B had the highest risk of PbB >10 µg/dL (OR=4.48; P=0.02), followed by children with blood group type O (OR=3.12; P=0.006), when compared to blood group type A.

1997 GENETIC SUSCEPTIBILITY TO ORGANOPHOSPHATE TOXICITY IN A GROUP OF MIGRANT SEASONAL FARMWORKER WOMEN OF MEXICAN ORIGIN RESIDING IN TEXAS.

N. Rivera-Del Valle¹, M. A. Hernandez², M. A. Smith³ and L. A. Jones¹. ¹Health Disparities Research, UT MD Anderson Cancer Center, Houston, TX, ²Epidemiology, UT MD Anderson Cancer Center, Houston, TX and ³Environmental Health, University of Texas School of Public Health, Houston, TX.

Organophosphate pesticides (OPs) are currently the most widely used pesticides in the world. Studies have demonstrated that the effect of OPs toxicity can be modified by genetic polymorphisms. These variations can place individuals at a higher risk for the toxic effects of OPs. The serum paraoxonase (PON1) gene at position 192 codifies for the synthesis of the paraoxonase enzyme. This enzyme is important in the hydrolysis of OPs. A common polymorphism (Q192R) has been established, and is mostly responsible for PON1 activity. The frequency of the Q192R polymorphism varies between individuals. Studies in Hispanics are still lacking. The Hispanic population is of special interest to health researchers because of their increasing number in the U.S., and because the majority of individuals occupationally exposed to OPs are of Mexican origin. The overall goal of this study was to predict OP sensitivity in a population of migrant seasonal farmworker (MSF) women of Mexican origin residing in Texas. A total of 200 women were randomly selected from an ongoing study conducted by The Center for Research on Minority Health at UTMDACC. The Q192R PON1 polymorphism was genotyped by Real-Time PCR using the TaqMan System and the serum PON1 Activity was analyzed spectrophotometrically using paraoxon as a substrate. Genotype frequencies were QQ=0.26, QR=0.495 and RR=0.245. The mean PON1 activity among genotypes were QQ=479.7 U/L, QR=969.4 U/L and RR=1518.5 U/L, respectively (p=.001), with the lowest PON1 activity observed among women with the QQ genotype, which makes them particularly vulnerable to OP toxicity. In summary, this study can help determine (1) which Hispanic sub-populations are at a higher risk for OP toxicity and (2) establish future policies regarding OP exposure to help reduce health disparities in Hispanic populations.

1998 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF PERSISTENT ORGANIC POLLUTANTS FOR LIFETIME EXPOSURE ASSESSMENT: A NEW TOOL FOR BREAST CANCER EPIDEMIOLOGICAL STUDIES.

M. Verner¹, M. Charbonneau² and S. Haddad¹. ¹sciences biologiques, TOXEN, Université du Québec à Montréal, MontrÉ-cital, QC, Canada and ²INRS-Institut Armand Frappier, Pointe-Claire, QC, Canada.

Persistent organic pollutants (POP) have been shown to promote breast cancer development in experimental models. Meta-analyses of epidemiological studies did not support an association between POP exposure and breast cancer incidence in humans. This may be due, in part, to difficulties in relevant exposure assessment and to the lack of tools to adequately estimate blood or tissue POP concentrations at critical time periods of the carcinogenic process. This study aimed to build a physiologically-based pharmacokinetic model (PBPK) which could be used as a tool for the estimation of past internal exposure to POP in epidemiological studies of breast cancer. The developed lifetime PBPK model simulates woman body physiological processes (e.g., growth, pregnancy, breastfeeding) and POP kinetics for given exposure scenarios. Using data on height, weight and age, the model estimates the values of physiological parameters (e.g., organ volume, blood flow and composition) throughout the entire life of a woman. The model allows to consider temporal variations in the daily intake from ingestion. The latter can be based on data obtained from a questionnaire on exposure or on theoretical average scenarios. Several model runs with different physiological profiles were simulated using the POP hexachlorobenzene. Simulations showed that women with a same blood concentration at 55 years of age may have completely different lifetime toxicokinetic profiles. Aside from exposure scenarios, factors that were shown to have the greatest impact on the lifetime toxicokinetic profile are the time and duration of lactation periods and weight history. This PBPK modeling tool will permit researchers conducting environmental epidemiology studies to reduce the uncertainty linked to past POP exposure estimation and to consider exposure time windows that are hypothesized to be mechanistically critical in carcinogenesis. (SH is recipient of a research scholarship from FRSQ)

1999 ESTIMATING HEALTH RISKS IN WORKERS ABOARD CRUDE OIL TANKERS DUE TO EXPOSURES TO N-HEXANE, TOLUENE, AND BENZENE.

J. Pierce, J. Warmerdam and B. L. Finley. ChemRisk, San Francisco, CA.

Most health studies of petroleum workers involve exposures at fixed facilities on land (e.g. refineries). There is a paucity of literature regarding the degree to which petroleum workers aboard ships (such as sea-going crude oil tankers) might represent an at-risk population, even though these workers are often aboard the ships in enclosed spaces for extended periods of time. We relied on historical on-board industrial hygiene data, employee work records and self-reported activities to estimate the magnitude of exposure to benzene, toluene, and n-hexane experienced by individuals aboard these vessels. A total of over 65 surveys performed on 15 ships spanning the years 1988 to 2003 were evaluated in this analysis. A Monte-Carlo model was developed that incorporated available concentration information during nine distinct work tasks that comprised a majority of work performed by crew members on these vessels during crude oil loading and while these vessels were underway. It was determined that airborne concentrations were location- and activity-dependent, with the highest levels experienced during work performed in partially enclosed spaces or near tank vents. Lifetime exposures to n-hexane, toluene, and benzene were calculated to be 9.6, 0.7, and 1.1 ppm-year at the 50th percentile and 28.4, 2.6, and 6.1 ppm-year at the 95th percentile. The estimated exposures are substantially below the levels suspected to cause clinical or subclinical neurological effects, and the estimated upper-bound cumulative benzene exposures are below the effects threshold for acute myelogenous leukemia reported in the well-studied "Pliofilm cohort" of rubber industry workers (200-400 ppm-year). Additionally, the estimated exposures are below the levels expected if the contemporaneous permissible exposure limit (PEL) concentrations were experienced over a working lifetime (20,000 ppm-year for n-hexane, 8000 ppm-year for toluene, and 40 ppm-year for benzene). These results are consistent with the available epidemiology literature on seamen aboard crude-oil tankers.

2000 A COMPREHENSIVE REVIEW OF OCCUPATIONAL EXPOSURE TO DIACETYL IN MICROWAVE POPCORN FACILITIES.

J. D. Roberts, D. A. Galbraith and B. L. Finley. ChemRisk, San Francisco, CA.

In May 2000, eight former employees of a microwave popcorn packaging plant were reportedly diagnosed with a pattern of respiratory symptoms "consistent with" respiratory obliterative bronchiolitis (OB), a severe and sometimes fatal lung disease. It was suggested that the symptoms were a result of exposure to diacetyl, a

chemical used in the popcorn butter flavorings. Since that time the National Institute of Occupational Safety and Health (NIOSH) has conducted cross-sectional industrial hygiene and medical investigations in four microwave popcorn facilities: Gilster-Mary Lee Popcorn Plant, Agrilink Popcorn Plant, American Popcorn Company, and Con Agra. The conclusions offered in the NIOSH reports appear to generally support the belief that respiratory disorders are elevated in certain workers and that diacetyl appears to be a likely candidate for the causative effects. This analysis summarizes the strengths and weaknesses of the existing information and identifies key data gaps. In addition to a detailed analysis of the NIOSH reports, we reviewed the PUBMED and MEDLINE databases for studies that reported animal toxicology and epidemiology results for diacetyl and artificial butter, known or suspected causes of OB, and diagnostic criteria for OB. There exists little toxicology or epidemiology literature for diacetyl, although cases of OB have been noted in agricultural workers and attributed to oxides of nitrogen. There are significant gaps in our knowledge of the effects of diacetyl and definitive conclusions regarding its toxicity to occupationally-exposed workers are difficult to offer.

2001 EXPOSURE OF CHILDREN TO VARIOUS CHEMICAL CONTAMINANTS THROUGH FISH CONSUMPTION.

J. M. Llober¹, R. Martí-Cid², A. Bocio², E. Mata³, A. Teixidó³ and J. L. Domingo². ¹Toxicology Unit, University of Barcelona, Barcelona, Spain, ²Toxicology & Environment Health, "Rovira i Virgili" University, Reus, Spain and ³Health, Generalitat de Catalunya, Barcelona, Spain.

Exposure to arsenic (As), cadmium (Cd), mercury (Hg), lead (Pb), polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/Fs), polychlorinated biphenyls (PCBs), polychlorinated naphthalenes (PCNs), polybrominated diphenylethers (PBDEs), polychlorinated diphenylethers (PCDEs), hexachlorobenzene (HCB), and polycyclic aromatic hydrocarbons (PAHs) through fish and seafood consumption by children of Catalonia, Spain, was assessed. In 2005, samples of the 14 most consumed edible marine species in Catalonia (sardine, tuna, anchovy, mackerel, swordfish, salmon, hake, red mullet, sole, cuttlefish, squid, clam, mussel, and shrimp) were randomly acquired in various cities of the country. Analysis of the above chemical contaminants was determined according to the appropriate analytical techniques. Intakes were subsequently estimated. The daily intakes for the analyzed contaminants were the following (boys/girls): total As, 126.5/110.6 µg; Cd, 0.48/0.61 µg; total Hg 7.45/5.60 µg; Pb, 1.55/1.27 µg; PCDD/Fs, 3.19/2.35 pg WHO-TEQ; PCBs (dioxin-like), 18.20/13.83 pg WHO-TEQ; PCNs, 0.97/0.52 ng; PBDEs, 12.17/8.21 ng; PCDEs, 21.08/17.58; HCB, 7.76/4.04 ng, and PAHs, 0.12/0.12 µg. For most pollutants, intake was higher in boys than in girls. Average exposure of children from Catalonia to metals through fish and seafood consumption did not exceed the respective tolerable daily intake of those pollutants for which it has been already established (metals, PCDD/Fs and dioxin-like PCBs, HCB, and PAHs). In relation to body weight, intake by children of most contaminants was higher than that found for other age groups of the general population of Catalonia.

2002 NON-LINEAR EXPOSURE-RESPONSE RELATIONSHIPS BETWEEN AMBIENT PM10 AND DAILY MORTALITY.

T. S. Bowers and P. A. Valberg. *Gradient Corporation, Cambridge, MA.*

PM time-series studies (e.g. NMAAPS, 2003; Zanobetti and Schwartz, 2005; Abrahamowicz et al., 2003) have suggested the existence of a non-linear exposure-response relationship between ambient particulate matter (PM10) and health endpoints such as non-accidental mortality, with steeper exposure-response slopes at lower PM10 levels compared to higher PM10 levels. Because this is diametrically opposed to what would be expected on the basis of toxicology, we explore the mathematical constraints placed on the shape of such exposure-response relationships when the environmental measure, or independent variable, is lognormally distributed (e.g. PM10) and the effect, or dependent variable, has a different distributional shape, for example, a Poisson or Gaussian distribution (e.g. daily mortality). For this analysis, we rely on published literature that reports correlations between daily fluctuations in PM10 (measured at central monitors) and daily fluctuations in population mortality (aggregated on the city or county basis) to establish the general magnitude of the relationship. We examine the shape of the exposure-response relationship that results from constraints imposed by the distributional shapes of the independent and dependent variables, considering as well the distributional properties of both confounders and error terms. Results of our analyses show that a non-linear slope is an expected outcome of correlations between data distributions where one is lognormally distributed and the other has a different distributional form. Comparisons with published data sets show that our analysis yields similar shapes of exposure-response curves and similar differences in slopes between low versus high PM10 levels. The analysis shows that caution should be exercised when assigning biological significance to non-linear exposure-response relationships in some instances, and that consistency of findings among numerous epidemiological

studies is an insufficient basis for concluding that the finding of steeper slopes at lower PM10 levels is of biological significance, as all studies share a common alternative explanation.

2003 EXPOSURE LEVELS OF ULTRAFINE PARTICLES DURING DIATHERMY SURGERY IN OPERATING THEATRES IN SWEDEN.

B. Sahlberg¹, H. Mahteme², H. Anundi¹, S. Blomgren², C. G. Ericsson¹, R. Wälinder¹ and G. Enlund². ¹Department of Occupational and Environmental Medicine, Uppsala University Hospital, Uppsala, Sweden and ²Department of Surgical Science, Uppsala University Hospital, Uppsala, Sweden.

Diathermy smoke contains complex hydrocarbons and organic material, and may also contain viable tumour cells or viral particles. These particles measure from 0.05 to more than 25 µm and exposure to such particles may have adverse effects on health. For that reason, the surgical operations personnel were concerned about the level of particles in the operating theatres. The objective of this study was to determine the exposure level of ultrafine particles for health care personnel working in an operating theatre.

Measurement of particles was performed during surgical operations using diathermal equipment. Personnel sampling equipments were carried by the physician using a TSI's P-TRAK® Ultrafine Particle Counter. The background levels in the operating theatre during surgery were measured with a TSI's P-TRAK® Ultrafine Particle Counter. Temperature, carbon dioxide (CO₂), and air humidity was also measured in the operating theatre.

The concentration of ultrafine particles in the operating theatres ranged from 73 to more than 300 000 particles/cm³. The background levels in the room during surgery were high with peaks levels of 160 000 particles/cm³. The temperature in the operating theatres was 19-26°C, the CO₂ level was 485-786 ppm and the air humidity was 16-38%.

The ultrafine particle levels in the operating theatres are extremely high compared to those of other work environments. For instance, the level in offices is 1000 – 2000 particles/cm³. The high levels of this study indicate that the local exhaust in the operating theater is not sufficient for particle removal.

2004 MEASUREMENT OF POLYCYCLIC AROMATIC HYDROCARBONS (PAHS) ASSOCIATED WITH FINE PARTICULATE MATTER TO ESTIMATE STATEWIDE CUMULATIVE EXPOSURES IN NORTH CAROLINA.

W. E. Funk^{1,2}, S. M. Rappaport², M. Clark³ and J. D. Pleil¹. ¹National Exposure Research Laboratory, U.S. EPA, Research Triangle Park, NC, ²Department of Environmental Sciences and Engineering, University of North Carolina, Chapel Hill, NC and ³North Carolina Department of Environment and Natural Resources, Raleigh, NC. Sponsor: L. Rusyn.

In the United States, there are over 1000 sites that routinely collect particulate matter less than 2.5 µm in aerodynamic diameter (PM_{2.5}) on Teflon filters for non-destructive gravimetric assay. By law, these filters are subsequently archived under refrigeration for at least 1 year. In the State of North Carolina, there are 32 sites that monitor PM_{2.5} every third day, but there are no routine measurements of organic species. Recently, analytical methods have been developed to exploit archived PM_{2.5} filters to retrospectively assess particle bound polycyclic aromatic hydrocarbons (PAHs) exposures without the need for special monitoring instrumentation. PAHs are of public health concern because they are ubiquitous in the environment (from all combustion sources) and have been linked to human carcinogenicity. We selected specific filters from the archives that corresponded to the 50 largest fire events from 2004 and 2005 and also chose spatial and temporal control filters. Each filter was analyzed for a suite of 9 PAHs ranging from 4- to 6-rings using solvent extraction followed by gas chromatography – mass spectrometry (GC-MS). From consideration of PM_{2.5} mass and measured PAHs content, we calculated the relative impact of forest fires to local environments. We also mapped overall PAHs across the State and interpreted the incremental risk posed by the State's 4000 wild fires documented each year with respect to the baseline risk.

2005 EXPOSURE TO ASBESTOS WITHIN THE AUTOMOTIVE REPAIR INDUSTRY BEYOND BRAKE COMPONENTS.

C. L. Blake¹, G. Dotson², G. Johnson² and R. D. Harbison². ¹Bureau Veritas-Clayton Group Services, Inc., Kennesaw, GA and ²Environmental and Occupational Health, USF-COPH, Tampa, FL.

Beyond those for brake friction material, limited exposure data are currently available to characterize the level of asbestos released during the maintenance work involving automotive asbestos-containing materials (ACMs). Two independent investigations were conducted to evaluate the potential release of asbestos during the

servicing of vehicles which incorporated ACMs. The first study was divided into 14 test sessions, in which seam sealant containing chrysotile fibers was removed from the wheel wells of vintage Ford Mustangs using either a hand scraper or a pneumatic chisel. A total of 70 area and 14 personal air samples were collected during this workplace simulation. In addition, asbestos exposure was assessed during clutch replacement. This investigation was divided into two sessions during which a total of 8 area and 4 personal samples were collected. The air samples collected during the individual exposure assessments were analyzed using NIOSH Methods 7400 Phase Contrast Microscopy (PCM) and 7402 Transmission Electron Microscopy (TEM). Among all air samples ($n = 84$) collected during the removal of seam sealant, 22 % ($n = 19$) of the samples were determined via TEM to contain chrysotile asbestos. The average PCM and Phase Contrast Microscopy Equivalent (PCME) airborne fiber concentrations were 0.025 and 0.005 fibers per cubic centimeter (f/cc), respectively. In comparison, 33% ($n = 4$) of all air samples ($n = 12$) collected during clutch replacement were identified via TEM to contain chrysotile fibers. The mean PCM fiber concentration was 0.041 f/cc, while the mean PCME fiber concentration was 0.002 f/cc for samples identified to contain asbestos during the clutch replacement study. The results of these current studies support the findings of previous exposure assessments that report asbestos concentrations well below the current occupational exposure limit for asbestos of 0.1 f/cc during automotive repairs.

2006 MTBE DETECTIONS IN GROUNDWATER OR DRINKING WATER SUPPLIES IN THE UNITED STATES.

P. R. Williams¹ and J. Pierce². ¹ChemRisk, Boulder, CO and ²ChemRisk, San Francisco, CA.

Detections of MTBE in ambient groundwater and some drinking supplies have raised concerns about the potential impact of MTBE on the nation's water quality. In this presentation, we provide a review and synthesis of the available water quality monitoring data that have been collected as part of various national, regional, statewide, and community-specific or focused assessments. Original data sets for each study were obtained and analyzed whenever possible. Based on analysis of more than 25 studies, we characterized the detection frequency and detected concentrations of MTBE for different geographic regions during the 1990s through early 2000s. The available data included a combination of water types, including drinking and non-drinking water, treated and untreated water, public and private water, and water served by groundwater and surface water. According to the most recent comprehensive national assessment, MTBE was found in about 9% of all community water supplies, but in only 5% of sources served by groundwater. MTBE was found in about 9% of all source waters sampled, but in only 5% of sources served by groundwater. Similar findings were observed in prior regional and national water quality assessments. A number of states or communities were found to have lower (<3%) or higher (>10%) detection frequencies for MTBE. In most cases, MTBE detections were associated with population density, use of reformulated gasoline, urban locations, or proximity to known leaking underground storage tanks. The median detected concentration of MTBE for most studies was less than 1 ppb, and few samples were found to exceed the U.S. EPA's organoleptic-based advisory levels for MTBE of 20-40 ppb. Comparisons between studies was sometimes limited due to differences in study purpose and design and data collection efforts. Despite these limitations, the available data indicate that although some drinking water supplies have been affected by MTBE, the majority of drinking water sources nationwide have either not been affected or have been found to contain MTBE at levels unlikely to pose an aesthetic or health risk.

2007 EUROPEAN CONSUMER EXPOSURE TO COSMETIC PRODUCTS A FRAMEWORK FOR CONDUCTING POPULATION EXPOSURE ASSESSMENTS.

B. Safford¹, B. Hall², S. Tozer³, M. Coroama⁴, W. Steiling⁵, M. Leneveu-Duchemin⁶, M. Cano⁷, M. Cronan⁸ and M. Gibney⁹. ¹SEAC, Unilever, Sharnbrook, Bedfordshire, United Kingdom, ²Worldwide Safety Evaluation, L'Oreal, Asnieres sur Seine, France, ³Procter & Gamble, Egham, Surrey, United Kingdom, ⁴Colipa, Brussels, Belgium, ⁵Henkel KGaA, Dusseldorf, Germany, ⁶Beiersdorf AG, Hamburg, Germany, ⁷LVMH Parfums et Cosmetiques, Saint Jean de Braye, France, ⁸Crema Software Ltd., Dublin, Ireland and ⁹University College Dublin, Dublin, Ireland. Sponsor: D. Baskettter.

In order to correctly evaluate the toxicological safety of ingredients contained in cosmetic products, the risk assessor must have access to reliable data on consumer exposure. This study was carried out under the sponsorship of COLIPA with the aim to construct a probabilistic European population model of exposure. The study updates the current data on the daily quantities of body lotion, shampoo, antiperspirant/deodorant spray and non-spray, facial moisturizer, lipstick and toothpaste used by consumers. The data were collected using a combination of the market information databases and a controlled product use study. In total 44,100 households

and 18,057 habitual users (males and females) of the products in five European countries provided data using their own products, including use out of home. The raw data were analyzed using Monte Carlo simulation to construct a European Statistical Population Model of exposure. Distributions obtained largely confirm the exposure data currently used by the cosmetics industry. A significant finding in the study was an inverse correlation between the frequency of product use and the quantity used per application for four of the product types. Thus it is not appropriate to calculate daily exposure to these products by multiplying maximum values for both frequency of use and quantity per application. Design of this study could serve as a model for conducting population exposure assessments to chemicals.

2008 COMPARISON OF XRF AND FIXED BASE LABORATORY METHODS FOR ANALYSIS OF METALS.

S. R. Custance¹, D. J. Oudiz², M. E. Valenzuela³, P. A. Schanen³, T. L. Watson³ and J. K. Tolson⁴. ¹Geosyntec Consultants, Santa Barbara, CA, ²California EPA, Division of Toxic Substances Control, Sacramento, CA, ³Los Angeles Unified School District, Los Angeles, CA and ⁴Geosyntec Consultants, Tampa, FL.

X-Ray Fluorescence (XRF) spectroscopy provides a tool for rapid and inexpensive field analytical measurements for metals. However, when XRF analysis is used for regulatory decision making, there is a concern that inaccuracy in the XRF results may lead to samples being misidentified as meeting regulatory requirements when, in fact, they exceed regulatory limits. Presumably these false negatives would in turn lead to cleanup decisions that might pose a risk to human health. To address this concern a subset of the samples analyzed by XRF in the field are also sent to a fixed-based laboratory. These paired data are then evaluated to assess the performance of the XRF field analysis. Traditional analysis has relied on correlation statistics to assess XRF performance. However, alternative statistical techniques may better address the performance associated with the ability of XRF to correctly identify a soil sample as above or below acceptable regulatory criteria. A dataset was assembled from multiple sites in southern California with analytical results from both XRF and a fixed-base laboratory. An analysis was conducted to compare the performance of different statistical techniques to evaluate the suitability of XRF results compared to the 'gold standard' fixed-based laboratory results. The analysis was conducted using several hypothetical regulatory criteria. Results suggest that correlation provides an estimate of the association between XRF and fixed-base laboratory results but may miss the true concern with XRF analysis, the predictive value for detecting exceedences in field use (i.e. the degree of false negatives). Based on our analysis, contingency table statistics may provide a better evaluation of XRF performance.

2009 COMPARATIVE DISTRIBUTION OF PERFLUOROOCTANOIC ACID IN MALE, FEMALE AND PREGNANT MICE FOLLOWING TREATMENT WITH 8-2 FLUOROTELOMER ALCOHOL (FTOH).

W. M. Henderson^{1,2} and M. Smith^{1,3}. ¹Interdisciplinary Toxicology Program, University of Georgia, Athens, GA, ²National Exposure Research Laboratory, U.S. Environmental Protection Agency, Athens, GA and ³Center for Food Safety, University of Georgia, Griffin, GA.

The global occurrence of perfluorooctanoic acid (PFOA) in environmental and mammalian matrices has spurred regulatory interest in potential sources of this stable compound. 8-2 FTOH, a primary compound used in polymer synthesis, has been shown to undergo biotic and abiotic transformation into PFOA. An appropriate animal model is needed to fully elucidate the mechanisms of metabolism and distribution in mammals. The objective of this study was to compare the metabolism of 8-2 FTOH in male, female and pregnant mice. CD-1 mice received a gavage dose (30 mg 8-2 FTOH/kg BW) in a propylene glycol/water (1:1) vehicle on day 0 and timed-pregnant mice were dosed on gestational day (GD) 8. Animals were serially sacrificed and tissues excised for analysis via GC/MS. 8-2 FTOH was rapidly metabolized and no longer present by 24 hrs post-treatment (PT) and the estimated half-life ($t_{1/2}$) of 8-2 FTOH in serum of male mice was 6.2 hrs. In male mice, maximal PFOA concentrations in serum (992±38 ng/mL) and liver (902±27 ng/g) were at 12 hrs PT and temporally decreased up to 120 hrs. The maximum concentrations in serum and liver of female (768±25 ng/mL and 699±38 ng/g) and pregnant (789±41 ng/mL and 673±23 ng/g) mice also occurred by 24 hrs PT. Using linear regression, the calculated $t_{1/2}$ in male mice was 15.1 d and was comparable to female mice (14.9 d). However, during gestation (GD 8-18), the $t_{1/2}$ was 31.3 d, but values after parturition were similar to non-pregnant females (12.9 d). Estimated PFOA $t_{1/2}$ in liver was 8.2, 9.2 and 28.4 d for male, female and pregnant mice, respectively. In conclusion, 8-2 FTOH is rapidly metabolized to PFOA in male, female and pregnant mice. Sex-mediated elimination is absent, but pregnant mice retain PFOA approximately 2x longer in serum than non-pregnant females suggesting that physiologic changes during pregnancy increase PFOA retention.

2010 A COMPARISON OF THE METABOLISM AND DISPOSITION OF TWO BROMINATED FLAME RETARDANTS: TBBPA AND TBBPA-DBPE IN MALE F-344 RATS.

G. Knudsen¹, R. Kuester¹, V. P. Rodriguez¹ and G. Sipes¹. ¹The University of Arizona, Tucson, AZ, ²pharmacology, The University of Arizona, Tucson, AZ and ³pharmacology, The university of arizona, Tucson, AZ.

Studies were conducted to characterize and compare the metabolic and dispositional fates of two brominated flame retardants, Tetrabromobisphenol A (TBBPA) and Tetrabromobisphenol A bis[2,3 dibromopropyl ether] (TBBPA-DBPE). Each compound was administered orally or intravenously (IV) to male Fischer-344 rats (20 mg/kg). Regardless of route of administration, [14C] TBBPA and [14C] TBBPA-DBPE were eliminated extensively in the feces (oral: >95%, IV: >70%). These results suggested that biliary excretion of [14C] equivalents of these compounds precedes fecal elimination. When bile was collected from rats dosed by oral gavage with [14C] TBBPA, 50% of the administered dose was found in the bile as metabolites within 2 h. However, by 24 h, only 1% of the dose of [14C] TBBPA-DBPE was detected in bile as metabolites following oral administration. These results suggest dramatic differences in absorption from the intestinal tract. Pharmacokinetic analysis of blood revealed that the systemic bioavailability of both compounds is low after oral administration (TBBPA: 1.6%, TBBPA-DBPE: 1.8%). Thus, although TBBPA is absorbed, it is extracted by the liver, extensively metabolized and excreted as glucuronide-conjugates (as determined LC-MS/MS analyses) into the bile, while TBBPA-DBPE is poorly absorbed from the GI tract and is excreted in the feces primarily as parent compound. Its slow fecal elimination following IV administration is due to retention in the liver. (This research was supported by NIEHS NTP Grant Number N01-ES-45529 and NIEHS-sponsored Southwest Environmental Health Science Center Grant Number P30-ES-06694.)

2011 ESTIMATION OF RELATIVE BIOAVAILABILITY OF DIOXINS AND FURANS IN SOIL IN RATS AND SWINE: IMPACT OF DIFFERENTIAL EROD INDUCTION ON BIOAVAILABILITY ESTIMATES.

R. Budinsky², L. Aylward¹, C. Cushing⁴, G. Fent³, M. Ruby⁵ and S. Casteel³. ¹Summit Toxicology, LLP, Falls Church, VA, ²The Dow Chemical Company, Midland, MI, ³College of Veterinary Medicine, University of Missouri-Columbia, Columbia, MO, ⁴Exponent, Inc., Chicago, IL and ⁵Independent Consultant, Boulder, CO.

A subchronic pilot study of relative bioavailability for a dioxin- and a furan-contaminated soil was conducted. Rats and swine were administered soils mixed with feed (rats) or in gelatin tablets (swine) and matched to dioxin and furan dosages administered in corn oil (rats) or in gelatin tablets (swine). Relative bioavailability (RBA) estimates were higher in rats than swine with different estimates across congeners noted in rats. Higher hepatic EROD activity (a marker for induction of hepatic CYP1A1) was observed in rats (but not swine) dosed with the corn oil formulations compared to the soil/feed groups. The differential EROD induction might have enhanced clearance for some congeners in rats thereby affecting RBA estimates. Therefore, a follow-up study in rats with the furan-contaminated soil was conducted with a 20%, 50% and 80% reduction in the corn oil-administered doses relative to the soil dosage in order to control for EROD induction. When EROD induction was equalized, the apparent RBA for one furan congener, 2,3,7,8-tetrachlorodibenzofuran, was reduced significantly. Rats exhibited approximately 30% and 60% RBA for the dioxin- and furan-contaminated soils, respectively. In contrast, results from swine showed approximately 20 to 25% RBA for both soils (and no differential EROD induction). The bioavailability difference between rats and swine suggests important species differences for soils contaminated with chlorinated dioxins and furans. Species differences and experimental design issues, such as controlling for enzyme induction between treatment groups, are relevant significant factors where relative RBA inputs are important for theoretical exposure characterization.

2012 DIFFERENTIAL URINARY PROTEIN BINDING OF PBDES IN MICE.

J. J. Diliberto¹, D. F. Staskal², H. Hakk³ and L. S. Birnbaum¹. ¹ETD, NHEERL, ORD, U.S. EPA, Research Triangle Park, NC, ²Curriculum in Toxicology, University of North Carolina, Chapel Hill, NC and ³ARS Biosciences Research Laboratory, USDA, Fargo, ND.

Polybrominated diphenyl ethers (PBDEs), commercial chemicals used as flame retardants in consumer goods, have become the focus of increasing scientific research due to their persistent detection in humans and the environment in conjunction with their potential for toxicity. PBDE congeners 47, 99, 100, 153, and 154, the primary congeners detected in human and wildlife samples, have different pharma-

cokinetic behaviors in rodents which appear to be species-, sex-, and congener-dependent. Many of these differences appear to be driven by urinary excretion. Therefore, this study investigated urinary excretion in C56BL/6 mice of PBDE congeners 47, 99, 100, and 153 in an effort to characterize mechanisms responsible for their excretion. Female mice were administered a single intravenous (iv) dose of PBDE 47, 99, 100, or 153 and urinary excretion was monitored for 5 days. Urine was analyzed for protein binding by Sephadex G-75 columns, gel electrophoresis and Western blotting. Analyses of 0-24h urine for PBDEs 47 and 99 dosed mice and pooled 0-120h urine (pooled due to limited amounts of urinary radioactivity) for PBDEs 100 and 153 dosed mice showed that the majority of PBDE in urine was protein-bound (>65%). All the PBDEs investigated were bound to three mouse Major Urinary Protein (mMUP) isoforms, and were readily excreted via urine. These results suggest that the physiological parameters associated with MUP, such as increased MUP secretion in male mice versus females, could therefore contribute to understanding of the different pharmacokinetic parameters observed in rodents. In conclusion, urinary binding proteins could affect the pharmacokinetics of PBDEs in rodents. (This abstract does not reflect EPA policy. Work partially funded by EPA DESE CT 826513.)

2013 DETECTION OF COCAINE AND METHADONE IN DIFFERENT POST-MORTEM FLUID AND TISSUE SAMPLES.

S. A. Menshaw¹, L. M. Al-Alousi², W. Madira² and M. Tsokos³. ¹Cancer Study and Molecular Medicine, University of Leicester, Leicester, United Kingdom, ²Forensic Pathology Unit, University of Leicester, Leicester, United Kingdom and ³Legal Medicine, Institute of Legal Medicine, Hamburg, Germany. Sponsor: A. Al-Naser.

The results of about 64 samples taken at postmortem examinations are presented and discussed. The samples analysed are blood (femoral and cardiac), urine, vitreous humour, liver, bile, muscle and stomach contents. Ethical requirements are fulfilled. Various analytical qualitative and quantitative techniques are used including Enzyme-Immuno-Assay (EIA), Gas-Chromatography/Mass Spectrometry (GC/MS) and Liquid-Chromatography/Mass Spectrometry (LC/MS). The mean drug ratio to femoral blood was studied. Cocaine mean ratio to femoral blood was as follow for cardiac blood 1.8 with range (1.6-2.0), Vitreous humour 2.7 with range (2.5-2.9), Stomach 57 with range (42.2-71.6), Bile 14.6 with range (4.3-24.8), Urine 37 with range (27.5-46.3). Liver 0.7 with range (0-2.2) and Muscle 0.37 with range (0-0.9). Statistical analysis of the results shows that concentrations of tissue cocaine, methadone and their metabolites tend to be proportional to those of the blood and that these drugs can be detected in the tissue including muscle and liver depending on the post-mortem interval and their volume of distribution. There are variations in the drug concentrations in both liver and muscle samples. Typically, liver samples tend to show higher drug concentrations than those of the muscle, however, in this study, some muscle samples have shown more drug concentrations than those of the liver within the same postmortem cases. Possible explanations of this observation are given and discussed. It is clear from this study that femoral blood is still the sample of choice for toxicological analysis of cocaine and methadone and their metabolites but muscle and liver samples can be good alternatives to blood if the latter is unavailable.

2014 BAYESIAN PBPK MODELING OF GENISTEIN IN RATS.

P. M. Schlosser^{1,2}, S. J. Borghoff², N. G. Coldham³, J. A. David⁴, R. Garcia⁵, R. Setzer⁶ and S. K. Ghosh⁷. ¹NCEA, U.S. EPA, Research Triangle Park, NC, ²CIIT, Research Triangle Park, NC, ³Veterinary Laboratories Agency, Surrey, United Kingdom, ⁴Cntr. for Research in Scientific Comp., NCSU, Raleigh, NC, ⁵Department of Biostatistics, UNC, Chapel Hill, NC, ⁶NCCT, U.S. EPA, Research Triangle Park, NC and ⁷Department of Statistics, NCSU, Raleigh, NC.

Genistein is an estrogen-receptor-binding compound that occurs at high levels in soy beans and derived food products, with widespread human exposure. Numerous scientific publications describe its dosimetry, mechanisms of action, and health effects. To relate effects in rats to its internal, target-tissue dosimetry, we developed a PBPK model and calibrated it using pharmacokinetic (PK) data from adult male and female rats. Complexities of the model include enterohepatic circulation, binding of both genistein and its conjugates to plasma proteins, and use of multiple compartments to describe transport through the bile duct and GI tract. In other ways the model is simple, assuming perfusion-limited transport to the tissue groups and first-order rates of metabolism, uptake, and excretion. Initially, point estimates and approximate confidence intervals were obtained for the model parameters by standard optimization methods. But given the individual animal PK data available, we sought to apply Markov Chain Monte Carlo (MCMC) Bayesian analysis to quantify population variability and uncertainty in the fitted parameters. A set of 15 physiological parameters (tissue volumes, blood flows) and 8 partition coefficients were described using fixed distributions since the current data contain little information on them. Then 21 genistein-specific parameters were estimated by Bayesian

analysis. The sparse data set (typical for PK studies) and lack of prior information on the parameters caused significant computational challenges, however. Ultimately we had to impose bounds derived from point-estimate likelihood calculations to obtain convergence to biologically realistic values.

2015 CLINICAL AND PHARMACOKINETIC CHARACTERISTICS OF AN ORALLY INGESTED TOBACCO PELLET.

G. R. Krautter¹ and M. H. AbdelHameed^{2,1}. ¹Scientific and Regulatory Affairs, R J Reynolds Tobacco Company, Winston-Salem, NC and ²Drug Metabolism, Covance Laboratories Inc., Madison, WI.

The tolerability and pharmacokinetic characteristics of a tobacco pellet intended to be entirely ingested was evaluated in 12 healthy adult Caucasian smokers (6 male; 6 female). The pellet prototype was comprised of powdered tobacco, fillers, binders, non-caloric sweeteners, flavors and pH modifiers with a finished weight, pH, and nicotine content of about 175 mg, 8.0, and 1.0 mg, respectively. Plasma nicotine and cotinine pharmacokinetic profiles from 4 randomized single-treatments compared smoking a cigarette to the oral ingestion of a pellet by 3 methods; dissolution in mouth, swallow whole and chew and immediately swallow. Profiles from 3 non-randomized multiple-treatments were also studied after oral ingestion of: 2 pellets; 1 pellet every 20 min for 1 h; and 1 pellet every 30 min for 6 h. Under all conditions the ingestion of pellets was well tolerated. Mean peak nicotine concentrations were 11.4 ng/ml after smoking and between 2.3-3.3 ng/ml after single-pellet ingestions. Times to these peak concentrations were 0.2 h after smoking and between 0.9-1.3 h after ingestion. Ingestion of 1 pellet every 30 min for 6 h resulted in a peak nicotine level of 15.7 ng/ml, a level within or below the range reported for regular tobacco users. Peak nicotine level increases were proportional when 1 or 2 pellets were ingested, but less than proportional when ingested over extended periods, attributed to nicotine's rapid terminal half-life (2.2-4.1 hr). Nicotine and cotinine bioavailability were proportional after multiple treatments. The lowest measures of nicotine bioavailability were after immediate swallowing, indicating rapid first-pass metabolism after GI tract absorption. Pharmacokinetic measures in this study demonstrated nicotine absorption rates from the pellet are relatively slower than achieved by cigarette smoking, and more similar to rates reported for other commercially available oral tobacco products.

2016 THE IMPORTANCE OF OXALATE RENAL CLEARANCE IN THE ENHANCED SENSITIVITY OF MALE WISTAR RATS TO ETHYLENE GLYCOL NEPHROTOXICITY.

R. A. Corley¹, M. J. Bartels², J. J. Soelberg¹, M. D. Dryzga², D. M. Wilson², K. E. McMartin³ and W. M. Snellings². ¹Pacific Northwest National Laboratory, Richland, WA, ²The Dow Chemical Co., Midland, WA and ³Health Sciences Center, LSU, Shreveport, LA.

Ethylene glycol-induced nephrotoxicity is caused by the precipitation of the metabolite, oxalic acid, with calcium in renal tubule epithelium. Male Wistar rats are the most sensitive animal studied, with a NOEL of 150 mg/kg/day identified in a recent chronic study where ethylene glycol was administered via the diets at 0, 50, 150, 300 or 400 mg/kg/day for up to one year. Animals in the 400 mg/kg/day group were sacrificed early (day 203) due to increased morbidity and mortality. Kidneys from all animals were analyzed for total oxalates with no differences observed among control, 50 and 150 mg/kg/day groups. At 300 and 400 mg/kg/day, oxalate levels increased proportionally with the nephrotoxicity score (5-point scale ranging from no nephropathy to end-stage) with the most severely affected animals having oxalate levels up to 10.6% of the total tissue mass. The renal clearances of oxalic acid and inulin were evaluated in 5 animals/dose that survived one year with no treatment-related effects observed. Based upon nephrotoxicity scores and oxalate levels, it is conceivable that clearances would have been impacted in animals exposed to 400 mg/kg/day had they survived. In studies with naïve male Wistar and F344 rats (a less sensitive strain), a significant difference was observed in oxalate clearances between young rats (i.e. Wistar clearance < F344) but not in age-matched old rats. Regardless, the ratios of oxalate:inulin clearances in these two strains of rats, including those exposed to ethylene glycol, were all <1, indicating that a fraction of the filtered oxalate is reabsorbed. Other species, including humans, typically have ratios >1 and are more effective at clearing oxalic acid. Thus, the lower renal clearance and kidney accumulation of oxalates in male Wistar rats enhances their sensitivity, which will be a factor in human risk assessments. *Funded by ACC EO/EG Panel.*

2017 PHARMACOKINETIC DATABASE OF PHOSPHORODIAMIDATE MORPHOLINO OLIGOMERS (PMOS).

P. L. Iversen and A. Amantana. *Toxicology, AVIBioPharma, Inc., Corvallis, OR.*

Phosphorodiamidate morpholino oligomers (PMOs) bind to their target mRNA sequences and suppress gene expression by blocking translation or interfering with pre-mRNA splicing. A pharmacokinetic database was established for various PMOs administered at different dosing levels via different routes in various species including rats, non-human primates (monkeys) and human. The PMOs ranged from two to thirty on the basis of the number of subunits. The database was designed to determine the relationship between molecular weight of PMO and pharmacokinetics so as to serve as a predictive model. The database revealed a strong positive correlation between molecular size and volume of distribution as well as the elimination half-life. The relationship between certain motifs in the base sequence and PMO pharmacokinetic profile is yet to be established. In summary, the database shows a strong influence of molecular size on tissue biodistribution of various PMOs.

2018 PHARMACOKINETIC PROFILES OF DIMER AND TRIMER PHOSPHORODIAMIDATE MORPHOLINO OLIGOMERS (PMOS) IN RATS.

A. Amantana, S. Crumley, M. Davis and P. L. Iversen. *Toxicology, AVIBioPharma, Inc., Corvallis, OR.*

Phosphorodiamidate morpholino oligomers (PMOs) are neutral antisense molecules that bind to complementary RNA sequences and suppress gene expression by blocking translation or interfering with pre-mRNA splicing. The objective of this study was to examine the pharmacokinetic profiles of pyrimidine dimer (TT, T=Thymidine) and pyrimidine-inosine trimer (TTI) PMOs and their distribution in the central nervous system. The compounds were administered at 5mg/kg by intravenous injection and plasma concentrations were monitored at different time points by fluorescence for pharmacokinetic evaluation. The plasma concentration versus time curve of the trimer but not the dimer PMO revealed enterohepatic circulation. The trimer and dimer PMOs showed elimination half-lives of 20.12 h and 5.07 h respectively. The trimer PMO showed urinary excretion of less than 1% of the dose administered compared to 95% of the dimer. Where as urinary excretion peaked at 12 h postdose in the case of the trimer PMO, the dimer PMO showed maximum urinary excretion at 4 h postdose. Both the dimer and trimer PMOs demonstrated broad tissue distribution following administration with the kidney being the primary site of accumulation. Also, measurable concentrations within the brain were observed at 1 h to 72 h postdose. The emerging data shows that a single base in a given PMO sequence can alter the pharmacokinetic profile of the compound.

2019 INFLUENCES OF INJECTABLE SEDATIVES ON INTRAVENOUS GLUCOSE TOLERANCE TEST (IVGTT) IN CYNOMOLGUS MONKEYS.

M. J. Reid¹, R. S. Jawando², J. Kelly³ and S. Meyer⁴. ¹Pharmacokinetics, SNBL USA Ltd., Everett, WA, ²Safety Assessment, SNBL USA Ltd., Everett, WA, ³Scientific Services, SNBL USA Ltd., Everett, WA and ⁴SNBL USA Ltd., Everett, WA. Sponsor: D. Warren.

Type 2 diabetes mellitus is a progressive and complex disorder that is difficult to treat and diagnose effectively. Glucose Tolerance Test (GTT) has been used in diagnosis of diabetes as a complicating factor in cardiovascular disease and has also been used as a disease model to study efficacy of glycemia-regulating therapeutics. Since the spontaneous occurrence of diabetes in cynomolgus monkeys is rare, GTT may be an important disease model in the development of therapeutics for hyperglycemia. Given that the effects of stress (from procedural handling) on glucose levels is well known, the influence of commonly used injectable sedatives on intravenous (IV) GTT in 3 female cynomolgus monkeys was studied. The following sedatives were administered intramuscularly ~ 10 min prior to IVGTT: ketamine (10 mg/kg) alone or with xylazine (2 mg/kg), acepromazine (1 mg/kg) and Telazol (5 mg/kg) and compared to results from IVGTT in the same 3 animals awake for the dosing and blood collection procedures. Food was withheld from the monkeys for 13 to 16 hours prior to each IVGTT. Blood samples were obtained pre-dose (twice, at least 5 min prior to each glucose injection) and at 2, 5, 10, 20, 30, 40, and 60 minutes after administration of glucose (0.6 g/kg, IV). Glucose and insulin levels were compared and analyzed using WinNonlin software to determine clearance and disposition. Glucose (0.6 g/kg) administered IV produced hyperglycemia within 2 minutes that was reduced to normoglycemic levels 30 to 60 minutes post-injection. Sedation did reduce the variability in IVGTT results and the choice of sedative for performance of IVGTT does influence the resultant glucose clearance in cynomolgus monkeys.

2020 DISPOSITION OF ORAL AND INTRAVENOUS DOSES OF [¹⁴C]CUMENE IN MALE F344 RATS.

K. J. Dix, H. B. Hoffman, B. M. Hedtk-Weber, K. Ghanbari and Z. Gao.
Lovelace Respiratory Research Institute, Albuquerque, NM.

Cumene, a petrochemical, is used in the manufacture of chemicals, as a thinner for paints, lacquers, and enamels, and in a variety of petroleum products. The oral LD50 of cumene in rats is 1.4 g/kg. We have investigated the disposition of oral (1.4, 14, and 140 mg/kg) and intravenous (IV) (1.4 mg/kg) doses of [¹⁴C]cumene in male F344 rats. Vehicles were corn oil for oral doses and 1:1:8 ethanol:Alkamuls:water for the IV dose, and the radiochemical purity of [¹⁴C]cumene in the dose formulations was ~98%. Urine, feces, and volatile organics (VOCs) were collected through 24 h after dosing. Recovery of radioactivity (% dose) was determined in excreta and in tissues at 24 h. Excretion of radioactivity in urine accounted for ~70-80% of the oral dose, with ~1% recovered in feces by 24 h. Recovery of radioactivity as volatile organics (VOCs) increased from ~1% at the 1.4 mg/kg oral dose to ~9% at the 140 mg/kg oral dose, which suggests saturation of one or more processes involved in cumene disposition at the high oral dose. After the 1.4 mg/kg IV dose, 90% was recovered in urine, ~1% in feces, and ~5% as VOCs. Urinary excretion of radioactivity was more rapid after the IV compared with oral doses; by 12 h ~60% was excreted after the IV dose versus 30-40% after oral doses. At 24 h after dosing 17-25% of the dose was present in tissues, primarily in the small intestine and cecum, regardless of dose or route of administration. The high degree of recovery in the gastrointestinal (GI) tract is consistent with incomplete absorption after the oral dose. However, the extent of recovery in the GI tract after the IV dose suggests significant biliary excretion of parent and/or metabolites. Based on these results we will conduct studies of [¹⁴C]cumene in bile-duct cannulated rats to further understand the metabolism and disposition of cumene. [Supported by NIEHS Contract No. N01-ES-25483]

2021 DISPOSITION AND METABOLISM OF N-BUTYL GLYCIDYL ETHER IN F344 RATS AND B6C3F1 MICE.

E. H. Lebetkin¹, L. Chen¹, E. I. Nwakpuda², M. Sanders¹ and L. T. Burka¹.
¹LPC, NIEHS, Research Triangle Park, NC and ²North Carolina Central University, Durham, NC.

The disposition and metabolism of ¹⁴C-labeled n-butyl glycidyl ether (BGE) was investigated in F344 rats and B6C3F1 mice. BGE is an industrial diluent of epoxy resins and is being studied by the Nation Toxicology Program (NTP). Animals were dosed by gavage in corn oil at 2, 20, and 200 mg/kg. The percentage of the radiolabeled BGE dosage recovered in the urine and feces of rats and mice ranged from 68-92% and 2.6-7.7%, respectively, within 24 hours. A higher percentage of the administered dose was recovered as ¹⁴CO₂ in respired air from mice (10-18%) than rats (1.5%). Trace amounts (0.1-0.4%) of non-¹⁴CO₂ volatiles were recovered in respired air. BGE did not accumulate in tissues, 1.5-4.4% of the dose remained after 24 hours. The highest concentrations were in the stomach, the site of dosing. There was no dose effect on the disposition from 2 to 200 mg/kg doses. Male rats were dosed at 20 mg/kg daily for 10 days. The concentration of BGE 24h after the last of the multiple doses was lower in all tissues than 24h after a single 200 mg/kg dose. A trace amount of BGE was covalently bound in the liver. BGE underwent extensive metabolism in both rats and mice; the parent compound was not present in urine. A species difference in BGE metabolism was observed. A total of fourteen metabolites were identified by NMR and MS analysis. Three of these metabolites are derived from a glutathione (GSH) conjugate of BGE. The remaining metabolites are from addition of water to BGE to form a diol followed by further metabolism. In vitro studies confirmed that BGE conjugated with GSH with or without the addition of glutathione S-transferase (GST). This addition is regiospecific to the C-1 position of the epoxy ring.

2022 DIFFERENTIAL SYSTEM MODELS [PROSTATE, COLORECTAL AND CNS] OF POLYCYCLIC AROMATIC HYDROCARBON TOXICITY.

O. Ogunkua¹, D. B. Hood¹, R. Matušík⁴, T. A. Ansah¹, A. Deutch³, A. Ramesh¹, J. Morrow³ and M. Aschner². ¹Biomedical Science, Meharry Medical College, Nashville, TN, ²Department of Pediatrics, Vanderbilt University, Nashville, TN, ³Department of Pharmacology, Vanderbilt University, Nashville, TN and ⁴Department of Internal Medicine, Vanderbilt University, Nashville, TN.

Polycyclic aromatic hydrocarbons are persistent environmental contaminants that exhibit a myriad of toxic symptoms in mammals. Because it is suspected that there is both a genetic and environmental contribution to the etiology of B(a)P-induced 1) prostate and colon cancer and 2) developmental CNS dysfunction, it has been hypothesized that exposure to B(a)P will shift the dose-response curve to the left in the 12t-7f transgenic LADY mouse model. Initial results from prostate specific cell lines are in support of this hypothesis in that these prostate specific cell lines are ca-

pable of metabolizing B(a)P. Congruent with this hypothesis is that B(a)P exposure will also accelerate the progression of colon cancer using the Apc Min transgenic mouse model. Results from B(a)P exposed microsomes from liver, small intestine and colon samples demonstrate a concentration-dependent increase in total B(a)P metabolite levels with the highest metabolite concentrations found in liver>jejunum>colon. B(a)P exposure was also hypothesized to generate reactive oxygen species which potentiates toxicity to cause deficits in motor function. This hypothesis was tested in C57BL mice and motor activity was significantly impaired suggesting B(a)P exposure-induced insult to dopaminergic mechanisms. Finally, the hypothesis that gestational exposure to B(a)P dysregulates glutamate receptor subunit composition development was tested in C57BL mice. The results from "ex vivo" primary cortical neuronal cultures from exposed offspring support this hypothesis and demonstrate significant downregulation of NR2B and GluR1 developmental expression. Collectively, our results using B(a)P exposure as a model environmental contaminant will contribute to understanding the etiology of B(a)P-induced neurological dysfunction and cancer. [Supported by NS041071 and 1S11ES014156].

2023 DIETARY FAT-MODULATED FLUORANTHENE METABOLISM AND DNA ADDUCT FORMATION IN F-344 RATS.

A. Ramesh. *Biomedical Sciences, Meharry Medical College, Nashville, TN.*

Harmful health effects such as cancer and toxicity to humans may be attributed to consumption of fatty foods contaminated with environmental toxicants. The objective of this study was to characterize the effect of dietary fat on disposition; metabolism and DNA adduct formation of fluoranthene (FLA), a polycyclic aromatic hydrocarbon compound. Fluoranthene was administered to 10-week old F-344 male rats in unsaturated (olive oil) and saturated (palm kernel oil) fats at doses of 50 and 100µg/kg via oral gavage. Blood, small intestine, liver, lung, testis, adipose tissue, urine and feces were collected at various time points post-FLA exposure. Samples were subjected to liquid-liquid extraction with methanol, chloroform and water. The extracts were concentrated under nitrogen, reconstituted in methanol and analyzed by reverse-phase high-performance liquid chromatograph equipped with a fluorescence detector for detection and quantitation of FLA parent compound and metabolites. DNA was isolated from the tissues of FLA-exposed rats, subjected to ³²P-post labeling and resolved by thin layer chromatography to measure FLA-DNA adducts. The concentrations of unchanged FLA (FLA parent compound) and its metabolites showed an increase for the saturated fat treatment group compared with the unsaturated fat group. The FLA-DNA adduct concentrations were high in tissues of rats that received FLA through saturated fat. The concentration of FLA metabolites and FLA-DNA adducts showed a dose-dependent increase, and this increase was statistically significant (P < 0.05) for saturated fat. These findings demonstrate that the high residence time of FLA parent compound in saturated fat contributes reactive metabolites of FLA that bind with DNA and cause damage to target organs (supported by NIH grants ES012168, GM08037, G12 RR03032, and 1S11ES014156-01A1).

2024 PRELIMINARY BIOLOGICAL SAMPLE ANALYSIS OF (R)-(+)-PULEGONE IN FEMALE AND MALE F344N RAT PLASMA SAMPLES FROM A PTK STUDY USING IV DOSING.

J. W. Algaier¹, P. J. Schebler¹, A. Y. Shan¹, B. Astroff¹, A. P. Clark¹, R. K. Harris¹, B. Jayaram² and C. S. Smith². ¹Product Sciences Division, Midwest Research Institute, Kansas City, MO and ²Environmental Toxicology Program, NIEHS, Research Triangle Park, NC.

Pulegone, a monoterpene ketone, is the major constituent of pennyroyal and other essential oils derived from the *Labiatae* plant family. Because it is primarily used as a mint fragrance or flavoring for foods, beverages and perfumes, pennyroyal oil is under toxicological evaluation by the NIEHS. In this work, an un-optimized gas chromatographic method with flame ionization detection (GC/FID) was developed to quantitate (R)-(+)-pulegone in female and male F344N rat plasma samples from a preliminary, single IV dose, toxicokinetic study (PTKS). A twelve-point (R)-(+)-pulegone spiked plasma curve defined the concentration range from ~0.02 to ~100 µg/mL. For sample preparation, proteins were precipitated using trichloroacetic acid (TCA) followed by extraction with 400 µL of hexane containing the internal standard, hexadecane. The experimental limit of quantitation (ELOQ) was estimated to be ~0.02 µg/mL of (R)-(+)-pulegone in rat plasma. The preliminary toxicokinetic study was conducted in 10 female and 10 male rats administered a single intravenous injection of (R)-(+)-pulegone at 10 mg/kg, with plasma samples drawn at 6, 15, 30, and 60 minutes and 2, 4, 6, 8, 12, and 24 hours post-dose. The PTKS determined (R)-(+)-pulegone concentrations ranged from 0.120 µg/mL to 0.417 µg/mL for the male rat plasma, while the female rat plasma

concentrations ranged from 0.021 µg/mL to 0.297 µg/mL. Using noncompartmental analysis for an IV bolus administration model with linear trapezoidal interpolation, the toxicokinetic parameters included: area under the concentration curve (AUC), maximum concentration (C_{max}), time to maximum concentration (T_{max}), and plasma half-life (t_{1/2}). These values for the male rats were: AUC = 103.8462 min µg/mL; C_{max} = 0.4170 µg/mL; T_{max} = 30 min; and t_{1/2} = 223.8356 min; and for female rats: AUC = 81.2049 min µg/mL; C_{max} = 0.2970 µg/mL; T_{max} = 120 min; and t_{1/2} = 166.3321 min.

2025 EFFECT OF DRINKING WATER PRECONDITIONING ON DICHOROACETIC ACID (DCA) AND DIBROMOACETIC ACID (DBA) TOXICOKINETICS (TK) IN F344 RATS AND B6C3F1 MICE.

V. Godfrey³, S. Hong¹, J. D. Johnson¹, S. Graves¹, M. Hawk¹, J. Merrill¹, I. Schultz² and C. Smith³. ¹Chemistry Technical Center, Battelle, Columbus, OH, ²Toxicology, Battelle, Sequim, WA and ³Chemistry, NIEHS, Research Triangle Park, NC.

Dihaloacetic acids (DHAs) have been detected in drinking water as a result of chlorine disinfection. Due to the potential for toxicity, NIEHS selected DCA and DBA for toxicity testing and, in support of these studies, TK studies were conducted to evaluate whether repeated exposure via the drinking water (preconditioning) affects the TK of DCA and DBA. Male or female F344 rats and B6C3F1 mice were used. Single gavage administration dosages (mg/kg) were 40 (DCA) and 40 and 100 (DBA) for the rats and 100 or 200 (DCA and DBA) for the mice. Preconditioned animals were given DCA or DBA in the drinking water for 14 days (ad libitum), untreated drinking water (overnight on Day 14), and a single gavage administration on Day 15. The drinking water and preconditioned gavage target dosages (mg/kg) were 42.6 (DCA) and 34.3 and 68.6 (DBA) for the rats and 74.0 and 148 (DCA) and 100 and 200 (DBA) for the mice. Rat and mouse dosing volumes were 5 and 10 mL/kg (gavage). Plasma samples were analyzed for DCA and DBA concentration using a validated capillary GC-ECD method. A one-compartment model with first order (or equal) absorption and elimination was used to describe the gavage profiles. For DCA, elimination was substantially decreased following preconditioning (k₁₀, 0.0342 vs 0.000842 min⁻¹; AUC, 762 vs 85700 µg/mL.min) for the rats, whereas a modest decrease was observed for the mice (e.g., 200 vs 148 mg/kg; k₁₀, 0.117 vs 0.0579 min⁻¹; AUC, 1380 vs 4840 µg/mL.min). For DBA, elimination was only mildly affected (approximate 2- to 3-fold decrease) by preconditioning for rats and mice. The results of this study indicate that the kinetics of DCA and DBA are affected by repeated exposure, which produced a large decrease in the elimination of DCA and only modest decreases in the elimination of DBA. [Study supported by NIEHS Contract No. N01-ES-55551.]

2026 DIBROMOACETIC ACID TOXICOKINETIC STUDY IN F344 RATS AND B6C3F1 MICE.

J. D. Johnson¹, S. Hong¹, S. Graves¹, J. Merrill¹, I. Schultz², V. Godfrey³ and C. Smith³. ¹Chemistry Technical Center, Battelle, Columbus, OH, ²Toxicology, Battelle, Sequim, WA and ³Chemistry, NIEHS, Research Triangle Park, NC.

Dihaloacetic acids (DHAs) have been detected in drinking water as a result of chlorine disinfection. Due to the potential for toxicity, three DHAs were selected by NIEHS for toxicity testing – dichloroacetic acid (DCA), bromochloroacetic acid (BCA) and dibromoacetic acid (DBA). In support of the toxicity studies, toxicokinetic (TK) studies were conducted and the results of the DBA TK study are presented here. Female F344 rats and male B6C3F1 mice were given a single intravenous (IV) administration of DBA in normal saline at 10 (rats) and 100 (mice) mg/kg or a single gavage administration of DBA in Milli-Q water at 10, 40, or 100 mg/kg (rats) and 100, 200, or 400 mg/kg (mice). Rat and mouse dosing volumes were 2 and 4 mL/kg (IV) and 5 and 10 mL/kg (gavage). Plasma samples were analyzed for DBA concentration using a validated capillary GC-ECD method (LOQ = 0.0934 µg/mL). A two- (rats) and one- (mice) compartment model with first order elimination were used to describe the IV profiles. For the rat, the C_{2min} (µg/mL), volume of distribution (mL/kg), k_e (min⁻¹), and AUC_{inf} (µg/mL.min) were 29, 172, 0.226, and 258 and, for the mice, were 147, 617, 0.0773, and 2110, respectively. A one-compartment model with equal first order absorption and elimination was used to describe the gavage profiles. For rats, the C_{max} (µg/mL), T_{max} (min), k_a or k_e (min⁻¹), and AUC_{inf} (µg/mL.min) values were 2.6, 20, 0.0267, and 202 at 10 mg/kg; 37, 20, 0.0320, and 2260 at 40 mg/kg; and 104, 40, 0.0183, and 15000 at 100 mg/kg. For mice (same TK parameters and units) were 42, 20, 0.0510, 1730 at 100 mg/kg; 133, 20, 0.0471, and 5770 at 200 mg/kg; and 247, 45, 0.0338, and 20400 at 400 mg/kg. In addition to providing TK parameters for DBA (IV), this study showed that in both species a larger than proportional increase in DBA plasma concentrations occurred following a single gavage administration over the dosage range tested. [Study supported by NIEHS Contract No. N01-ES-55551.]

2027 PHARMACOKINETICS OF A SINGLE DERMAL DOSE OF DEET (N, N-DIETHYL-M-TOLUAMIDE), ALONE OR IN COMBINATION WITH PERMETHRIN, AND/OR PYRIDOSTIGMINE BROMIDE (PB) IN MALE RATS.

A. W. Abou-Qare, A. A. Abdel-Rahman and M. B. Abou-Donia. *Pharmacology and Cancer Biology, Duke University Medical Center, Durham, NC.*

We examined pharmacokinetic interactions of a single dermal dose of the insect repellent, DEET (400 mg/kg), when administered with a single dermal dose of the insecticide permethrin [3-(2,2-dichloroethyl)-2,2 dimethylcyclopropanecarboxylic acid (3-phenoxyphenyl)methyl ester] (1.3 mg/kg), and/or a single oral dose of the nerve agent prophylaxes, PB (13 mg/kg), in male rats. Blood, tissues, and urine samples were collected at 0.5, 1, 2, 4, 8, 24, 48 and 72 hr after dosing. Plasma, liver, kidneys, brain, testes, stomach and urine samples were analyzed for the parent compounds and selected metabolites. The application site of the skin retained approximately 0.1% of DEET following administration, 72 hr after dosing, either alone or in combination with PB, or permethrin. DEET and its metabolites m-toluamide and m-toluic acid were identified in rat plasma, tissues and urine samples. Concurrent application of DEET, PB and/or permethrin significantly increased bioavailability of DEET and decreased the urinary excretion of its metabolites compared to its application alone. The data show that the pharmacokinetic of DEET was altered in the presence of the other test compounds, alone or in combination. These results demonstrate that a profound interaction was observed between DEET, permethrin and/or PB indicating possible competition for metabolism enzymes/distribution processes in the rat. Alterations of the pharmacokinetic profiles in the presence of the other compounds could explain previous reports of increased toxicity following combined exposure of test compounds that may have contributed to the Gulf War Veterans, illnesses. Supported in part by the U.S. Army Medical Research and Materiel Command under the contract number: DAMD 17-99-1-9020.

2028 COMPARATIVE TOXICOKINETIC STUDY OF VICRIVIROC IN CYNOMOLGUS MONKEYS OF DIFFERENT ORIGINS.

C. Rosenfeld¹, K. Fellows¹, H. Weisbrot¹, P. Sherratt¹, P. Beaumier³, L. Sultatos² and G. Pastino¹. ¹Schering Plough Corporation, Summit, NJ, ²UMDNJ, Newark, NJ and ³SNBL, Everett, WA.

The cynomolgus monkey (*Macaca fascicularis*) is one of the non-rodent species of choice for pre-clinical safety evaluation studies conducted in support of drug registration. These monkeys originate from various geographical regions, including mainland China (Chinese), as well as the Indonesian and Philippine islands (Island). Baseline hematological parameters, such as reticulocyte, erythrocyte and white blood cell counts, as well as various serum biochemistry parameters, have been shown to differ in cynomolgus monkeys of different origins. These differences have the potential to alter the pre-clinical toxicity profile secondary to alterations in the pharmacokinetics and systemic exposure. This study was undertaken to examine whether the toxicokinetics (TK) of vicriviroc (VCV), a CCR-5 antagonist in clinical development for the treatment of HIV, could be altered when administered to cynomolgus monkeys of different origins. Chinese and Island monkeys received VCV by nasogastric gavage at a daily dose of 15 or 40 mg/kg, doses that encompassed the range in prior TK studies. On Days 1 and 7, blood samples were collected from VCV-dosed monkeys at 1, 2, 4, 8 and 24 hr post dose. Plasma concentrations of VCV and its carboxylic acid metabolite were determined using a liquid chromatographic with tandem mass spectrometric (LC MS/MS) method. TK parameters, including C_{max}, T_{max}, AUC and metabolite:parent ratios, were determined using non-compartmental analysis. Additional blood samples were collected from control monkeys for the determination of VCV plasma:red blood cell partition coefficients (PC) using equilibrium dialysis. Certain differences in the hematological parameters between Chinese and Island monkeys that could have altered the TK profile of VCV would have been reflected by differences in the PCs. Our findings demonstrated that the systemic exposure to VCV and its metabolite, and the VCV plasma:red blood cell partition coefficients were similar between Chinese and Island monkeys.

2029 COMPUTATIONAL MODELING OF THE IMPACT OF PLASMA LIPID LEVELS ON CHOLINESTERASE INHIBITION AND DOSIMETRY OF CHLORPYRIFOS IN THE DAM AND FETUS.

T. S. Poer¹, M. J. Bartels², J. L. Mattsson² and C. Timchalk¹. ¹Center for Biological Monitoring and Modeling, Pacific Northwest Nat, Richland, WA and ²Dow AgroSciences LLC, Indianapolis, IN.

Developing fetuses are a unique subpopulation with potentially altered susceptibility to the effects of chemical exposures. Chlorpyrifos pharmacokinetics (PK) and pharmacodynamics (PD) are altered in the pregnant rat and fetus and

cholinesterase (ChE) inhibition is generally less in fetal than maternal tissues. During gestation, changes in physiology and metabolic capacity will impact fetal and maternal PK/PD. Placenta and mammary compartments and a fetal sub-model were added to a previously published chlorpyrifos physiologically based pharmacokinetic (PBPK) and PD model. Altered lipid levels are one of the many physiological changes observed during pregnancy, where lipid levels increase up to 5-fold. The effect of increasing total plasma lipid fraction on predicted partitioning, PK, and ChE inhibition in the dam and GD18-20 fetus was assessed. The fetal model included brain, liver, and fat compartments with esterase inhibition in the brain, liver, and plasma, and transfer to the fetus was based on blood flow. Bioactivation and detoxification were included in the fetal liver as a fraction of the rates in adult liver. This uncomplicated late gestational PBPK model either predicted, or slightly under-predicted literature-reported fetal plasma chlorpyrifos levels and plasma and brain ChE inhibition following repeated gavage exposures to the dams. An algorithm was used to predict changes in blood partitioning of chlorpyrifos when total plasma lipid levels increase 2-3.5x. Increased solubility in the blood resulted in an improved model fit by predicting increases in plasma chlorpyrifos and in plasma ChE inhibition in the dam and GD18-20 fetus. Predicted brain inhibition was also predicted to be increased in dams, but was not appreciably altered in the fetus. These results show the potential impact of lipid changes during pregnancy and the importance to predict PK/PD differences of a lipophilic compound like chlorpyrifos during pregnancy and gestation.

2030 DISPOSITION OF PYRITHIONE IN THE RAT AFTER ORAL, DERMAL AND INTRAVENOUS ROUTES OF ADMINISTRATION.

Zinc pyriethione (ZPT) is used in commercial and consumer products as a fungicide. In the present study, radiolabeled and unlabeled pyriethione (PT) were measured in female, Sprague-Dawley rats at select time points after single administration. Rats were prepared with an indwelling jugular cannula for serial blood samples and allowed at least 1-day to recover. Cannula patency was maintained with daily flushings of heparinized saline. Blood was collected at baseline and 0.25, 0.5, 1, 2, 4, 6, 8, 12, 24, 48 and 72 hr following gavage, dietary and dermal routes of exposure. For intravenous administration, blood was collected at baseline and 5, 10, 30 min, 1, 2, 4, 24, 48, and 72 hr after injection. Approximately 250 μ L of blood was withdrawn at each time point. Radioactivity was determined in blood at each time point and in urine and feces at 8, 24, 48 and 72 hr after dosing. The concentration of ¹⁴C-PT was measured in select tissues 72 hr after dosing. Plasma concentration of PT was determined using LC/MS/MS. Urine excretion was the primary route of elimination for all routes of administration. The concentration of total radioactivity in blood was higher and more persistent than plasma PT. This is consistent with studies in which PT metabolites, including 2-methylsulfonylpyridine, were found as the main constituents in the blood. There was no apparent bioaccumulation of radiolabel PT in any of the tissues evaluated in this study. The highest amounts of radioactivity were in the liver, kidney and blood for all routes of administration. Approximately 70-80% of the gavage or dietary ¹⁴C-ZPT was bioavailable compared to <10% for dermal application. There was an 8-12 hr lag time for ¹⁴C-PT or PT to appear in the blood/plasma following dermal exposure. From this study, it is concluded that urinary excretion is the principle route of elimination of ZPT, systemic availability of ZPT following topical administration is limited and concentrations of blood ¹⁴C-PT over predicts the plasma PT.

2031 TOXICOKINETIC AND TISSUE DISTRIBUTION STUDY OF DELTAMETHRIN IN ADULT SPRAGUE-DAWLEY RATS.

Deltamethrin (DLM) is a widely-used type II pyrethroid insecticide and a relatively potent neurotoxicant. The objective of this project was to evaluate the toxicokinetic behavior and tissue distribution of DLM in male, adult Sprague-Dawley (S-D) rats. For the toxicokinetic study, 10 mg DLM/kg was administered by gavage and 2 mg/kg iv in glycerol formal to cannulated rats. Serial plasma samples were collected over 96 hr and analyzed for DLM content by HPLC. For the dose-dependent tissue distribution study, male S-D rats received 0.4, 2, or 10 mg/kg by gavage. Serial plasma, whole brain, fat, liver, and skeletal muscle were collected for up to 3 weeks. The absolute bioavailability of DLM was 15%, and the peak concentration in plasma was 0.84 ± 0.24 μ g/ml. The area under the curve (AUC_0^∞) was 5.49 ± 0.22

μ g $\cdot$ hr/ml. In the tissue distribution study, DLM concentrations vs time curves showed dose-dependent kinetics in plasma and tissues. After a single oral dose, DLM was rapidly absorbed (T_{max} = 1, 1 and 2 hr for 0.4, 2 and 10 mg/kg, respectively). The maximum plasma concentrations of DLM were 0.5 and 1.2 μ g/ml for 2 and 10 mg/kg, respectively. Fat showed the highest AUCs (143 and 514 μ g $\cdot$ hr/ml for 2 and 10 mg/kg, respectively) and long elimination half-lives (168 and 200 hr for 2 and 10 mg/kg, respectively). Muscle also showed long elimination half-lives (191 and 190 hr for 2 and 10 mg/kg, respectively). These long elimination half-lives of DLM in fat and muscle suggest that DLM may accumulate in these tissues. The AUC for DLM in the brain, the target organ, was much less (13%) than that in plasma at 10 mg/kg. This is, to our knowledge, is the most complete internal dosimetry data set available for a pyrethroid. It provides a basis for beginning to understand the internal disposition of pyrethroid insecticides, as well as data for development of a PBPK model. (Supported by EPA STAR Grant R830800)

2032 BLOOD AND BRAIN CONCENTRATIONS OF BIFENTHRIN CORRELATES WITH DECREASED MOTOR ACTIVITY INDEPENDENT OF TIME OF EXPOSURE.

Pyrethroids are neurotoxic insecticides used in a variety of agricultural and household activities. Due to the phase-out of organophosphate pesticides, the use of pyrethroids has increased. The potential for human exposure to pyrethroids has prompted pharmacodynamic and pharmacokinetic research to better characterize exposure and risk. This work tested the hypothesis that blood and brain pyrethroid concentrations are predictive of neurotoxic effects. Adult male rats received acute oral bifenthrin in corn oil vehicle. Exposures for the 4 and 7 hr time points were 0, 0.1, 1, 2, 4, 6, 8, 12, 16 mg/kg and 0, 0.05, 0.5, 1, 3, 4.5, 6, 9 mg/kg, respectively (n=4 or 8/group). Motor activity was measured in figure 8 mazes for 1 hr at 4- and 7-hr post exposure. Whole blood and brain tissue were collected immediately following behavioral testing. Tissues were vortex extracted in hexane, eluted through silica solid phase extraction cartridges, and analyzed using LC/MS/MS. Limits of quantitation were 100 pg/ml and 150 pg/g for blood and brain. Bifenthrin exposure decreased motor activity in a dose dependent manner. Doses of 3 mg/kg or higher decreased motor activity 20% to 70% of vehicle control levels in both the 4- and 7-hr groups. Combining the 4- and 7-hour groups, the relationship between whole blood or brain bifenthrin concentrations and motor activity were described using a Hill model. Model fits to the blood data ($R^2=0.68$, $p<0.0001$) estimated ED50 of 323 ng/ml tissue with a slope factor of 1.4. Model fits to the brain concentration data ($R^2=0.69$, $p<0.0001$) estimated the ED50 of 219 ng/g with a slope factor of 2.3. These data suggest that blood or brain concentrations can be used as a dose metric to estimate effects on motor function, and that this relationship is independent of time of exposure. (This abstract does not represent EPA policy).

2033 DISPOSITION AND MUSCLE WEAKNESS IN THE RAT AFTER REPEAT DOSE ADMINISTRATION OF ZINC PYRITHIONE.

J. Nash¹, A. R. Jeffcoat², D. P. Coleman², A. J. Parham², E. C. Garner² and N. P. Skoulis³.
¹Procter & Gamble Company, Cincinnati, OH, ²RTI International, Research Triangle Park, NC and ³Arch Chemicals, Inc., Cheshire, CT.

In the present study, ZPT-derived radioactivity (¹⁴C) and parent, i.e., pyriethione (PT), were determined in female, Sprague-Dawley rats at select time points after single and repeat dose (10-day) administration of ¹⁴C-ZPT. Muscle weakness and tone were measured in the same group of rats to determine the relationship between PT plasma/blood concentrations and toxicity. Rats were prepared with indwelling jugular cannula for serial blood samples. ZPT (1.25, 3 and 10 mg/kg, gavage; 10, 30 and 100 mg/kg, dermal; 250 ppm, diet) was administered for 10 days. Blood or plasma concentrations of ¹⁴C-PT or PT, respectively, were determined at select time points following day 1 and day 10 of dosing. Comparison of the pharmacokinetic parameters across routes of exposure shows that the time to reach maximum concentrations of PT was much greater with dermal exposure than either oral route. This is consistent with the long dermal exposure (6 hr/day) and the lag time required for ZPT-derived compounds to penetrate the skin. Area-under-the-curve (AUC) for rats exposed to ZPT via diet or gavage was similar. In contrast, the AUC values adjusted for dose for rats treated topically with ZPT were much lower than the corresponding values for animals administered ZPT orally. These differences in bioavailability of ZPT following 10-days of dosing were supported by analysis of urinary excretion which provided the same relationship. There was no evidence of

accumulation of ¹⁴C-PT following any route of exposure, which is consistent with a log P value for ZPT of 0.97. The day 10 plasma AUC(0-∞) for PT was positively correlated with combined measures of muscle weakness and tone. The concentration of plasma PT after 10 days of administration determines the degree of muscle weakness independent of the route of administration. These data are the first to show repeated administration of ZPT does not accumulate in the rat and that the concentration in plasma is predictive of the degree of muscle weakness in this species.

2034 PHARMACOKINETICS AND TISSUE DISPOSITION OF ATRAZINE IN MALE C57BL/6 MICE.

N. M. Filipov¹, T. L. Jones and M. K. Ross. *CEHS, Basic Sciences, Mississippi State University, Mississippi State, MS.*

Atrazine (ATR) is a widely used herbicide and exposure to it has been associated with a number of toxicological effects on reproductive, endocrine, nervous, and immune systems. As is the case with many other environmental contaminants, a growing number of in vivo toxicity studies with ATR are conducted in mice. Yet, at present, there are no data describing ATR's pharmacokinetics and tissue dosimetry in the mouse. Hence, the objective of this study was to address this data gap. Male C57BL/6 mice were orally exposed to a dose range (5-250 mg/kg) of ATR. Plasma, tissues (liver, spleen, thymus, kidneys, and brain), urine, and fecal material were collected at various time points up to 96 h post dosing. Using our newly developed LC-MS method, levels of ATR and its metabolites didealkyl ATR (DACT), desisopropyl ATR (DIP), desethyl ATR (DE), ATR-glutathione conjugate (ATR-GSH), and ATR-mercapturate (ATR-MER) were determined in the various matrices. ATR was rapidly metabolized in mice and DACT was the most abundant metabolite detected in the urine and plasma samples, as well as in the various tissues. For example, in the 0-24 h urine samples, DACT levels in mice exposed to 250 mg/kg ATR were more than 150-fold greater than ATR and more than 60-fold greater than the levels of DE and DIP. There was a good correlation between plasma and tissue levels of ATR and its metabolites, with the highest levels observed within the first 4 h after exposure. In addition to determining the levels of ATR and its metabolites in the liver and kidneys, we also readily detected them in potential target organs such as the brain, thymus and spleen. Therefore, in addition to accurately describing the pharmacokinetics and tissue disposition of ATR in the mouse, this study also provides the basis for the development of a mouse-specific PBPK model, as well as for the calibration of models that are being developed by others in the rat. [Supported by NIH P20RR017661].

2035 INHIBITION OF HUMAN GLUTATHIONE S-TRANSFERASE OMEGA BY TOCOPHEROL SUCCINATE.

A. Sampayo-Reyes¹ and R. A. Zakharyan². ¹*Toxicology and Pharmacology, Centro de Investigaciones Biomédicas del Noreste, Monterrey Nuevo Leon, Nuevo Leon, Mexico* and ²*Department of Molecular and Cellular Biology, University of Arizona, Tucson, AZ.*

Glutathione S-transferases (GSTs) are a family of multifunctional enzymes that are present in all living organisms. Their main function is the detoxification of electrophilic compounds. Glutathione conjugation is the major detoxification pathway available to the organism to trap toxic substances. Based on their substrate specificity, sequence structure, catalytic activity, immunogenicity and sensitivity to inhibitors, the mammalian

GSTs form seven distinct classes termed alpha, mu, pi, sigma, theta, zeta, and new class of human GSTs designated omega. Human GST omega 1-1 (hGSTO1-1) is identical to human monomethylarsenic acid (MMAV), the rate-limiting enzyme for biotransformation of inorganic arsenic. It is expressed in a wide range of human tissues, including brain. Several studies have indicated a role for an Omega-class GST gene in the early onset of both Alzheimer's and Parkinson's diseases, and it is possible that hGSTO1-1 may be involved in the modulation of the activity of interleukin-1 (IL-1) which play a major role in a wide range of inflammatory disease. Compounds that target IL-1 production are being investigated. We found that (+)-α-tocopherol succinate inhibited the reduction monomethylarsenate (MMAV) and dimethylarsenate (DMAV) in a concentration-dependent manner with an IC₅₀ of 4 and 3 μM, respectively. The kinetics indicated an uncompetitive inhibition of the MMA(V) and DMA(V) reducing activity of hGSTO1-1.

2036 IMPACT OF ANIMAL HANDLING ON THE TOXICOKINETICS OF BIS(2-CHLOROETHOXY)METHANE IN MALE F344 RATS.

S. Hong¹, J. D. Johnson¹, S. W. Graves¹, V. Godfrey² and C. Smith². ¹*Battelle Memorial Institute, Columbus, OH* and ²*NIEHS, NIH, Research Triangle Park, NC.*

Conventional methods for conducting toxicokinetic (TK) studies with rodents require not only large numbers of animals, but also significant handling of the animal for dosing and sample collection. Advent of automated instruments for dosing and

blood sample collection allows TK studies to be conducted using fewer animals that are freely-moving and non-handled for dosing and sampling. This work compared the TK profile of bis(2-chloroethoxy)methane (CEM), a potential cardiotoxin, from the manual to an automated method. F344 male rats were given a single intravenous (IV) administration of CEM at 20 mg/kg by the automated dosing instrument or manually via an indwelling jugular vein catheter. Plasma samples were collected at specified time points by the automated sample collection instrument via a surgically implanted femoral vein catheter or manually from the retro-orbital plexus. CEM plasma samples were analyzed by a validated GC/MS method. The plasma CEM concentration-time profiles were characterized by a two-compartment kinetic model with bolus input and first-order elimination. The TK parameter estimates for the initial decay rate (alpha), elimination from the central compartment (K₁₀), distribution from the central to the peripheral compartment (K₁₂), AUC, and systemic clearance were not statistically different between the manual and automated methods. There were statistically significant differences (p<0.05) for the terminal decay phase (beta), volume of distribution, and rate of distribution from the peripheral to the central compartment (K₂₁) between the manual and automated methods. However, the differences in these TK parameters were considered marginal, thereby suggesting they were biologically insignificant. These results demonstrated that the automated method for dosing and sample collection resulted in similar estimates for CEM TK parameters when compared to the manual method. [Supported by NIH-ES-05-03]

2037 DETERMINATION OF THE PHARMACOKINETICS FOR MODIFIED RELEASE RECOMBINANT HUMAN THYROID STIMULATING HORMONE (MR-RHTSH) IN RATS AND DOGS.

C. Rogers¹, E. Clark¹, B. Tyler¹, N. Moore¹, M. Huff¹, K. Culm-Merdek¹, S. Romano¹ and L. Andrews¹. ¹*Genzyme corp., Framingham, MA* and ²*Pharmacology/Toxicology, Genzyme Corporation, Framingham, MA.*

Purpose: Pharmacokinetics (PK) studies were executed in Sprague Dawley rats and Beagle dogs to assess and compare the pharmacokinetics of recombinant human thyroid stimulating hormone (rhTSH) prepared in sodium carboxymethylcellulose (mr-rhTSH) and rhTSH prepared in sterile water for injection (rhTSH). More specifically, studies were conducted to evaluate the effect of concentration, viscosity, and injection volume on the PK of mr-rhTSH.

Methods: Test articles were intramuscularly (IM) administered to rats and dogs at doses ranging from 0.05 to 1.0 mg/kg with various viscosities of mr-rhTSH ranging from 18-149 cps. In addition, dogs received IM administration of mr-rhTSH at dose volumes of 0.07 or 0.15 ml/kg. PK blood samples were collected at various post dosage timepoints via jugular vein cannulas and evaluated by ELISA.

Results: Pharmacokinetic analysis demonstrated a statistically significant decrease in C_{max} and an increase in T_{max} for mr-rhTSH compared to rhTSH without eliciting significant differences in exposure (area under the curve, AUC). Further analysis indicated that altering the viscosity range in between 18 and 149 had no significant impact on mr-rhTSH pharmacokinetics. Injection volume studies in beagle dogs demonstrated a statistically significant shift in C_{max} and T_{max} for mr-rhTSH relative to rhTSH, regardless of whether the injection volume was 0.07 or 0.15 ml/kg. Significant changes in C_{max}, T_{max}, and t_{1/2} were also observed with mr-rhTSH dosed at either, 0.1, 0.2, or 0.05 mg/kg compared to rhTSH.

Conclusions: These results indicate that following intramuscular administration, maximal concentrations are reduced and the time to C_{max} is prolonged with mr-rhTSH relative to rhTSH. Such changes occur in the absence of differences in exposure and occur independent of mr-rhTSH viscosity, concentration and injection volume.

2038 TISSUE DISPOSITION OF GOLD NANOPARTICLE FOLLOWING IV INJECTION IN SWINE.

G. M. Fent¹, S. W. Casteel¹, K. V. Katti², R. Kannan², K. Katti², V. Kattumuri³ and E. Boote². ¹*Veterinary Pathobiology, University of Missouri, Columbia, MO,* ²*Radiology, University of Missouri, Columbia, MO* and ³*Physics and Astronomy, University of Missouri, Columbia, MO.*

Gold nanoparticles have many potential uses in biology and medicine, including molecular level imaging and treatment of diseases such as cancer. The ability to image morphological changes associated with disease at the molecular level will lead to earlier disease detection and treatment and increase the possibility of a successful outcome. Preliminary experiments have been conducted with the objective of determining the disposition of hybrid gold nanoparticles (AuNPs) in blood and tissues following the I.V. administration of a gum-arabic preparation of AuNPs to juvenile swine. In these studies juvenile male swine were anesthetized with isoflurane, and venous catheters were placed in the cranial vena cava. While anesthetized, the gold nanoparticles were administered via the catheter at dosages ranging from 1.88 to 4.00 mg/kg BW. Serial blood samples were collected at 5, 15, 30, 60, 120, and

240 minutes post-dosing. A final blood sample was then collected 24 hours post-dosing and pigs were humanely sacrificed and tissues were collected for gold analysis using atomic absorption spectrophotometry. In these experiments gum-arabic AuNPs were distributed according to a two-compartment model, with a distribution phase lasting approximately 4 hours and an elimination phase that continues through 24-hours. There were measurable levels of gold in several tissues, however, the lung and liver had the greatest concentrations. Preliminary results indicate that these hybrid gold nanoparticles are distributed rapidly to many tissues in the body and the lung and liver are sites of accumulation. These hybrid gold nanoparticles could potentially be used to increase the sensitivity of CT or ultrasound imaging of these organs or in targeted treatment and radiotherapy of cancer and other disease in these organs. Work supported by the National Institutes of Health/National Cancer Institute, Cancer Nanotechnology Platform program (grant number: 1R01CA119412-01).

2039 NASAL AND PULMONARY UPTAKE AND METABOLISM OF INHALED SULFURYL FLUORIDE IN ADULT RATS.

J. Hotchkiss¹, S. M. Krieger¹, D. L. Rick¹, D. A. Markham¹, M. J. Bartels¹ and D. L. Eisenbrandt². ¹The Dow Chemical Company, Midland, MI and ²Dow AgroSciences, LLC, Indianapolis, IN.

Sulfuryl fluoride (SF), a structural and post-harvest fumigant, is a key alternative to methyl bromide, a stratospheric ozone depleting substance scheduled for phaseout by the Montreal Protocol. Extensive toxicological studies suggest that fluoride (F) ion may play a role in the mode of action of SF in insects and mammals. This study was designed to determine contribution of the upper (URT; nasal) and lower (LRT; pulmonary) respiratory tract to the absorption and metabolism of inhaled SF and to provide data necessary to develop a PBPK model to describe tissue dosimetry of SF, and the hydrolysis products fluorosulfate (FS), and F in the adult rat. Male F344/DuCrI rats (n=6/group), anesthetized with urethane, were exposed to 0 or 300 ppm SF for 4 h. One half of the rats were surgically-modified to separate the URT from the LRT before exposure. In surgically-modified rats humidified breathing air (0 ppm SF) was supplied directly to the lungs via a tracheal cannula, while the test atmosphere was pulled through the URT at a rate of 150 ml/min. The fractional uptake of SF by the URT was estimated from the difference in the SF concentration, determined by GC/FID, before and after passage through the URT. After exposure, the concentration of SF in blood and lavage fluids and the concentration of FS and F in serum, lavage fluids, and tissue homogenates of nasal mucosa, lung, cerebrum, olfactory bulb and cerebrum were determined by GC/MS or ion chromatography, respectively. Based on the difference in SF concentration before and after passage through the URT, the average percent of SF absorbed by the URT was 5%. No SF was detected in any sample from either surgically-modified or unmodified rats, however, elevated levels of FS and F were detected in serum, lavage and tissue samples of SF-exposed rats. These data indicate that even at high exposure concentrations, absorbed SF is rapidly and completely hydrolyzed to FS and F, and is, therefore, not available for systemic exposure of tissues beyond the point of contact (URT and LRT).

2040 PULMONARY ABSORPTION AND LUNG DOSIMETRY; THE ISOLATED AND PERFUSED RAT LUNG EXPOSED TO DRY POWDER AEROSOLS OF BUDESONIDE, FORMOTEROL AND TERBUTALINE.

P. Ewing¹, P. Gerde^{1,3}, P. Andersson², S. Eirefelt², A. Blomgren² and A. Ryrfeldt¹. ¹Environmental medicine, Karolinska Institute, Stockholm, Sweden, ²Discovery DMPK, Astra Zeneca Pharmaceuticals Ltd., Lund, Sweden and ³DustGun Technologies AB, Stockholm, Sweden.

When rats are exposed nose-only to aerosols of solutes, disposition in the respiratory tract proceeds along several routes; absorption through the air/blood barrier, mucociliary clearance with swallowing, macrophage engulfment of slow dissolving particles and various systemic effects. These overlaying processes tend to obscure the key process of solute absorption through the air/blood barrier. Our aim was to create a model for measuring the pulmonary absorption of inhaled solutes in great detail. Hence, one important task is to link the systemic concentration profile with the dosimetry of the exposed tissue; primarily the air/blood barrier of the peripheral lung. The isolated and perfused rat lung (IPL) has been widely used to study deposition, absorption and metabolism of inhaled drugs and toxicants. However few options have been available for exposing the IPL to dry powder aerosols in a controlled way. The recently developed DustGun aerosol technology can reproducibly expose the IPL to a respirable dry powder aerosol. We studied the pulmonary absorption of three generic drugs by exposing distal regions of the IPL to respirable aerosols of budesonide, formoterol and terbutaline. The IPL was perfused in a single pass mode and repeated samples of the perfusate were taken up to 80 min post exposure. The concentration of drug in perfusate and in lung extracts was measured using LC-MS/MS. An overall mass balance was established by summing up cumu-

lative clearance with the tissue dose at the end of the perfusion period. To describe absorption and retention of the substances in the lungs, independent of the concentrations, the retention of total deposited dose as a function of time was calculated. The fractional retention in the lung at 80 min post exposure for budesonide, formoterol and terbutaline was 0.2, 0.18 and 0.04 respectively.

2041 BIOAVAILABILITY OF PBDES IN MALE RATS FROM ORALLY ADMINISTERED HOUSEHOLD DUST.

H. Hakk¹, J. K. Huwe¹, J. J. Diliberto², H. Stapleton³ and L. S. Birnbaum². ¹ARS Biosciences Research Laboratory, USDA, Fargo, ND, ²ORD/NHEERL/ETD, U.S. EPA, Research Triangle Park, NC and ³Nicolas School Environmental Sciences and Policy Division, Duke University, Durham, NC.

Recently, household dust has been implicated as a major source of polybrominated diphenyl ether (PBDE) exposure in humans. This finding has very important implications especially for young children, who are thought to ingest more dust than adults, and may be more susceptible to some of the putative developmental effects of PBDEs. No absorption parameters of PBDEs from ingested dust have ever been determined, therefore, the objectives of this study were to determine the absorption, distribution, and excretion of PBDEs in male Sprague-Dawley rats fed either dust (NIST Standard Reference Material 2585) or oil contaminated with ppb levels of 20 PBDE congeners for 21 days in the diet. Following cleanup by an automated Fluid Management System utilizing triphasic silica and basic alumina cartridges, the tissue residues were quantitated by HR-GC/HR-MS analysis. Results from adipose tissue and livers showed that uptake of individual PBDE congeners did not differ between comparable doses of either vehicle. Bioconcentration factors of PBDEs in adipose were the same for all dosage groups, i.e. 10-20 for tri- to hexa-BDEs, 1-4 for hepta- to nona-BDEs, and <1 for deca-BDE. The liver-to-adipose ratios on a lipid-weight basis (L:A) for tri- to hexa-BDEs were <0.5, while the L:A was >1.0 for hepta- to deca-BDEs. The present results show that PBDEs in dust are at least as bioavailable as those dissolved into an oil vehicle, and that higher brominated congeners are less bioavailable than lower brominated congeners. These results indicate that dust can be a facile source of PBDEs in mammals, and that the familiar PBDE fingerprints in biota is a result, at least in part, of bioavailability of individual congeners. (This abstract does not reflect Agency policy.)

2042 OLD PRINCIPLES IN A NEW FIELD: PARTICOKINETICS AFFECTS SIZE AND TIME DEPENDENT TOXICITY OF NANO SILICA IN MACROPHAGES.

J. G. Teeguarden¹, P. M. Hinderliter¹, R. D. Quesenberry², W. B. Chrisler², B. D. Thrall¹ and J. G. Pounds². ¹Biological Monitoring and Modeling, Pacific Northwest National Laboratory, Richland, WA and ²Cell Biology, Pacific Northwest National Laboratory, Richland, WA.

The rapid growth in the use of in vitro methods for nanoparticle toxicity assessment has proceeded with limited consideration of the unique kinetics of these materials in solution. Cellular dose is a function of several systemic and particle factors: media density and viscosity, particle size, shape and density. Collectively, these processes determine the rate of transport of nanoparticles to cells in culture. Here we use a computational model of particle kinetics and dosimetry in vitro to study the influence of size and agglomeration dependent nanoparticle delivery rates on the pharmacodynamics of the macrophage inflammatory response to amorphous silica. RAW267 macrophages were exposed to 10, 150, 500 and 1000 nm amorphous silica and the expression of TNF α mRNA was determined 2, 4 or 8 hours after exposure. Two sets of doses were selected, equal nominal media surface area concentrations, and equal delivered particle surface area determined with the computational dosimetry model. The agglomeration state of these particles was determined by scanning electron microscopy and used as input into the dosimetry model. We show that the kinetics of delivery significantly impact the apparent dynamics of the inflammatory response and of the relative potency of particles of different sizes. Additional experiments demonstrate that media volume in vitro can affect dose to the cell and the dynamics of the measured inflammatory response, particularly for dense particles. Incorporating particokinetics and principles of dosimetry are critical for nanomaterial toxicity assessment. Funded through U.S. Department of Energy under Contract DE-AC05-76RL01830.

2043 PERCUTANEOUS ABSORPTION OF POLYCYCLIC AROMATIC COMPOUNDS (PAC) FROM PAVING- ASPHALT FUME CONDENSATES.

C. R. Mackerer¹, T. A. Roy², L. V. Osborn³ and A. J. Kriech³. ¹C&C, Consulting in Toxicology, Pennington, NJ, ²Port Royal Research and University of SC, Beaufort, Hilton Head Island, SC, ³Heritage Research Group, Indianapolis, IN and ⁴Heritage Research Group, Indianapolis, IN.

Four asphalt fume condensates (AFCs) were obtained from the head-space vapors of storage tanks containing straight-run paving asphalts at 147 $\pm$ 2.7 deg.C, for measuring percutaneous absorption through human skin. The Asphalt Institute

(Lexington, KY) provided the AFCs, which were analyzed by the Fraunhofer Institute (Hannover, Ger.) for specific polycyclic aromatic hydrocarbons (PAH). The Heritage Research Group provided analyses of total 3-6 ring PAC. One inch circular pieces of human back skin from a single donor (250-350 μ m thickness) were mounted in Franz diffusion cells. Tissue integrity was assured by measuring electrical resistance. Neat condensate was applied at "infinite dose" (200 μ l/tissue) to the stratum corneum; the dermis was in contact with the receptor fluid, which was an aqueous solution of polyoxyethylene 20 oleyl ether. Receptor fluids were sampled at intervals over 48 hr and analyzed by HPLC using fluorescence detection; the mobile phase was 60-100% acetonitrile/water gradient. Flux rates of anthracene, fluoranthene, pyrene, and total 3-6 ring PAC were measured. The average ($n=4$) neat AFC concentration (ppm) was: anthracene, 50.6 $\pm$ 14; fluoranthene/pyrene, 66.5 $\pm$ 47; and 3-6 ring PAC, 833 $\pm$ 302. Flux rates (ng/cm²/hr) were: anthracene, 4.4 $\pm$ 1.2; fluoranthene/pyrene, 3.8 $\pm$ 2.8; PAC, 34.3 $\pm$ 14.4. The apparent permeability coefficient (Kp) for the four samples, as determined by results for anthracene was 1.0 $\pm$ 0.10 $\times 10^{-4}$ cm/hr. Results show that skin penetration of PAH, at concentrations naturally present in fume condensates are measurable by *in vitro* methods. Rate and extent of PAH and PAC skin penetration can be a useful parameter in the risk assessment of potential toxicity from asphalt fume exposure. This research was supported by the Asphalt Paving Environmental Council.

2044 IN VITRO ABSORPTION OF ¹⁴C-DECAMETHYLTETRASILOXANE (¹⁴C-L4) IN HUMAN SKIN.

M. L. Jovanovic¹, J. M. McMahon¹, S. D. Crofoot¹, K. P. Plotzke¹ and J. Bazinet². ¹Dow Corning Corporation, Midland, MI and ²Silicones Environmental, Health and Safety Council, Herndon, VA.

The absorption of ¹⁴C-L4 was evaluated when applied to human skin *in vitro* using flow-through diffusion cells. Human epidermis with a top layer of dermis (300-500 μ m) was prepared from intact abdominal skin by dermatoming. Skin discs from four donors were assessed in triplicate. A physiological receptor fluid was pumped underneath the skin samples for 24 hr and collected at predetermined time points using a fraction collector. Barrier integrity of the skin was initially screened with ³H-H₂O. Each skin sample was dosed with neat ¹⁴C-L4 at a targeted dose of 10 mg/cm². Immediately after dosing, charcoal baskets were placed above the exposure site and secured into a custom designed holder to capture volatilized material. At the end of 24 hr, the charcoal baskets were removed and extracted, skin was washed, tape stripped and solubilized, and receptor fluid was collected. The radioactivity content in each sample was measured by liquid scintillation counting. The percent dose absorbed was determined as the amount of radioactivity in the receptor fluid combined with the amount remaining in the skin after washing and tape stripping relative to the applied dose. Almost all (99.9%) of the recovered ¹⁴C-L4 was captured in the charcoal baskets placed above the exposure site. The percent of applied ¹⁴C-L4 recovered from all analyzed samples was 104.7%. Only a small amount of applied dose (0.06%) was found on the skin surface after a 24 hr exposure or remained in the skin after washing (0.03%). Little, if any (0.001%) of the applied dose penetrated through the skin into the receptor fluid with the mean cumulative penetration ($\pm$ SEM) over the 24 hr being only 0.07 $\pm$ 0.007 μ g equivalents L4/cm² of exposed skin. The total percent dose absorbed was estimated to be 0.03% of applied dose with virtually all of the absorbed ¹⁴C-L4 retained in the skin. (Supported by the Silicones Environmental, Health and Safety Council of North America)

2045 DISPOSITION AND ELIMINATION OF TUNGSTEN IN RODENTS AFTER REPEAT GAVAGE AND DRINKING WATER EXPOSURES.

R. Marr¹, D. Kracko¹, R. Arimoto², W. M. Weber¹ and J. McDonald¹. ¹Lovelace, Albuquerque, NM and ²Carlsbad Environmental Monitoring and Research Center, Carlsbad, NM.

Tungsten (W) has been nominated for study to the National Toxicology Program (NTP) because of reported associations between concentrations of W in drinking water and childhood leukemia. As part of the NTP program, the chemical disposition of W (administered as sodium tungstate dihydrate in water) in plasma, liver, kidney, uterus, femur, and intestine of rodents (Sprague-Dawley Rats and C57Bl/6N mice) have been characterized after repeat exposure by gavage (10 mg/kg) or drinking water (560 mg/L) for 14 consecutive days. Separately, the same species were exposed to drinking water (560 mg/L) during gestation for 9 (mice) or 10 (rats) days. For the rodents exposed during gestation, all the aforementioned tissues were analyzed in addition to pups to assess transplacental disposition. Animals were euthanized 24 hr after the last day of dosing. At sacrifice, plasma, intestine, liver, kidney, femur, uterus, and fetus were collected for analysis by

Inductively Coupled Plasma Mass Spectrometry. W was detectable in plasma and all tissues and in pups of both rats and mice. In many tissues, W accumulation was readily apparent with concentrations in intestine, kidney, and femur significantly above baseline levels. Explanations for enrichment/retention in these tissues include intestine being the primary route of entry for oral exposures, kidney being the primary route of elimination (>95% eliminated through the urine as shown in previous studies), and the ability of W to displace P in bone and become retained in femur. Funding from NIEHS Contract # N01-ES-25483

2046 NON-COMPARTMENTAL PHARMACOKINETIC AND PHARMACODYNAMIC ANALYSIS OF A RECOMBINANT IFN- β AND NEOPTERIN FOLLOWING A SINGLE SUBCUTANEOUS INJECTION IN CYNOMOLGUS MONKEYS.

K. R. Trimm¹, K. Blouin¹, I. Boulay¹, A. Steff¹, A. Nelson¹, C. Petit-Turcotte¹, G. Washer¹ and D. Kim². ¹LAB Research Inc., Laval, QC, Canada and ²CJ Pharmaceutical Research Institute, Ichon-Si, South Korea.

Noncompartmental pharmacokinetic (PK) and pharmacodynamic (PD) analyses are an integral part of Investigative New Drug (IND) submissions. Here, WinNonlin (v. 5.0.1) was used to determine the PK and PD profile of a recombinant human IFN- β and Neopterin, an established biomarker of IFN- β activity, in the plasma of cynomolgus monkeys following a single subcutaneous injection. Molecular quantifications were performed using validated ELISAs. Separate groups of animals (3-5/sex/group) were dosed at 0, 3.5, 11, or 35 μ g/kg IFN- β , and bled at ten time points for the purpose of PK/PD analyses on Day 1 of a 13-week repeat dose safety study. Animals were also bled on Day 89, but neither IFN- β nor Neopterin were detected. Maximum IFN- β plasma concentrations (C_{max}) were reached between 4 to 8 hours (T_{max}) following administration, with the fastest absorption occurring at the high dose level. Both the C_{max} and the area under the curve (AUC(0- ∞)) increased beyond dose proportional rates. The goodness-of-fit statistic (R²) applied to the data indicated that estimations based on the terminal elimination rate constant (K_{el}) were reliable. The terminal half-life (T_{1/2}) of IFN- β was estimated to be between 5 and 6 hours. Neopterin plasma concentrations linearly increased beyond baseline values at approximately the IFN- β T_{max} for each group, with a dose dependent slope increase until the maximum effect (R_{max}) was observed at the final time point (T_{max} = 24 hrs). However, Neopterin R_{max} and AUC(>B) increases across dose levels fell short of dose proportionality. Interestingly, C_{max} and AUC(0- ∞) for IFN- β in this experiment were substantially higher than those found in the published data for a commercially available IFN- β at the same dose levels in the same species, despite a similar T_{max} and T_{1/2}, suggesting improved bioavailability.

2047 ALTERATION OF TRICHLOROACETIC ACID (TCA) RENAL ELIMINATION BY PROBENECID IN SPRAGUE-DAWLEY (S-D) RATS.

S. Lee, C. A. White, S. Muralidhara and J. V. Bruckner. *Interdisciplinary Toxicology Program/Department of Pharmaceutical and Biomedical Sciences, College of Pharmacy, University of Georgia, Athens, GA.*

Probenecid (PRB), a nonspecific inhibitor of the organic anion transporter/multidrug resistance-related protein (OAT/MRP), members of ATP-binding cassette transporter superfamilies, was used to investigate the role of active transport in the renal clearance of TCA in young S-D rats. Previous studies from our group showed that the induction of CYP2E1 by pyridazine enhanced trichloroethylene (TCE) metabolism and increased the renal clearance of TCA in animals dosed with TCE or TCA. The roles of the transporters for the small organic anions and their conjugates are well established, but there is apparently no information on the involvement of these transporters with TCA.

Male S-D rats (~ 175 g bw) were cannulated (carotid artery and/or jugular vein), housed in metabolism cages individually, allowed to recover from surgery for 24 hr, given PRB (500 mg/kg in 5% emulsion) ip (controls were given saline), followed by the administration of TCA (50 mg/kg, iv). Serial blood samples were taken for 72 hr via the indwelling catheter, and urine collected and stored at -20 $^{\circ}$ C until analysis. TCA in blood and in urine were derivatized and analyzed using the headspace gas chromatography. Basic pharmacokinetic parameters (AUC, t_{1/2}, CL, CLR and VD) for TCE and TCA were estimated using WinNonLin. The excretion of TCA in urine was significantly reduced from that of controls as expected. The modulation of TCA clearance may have important implications in cancer risks thought to be posed by TCE to certain subpopulations (e.g., diabetics, alcoholics, obese individuals and persons taking CYP2E1-inducing medications). This work was supported by DOE Cooperative Agreement DE-FC09-02CH11109.

2048 DIFFERENTIAL GENE EXPRESSION IN THE UTERUS AND THE CERVIX: IMPLICATIONS FOR CHARACTERIZING THE EFFECTS OF ESTROGEN AND SERMS.

P. H. Koza-Taylor¹, W. Nowland¹, S. Deng², C. Sawaryn¹, G. Cappon¹, M. Mirsky¹ and M. Lawton¹. ¹DSRD, Pfizer Global Research, Groton, CT and ²NCS, Pfizer Global Research, Groton, CT.

When analyzing gene expression data, it is critical to minimize variation within dose-groups in order to enhance the ability to identify mode-of-action pathways. One contribution to heterogeneity within dose-groups can occur when tissues have regional variations of cell-types, such as the female reproductive tract. We describe a study where uterine gene expression data were generated on Affymetrix RAE230V2.0 GeneChips using ovariectomized (OVX) Sprague-Dawley rats. The rats were dosed daily with vehicle, 17 α -ethinylestradiol (EE) or tamoxifen (tam) for 28 days and at necropsy, the uterus was collected, weighed, and a portion flash frozen in liquid nitrogen for RNA isolation. The remaining portion was fixed in formalin and paraffin embedded. Global data analysis utilizing Principal Component Analysis (PCA), Multiple Dimensional Scaling (MDS) and Hierarchical Clustering (HCA) revealed that both the EE and tam dose-groups contained two samples that looked very different from the remaining three samples in each dose-group and that these four samples appeared to be more similar to each other than to their respective dose-groups. Detailed analysis of the gene changes in the outlier samples suggested the presence of a stratified squamous epithelium consistent with that found in cervix. Further investigation, including histological examination and molecular analysis of the formalin fixed and paraffin embedded sections, confirmed that cervical contamination of the uterus resulted in a dramatically different expression profile for the animals dosed with EE or Tam. In a separate confirmatory study in OVX rats with EE and tam, the uterine horns were dissected from the cervix and the two tissues were profiled separately on Affymetrix arrays. Analysis of these expression profiles revealed that the cervix and uterus have distinct profiles with some overlap of EE and tam induced genes. This work demonstrates the importance of removing cervical tissue as it confounded pathway analysis in the uterus.

2049 INTERACTIONS BETWEEN CYTOCHROME P450 2E1 AND MICROSOMAL EPOXIDE HYDROLASE IN EFFECTS OF 4-VINYLCYCLOHEXENE DIEPOXIDE IN THE MOUSE OVARY.

A. Keating¹, K. Rajapaksa¹, I. Sipes² and P. B. Hoyer¹. ¹Physiology, University of Arizona, Tucson, AZ and ²Pharmacology, University of Arizona, Tucson, AZ.

4-Vinylcyclohexene diepoxide (VCD) is an occupational chemical that destroys ovarian small pre-antral follicles in rodents. VCD is detoxified to an inactive tetrol metabolite, 4-[1,2-dihydroxy] ethyl-1,2-dihydroxycyclohexane by microsomal epoxide hydrolase (mEH). *In vivo* dosing with VCD (80mg/kg, i.p.) showed no difference ($p>0.05$) in follicle loss between CYP2E1 +/+ and CYP2E1 deficient (-/-) mice (28-day old). A post-natal day 4 (PND4) mouse whole ovary culture system (enriched in target small pre-antral follicles) has been used to investigate ovotoxic effects of VCD as well as another ovarian toxicant, 7, 12-dimethylbenz[a]anthracene (DMBA), *in vitro* and it was shown that CYP2E1 deficient (-/-) mouse ovaries are less susceptible to VCD-induced follicle loss than their wild-type counterparts (129S1/SvImJ). Conversely, when incubated with DMBA, which, unlike VCD is bio-activated by mEH, there was more follicle loss in cultured ovaries from CYP2E1 -/- compared with CYP2E1 +/+ mice. Thus, these studies suggest a possible interaction between ovarian CYP2E1 and mEH activity. Lack of correlation between *in vivo* and *in vitro* studies may be explained by differences in age and heterogeneity of the older ovary. The present study was designed to evaluate expression of mEH in CYP2E1 +/+ and -/- PND4 mouse ovaries exposed to VCD. Ovaries were cultured in VCD (5 μ M) or control medium for 15d and expression of mRNA encoding mEH was measured by Real-Time PCR. Basal expression levels of mEH mRNA in CYP2E1 -/- ovaries was lower than that in +/+ ovaries, however, exposure to 5 μ M VCD caused a 3.5-fold increase in expression of mEH in -/- ovaries, whereas there was no change in +/+ ovaries. These findings suggest that CYP2E1 may play a role in regulation of mEH expression in the mouse ovary. (ES09246 and Center grant 06694)

2050 OVARIAN MICROSOMAL EPOXIDE HYDROLASE (MEH) IS INVOLVED IN 7, 12-DIMETHYLBENZ[A]ANTHRACENE (DMBA) INDUCED FOLLICLE LOSS IN AN IN VITRO OVARIAN CULTURE SYSTEM.

K. Rajapaksa¹, I. Sipes² and P. B. Hoyer¹. ¹Physiology, University of Arizona, Tucson, AZ and ²Pharmacology, University of Arizona, Tucson, AZ.

DMBA causes ovarian follicle disruption in mice. Disruption of follicles by DMBA is attributed to the bioactivation of DMBA to a 3,4-diol-1,2-epoxide intermediate. DMBA is bioactivated in hepatic tissue by CYP 1B1 to a 3,4-epoxide which is then

hydrolyzed to form a 3,4-diol by mEH enzyme. This compound further undergoes epoxidation at the 1,2 position by CYP 1A1 or 1B1 to form the ultimate ovotoxicant DMBA-3,4-diol-1,2-epoxide. The mouse ovary expresses CYP 1A1, CYP 1B1 and mEH, and mRNA for these enzymes is inducible. These findings suggest that the ovary is capable of bioactivating DMBA to the 3,4-diol-1,2-epoxide. Previous studies have shown that DMBA induces significant ($p<0.05$) follicle loss by 6h in an ovarian culture system. The present study was designed to evaluate whether this loss of follicles in culture depends on ovarian mEH enzyme activity. Ovaries from post natal day 4 (PND4) B6C3F1 mice were incubated with vehicle medium (1% DMSO), mEH enzyme blocker cyclohexene oxide (2mM; CHO), 1 μ M DMBA, or 1 μ M DMBA and 2mM CHO for 6h. Following incubation, ovaries were collected and prepared for histological evaluation by classification and counting of follicles. Following 6h incubation, follicle numbers in control medium (DMSO) were: primordial, 386 $\pm$ 19.9 follicles counted/ovary; and primary, 311 $\pm$ 26.4 follicles counted/ovary. There was no effect of CHO on follicle numbers. DMBA incubation significantly ($p<0.05$) decreased follicle numbers (primordial, 204 $\pm$ 22.3 follicles counted/ovary; and primary, 203.5 $\pm$ 10.6 follicles counted/ovary). Whereas, addition of CHO to ovaries incubated with DMBA prevented ($p<0.05$) follicle loss (primordial, 357 $\pm$ 18 follicles counted/ovary; and primary, 297 $\pm$ 36.9 follicles counted/ovary). These observations support the hypothesis that PND4 mouse ovary is capable of bioactivating DMBA to its ovotoxic form 3,4-diol-1,2-epoxide, and ovarian mEH enzyme activity is likely involved (ES09246 and Center Grant 06694).

2051 TOXICITY OF A CLINICALLY RELEVANT DOSE OF HYDROXYUREA (HU) ON EMBRYO DEVELOPMENT.

A. E. Archibong. *Obstetrics & Gynecology, Meharry Medical College, Nashville, TN.*
Sponsor: A. Ramesh.

The purpose of this study was to investigate the risks associated with a dose of HU used for the treatment of sickle cell disease (SCD) on ovarian physiology and embryo development. In Expt 1, 21 day-old female C57BL/6J mice were randomly assigned to a treatment or a control group (N=20/gp). Treatment consisted of oral HU (30 mg/kg) for 30 days; while control mice received saline (HU carrier). Four days to the cessation of HU dosing, all mice were subjected to folliculogenesis induction with PMSG (2.5 IU; IP) followed 48 hours later by ovulation induction with hCG (2.5 IU; IP). Ten mice/gp were anesthetized at 48 hours post PMSG to facilitate blood collection via cardiac puncture for E2 measurement by RIA. 16 hours post hCG, the remaining mice were sacrificed, ovaries excised and weighed and embryos harvested and cultured in Whitten's medium supplemented with CZBt (WCZBt). In Expts 2 and 3, folliculogenesis and ovulation were induced in untreated mice as described above, followed by embryo recovery. Embryos were either cultured continuously (Expt 2) or intermittently (Expt 3) in the presence or absence of bioavailable HU (18 μ g HU/ml of WCZBt). Data on ovarian wt, ovulation rate and serum E2 were compared with unpaired "t"-test, while those on embryo development were analyzed by Chi-square. Treated mice sustained decreased ovarian wt, ovulation rate and circulating E2 compared with controls ($P<0.05$). Fewer embryos retrieved from HU treated mice developed to blastocyst stage (32%) compared with those from controls (60%; $P<0.05$). Furthermore, continuous or intermittent *in vitro* exposures of embryos to HU also resulted in reduced development to blastocyst stage ($P<0.05$), with continuous *in vitro* exposure to HU fairs worse compared with controls. Though HU is beneficial for the alleviation of the clinical manifestations of SCD, it compromises ovarian physiology and the ability of generated embryos to develop and consequently, women on HU should not attempt pregnancy (Supported by NIH grants G12 2RR003032, U-54 HD044315 & RO1 HD020419-19S1).

2052 AN INNOVATIVE STUDY OF OVARIAN AND REPRODUCTIVE EFFECTS OF LANSOPRAZOLE ADMINISTERED TO JUVENILE RATS.

S. Levin¹, L. Pinsonneault² and K. Colman². ¹TAP Pharmaceutical Products Inc., Lake Forest, IL and ²Charles River Laboratories, Montréal, QC, Canada.

In earlier studies, ovarian weights and corpora lutea numbers were reduced in neonatal rats (7 days old) dosed with the proton pump inhibitor lansoprazole for 28 days at 50 mg/kg/day. In contrast, weanling rats (21 days old) dosed for 40 days at 150 mg/kg/day had no ovarian effects. The day of vaginal opening was not adequately assessed in either study. We designed a study to reconcile the different outcomes and determine any lasting effects on ovaries or reproductive capacity. Neonatal female rats were given vehicle, 1.5 or 50 mg/kg/day lansoprazole by gavage from 7 days old. Weanling female rats were given vehicle or 150 mg/kg/day from 21 days old. Both age cohorts were treated daily until 8 days after vaginal opening for all animals in the age cohort. Ten female pups (2/litter) from each of these groups were then necropsied (Interim) and an additional 2 female pups/litter were held until 70 days of age and then bred to untreated males (Reproductive). In

the Reproductive phase, estrous cycling was followed prior to mating and continued until mating was verified. Mated females were allowed to litter. Their parturition and offspring were assessed. Reproductive phase dams were necropsied 4 or 5 days after parturition. Ovaries from all Interim and Reproductive phase rats were weighed and examined for numbers of corpora lutea. The uteruses of Reproductive phase dams were examined for implantation sites. The day of vaginal opening was not affected by lansoprazole administration except in weanlings dosed at 150 mg/kg/day, where the mean day of opening was significantly increased (Day 34) compared to their controls (Day 31). Individual values were all within the historical range. This delay was attributed to a nonspecific slower growth rate in this group, rather than a specific effect on the reproductive system. Vaginal opening occurred at approximately 110 grams of body weight for the 150 mg/kg/day group and their controls. Lansoprazole had no effects upon ovarian weights, numbers of corpora lutea or reproductive function in this study.

2053

THE INHIBITION OF PROGESTERONE (P) FORMATION OF CULTURED OVARIAN THECA-INTERSTITIAL (TI) CELLS BY THE METHOXYCHLOR (MC) METABOLITE, HPTE, IS NOT MEDIATED THROUGH THE ESTROGEN RECEPTOR (ER) OR ANDROGEN RECEPTOR (AR).

Y. Akgül^{1,2}, R. C. Derk^{1,2} and E. P. Murono¹. ¹PPRB, NIOSH, morgantown, WV and ²physiology and pharmacology, west virginia university, morgantown, WV. Sponsor: V. Castranova.

The pesticide MC is used on agricultural crops and livestock. MC exposure in rodents is linked to impaired steroid production, ovarian atrophy and reduced fertility. Following in vivo administration, it is rapidly converted to HPTE, reported active metabolite, by the liver. Both MC and HPTE have weak estrogenic and antiandrogenic activities, and these effects are thought to be mediated through the ER and ARs, respectively. Previous in vivo studies in female animals demonstrated decreased P production but no change in serum estrogen levels following exposure to MC. We showed a decrease in androgen and P production of follicular cells by HPTE in-vitro. The current studies examined the mechanism of actions of HPTE on P production by cultured ovarian TI cells from immature rats. To isolate TI cells, 24-25-day-old female Sprague-Dawley rats were injected (s.c.) with 20 I.U. of pregnant mare serum gonadotropin. Approximately 48 h following treatment, ovarian tissue was digested with collagenase and dispersed. TI cells were cultured in DMEM / F12 medium and exposed to HPTE for 24 h on the day of plating. Exposure to HPTE (0, 10, 50, 100 nM) alone inhibited P formation in a dose-dependent manner with a significant decline to ~12 % of control at 100 nM. In contrast, estrogens (estradiol, bisphenol-A, and 4-tert-octylphenol), pure anti-estrogen ICI 182,780 (ICI), and anti-androgens (4-OH-flutamide or the vinclozolin metabolite M-2) had no effect on P production even at 1000 nM. Co-treatment of HPTE with ICI did not block the effect of HPTE on P formation. These studies revealed that HPTE inhibition of P production by cultured TI cells is unique, and does not appear to be mediated through the ER or AR.

The findings and conclusions in this abstract have not been formally disseminated by NIOSH and should not be construed to represent any agency determination or policy.

2054

IN VIVO METHYL-PARATHION EXPOSURE IMPAIRS MALE FERTILIZING ABILITY IN MICE.

B. Piña-Guzmán¹, M. Sánchez-Gutiérrez², I. Hernández-Ochoa¹, M. Solís-Heredia¹ and B. Quintanilla-Vega¹. ¹Toxicology Section, CINVESTAV, Mexico City, D.F., Mexico and ²Instituto de Ciencias de la Salud, Universidad Autónoma del Estado de Hidalgo, Pachuca, Hidalgo, Mexico.

Evidence supports that some environmental agents can interact with sperm DNA causing genetic damage that may affect fertility. Organophosphorous pesticides (OP) are among the most used agrochemicals and have been associated with male reproductive effects. We previously showed that methyl-parathion (Me-Pa), an OP, alters sperm quality and induces genotoxic effects in sperm that were related to oxidative damage. This study was conducted to determine the ability of mice spermatozoa to fertilize oocytes after Me-Pa exposure (20 mg/kg bw/ip), evaluating two stages of spermatogenesis in spermatozoa collected from cauda epididymis-vas deferens at 7 days post-treatment (dpt; cells at epididymal maturation at the time of exposure) and at 28 dpt (cells at meiosis at the time of exposure). Sperm quality, mitochondrial function using JC-1 staining, acrosome reaction induced by GABA (induced-AR), fertilization rate at 8 h after IVF, and lipid peroxidation (LPO) as malondialdehyde (MDA) production, were evaluated. Acute exposure to Me-Pa altered sperm quality (viability and motility) at both times, and a decrease in mitochondrial function was observed that was more pronounced at 7 than at 28 dpt

(19% and 77% of the control). The fertilization rate (pronuclear formation) was decreased and was also more severe at 7 dpt than at 28 dpt (21% and 55%) compared with the control group (73%). This suggests that cells at both spermatogenic stages are target of Me-Pa toxicity. An increase (3.2-fold) in MDA production was observed only at 7 dpt and was negatively correlated with mitochondrial activity ($r = -0.886$) and induced-AR ($r = -0.880$). These correlations observed between LPO and mitochondrial activity and AR suggests that the induction of oxidative stress by Me-Pa exposure may be involved in the alteration of events preceding fertilization, therefore, compromising the ability of spermatozoa to fertilize. This study was supported by CONACyT-Mexico (Grant #44643 given to BQV).

PROTECTIVE ROLE OF α -TOCOPHEROL ON THE OXIDATIVE AND GENETIC DAMAGE CAUSED BY METHYL-PARATHION EXPOSURE IN MICE SPERMATOZOA.

M. Urióstegui-Acosta, M. Solís-Heredia, B. Piña-Guzmán and B. Quintanilla-Vega. Toxicology Section, CINVESTAV, Mexico City, D.F., Mexico.

Organophosphate pesticides (OP) are widely used in Mexico and OP exposure has been associated with fertility problems in agricultural workers. OP induces the generation of reactive oxygen species which alter DNA integrity. We previously showed that methyl parathion (Me-Pa), an OP, alters sperm DNA that was associated with oxidative damage. Since oxidative stress can be reversed by antioxidant treatment, we evaluated the protective effect of α -tocopherol on the oxidative and genetic damage caused in spermatozoa by Me-Pa treatment. Adult ICR male mice were exposed to Me-Pa (3, 6 and 12 mg/kg, bw/i.p/5 days) or co-exposed with the highest dose of Me-Pa (12 mg/kg, bw/i.p/5 days) and α -tocopherol (50 mg/kg/i.g/5 days). Blood and sperm cells from cauda epididymis-vas deferens were extracted 24 h after the last administration, and erythrocyte acetylcholinesterase (AChE), sperm quality, lipid-peroxidation (LPO) by malondialdehyde (MDA) production and the chromatin structure by SCSA (DFI% parameter) were evaluated. Me-Pa exposure caused a dose-response decrease in AChE (52% to 71% inhibition). An increase in MDA at 6 (1.9-fold) and 12 mg/kg (2.5-fold) was observed, as well as an increase in DFI% (fragmented DNA), showing higher values of 6- and 22-fold at doses of 6 and 12 mg/kg, respectively, compared to the controls. Sperm viability and motility also showed dose-response decreases after Me-Pa exposure. On the other hand, animals co-exposed with Me-Pa and the antioxidant α -tocopherol showed values of LPO, DNA damage and sperm quality similar to the controls, compared with the exposed group; while inhibition of AChE was similar to the Me-Pa exposed group. These results strongly suggested that oxidative damage caused by Me-Pa is prevented by the antioxidant treatment, and that oxidative stress is involved in the sperm chromatin structure damage observed after OP exposure, but not in the AChE inhibition. This study was supported by CONACyT-Mexico (Grant #44643 given to BQV).

2056

TIME-DEPENDENT EFFECTS OF DI(N-BUTYL) PHTHALATE ON THE GENE EXPRESSION PATTERNS IN THE TESTIS OF SPRAGUE-DAWLEY RATS.

H. Kim, J. Ryu, H. Park, J. Kim and J. Im. College of Pharmacy, Pusan National University, Busan, South Korea. Sponsor: L.Yu.

Time-dependent effects of di(n-butyl) phthalate (DBP) on expression patterns of testicular gene were studied in Sprague-Dawley for different periods of exposure (1, 7, 14, and 28 days). A control group receiving corn oil was also monitored for comparative purposes. Gene expression patterns were measured using the reverse transcription-polymerase chain reaction (RT-PCR). Serum concentrations of DBP were increased with the time of exposure and were significantly higher in treated rats when compared to controls. Similar to significant decrease in testes weights, for 14 and 28 days, epididymis weight was also markedly reduced after 14 and 28 days exposure. DBP caused significant induction of steroidogenic acute regulatory (StAR) and SR-B1 mRNA at 14 and 28 days exposure in the group receiving 750 mg/kg/day. P450_{sc} mRNA was decreased in the group treated with 750 mg/kg/day at day 7; thereafter, an apparent increase in P450_{sc} mRNA was observed after 14 and 28 days exposure. High dose of DBP significantly increased the CYP17 mRNA level after 28 days exposure. At 7 days, significant reduction of CYP19 mRNA was observed only in the group exposed to 750 mg/kg/day of DBP. In addition, DBP significantly decreased mRNA levels of Spag4 and LDHA after 7 days exposure. Data indicate that acute and chronic exposure to DBP showed mechanistically distinct effects on steroidogenesis pathway in the testes of Sprague-Dawley rats. These results indicate that the steroidogenesis-related genes investigated in this study may provide insights into the molecular mechanisms underlying DBP induced testicular dysgenesis in humans.

2057 REVERSIBILITY OF THE ADVERSE EFFECTS OF 1-BROMOPROPANE EXPOSURE IN RATS.

S. Banu¹, S. Ichihara^{2,1}, F. Huang¹, H. Ito³, Y. Inaguma³, K. Furuhashi¹, S. Fukunaga¹, Q. Wang¹ and G. Ichihara¹. ¹Nagoya University Graduate School of Medicine, Nagoya, Japan, ²Mie University Life Science Research Center, Tsu, Japan and ³Institute for Developmental Research, Kasugai, Japan.

Previous experiments have revealed that 1-Bromopropane (BP), an alternative to chlorofluorocarbons, is toxic to the nervous and reproductive system. Here we investigated the reversibility of its toxic effects in rats. 72 male Wistar rats were divided into 3 groups of 24 each and exposed to 0, 400 and 1000 ppm of 1-BP via inhalation for 6 wks (8h/d, 7d/w). 8 rats from each group were sacrificed at the end of 6 wks of exposure. 4 and 14 wks postexposure, 8 rats from each group were again sacrificed to see the recovery changes. Sperm count, motility, morphology and testicular histopathology were studied. Blood pressure, skin temperature (for autonomic nervous system assessment) and hind limb muscle strength were also measured every 2 wks. For 1000 ppm the testicular and epididymal weights, sperm count and motility all remained significantly reduced for 14 wks postexposure along with an increase in abnormal sperm morphology. Testicular histopathology at 1000 ppm showed marked atrophy with no signs of recovery even until 14 wks postexposure. Retained spermatids were increased at 400 ppm at the end of 6 wk exposure. Also at 1000 ppm skin temperature got reduced following 6 wk exposure, blood pressure remained elevated until 4 wk postexposure and hind limb muscle strength remained reduced even until 14 wks postexposure. Brain Gamma enolase was also measured but not significant between the different groups. In terms of reversibility, 1-BP like 2-BP caused testicular atrophy with spermatogonial damage and remained irreversible until 14 wks postexposure. In the nervous system blood pressure and skin temperature effects were reversible but the muscle strength effects lasted longer until the end of the experiment. Differently from the previous study showing less toxic effect of 1-BP to spermatogonia at 800 ppm or below, 1-BP at a higher dose may cause depletion of spermatogenic cells and a longer lasting adverse effect on the nervous system.

2058 DISRUPTION OF TESTOSTERONE HOMEOSTASIS AS A MODE OF ACTION FOR THE REPRODUCTIVE TOXICITY OF TRIAZOLE FUNGICIDES IN THE MALE RAT.

A. K. Goetz^{1,2}, H. Ren², J. E. Schmid², C. R. Blystone^{1,2}, I. Thillainadarajah², D. S. Best², H. P. Nichols², L. F. Strader², D. C. Wolf², M. G. Narotsky², J. C. Rockett² and D. J. Dix². ¹Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC and ²Office of Research and Development, U.S. Environmental Protection Agency, Research Triangle Park, NC.

Triazoles associated with a range of reported reproductive effects in experimental animals were selected to assess potential toxic modes of action. Wistar Han rats were fed myclobutanil (M: 100, 500, or 2000 ppm), propiconazole (P: 100, 500, or 2500 ppm), or triadimefon (T: 100, 500, or 1800 ppm) from gestation day 6 to postnatal day (PND) 120. One male per litter was necropsied on PND1, 22, 50, or 92. Measurements included anogenital distance (AGD) at PND0, body/organ weights, serum hormones, age at preputial separation (PPS), sperm morphology and motility, and fertility and fecundity. AGD increased by the high dose of all 3 triazoles. T1800 delayed PPS. Relative liver weights increased at PND1, 50, and 92 by all 3 triazoles. Hepatocellular hypertrophy was present (PND50: P2500 and T500; PND92: M2000, P2500, and T1800). Relative pituitary weights decreased (PND92: M500 and M2000). Absolute testis weights increased (PND1: M100 and M500; PND22: M500; PND50: P500, T100, and T500). Relative ventral prostate weights increased (PND92: M500, T100, and T500). Serum testosterone increased (PND50: T500 and T1800; PND92/99: M2000, P500, P2500, T500 and T1800). Insemination and fertility were impaired (M2000 and T1800). In addition to the reproductive system effects, total serum thyroxine levels decreased (PND92: T1800). The reproductive effects are consistent with disruption of testosterone homeostasis as a key event in the mode of action for triazole-induced reproductive toxicity. [AKG and CRB were funded by U.S. EPA Cooperative Research Agreement No. CT826512010 with NCSU. This work was reviewed by EPA and approved for publication but does not necessarily reflect official Agency policy.]

2059 EFFECT OF MOTORCYCLE EXHAUST INHALATION EXPOSURE ON THE REPRODUCTIVE SYSTEM IN MALE RATS.

T. Ueng¹, J. Liao² and J. Hwang¹. ¹Institute of Toxicology, National Taiwan University, Taipei, Taiwan and ²Institute of Veterinary Pathology, National Chung Hsing University, Taichung, Taiwan.

Motorcycle exhaust (ME) is a major source of air pollution in the urban areas where motorcycles are a popular means of transportation. ME contains carcinogenic benzene and benzo(a)pyrene and poses a potential health hazard. The major objective

of the present study was to determine the male reproductive effects of ME using rats exposed to diluted ME by inhalation one hour each in the morning and afternoon, Monday through Friday, for 4 weeks. The ME inhalation exposure resulted in decreases of organ weights and sperm numbers in testis and epididymis. ME exposure produced testicular histological changes including seminiferous tubule atrophy and germ cell necrosis. The exposure induced epididymal pathological effects such as empty of sperm cells and formation of clusters of pyknotic and necrotic sperm cells. ME inhalation exposure decreased cytosolic superoxide dismutase and microsomal 7-ethoxycoumarin O-deethylase activities in the reproductive organs. ME increased the formation of thiobarbituric acid reactive substances by epididymis homogenate in lipid peroxidation assay. The results of RT-PCR analysis indicated that ME increased proinflammatory cytokine interleukin-6 and cell death regulators bax and cyclooxygenase-2 mRNA expression in testis and epididymis. These present results suggest that inhalation exposure to ME has the ability to induce reproductive toxicity in male rats and oxidative stress is a possible mechanism of toxicity.

2060 RECOVERY FROM ETHYLENE GLYCOL MONOETHYL ETHER-INDUCED DAMAGE IN THE REPRODUCTIVE SYSTEM OF MALE RATS.

R. Wang, K. Ohtani and M. Suda. *Japan National Institute of Occupational Safety and Health, Kawasaki, Japan.* Sponsor: X. Yu.

Ethylene glycol monoethyl ether (EGEE) can cause damage in the testes of several animals. In the present study, we examined the dose-dependent effects of chronic inhalation of the solvent on reproduction and sperm motion in male rats, and the recovery from the damage after termination of the exposure. Male Sprague-Dawley rats at 8 weeks old were exposed to EGEE at 0, 80, 250 and 700 ppm by inhalation, 8 hr/day, 6 days/week, for 9 weeks. The ratios of testes, epididymides and prostate to body weight were decreased by about 20% and significantly lower in the highest EGEE group than in the control. The percentages of motile sperm in cauda epididymis were dose-dependently decreased in the three EGEE groups, with significant difference between each of the EGEE groups and the control. The progressive sperm was also decreased in a similar manner to that of motile sperm. Velocity parameters (curvilinear velocity, VCL, average path velocity, VAP, and straight line velocity, VSL), parameter showing the swimming pattern (amplitude of lateral head displacement, ALH, and beat cross frequency, BCF), parameters such as straightness (STR) and linearity (LIN) were also affected in the medium and highest EGEE groups. With the sperm from spermatids, similar results were obtained as in the cauda epididymides. Some animals were allowed to live for 10 weeks after exposure, and the recovery was estimated. Although the ratios of reproductive organs to body weight were still lower in the highest EGEE group, the motion of sperm was normal, and there was not statistically significance between the control and any of EGEE groups. Part of the animals was mated with female rats after the termination of exposure, and the effect of EGEE on the reproduction of male rats was evaluated.

2061 TESTICULAR EFFECTS OF DI(2-ETHYLHEXYL)PHTHALATE (DEHP) FED IN A LOW PHYTOESTROGEN DIET TO SPRAGUE-DAWLEY RATS.

X. Fu¹, J. R. Latendresse², L. Muskhelishvili² and K. B. Delclos¹. ¹Division of Biochemical Toxicology, NCTR, Jefferson, AR and ²Toxicologic Pathology Associates, Jefferson, AR.

DEHP, a major plasticizer in polyvinylchloride plastics, shows toxicity in multiple rat organs. Testes are the most sensitive target of DEHP, with developing animals more sensitive than adults. Most studies have utilized standard chow diets, and we have examined the effects of DEHP administered in a low phytoestrogen (soy- and alfalfa-free) diet. Weanling Sprague-Dawley rats were placed on Purina 5K96 diet and mated at PND 75. Pregnant dams were given feed containing 0, 2.5, 25, 250, 2500, and 10000 ppm DEHP from gestation day 7. Pups were continued on the same treatment as their dams after weaning and were terminated on postnatal day (PND) 14, 21, or 70. Absolute testes weights were significantly less than controls for all ages at 10000 ppm. Histopathological examination of testes revealed severe depletion of germ cells in all PND 70 males treated with 10000 ppm DEHP, but not in other dose or age groups. Mild Leydig cell hyperplasia was observed on PND 14 at 2500 and 10000 ppm, and on PND 70 at 10000 ppm. Serum and testicular testosterone levels were significantly lower than controls at 10000 ppm on PND 70, but serum inhibin B levels were not altered. However, relative to controls, testicular inhibin B, Sertoli cell counts (determined by sox-9 immunostaining), and serum FSH were significantly higher at 10000 ppm on PND 70. mRNAs for markers of Sertoli cells (inhibins, anti-müllerian hormone, androgen-binding protein) and Leydig cells (3 β -hydroxysteroid dehydrogenase) were significantly induced by DEHP treatment in PND 70 males. These results are consistent with studies utilizing standard chow diets in that high dose DEHP, approximately 1200 mg/kg/day, decreased germ cells and testosterone in adult F₁ males. In addition, dietary exposure of DEHP under the conditions of this study induced gene expression of markers for Sertoli and Leydig cells, increased Sertoli cell numbers, and increased serum FSH in F₁ adult male rats.

2062 AN ORAL TWO-GENERATION REPRODUCTIVE TOXICITY STUDY OF S-111-S-WB IN RATS.

D. G. Stump¹, J. F. Holson¹, S. R. Murphy², C. H. Farr², B. Schmit³ and M. Shinohara⁴. ¹WIL Research Laboratories, LLC, Ashland, OH, ²Arkema Inc., Philadelphia, PA, ³Solvay SA, Brussels, Belgium and ⁴Asahi Glass Company Ltd., Tokyo, Japan.

S-111-s-WB, a mixture of perfluoro fatty acid ammonium salts with varying carbon chain lengths (C7-C13), was administered via oral gavage to 30 animals/sex/group at dosage levels of 0.025, 0.125 and 0.6 mg/kg/day over two generations in Crl:CD(SD) rats. This study was conducted to evaluate potential adverse effects on reproductive outcome and on neonatal survival, growth and development. One litter per dam was produced in each generation. In addition, blood levels of the major components were determined one week prior to mating, and during gestation and lactation for dams and their offspring. No test article-related morbidity or deaths occurred except for one F0 male that was euthanized in extremis following 14 weeks of dose administration. Parental reproductive performance, reproductive organ weights, mean number of F1 or F2 pups born, survival, general physical condition and pre-weaning weights, and developmental landmarks were unaffected at any dose. Lower mean body weight gains and/or body weight losses were observed in F0 and F1 males in the 0.6 mg/kg group after 7-8 weeks of dosing and continuing throughout the remainder of each generation. Higher liver weights were noted for F0 and F1 parental males in the 0.125 and 0.6 mg/kg groups, F0 and F1 parental females in the 0.6 mg/kg group, F1 male and female pups in the 0.125 and 0.6 mg/kg groups and F2 male and female pups in the 0.6 mg/kg group. Hepatocellular hypertrophy was noted for the majority of F0 and F1 males in all test article-treated groups and several F0 females in the 0.6 mg/kg group. Higher kidney weights were observed for F0 and F1 parental males and females in the 0.125 and 0.6 mg/kg groups and correlated to renal tubule hypertrophy, noted for the majority of F0 males, all F1 males and several F0 females in the high dosage group. Serum concentrations in dams and pups were generally considered to be proportional to the dosage.

2063 EVALUATION OF HEXAMETHYLDISILOXANE (HMDS) IN A 2-GENERATION REPRODUCTIVE TOXICITY STUDY IN RATS.

W. H. Siddiqui¹, D. G. Stump², D. T. Kirkpatrick², J. L. Knochel¹, S. D. Crofoot¹ and K. P. Plotzke¹. ¹Health and Environmental Sciences, Dow Corning Corporation, Midland, MI and ²WIL Research Laboratories, LLC, Ashland, OH.

Hexamethyldisiloxane is an intermediate for the manufacture of other silicone materials. It is also used as a solvent in the electronics industry and as an ingredient in a variety of personal care products. Groups of male and female Sprague-Dawley rats (30/sex/group, ~7 weeks old) were exposed via whole-body vapor inhalation to a concentration of 0, 100, 400, 1600 or 5000 ppm for 6 hr/day. Exposure for the F0 and F1 generations started at least 70 days prior to mating and lasted through weaning of the respective pups on postnatal day (PND) 21. Female exposures were interrupted from gestation day 21 through PND 4, resumed on PND 5 and continued until weaning on PND 21. Clinical signs, body weights and food consumption were recorded at appropriate intervals. Unselected F1 and F2 weanlings were necropsied on PND 21 or 28. There were no test article-related clinical signs in any generation. Mean body weights for both sexes in the 5000 ppm group were reduced throughout the majority of both generations. Increased kidney weights were noted in the 1600 and 5000 ppm group males of both generations with corresponding microscopic findings at 5000 ppm of hyaline droplets (consistent with alpha-2 urinary globulin) and basophilic renal tubules. Reproductive performance, offspring physical condition, postnatal survival and attainment of landmarks of sexual development were unaffected by HMDS exposure. Estrous cyclicity, time between pairing and mating, mating and fertility indices, duration of gestation and parturition in F0 and F1 generations were unaffected by HMDS exposure. HMDS-related decreased offspring body weight gains were observed for F1 and F2 pups in the 5000 ppm group from PND 4-21 and PND 4-14, respectively. In this study, the NOEL for parental reproductive toxicity was 5000 ppm HMDS and was 1600 ppm for neonatal toxicity due to decreased offspring weight at 5000 ppm. (Supported in part by the Silicones Environmental, Health and Safety Council of North America).

2064 EVALUATION OF THE REPRODUCTIVE AND DEVELOPMENTAL TOXICITY OF SODIUM TUNGSTATE IN RAT MODEL.

G. D. Chapman, E. R. Wilfong, H. J. Fullenkamp, E. W. Johnson, D. P. Arfsten, K. W. Reilly and A. O. Olabisi. Naval Health Research Center Detachment, Environmental Health Effects Laboratory, Wright-Patterson AFB, Dayton, OH.

The Green Armament Technology (GAT) program, a U.S. Army pollution prevention initiative recommended substitution of lead (Pb) with tungsten (W) in military munitions. Accordingly, this led to increased W utilization in several military

applications with potential rise in occupational exposure of military personnel to W. The toxicological profile of W is sketchy and incomplete and recent events such as high solubility of W in drinking water have generated new concern. Consequently, the purpose of this study is to investigate one-generation reproductive effects of soluble W using USEPA OPPTS Guideline 870.3800 with minor modification. Adults Sprague-Dawley rats (P0 generation) were dosed daily by oral gavage with 125, 62.5 or 5 mg/kg/day of sodium tungstate (NaW) or dH2O (n=40/sex group) for 70 consecutive days. Mating occurred after 14 days and dosing continued through pregnancy. Evaluated effects include weight gain, gestation and offspring viability. Significant tissue retention of W (p<0.001; n≥3) was detected in the spleen, ovaries and femur of P0 and F1 (offspring) generation exposed to NaW when compared to the controls. Gestation lengths (22.081±0.089) in days for 125 mg/kg/day group were significantly different (p<0.05; n≥37) from controls (21.548 ± 0.097). Weight gain in P0 (5 mg/kg/day) males was 16.4% (p<0.001; n≥30) more than the controls. Weight gain in F1 generation (62.5mg/kg/day) on PND 20 when weaning occurred and on PND 70 was 5.2% to 33.3 % (p<0.05; n≥25) more than the controls for both sexes. Histopathology report in several P0 males (125 mg/kg/day) includes histological lesions, lymphohistiocytic inflammation with cardiomyocyte degeneration and necrosis within the heart. Hematology, serum chemistry and immunology effects are ongoing. These results suggest that oral exposure to high levels of soluble W may cause some signs of reproductive, developmental or systemic toxicity.

2065 28-DAY ORAL AND REPRODUCTIVE/DEVELOPMENTAL SCREENING TOXICITY STUDIES OF VINYL-TRIS(2-METHOXYETHOXY)SILANE.

E. D. Sloter¹, W. H. Siddiqui², D. G. Stump¹ and K. P. Plotzke². ¹WIL RESEARCH LABORATORIES, LLC, ASHLAND, OH and ²Health and Environmental Sciences, Dow Corning Corporation, Midland, MI.

Vinyl-tris(2-methoxyethoxy)silane (VTMES) is used as a cross-linker in ethylene propylene diene monomer rubber and for moisture-curable thermoplastic polyolefin applications. The potential toxicity of VTMES, a High Production Volume Chemical (HPV), was evaluated in a combined repeated dose toxicity with a reproductive/developmental toxicity screening test. The study design utilized the protocol in accordance with the OECD and EPA test guidelines Nos. 422 and 870.3650, respectively. The test article was administered in dehydrated corn oil by gavage to 10 rats/sex/group, seven days a week, at 0, 25, 75 and 250 mg/kg/day. There were no test article-related effects on body weight, body weight gains, Functional Observation Battery or locomotor activity evaluation except for a reduction in body weight gain in the high dose males. Reductions in red blood cells, reticulocytes, platelets, eosinophils and basophils in both sexes in the high dose group correlated microscopically with bone marrow hypocellularity. An overall decrease in the erythroid:myeloid ratio was considered a disproportionate mild suppression of both myeloid and erythroid elements. Reduced thymic weights in both sexes in the high dose group correlated microscopically with lymphoid depletion. Reductions in testicular weights in the 250 mg/kg group correlated microscopically with seminiferous tubule degeneration. Decreased prostate weights in the 75 and 250 mg/kg groups males correlated with decreased secretion and/or atrophy. Reduced fertility, increased mean number of days between pairing and coitus and gestation length were observed in the 250 mg/kg group. Only one female in the high dose group delivered, but all pups were dead on PND 0. Live litter size and postnatal survival were also reduced in the 75 mg/kg group. The NOELs were 25 and 75 mg/kg for male and female systemic toxicity, respectively, and 25 mg/kg for reproductive and developmental toxicity. (Sponsored by the Silicones Environmental, Health and Safety Council).

2066 TWO-GENERATION REPRODUCTION STUDY OF BISPHENOL A (BPA) IN CD-1® SWISS MICE.

R. W. Ty¹, C. Myers¹, M. Marr¹, C. Sloan¹, N. Castillo¹, J. Seely², S. Dimond³, J. Van Miller⁴, R. Shiotsuka⁵, D. Beyer⁶ and J. Waechter⁷. ¹Health Sciences Unit, RTI International, Research Triangle Park, NC, ²EPL, Inc., Research Triangle Park, NC, ³GE Plastics, Pittsfield, MA, ⁴TRS, Charlottesville, VA, ⁵Bayer MaterialScience, Pittsburgh, PA, ⁶Bayer HealthCare AG, Wuppertal, Germany and ⁷The Dow Chemical Company, Midland, MI.

A 2-generation study (OECD Test Guideline 416), incorporating estrogen sensitive endpoints, was conducted to evaluate the potential reproductive/developmental effects of BPA in mice. The following groups (28 parental mice/sex/group) were 6 BPA groups with doses from ~0.003 to 600 mg/kg/day (mkd; 0.018-3500 ppm); 17-β-estradiol (E2) positive control (0.08 mkd; 0.5 ppm); 2 negative control groups; 1 unbred F1 male/litter/group exposed concurrently with the F1 parental males. The F0 generation was exposed through weaning (pnd 21) of the F1 pups when selected F1 pups were similarly exposed to study termination at F2 weaning.

Body weights (wt), feed consumption, clinical observations, F0/F1 estrous cyclicity, F1/F2 anogenital distance and acquisition of F1 puberty (vaginal patency and preputial separation [PPS]) were recorded. Organ wt and histopathology were recorded for F0/F1 adults and F1/F2 weanlings, and andrology was assessed for F0/F1 males. E2 resulted in systemic, reproductive and developmental effects consistent with a potent estrogen and comparable to effects observed in a previous E2 reproduction study. At 3500 ppm BPA (~600 mkd), systemic effects included reduced body wt (F1 only), increased kidney and liver wt, centrilobular hepatocyte hypertrophy, and kidney nephropathy in F0/F1 adults; reduction in pup body wt (F1 only), reduced spleen wt (both sexes). Reduced testes wt, with seminiferous tubule hypoplasia (F1/F2 weanlings), and delayed PPS (F1) were indicative of delayed development. At 300 ppm BPA (~55 mkd), the only treatment-related effect was an increased incidence of centrilobular hepatocyte hypertrophy in adults (both sexes). The NOEL was 30 ppm BPA (~5.5 mkd) for systemic toxicity and 300 ppm BPA for developmental toxicity. There were no reproductive effects at any BPA dose.

2067 AN UPDATED WEIGHT OF THE EVIDENCE EVALUATION OF REPRODUCTIVE AND DEVELOPMENTAL EFFECTS OF LOW DOSES OF BISPHENOL A.

L. R. Rhomberg¹, J. E. Goodman¹, E. E. McConnell², J. Sipes³, R. J. Witorsch⁴, T. M. Slayton¹, C. J. Yu¹ and A. S. Lewis¹. ¹Gradient Corporation, Cambridge, MA, ²ToxPath, Inc., Raleigh, NC, ³Department of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ and ⁴Department of Physiology, School of Medicine, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA.

Recent public concern has focused on potential reproductive and developmental human health effects from exposure to low levels of Bisphenol A (BPA). An expert panel convened by Harvard's Center for Risk Analysis published a weight-of-evidence evaluation of reproductive/developmental toxicity from BPA exposure ≤5 mg/kg-day (Gray et al., 2004), and we updated this to include >50 studies published through February 2006 (Goodman et al., 2006). Since then, several additional relevant low-dose studies have been conducted, including a two-generation study in CD-1 Swiss mice. Results from these studies are consistent with those reviewed by the Harvard Panel and by us, including two multi-generation rat studies. Overall, although some statistically significant effects of BPA have been reported in rats and mice, positive findings for most endpoints are countered by more numerous studies showing no effects. Thus far, positive findings have not been replicated, do not exhibit coherence and plausibility, and do not show consistency across species, doses and time points. These unconfirmed positive findings include morphological changes in testes and sperm in oral mouse studies. In addition, some mouse studies report morphological changes in male and female reproductive organs after non-oral exposures to BPA. Owing to the lack of first-pass metabolism, results from non-oral studies are of limited relevance to oral human exposure. Human biomonitoring indicates exposures significantly lower than the "low" doses in the reviewed animal studies, and reports of human health impacts are very limited and inconsistent. Taken together, the weight of evidence does not support the hypothesis that low oral doses of BPA adversely affect human reproductive and developmental health.

2068 BENZO(A)PYRENE DECREASES BRAIN AND OVARIAN AROMATASE mRNA EXPRESSION.

W. Dong, L. Wang, C. Hickman and K. L. Willett. *Pharmacology and Environmental Toxicology Research Program, University of Mississippi, University, MS.*

Aromatase catalyzes the conversion of androgens to estrogens. In fish, there are two isoforms of aromatase (CYP19): CYP19A1, a gonad form and CYP19A2, a brain form. Estrogen affects the dimorphic, anatomical, functional and behavioral aspects of development of both sexes. CYP19 expression was measured following BaP exposure (0, 10, 100 µg/L waterborne for 10 or 15 days) in *Fundulus* adults, juveniles and embryos by *in situ* hybridization. Constitutively, CYP19A1 was expressed mainly in the ooplasm of stage I and II oocytes (primary growth stage) as strong and evenly distributed signals, but in the BaP treated group, the CYP19A1 expression was significant decreased in the 3 month old *Fundulus*. Expression of CYP19A2 was detected in the brain including the hypothalamus in 4, 6, 8, 10, and 14 dpf embryos. In adult fish brain, the highest expression was detected in the hypothalamus and hypophysis of both sexes. At 14 dpf, BaP exposed embryos had significantly decreased (3.31-fold) CYP19A2 compared to controls. Similarly, in adults, CYP19A2 expression was significantly decreased particularly in the brain hypophysis and hypothalamus regions (85% and 81% of controls, respectively). These studies provide a greater molecular understanding of the mechanisms of action of BaP and its potential to impact reproduction or development. Supported by NIEHS R01ES012710.

2069 ASSESSING THE TOXICITY AND ESTROGENICITY OF 4-PENTYLANILINE USING MEDAKA (*ORYZIAS LATIPES*).

M. L. Haasch¹, D. B. Lothenbach², K. M. Flynn², F. W. Whiteman², D. E. Hammermeister², J. Nagel³, W. J. Backe³, D. Shadwick⁴, P. K. Schmieder² and R. D. Johnson². ¹NRC Res Assoc Senior Scientist, U.S. EPA, MED, Duluth, MN, ²U.S. EPA, MED, Duluth, MN, ³SSC, U.S. EPA, MED, Duluth, MN and ⁴CSC Corporation, Morrisville, NC.

A variety of natural and synthetic chemicals have been shown to be estrogenic and capable of altering reproduction in aquatic organisms. *In vitro* methods using rainbow trout (RBT) for determining estrogen receptor (ER) binding and liver slice vitellogenin mRNA (VTG) induction are being used to develop QSARs for predicting the estrogenic activity of chemicals in lower vertebrates. For risk assessments, it is important to establish the relationship of *in vitro* screening methods to higher level effects such as growth, survival and reproduction. The goal of this study was to use reproduction assessments in medaka to determine the relationship of higher level effects to *in vitro* endpoints. These comparisons were performed with 4-pentylaniline (PA, CAS 33228443) a chemical shown to be estrogenic using RBT *in vitro* assays. Thirty-six medaka breeding pairs were distributed (unbalanced) into 2 L glass aquaria and exposed to PA at 0.06, 0.28, 0.69, 2.45, and 8.76 µM. The fecundity and fertility of these pairs were assessed for 21 days. Spawns from days 15-16 were incubated to measure hatching success. A kinetic uptake study indicated that the BCF of PA in medaka livers was ~ 65. At the LOEC of 2.47 µM PA, the following effects were observed; VTG induction (100-fold) in males, reductions in fecundity, male mortality (2 of 4) and decreased hatching success. At higher PA levels, female mortality (4 of 4) and 375-fold VTG induction in males were observed. Using the BCF of 65, the medaka liver PA level at the LOEC was 160 µM, a level similar to the RBT *in vitro* EC50 for VTG induction. The *in vivo* LOEC for fecundity and male VTG induction were similar to the *in vitro* EC50 for VTG induction. These data suggest, with further *in vivo* testing, that QSARs based on *in vitro* assays for weak estrogens are useful for prioritizing environmental chemicals most likely to impact reproduction.

2070 REPRODUCTIVE TOXICITY TESTING AND CONTROL BACKGROUND DATA IN THE CYNOMOLGUS MONKEY.

S. Oneda, N. Makori, J. Kenfield, S. Herrin, Y. Mori, W. Congdon, B. Baker and S. Meyer. *Safety Assessment, SNBL USA, Ltd., Everett, WA.*

To assess the effects of test substances on reproductive functions and embryo-fetal development in cynomolgus monkeys (*Macaca fascicularis*), menstrual cycle and fetal evaluation control data are particularly important. Menstrual cyclicity in cynomolgus monkeys (146 female monkeys for a total of 907 cycles), pregnancy ratio, control background data from teratology studies (fetuses evaluated at gestation day [GD] 100) and peripheral blood lymphocyte subsets data (flow cytometry) were evaluated. The menstrual cycles were variable within and between females (average of all individual cycles: 30.5 ± 7.7 days, average of mean value of each female: 30.9 ± 4.5 days). In teratology studies (control animal data), the mean abortion/embryo-fetal death incidence was 7.7%, and 62% of the abortions occurred during the first half (GD20-GD35) of the organogenesis period (GD20-GD50). The mean fetal weight at GD 100 was 114 g. There were no external fetal abnormalities, a low incidence of visceral abnormalities (absence of left thyroid in 1 out of 98 fetuses, 1.0%), and a 2.6% incidence of skeletal abnormalities. The most common variation was lumbar rib (10.4%). In a teratology validation study using thalidomide as the proximate teratogen (15 to 20 mg/kg/day; dams dosed on GDs 26, 27, and 28), abnormalities extensively published such as micromelia/amelia, paw/foot hyperflexion, ectrodactyly, polydactyly, syndactyly or brachydactyly were observed. The continued accumulation of normal background data accompanied by the low incidence of abortions and fetal abnormalities/variations establishes the female cynomolgus monkey as a more suitable nonhuman primate animal model for reproductive and developmental toxicity testing.

2071 FEASIBILITY OF GROUP HOUSING OF SEXUALLY MATURE CYNOMOLGUS MONKEYS FOR REPRODUCTIVE TOXICITY STUDIES.

G. Weinbauer¹, M. Niehoff¹, M. Bergmann² and W. Mueller¹. ¹Covance Laboratories GmbH, Muenster, Germany and ²Justus-Liebig-University, Giessen, Germany.

Among nonhuman primates, cynomolgus monkeys (*Macaca fascicularis*) are the species most commonly used for reproductive and developmental toxicity evaluation and animals are housed singly in order to avoid interferences imposed by social rank and associated behaviour. However, European guidelines emphasize social housing for nonhuman primates in order to provide improved social interactions

and enriched environments. We, therefore investigated the effects of single vs same sex group housing of mature monkeys on reproductive parameters (semen analysis, testis size, ovarian cycle length, endocrine analysis). Initially, a newly formed group of 7 males was studied over 26 weeks and a group of 8 females over 15 cycles (3 pre-dose, 12 following group formation). Social rank was determined by food challenge test. First analysis revealed (1) marked albeit transient alterations of testicular size without consistent changes of semen parameters (ejaculate weight, sperm motility and number) in subordinate animals and females transiently exhibited irregular ovarian cycles. Among females these effects correlated with absent/decreased pre-ovulatory estradiol peak and luteal progesterone increase. In contrast, no effects on testosterone, inhibin B and FSH could be found in males. Importantly, reproductive parameters were less affected when smaller groups (n= 4) and animals sharing the room prior to group transfer were used (n=10). In conclusion, group housing of sexually mature animals markedly affected certain reproductive parameters. Small group size and appropriate animal selection might provide a feasible avenue towards using group-housed mature cynomolgus monkeys in reproductive toxicity studies. Further work is needed to confirm and extend the latter aspect.

2072 MARMOSETS (CALLITHRIX JACCHUS) AS MODEL FOR DEVELOPMENTAL AND REPRODUCTIVE TOXICITY (DART) EVALUATION.

G. Weinbauer, A. Fuchs and S. Korte. *Covance Laboratories GmbH, Muenster, Germany.*

Generally, for nonhuman primate DART studies, macaque monkeys are the model of choice. However, due to development of therapeutic antibodies with limited cross-reactivity or test items with specific metabolic properties, DART studies in the marmoset model became a need. In general, reproductive physiology of the marmoset is different from that of human and Old World Monkeys (1) with the clinical relevance of this animal model being unclear (2). However, the sensitivity of marmosets to teratogens such as thalidomide derivatives is proven (3). This evaluation deals with the feasibility of DART studies in the marmoset model. Since marmosets lack menstrual bleedings, a standardized approach based upon progesterone (not estradiol) determination and experimental induction of luteolysis using 0.8 µg cloprostenol was established for the monitoring of ovarian cyclicity and ovulation: Cycle duration was 28.7 ± 6.3 days for 110 individual cycles. This approach permits female fertility evaluation and was used to develop an embryofetal development study regimen. Controlled cycling females were housed with males (1:1), pregnancy was detected by ultrasonography (mating success of >70% in >130 matings) and dosing lasted from day 25 to 85 post-ovulation or longer. Cesarean sections were performed on day 110±1 yielding 1-4 live fetuses/female. Fetal evaluation was feasible using standard macaque protocols. A panel of male fertility parameters was also established comprising testosterone, testicular volumes (by caliper), semen evaluation (sperm number, motility and morphology), testicular flowcytometry and spermatogenesis staging. However, unlike in macaques, reliable assays for inhibins and FSH are not available for marmosets. In conclusion, (limited) DART evaluation is feasible in marmosets if macaque models cannot be used. 1. Abbott et al 2003 Comp Med 53:339; 2. Zuehlke & Weinbauer 2003 Toxicol Pathol 31:123; 3. 2073 COMPARISON OF VAGINAL CYTOLOGY CONTROL DATA GENERATED AT SEVEN LABORATORIES IN FISCHER 344 RATS AND B6C3F1 MICE.

B. Atkinson¹, Y. Wang¹, H. Seung¹ and J. B. Bishop². ¹Gene Logic, Inc., Gaithersburg, MD and ²NIEHS, Research Triangle Park, NC.

To understand variations in vaginal cytology analysis, the control animal data from 51 studies were compiled for comparison. The slides and necropsy data came from seven different NTP contract laboratories performing 90-day toxicology studies for NIEHS.

Twelve-day vaginal cytology samples were collected by seven NTP laboratories following the same sampling procedures. Slides were fixed, stained and subsequently submitted to Gene Logic, Inc. for evaluation. Estrous stages were determined and the data were evaluated for cycling or non-cycling, cycle numbers and cycle length. Data from the control groups of 51 studies were summarized, and discrepancies between studies and laboratories on these parameters are exemplified and compared. In conclusion, there were no obvious discrepancies noted in the percent cycling, percent regular cycle, cycle numbers or cycle length among studies or laboratories, in either F344 rat or B6C3F1 mouse studies. The percent of the cycle spent in the various stages was also comparable.

AN ASSESSMENT OF THE EFFECT OF THE ROUTE OF DOSE ADMINISTRATION ON ESTROUS CYCLES OF CDOIGS RATS FOR FEMALE FERTILITY (ICH-1) STUDIES.

S. McPherson, M. Adamo, L. Pinsonneault, L. Pouliot, S. Barbeau, C. Banks and K. Robinson. *Toxicology, Charles River Labs, Montréal, Senneville, QC, Canada.*

During the course of female fertility and early embryonic development (ICH-1) studies estrous cycles are monitored. Various methods of dose administration are employed during the course such studies e.g., oral gavage, subcutaneous injection, nose-only inhalation exposure and continuous intravenous. Data was obtained from rats (CD-IGS) that were 10 to 12 weeks of age at the start of treatment. Stages of the estrous cycles were determined daily by examination of wet smears prepared from a vaginal lavage. Cyclicity data were collected during the 2-week acclimation period prior to the start of dosing and only females with normal estrous cycles were assigned to the studies. Estrous cycle data was then collected during the 2-week pre-mating treatment period and during the mating period until identification of mating. For inhalation studies, the females were acclimated to the restraint tubes for increasing periods of time for a minimum of 3 consecutive days prior to the initiation of treatment, of up to 1-hour duration. The females dosed by continuous infusion had catheters surgically implanted under general anesthesia in the vena cava, via the femoral vein, at least 1 week before the start of the pre-mating dosing period and two weeks prior to the start of treatment. Comparison of data for the pre-study period shows no effect of pre-study procedures for either the inhalation or intravenous infusion groups. During the dosing period values for cycle length, number of days in estrous and number of cycles were comparable for the various treatments. The various methods of administration showed no adverse effect on the estrous cycle parameters of female CDO IGS rats. It was concluded that estrous cyclicity data collected during the pre-mating dosing period for fertility studies with CDO IGS rats were unaffected by either routine, nose-only inhalation exposure or continuous infusion treatment procedures.

2075

COMPARISON OF CONTROL MALE REPRODUCTIVE DATA FROM SEVEN LABORATORIES.

H. S. Seung¹, Y. Wang¹, B. A. Atkinson¹ and J. B. Bishop². ¹Gene Logic, Inc., Gaithersburg, MD and ²National Institute of Environmental and Health Sciences (NIEHS), Research Triangle Park, NC.

To understand variations between strains and laboratories in sperm motility, sperm density, spermatid head counts and male reproductive organ weights, the control animal data obtained from studies of NTP chemicals conducted at 7 different contract laboratories are compiled for comparison.

Data on sperm motility (manual evaluation), sperm density, organ weight (right testis, right epididymis, and right cauda epididymis), and terminal body weights were collected by NTP laboratories performing 90-day toxicology studies (55 studies). The spermatid head counts were collected by Gene Logic from frozen testes harvested by the NTP laboratories. Fischer 344 rats and B6C3F1 mice were the species and the strains used predominantly; a few studies used Long Evans rats or AM3-C57B1/6, BALB/c, TgAC, or FVB mice.

In general, all measured parameters are comparable between Fischer 344 and Long Evans rats. Variations among the 7 laboratories are considered minimal in all tested endpoints. When compared to B6C3F1 mice, sperm density (per mg cauda epididymis and per cauda epididymis) was lower in TgAC and FVB; the spermatid concentration (per testis) was lower in TgAC, FVB, and BALB/c mice; the reproductive organ-to-body weight ratios were lower in TgAC, FVB, and AM3-C57B1/6 mice; and the terminal body weight and reproductive organ-to-body weight ratios were lower in BALB/c mice.

2076

EVALUATIONS IN CD-1 MICE INCLUDING REFLEX AND PHYSICAL DEVELOPMENT, PASSIVE AVOIDANCE AND SPERM ANALYSES IN FERTILITY, PERI-POSTNATAL, PEDIATRIC AND/OR DEVELOPMENTAL NEUROTOXICOLOGY EVALUATIONS.

A. M. Hoberman¹ and M. S. Christian². ¹Charles River Preclinical Services, Horsham, PA and ²Argus International, Inc., Horsham, PA.

Although rats are more frequently used than mice in reproductive/developmental, pediatric and developmental neurotoxicology studies, because of a smaller size and/or specific sensitivity to a test material there is often a need to evaluate mice. The current presentation provides historical control data for reproductive performance, peri-postnatal development and sperm evaluation. Data are from studies performed under GLP conditions using Crl:CD1(ICR) mice. In 21 studies, mean estrous stages/14 days = 3.0 pretreatment and 3.5 with treatment. Mean time in

cohabitation was 4.2 days (87% mated by the male 1 and 13% mated by male 2), with 96% fertility. Daily evaluations of surface righting showed that 23.8% of the mice were able to right on postpartum day (PPD) 1, and that by PPD 10, 100% attained criterion. Pinna unfolding was first evident PPD 3 and present for all mice PPD 7. Eye opening was first present PPD 13 and present for all mice PPD 17. The acoustic startle reflex was present in 57.9% of the pups on PDD 13 and for all pups on PPD 19. In 4 studies, passive avoidance learning for both male and female mice required 4.1 (3.6 to 4.6) trials to criterion on day 1 of training. No mouse failed to learn. Passive avoidance retention was evident for both male and female mice, with 2.6 (2.3 to 2.9) trials to criterion on day 2 of training. Females had slightly lower latencies than males [mean latency of 50.2 sec. (41.6 to 59.4) versus 47.3 sec. (36.8 to 58.9) on day 2, although the variability precludes a sex-related difference. Sperm analyses (Hamilton Thorne IVOS) in 11 studies (269 male mice) gave a vas deferens sperm count mean of 416.7 motile (348.2 to 498.1) and 90.8% motile (87.8% to 93.8%) and an epididymal sperm count of 75.9 (55.6 to 103.1) and sperm density of 2097.40 (1510.10 to 2858.84). Based on these data, mice can be studied for these parameters, and the data are no more variable than for rats.

2077 CAESAREAN DERIVATION AND FOSTERING OF RAT PUPS IN ICH PRE- AND POST-NATAL DEVELOPMENTAL TOXICITY STUDIES.

E. Marsden, J. Briffaux and P. C. Barrow. *Drug Safety Assessment, MDS Pharma Services, St Germain sur L'Arbresle, France.*

The ICH pre- and post-natal study design involves treatment during gestation and lactation up to weaning. Such studies are almost exclusively performed in the rat, with no feasible non-rodent species. This limitation poses a severe problem for drugs, such as non-steroidal anti-inflammatory agents, that block the onset of parturition in rodents by interference with prostaglandin synthesis (an effect that is not pertinent to non-rodent species). For short-acting agents, it is usually considered acceptable to suspend treatment at the end of gestation for two or three days while parturition takes place, but this is not applicable for long-acting drugs. A possible solution is to treat rats throughout gestation, remove the pups by caesarean on the presumed day of parturition and have the pups raised by a treated foster mother. Having developed the technique in a small investigative trial, a larger experiment was performed to generate reference data for use in regulatory studies. 30 female SD rats were treated with 5 mL/kg of 2 % cremophor in isotonic saline by gavage from days 6 to 20 of gestation. The females were submitted to a caesarean section on day 21 or 22 of gestation. The live pups were removed and given to a foster dam that had littered within the last 24 hours. The foster dams were then treated at the same dose volume from days 1 to 20 of lactation. 24 litters were successfully fostered. One further dam failed to adopt 2 successive litters. In total, 31 out of 286 pups (11%) adopted by the foster dams died before litter standardisation on day 4 of lactation. This compares with a historical average of 4% or less for non-fostered pups born to untreated rats in our laboratory. There were no pup deaths after day 4. The pup weights on day 1 were lower than usual (6.6g on average, compared with 7.6g), but the difference was recovered by the time of weaning. In conclusion, the caesarean derivation and fostering technique is considered feasible for use in regulatory developmental toxicity studies for drugs that block the onset of parturition in rodents.

2078 OCCURRENCE OF HEADLESS SPERMS IN ADOLESCENCE RAT URINE.

K. Sakurai, M. Hagiwara, M. Shimada, K. Shimomura, M. Kato and K. Furuhashi. *Drug Safety Research Laboratory, Daiichi Pharmaceutical Co., LTD, Tokyo, Japan.*

Increased incidence of headless sperms (HS) in urine was spontaneously observed in adolescence naive male Crj:CD(SD) rats. To clarify the factors contributing to this event, the incidence of HS in urine and the epididymis was periodically examined in conjunction with the measurement of testis and epididymis weights, motility of sperms, testicular testosterone and transferrin or serum FSH levels. The urinary HS incidence was 61%, 69%, 44%, 30%, 14%, 9% and 7% in 100 sperms counted at 8, 9, 10, 11, 12, 13 and 14 weeks old, respectively; namely, peaked at 9 weeks old, gradually decreased from 10 weeks old, and became almost a plateau from 12 weeks old onwards. The epididymal HS incidence, 14.7%, 3.6%, 0.4% and 0.4% at 8, 10, 12 and 14 weeks old, which was extremely less than that in urine, decreased from 10 weeks old with increased sperm motility, and became mostly zero from 12 weeks old. In scanning electron microscopy of HS in the epididymis, a narrow gap between the head and neck of sperm was clearly seen along with the posterior ring. Testicular transferrin concentrations, a marker for Sertoli cell maturation, increased from 10 weeks old, and testicular testosterone increased from 12 weeks old. In contrast, no change in serum FSH concentration was seen

throughout the study period. These results demonstrate that an increase in urinary and epididymal HS incidence in adolescence naive rats aged 8 to 9 weeks old would be a physiological phenomenon seen in the process of the Sertoli cell maturation.

2079 MATERNAL MORTALITY ASSOCIATED WITH A TWO-GENERATION REPRODUCTION TOXICITY STUDY WITH HFC 245FA IN SPRAGUE DAWLEY RATS.

G. Rusch. *Honeywell International, Morristown, NJ.*

G. M. Rusch1, R. Fuhst2, H. Ernst2, A. Kolling2, G. Pohlmann2, A. Preiss2, E. Berger-Preiss2, T. Hansen2, J. Buschmann2
1 Honeywell, Morristown, NJ

2 Fraunhofer Institute of Toxicology and Experimental Medicine, Hannover, Germany

The study was conducted following the OECD Guideline 416 "Two-Generation Reproduction Toxicity Study". The exposure levels of 0; 2,000; 10,000 and 50,000 ppm were based on results from a 13-week study.

Unexpected mortality of lactating dams in the medium and high dose group was observed in both generations beginning with day 10 of lactation. Histopathology revealed that the brain, particularly the cerebellum and to a minor degree the heart, turned out to be the toxicological target tissues of the substance.

Statistically significant histopathological alterations were observed in the cerebellum of females of the high dose group of both generations. No changes were found in the brain in males or non-pregnant females for all exposure groups.

The neuronal necrosis and degeneration mainly in the cerebellar cortex was the most severe finding. Spongiosis in diverse severities was found in 7 females of the F0-generation and in 9 females of the F1-generation of the high dose group. The vacuolation of the brain tissue appeared more pronounced in the cases of the F1-generation. The vacuolation was most severe in the Purkinje cell layer due to accumulation of fluid in the astrocytes.

The lesions found in the cerebrum were restricted to the F0-generation and less pronounced than in the cerebellum. The main findings were glial scars in the corpus callosum of two female rats of the high dose groups.

The increased incidence of myocardial fibrosis and mononuclear cell infiltration in the males, indicating a cardiomyopathy, was only seen in the F0-generation. Only the females of the F1-generation showed a statistically significant increase of minimal myocardial fibrosis. Serum enzyme measurements showed no evidence for acute myocardial damage.

The reason for the maternal mortality is possibly an indirect interaction of the compound and the stress associated with lactation.

2080 THE EFFECT OF INHIBITORS ON JET FUEL ALIPHATIC HYDROCARBON INDUCED TOXICITY IN HUMAN EPIDERMAL KERATINOCYTES.

A. O. Inman, N. A. Monteiro-Riviere and J. E. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Human epidermal keratinocytes (HEK) were exposed to JP-8, pentadecane (pent), tetradecane (tetra), tridecane (tri), undecane (un), or control for 5 min. The hydrocarbons (HC) were removed, cells rinsed and incubated for 0, 1, 4, 8, and 24 h. Media from each set of treatments was pooled and stored at -80°C until assayed for cytokines. Cell viability was determined by neutral red. Additional studies were conducted to determine the ability of inhibitors to block HC-mediated inflammation. Studies were identical, with a 1 h preincubation of HEK with parthenolide (P), isohelenin (I), SB 203580 (SB), substance P (SP), or recombinant human IL-10 (rHIL-10). HEK were incubated in media containing the inhibitor after HC exposure. At 24 h, JP-8 and un caused the highest HEK mortality, followed by tri, tetra, and penta. While the addition of the inhibitors did not change this trend, each inhibitor alone significantly (p<0.05) decreased HEK viability within each treatment. DMSO, the vehicle for P, I, and SB, had minimal effect on viability. Overall, terminal IL-8 was suppressed by each inhibitor. P was the most effective inhibitor of IL-8; un, tri, tetra, and penta caused significantly less IL-8, while JP-8 caused significantly higher release than controls. Normalizing by the control indicates which inhibitors suppress IL-8 to control levels. In addition to P, SP suppressed HC effects; I suppressed un and penta, while SB and rHIL-10 had little effect. No inhibitor suppressed JP-8 to control levels. P, I, and SB suppressed IL-6 values below the controls. HEK viability, IL-8, and, to a lesser extent, IL-6 are reliable biomarkers to assess the effectiveness of these inhibitors. JP-8, a mixture of over 200 HC, had the greatest toxic effect on HEK viability and inflammation, followed by un. No difference was noted between tri, tetra, and penta. P, SP, and I, inhibitors of the NF-κB pathway, are effective in suppressing HC-induced inflammation in HEK. (Supported by AFOSR FA 9550-04-1-0376.)

2081 A COMPARISON OF TRENDS IN THE PARTITIONING OF 32 ALIPHATIC AND AROMATIC JET FUEL CONSTITUENTS IN VARIOUS SPME/SOLVENT MATRIXES.

B. M. Barlow, R. E. Baynes, X. R. Xia and J. E. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics (CCTRP), North Carolina State University, Raleigh, NC.*

Recently publications have highlighted the difference in accepted octanol/water (Ko/w) values that exist for many analytes. In addition to the range of values available, a decision must be made whether to use calculated or experimentally derived values. For many researchers the choice of Ko/w value to use can be arbitrary, habitual, or based upon the values that give the best fit their distinct data. Using 3 commercially available SPME matrixes, Polydimethylsiloxane (PDMS), Polyacrylate (PA), and Carbowax/divinylbenzene (CAR), to represent varying degrees of hydrophobicity (from hydrophobic to hydrophilic respectively) we are exploring the partitioning trends of 32 aliphatic and aromatic jet fuel constituents from a 50% aqueous/50% organic (water/ethanol) or 4% BSA solutions. Once the mixture reaches equilibrium the experimental K value, determined from the membrane coated fiber technique (K_{mcf}), should more accurately describe the partitioning in skin than available Ko/w values for the same analytes of interest. Calculated values were obtained from well-known sources such as SPARC's, ClogP, ADME, and Syracuse Research Corporation (SRC), and experimental values from SRC and ChemDraw. In initial comparisons there was a 3-25% variance of Ko/w's between found values. Comparisons of K_{mcf} values and experimental databases resulted in R² of 0.60-0.83, while calculated comparisons varied between 0.33-0.84. In making a decision of what value to compare our results against we could have chosen several options; the most complete data set (from one source), the one set that gave the best fit for the majority of comparisons, the dataset that fit the best based on each individual scenario (SPME/solvent matrix), or even selecting the individual value that best fit from all available sources. These initial results further support creation of an in vitro system, such as K_{mcf}, to predict trends of skin partitioning in untested analytes of interest. Supported by USAFOSR FA9550-04-1-0376.

2082 PROPOSED MECHANISM OF JP-8-INDUCED MOLECULAR RESPONSES IN THE SKIN.

J. N. McDougal¹, C. M. Garrett¹, C. M. Amato¹ and S. J. Berberich². ¹Pharmacology/Toxicology, Wright State University, Dayton, OH and ²Biochemistry and Molecular Biology, Wright State University, Dayton, OH.

The jet fuel, JP-8, has been shown to cause an inflammatory response in the skin, which is characterized histologically by erythema, edema and hyperplasia. Studies in laboratory animal skin and cultured keratinocytes have identified a variety of changes in protein levels related to inflammation, oxidative damage, apoptosis and cellular growth. Most of these studies have focused on prolonged exposures and subsequent effects. In an attempt to understand the earliest responses of the skin to JP-8, we have investigated changes in gene expression in the epidermis for up to 8 hrs after a 1-hr cutaneous exposure in rats. After exposure, we separated the epidermis from the rest of the skin with a cryotome and isolated total mRNA. Gene expression was studied with microarray techniques and changes from sham-treatments were analyzed and characterized. We found consistent two-fold increases in gene expression of 27 transcripts at 1, 4 and 8 hrs after the beginning of the 1-hr exposure that were related primarily to structural proteins, cell signaling, inflammatory mediators, growth factors and enzymes. Canonical signaling pathways from Ingenuity's Pathway Analysis (IPA) were used to identify pathways that were activated by JP-8 at the various time points. Analysis of pathways changed showed that several signaling pathways (for example, IL-6, ERK/MAPK, and chemokine) were increased at one hour and that the most significant changes at eight hours were related to metabolic pathways, many of which were downregulated. These results confirm and expand many of the previous molecular studies with JP-8. Based on the one-hour changes in gene expression, we hypothesize that the "trigger" of the JP-8-induced, epidermal, stress response is a "physical" disruption of osmotic, oxidative and membrane stability which activates gene expression in the signaling pathways and results in the inflammatory, apoptotic and growth responses that have been previously identified. (Sponsored by the Air Force Office of Scientific Research, AFOSR/NL)

2083 INVESTIGATION OF DERMAL IRRITATION POTENTIAL OF SELECTED JET FUEL CHEMICALS (NONANE, DODECANE AND TETRADECANE) BY IN VIVO MICRODIALYSIS.

S. Fulzele¹, R. Babu², E. Ahaghotu¹ and M. Singh¹. ¹Florida A&M University, Tallahassee, FL and ²Auburn University, Auburn, AL.

Purpose: To quantify the release of inflammatory markers in the skin using dermal microdialysis after topical application of selected aliphatic hydrocarbons (nonane, dodecane and tetradecane) in hairless rats. Methods: Linear microdialysis probes,

10 mm, were inserted in the dermis of hairless rats under urethane anesthesia. Dermal exposures were carried out by occlusive application of chemicals (230 µl for 2 h using Hill top Chambers®). The expression of neuropeptides [substance P (SP)] and prostaglandin E₂ (PGE₂) in the skin as a result of dermal exposures was measured for 7 h in dialysate by enzyme immunoassay. The in vitro recovery of SP from the microdialysis probes was determined at a flow rate of 2 µl / min. At the end of the study, plasma and exposed skin samples were subjected to quantitative analysis for IL-1α and TNF-α using enzyme immunoassay (EIA) kits. Results: The mean concentrations of SP after insertion of the probe (20.73 ± 1.58 pg/ml), application of nonane and dodecane (70.441 ± 4.69 and 49.71 ± 6.66 pg/ml) and 5 h after their removal demonstrated significant (P < 0.001) SP release following 2 h dermal exposure. Tetradecane did not show significant influence on SP release. Similarly, the mean concentrations of PGE₂ after insertion of the probe (230.51 ± 25.39 pg/ml), application of nonane (396.80 ± 7.35) and 5 h after its removal demonstrated significant (P < 0.05) nonane induced PGE₂ release. Dodecane and tetradecane showed no significant effect on PGE₂ release. Furthermore, nonane significantly (P < 0.001) increased while dodecane and tetradecane did not show any increase in the expression of IL-1α and TNF-α in the blood and skin as compared to untreated animals. Thus, microdialysis (SP and PGE₂) and cytokine data demonstrated irritant potential of the chemicals in the order of nonane > dodecane > tetradecane. Conclusion: Dermal microdialysis data correlates well with biomarker expressions after dermal exposures with irritant chemicals and thus can be used to quantify dermal irritation.

2084 TATTOO PIGMENTS SKIN: TATTOOING AND QUANTITATIVE EXTRACTION OF PIGMENT RED 22.

E. Engel¹, F. Santarelli², R. Vasold¹, T. Maisch², H. Ulrich², B. Koenig¹, M. Landthaler² and W. Bäumler². ¹Organic Chemistry, University of Regensburg, Regensburg, Germany and ²Dermatology, University of Regensburg, Regensburg, Germany. Sponsor: P. Howard.

In the western world millions of people have a tattoo to decorate the skin. Frequently tattoo colorants are mixtures of organic pigments containing also precursors and byproducts of pigment synthesis. Exposure to UV light or laser removal is proven to result in potentially toxic or carcinogenic decomposition products. To assess the health risk of tattooing and the light interaction with the respective pigments, it is important to determine the concentration of pigments in tissue. Surprisingly, this concentration is unknown. Thus, we developed an extraction method and quantified the amount of pigment that is punctured in the skin. Pig skin is tattooed using a standard tattooing machine and the original tattoo pigment Pigment Red 22 (purity of 80%), as well as the highly pure synthesised pigment with the concentration of 10% and 25% (w/vol). After tattooing, the skin specimen is punched and gently dissolved using a tissue lysis buffer. The pigment is extracted via liquid extraction with isopropanol/ dichloromethane and concentrated in a keeper by heating and nitrogen stream. The samples are dissolved in methylene chloride and analysed by HPLC. Preliminary studies have yielded recovery rates of the extraction method with > 95%. The amount of pure pigment punctured into skin is ranging from 140 – 500 mg per 100 cm² of tattooed skin. Our results show that the concentration of pigments in the skin depends critically on the size of the pigments and the concentration of the pigment applied to the skin surface.

In light of these high concentration punctured into the skin we should remind the fact that the application of such pigments have no established history for safe use. Moreover, after puncturing into the skin a part of the pigments is transported away into the human body and can be found in other organs like the lymph nodes. The work is supported by a grant of the 'Deutsche Forschungsgemeinschaft' (DFG), grant number BA1741/3-1.

2085 MEASUREMENT OF SKIN THICKNESS IN CONTROL RATS (SD) AND MICE (CD1) FROM TWO SUBCUTANEOUS CARCINOGENICITY STUDIES.

M. Y. Wells², C. Tremblay³, R. Gregson³, N. Mellal³, V. Boulifard¹, C. Fisch¹ and P. Picaut¹. ¹IPSEN SCRAS, Les Ulis, France, ²Toxicology/Pathology Services Inc., Paris, France and ³Charles River Laboratories, Senneville, QC, Canada. Sponsor: C. Banks.

Epidermal, dermal and hypodermal thickness of control male and female Sprague-Dawley rats and CD1 mice from two subcutaneous carcinogenicity studies was measured in an attempt to understand the implications of variable skin thickness on the incidence and distribution of the neoplastic and vascular injection site lesions observed during these studies. To our knowledge, this report represents the first comprehensive assessment of skin thickness in aged rodents. Skin sections from 40 rats and 40 mice were evaluated morphometrically at the following injection sites: upper dorsal thoracic (rats only), left and right scapular, left and right dorsal thoracic and left and right lumbar. The thickness of each site was averaged

and each average was submitted to two-sided statistical analysis. Differences in the thickness of the epidermis, dermis and hypodermis (the skin layer in which the compound was deposited) were observed craniocaudally in rats of both sexes, while differences in mice were limited to the dermis in males and the hypodermis in both sexes. In male rats, the epidermis and dermis were thinnest and the hypodermis was thickest at the scapular region. In female rats, greater epidermal thickness at each region compared to the lumbar region was deemed biologically insignificant due to its small magnitude (<2 microns). As was found in males, the dermis was thinnest and the hypodermis thickest at the scapular region. In mice, similar differences were observed – the dermis was thinnest at the scapular region in male mice and the hypodermis was thickest at this region in mice of both sexes. In conclusion, sites used for dorsal subcutaneous injection of xenobiotics in rodents are not equivalent. In particular, the thickness of the hypodermis varies significantly. This, along with the volume and formulation of the compound injected, may influence the occurrence of injection site lesions and make their interpretation difficult regarding relevance for human safety.

2086 2, 3, 7, 8-TETRACHLORODIBENZO-P-DIOXIN
INDUCED MATRIX METALLOPROTEINASE-1
EXPRESSION IN A2058 MELANOMA CELLS REQUIRES
THE AHR AND ERK PATHWAYS.

K. A. Murphy and L. A. White. *Rutgers University, New Brunswick, NJ.*

There has been a 34% increase in melanoma-related mortality in the United States from 1973 to 1992. Although excessive UV exposure is considered the main etiological factor in melanoma initiation, epidemiological and experimental evidence suggests that exposure to environmental carcinogens contributes to melanoma. Our data show that activation of the aryl hydrocarbon receptor (AhR) pathway activates expression and activity of the matrix metalloproteinases (MMPs). Matrix metalloproteinases are a family of zinc- and calcium-dependent proteinases classified by extracellular matrix substrate specificity and are essential for tissue remodeling events and cancer progression. We examined the effect of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on the expression of MMP-1, a proteolytic enzyme that degrades type I collagen, in A2058 melanoma cells. We have shown that TCDD increased MMP-1 expression is AhR dependent and that it requires sequences in the distal portion of the promoter region. Recently it has been discovered that approximately 60% of all melanomas contain an activating mutation, V599EBRAF, in the Ras/Raf MAP kinase pathway. To investigate the contribution of the Ras/Raf signaling pathway on TCDD/AhR-induced MMP expression, we used specific chemical inhibitors for several signaling pathways and examined the effect of TCDD and AhR-activation on phosphorylation events in these cascades. TCDD treatment caused alterations in ERK phosphorylation, and co-treatment with the MEK inhibitor, U0126, abolished phosphorylation of ERK. Further, a minimal MMP-1 promoter construct is induced 4 fold by TCDD, but is not inducible upon co-treatment with U0126. These data demonstrate that TCDD-induced expression of MMP-1 in A2058 cells requires Ras/Raf signaling as well as the AhR pathway.

2087 GLUTATHIONE-MEDIATED PROTECTION AGAINST
CHROMIUM-INDUCED DERMAL TOXICITY.

P. Joseph, J. Noore and C. Umbright. *National Institute for Occupational Safety and Health, Morgantown, WV.*

Occupational exposure to compounds containing chromium has been identified as a risk factor for developing irritant and contact dermatitis among workers. Induction of oxidative stress has been implicated as one of the major mechanisms responsible for the toxicity and the adverse health effects due to exposure to chromium. Presently, we have studied the role of glutathione in the toxicity of chromium following its dermal exposure in mice. The tissue glutathione levels of C57BL/6 mice were depleted by providing them with drinking water containing 20 mM buthionine sulfoximine (BSO). Hexavalent chromium (K₂Cr₂O₇) was applied on the skin of control and BSO-fed mice on alternate days at doses of 0, 1, 5 and 10 mg/kg b.w. either for 2 or 4 weeks. The chromium-induced lesions noticed on the skin of the mice correlated with the dose and duration of the chemical application. In general, the animals with depleted tissue levels of glutathione exhibited more severe skin lesions compared with the control animals indicating the enhanced susceptibility of the GSH-depleted mice to chromium-induced dermal toxicity. Similarly, the amounts of 8-hydroxydeoxy guanosine (8-OHdG) and malondialdehyde (MDA) – indicators of oxidative damage to tissue DNA and lipids, respectively, were higher in the skin of the GSH-depleted mice treated with chromium compared with the controls. The enhanced dermal toxicity of chromium noticed among the GSH-depleted mice compared with the corresponding controls was further supported by the results of gene expression and histopathology studies. In conclusion, these results suggest that the tissue level of glutathione is an important determining factor in the response of mice to the dermal toxicity induced by hexavalent chromium.

2088 DEVELOPMENT OF A METHOD FOR
PHARMACOLOGICAL MANIPULATION OF EPIDERMIS
USING INTRADERMAL INJECTIONS IN THE RAT.

T. J. Kannanayakal¹, C. M. Garrett¹, B. E. Hull² and J. N. McDougal¹.
¹Pharmacology/Toxicology, Wright State University, Dayton, OH and ²Biological Sciences, Wright State University, Dayton, OH.

Our goal is to deliver signaling molecules or their antagonists directly to epidermal cells of intact rat skin in an attempt to understand chemical-induced changes in signaling pathways. The Stratum corneum limits penetration of most molecules including signaling proteins or their antagonists. We used an intradermal injection technique that avoids disrupting the skin at the site of experimental chemical exposures, by penetrating the skin with a needle about 20 mm away from the exposure site and tunneling subcutaneously to beneath the future site of exposure. In an attempt to determine if injected molecules would diffuse through the basal layer of the epidermis from below, we injected 50 µL of a 0.27 mg/mL solution of recombinant Enhanced Green Fluorescent Protein (EGFP) (27 KDa) in phosphate buffered saline. After 1.5 hours, injected skin was sectioned and studied under a fluorescent microscope. A high concentration of EGFP was observed in the injected region of the dermis. In addition, we were able to visualize some EGFP that moved from the injection site into the epidermal region. To investigate the efficacy of delivering signaling molecule antagonists, we also intradermally injected 100 µL of interleukin 1 receptor antagonist (Il-1ra) (17 KDa) or phosphate buffered saline as a control. We used antibody conjugated with Cy3 to detect Il-1ra, and a FITC-conjugated antibody to keratin 14 to locate the position of the basal membrane of epidermis. Preliminary results from the fluorescent microscopic study show the presence of Il-1ra in the epidermal region. The epidermis was stretched compared to control skin. Although the successful intradermal injection caused a protrusion on the surface like a blister, there was no separation of dermal layers in the region of the skin where the bleb is formed. We conclude that this intradermal injection technique could deliver signaling molecules and their antagonists, which are smaller than 27 KDa, to the rat epidermis. (Supported by the AFOSR)

2089 HUMAN SKIN IN ORGAN CULTURE AND HUMAN
SKIN CELLS (KERATINOCYTES AND FIBROBLASTS) IN
MONOLAYER CULTURE FOR ASSESSMENT OF
CHEMICALLY-INDUCED SKIN DAMAGE.

K. Diegel¹, R. Dunstan¹, P. Perone², D. Spahlinger², W. Bobrowski¹, L. Singer¹ and J. Varani². ¹Pfizer GR&D, Ann Arbor, MI and ²Department of Pathology, University of Michigan, Ann Arbor, MI.

Human skin cells (epidermal keratinocytes and dermal fibroblasts) in monolayer culture and human skin in organ culture were exposed to agents that are known to produce irritation (redness, dryness, edema and scaly crusts) when applied topically to skin. Among the agents used were three well-accepted contact irritants (i.e., all-trans retinoic acid [RA], sodium lauryl sulfate [SLS] and benzalkonium chloride) and five contact allergens (oxazolone, nickel sulfate, eugenol, isoeugenol and ethylene glycol dimethacrylate [EGDM]). The corrosive organic mercury compound, aminophenyl mercuric acetate (APMA), was used as an addition test agent. Based on dose-dependent differences in i) cytotoxicity in a 4-hour assay with keratinocytes and fibroblasts, ii) growth suppression in a 2-day assay with the same cells, iii) histological changes (necrosis, altered proliferation and differentiation) in organ-cultured skin, and iv) the profile of secreted molecules from organ-cultured skin, the corrosive agent could be distinguished from the other contact irritants, which, in turn, could be distinguished from the agents with allergenic potential. The use of organ-cultured skin in conjunction with cells derived from the skin in monolayer culture may provide an initial approach to screening agents for deleterious changes in skin.

2090 SUSPECTED INFLUENCE OF P-GLYCOPROTEIN ON THE
PENETRATION OF IVERMECTIN IN PORCINE SKIN.

A. G. Wood², B. M. Barlow^{1,2}, C. L. Schultz³ and R. E. Baynes^{1,2}. ¹Center for Chemical Toxicology Research and Pharmacokinetics (CCTR), North Carolina State University, Raleigh, NC, ²Population Health and Pathobiology, North Carolina State University, Raleigh, NC and ³Department of Biochemistry, North Carolina State University, Raleigh, NC.

The purpose of this study was to determine the contribution of P-glycoprotein (P-gp), a transmembrane energy-dependent drug efflux pump, on the dermal absorption of ivermectin, as a possible P-gp substrate. An 8 hour flow-through diffusion cell experiment was performed on porcine skin with perfusate samples collected hourly. The skin was dosed with Ivomec Pour-On for cattle (Ivomec®) spiked with BODIPY-ivermectin (Molecular Probes, Eugene, OR). Verapamil was used as a P-gp inhibitor, while DMSO was used with the BODIPY-ivermectin as a positive control. The skin samples were frozen and viewed on a Nikon C-1 confocal system

to visualize the localization of the fluorescently labeled ivermectin using a combination of confocal-differential interference contrast (DIC) microscopy and confocal fluorescent microscopy. The samples treated with Ivomec® and BODIPY-ivermectin exhibited fluorescence in the outermost layers of the stratum corneum. The samples that had verapamil added showed more fluorescence, and penetration through the stratum corneum and into the stratum granulosum. In the DMSO controls, fluorescence was present throughout the entire cross section of porcine skin with a higher concentration in the stratum corneum. The presence of ivermectin in the stratum corneum is consistent with what was expected because the highly lipophilic ivermectin would have an affinity for the lipid matrix of the stratum corneum. The co-administration of verapamil increased the absorption of ivermectin, presumably by inhibiting the action of P-glycoprotein. It is important to note that topical ivermectin is usually applied monthly, and an 8 hour experiment is a preliminary step in understanding its transport process.

2091 IN-VITRO HUMAN SKIN PENETRATION OF THE FRAGRANCE MATERIAL HMPCC.

S. P. Bhatia¹, J. Lalko¹, K. R. Brain², D. M. Green² and A. M. Api¹. ¹Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ and ²AN-EX, REDWOOD BUILDING, CARDIFF, CF10 3XF, United Kingdom.

An in vitro human skin absorption study was conducted on the fragrance material HPMCC (4-(4-hydroxy-4-methylpentyl)-3-cyclohexene-1-carboxyaldehyde), under both unoccluded and occluded conditions. Skin permeation and distribution of HPMCC was determined using epidermal membranes from cosmetic surgery donors. Skin membranes were mounted into Franz-type diffusion cells with the stratum corneum facing the donor chamber. The average area available for diffusion was 1.2 cm². HMPCC was applied, at the maximum in-use concentration of 1.5% in 70/30 (v/v) ethanol/water to the skin surface at a target dose of 5 µl/cm². The donor chamber of the occluded cells was covered with a greased, glass coverslip immediately after dosing. Permeation was measured over 24 h at 12 time points, using PBS as receptor. At 24 h, 5.54 ± 0.6 µg/cm² (unoccluded) and 18.6 ± 1.9 µg/cm² (occluded) (mean ± standard error, SE) of HMPCC had permeated, corresponding to 7.37 ± 0.86% (unoccluded) and 24.8 ± 2.5% (occluded) of the applied dose of 75.2 µg/cm². The 24 hour surface wipes contained 43.4 ± 2.8% (unoccluded) and 31.2 ± 2.2% (occluded) HMPCC and donor chamber wash/wipes contained 20.7 ± 1.5 (unoccluded) and 16.8 ± 0.8% (occluded) of the applied dose. The stratum corneum contained 7.75 ± 0.62% (unoccluded) and 6.20 ± 0.61% (occluded) of the applied HMPCC. The epidermis plus any remaining stratum corneum after tape stripping contained 6.06 ± 0.60% (unoccluded) and 8.69 ± 0.57% (occluded). Levels of HMPCC in the epidermis (plus any remaining stratum corneum after tape stripping), filter paper membrane support and receptor fluid were combined (as per SCCNFP guidelines) to result in a total absorbed dose value of 14.3 ± 0.9% (unoccluded) and 36.4 ± 2.6% (occluded). Overall recovery of HPMCC at 24 h was 86.2 ± 2.0% (unoccluded) and 90.5 ± 0.7% (occluded). The evaporative loss of HMPCC was low when estimated by measuring the loss from PTFE (polytetrafluoroethylene) sheets.

2092 PREDICTING CUTANEOUS PERMEABILITY OF BIOCIDES USING LSER APPROACH.

V. Vijay, B. M. Barlow, J. L. Yeatts and R. E. Baynes. Center for Chemical Toxicology Research and Pharmacokinetics (CCTRP), North Carolina State University, Raleigh, NC.

The permeation of a chemical through skin is influenced by its physico-chemical characteristics and the biological characteristics of the skin. In predicting dermal absorption, scientists have proposed different mathematical models to correlate physico-chemical (especially solvatochromatic parameters) and biological interactions occurring in the process of permeation. Previous studies have shown that hydrophobicity, polarity, molecular volume and hydrogen bonding capability of chemicals are among the most important characteristics to be used for predicting permeability. The aim of this study is to predict dermal absorption of different biocides (with wide range of Kow) using modified Linear Solvation Energy Relationship (LSER) approach, with a calibrated flow through diffusion system. Infinite doses of biocides belonging to five different classes; phenols, morpholines, oxazolindines, isothiazolines and triazines in aqueous solutions were applied to porcine skin flow through diffusion cells. These perfusates were analyzed by GC-MS and HPLC to determine skin permeability. The system coefficients (r, s, a, b, v) of a calibrated set of solutes of the system were determined from multiple linear regression analysis and plugged into the LSER equation to predict permeability values for the several biocides. Our preliminary data with 2 phenols; o-phenylphenol and p-chloro-o-cresol, have shown that the predicted permeability values were very close to observed values, demonstrating that our calibrated system can efficiently predict permeability of biocides. In further studies, the permeability of biocides will be determined in various solvents and commercially available metalworking fluids,

so to assess the behavior of biocides in mixtures and to determine the solvatochromatic parameter that has the most prominent effect in predicting permeability. NIH OH003669-06 supported this research.

2093 METABOLIC TRANSFORMATIONS OBSERVED DURING IN VITRO DERMAL PENETRATION STUDIES.

A. B. McEwen, G. R. Ford, S. G. Wood and K. H. Dummer. *BioDynamics Research Limited, Rushden, United Kingdom*. Sponsor: R. Harling.

Since the adoption of the European Commissions chemical strategy (REACH) and the Ground Water Directive (COM(2003)550) the environmental fate of a large number of chemicals, including pharmaceuticals, is becoming of increased public and regulatory concern. Under the proposed legislation risk assessments of a large number of chemicals, including dermal exposure, will be required.

The dermal penetration of [14C]-labelled parabens (octyl and propyl) was investigated in static Franz cells using isolated skin preparations obtained from both man and Sprague-Dawley rats. The rates of percutaneous absorption were compared to those obtained using standard reference compounds, [14C]-benzoic acid, [14C]-caffeine and [14C]-testosterone.

Since the skin possesses significant enzyme activities, some topically applied substances are metabolised as they pass through the skin. In the present study, the effect of metabolism on the percutaneous penetration of topically applied substances was investigated. Both octyl and propyl paraben were metabolised to p-hydroxy benzoic acid on passage through the skin, although the permeation rates were notably different. Testosterone was also metabolised, to androstenedione, on passage through the skin.

2094 HUMAN IN VITRO MODELS OF DERMAL METABOLISM.

A. Koganti, L. Brown, J. Smith, D. Mesa, J. Bonass, M. Fleischer and P. Silber. *Celsis In Vitro Technologies, Baltimore, MD*.

Dermal metabolism is recognized as an important consideration in evaluating the topical exposure of chemicals present in topically applied pharmaceutical and cosmetic products. Intact skin placed in flow-through diffusion cells, skin homogenates, and isolated keratinocytes are some of the models that have been used to study the metabolism of specific chemicals. The objective of this research was to establish human in vitro models for studying the dermal metabolism of chemicals. The metabolic capacity of freshly excised full thickness human skin and human keratinocytes was evaluated using probe substrates for known xenobiotic metabolizing cytochrome P450 (CYP) enzymes, transferases (N-acetyl, glucuronosyl, and sulfonyl) and esterases. Measurable CYP enzyme activities were observed for all transferases and esterases as well as for CYP1A2, CYP2B6, CYP2E1, and CYP3A4. Both freshly excised full thickness human skin and keratinocytes exhibited a similar pattern of enzymes with measurable activities, which correlated with enzyme activities previously reported in the literature. The effects of storage conditions, (1) storage medium, (ice vs Belzer UW solution) and (2) length of storage (up to 48 hours), on the metabolic capacity of freshly excised skin were also evaluated. The observed metabolic activities were well maintained by storage of the skin on ice for up to 48 hours. In conclusion, freshly excised human full thickness skin and human keratinocytes are suitable models for evaluating potential dermal metabolism of chemicals.

2095 IN VIVO AND IN VITRO DIBUTYL PHTHALATE SKIN ABSORPTION IN HAIRLESS GUINEA PIG SKIN.

J. J. Yourick, K. Doan and R. L. Bronaugh. *Office of Cosmetics and Colors, U.S. Food and Drug Administration, Laurel, MD*.

The in vitro assessment of skin absorption of lipophilic chemicals can be problematic when conducting in vitro diffusion cell skin absorption studies, because the chemicals may not freely partition from skin into an aqueous receptor fluid. In order to evaluate the in vitro-in vivo agreement in absorption of lipophilic chemicals, the cosmetic ingredient, dibutyl phthalate (DBP), was chosen as a model lipophilic compound due to reported toxicological concerns. Studies were done to measure DBP dermal absorption in vitro and in vivo using hairless guinea pig skin. Skin absorption was determined in these studies using an emulsion dosing vehicle containing 14C-DBP. In vitro absorption was measured for 24 or 72 hr by using flow-through diffusion cells (0.64 cm²) with a receptor fluid consisting of HHBSS (pH 7.4). In vivo absorption of DBP 24 hr after dermal application resulted in systemic absorption of 62.0 ± 2.0 (mean ± SEM) of the applied dose absorbed (%ADA) with 2.2 %ADA remaining in the skin. The majority of systemically ab-

sorbed DBP *in vivo* was found excreted in urine. *In vitro* DBP absorption over 24 hr found 28.9 ± 2.1 %ADA in receptor fluid with approximately 21.8 % remaining in skin. Extended absorption studies for 72 hr found receptor fluid levels of 55.9 ± 3.9 %ADA with 17.3 %ADA remaining in skin. Charcoal impregnated filter paper attached (for 1 hr) to the top of the diffusion cell or to the top of the *in vivo* dosing chamber improved recovery by trapping the volatile DBP. These studies indicate there is considerable DBP absorption in skin. In conclusion, DBP tends to form a skin reservoir *in vitro* as shown by the increased receptor fluid levels found after 72 hr when compared to 24 hr. The 72 hr *in vitro* absorption values correlated most closely with the 24 hr *in vivo* results. These studies help determine the importance of including DBP remaining in the skin at the end of an *in vitro* study as potentially available for systemic absorption.

2096 ASSESSMENT OF DERMAL ABSORPTION BY THERMAL GRAVIMETRIC ANALYSIS – DEVELOPMENT OF A 2-COMPARTMENT DIFFUSION MODEL.

M. Rauma and G. Johanson. *Work Environment Toxicology, Karolinska Institutet, Stockholm, Sweden.*

Recent work in our laboratory shows that it is possible to register the dermal uptake of chemicals *in vitro* by thermal gravimetric analysis (TGA), i.e. by exposing a piece of skin to chemical vapour of known concentration while recording its weight in a high-precision scale during carefully controlled temperature and humidity conditions.

We have previously studied several organic solvents with the TGA technique using trypsinated porcine skin. The data indicate that the shape of the weight curve is related to the skin:air partition (P) and diffusion (D) coefficients of the chemical. To define the relations more precisely, a solution to Fick's second law of diffusion was derived, for the special case of recording total weight over time in the TGA setup. A good fit to observed data was obtained using a 2-compartment diffusion model. The parameters P and D were obtained by best fit to observed weight curves of butyl acetate, methanol, 2-propanol and toluene using the Berkeley Madonna software.

The same chemicals were also studied using conventional Franz' diffusion cells and dermatomed porcine skin. A good correlation was obtained between the diffusion coefficients derived from the Franz' cell experiments and those derived from the faster of the two compartments in the TGA diffusion model.

In conclusion, experiments with a limited number of chemicals indicate that skin:air partition and diffusion coefficients can be obtained by fitting a TGA-specific solution to Fick's second law to TGA weight curves and that the numerical values correlate well to the those obtained in conventional diffusion cell experiments. Further studies on several different types of chemicals are needed to confirm the usefulness of the method.

This study was supported by the Swedish Council for Working Life and Social Research (FAS).

2097 MARKOV CHAIN MODEL FOR QUANTITATING DERMAL ABSORPTION FROM COMPLEX MIXTURES.

C. S. Pitts^{1,2}, C. E. Smith², R. E. Baynes¹, J. D. Brooks¹ and J. E. Riviere^{1,2}. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and ²Biomathematics Program, North Carolina State University, Raleigh, NC.

Exposure to pesticides dosed in complex chemical mixtures is a common environmental and occupational health concern. Risk assessors need to know the rate at which a pesticide is absorbed in to the skin in order to predict the toxicity of exposure to the pesticide. However, experimentally obtaining the absorption rates for even a small number of possible pesticide mixtures are expensive and time consuming. The objective of this study is to create a Markov chain model to predict pesticide absorption rates through the skin. The model parameters were fit to absorption data collected in the isolated perfused porcine skin flap (IPPSF) for a mixture of ethyl-parathion in ethanol. The model was investigated both analytically and through simulations using Gillespie's algorithm and was fit to the data using least squares methods. A model with three internal states, two absorbing states plus a delay appears to describe these data adequately. The structure of this model was compared to classical modeling approaches commonly used in dermal absorption studies (e.g. compartmental models and their reduction, PBPK models). Future work will expand the number of pesticide mixtures analyzed as well as search for correlations between absorption parameters and the physical and chemical properties of the pesticides and the mixture components into which they are exposed. These correlations may enable risk assessors to predict absorption profiles after chemical exposures in complex mixtures or formulations based on mixture component physical and chemical properties. (Supported by NIOSH R01 OH 07555).

2098 INCORPORATION OF COMPLEX CHEMICAL MIXTURE EFFECTS INTO A QSAR MODEL OF DERMAL ABSORPTION.

J. E. Riviere^{1,2} and J. D. Brooks¹. ¹Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and ²Biomathematics Program, North Carolina State University, Raleigh, NC.

Significant progress has been made on predicting dermal absorption/penetration of topically applied compounds by developing quantitative structure activity relationship (QSAR) models based on linear free energy relations (LFER). However, all of these efforts have employed compounds applied to the skin in aqueous or single solvent systems, a dosing scenario that does not mimic occupational, environmental nor pharmaceutical exposure. We have explored using hybrid QSAR equations describing individual compound penetration based on the molecular descriptors for the compound modified by a mixture factor (MF) which accounts for the physicochemical properties of the vehicle/mixture components. The MF is calculated based on percentage composition of the vehicle/mixture components and physical chemical properties selected using principal components analysis. This model has previously been applied to 12 different compounds in 24 mixtures for a total of 288 treatment combinations obtained from flow-through porcine skin diffusion cells (Toxicol. Appl. Pharmacol. 208:99-110, 2005). The data reported here includes using three fundamentally different LFER models (Abraham, Potts and Guy, Hostynek and Magee) on this diffusion cell dataset as well as applying them to a new experimental dataset in the *ex vivo* isolated perfused porcine skin flap model consisting of 10 of the same compounds in 5 mixtures for a total of 50 treatment combinations. The use of the MF in combination with classic LFERs based on penetrant properties significantly improved the ability to predict dermal absorption of compounds dosed in complex chemical mixtures across three different LFER models and two biological systems. (Supported by NIOSH R01 OH 07555).

2099 CUSTOM MADE PANI FIBER TO ASSESS DERMAL PARTITIONING AND ABSORPTION OF BIOCIDES.

J. L. Yeatts, R. E. Baynes and J. E. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics (CCTRP), North Carolina State University, Raleigh, NC.*

A custom-made polyaniline (PANI) coated metal alloy fiber was evaluated for its use in assessing dermal partitioning and absorption of certain biocides. This PANI coating provides a unique functionality compared to three commercially available fibers polyacrylate (PA), polydimethylsiloxane (PDMS), and Carbowax/templated resin. The production of this custom-made fiber is a relatively simple process that can be controlled by utilizing cyclic voltammetry (CV). The CV program for coating the metal alloy fiber consisted of one initial scan from -0.2V to +1.1V followed by several sets of scans from -0.2V to +0.8V with a 15 second equilibration time at -0.2V between scan sets and scan rate of 50 mV/sec. The electrolyte solution was 0.1M aniline in 1.0M sulfuric acid. The bare metal alloy fiber SPME assembly, commercially donated, served as the working electrode. In our experiments, cyclic voltammetry appeared to give more consistent results and control in coating the metal alloy fiber with PANI as opposed to using a constant deposition potential. To assess the PANI fiber, solid-phase microextraction (SPME) was performed by direct immersion into water solutions containing either a single component or a mixture of biocides at 37°C and stir rate of 400 R.P.M. The PANI fiber was desorbed directly in the GC-MS injector port for 5 minutes at 200°C following immersion. This PANI coated fiber exhibited good reproducibility and durability. The RSD's averaged 6 to 9% over a period of three days for the first 46 injections of a single component (5ppm 2-phenylphenol) in water with only three outliers. Time profile experiments revealed that both p-chloro-o-cresol and o-phenylphenol reached equilibrium before 10 minutes while the equilibrium time for o-benzyl-p-chlorophenol was greater than 90 minutes. This research was supported by NIH OH003669-06.

2100 PREDICTING SKIN PERMEABILITY OF MOLECULES FROM CHEMICAL MIXTURES USING AN INERT MEMBRANE-COATED FIBER ARRAY.

X. R. Xia, R. E. Baynes, N. A. Monteiro-Riviere and J. E. Riviere. *Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.*

Predicting skin permeability of compounds from chemical mixtures is required for transdermal drug delivery, safety evaluation of cosmetics and risk assessment of chemicals, where most exposure occurs in complicated chemical mixtures, not individual chemicals. We have developed a membrane-coated fiber technique that can be used to measure the partition coefficients of molecules from chemical mixtures with high precision and throughput. This novel approach predicts skin permeability based on its correlation with the partition coefficients from chemical mixtures determined in a fiber array. Each of the membrane-coated fibers represents a pattern of molecular interactions: polydimethylsiloxane (PDMS, lipophilic), polyacrylate (PA, polarizable) and CarboWax (Wax, polar). Molecular interactions occurring during percutaneous absorption can be simulated by the multiple fibers:

$\log(kp) = c + a \log K_{MCF1} + b \log K_{MCF2} + \dots + \log K_{MCFn}$. The feasibility of this approach was demonstrated with 25 diverse chemicals; their skin permeability [$\log(kp)$] from chemical mixtures were measured by in vitro flow through diffusion experiments and partition coefficients of the chemicals ($\log K_{MCFn}$) were determined by the membrane-coated fiber technique. Multiple regression analysis was used to define equations linking $\log(kp)$ to $\log K_{MCFn}$ for the three MCFs. A significant correlation equation was defined: $\log(kp) = -2.73 - 1.31 \log K_{wax} - 0.31 \log K_{pdm} + 2.34 \log K_{pa}$ with a R^2 of 0.92. The correlation coefficients in the equation reflected the mixture-skin interactions in different vehicles. These data clearly demonstrate that dermal absorption of diverse chemicals can be estimated from data collected in the inert fiber array which reflect the physicochemical diversity of interactions seen when chemicals partition into the stratum corneum. (Supported by NIOSH OH-07555 and USAFOSR FA 9550-04-1-0376).

2101 ENVIRONMENTAL TOBACCO SMOKE (ETS) EXACERBATES ATHEROSCLEROSIS PROGRESSION IN APOE^{-/-} MICE USING NON-INVASIVE REAL-TIME ULTRASOUND BIOMICROSCOPY (UBM) IMAGING.

C. Quan¹, Q. Li¹, X. Jin¹, M. Zhong¹, A. Wang², Q. Sun² and L. Chen¹.

¹Environmental Medicine, New York University, Tuxedo Park, NY and

²Environmental Health Sciences, Ohio State University, Columbus, OH.

Environmental tobacco smoke (ETS) has been listed by American Heart Association as a significant risk factor for cardiovascular diseases. Atherosclerosis is a major underlying cause of angina, heart attacks, strokes, and peripheral vascular disease. In this study, using non-invasive in vivo ultrasound biomicroscopy (UBM), we developed a novel imaging protocol to follow lesion progression in atherogenic mice. We also employed this protocol to assess the effects of long-term, low-concentration ETS exposure on plaque acceleration in atherosclerosis susceptible mice. Tobacco and Health Research Institute's 1R4F cigarettes were used to generate a side-stream cigarette smoke (SS, a surrogate for ETS) atmosphere. ApoE^{-/-} mice (n=24/group) fed with either high-fat chow (HFC), or normal chow (NC), were exposed to a low dose of SS (480 ug/m³) or filtered air (FA) for 6 hr/d, 5 days/wk, for up to 6 months. Before exposure and at 2, 4, 6 months during exposure, non-invasive UBM (Vevo660, Visualsonics, Canada) was performed on each mouse to assess plaque progression in aorta, brachiocephalic and left carotid arteries. The plaque volume was then measured by ImageJ. In addition, after each UBM assessment, 8 mice per group were sacrificed and histological analysis was performed for comparison with the results obtained using UBM. At 4 and 6 months, using UBM, SS exposure produced the greatest change in plaque volume in the left common carotid artery of HFC mice as compared to FA controls or NC controls, but not in brachiocephalic artery. Furthermore, UBM showed significant increases of plaque volume in the brachiocephalic artery in all four groups every other month. Our results show that this novel UBM imaging protocol is a useful non-invasive tool to follow plaque progression in atherogenic mice. The results also suggest that ETS exposure exacerbates plaque development in atherosclerosis susceptible mice.

2102 ESTROGEN REPLACEMENT THERAPY AND DEVELOPMENT OF VASCULAR LESIONS.

N. Porther and Q. Felty. Environmental & Occupational Health, Florida International University, Miami, FL.

Estrogen is known to increase vascular endothelial cell growth which may contribute to the increase in risk of coronary heart disease in women exposed to unopposed estrogen replacement therapy (ERT). Although the mechanism is not clear, estrogen may put women at risk by its promotion of abnormal proliferative vascular lesions and subsequent thickening of the vasculature. How estrogen may support or promote vascular lesions is not clear. In this study, we have examined whether estrogen stimulated endothelial tube formation is dependent on cellular redox state. Methods: Vascular lesion formation was determined in a 3-dimensional Matrigel assay. Prior to estrogen treatment, MnSOD and catalase were overexpressed in human umbilical vein endothelial cells (HUVEC) via adenoviral vectors. Endothelial tube formation was measured by AngioQuant software, an automated image analysis tool for quantification of angiogenesis. Results: Physiological concentrations of E2 found in human serum were tested. Estrogen (100pg/ml) treatment for 6 h stimulated a 2-fold increase in endothelial tubes. Endothelial tube formation was significantly inhibited to the level of control by overexpression of both MnSOD and catalase. In addition, co-treatment with the antioxidant ebbsen showed a significant reduction in tube formation. Conclusions: We have shown that overexpression of MnSOD and catalase significantly inhibits endothelial tube formation. It appears that early estrogen signaling does not require estrogen receptor genomic signaling because we can inhibit tubule formation by antioxidants. Findings of this study highlight the potential damaging consequences of unopposed ERT in vascular disorders dealing with oxidative stress conditions.

2103 THE DIETARY FLAVONOID QUERCETIN BLOCKS PCB77 INDUCED PRO-INFLAMMATORY RESPONSES IN VASCULAR ENDOTHELIAL CELLS.

C. T. Kluemper³, X. Arzuaga^{1,2}, M. Toborek^{2,4} and B. Hennig^{1,2}. ¹Animal and Food Sciences, University of Kentucky, Lexington, KY, ²Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY, ³Department of Biology, University of Kentucky, Lexington, KY and ⁴Department of Surgery, University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) are widespread environmental contaminants that can cause a wide variety of toxic effects in exposed organisms. Co-planar PCBs can induce oxidative stress and activation of pro-inflammatory signaling cascades which are associated with atherosclerosis. Vascular endothelial cells have been shown to be sensitive to chemical insult and cellular dysfunction after co-planar PCB exposure. The majority of the toxicological effects elicited by co-planar PCB exposure are associated to activation of the aryl hydrocarbon receptor (AHR) and subsequent induction of responsive genes. Quercetin, a dietary flavonoid, has been demonstrated to possess antioxidant and anti-inflammatory properties in various in-vivo and in-vitro models. Previous studies from our group have shown that flavonoids can significantly reduce PCB77 induction of oxidative stress and expression of the AHR responsive gene cytochrome P450 1A1 (CYP1A1). To determine if quercetin can block PCB77 induced expression of pro-inflammatory genes associated with atherosclerosis, porcine endothelial cells were exposed to PCB77 in combination with quercetin, and expression of pro-inflammatory proteins was analyzed by western blot. Upon confluence, cells were serum deprived for 8 h, then treated with PCB77 (1 µM), quercetin (10 µM), or PCB77 plus quercetin for a period of 16 h. Quercetin co-treatment significantly blocked PCB77 induction of the pro-oxidative and inflammatory proteins: CYP1A1 and vascular cell adhesion molecule 1 (VCAM1). These results suggest that quercetin intervention is protective against PCB77 induced endothelial cell dysfunction. (Supported by grants from NIEHS, NIH (P42ES07380) and the University of Kentucky AES).

2104 HIV ANTIRETROVIRAL DRUG COMBINATIONS INDUCE ENDOTHELIAL MITOCHONDRIAL DYSFUNCTION AND ROS PRODUCTION, BUT NOT APOPTOSIS.

B. Jiang¹, V. Y. Hebert¹, J. Mathis² and T. R. Dugas¹. ¹Department of Pharmacology, LSU Health Sciences Center, Shreveport, LA and ²Department of Anatomy, LSU Health Sciences Center, Shreveport, LA.

Numerous studies report that HIV patients administered antiretroviral therapy are at a greater risk for cardiovascular diseases. Endothelial dysfunction is an early event and a sensitive marker for cardiovascular diseases, such as atherosclerosis. We previously reported that HIV antiretroviral therapy induces direct endothelial dysfunction in vivo, and induces only a slight increase in cell death, as indicated by the LDH release assay. We also observed that endothelial mitochondrial function was compromised following antiretroviral treatment. To determine whether antiretroviral-induced endothelial dysfunction is via mitochondrial dysfunction and whether mitochondrial dysfunction culminates in endothelial cell apoptosis, we treated HUVEC with micromolar amounts of AZT, indinavir, or AZT plus indinavir. These treatments induced a decrease in cellular O₂ consumption, a collapse in the mitochondrial membrane potential, and an increase in the production of reactive oxygen species (ROS) in endothelial cells. An MnSOD mimetic, MnTBAP, abolished the increased ROS production, suggesting that the ROS were generated by mitochondria. Transfection of the endothelial cells with a mitochondrially-targeted catalase decreased antiretroviral-induced ROS and 8-isoprostane production, confirming the mitochondrial localization of the ROS produced. Finally, to determine whether antiretroviral-mediated mitochondrial dysfunction culminates in endothelial cell apoptosis, we assessed levels of apoptosis using the TUNEL, the DAPI staining, the caspase activation, and the DNA fragmentation assays, but none of these assays indicated a marked increase in apoptotic cells following antiretroviral treatment. Our studies thus suggest that antiretrovirals induce mitochondrial dysfunction and increase mitochondrial ROS in endothelial cells, but the decreased mitochondrial function does not culminate in apoptosis.

2105 PCB 77 ACTIVATES ENOS VIA PI3K AND AKT PHOSPHORYLATION IN ENDOTHELIAL CELLS BY A CAVEOLIN-1 DEPENDENT MECHANISM.

E. Lim^{2,3}, E. Smart⁵, M. Toborek^{3,6} and B. Hennig^{1,2,3}. ¹College of Agriculture, University of Kentucky, Lexington, KY, ²Animal and Food Science, University of Kentucky, Lexington, KY, ³Graduate Center for Nutrition Science, University of Kentucky, Lexington, KY, ⁴Graduate Center for Toxicology, University of Kentucky, Lexington, KY, ⁵Pediatrics, University Kentucky, Lexington, KY and ⁶Surgery, University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) are persistent environmental contaminants that can contribute to the pathology of atherosclerosis by activating inflammatory responses in vascular endothelial cells. We hypothesize that plasma membrane mi-

crodomains called caveolae are critical in endothelial activation and toxicity mediated by PCBs. Caveolae are particularly abundant in endothelial cells and play a major role in endothelial trafficking and signaling pathways associated with the pathology of vascular diseases. eNOS is co-localized with caveolae and is a critical regulator of vascular homeostasis. Dysfunctional eNOS signaling may be important in the early pathology of atherosclerosis and the activation of eNOS can lead to excessive NO formation. The current study was designed to test the hypothesis that PCBs can activate endothelial cells via eNOS signaling. Human endothelial cells (EA.hy926) were treated with PCB77 (2.5 μ M) for 5 and 10 minutes to explore protein activation. Exposure to PCB77 rapidly induced caveolin-1 and eNOS phosphorylation as well as activation of PI3K and Akt. Caveolin-1 silencing abolished the PCB-stimulated eNOS phosphorylation. Furthermore, PI3K inhibitors (Wortmanin, Ly294002) blocked eNOS and caveolin-1 phosphorylation. Cellular exposure to PCB77 also increased nitrotyrosine levels, which may have implications in oxidative-stress mediated inflammatory mechanisms. These findings suggest that PCB77 induces eNOS phosphorylation in endothelial cells through an Akt-dependent mechanism, events regulated by caveolin-1. Our data provide evidence that caveolae may play a critical role in regulating vascular endothelial cell activations and toxicity induced by persistent environmental pollutants such as coplanar PCBs.

2106 INSIDIOUS VASCULAR INFLAMMATORY RESPONSE AND IDENTIFICATION OF EARLY PREDICTIVE BIOMARKERS IN RAT FOLLOWING ORAL ADMINISTRATION OF THE PDE IV INHIBITOR SCH 351591.

J. Zhang¹, R. Snyder², A. Knapton¹, T. J. Miller¹, P. Espandiar¹, E. H. Herman¹, R. Honchel¹, J. Hanig¹ and J. L. Weaver¹. ¹CDER, FDA, Silver Spring, MD and ²Schering-Plough Research Institute, Lafayette, NJ.

We previously reported that the PDE IV inhibitor SCH 351591 induced mesenteric arterial hemorrhage and necrosis in rats. The objective of the current study was to characterize the SCH 351591-induced vascular injury that precedes arterial hemorrhage and necrosis. Male Sprague-Dawley rats were administered orally a single dose of 20 mg/kg SCH 351591. Groups of animals (n=6) were then sacrificed at 15, 30, 45, 60, 90, 120, 150, 180, 210, and 240 min after dosing. Microscopic evaluation of the mesentery at the 15 min time point revealed an increase in the number of mast cells, apparent activation of mast cells and vasodilatation in the microvasculature. This was paralleled by a transient increase in circulating lymphocytes at 15 minutes. Serum beta-hexosaminidase showed a similar but non-significant increase. Responses observed at the 30-45 min time point included a significant increase in the number of mast cells, recruitment of eosinophils, marked vasodilatation, endothelial cell activation, and perivascular inflammatory reaction in small veins. Recruitment of neutrophils, eosinophils, lymphocytes, and mononuclear cells with progressively worsening perivascular inflammatory reactions in the arteries and veins was observed from 60-240 min after dosing. Adhesion of leukocytes to activated endothelial cells and transendothelial migration of circulating leukocytes were also observed at these later time points. Circulating granulocytes significantly increased by 240 minutes as had the circulating levels of GRO/CINC-1. Arterial hemorrhage and necrosis had not developed by the 240 min time point. Confirming previous pilot studies, IL-6 was not elevated at any time point studied. Mast cell degranulation was very rarely observed at any time point. Pathological, hematological and biomarker changes were seen in the very early stage of drug-induced mesenteric vascular injury, well before medial hemorrhage and necrosis.

2107 PLASMA CYTOKINE LEVELS ARE INCREASED IN OLDER APOLIPOPROTEIN E DEFICIENT MICE FOLLOWING EXPOSURE TO DIESEL EXHAUST.

L. M. Corey, C. Baker, E. C. Peck, J. H. Wilkerson, D. L. Luchtel, J. D. Kaufman, T. J. Kavanagh and M. E. Rosenfeld. *Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.*

The cardiovascular (CV) system is exquisitely sensitive to adverse effects following increases in ambient particulate matter (PM), as exemplified by increases in morbidity and mortality following periods of greater air pollution. Diesel accounts for a large percentage of PM in an urban setting. Inflammation is associated with coronary events such as atherosclerotic plaque rupture, thrombogenesis and embolization. Plasma cytokines play a critical role as both mediators and markers of the inflammatory response to PM. We hypothesize a change in plasma cytokine levels following exposure to diesel exhaust (DE) in a model of CV disease, the apolipoprotein E null (apoE^{-/-}) mouse, that will suggest the mechanisms involved in PM mediated CV events. To test this, male apoE^{-/-} mice 25-35 weeks old (N = 15/group) were exposed to 200 μ g/m³ DE or filtered air (FA) for 1 day, 1 week or 8 weeks. At sacrifice, plasma was analyzed for interleukin (IL)-1 β , IL-2, IL-4, IL-5, IL-6, IL-10, IL-12, granulocyte-macrophage colony stimulating factor (GM-CSF), interferon (IFN)- γ and tumor necrosis factor (TNF)- α using the BioRad BioPlex cytokine kit. All of the cytokines had the greatest increases following 1 day of DE

exposure with a return to FA exposed levels with longer DE exposures. IL-4, IL-10, and IL-12, were significantly increased following exposure to DE compared to FA. With the cytokines IL-2, IFN- γ , GM-CSF and TNF- α , the FA exposed groups were below the limits of detection, as plasma concentrations are usually low, while the DE exposed groups were measurable. As both T_H1 and T_H2 cytokines were increased in the circulation following DE exposure, we can infer both a cell mediated and antibody mediated response to DE. This change in circulating cytokines may directly affect the vasculature, cardiac muscle, or atherogenesis to produce an adverse effect. We conclude that the complex inflammatory response that may signal CV effects to DE exposure is mediated by cytokines.

2108 DIESEL EXHAUST ENHANCES VENOUS CONGESTION IN A MODEL OF HEART FAILURE.

T. L. Knuckles, A. K. Lund and M. J. Campen. *Lovelace Respiratory Research Institute, Albuquerque, NM.*

Air pollution has been associated with hospital admissions and death due to heart failure. However, the exact mechanism(s) and causal components remain to be clarified. Recent studies suggest that air pollution enhances vasoconstriction systemically. Thus, we hypothesized that exposure to air pollutants induce vasoconstriction that, in the presence of a failing heart, leads to venous and pulmonary congestion. To study this, we used 1) isolated arteries and veins exposed to organic components common to many combustion sources, and 2) a hamster model of cardiomyopathy exposed to a common ambient air pollutant, diesel exhaust via inhalation. Previous work in our laboratory has demonstrated that the gaseous components of diesel exhaust increased the vasoconstrictive effects of ET-1 in isolated ApoE^{-/-} septal coronary arteries. Current work in our laboratory is focused on mesenteric arteries and veins from C57BL/6. Isolated mouse mesenteric veins and arteries showed similar proconstrictive effects when exposed to combined acetaldehyde, formaldehyde, acetone, hexadecane and octadecane at concentrations found in particle filtered diesel exhaust exposed saline; however, the individual compounds did not appear to replicate the effects. In a related study, cardiomyopathic hamsters (HCM) were obtained late in life exhibiting cardiac impairment (fractional shortening 0.15-0.20, normal ~0.60). HCM were exposed to 300 mg/m³ of whole diesel exhaust for 1 hr/day for 2 days and venous pressures (Pven) were taken via radiotelemetry through catheterization of the thoracic vena cava. Exposure to whole diesel exhaust significantly increased Pven to ~13 mmHg compared to control animals (Pven ~5 mmHg). Furthermore, aortas taken from the diesel exposed animals exhibited significantly more oxidant generation than control as measured by lucigenin-enhanced chemiluminescence, indicating elevated vascular oxidative stress. These data suggest that air pollutants can induce congestion and vasoconstriction, which may play a role in exacerbation of cardiopulmonary symptoms related to congestive heart failure.

2109 SUB-CHRONIC EXPOSURE TO CONCENTRATED AMBIENT PARTICULATE AIR POLLUTION AND CARDIOPULMONARY RESPONSES IN RATS.

I. M. Kooter¹, M. E. Gerlofs-Nijland¹, J. Boere¹, D. L. Leseman¹, P. H. Fokkens¹, T. van de Kuil², M. R. Miller³, H. ten Cate⁴ and F. R. Cassee¹. ¹MGO, National Institute for Public Health and the Environment, Bilthoven, Netherlands, ²TOX, National Institute for Public Health and the Environment, Bilthoven, Netherlands, ³Centre for Cardiovascular Science, University of Edinburgh, Edinburgh, United Kingdom and ⁴Department of Internal Medicine, University of Maastricht, Maastricht, Netherlands.

Ambient particulate matter (PM) has been linked with intensification of respiratory and cardiovascular diseases. The central hypothesis tested in this *in vivo* study was that long-term exposure to PM will result in adverse pulmonary and systemic effects. Specifically, we expected a diminished endothelial function (as monitored by von Willibrand Factor and endothelin-1), reduced fibrinolysis (as monitored by tissue plasminogen activator and plasminogen activator inhibitor-1) and increased blood coagulation (as monitored by thrombin generation tests). To test this hypothesis the effect of concentrated ambient particles (CAPs) was studied in rats that had a mild pulmonary inflammation at the onset of CAPs exposures induced by ozone.

Using an Ambient Fine Particle Concentrator (AFPC) in total 20 male Fischer F334 rats were exposed to CAPs (0.15-2.5 μ m). 15 animals were exposed for 4 weeks, 5 days/week for 6 hours a day and 5 animals, equipped with radiotelemetry for recording ECG, were prolonged exposed for 13 weeks. On average CAPs concentrations of 285 and 227 μ g/m³ were reached. Cardiopulmonary responses were investigated 24 hours after the last exposure in both groups. The effect on inflammation (protein, lactate dehydrogenase and several cytokines in broncho alveolar lavage fluid), pathological and haematological indicators (see above) were examined. Vascular function was assessed in arteries using the myograph system. First results suggest that neither CAPs exposure for 4 weeks nor for 13 weeks induced significant changes of inflammation in the lung, in haematological indicators, ECG measurement or vascular function.

Contrary to our expectations no major effects were associated with CAPs exposure for 4 weeks up to 13 weeks.

2110 ROLE OF THE NITRIC OXIDE PATHWAY IN FENOLDOPAM-INDUCED VASCULAR INJURY.

D. Brott^{1,2}, L. Foster-Brown¹, R. J. Richardson² and C. Loudon^{3,2}. ¹Global Safety Assessment, AstraZeneca Pharmaceutical, Wilmington, DE, ²Toxicology Program, Department of Environmental Health Sciences, The University of Michigan, Ann Arbor, MI and ³Global Safety Assessment, AstraZeneca Pharmaceutical, Alderly Park, United Kingdom.

Fenoldopam, a dopaminergic DA1 agonist, causes mesenteric vascular injury in the rat but also increases mesenteric and renal arterial blood flow. This vasodilation is mediated by nitric oxide (NO). Nitric Oxide synthase (NOS) is regulated by the shear-stress mediating cell surface protein caveolin-1 (cav-1). Profound vasodilation and accompanied decreased shear stress are early events that could initiate vascular injury. Therefore, determining the role of cav-1 and the NO pathway in fenoldopam-induced vascular injury would be of interest. At specific sites of mesenteric arterial injury induced by fenoldopam, there was loss of cav-1 and apoptosis determined immunohistochemically in endothelial and smooth muscle cells (SMC). Additionally, evidence of gap and tight junction loss localized to injury sites was seen in response to fenoldopam-induced vascular damage. In order to determine the sequence of events, rat SMC were cultured with pharmacologically and structurally diverse in vivo vascular toxicants and the cells analyzed temporally for activated caspase 3, annexin V and cav-1 using cellomics, flow cytometry and western blot analysis. The results showed a dose and time dependent cav-1 loss 6 hours post-treatment that preceded activation of caspase 3 and expression of annexin V as markers of apoptosis. Because functional loss of cav-1 is associated with increased NOS activity and vasodilation via NO, in vivo studies were conducted to show that continuous intravenous infusion of a NO donor produced vascular lesions morphologically similar to those induced by fenoldopam. Moreover, the incidence and severity of vascular injury were reduced when a nitric oxide synthase inhibitor (L-NAME) or a scavenger of NO-generated free radicals were co-administered with fenoldopam. Collectively, these data suggest that the NO pathway may play an important role in vasodilatory drug-induced vascular injury.

2111 THE EFFECT OF DIESEL PARTICLES ON CAPILLARY ENDOTHELIAL TUBES GROWN IN VITRO.

M. Chao¹, A. Pettit¹, R. Song¹, D. R. Gerecke¹, R. Laumbach² and M. K. Gordon¹. ¹Pharmacology and Toxicology, Rutgers University, Piscataway, NJ and ²Environmental and Occupational Medicine, UMDNJ, Robert Wood Johnson Medical School, Piscataway, NJ.

To determine whether inhaled diesel particles have deleterious effects on the lung vasculature, we used an in vitro culture model system. 125,000 human umbilical vein endothelial cells were plated in the wells of 6-well dishes. Some wells were evenly coated with 2 mg Matrigel (Becton Dickinson). On a plastic substratum, cells proliferated, doubled every 24 hr, and formed a confluent monolayer by 48 hr. On Matrigel, cell proliferation was limited and capillary tubes began forming within 3 hr. Microscopy revealed that capillary tube formation was complete by 12 hr and that every cell was a component of a tube. With daily changes of medium, capillary tubes were stable for a minimum of 8 days. Next we tested how different concentrations of diesel particles affected the survival of endothelial cells and tubes. The "zero" time point for addition of diesel particles was defined as 12 hr after plating cells on plastic or Matrigel. Automobile diesel particles from Japan (courtesy of Dr. Sagai, Tokyo) were sonicated in PBS for 5 min, then added at 1 ug/ml, 10 ug/ml, and 100 ug/ml medium to monolayers or capillary tubes. Within 4 hr, microscopy showed that the highest concentration of particles caused monolayer cells to extend processes, and caused capillary tubes to appear swollen or inflated. To understand this effect, monolayers were examined by a quantitative assay [the Cell Titer 96 Aqueous One Solution Assay (Promega)] to detect viable cells. This colorimetric method is capable of evaluating either proliferation or cytotoxicity, and demonstrated that 100 ug/ml particles caused cell death: Within 24 hr, 50% of the cells died. By 48 hr 80% died. However, 1 ug/ml and 10 ug/ml diesel particle concentrations had no effect on cell survival. Cell doublings occurred every 24 hr, equivalent to the rate of proliferation of non-treated cells.

2112 SHORT-TERM EXPOSURE TO PARTICULATE MATTER POTENTIATES VASOMOTOR TONE CHANGE.

S. Rajagopalan¹, Q. Sun¹, P. Yue¹, A. Wang¹, X. Jin², D. Duquaine³, Q. Li², M. Zhong², M. Lippmann³, R. D. Brook³ and L. Chen². ¹Division of Environmental Health Sciences and Davis Heart & Lung Research Institute, The Ohio State University, Columbus, OH, ²Department of Environmental Medicine, New York University, Tuxedo, NY and ³Department of Internal Medicine, University of Michigan, Ann Arbor, MI.

Recent studies have implicated air-borne particulate matter <2.5 µm (PM_{2.5}) in vasoconstriction and potentiation of hypertension in humans. The precise mechanisms remain to be characterized. We investigated the effects of short-term exposure to PM_{2.5} in an angiotensin II (A II) rat model.

Sprague-Dawley rats were exposed to concentrated ambient PM_{2.5} or filtered air (FA) in a whole-body exposure chamber for 10 weeks. Blood pressure (BP) was monitored by radiotelemetry. At week 9, an osmotic minipump containing A II was implanted subcutaneously. Rats were sacrificed 1 week after A II intervention, and the aorta excised and subjected to evaluation.

Baseline BP after 9-week of PM_{2.5} exposure was similar between groups. Mean BP (MBP) was higher in A II-PM_{2.5} starting at day 3 (ΔMBP = 57±3 vs. 20±4 mmHg at day 5, p<0.05 vs. A II-FA). Vasoconstrictor response to phenylephrine was exaggerated in the PM_{2.5} group (107.1±6.9 vs. 78.3±5.5%, p<0.05 vs. FA) while dilator response to acetylcholine was potentiated in precontracted aortic segments (-74.5±2.7 vs. 95.3±3.2%, p<0.05 vs. FA). Superoxide production in aorta was increased by PM_{2.5} (3378±159 vs. 1528±151 pixels/mg dry weight in A II-PM_{2.5} and A II-FA groups, respectively) by an NAD(P)H oxidase mediated mechanism, as evidenced by inhibition with apocyanin and upregulation of the NAD(P)H oxidase subunits, p22phox and p47phox (2.4 and 2.6 fold increase in A II-PM_{2.5} vs. A II-FA by real time RT-PCR, p<0.05) in the aortic vessel wall. There were no differences in expression of p67phox, gp91phox, nox1, and nox4. RhoA protein and mRNA were similar; while Rho associated kinase-1 (ROCK-1) mRNA was increased (2.1 fold increase in A II-PM_{2.5} vs. A II-FA).

Short-term air pollution exposure may exaggerate A II-induced hypertension through NAD(P)H oxidase and Rho-kinase dependent pathways.

2113 FINE AMBIENT AIR PARTICULATE MATTER EXPOSURE INDUCES MOLECULAR ALTERATIONS INDICATIVE OF CARDIOVASCULAR DISEASE PROGRESSION IN ATHEROSCLEROTIC SUSCEPTIBLE MICE.

H. S. Floyd¹, L. Chen², B. Vallanat³ and K. Dreher³. ¹NC State College of Veterinary Medicine, Raleigh, NC, ²New York University School of Medicine, Tuxedo, NY and ³U.S. EPA, Research Triangle Park, NC.

Epidemiological, clinical, and toxicological studies have demonstrated that exposure to ambient air particulate matter (PM) can alter cardiovascular function and may influence cardiovascular disease (CVD). It has been shown that exposure to concentrated ambient air particles (CAPs) results in an increase in plaque area in mice that are susceptible to CVD development. Although the effects of CAPs on plaques have been well characterized phenotypically, alterations at the gene expression level have not yet been examined. The present study utilizes laser capture microdissection to recover atherosclerotic plaques from ApoE^{-/-} male mice exposed daily for 6 months to either air or CAPs (Inhal Tox 17:217-224, 2005). Total RNA extracted from the microdissected plaques was amplified and analyzed for alterations in gene expression using the Affymetrix platform and mouse genome 430 2.0 array. Differential gene expression analysis was conducted at a Bayesian p-value estimate of 0.05 and 1.2 fold change. Approximately 2000 genes were altered: 500 genes down regulated and 1500 genes up regulated. Ontological analysis ranked alterations to groups of genes, in order of significance, involved in serotonin receptor, phospholipase C activating pathway, neutrophil chemotaxis, cardiac inotropy, inflammatory response, regulation of muscle contraction, cell proliferation, oxidative stress, and heart development. These data are consistent with previous studies demonstrating an increase in lesion area, cellularity, and oxidative stress following CAPs exposure. These technologies will aid in the identification of specific molecular changes which influence CVD progression following ambient PM exposure as well as provide insight into the contribution that environmental air pollution has on chronic health effects. (Funding: USEPA-NCSCU Cooperative Training Agreement CT 833235-01-0. This abstract does not necessary reflect EPA Policy)

2114 SHORT-TERM AIR POLLUTION EXPOSURE POTENTIATES INSULIN RESISTANCE.

Q. Sun^{1,2}, P. Yue², A. Wang², X. Jin³, D. Duquaine⁴, Q. Li³, M. Zhong³, M. Lippmann³, R. D. Brook⁴, L. Chen³ and S. Rajagopalan^{2,1}. ¹Division of Environmental Health Sciences, The Ohio State University, Columbus, OH, ²Davis Heart & Lung Research Institute, The Ohio State University, Columbus, OH, ³Department of Environmental Medicine, New York University, Tuxedo, NY and ⁴Department of Internal Medicine, University of Michigan, Ann Arbor, MI.

Background: Although there are no direct links implicating air pollution with metabolic syndrome (MS), there is a correlation between the latter and urbanization. We hypothesized that short-term exposure to fine particulate matter <2.5 µm (PM_{2.5}) induces insulin resistance, and potentiates vasoconstriction.

Methods: C57BL/6 mice (n=32, male) fed with high fat chow (HFC) for 5 months, were exposed to concentrated ambient PM_{2.5} or filtered air (FA) in a whole-body exposure chamber for 10 weeks (6 h/d, 5 d/wk).

Results: Insulin/glucose ratios, glucose tolerance test, and weights were identical prior to exposure; PM_{2.5} exposure worsened fasting hyperglycemia (168±6 vs. 126±7 mg/dl p<0.01 vs. FA-HFC), and after glucose loading (370±35 vs. 315±25 mg/dl at 30 minutes, both p<0.01 vs. FA-HFC). Basal nitric oxide (NO) release

assessed by the degree of constriction to NG-monomethyl-L-arginine (L-NMMA, 10^{-4} M) was reduced in PM_{2.5} vs FA-HFC group. Stimulated NO release in the aorta assessed by response to acetylcholine (10^{-5} M) and insulin (500 mU) was attenuated in the PM_{2.5}-HFC group vs. FA-HFC ($51 \pm 6\%$ vs. $75 \pm 4\%$; $17 \pm 6\%$ vs. $29 \pm 9\%$, $p < 0.01$ vs. FA-HFC respectively). Response to phenylephrine was potentiated (136 ± 6 vs. $100 \pm 6\%$, PM_{2.5}-HFC vs. FA-HFC, $p < 0.01$) in denuded aortic segments, with the exaggerated response inhibitable by LY294002 and Wortmannin, inhibitors of phosphatidylinositol 3-kinase. Phosphorylation levels of Akt and eNOS were significantly down-regulated in the PM_{2.5} group compared with FA group ($49 \pm 11\%$ vs. $100 \pm 19\%$; $51 \pm 3\%$ vs. $100 \pm 16\%$, respectively).

Conclusion: PM_{2.5} aggravates insulin resistance, attenuates NO release and potentiates vasoconstriction at the level of the vasculature through PI3K/Akt pathways. These findings suggest an important new link between air pollution and MS.

2115 MECHANISM OF DISRUPTION OF ENDOTHELIAL MONOLAYER INTEGRITY BY SODIUM ARSENITE.

F. E. Pereira, J. D. Coffin and H. D. Beall. *BPS/CEHS, The University of Montana, Missoula, MT.*

Arsenic contamination of ground water is a global problem and drinking water is a significant source of arsenic exposure to humans. Epidemiological studies have shown an association between elevated arsenic levels in drinking water and cardiovascular disease. Arsenic exposure has been shown to exacerbate atherosclerosis, beginning with activation of the endothelium that lines the vessel wall. Endothelial barrier integrity is maintained by proteins of the adherens junction such as vascular endothelial cadherin (VE-cadherin) and β -catenin and their association with the actin cytoskeleton. In the present study, human aortic endothelial cells were exposed to 1, 5 and 10 μ M sodium arsenite [As(III)] for 1, 6, 12 and 24 h, and the effects on endothelial barrier integrity were determined. Immunofluorescence studies revealed formation of actin stress fibers and non-uniform VE-cadherin and β -catenin staining at cell-cell junctions that were concentration and time-dependent. Intercellular gaps were observed with a measured increase in endothelial permeability. In addition, concentration-dependent increases in tyrosine phosphorylation (PY) of β -catenin and activation of protein kinase C γ (PKC γ) were observed. Inhibition of PKC γ restored VE-cadherin and β -catenin staining at cell-cell junctions and abolished the As(III) induced formation of actin stress fibers and intercellular gaps. Endothelial permeability and PY of β -catenin were also reduced to basal levels. These results demonstrate that As(III) induces activation of PKC γ , which leads to increased PY of β -catenin downstream of PKC γ activation. Phosphorylation of β -catenin plausibly severs the association of VE-cadherin and β -catenin, which along with formation of actin stress fibers, results in intercellular gap formation and increased endothelial permeability. The intercellular gaps and increased permeability induced by arsenic could potentially accelerate/enhance the process of atherosclerosis. (Supported by NIH grant P20 RR17670)

2116 SMOOTH MUSCLE DYSFUNCTION INDUCED BY MONOMETHYLARSONOUS ACID (MMAIII): A CONTRIBUTING FACTOR TO ARSENIC-ASSOCIATED CARDIOVASCULAR DISEASES.

J. Noh, E. Lim, O. Bae, K. Lim, S. Chung and J. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Arsenic in drinking water is reported to be associated with cardiovascular diseases and cancers in humans. Recent studies suggested that methylated trivalent arsenicals, the metabolites of inorganic arsenic, could be responsible for the arsenic toxicity. To study the role of monomethylarsonous acid (MMAIII), a major methylated trivalent arsenicals, in arsenic-induced cardiovascular diseases, we investigated the effect of MMAIII on blood vessels using organ bath systems. In isolated rat thoracic aortic rings, pre-treatment of MMAIII suppressed agonist-induced vasoconstriction irreversibly in a dose-dependent manner, regardless of agonist type, such as phenylephrine (PE), serotonin or endothelin-1. Similar effects were also observed in aortic rings without endothelium, suggesting that vascular smooth muscle function was directly affected by MMAIII. In contrast to the pre-treatment, a post-treatment of MMAIII after induction of vasoconstriction by PE has no inhibitory effect, showing that MMAIII affected on the initiation process of vasoconstriction, not on the maintenance of vasoconstriction. The effect of MMAIII was mediated by inhibition of PE-induced Ca²⁺ increase as found in aortic strips and rodent smooth muscle cells, A7r5 using confocal microscopy. Extracellular influx and release from intra-cellular store were blocked concomitantly by MMAIII treatment. In calcium-permeabilized aortic strips, MMAIII did not affect vasoconstriction stimulated by Ca²⁺ addition, confirming the specific effect on Ca²⁺ mobilization, not through effect on other contractile machinery. Consistent with the in vitro results, pre-treatment of MMAIII intravenously attenuated PE-induced blood pressure increase in in vivo rat models. In conclusion, MMAIII induces smooth muscle dysfunction mediated through inhibition of Ca²⁺ increase, which results in impaired vasoconstriction and blood pressure change. This study will provide a new insight into the role of trivalent methylated arsenicals in arsenic-associated cardiovascular diseases.

2117 ARSENITE ENHANCES PLATELET ADHESION TO ENDOTHELIAL CELLS THROUGH MODULATING ADHESION MOLECULE EXPRESSION ON PLATELET SURFACE.

O. Bae, J. Noh, S. Chung, K. Lim and J. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Arsenic, an important contaminant in drinking water, is known to be a risk factor to cardiovascular diseases (CVD) in human, but the exact mechanism underlying remains unclear. In this study, we investigated whether arsenic could affect adhesion of platelet to vascular tissue that is, endothelial cell, which can accelerate the progression of CVDs ultimately. To examine the effect of arsenite on the platelet adhesion molecules, expression level of glycoprotein (GP) IIb/IIIa, GP Ib/IX/V, or P-selectin on platelet was measured using flow cytometric analysis after arsenite treatment. As a result, arsenite did not affect the expression of these adhesion molecules in human platelets independently. However, in the presence of sub-threshold level of thrombin, arsenic potentiated increases of GP IIb/IIIa and P-selectin expression, important adhesion molecules that serve as a receptor for adhesive proteins, in a concentration-dependent manner. In contrast, GP Ib/IX/V, which is decreased in activated platelets on the platelet surface, was found to disappear from surface in arsenite-exposed platelets. In accordance with the adhesion molecule expression, arsenite increased the adhesion of platelets to human aortic endothelial cells. In conclusion, arsenic-exposed platelets become more active in adhesion molecule expression and it leads to enhanced adhesiveness to endothelial cells. These results suggest that arsenic enhances the sensitivity of platelet adhesion to endothelium, and potentiated platelet adhesion could be an important aggravating factor to CVDs in arsenic-exposed human populations.

2118 A NEW METHOD FOR STUDYING PLATELETS, BASED UPON THE LOW-ANGLE LIGHT SCATTERING TECHNIQUE, AND ITS APPLICATION IN EXPERIMENTAL TOXICOLOGY.

I. Minduksheva¹, N. Goncharov², E. Ermolaeva², I. Dobrylko¹, E. Senchenkova², M. Mironova², R. Jenkins³, A. S. Radilov² and A. Krivchenko¹. ¹*I.M. Khamidulina.

Platelets, being highly-labile structures, can be activated or inhibited under small influences. Despite understanding of the role of platelets in hemostasis, and a variety of methods for investigating their functionality, there is a need for simple quantitative analysis of their sensitivity to the main physiological agonists: ADP, thrombin, PAF, etc. A new method is presented for simultaneous monitoring of changes in shape and aggregation of platelets. The signal of light scattering alterations at angles below 6 degrees was shown to be determined by platelet aggregation dynamics. Over a range of larger angles (6-15 degrees), cell shape changes also contributed to the signal: (I) rounding, and (II) pseudopodia formation. The EC₅₀ value for ADP-induced rounding was 40 nmol l⁻¹. Aggregation kinetics showed 2nd order kinetics in relation to initial cell concentration. The rate constant depended on stirring conditions and on [Ca²⁺] in the medium. The method was used as a tool in experimental low-level intoxication by organophosphates and for studying delayed effects. Platelets of rats exposed to Russian VX differ from the control ones by their pronounced instability, which was sometimes expressed by the development of spontaneous activation and aggregation without adding ADP into the medium. Kinetic parameters of aggregation were significantly increased with regards to both maximal velocity of aggregation U_{max} and effective concentration EC₅₀. Toxicological experiments with fluoroacetate (FA), an inhibitor of TCA cycle, showed a hypersensitivity followed by a refractory (insensitive) state of rat platelets. The work was supported by the BioIndustry Initiative (BII) of the U.S. Department of State (Grant# BII-ISTC-2629).

2119 COOXIDATION MEDIATED XENOBIOTIC ACTIVATION AND CYTOTOXICITY BY 12-LIPOXYGENASE IN INTACT PLATELETS.

K. Lim, J. Kim, O. Bae, J. Noh, S. Chung and J. Chung. *College of Pharmacy, Seoul National University, Seoul, South Korea.*

Peroxidase mediated cooxidation process has been suggested as a major alternative pathway for xenobiotic activation other than hepatic cytochrome P450 monooxygenase system. Despite the wealth of reports on the potential involvement of cooxidation in the activation of various compounds, manifestation of cooxidation mediated xenobiotic activation in intact cell system without extra sources of peroxidase system has been very difficult to demonstrate, mainly due to the natural scarcity of peroxidase enzymatic activities. In the present study, arachidonic acid dependent

activation of the representative phenolic compound, α -naphthol was observed in intact platelet system as shown by covalent binding increases in arachidonic acid and α -naphthol concentration dependent manner. It suggests that prostaglandin H synthase (PHS) or 12-lipoxygenase (12-LPO), two major arachidonic acid dependent peroxidase systems in platelets, can mediate bioactivation of α -naphthol. Furthermore, this cooxidation process has resulted in enhanced cytotoxicities of α -naphthol against platelets. Interestingly, baicalein and CDC, inhibitors of 12-LPO attenuated the bioactivation of α -naphthol while inhibitors of PHS, indomethacin or aspirin was not effective, implying dominant role of 12-LPO in arachidonic acid initiated cooxidation in intact platelets. In addition, anti-oxidants prevented bioactivation and manifestation of α -naphthol cytotoxicity effectively, supporting the generation of radical or reactive oxygen species in the course of α -naphthol cooxidation. With these results, we believe that an important in vitro evidence of peroxidase-mediated xenobiotic activation was provided for understanding toxicological significances of peroxidase-mediated cooxidation in the xenobiotic bioactivation.

2120 DIFFERENTIAL ROLE OF NRF2 IN REGULATING THE INDUCIBILITY OF ANTIOXIDATIVE/ANTI-INFLAMMATORY DEFENSES BY 3H-1, 2-DITHIOLE-3-THIONE AND SIMVASTATIN IN MACROPHAGES.

H. Zhu^{1,3}, L. Zhang¹, M. Trush² and Y. Li^{1,3}. ¹DHLRI, The Ohio State University, Columbus, OH, ²The Johns Hopkins University, Baltimore, MD and ³VCOM, VTCRC, Blacksburg, VA.

Macrophages release reactive intermediates, including oxyradicals, which mediate inflammatory responses. On the other hand, macrophages are also targets of oxidative stress. These cells play a critical role in the pathogenesis of various chronic inflammatory disorders, such as atherosclerosis. Thus, understanding the signaling mechanisms controlling the antioxidative/anti-inflammatory defenses in macrophages is of importance for developing strategies for intervention of chronic inflammatory disorders. Accordingly, this study was undertaken to investigate the role of Nrf2 signaling in regulating both constitutive and inducible expression of antioxidative/anti-inflammatory defenses in mouse macrophages. The basal expression of a series of antioxidative/anti-inflammatory defenses was significantly lower in Nrf2^{-/-} macrophages than in wild-type (Nrf2^{+/+}) cells. These included catalase, glutathione (GSH), GSH peroxidase, glutathione reductase, GSH S-transferase, NAD(P)H:quinone oxidoreductase 1, and heme oxygenase-1. Incubation with 3H-1,2-dithiole-3-thione (D3T), a chemoprotectant, resulted in significant induction of the above antioxidative/anti-inflammatory defenses in Nrf2^{+/+} macrophages, but not in Nrf2^{-/-} cells. Notably, incubation of macrophages with the lipid-lowering drug, simvastatin at 1-10 μ M also led to significant induction of the above antioxidative/anti-inflammatory defenses. Surprisingly, induction of the above cellular defenses by simvastatin was independent of Nrf2 signaling. Regardless of the differential role of Nrf2 signaling in D3T- and simvastatin-mediated upregulation of cellular defenses, treatment of macrophages with either D3T or simvastatin afforded significant protection against oxidative and electrophilic injury. Studies are currently underway to investigate if upregulation of the above cellular defenses also attenuates the formation of macrophage proinflammatory cytokines.

2121 INHIBITION OF CHOLESTERYL ESTER HYDROLASE IN THP-1 CELLS BY ORGANOPHOSPHORUS OXONS.

J. A. Crow, B. L. Middleton and M. K. Ross. Center for Environmental Health Sciences, Mississippi State University, Mississippi State, MS.

Cholesteryl ester hydrolase (CEH) is an enzyme found in human monocytes and macrophages that catalyzes the hydrolysis of cholesteryl esters to yield free cholesterol. This step is believed to play an important regulatory role in macrophage reverse cholesterol transport, the process in which cholesterol in atherosclerotic plaques is transported to the liver via high density lipoprotein particles for secretion in bile. Human CEH differs from hepatic carboxylesterase 1 (CES1) by only 5 amino acids. CES1 is inhibited stoichiometrically by organophosphorus (OP) oxons, the active metabolites of OP pesticides. We hypothesize that exposure to OP pesticides may adversely affect macrophage reverse cholesterol transport thus increasing the risk of atherosclerosis. To test this hypothesis, we have measured the ability of several OP oxons to inhibit CEH/CES1 activity. CEH/CES1 activity was measured using para-nitrophenyl valerate as the substrate. Chlorpyrifos oxon, paraoxon, and methyl paraoxon all inhibited CEH/CES1 activity in THP-1 cell lysates. IC50 values are in the nanomolar range with chlorpyrifos oxon being the most potent and methyl paraoxon the least potent. We also treated intact cells in culture with the three oxons and found that CEH/CES1 was inhibited by each of the three oxons with paraoxon being the most potent. Chlorpyrifos oxon was found to be less stable in the culture media than paraoxon possibly accounting for the difference in relative potency in cell lysates versus whole cells. THP-1 cell viability was not affected by exposure to the oxons. Our results also suggest that treatment of THP-1 cells inhibits CEH/CES1 in the intact cell. We conclude that exposure to OP oxons does have the potential to slow macrophage reverse cholesterol transport by inhibiting CEH/CES1. (Supported by NIH-NCRR RR070710 and NIH-P20 RR017661)

2122 IMPACT OF RNA DEGRADATION ON AFFYMETRIX GENE EXPRESSION PROFILES.

P. Ancian, S. Leuillet, A. Milicov and R. Forster. CIT, Evreux, France.

RNA quality appears to be one of the most important factors influencing the success of in vivo gene expression experiments. RNA degradation can occur within minutes after the animal sacrifice due to the presence of RNases in tissues, or can be induced by the treatment with toxicants that produce tissue necrosis. The present study was undertaken to evaluate the impact of RNA degradation on reproducibility and comparability of gene expression profiles. Rat liver total RNA was extracted from frozen tissue using a combined Trizol/RNeasy® method. RNA was then partially degraded by incubation with different RNase A concentrations. RNA quality was assessed on the Agilent 2100 bioanalyzer and expressed as the RNA Integrity Number (RIN), a new metric developed by Agilent® based on the overall electropherogram profile of the RNA sample. Four groups of three RNA samples were prepared with decreasing qualities, corresponding to RIN values of 9, 8, 7 and 5, respectively. RNA were then analyzed on pangenomic Affymetrix GeneChip® Rat Genome 230 2.0 arrays. Comparisons were performed between lower and high quality RNAs (taking the highest RIN RNA as the baseline). Transcripts with more than a 1.5-fold modulation factor and a p-value lower than 0.05 were selected. Our results show that RNA degradation produced artefactual changes of transcriptomes and that the number of modulated transcripts increased with RNA degradation: 33 transcripts were found to be modulated between RIN 9 and 8 groups, 281 between RIN 9 and 7 groups and 878 between RIN 9 and 5 groups. In addition, we found that the more pronounced the degradation of the RNA, the greater the apparent modulation of the transcripts. Sample clustering analysis showed a clear separation between RNA with a RIN of 5 and the other samples. We have shown in this experiment that RNA degradation can lead to biases which lead to erroneous conclusions on Affymetrix gene expression profiling experiments. These findings show the pertinence of the RIN as a RNA quality parameter and its potential value in the definition of RNA quality thresholds.

2123 DETECTION OF HIGH MW PROTEINS IN MALDI-TISSUE IMAGING.

B. Leinweber, J. D. Cohen, T. J. Monks and S. S. Lau. Pharmacology and Toxicology, University of Arizona, Tucson, AZ.

BTraditional matrix assisted laser desorption/ionization (MALDI) mass spectroscopy tissue imaging provides excellent coverage of protein profiles within the 2-25 kDa range. We used the traditional method applying matrix with a robotic spotter to the surface of a tumor bearing kidney section from an Eker rat treated with a renal carcinogen 2,3,5-tris-(glutathion-S-yl) hydroquinone. Tumor specific proteins with MW at 10944 (annexin II light chain), 11636 (β -2-microglobulin), histone H4 (11234 Da), 13901 Da (acetylated histone H2B), and 14005 Da (methylated histone H2A.3) were detected. In order to detect proteins with higher MW and resolution to determine posttranslational modifications, we developed a method that offers sensitive coverage of proteins of 25-100 kDa. The new method is derived from the MALDI sandwich method where a frozen tissue section is placed on top of a drop of matrix dissolved in a fixation solution. More matrix is deposited on top of the tissue in a manner to limit protein delocalization and to enhance the signal. Triton X-100 doubled the number of separate MALDI peaks to >1000 peaks. A series of quality controls was developed. Protein peaks of 41841 and 41873 Da, corresponding to the α -cardiac and α -skeletal muscle isoforms of actin, were detected in the heart. Evidence for phosphorylation of cardiac myosin light chain (MLC) was region specific. MALDI images of a contracting rat colon and stomach were obtained. Similar to the heart, it was possible to distinguish between isoforms of actin differing by 20-40 Da. Signals of the appropriate M/z to be regulatory smooth muscle MLC and MLC-P were also observed. Evidence from MALDI and immunohistochemistry is presented for the presence of a phosphoprotein upstream of MLC-P. In summary, the ethanol Triton X-100 sandwich method allows the detection of large MW proteins in tissue images. The strength of the signal will allow hypothesis testing, in conjunction with other techniques, rather than simple profiling. (GM39338, ES06694)

2124 MICROARRAY ANALYSIS OF THE GLOBAL GENE EXPRESSION RESPONSE TO N-NITROSODIMETHYLAMINE EXPOSURE UNDER DIABETIC CONDITIONS.

A. Dombkowski¹, M. A. Abdelmegeed¹, J. Xiao², D. Cukovic¹, S. Kain² and R. E. Novak¹. ¹Institute of Environmental Health Sciences, Wayne State University, Detroit, MI and ²Agilent Technologies, Santa Clara, CA.

The incidence of diabetes has risen dramatically in the United States during the past decade. Recent evidence implicates diabetes as a risk factor for development of chronic non-alcoholic liver disease and hepatocellular carcinoma (HCC). The ex-

pression of CYP2E1 is increased under low insulin (diabetic) conditions, and CYP2E1 catalyzes the metabolism and bioactivation of numerous xenobiotics, including nitrosamines. To examine the hypothesis that diabetic conditions result in increased risk of hepatic disease and HCC associated with increased xenobiotic metabolism, global gene expression profiles resulting from N-nitrosodimethylamine (NDMA) treatment were obtained using high density microarrays. Primary cultured rat hepatocytes, maintained under low insulin were treated with 1, 10, and 100 μ M NDMA for 24 hours. Gene expression changes in the NDMA-treated samples were compared with untreated controls using Agilent Rat whole genome oligonucleotide microarrays. Stringent data filtering by statistical analysis, minimum intensity criteria, and fold change cutoffs identified over 100 genes that fall into two primary clusters, which are up- and down-regulated in a dose-dependent manner. Principal components analysis reveals subtle changes in expression between untreated cells and those treated at the two lower concentrations, while the 100 μ M treatment results in a significant change in expression for many genes. Pathway analysis of the differentially expressed genes indicates that the phosphatidylinositol signaling, calcium signaling, and MAPK pathways are altered in response to NDMA treatment. Bioinformatics analysis of the upstream regions of co-clustered genes provides evidence of common transcription factors, including Sp1, Egr, and RREB. This research has been supported by National Institute of Environmental Health Sciences grants ES03656, ES06639 and Agilent Technologies.

2125 ENVIRONMENTAL INFLUENCES ON THE FETAL EPIGENOME.

D. C. Dolinoy, J. R. Weidman and R. L. Jirtle. *Department of Radiation Oncology, Duke University, Durham, NC.*

A growing body of evidence suggests that epigenetic mechanisms of gene regulation, such as DNA methylation and histone modifications, are influenced by the environment, and play an important role in the early origins of adult disease. Using the viable yellow Agouti (Avy) mouse, we investigated environmental determinants of DNA methylation following maternal exposures. Methylation of cytosine-guanine (CpG) dinucleotides is stochastic among isogenic Avy mice, causing variation in coat color from yellow (unmethylated) to pseudoagouti (methylated). Unmethylated mice also experience higher rates of obesity, diabetes, and tumorigenesis due to constitutive ectopic Agouti expression. Since the epigenome is particularly susceptible to dysregulation during embryogenesis, we investigated the effect of dietary genistein supplementation of mice during gestation, at levels comparable with humans consuming high-soy diets. Maternal genistein shifted the coat color distribution of Avy offspring toward pseudoagouti and increased methylation of six CpG sites in the Avy retrotransposon. We also investigated the effect of low-level dietary bisphenol A (BPA) exposure of mice during gestation. Maternal BPA shifted the coat color distribution of Avy offspring toward yellow and decreased methylation of six CpG sites in the Avy retrotransposon. These studies provide the first evidence that *in utero* dietary exposure to genistein or BPA affects gene expression and alters susceptibility to disease by permanently modifying the epigenome. Interestingly, maternal co-exposure to BPA and genistein or BPA and methyl donors such as folic acid, choline, and betaine restores normal stochastic variation in offspring coat color. Similar to rescuing the adverse phenotype of a genetic knockout, these results indicate that environmental co-exposures may result in a cumulative effect that restores normal stochastic variability at Avy and other metastable epialleles, providing interesting implications for public health interventions for environmental exposures affecting the epigenome.

2126 EFFECT OF BISPHENOL A ON SELECTED DIFFERENTIATION MARKER GENES IN EMBRYOID BODIES DERIVED FROM CYNOMOLGUS MONKEY EMBRYONIC STEM CELLS.

Embryonic stem (ES) cells are useful model systems to test drugs and chemicals and a potential to predict or anticipate toxicity in humans. Experiments using murine ES cells to determine embryotoxicity have been reported, but there is little information available concerning embryotoxicity tests using primate ES cells. In this study, we examined the effect of 0.1 μ M and 10 μ M bisphenol A (BPA) on differentiation of the CMK-6 Cynomolgus monkey ES cell line to determine embry-

otoxicity. Embryoid bodies (EB) were cultured for 7, 14, and 21 days, and a real time RT-PCR was performed to determine gene expression of Oct-3/4, a stem cell marker gene, and several other differentiation markers. Treatment with 0.1 μ M BPA slightly stimulated the expression of Oct-3/4, indicating an inhibition of EB differentiation. BPA also slightly stimulated the expression of α -fetoprotein, an endoderm differentiation marker, suggesting BPA can affect the differentiation of ES cells to various cell types. These results indicate that this system may work as a model for determining embryotoxicity.

2127 TAMOXIFEN AND ETHYNYLESTRADIOL CO-TREATMENT IN C57BL/6 MOUSE UTERUS: GROSS, MORPHOMETRIC AND CDNA MICROARRAY GENE EXPRESSION ANALYSIS.

C. J. Fong, L. D. Burgoon, K. J. Williams, A. L. Forgacs and T. R. Zacharewski. *Biochemistry and Molecular Biology, Michigan State University, East Lansing, MI.*

Tamoxifen (TAM), the treatment of choice for estrogen receptor positive (ER) breast cancer, has been associated with an increased incidence of endometrial cancer in post-, but not pre-menopausal women. Compared to ethynyl estradiol (EE), a potent agonist, TAM elicits a partial ER-mediated uterotrophic response in immature rodents. Moreover, cotreatment with 1000 μ g/kg TAM antagonizes the uterotrophic effect induced by 30 μ g/kg EE. To further investigate the molecular basis of the antiestrogenicity of TAM in the uterus, a time course analysis was conducted in immature, ovariectomized C57BL/6 mice treated with EE, TAM, EE with TAM or vehicle (sesame oil) following a single dose at 2, 4, 8, 12, 18, 24 hrs or after three daily treatments (3x24 hrs). Uterine wet weight increased by 18 hrs for all treatments. However, at 3x24 hrs, EE-induced uterotrophy is hindered upon cotreatment with TAM. This inhibitory effect is reflected by the absence of an EE-mediated increase in luminal circumference. However, TAM did not antagonize the hallmark estrogenic increase in luminal epithelial cell height. cDNA microarray analysis at 3x24 hrs, using a 2x2 factorial study design, identified 127 EE-induced genes that were further induced in the presence of TAM. These differentially expressed, TAM-augmented genes represented pathways involved in vascularization (i.e. Pgf, Smad5) and ion homeostasis (i.e. App, Commd1). In addition, the expression of 107 EE-induced and 16 EE-repressed genes were antagonized by TAM cotreatment. These antagonized genes were associated with cell cycle regulation (i.e. Cdc25c, Rb) and DNA replication (i.e. Helb, Nusap1), and, in general, consistent with morphometric results. These changes indicate that TAM selectively alters EE-elicited gene expression, consistent with its ability to antagonize EE induction of uterine wet weight.

2128 THE ISOTHIOCYANATE MOIETY IS REQUIRED FOR SULFORAPHANE (SFN)-MEDIATED INHIBITION OF LIGAND ACTIVATION OF THE HUMAN STEROID AND XENOBIOTIC RECEPTOR (SXR).

E. Poulton¹, D. L. Eaton¹, C. Zhou², K. E. Thummel² and T. K. Bammler¹. ¹*Env. Occup. Health Sciences, University of Washington, Seattle, WA* and ²*Pharmaceutics, University of Washington, Seattle, WA.*

SFN [1-isothiocyanato-4-(methylsulfonyl)butane] is one of several naturally occurring isothiocyanates (ITC) found in broccoli. SFN has chemoprotective properties, demonstrated both in vitro and in a number of animal models. Chemoprevention is presumed to occur via activation of the NRF2/Keap1/ Antioxidant Response pathway. We previously demonstrated that SFN is an effective antagonist of the human SXR (also called hPXR). SXR is involved in the regulation of expression of many genes integral to drug metabolism, including CYP3A4 and MDR1. HEPG2 cells were transiently transfected with human SXR and a luciferase reporter coupled to the CYP3A4 promoter. We then evaluated the ability of the ITCs Cheirolin [1-isothiocyanato-3-(methylsulfonyl)propane], Iburin [1-isothiocyanato-3-(methylsulfonyl) propane], Erucin [1-isothiocyanato-4-(methylthio)butane] and phenylethyl isothiocyanate (PEITC), and SFN-nitrile (5-(methylsulfonyl)pentanenitrile, which lacks the ITC moiety) to inhibit rifampicin activation of SXR. SFN-nitrile had no inhibitory activity towards SXR, but Iberin and Cheirolin showed antagonistic activity nearly equipotent to SFN. The results also demonstrated that the alkyl sulfide moiety must be at least partially oxidized to maintain strong SXR antagonism, as Erucin, the analog with a fully reduced alkyl sulfide moiety, showed significantly less antagonism than the other analogs. Molecular modeling identified several cysteine and lysine residues in the ligand binding domain that might be targets for covalent interaction with ITCs. Future studies will evaluate the functionality of these sites via site directed mutagenesis. (Supported by a pilot project from P30 CA15704).

2129 EVALUATION OF THE EFFECTS OF XENETIX® AND DOTAREM® ON HEPATIC AND RENAL GENE EXPRESSION IN RATS.

P. Bourriner², S. Leuillet¹, A. de Sousa¹, B. Bonnemain², P. Ancian¹ and R. Forster¹. ¹CIT, Evreux, France and ²Guerbet, Roissy, France.

Xenetix® and Dotarem® are leading contrast agents for X-ray and magnetic resonance imaging, respectively. The present study was undertaken to evaluate the effects of these compounds on hepatic and renal gene expression in rats. Male Wistar Han rats were treated by a single intravenous injection of Dotarem® at 2.5, 5 or 10 mmol/kg or Xenetix® at 2, 4 and 10 g iodine/kg. Liver and kidneys were sampled 4 and 48 hours after treatment. Blood biochemistry investigations were performed on blood samples taken at necropsy. A microscopic examination was carried out for liver and kidney samples preserved in buffered formalin. RNA was extracted from the tissues and transcriptomes were studied with Affymetrix pangenomic rat arrays. Transcripts with at least a statistically significant two-fold modulation factor between treated and control groups were retained at each time point. Concerning the in-vivo part of the study, effects of the compounds were low in intensity, consistent with those described in the literature and included increased blood urea levels in high dose groups on day 1 and liver and kidney vacuolations at microscopic examination on both days. In animals given Dotarem®, 109 genes (85/31 on day 1/3) were modulated in the kidney and 86 (62/26 on day 1/3) in the liver. Some of these modulated genes were implicated in oxydoreductase activity. After treatment with Xenetix®, gene expression profiling showed that 201 genes (169/22 on day 1/3) were differentially expressed in the kidney and 97 (66/34 on day 1/3) in the liver. The principal ontologies involved were symporter activity, cell migration in the kidney and cation homeostasis in the liver. The effect of treatment with Dotarem® or Xenetix® on the whole kidney and liver transcriptomes appeared to be immediate, with more pronounced effects in the kidney. However, these changes were rapidly reversible, with a return to basal levels on day 3. These results are consistent with the low toxicity in non-clinical studies and with the good tolerance profile of these products in clinical use.

2130 DOWN-REGULATION OF THE UVA-INDUCED COLLAGENASES EXPRESSION BY THE SAPONINS ISOLATED FROM ROOTS OF PLATYCODON GRANDIFLORUM IN HUMAN FIBROBLASTS.

K. Oh^{1,2}, Y. Chung³, S. Roh⁴ and H. Jeong^{1,2}. ¹Pharmacy, Chosun University, Kwangju, Kwangju, South Korea, ²Research Center for Proteineous Materials, Chosun University, Kwangju, South Korea, ³Division of Food Science, Chinyu International University, Chinyu, South Korea and ⁴Jangsaeng Doraji Research Institute of Biotechnology, Jangsaeng Doraji Co., Ltd., Chinyu, South Korea.

Exposure of ultraviolet (UV) light, a harmful environmental stress, on the skin often induces chronic skin diseases such as skin cancer as well as photoaging, and the mechanisms of these skin damages are closely associated with up-regulation of collagenases activities. Moreover, UV-induced collagenases cause connective tissue damage and the skin to become wrinkled and aged. In this study we investigated the effect of saponins isolated from Roots of Platycodon grandiflorum (CKS) on UVA-induced collagenase-1 and collagenase-3 expression in human fibroblasts. Treatment with CKS significantly decreased the reactive oxygen species (ROS) formation under UVA irradiation. To investigate the significant cis-acting regions which collagenases promoters, transient transfection experiments were carried out using reporter vectors harboring deleted collagenases promoters. The transcriptional factor binding sites for AP-1 could be important for the induction of collagenase-1 and -3 by CKS. These results suggested that CKS can inhibit UVA-induced collagenase-1 and -3 expressions might be mediated through the AP-1 inactivation and inhibited ROS formation in human fibroblasts.

2131 CCAAT/ENHANCER BINDING PROTEIN β AND STEROIDOGENIC FACTOR-1 BINDING REGIONS IN THE PROMOTER OF TESTOSTERONE BIOSYNTHESIS ENZYMES ARE DIFFERENTIALLY BOUND FOLLOWING IN UTERO DIBUTYL PHTHALATE EXPOSURE IN RATS.

A. Kuhl, S. M. Ross and K. W. Gaido. CIIT Centers for Health Research, Research Triangle Park, NC.

It has been repeatedly demonstrated that prolonged *in utero* exposure of fetal male rats to dibutyl phthalate (DBP) can result in feminized phenotype characterized by malformed epididymides, hypospadias, cryptorchism, and retained thoracic nipples among others. These symptoms likely result from decreased expression of steroidogenic enzymes, and therefore reduced testosterone biosynthesis. However, the molecular mechanisms involved in changes in gene expression profiles are unknown. To understand these mechanisms in rats, an *in vivo* DNase footprinting protocol

was developed to provide a quantitative map of changes in DNA-protein interactions in the promoter region of steroidogenic genes, including StAR, SR-B1, CYP11A1, and CYP17, that are down-regulated following an *in utero* DBP exposure. This map was compared to vehicle control and a non-toxic phthalate diethyl phthalate (DEP). Regions with altered DNase protection were coordinated with a specific DNA binding protein by electrophoretic mobility shift assay, and binding activity confirmed with chromatin immunoprecipitation. Results demonstrated altered DNase protection at multiple putative transcription factor binding sites in each gene. These results were observed along with diminished testis testosterone and mRNA levels of the corresponding steroidogenic gene. Of these DNA binding proteins, only regions mapping to CCAAT/enhancer binding protein beta (c/ebp β) and steroidogenic factor-1 (SF-1) were altered in all genes examined. ChIP confirmed declines in DNA-protein interactions of c/ebp β in DBP treated animals, while SF-1 was observed to be reduced in both DEP and DBP treatments. These results suggest that while decreased SF-1 activity is involved, interference of c/ebp β binding is critical in the observed inhibition of transcription. These observations provide a snapshot of changes in the structure of transcriptional machinery and suggest a possible mechanism of action resulting from DBP exposure.

2132 CHARACTERIZATION OF GENOMIC EXPRESSION IN THE ZUCKER DIABETIC FATTY RAT MODEL SYSTEM VERSUS ZUCKER RATS.

P. Shaver-Walker², R. Rooney¹, D. Patel¹ and S. Groom¹. ¹Genome Explorations, Memphis, TN and ²Charles River Labs, Preclinical Services Montréal Inc., Senneville, QC, Canada. Sponsor: C. Banks.

Three groups of 10 males (resulting in 2 pools of n=5) representing 3 Zucker strains were included in the study. Two strains of Zucker diabetic fatty (ZDF) rats (an accepted rodent model for Type 2 diabetes) and normal Zucker rats were subjected to weekly oral glucose tolerance (OGT) tests at 10 to 13 weeks of age to assess the onset of diabetic symptoms. ZDF animals exhibited associated symptoms starting at approximately 12 weeks of age.

Liver was isolated from test animals and total RNA was analyzed for global gene expression using Affymetrix Rat Genome 230 2.0 arrays. Discriminant analysis was able to distinguish male Zucker Diabetic Fatty rats (Obese and Hyperinsulinemic) from male Zucker rats (Normal). Previous analyses of both male and female 18 week old strains and of younger Diabetic and/or Hyperglycemic animals identified 19 relevant probe sets. Of these common sets, 18 distinguished the normal strain from the two Obese/Hyperinsulinemic strains. Only one probe set distinguished each diseased strain from the other.

The results indicate that gene expression changes in the ZDF model system are highly consistent between diseased strains and differ significantly from normal strains.

2133 COMPENSATORY MECHANISMS IN BILIARY EXCRETION AFTER 2/3-PARTIAL HEPATECTOMY (2/3-PH) IN MICE.

I. L. Csanaky, X. Lei and C. D. Klaassen. Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS.

Bile formation is one of the most important functions of liver and maintenance of biliary excretory function is crucial in various pathological conditions. Bile flow and composition are good indicators of liver function. During the last decade, mice have become a very important model in biomedical research, because of the availability of genetically modified mice. However, neither the flow nor composition of bile is well characterized in mice. Therefore, we examined the effects of an important model of liver regeneration, 2/3-PH, on bile formation and composition of main bile constituents; and on gene expression of important transporters in liver. Bile and liver samples were collected from sham and 2/3-PH mice 24 and 48 hrs after surgery. Bile flow in 2/3-PH mice was similar to that of the sham-operated control mice, calculated per body weight, and about 55% higher in 2/3-PH mice when calculated per liver weight. Bile flow depends mainly on bile acid and glutathione excretion. After 2/3-PH, the biliary excretion of glutathione decreased, whereas bile acid excretion increased per gram liver weight. Therefore, the compensatory increase in bile flow was due to a 2.4-fold increase in bile-acid excretion per gram of liver. The mRNA expression of neither the bile acid uptake transporter, Ntcp, nor the canalicular efflux transporter, Bsep, was altered by 2/3-PH, indicating that these bile acid transporters may have functional reserve capacity. The biliary excretion of cholesterol did not change after 2/3-PH, but phospholipid excretion into bile was markedly increased. The increased expression of the phospholipid transporter, Mdr2, may be responsible for this latter phenomenon. In conclusion, the compensatory maintenance of bile flow in mice after 2/3-PH is largely due to an increased excretion of bile acid, and the increased expression of Mdr2 markedly enhances the excretion of phospholipids, that is known to protect the biliary tree against the harmful effect of enhanced bile acid excretion. (Supported by NIH-grant ES-09716)

2134 CHEMICAL GENETIC APPROACHES TO UNRAVEL THE MOLECULAR PATHWAYS CONTROLLING REGENERATION.

S. Sengupta^{1,2,3}, L. K. Mathew^{1,2,3}, E. Andreasen^{1,2,3}, R. T. Peterson⁴ and R. L. Tanguay^{1,2,3}. ¹Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR, ²EHSC, Oregon State University, CORVALLIS, OR, ³MFBS, Oregon State University, CORVALLIS, OR and ⁴Cardiovascular Research Center, Massachusetts General Hospital, Charlestown, MA.

Zebrafish have the remarkable ability to regenerate a number of tissues following amputation or injury. Previously, we have demonstrated that TCDD exposure impairs caudal fin regeneration and we have used TCDD as a small molecule probe to disrupt the normal regenerative process to define the interactions between AHR and other signal transduction pathways. Our work with TCDD suggested that a small molecule screening approach may be a powerful way to identify molecular pathways that choreograph tissue regeneration. As a proof of this principle, we have developed a rapid throughput in vivo regeneration assay to identify chemicals that disrupt tissue regeneration. Two days post fertilization larvae were amputated and continuously exposed to individual chemicals from a 2000 member structurally diverse small molecule library. Regenerative progression was assessed microscopically at three day post amputation. A "hit" was defined as a small molecule that led to aberrant regeneration and approximately 2.6% of the chemicals were scored as "hits" in the primary screen. The hits were grouped into chemical classes and the largest chemical cluster consisted of 12 glucocorticoids. Consistent with the known actions of glucocorticoids as ligands for glucocorticoid receptors (GR), a number of known GR-target genes such as GILZ, FKBP5 and SOX9b were induced in glucocorticoid exposed larvae. To further reveal that small molecule targets can be defined in this model, we demonstrate that the GR is necessary and sufficient for the inhibitory response. We further characterized that glucocorticoids specifically target early stages of regeneration such as wound healing and blastema formation. Collectively, our studies indicate the feasibility of exploiting chemical genetics to unravel molecular signaling networks in vivo. Supported by NIEHS grants ES10820, ES00210, and #ES03850

2135 LOSS OF C/EBP ALPHA RESULTS IN DIMINISHED DNA DAMAGE INDUCED G1 CHECKPOINT.

R. Ranjan and R. C. Smart. Cell Signaling and Cancer Group, Department of Environmental and Molecular Toxicology, North Carolina State University, Raleigh, NC.

The ability of cells to respond to DNA damage is essential to ensure the integrity of the genome. DNA damage can initiate the activation of cell cycle checkpoints in G1, S and G2 phases preventing the replication of damaged DNA and allowing time for DNA repair. The basic leucine zipper transcription factor, CCAAT/enhancer binding protein α (C/EBP α) is involved in the regulation of mitotic growth arrest and differentiation in some cells. C/EBP α is induced by DNA damage through a p53-dependent pathway in keratinocytes. C/EBP α knockdown by siRNA resulted in a diminished G1 checkpoint after UVB-induced DNA damage suggesting a role for C/EBP α in the G1 checkpoint. Recently, we have shown that C/EBP α is induced by DNA damaging agents in cell types other than keratinocytes such as dermal fibroblasts. The objectives of this study are to determine the pathway of C/EBP α induction in fibroblasts and the physiological consequences of C/EBP α induction. We report here that C/EBP α induction by UVB in fibroblasts does not require p53, however, caffeine, an inhibitor of ataxia-telangiectasia-mutated kinase and ataxia-telangiectasia-mutated and Rad3-related kinase (ATM/ATR), blocks C/EBP α induction by UVB. Inhibitors of glycogen synthase kinase 3 beta (GSK-3 β) also block C/EBP α induction by UVB. To determine whether C/EBP α has a role in cell cycle regulation, fibroblasts were isolated from C/EBP α -null and wild type mice, placed in culture and synchronized by serum deprivation. After release into the cell cycle, fibroblasts from the two genotypes progressed similarly into S-phase and no differences were observed between the two genotypes. When cells were treated with UVB in early G1 phase, entry of cells into S-phase was increased in C/EBP α -null fibroblasts compared to wild type. These results provide genetic evidence that C/EBP α has a role in the G1 checkpoint. Our results also suggest that C/EBP α induction by DNA damage in fibroblasts involves ATM/ATR and GSK-3 β but does not require p53.

2136 PHARMACOKINETIC AND PHARMACODYNAMIC EFFECTS OF 2'-MOE MODIFIED PHOSPHOROTHIOATE ANTISENSE OLIGONUCLEOTIDES ADMINISTERED DIRECTLY TO LUNG AND CEREBROSPINAL FLUID.

R. S. Geary¹, M. Pearce¹, E. Wanciewicz¹, G. Hung¹, S. P. Henry¹, J. Matson¹, J. Crosby¹, J. Karras¹, S. Gregory¹ and R. Z. Yu¹. ¹Pharmacokinetics, ISIS Pharmaceuticals, Inc., Carlsbad, CA and ²ISIS Pharmaceuticals, Carlsbad, CA.

Objective: To determine the PK/PD relationships for proprietary modified antisense oligonucleotides (ASO) following either intrapulmonary delivery utilizing aerosols targeting IL-4R α mRNA in the mouse lung or direct intracerebroventricular

lar (ICV) or intrathecal (IT) injection targeting SOD-1 mRNA in the rat central nervous system (CNS). Methods: Animal studies were conducted to characterize the tolerability and pharmacokinetics. ASO concentrations in target tissues were measured using either hybridization ELISA or capillary gel electrophoresis (CGE). IL-4R α protein in lung was measured by flow cytometry and target mRNA measurements by qRT-PCR. Results: Aerosol doses up to 1 mg/kg IL-4R α ASO were well-tolerated in mice. Significant reduction in IL-4R α protein expressed in pulmonary epithelial cells and inflammatory cells resulted in significant amelioration of asthma symptoms in mice during induced acute inflammation. Minimum effective doses were observed at 1 to 10 μ g/kg and lung tissue concentrations < 50 ng/gram. The ASO half-life in the lung was estimated to be 2 to 4 days, and once weekly dosing sustained the IL-4R α antisense effect and reduced AHR and airway inflammation in mice. In a brain study, ICV administration in rats was well tolerated up to 100 μ g/day for one month of continuous infusion. At this dose, the brain and spinal cord SOD-1 ASO concentrations were 55 $\pm$ 15 μ g/g and 20 $\pm$ 12 μ g/g, respectively. The SOD-1 mRNA reduction was 40-60% of saline treated animals in brain and approximately 20% in spinal cord. The ASO half-life in the brain ranged from 14 to 30 days. Comparison of IT and ICV administration on kinetics and antisense effects will also be presented. Conclusions: Direct topical administration to lung and brain of 2'-MOE modified PS ASOs was well tolerated, exhibited potent dose and concentration-dependent antisense activity, and was well-correlated with the ASO pharmacokinetics.

2137 REGIONS OF ALTERED METHYLATION (RAMS) IN LUNG/BRONCHI OF RATS EXPOSED TO MAINSTREAM TOBACCO SMOKE (MTS).

J. I. Goodman¹, J. M. Phillips², G. M. Curtin³ and D. J. Doolittle³. ¹Pharmacology & Toxicology, Mich. State U., East Lansing, MI, ²Biochem. & Mol. Biol., Mich. State U., East Lansing, MI and ³Research and Development, R. J. Reynolds Tobacco Co., Winston-Salem, NC.

DNA methylation, i.e., 5-methylcytosine, is an epigenetic modification regulating gene expression. Aberrant methylation plays a key role in carcinogenesis and we hypothesize that it also contributes to other toxicities. We evaluated the effect of MTS on the methylation status of rat lung/bronchiole DNA. Male and female Sprague Dawley rats were exposed to air only, sham or low, medium, or high (0.06, 0.20, or 0.80 mg wet total particulate matter/L) doses of MTS for 1 hr/day, 5 days/wk for 13 wk. After treatment, a procedure involving methylation-sensitive restriction digestion, arbitrarily primed PCR, and capillary electrophoretic separation of the PCR products was utilized to identify regions of altered DNA methylation (RAMs). In males, a dose-response relationship was evident based on the total number of RAMs that formed in each treatment group, and a trend towards increasing RAMs was observed for the females. In the males, total RAMs detected in the low, medium and high dose groups were 26, 32 and 41, respectively. In the females, total RAMs discerned in the low, medium and high dose groups were 29, 31 and 33, respectively. Of the 41 total RAMs in the males at the high dose, 3 were also seen in the low/medium dose groups, while 38 were unique to the high dose rats. The females displayed 33 RAMs at the high dose, 4 of which were also observed in the low/medium dose groups while 29 were unique to the high dose. While new methylations predominated, complete hypomethylations exhibited a dose-response relationship. Histopathological analysis revealed minor changes, an increase in the number of macrophages in both sexes in all dose groups, and an increase in goblet cells at the high dose in the male rats only. Importantly, this group exhibited the most RAMs. In conclusion, MTS treatment of both male and female rats alters DNA methylation in lung/bronchi, and it is possible that this epigenetic change may serve as a biomarker of exposure.

2138 AGING AS A MODULATOR OF CHEMICAL TOXICITY.

C. Corton¹ and H. M. Mehendale². ¹NHEERL, U.S.-EPA, Research Triangle Park, NC and ²Department of Toxicology, University of Louisiana, Monroe, LA.

One of the greatest achievements of the last 8 decades is better health care, which has led to a burgeoning aging population. By 2030, the number of individuals older than 65 will more than double to 72 million, and one of every five Americans will be older than 65. The rapid growth in the number of older Americans has many implications for public health, including the need to better understand the risks posed to older adults by environmental exposures to chemicals. The capacity to appropriately respond to toxicant exposure declines with normal aging and may be exacerbated in individuals with pre-existing health conditions. This decline can result in compromised pharmacokinetic and pharmacodynamic responses to environmental exposures encountered in daily activities. The objective of this symposium is to highlight recent examples of altered sensitivities to xenobiotic exposure by aging in a number of tissues and to bring forward substantial new information on what is

known about their mechanisms. This symposium will include an overview of molecular pathways that are altered in aging including those involved in xenobiotic metabolism and will include important examples of how aging alters chemical sensitivity in the liver, kidney and brain.

2139 GENETIC PATHWAYS THAT REGULATE AGEING IN MODEL ORGANISMS.

V. Longo. *University of Southern California, Los Angeles, CA.* Sponsor: C. Corton.

Mutations in genes affecting metabolism, stress responses, endocrine signaling, and telomeres can increase the life spans of a number of model organisms. These mutations revealed evolutionarily conserved pathways for aging that extend life span in response to sensory cues, caloric restriction, or stress. This talk will focus on how mutations affecting longevity pathways delay age-related disease, and how the molecular analysis of these pathways is leading to a mechanistic understanding of linkage of aging and chemically-induced disease susceptibility.

2140 IDENTIFICATION OF CHANGES IN XENOBIOTIC METABOLISM ENZYME EXPRESSION DURING AGING USING COMPREHENSIVE TRANSCRIPT PROFILING.

C. Corton. *NHEERL, U.S.-EPA, Research Triangle Park, NC.*

Aging changes the expression of enzymes and transporters important in the metabolism and fate of xenobiotics in the liver, kidney and intestine. Most notable are the changes in a number of CYP and xenobiotic transporter genes regulated by the nuclear receptors PXR, CAR and PPARalpha. In order to gain a comprehensive understanding of the effects of aging on xenobiotic metabolism, we are using DNA microarray analysis to study the changes that occur in a number of tissues relevant to metabolism of xenobiotic chemicals at different life stages in mice and rats. We show remarkable changes in phase I, II and III gene expression in the liver that are both species-dependent and -independent. We are using this information to create a biologically realistic pharmacokinetic model that predicts altered metabolism of xenobiotics in aged populations.

2141 INCREASED SUSCEPTIBILITY OF AGING KIDNEY TO ISCHEMIC INJURY: ROLE OF INCREASED MMP EXPRESSION.

A. Parrish. *College of Medicine, Texas A&M, College Station, TX.* Sponsor: C. Corton.

Aging is associated with an increased incidence and severity of acute renal failure; however, the molecular mechanisms underlying the increased susceptibility remain undefined. These experiments were designed to investigate the influence of age on the response of the kidney to ischemia. Renal slices were prepared from young (5 month), aged ad libitum (24 month) and aged caloric restricted (24 month) male Fischer 344 rats and subjected to ischemic stress (anoxia, 100% N₂) for 0-60 min or to the nephrotoxicant cisplatin (2 mM, 4 hr). As assessed by intracellular ATP and GSH content, and LDH and alpha-GST leakage into the culture media, slices from aged ad libitum rats were more susceptible to injury than young counterparts. Importantly, caloric restriction attenuated this increased susceptibility to injury. In an attempt to identify molecular pathway(s) underlying this response, microarray analysis was performed on tissue harvested from the same animals used for the functional analysis. Several age-related changes in the expression of MMPs were identified via microarray. Therefore, we examined the impact of aging, and caloric restriction, on the expression of MMPs and TIMPs in the rat kidney using quantitative RT-PCR. Aging was associated with increased expression of MMP-7, -9, -13 and -14 (MT1-MMP) and TIMP-1; interestingly these changes were attenuated by caloric restriction. The increased expression of these MMPs was associated with increased gelatinase, collagenase and matrix type MMP activity. Ablation of MMP-14 expression in NRK cells using shRNA attenuated several changes associated with ischemia, suggesting that MMPs may mediate ischemic injury in the kidney. In summary, overexpression of MMPs may be associated with the increased susceptibility of aging kidney to ischemic insult.

2142 AGING PROTECTS AGAINST CHLORDECONE AMPLIFIED PROGRESSION OF HALOALKANE HEPATOTOXICITY.

H. M. Mehendale. *Department of Toxicology, University of Louisiana, Monroe, LA.*

The prevailing general perception is that aging increases drug- and chemical-induced hepatotoxicity. Although considerable age-dependent adverse drug reactions and hepatotoxicity are known, the reasons for this variation remain to be fully ex-

plored. Among the different models used to study hepatotoxicity, chlordecone (CD) + CCl₄ interactive model is the most potent and well known for its advantages: toxicity at individually nontoxic levels, extensive liver damage leading to death due to hepatic failure, and mechanisms studied at length, etc. In adult rats (3 months) this interactive toxicity results in 67-fold amplification of hepatotoxicity and lethality. However, older F344 (14 months) and SD and F344 rats (24 months) are completely resilient to the interactive toxicity of CD+CCl₄. The toxic effects of this interaction in adult rats (3 months) include extensive hepatotoxicity characterized by elevated ALT and AST enzyme levels, hepatic necrosis, bankruptcy in cellular energy, failed tissue repair leading to progression of injury, hepatic failure, and death. In contrast, in aged rats, only transient hepatic damage was observed even though the initial bioactivation-mediated liver injury of CCl₄ in CD pre-exposed rats is the same as adults. Molecular changes in genes involved in the cell cycle may be the basis for this protection. The mechanisms underlying this remarkable resiliency in advanced age towards highly amplified toxicity of CCl₄ are of significant interest, particularly because these findings suggest that it may be possible to stimulate liver tissue repair in advanced age.

2143 AGING AND SENSITIVITY TO ORGANOPHOSPHORUS INSECTICIDE: TOXICOKINETIC AND TOXICODYNAMIC FACTORS.

C. Pope. *Oklahoma State University, Stillwater, OK.*

Organophosphorus insecticides inhibit acetylcholinesterase to elicit neurotoxicity. Aged rats exhibit higher acute sensitivity than adults to the prototype organophosphorus insecticide parathion. We studied possible toxicokinetic and toxicodynamic processes that may contribute to the differential sensitivity. While detoxification potential (paraoxonase, carboxylesterase activities) in liver and lung was generally similar between age groups, plasma carboxylesterase activity was significantly lower in aged rats and was highly correlated with acute sensitivity to parathion across multiple age groups. As carboxylesterase is particularly important in detoxification of parathion (by stoichiometric binding to its active metabolite, paraoxon), age-related differences in plasma carboxylesterase activity could contribute to the differential sensitivity. The neurochemical consequence of extensive acetylcholinesterase inhibition is accumulation of synaptic acetylcholine, which in turn causes overstimulation of cholinergic receptors and a variety of cholinergic signs of toxicity. We thus compared striatal acetylcholine release/accumulation in adult and aged rats both in vitro using brain slices and in vivo using microdialysis. Using superfused striatal slices, the muscarinic autoreceptor agonist carbachol was less potent at inhibiting acetylcholine release in aged rats compared to adults, suggesting potentially lesser presynaptic adaptation to elevated acetylcholine levels following anticholinesterase exposure in aged rats. In contrast, using in vivo microdialysis, markedly less striatal acetylcholine accumulation was noted in aged rats compared to adults after treatment with equitoxic dosages of parathion (9 vs 27 mg/kg, sc). These results suggest that presynaptic inhibition of acetylcholine release may be less effective with aging, but that cholinergic toxicity may be elicited by lesser brain acetylcholine accumulation in aged animals. Both toxicokinetic and toxicodynamic factors may therefore play a role in the differential sensitivity to anticholinesterases in aging.

2144 GENE EXPRESSION AND IMMUNE SYSTEM SUSCEPTIBILITY.

D. Germolec¹ and R. Luebke². ¹*Integrative Toxicology Group, NIEHS, Research Triangle Park, NC* and ²*Immunotoxicology Branch, U.S. EPA, Research Triangle Park, NC.*

Differences in gene expression, resulting from an individual's genetic makeup or induced by environmental exposures, may have a significant impact on an organism's response to pathogens, neoplastic cells and/or exogenous antigens. Immune system homeostasis and responses to pathogens or neoplastic cells requires a tightly regulated and progressive cascade of gene expression, protein synthesis and effector function. Exposure to drugs or chemicals may alter expression of genes culminating in suppression of function or inappropriate stimulation of normally protective responses. Inherited polymorphisms may also predispose the host to express greater sensitivity or susceptibility to exogenous agents, either as a direct result of xenobiotic-gene product interaction or indirectly by increasing effects of xenobiotics on gene expression. The use of microarray technologies as discovery tools to detect altered immune pathways and/or function by examining genome-wide changes in expression patterns following exposure to environmental agents is increasing. This technology can be used to evaluate human and laboratory animal samples for similarities in expression profiles following accidental or voluntary exposure to a variety of potential toxic compounds. The symposium will address two separate but related uses of genomics techniques: detection of modified gene expression in ostensibly normal individuals following exposure to xenobiotics, and characteriza-

tion of gene expression profiles that predispose an individual to greater adverse effects of xenobiotics. Presenters will address gene expression as a means to discover mechanisms of toxicity and/or targeted pathways that would not have been evident if standard functional assays were used in isolation, and how gene expression can be used to screen chemicals for skin sensitization potential and explain differential susceptibility to dermal sensitization or demonstrate systemic immune effects following exposure to inhaled metals. The influences of host genotype on inflammatory responses to environmental factors such as ozone and particulate materials will also be discussed.

2145 USE OF MICROARRAYS TO INVESTIGATE MECHANISMS OF IMMUNOTOXICITY.

S. B. Pruett. *Cellular Biology & Anatomy, LSU Health Sciences Center, Shreveport, LA.*

Mechanistic risk assessment for cancer has proved to be very useful and has allowed more realistic evaluation of risks for compounds that cause cancer in rodents by mechanisms that are not operative in humans. However, mechanistic risk assessment has not been actively pursued with regard to immunotoxicology end points. As genomic data are considered along with functional parameters used to screen for immunotoxicity, we will obtain information on both their predictive value as screening tools and their ability to identify potential mechanisms of action. Several practical issues must be considered in conducting such studies, including but not limited to: selection of a microarray platform, use of a purified cell type vs. whole organ homogenates, use of animals or cells that are or are not challenged to induce an immune response prior to analysis, the number of replicates needed, whether samples should be pooled or not, and whether confirmation by other methods is required. A study investigating the mechanisms by which ethanol inhibits innate immunity to bacteria in mice provides an example indicating that microarrays can provide mechanistic clues that would be difficult to obtain in any other way. Preliminary data suggest that following exposure to ethanol, similar changes in gene expression are observed in both stimulated and non-stimulated macrophages. Finally, the use of microarrays to develop a systems biology approach to immunotoxicology would seem to now be feasible, and this may allow generalizations and predictions of immunological effects not possible at the present time. This work was supported by grants from NIEHS and NIAAA.

2146 IDENTIFICATION AND PRIORITIZATION OF GENE EXPRESSION CHANGES IN DENDRITIC CELLS AS A SCREEN FOR CONTACT ALLERGY.

C. Ryan¹, L. Gildea¹, L. Foertsch¹, J. Kennedy¹, R. Dearman², I. Kimber² and E. Gerberick¹. ¹Procter & Gamble Company, Cincinnati, OH and ²Syngenta Central Toxicology Laboratory, Macclesfield, United Kingdom.

Allergic contact dermatitis (ACD) resulting from skin exposure to sensitizing chemicals is a common occupational and environmental health problem. A critical step in the induction of ACD is the uptake and processing of protein-bound allergens by Langerhans cells (LC), resident immature dendritic cells of the skin. Following an encounter with a chemical allergen, LC become activated and subsequently migrate from the skin to the draining lymph nodes, undergoing a maturation process during the journey. Many changes have been reported to occur in LC as a result of hapten exposure including the induction of signal transduction pathways and the modulation of cell surface markers and cytokine expression. To explore further the concept of chemical allergen induced LC activation and maturation, the process has been modeled in vitro using human peripheral blood-derived dendritic cells (DC) as surrogates for LC. Microarray analysis provided a list of genes which were significantly changed, at the transcriptional level, following exposure of the DC to a model contact allergen. Subsequent analysis of a sub-set of those genes identified specific genes which appear to demonstrate good sensitivity, specificity, dynamic range, and reproducibility and thus may prove useful in the development of screening methods for skin sensitization and may also provide mechanistic information on the immune recognition phases of ACD.

2147 CYTOKINE GENE POLYMORPHISMS AND SUSCEPTIBILITY TO CHRONIC INFLAMMATORY DISEASES IN OCCUPATIONAL SETTINGS.

B. Yucesoy and M. I. Luster. *HELD/TMBB, CDC/NIOSH, Morgantown, WV.*

There is a wide range of inter-individual variation in susceptibility to occupational and environmental related diseases. Mechanisms underlying susceptibility are largely unknown, but genetic predisposition is suspected to be a major factor. Recent evidence suggests that common polymorphisms in immune/inflammatory and antioxidant genes contribute to the pathogenesis of many complex human dis-

eases. In light of this, functional variants of these genes have been examined for evidence of association with pulmonary fibrosis in a group of ex-coal miners, accelerated decline in lung function in firefighters and irritant contact dermatitis in healthcare workers. Several significant associations appeared between cytokine gene variants and disease progress and/or severity. The tumor necrosis factor- α (TNF α) -308, -238 and interleukin-1 receptor antagonist (IL-1RA) +2018 variants were found associated with the development and severity of silicosis. Also, associations between accelerated decline in lung function and genetic variations in several genes which regulate inflammation were found in firefighters that can not be explained by smoking history. Specifically, the presence of IL-1 RA +2018, TNF α -238 and -308 variants were associated with the decline rate of lung function as measured by FEV₁. Individual differences in response to common irritants (sodium dodecyl sulfate, benzalkonium chloride and sodium hydroxide) were investigated in a group of healthcare workers. Initial results confirmed interindividual variability in irritant susceptibility and provided base for investigating the role of genetic variations in response to irritants. In conclusion, the data suggest that genetic variations play a role in individual variability to certain occupational diseases. Such information can be used to help identify the most susceptible populations and apply relevant information to the risk assessment process by determining safe exposure levels for the most susceptible groups of workers.

* These studies were supported in part by an IAG with the NIEHS (Y1-ES-6927266) and a grant from the CDC/OGDP (921Z4FP)

2148 A PROSPECTIVE STUDY OF GLOBAL EXPRESSION PROFILING IN WHOLE BLOOD SAMPLES FROM INDIVIDUALS EXPOSED TO METAL FUMES.

D. Christiani^{1,5}, Z. Wang¹, D. Neuberg², L. Su¹, J. Kim³ and J. Chen⁴. ¹Harvard School of Public Health, Boston, MA, ²Harvard Medical School, Boston, MA, ³U.S. EPA, Research Triangle Park, NC, ⁴UNC School of Public Health, Chapel Hill, NC and ⁵Massachusetts General Hospital, Boston, MA. Sponsor: R. Luebbe.

Although inhalation of metal particulates is a documented cause of pulmonary and airway inflammation, an exploratory study of microarray analyses in whole blood total RNA sampled before and after occupational welding-fume exposure supported the existence of systemic responses following inhalation of metal particulate. To evaluate the duration of particulate-induced gene expression changes, we conducted a follow-up study using a similar population one year after the original study. We recruited 15 individuals with welding fume exposure and 7 non-exposed individuals. Twelve of the 22 individuals (8 in exposed group and 4 in non-exposed group) also were monitored in our previous study. Whole blood total RNA corresponding to three time points, including baseline, immediately after ~6 h of exposure, and 24 h after baseline, was analyzed using cDNA microarray technology. Similar to our previous observations, exposure-induced expression alterations in non-smoking individuals were found in genes clustered in several Gene Ontology Biological Processes, related to Immune Response and Programmed Cell Death. The small number of genes with changed expression 24 hours after baseline compared to baseline suggest that acute particulate-induced effects were transient. Comparison of paired *t* statistic distributions indicate more global changes of gene expression in the previous study, which had significantly higher level of exposure. Although smoking was a confounding factor, a dose-response pattern of global expression was evident in smokers with higher level exposure in the previous study, in contrast to almost no changes in smokers with lower level of exposure in this study. Taken together, our results demonstrated the importance of applying a paired-sample study design in population studies that generate high dimensional data and an expected high degree of inter-personal variations.

2149 ENVIRONMENTAL EXPOSURES, IMMUNE FUNCTION, AND HOST VULNERABILITY.

J. Hollingsworth. *Duke University, Durham, NC.* Sponsor: D. Germolec.

The severity of airways disease can result from a complex interaction between host genetic vulnerability and environmental exposures. Studies in humans and mice indicate that both the biologic response to inhaled toxins and immunologic function are dependent on genetic background. This presentation will focus on the mechanisms through which common environmental exposures, such as ambient ozone (O₃), can modify both innate and adaptive immune function, and the role of host genotype in determining the severity of effects. The biological response to inhaled O₃ includes: recruitment of inflammatory cells, enhanced airway hyperreactivity, perturbations in alveolar macrophage function, and alterations in the production of pro-inflammatory mediators. Exposure to ambient O₃ can enhance or suppress allergic inflammation depending on the dose and timing of exposure, indicating that inhaled O₃ can modify adaptive immune function. We recently observed that innate immunity was modified in mice exposed to O₃ and subsequently challenged

with an aerosol of LPS. Pre-exposure to O₃ dramatically reduced total cells, alveolar macrophages, and neutrophils in the lung following inhalation of LPS. However, mice that were pre-exposed to O₃ had higher concentrations of total protein in lavage fluid, suggesting enhanced lung injury. Moreover, O₃ pre-exposure resulted in elevated levels of proinflammatory cytokines in the lavage fluid and serum following LPS challenge. Studies using genetically-engineered animals demonstrated that the biologic response to O₃, inhaled endotoxin, and allergic response to antigen are dependent on the expression of innate immune genes. We have demonstrated the role of toll-like receptor 4 in airway response to O₃, inhaled endotoxin, and allergic asthma. Current studies are focused on characterization of novel innate immune genes, which can regulate the severity of airways disease to a variety of inhaled challenges. Cumulatively, these studies support a complex interaction between a commonly inhaled toxin, innate immune function, and host genetic vulnerability. Supported by NIEHS (ES12717, ES101945, and ES11961) and NIAID (AI058161).

2150 IMPACT OF THE QUALIFICATION OF SAFETY BIOMARKERS ON DRUG DEVELOPMENT AND REGULATORY REVIEW: ROLE OF THE PREDICTIVE SAFETY TESTING CONSORTIUM.

L. Y. Rosenblum¹ and D. Robinson-Gravatt². ¹*International Drug Development, Kyowa Pharmaceutical Inc., Princeton, NJ* and ²*Pfizer Global Research and Development, Groton, CT.*

Progress in the application of biomarkers of drug-induced toxicity in both drug development and regulatory decision-making processes depends upon two important achievements: (1) scientific consensus on the identification and qualification of biomarkers of toxicity that are animal-model specific and able to bridge preclinical and clinical applications; and (2) regulatory acceptance of newly qualified biomarkers. Both achievements require a formal venue for sharing data, assays and samples across multiple pharmaceutical companies; a process for the review of qualification study protocols and data at the FDA; and entry points for application of qualified biomarkers in regulatory decision-making. The Predictive Safety Testing Consortium (PSTC) has been organized through the C-Path Institute as a venue for sharing and critically evaluating qualification data from studies using model as well as proprietary compounds. In collaboration with the FDA, the PSTC will share data to support the development of a process for review and acceptance of biomarkers, as well as to define potential regulatory applications of accepted biomarkers. The PSTC has initially organized itself around four biomarker areas: nephrotoxicity, hepatotoxicity, vascular injury, and genotoxic and non-genotoxic carcinogenicity. This Symposium will highlight the collaborative work of the PSTC and discuss current and future regulatory applications at the FDA.

2151 PROCESS MAP FOR QUALIFICATION OF GENOMIC BIOMARKERS OF DRUG SAFETY.

F. M. Goodsaid. *Genomics/OCP/OTS/CDER/FDA/HHS, Silver Spring, MD.*
Sponsor: L. Rosenblum.

A key deliverable of the Critical Path at the FDA are biomarkers for drug safety evaluation that can improve drug safety for new drugs and the efficiency of drug development. A draft process map for biomarker qualification was developed as part of a CRADA and other collaborations. This process map has been discussed internally at the FDA and used in the design of enabling regulatory mechanisms for the evaluation of qualification data submissions. The results of the collaborations we have had thus far help in the discussion of these mechanisms. Our collaborations show that comprehensive biomarker qualifications must be defined in the context of the application of each biomarker. These qualifications are expensive and will require the knowledge, experience, compounds and tissue banks from more than one company to qualify for known valid biomarker classification. Our experience also shows a clear synergy between the willingness of the industry to generate qualification data and of the FDA to have an efficient and transparent qualification process in place to evaluate this data.

2152 OVERVIEW OF THE PREDICTIVE DRUG SAFETY TESTING CONSORTIUM.

W. B. Matres¹ and J. Vonderscher². ¹*The Critical Path Institute, Tucson, AZ* and ²*Genomics Institute of the Novartis Research Foundation, San Diego, CA.*

In keeping with the Critical Path Initiative, a collaborative qualification of preclinical biomarkers of drug safety benefits the drug-development process, and a clear definition on the application of qualified biomarkers in regulatory decision-making is a powerful driver for participating in such a collaboration. The Predictive Safety

Testing Consortium (PSTC) is the result of an effort by the pharmaceutical industry, the FDA and the C-Path Institute to assemble a team of scientists from the pharmaceutical industry and from health authorities to share data from studies on multiple compounds leading to a consensus both on the data as well as the regulatory process for the qualification of these biomarkers. Key to the successful founding of the PSTC was the creation of a novel legal framework to provide benefits to both those who discover the exploratory markers as well as those who participate in their qualification. In addition to addressing anti-trust issues, the legal agreement among participating companies and C-Path specifically addresses intellectual property (IP) considerations, including IP that companies may bring into the consortium, as well as that which may be developed during the efforts of the consortium, and describes data sharing processes and obligations. One of the challenges facing the PSTC is the development of a data management resource for biomarker qualification. These data include not only the discrete new biomarker measurements, but also the standard toxicological and histopathological parameters collected during biomarker studies. These data must be collected and stored in a standard format (e.g. SEND/CDISC) that 1) supports the range of analyses and correlation testing necessary for biomarker qualification, and 2) anticipates clinical as well as preclinical data. This session will review the organizational structure, plans, schedule, and data management tasks of this Consortium, as well as the impact of the PSTC on discussions of regulatory policy at the FDA.

2153 IMPACT ON DRUG DEVELOPMENT AND REGULATORY REVIEW OF THE QUALIFICATION OF NOVEL BIOMARKERS OF NEPHROTOXICITY.

F. D. Sistare¹ and J. Vonderscher². ¹*Safety Assessment, Merck and Co., Inc., West Point, PA* and ²*Genomics Institute of the Novartis Research Foundation, San Diego, CA.*

The need for improved biomarkers of nephrotoxicity in drug development is exemplified by experiences where routine measures of BUN and serum creatinine fail to report the low grade kidney histopathological lesions that can be seen in animal toxicology studies. The C-Path Predictive Safety Testing Consortium's Kidney Toxicity Working Group has collected and pooled comparative performance data from rat studies using 17 different kidney toxicants and 3 kidney non-toxicants, that are anchored in traditional histopathology and measurements of BUN, serum creatinine, and/or urinary albumin. Measurements were made among samples from these studies using several of 16 candidate accessible urinary biomarkers including lipocalin-2, uromodulin, trefoil factor-3, osteopontin, GST-alpha, GST-mu, clusterin. Initial data are demonstrating that some candidate biomarkers can add significant value over BUN and serum creatinine, but keen awareness of important limitations, especially regarding the kinetics of the biomarker response duration, regional specificity of the injury, and biological relationship to the underlying histopathologic process will define their potential clinical utility. Samples remaining from these studies, along with additional independent sample sets identified from rat and non-human primate studies of the member companies with 9 additional kidney toxicants and 2 kidney nontoxicants are targeted for expanded assessments of these endpoints to establish the most promising panel to bridge into a clinical qualification strategy.

2154 IMPACT ON DRUG DEVELOPMENT AND REGULATORY REVIEW OF THE QUALIFICATION OF NOVEL BIOMARKERS OF HEPATOTOXICITY.

P. Wier. *Safety Assessment, GlaxoSmithKline Pharmaceuticals, King of Prussia, PA.*

Hepatotoxicity is probably the most prevalent preclinical and clinical adverse drug effect. Traditional biomarkers of liver injury include serum enzyme activities and levels of bile constituents that variably reflect cholestatic injury or cytotoxic hepatocellular injury, serum markers of hepatic synthetic functions, and certain acute phase proteins. These markers have proven, practical utility but improvements in sensitivity and specificity of biomarkers for hepatotoxicity are still needed. Within the Predictive Safety Testing Consortium, the Liver Working Group (LWG) is primarily focused on the progression to validation and regulatory acceptance of novel, exploratory liver toxicity biomarkers with added value over current markers. This presents a unique opportunity to collectively define the largest gaps in the current arsenal of biomarkers for hepatotoxicity, to harvest toxico-/proteo-/metabolic biomarker-discovery research, generate cross-validation data, and foster a common understanding of validated uses for new biomarkers. The "omics" era of biomarker research has yielded novel candidate markers that may increase sensitivity or specificity for cholestatic and cytotoxic hepatocellular injury, candidate markers for manifestations of liver toxicity (e.g., steatosis) not well-covered traditionally, and candidate markers to suggest modes of hepatotoxicity. These candidate markers include non-invasive (e.g., blood or urine based) markers for use in concert with established Clinical Pathology makers as well as those for use in conjunction with histopathology, such as mRNA signatures. The LWG has embarked on a collective

process to identify the most promising of these novel markers, collect the breadth of data necessary to define their uses and limitations, and achieve consensus on their validation.

2155 IMPACT ON DRUG DEVELOPMENT AND REGULATORY REVIEW OF THE QUALIFICATION OF NOVEL BIOMARKERS OF VASCULAR INJURY.

M. P. Lawton¹ and R. Snyder². ¹Drug Safety Research and Development, Pfizer Inc., Groton, CT and ²Schering-Plough Research Institute, Lafayette, NJ.

There are no sensitive or specific biomarkers for drug-induced vascular damage. Moreover, extrapolation from preclinical findings of vascular injury to human risk is poorly understood. Restrictions in available knowledge and tools limit accurate risk management of vascular injury. These weaknesses can be addressed through the development and clinical translation of predictive biomarkers, mechanistic and clinical investigations to increase understanding of species differences, and advances in regulatory practices and policy based on emerging science and validation of new biomarkers. The Vascular Injury Working Group has exchanged data, samples, and reagents that members have generated and has used this information to help identify candidate exploratory and probable valid biomarkers for which comprehensive prospective qualification studies across Consortium members can be designed. Some of the candidate biomarkers resulted from the application of Systems Toxicology, in which the overlap of information across genomic, proteomic and metabolomic platforms has synergistically defined exploratory biomarker sets.

2156 AIR POLLUTION, OXIDATIVE STRESS AND NEUROTOXICITY: AN OVERVIEW.

B. Veronesi. NHEERL/NTD/CTMB, U.S. EPA, Research Triangle Park, NC.

Increases in neurodegenerative diseases (classic and variant patterns suggest a multifactorial etiology, that combines environmental exposures with susceptibility factors. The numerous biological and chemical contaminants carried on particulate matter (PM) can damage target cells and tissues through oxidative stress pathways. It is also known that inhaled particles exit the lungs and enter the circulation where they distribute to numerous organ systems, including the brain. Since the brain is highly vulnerable to oxidative stress damage, the possibility that it is also targeted by PM is of great concern. This workshop will present experimental evidences that identifies PM also damages the brain and defines oxidative stress as an important factor to that damage.

Dr. Veronesi (US EPA) will begin by describing the neuropathic response of transgenic (ApoE^{-/-}) mice chronically exposed to concentrated ambient PM (CAPs). Cultures of immortalized microglia, later exposed to the same CAPs responded with cellular and genomic evidence of oxidative stress-stimulated pathways and an up-regulation of the innate immunity, Toll-like receptor. Dr. Campbell (Western University of Health Sciences) will report on the response of ovalbumin sensitized BALB/c mice exposed to PM sampled from several California sites. Her data suggest that PM may induce CNS inflammation through innate immunity pathways. Dr. MohanKumar (Michigan State University) will present recently published data which indicate that PM can affect parts of the brain that are involved in neuroendocrine functions, such as stress. Finally, Dr. Block (NIEHS) will describe the microglia-mediated, degeneration of dopaminergic neurons in mouse mesencephalic cultures, exposed to diesel emission particles. She will also present new data indicating that the MAC1 pattern recognition receptor mediates the diesel induced, DA neurotoxicity. These presentations confirm that the brain is affected in many ways by PM exposure. It is hoped that a rigorous exchange of comments and suggestions for future research results from this workshop.

2157 AIR POLLUTION, OXIDATIVE STRESS AND NEUROTOXICITY: INTRODUCTION.

L. Chen¹ and B. Veronesi². ¹Environmental Medicine, New York University, Sterling Forest, NY and ²NHEERL/NTD/CTMB, U.S. EPA, Research Triangle Park, NC.

Long-term exposure to fine particulate air pollution (PM_{2.5}) is associated with an increased risk of death from cardiopulmonary diseases. In addition to cardiopulmonary effects, ambient PM can also produce neuropathic effects such as histopathological changes in the nasal tissues and in the olfactory and respiratory nasal mucosa, olfactory bulb, cortical and subcortical structures, alterations of the blood-brain barrier, damage to cortical neurons, apoptotic glial cells and neurofibrillary tangles. These changes are plausibly related to the oxidative stress- produced by inhalation of ambient air pollutants. It has been shown that inhaled particles quickly enter the systemic circulation and distribute to numerous organ systems. Through this mechanism, the brain could be targeted by ambient PM. Another

mechanism that PM could affect CNS is the transport of ultrafine particles through the olfactory tubercles to gain entry to various CNS targets. PM may also affect the CNS, indirectly, through oxidative stress-cytokine/chemokine pathways. Ambient PM may also perturb the normal variations in metabolism, energy utilization, and organ function to produce neurodegenerated effects. Furthermore, ambient PM could also enhance the recruitment and maturation of monocytes to produce cytokines and chemokines and promote local inflammatory response. Acting independently or in combination, these pathways could produce systemic effects leading to morbidity and mortality in subjects chronically exposed to elevated levels of ambient PM.

In this workshop, experimental evidence of PM's multiple effects on the brain will be presented. Such evidence indicates that PM exposure causes neuropathological, neuroimmunological, and neurochemical changes to the mammalian CNS and identifies the brain as an additional and critical target of air pollutants.

2158 PARTICULATE MATTER, OXIDATIVE STRESS AND NEURODEGENERATION.

B. Veronesi¹, P. Gillespie² and L. Chen². ¹NHEERL/NTD, U.S. EPA, Research Triangle Park, NC and ²Environmental Medicine, New York University, Tuxedo, NY.

Particulate matter (PM) damages target tissues through oxidative stress (OS). Several reports indicate that inhaled ultrafine particles quickly exit the lungs, enter the blood stream and distribute to various organs, including the brain. To determine if there was a causal relationship between PM and neurodegeneration and if OS played a role in this susceptibility, the follow experiment was done. OS-prone, transgenic mice (Apo E^{-/-}) were chronically (4-6 mo) exposed by inhalation to concentrated ambient air pollution (CAPs) sampled from Tuxedo, NY. Morphometric analysis of serial brain sections showed a 29% reduction of immunohistochemically stained dopaminergic neurons sampled in the brain's substantia nigra. There was no significant loss of neurons in the brains of the CAPs-exposed background strain C57 mice, implicating the condition of OS as a predisposing factor to the susceptibility.

Since microglia mediate neuronal degeneration, their response to the above CAPs was examined in culture. Immortalized, mouse microglia (BV2), exposed to CAPs (>12 µg/ml) exhibited mitochondrial depolarization after 15 min exposure and significant increases in TNFα and IL-1β after 6 and 24 hr, respectively. The endogenous scavengers, glutathione and non-protein sulfhydryl, were significantly depressed after 2 hr exposure to CAPs (>25 µg/ml). Finally, cultures of BV2 microglia were exposed (4 hr) to CAPs (75 µg/ml) or to LPS (10ng), an endotoxin known to stimulate OS in microglia. RNA isolated from these cells, examined in Affymetrix microarrays, showed significant increases in genes coding for apoptotic pathways, superoxide demutase, TNFα and Toll receptors; and cell adhesion molecules. Together, these data suggest that the brain of OS-compromised animals can be damaged by exposure to CAPs and that microglia respond to CAPs with measurable expressions of OS.

2159 PARTICULATE MATTER PRESENT IN URBAN AIR POLLUTION ENHANCES INNATE IMMUNE RESPONSES IN THE MOUSE BRAIN.

A. Campbell¹, A. Nel², J. Araujo² and M. Kleinman³. ¹Department of Pharmaceutical Sciences, Western University of Health Sciences, Pomona, CA, ²Department of Medicine, University of California, Los Angeles, CA and ³Department of Environmental Medicine, University of California, Irvine, Irvine, CA.

While epidemiological studies demonstrate that exposure to particulate matter (PM) is associated with increased morbidity and mortality related to pulmonary and cardiovascular dysfunction, few reports have addressed adverse CNS effects. Since the etiology of most cases of neurodegenerative disorders is unknown, gene-environment interactions are likely to play a role in initiation and progression of such disorders. Studies were conducted to determine if PM, derived primarily from vehicle emissions, can up-regulate innate immune responses in mouse brains. Two different size fractions of PM were evaluated. Ultrafine (UF) fractions have an aerodynamic diameter < 0.15 µm and fine plus ultrafine particles (F+UF) have an aerodynamic diameter < 2.5 µm. In the first study, exposure to particulate matter (4 hr/day, 5 days/wk, for 2 weeks) from a site in Los Angeles, CA, increased NF-κB activation and levels of proinflammatory cytokines in the brain of ovalbumin sensitized BALB/c mice. In the second study, the same animal model and exposure paradigm was used but at a site in Riverside, CA. There was an upward trend in the CNS levels of NF-κB activation, the innate immune receptor Toll-like receptor 2 (TLR2), and nitrotyrosine content. However, the levels did not reach statistical significance. In the third study, ApoE^{-/-} animals were exposed (5 hrs/day, 3 days/wk for 5 weeks) at a Site at Los Angeles, CA. There was a significant increase in NF-κB activation and the levels of TLR2. Evaluation of the PM from both Los Angeles and Riverside shows that there are differences in the composition. This suggests that the

chemical makeup and duration of exposure significantly determines the extent of CNS responses. Since inflammatory events contribute to the pathogenesis of neurodegenerative diseases, the potential of PM to accelerate progression of such disorders requires further examination.

2160 EXPOSURE TO CONCENTRATED AMBIENT PARTICLES INCREASES STRESS AXIS ACTIVITY BY AFFECTING BRAIN STEM NORADRENERGIC NEURONS.

S. M. MohanKumar^{1,2}, M. P. Sirivelu², J. Harkema³ and P. S. MohanKumar^{2,3}.
¹Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI, ²Comparative Medicine and Integrative Biology Program, Michigan State University, East Lansing, MI and ³Department of Pathobiology and Diagnostic Investigation, Michigan State University, East Lansing, MI. Sponsor: B. Veronesi.

Exposure to concentrated ambient particles (CAPs) has been shown to increase stress axis activity. However, the underlying mechanism(s) for this effect is unknown. The paraventricular nucleus (PVN) of the hypothalamus contains corticotrophin releasing hormone neurons that are under the stimulatory control of noradrenergic neurons located in the brain stem. We hypothesized that CAPs exposure may lead to stimulation of noradrenergic neurons in the brain stem leading to increases in stress axis activity. Preexisting allergic airway disease may aggravate this phenomenon. In the present experiment, adult male Brown Norway rats were exposed to CAPs exposure (8 hr) with or without ovalbumin (OVA)-induced allergic airway disease. Rats were sacrificed 24 h after exposure and the brains were removed, frozen and sectioned. The PVN and brain stem noradrenergic neurons were microdissected. Serum was collected for corticosterone radioimmunoassay. Norepinephrine (NE) levels were measured in the PVN and the levels of tyrosine hydroxylase (TH) the rate-limiting enzyme in NE biosynthesis was measured in the brain stem. CAPs exposure significantly increased NE levels in the PVN, similar to that seen in OVA pretreatment. Corticosterone levels were elevated paralleling NE levels in the PVN. Site-specific changes were observed in TH levels with some noradrenergic nuclei showing a more pronounced increase than others. These results indicate that exposure to CAPs acts on the neuroendocrine system to stimulate the stress axis. The ability of CAPs exposure to affect brain stem neurons could have implications in autonomic regulation. The potential involvement of inflammatory mediators in this phenomenon is currently under investigation. Supported by NSF IBN 0236385 and NIH AG-027697.

2161 MICROGLIA MEDIATE DIESEL EXHAUST PARTICLES-INDUCE DOPAMINERGIC NEUROTOXICITY: THE ROLE OF MAC1.

M. Block¹, X. Wu¹, J. Hong¹ and B. Veronesi². ¹Laboratory of Pharmacology and Chemistry, NIEHS, Research Triangle Park, NC and ²NHEERL/NTD, U.S. EPA, Research Triangle Park, NC.

Inflammation and microglial activation are associated with Parkinson's (PD, a neurodegenerative disease that has been linked to environmental chemical exposure. Experimental reports indicate that exposure to air pollution can cause neuroinflammation and neuropathology. However, the underlying mechanisms are largely unknown. In this presentation, the response of microglia to nanometer-sized diesel exhaust particles (DEP) (< 0.22 µM) is examined. Mesencephalic neuron-glia cultures treated with DEP (5-50 µg/ml) responded with a dose dependent reduction of dopaminergic (DA) neurons, as determined by DA-uptake assay and tyrosine-hydroxylase immunocytochemistry (ICC). The selective toxicity of DEP for DA neurons was demonstrated by the lack of DEP effect on both GABA uptake and Neu-N immunoreactive cell number. The critical role of microglia was shown by the failure of neuron-enriched cultures to show DEP-induced DA neurotoxicity, where DEP-induced DA neuron death was reinstated with the addition of microglia to neuron-enriched cultures. OX-42 ICC staining of DEP treated neuron-glia cultures indicated microglia activation. Intracellular reactive oxygen species and superoxide were produced from enriched-microglia cultures in response to DEP. Neuron-glia cultures from NADPH oxidase deficient (PHOX^{-/-}) mice were insensitive to DEP neurotoxicity when compared to control mice (PHOX^{+/+}), emphasizing the importance of extracellular superoxide in DEP-induced neurotoxicity. Neuron-glia cultures from MAC1 knockout mice (MAC1^{-/-}) revealed that DEP (50 µg/ml) morphologically activated microglia in MAC1^{+/+} cultures, but not in MAC1^{-/-} cultures. Further, DEP failed to exert DA neurotoxicity in MAC1^{-/-} cultures, as determined by DA uptake and TH-positive cell counts. We conclude that DEP is selectively toxic to DA neurons through activation of the MAC1 receptor and the consequent production of extracellular superoxide.

2162 MOLDS, MYCOTOXINS AND DAMP BUILDING-RELATED ILLNESSES.

A. J. Harris¹ and J. J. Pestka². ¹Center for Toxicology & Environmental Health LLC, Little Rock, AR and ²Michigan State University, East Lansing, MI.

Health risks arising from mold contamination in water-damaged residential and commercial structures remain a major concern to the U.S. public. The black mold *Stachybotrys* and its toxins have been suggested to cause a spectrum of illnesses in exposed building occupants ranging from respiratory to neurological problems. Although this mold represents a small component of the indoor air mycoflora, it readily propagates on cellulose-based building materials subjected to water damage from condensation, leakage and flooding. Lawsuit and remediation costs to the insurance and building industries due to *Stachybotrys* have reached into the billions of dollars. However, significant questions remain relative to (1) specific hazards posed by the fungus, (2) whether it has unique mechanisms compared to other airborne fungi, and (3) the doses of the fungus or its toxins required for putative adverse effects. Furthermore, there has been a lack of validated methods to measure contamination by this organism and estimate actual human exposure. These problems have exacerbated by extensive litigation and media attention which sometimes interfere with scientific judgment and prevent reasoned dialogue. Recognizing these concerns, the 2004 Institute of Medicine (IOM) report "Damp Indoor Spaces and Health" stated that although "in vitro and in vivo research on *Stachybotrys chartarum* suggests that effects on humans may be biologically plausible; these observations require validation from more extensive research before conclusions can be drawn". This symposium will focus on new advances in our understanding of *Stachybotrys* and its toxins since the IOM report relative to: (1) detection and quantitation in indoor air environments, (2) capacity to target specific tissues and cause illness in animal models, (3) novel mechanisms of action and (4) identification and use of unique biomarkers of exposure.

2163 INDOOR MOLD AND ILLNESS IN TEXAS HOMES WITH VISIBLE WATER DAMAGE AND/OR MOLD.

A. J. Harris. Center for Toxicology and Environmental Health, Little Rock, AR.

Since the mid to late 1990s there has been increasing public attention on the presence of *Stachybotrys*, dubbed "black mold" by the lay media, in indoor air. An extremely wide range of symptoms and illnesses has been attributed to *Stachybotrys* by individuals in buildings where the mold has been found. This has led to a wave of litigation based largely on public perception of risks in the absence of sufficient scientific evidence to conclude that the presence of *Stachybotrys* in buildings is more likely to cause health effects than any other mold. Some molds, such as *Stachybotrys* and *Aspergillus* produce mycotoxins which have been shown to cause toxicity when ingested in foods highly contaminated with mold spores, but there is no evidence that inhalation of mycotoxin containing spores at concentrations found in indoor environments is sufficient to cause toxic effects. Current gaps in knowledge include an understanding of acute and/or chronic toxic effects of mycotoxins produced by indoor molds, assessment of likely exposure pathways in indoor environments, and the dose response relationship of mold spore inhalation and toxicity. In order to evaluate reported health effects after exposure to indoor mold, the indoor air mold spore level from 215 Texas homes with visible water and/or mold damage was compared to symptoms reported in building occupants. The most commonly reported health complaints by building occupants were allergies, allergy-like symptoms, sinus problems, respiratory symptoms, headache, and asthma. Twenty-two percent of the investigated homes had detectable airborne *Stachybotrys* spores ranging from 13 - 88,400 spores/m³. The mean *Stachybotrys* air concentration in homes was 1,082 spores/m³ (CI = 1,309). *Stachybotrys* spores contributed a median of 3% of the total spore count in indoor air. There was no statistical difference in the indoor airborne *Stachybotrys* spores in homes with occupants who reported health complaints and those that did not. In summary, the most commonly reported symptoms in homes with health complaints were those typically associated with exposure to many types of mold.

2164 ALLERGIC POTENTIAL OF INDOOR MOLDS.

M. D. Ward¹, Y. Chung¹, L. B. Copeland¹, M. K. Selgrade¹ and S. Vesper².
¹NHEERL, U.S. EPA, Research Triangle Park, NC and ²NERL, U.S. EPA, Cincinnati, OH.

Many fungi have been associated with allergic lung disease, but few are well studied and even fewer allergens of fungal origin are well characterized. Exposure to damp moldy environments has been associated with the exacerbation of asthma, but the role of molds in the induction of allergic asthma is less clear. Genetically predisposed individuals who inhabit water-damaged buildings may be susceptible to the development or exacerbation of respiratory allergy. Five molds (*Scopulariopsis brevi-*

caulis, *Trichoderma viride*, *Penicillium crustosum* Group, *Stachybotrys chartarum*, *Walleria sebi*) found in water-damaged homes in the Cleveland area have been linked to asthmatics. The moderately severe asthmatic children from homes that underwent mold remediation subsequently had a lower rate of asthma exacerbations compared to control asthmatics (non-remediated homes). Our hypothesis is that certain mold species may be more potent than others in asthma induction. Our mold/allergy mouse model exhibits many characteristics of human allergic asthma and has been used to demonstrate cause and effect, dose response, has compared the potency of 3 molds including *S. chartarum* to house dust mite (HDM), and has identified specific allergens. Studies have found that *S. chartarum* causes sensory irritation in immunized and non-immunized mice and elevated IgE with repeated exposures, in addition to anecdotal and published reports associating it with asthma. Studies from our laboratory have found that *S. chartarum* extracts induces both antigen non-specific and specific allergic asthma-like responses and that it is half as potent as HDM in the induction of allergic responses (rat leukemia basophil assay). Currently, we are evaluating the allergic potential of the other 4 molds in the Cleveland area homes that have been linked to asthma in our mouse model. There are still questions, both qualitative and quantitative, that need to be answered before the risks associated with indoor exposure to molds can be adequately assessed.

(This abstract has been reviewed by the NHEERL, US EPA and does not reflect the EPA policies.)

2165 TRICHOECENE-INDUCED INFLAMMATION AND APOPTOSIS: CELLULAR TARGETS AND MOLECULAR MECHANISMS.

J. J. Pestka, Z. Islam, J. R. Harkema, H. Bae and M. Li. *Center for Integrative Toxicology, Michigan State University, East Lansing, MI.*

Trichothecenes are a family of over 180 sesquiterpenoid mycotoxins that induce immediate early gene responses and apoptosis via the ribotoxic stress response and activation of mitogen-activated protein kinases. These include the satratoxins and the macrocyclic trichothecenes produced by *Stachybotrys* and *Myrothecium*. Double-stranded RNA associated protein kinase (PKR), Src family kinases and other kinases transduce this response, possibly through direct interaction with the ribosome. These pathways are operable in both in vitro leukocyte and neuronal models. The macrocyclic ring plays a key role in the molecular toxic effects of satratoxin which can bind and modify eukaryotic ribosomes. Downstream pathotoxic sequelae of the trichothecene-induced ribotoxic stress response are demonstrable in several in vivo models which are shedding light on potential human health hazards.

2166 ESTIMATION OF HUMAN EXPOSURE TO STACHYBOTRYS CHARTARUM AND ITS MYCOTOXINS.

D. C. Straus and T. L. Brasel. *Microbiology and Immunology, Texas Tech University health sciences Center, Lubbock, TX.* Sponsor: J. Pestka.

The spores of *Stachybotrys chartarum* (SC), which are about 7 to 10 microns in diameter, are rarely found in the air of buildings. The mycotoxins (trichothecenes) produced by SC, aka satratoxins, are found in the greatest abundance on the spores of SC. People inhabiting SC contaminated buildings sometimes demonstrate symptoms associated with trichothecene poisoning. This was difficult to explain because it was thought that the only way in which the satratoxins could get into the human body was by inhalation of SC spores. The presence of airborne satratoxins on particles smaller than spores was investigated using graded filters. A competitive enzyme linked immunosorbent assay (ELISA) was used to analyze the filter extracts. The results showed that extracts from spore free filters demonstrated statistically significant ($p < 0.05$) antibody binding that increased with sampling time. These data showed that satratoxins can become airborne free of SC spores. We next examined the presence of airborne macrocyclic trichothecene mycotoxins (MTM) in indoor environments (8 test buildings with known SC contamination and 4 control buildings). We used a high volume liquid impaction bioaerosol sampler under static or disturbed conditions and the above described ELISA. For test buildings, the results showed that detectable trichothecene levels increased with sampling time and short periods of air disturbance. Trichothecene levels ranged from <10 to $>1,300$ pg/cubic meter of air. Our data showed that airborne MTM can exist in SC contaminated buildings. Finally, we wanted to see if we could detect MTM in the tissues of people who were exposed to SC in contaminated buildings. Sera from occupants of contaminated buildings (test samples, $n=45$) and uncontaminated buildings (controls, $n=27$) were analyzed using the above described ELISA. Twenty three samples were significantly different ($P < 0.05$) from normal human serum, whereas only one of the control samples tested positive. These data suggest that trichothecene mycotoxins can be demonstrated (by ELISA) in the tissues of certain individuals exposed to SC in contaminated buildings.

2167 PULMONARY TOXICITY OF STACHYBOTRYS AND THE IDENTIFICATION OF A NOVEL BIOMARKER.

D. G. Dearborn^{1,2}, I. Yike^{1,2}, A. Distler³ and A. Ziady². ¹*Environmental Health Sciences, Case Western Reserve University, Cleveland, OH,* ²*Pediatrics, Case Western Reserve University, Cleveland, OH and* ³*Pharmacology, Case Western Reserve University, Cleveland, OH.* Sponsor: J. Pestka.

The lung as a target for *Stachybotrys* and its toxins will be discussed relative to animal models and human epidemiologic data. Acute pulmonary hemorrhage in young human infants continues to occur in the Cleveland area. The initial epidemiological suggestion of the involvement of *Stachybotrys* is substantiated by the continued observation that 90% of these infants (now 40 cases) come from *Stachybotrys* contaminated homes. Quantitative PCR has documented *Stachybotrys* elements in three of the infants' tracheal secretions. An infant animal model of acute instillation of *Stachybotrys* spores in the lungs of rat pups implicates macrocyclic trichothecenes (e.g. satratoxin G) in lung injury, although spores from isolates that produce only the simple trichothecenes ($>100\times$ less toxic) still produce extensive injury. The interplay of several mechanisms of pathogenesis will be presented. We have documented the formation of covalent adducts of purified human serum albumin by the macrocyclic trichothecene, satratoxin G (Yike et al., *Environ Health Perspect*, 114:1222 (2006)). These adducts have also been found in the serum of patients who were exposed to *Stachybotrys* in their homes including the most recent infant with pulmonary hemorrhage and both of his parents. Infant rats exposed intra-tracheally to *Stachybotrys* spores also have the satratoxin-albumin adducts in their serum. These adducts are the basis of a novel quantitative biomarker assay currently being developed.

2168 NASAL TOXICITY OF STACHYBOTRYS TOXINS.

J. R. Harkema, Z. Islam, K. N. Corps, C. J. Amuzie and J. J. Pestka. *Michigan State University, East Lansing, MI.*

Nasal airways are likely deposition sites for inhaled fungal spores and potential sites for toxicity caused by associated mycotoxins. Satratoxin G (SG) is a macrocyclic trichothecene mycotoxin produced by *Stachybotrys chartarum*, the black mold suggested to contribute to illnesses associated with water-damaged buildings. This presentation will 1) review comparative nasal anatomy and physiology, 2) describe nasal and neurotoxicity of SG and other related mycotoxins in mice, and 3) discuss the implications of these murine studies for assessing the risk to human health. In a recent study, mice were exposed to a single intranasal instillation of SG in saline or saline alone (controls) and killed 6h, 24h, 3days, 7days, or 28 days post instillation (PI). Nasal and brain tissues were examined for SG-induced microscopic and molecular alterations. At 24h PI, SG induced an acute rhinitis and elevated mRNA expressions of pro-inflammatory cytokines in both nasal ethmoid turbinates and in the adjacent olfactory bulb (OB) of the brain. SG also induced apoptosis of olfactory sensory neurons (OSN) in olfactory epithelium (OE). Apoptosis of OSN was identified with immunohistochemistry for caspase-3, electron microscopy for ultrastructural cell morphology, and RT-PCR for elevated expression of pro-apoptotic genes. Dose-response analysis revealed that the no effect and lowest effect levels at 24 h PI were 5 and 25 μg SG/kg bw, respectively, with severity increasing with dose. Time course studies with a single instillation of SG (500 μg /kg bw) indicated maximum atrophy of OE at 3 days PI. Atrophy of the olfactory nerve and glomerular layers of the OB was detectable by 7 days PI along with mild encephalitis. OE atrophy and OSN loss were still evident at 28 days PI. These results suggest that neurotoxicity and inflammation in the nose and brain are potential adverse health effects of exposure to satratoxins and *Stachybotrys* in water-damaged buildings.

2169 SAFETY OF DIETARY SUPPLEMENTS USED FOR WEIGHT REDUCTION: LESSONS LEARNED.

M. G. Soni¹ and P. Bolger². ¹*Vero Beach Hematology Oncology, Vero Beach, FL and* ²*Center for Food Safety and Applied Nutrition, U.S. Food and Drug Administration, College Park, MD.*

Recent results from the Center for Disease Control Survey indicate that an estimated 66% of U.S. adults are either overweight or obese. Use of dietary supplements to control body weight is rapidly increasing. A number of supplements that claim to help burn fat, block fat absorption, modulate carbohydrate metabolism, boost energy expenditure, suppress appetite, flush out excess water weight and control food cravings — all good outcomes for an eager dieter are readily available. A recent survey suggests that 7% of adults and 28% young obese women use weight loss supplements. Commercially, over 50 individual and 125 combination products of dietary supplements are available for weight reduction. Understanding the evidence of safety, efficacy, and quality for dietary supplements is critical when considering the potential public health impact of consuming these products. For example, although evidence of modest weight loss from ingestion of ephedra exists, potential

adverse effects have led the U.S. FDA to ban the sale of ephedra containing products. Evidence regarding the safety and efficacy of chromium, hydroxycitric acid, guar gum, chitosan, conjugated linoleic acid, ginseng, glucomannan, green tea, l-carnitine, psyllium, pyruvate, and St. John's Wort in weight loss has also been claimed by the manufacturers. The amount of well-designed research to substantiate the safety of many supplements for weight loss is sparse. In a recent article, Consumer Reports magazine published a list of the "dirty dozen" — 12 supplements, including some used for weight reduction, that have been linked either to serious adverse effects or to a strong theoretical risk. Critical safety assessment is the most logical way of understanding this issue. This session will take a critical look at previous safety assessments of dietary supplements used in weight loss and where and how the consideration of safety should or could be improved.

2170 ASSESSING THE HEALTH EFFECTS OF DIETARY SUPPLEMENTS.

P. M. Coates. *Office of Dietary Supplements, National Institutes of Health, Bethesda, MD.* Sponsor: M. Soni.

There is an increasing need for documentation of the health effects (both positive and negative) of dietary supplements used for weight management and weight reduction. Health effects identified in ecological or epidemiological studies have not always been replicated when ingredients are subjected to randomized controlled trials (RCTs). This is important, since there can be many confounding factors in assessing weight. Likewise, historical use of an ingredient (e.g., as part of an indigenous healing system) is no guarantee of safety or efficacy when it is provided as a dietary supplement for a 21st century application. There is a debate between accepting historical use without further testing and conducting the best RCTs whose applicability under different circumstances may be questioned. All of these issues must be considered when mounting a research agenda on the challenging topic of dietary supplements for weight management.

2171 EVIDENTIARY BASES FOR SAFETY AND EFFICACY CLAIMS IN SUPPLEMENTS FOR WEIGHT LOSS.

D. B. Allison. *Biostatistics, The University of Alabama at Birmingham, Birmingham, AL.* Sponsor: M. Soni.

The evidentiary bases for safety, efficacy, or toxicity claims in supplements for weight loss are sometimes difficult to discern. Different 'players' in the field (e.g., regulatory bodies, health care practitioners, consumer advocates, and the civil courts) often hold different views as to what constitutes adequate evidence. Indeed, the different evidentiary standards in such diverse settings are often quite appropriate and reflect fundamentally different goals of these groups. However, the critical questions are: What constitutes adequate evidence and from whose point of view? How studies should be designed and analyzed to offer such evidence? So, there is a need to review studies that are currently being designed and analyzed. The available data suggest that there is a large gap between a sound evidentiary basis and the type and amount of evidence that is actually collected in the weight loss supplement arena by virtually any standard. Finally, to make greater progress in this field, there is a need to highlight and discuss methodologic questions.

2172 SAFETY AND EFFICACY OF TRIVALENT CHROMIUM IN WEIGHT LOSS.

R. A. Anderson. *Beltsville Human Nutrition Research Center, Beltsville, MD.* Sponsor: M. Soni.

Trivalent chromium is an essential nutrient required for normal sugar and fat metabolism. Initial studies of supplemental Cr on lean body mass reported highly significant effects of Cr, 200 ug/d, as Cr picolinate within 6 weeks. The results appeared to be greater than would be expected and have been difficult to reproduce. However, others studies of longer duration, more than 12 weeks, and higher levels of Cr, at least 400 ug/d, have also reported significant effects of Cr on body weight and composition. In contrast, there have also been a number of well controlled studies that have not observed improvements in body weight and composition.

Several studies have also documented the safety of Cr but recent studies have questioned the potential toxicity of trivalent Cr. We have shown that the incorporation of Cr into tissues of rats for Cr chloride and Cr picolinate is linear in the range of intake from 5 to 100 ug of Cr per gram of diet. On a per kg body weight basis, this would be roughly a daily intake of 5000 ug/kg compared with less than 15 ug/kg for a person consuming 1000 ug per day of supplemental Cr. Recent studies in mice suggest that at intakes of roughly 25 ug of Cr per gram of diet by pregnant mice leads to signs of toxicity in the offspring for Cr picolinate but not for Cr chloride. There are also reports that Cr in the form of Cr picolinate can lead to free radical DNA damage in the presence of oxidants. We subjected human cultured HaCaT keratinocytes to cytotoxic levels of Cr chloride and Cr histidinate (the highest soluble levels of Cr picolinate did not cause cell toxicity) for 24 hours and then submitted cells to hydrogen peroxide-induced oxidative stress and did not observe DNA damage. In contrast, there were protective effects on DNA monitored by a decrease in % tail moment in the Comet assay. In summary, the apparent safety of Cr varies with the form of Cr and the test system used. While there are individual reports of possible Cr toxicity in people taking supplemental Cr, there are no confirmed cases of toxicity of supplemental trivalent chromium at intakes ranging from 50 to 1000 ug daily.

2173 MISLEADING TOXICITY REPORTS ON SAFETY OF WEIGHT REDUCING DIETARY SUPPLEMENTS: EXAMPLE OF *GARCINIA CAMBOGIA* EXTRACT.

D. Bagchi. *InterHealth Nutraceuticals, Benicia, CA.*

Garcinia cambogia extract is frequently used in dietary supplements for weight loss. (-)-Hydroxycitric acid, the principal acid of the extract, has been shown to inhibit ATP citrate lyase thus limiting the availability of acetyl-CoA units required for fatty acid synthesis and lipogenesis during a lipogenic diet. Recent reports on *Garcinia cambogia* extract indicate that high doses are effective in suppressing fat accumulation but highly toxic to the testis. A critical review of such information raises several questions such as (1) different isomers/forms of the active ingredient hydroxycitric acid in the extract, responsible for weight control and toxicity, (2) animal models, experimental study design used in safety assessment, (3) use of uncertainty factor for agents acting at physiological levels. These questions need logical consideration for safety assessment of dietary supplement used in weight reduction. In these evaluations, consideration such as use of lactone (which appears to be more toxic) form of hydroxycitric acid, inclusion of pair fed group, use of obese animal model (with higher lipogenic properties), etc. deserves important consideration in safety assessment.

2174 SAFETY ASSESSMENT OF DIETARY SUPPLEMENTS MARKETING FOR WEIGHT LOSS: FDA PERSPECTIVES.

V. H. Frankos. *Division of Dietary Supplements, Food and Drug Administration, College Park, MD.* Sponsor: M. Soni.

In evaluating dietary supplements, FDA looks at scientific information from a range of sources, including published research, evidence-based reports, adverse event reports, and data about the pharmacology or toxicology of a compound. The agency has particular interest in gathering safety data about certain weight loss dietary supplements suspected to cause cardiovascular stress such as the biogenic amines synephrine, octopamine and tyramine present in *Citrus aurantium*, also known as bitter orange. Concern has also been raised about usnic acid derived from *Usnea barbata*, marketed for weight loss and linked to human liver damage. It appears that supplements marketed for weight loss need custom studies to establish their safety. This presentation will discuss FDA's perspective on safety assessment of dietary supplements for weight reduction.

Key Word Index

(Q)SARs	589	adhesion molecules	1573	Alveolar Macrophage	1111
1,1,2,2-tetrachloroethane	1607	Adipose tissue	826	Alzheimer's disease	113, 1098
1,3-dibromopropane	319	adolescence	1799	Ambient Particulate Matter	2002
1,3-Dinitrobenzene	1054	Adverse Event Report	956	ames	1662, 1663
1,4-dioxane	1559	AEGL	1566	Ames II	1661
1-Aminobenzotriazole	1901	Affymetrix	73, 2129	Ames Test	1759
1-bromobutane	320	affymetrix gene array	72	AmesII	1660
1-bromopropane	317, 416	aflatoxin	733, 749, 1451, 1453	Amiodarone	486
1-butyl-3-methylimidazolium chloride	975	aflatoxin B1	1894	ammonia emission	684
14-3-3	1576	Aflatoxin-albumin adduct	1454	Ammonium Perchlorate	1800
16-HBE	1089	age 763, 1155		amphetamine	793, 1799
17-DMAG	230	Age-dependent	1256	amphibian	536
		age-dependent pharmacokinetics	1072	AMPK	469
		age-related	879	amylase	284
2,3 Butanedione	1153	Agent Orange	1993	Amyloid Precursor Protein	112
2,3,4,7,8-Pentachlorodibenzo(p)dioxin	1561	Agglomeration	1071, 1118, 1384	amyloid-beta	1051
2,3-Butanedione monoxime (DAM)	171	Aging	192, 342, 894, 1037, 1484, 1809, 2138, 2139, 2140, 2141, 2142, 2143	Anagen	423
2-butoxyethanol	324			analgesia	1426
2-De Oxy Glucose	721	agribusiness	679	Analgesic	1485
2-generation	2063	Ah	1345	analysis	1729
		Ah Receptor	49, 51, 52, 55, 575, 1341, 1344, 1871	analytical method development	348, 1770
3,4-Dihydroxyphenylacetaldehyde	1030, 1031	AhR	48, 50, 54, 136, 362, 574, 606, 671, 739, 772, 838, 842, 912, 914, 918, 922, 924, 1170, 1407, 1408, 1409, 1414, 1415, 1420, 1872, 1903, 2086, 2103	Analytical Methods	2008, 2024
3-caffeoyl-4-dihydrocaffeoyl quinic acid	1749			anatoxin-a	1491
3-methylcholanthrene	1909	AhR knockout mouse	764, 980	androgen	122
3A4 Far enhancer	615	AHR repressor	917	androgen and estrogen	133
3D echocardiography	375	AHR signaling	552	androgen receptor	132
3T3 NRU PT	1523	AIN-93G	259	anencephaly	1589
		air modeling	1285, 1625	Anesthetic	1224
4-amino TEMPO	207	air particulates	545	aneuploidy	1958
4-chlorobenzotrifluoride	1556	air pollution	482, 492, 663, 665, 1376, 1615, 1810, 2108	angiogenesis	1828
4-Hydroxynonenal	215, 219	Air Pollution Oxidant	1358	Angiotensin II	190, 379, 486
4-monochlorobiphenyl	767	Air Pollution Oxidant inhalation	506	Aniline	1571
		airborne particulate matter	509	Animal	802
6-OHDA	93	airway	815, 1870	animal agriculture	681
		airway epithelial cells	1132	animal alternative	1863
8-hydroxydeoxyguanosine	1647, 1648	Airway Inflammation	811	Animal Alternatives	1171, 1194
		Airway Pathology	1350	animal extremists	605
ABC	568	airway repair	316	animal feed	129
absorption	1504, 2040, 2044, 2091	Akr380, 1948		animal feeding operations	679, 680
absorption/metabolism	2039	Alacramyn	928	Animal model	304, 501, 818, 819, 823, 1365, 1435, 1942
Accumulation	518	albumin	645	animal models	484, 952
acetaldehyde	1548, 1599	Alcohol	62, 233, 351	animal rights	600, 601, 602, 603, 604
Acetaminophen	174, 623, 626, 628, 858, 859, 860, 861, 863, 1002, 1213, 1218	Alcohol-induced hypertension	190	animal welfare	600
		Alcoholic Steatohepatitis	990	anionic lipids	292
acetic acid	808	Aldehyde dehydrogenase	62	anogenital distance	1985
Acetaminophen	248	alexidine	1512	antagonist	138, 1753
acetylcholine	879	All-trans-retinoic acid	942	Anthozoans	523
acetylcholinesterase	880, 1854, 1977	allergen	822	anthraquinones	475
Acid Sphingomyelinase	360	allergenic potency	1816	anti-inflammatory drugs	1722
Acizol	381	Allergic asthma	821	anti-inflammatory effects	209
acrolein	578, 668, 1962	Allergic contact dermatitis	588, 1157, 2146	Antiandrogens	120, 141, 1862
acrosome reaction	2054	allergic dermatitis	1591	Antibodies	232
acrylamide	240, 972, 1588, 1616, 1802	allergic inflammation	1359	Antibody Drug Conjugate	930
acrylate	706	Allergic response	1134	Antibody-forming cell	1721
Acrylonitrile	193, 1298	Allergy	4, 70, 1815	Anticancer agents	1189
activation	1147	Aloe vera	1758	antidiabetic	1175
Activity	1800	alpha 2u globulin	466	Antifibrosis	993
ACUC	600	alpha 2u-globulin	1557	antifungal	286
acute effects	1558	ALT	227	antigen-specific T cell proliferation	331
acute lung injury	487	Alternative Animal Models	1173	antilipedemic	1175
Acute Oral Toxicity	169, 1223	alternative method	1144, 1449	antimony trioxide	1093
Acute Pain	274	Alternative methods	1164, 1183, 1225	antioncogenes	396
acute poisoning	877	Alternative Test Methods	1226	antioxidant	1587, 2102
Acute Renal Failure	170	alternatives	587, 593, 703, 1179, 1182	Antioxidant enzymes	201, 202
Acute Toxicity	1004, 1179, 1282, 1346, 1347	Alumina	1393	antioxidants	105, 2120
adduct	994	alveolar epithelial cells	644	Antiretrovirals	2104
adducts	1057			Antisense	372, 2017, 2018
Adenine Nucleotide Translocator	1522			Antisense Oligonucleotide	471, 1708
adenovirus	282, 287			Antisense Oligonucleotides	472, 2136
adhesion molecule	2117			antisense therapeutics	1821

anuran	846	autoimmune response	322	biomarker discovery	155, 214, 239
