Deadline for Proposals for SOT 2013 Annual Meeting Sessions: April 30, 2012

Why Submit a Proposal?
1. To present new developments in toxicology.
2. To provide attendees an opportunity to learn about state-of-the-art technology and how it applies to toxicological research.
3. To provide attendees an opportunity to learn about emerging fields and how they apply to toxicology.

2013 Thematic Approach and Continuing Education Target Areas

Themes
- Application of Systems Biology to Toxicology
- Biomarkers for Exposure Assessment, Safety Evaluation, and Translational Medicine
- Effects of Nanomaterials on Biological Systems
- Molecular Basis of Genetic Variability and Susceptibility to Toxicants
- Regulatory Science: Advancing New Approaches for Hazard Identification and Risk Assessment

Continuing Education Target Areas
- Developmental Origins of Health and Disease (DOHaD)
- Molecular Imaging
- Personalized Toxicology

Session Types
- Continuing Education—Emphasis on quality presentations of generally accepted, established knowledge in toxicology
  Note: CE Courses will be held on Sunday.
- Symposia—Cutting-edge science; new areas, concepts, or data
- Workshops—State-of-the-art knowledge in toxicology
- Roundtables—Controversial subjects
- Historical Highlights—Review of a historical body of science that has impacted toxicology
- Informational Sessions—Scientific planning or membership development
- Education-Career Development Sessions—Sessions that provide the tools and resources to toxicologists that will enhance their professional and scientific development
- Regional Interest Session—Central topics of relevance that describe public health and/or ecological problems of a particular region

Submit your proposal online at www.toxicology.org
Preface

This issue of *The Toxicologist* is devoted to the abstracts of the presentations for the Continuing Education courses and scientific sessions of the 51st Annual Meeting of the Society of Toxicology, held at the Moscone Convention Center, March 11–15, 2012.

An alphabetical Author Index, cross referencing the corresponding abstract number(s), begins on page 591.

The issue also contains a Key Word Index (by subject or chemical) of all the presentations, beginning on page 617.

The abstracts are reproduced as accepted by the Scientific Program Committee of the Society of Toxicology and appear in numerical sequence.

The Next Generation Mobile Itinerary Planner

With MyItinerary, you have the option of using our traditional meeting materials or browsing and searching the meeting program and creating a personalized itinerary with a mobile version of the SOT Annual Meeting Itinerary Planner. *Available for a limited time after the SOT 2012 Annual Meeting.*

Download a QR code reader and scan with your smartphone or mobile device to access the mobile app.

Copies of *The Toxicologist* are available at $45 each plus $5 postage and handling (US funds) from:

Society of Toxicology
1821 Michael Faraday Drive, Suite 300 • Reston, VA 20190

www.toxicology.org

This abstract book has been produced electronically by ScholarOne, Inc. Every effort has been made to faithfully reproduce the abstracts as submitted. The author(s) of each abstract appearing in this publication is/are solely responsible for the content thereof; the publication of an article shall not constitute or be deemed to constitute any representation by the Society of Toxicology or its boards that the data presented therein are correct or are sufficient to support the conclusions reached or that the experiment design or methodology is adequate. Because of the rapid advances in the medical sciences, we recommend that independent verification of diagnoses and drug dosage be made.
Over the last two decades, alternatives to animal testing were strongly driven by animal welfare considerations. A culture of organotypic cell models, quality assurance and validation developed, which resulted in a number of novel approaches for regulatory testing. Progress to replace especially the systemic and chronic types of tests has been limited. Novel programs to assess large number of substances such as existing chemicals (REACH and the emerging TSCA e生态圈化), nanoparticles or mixtures, as well as new products such as biologicals and cell therapies now add to the need to move to another approach for toxicology testing. Additionally, interest in health effects like endocrine disruption, developmental neurotoxicity, immunotoxicity, obesity, attherosclerosis or childhood asthma require extensive and new types of testing. This is often referred to as Toxicity Testing for the 21st Century (Tox-21c), after the respective NAS vision document from 2007, which has been made EPA’s toxicity testing strategy in 2009. The central change is moving from apical “black box” animal models to mechanism or pathway of toxicity (PoT). The biotechnology and bioinformatics revolution of recent years has made it possible to develop systems biology, here systems toxicology, approaches. The experiences from the field of alternative methods now prove to be the most important to implement a new regulatory approach. Standardization and validation of cell cultures is crucial for PoT identification as well as the implementation of high-throughput type of tests based on PoT. The first projects to systematically map the entirety of human PoT, the human Toxome, have started. The validation of these novel tests represents an enormous challenge. It is proposed to follow the role model of evidence-based medicine. For this purpose, the evidence-based toxicology collaboration was started at SOT 2011 and is currently shaping its procedures and governance.

Biomarkers serve as quantitative measures of chemical exposures and biologically effective doses, provide early warning signals of biologic effect, predict outcome in a patient with disease, and identify who will respond to an intervention and whether the intervention is working. The current era of scientific discovery has brought seemingly limitless opportunities for improvements in medical care. Translational biomarkers that can be measured in blood or urine in both experimental animals and man are of particular interest. Given the importance to the clinical, pharmaceutical, and regulatory communities motivated by more specific and timely diagnoses, early intervention and safer therapies, clinically useful biomarkers have evolved over time, reflecting the scientific and technologic progress made over the centuries. An increasing number of clinically relevant tests and procedures are available to estimate organ injury and guide treatment. The use of molecular signals in the assessment of health and disease is not new; however, the concept of what constitutes a useful biomarker has evolved considerably in the past two to three decades given the advanced enabling technologies, deeper molecular understanding of disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these molecular signals in the assessment of health and disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these molecular signals in the assessment of health and disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these molecular signals in the assessment of health and disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these molecular signals in the assessment of health and disease, and the advent of a regulatory framework for biomarker qualification. Our panel experts will highlight the potential of these molecular signals in the assessment of health and disease, and the advent of a regulatory framework for biomarker qualification.

Embryonic and fetal development in mammalian species is a complex process which is sensitive to the effects of maternal and environmental factors. The timing of development of the major organ systems varies between humans and other animal species, but the basic biology of development is similar in all species thus allowing extrapolation of animal testing results for xenobiotics to humans. The course will begin by providing an overview that highlights developmental biology from fertilization of the gametes to normal maturation of a full term placenta and fetus including examples of developmental toxicants and teratogens with known modes of action. Subsequently, applied toxicology concepts for evaluation of the potential for bioaccumulation of chemicals to affect pregnancy and embryofetal development will be discussed. Global regulatory strategies and requirements to minimize health effects on women and unborn children will also be addressed. Finally, key information will be presented to provide for a better understanding of the biological and toxicological basis of prenatal developmental toxicity testing and the impact of various outcomes on drug development, chemical use, environmental impact, and human health risk.

Skin is the largest external organ and serves as a living, dynamic protective envelope surrounding the body. As such, it is constantly exposed to environmental hazards, including hazardous compounds; these exposures account for a major portion of all reported industrial illnesses. Skin exposures may also occur from pharmaceuticals or consumer products that are intentionally applied. In vitro methods are important as a first step to estimate skin permeation, and the potential of skin irritation and senescent chemical sensitization for compounds or mixtures of compounds that are directly toxic to the skin or systemically toxic. In exploration of these issues we will provide an overview of the current status of in vitro models for cutaneous toxicity safety evaluations and the regulatory requirements for establishing the nonclinical safety of dermal drug products. This important topic has relevance to toxicologists involved in safety evaluations and risk assessments for chemicals that contact the skin.

With the integration of open source programs, in silico tools, and bioinformatics, the role of the computer continues to transform daily activities and work for the modern scientist. Furthermore, the call for reduced animal testing in toxicity evaluation led to an expansion of in silico resources, quantitative structure-activity relationship (QSAR) programs, chemoinformatics systems, and predictive metabolism tools. Regulatory authorities, pharmaceutical, chemical, and food industries are actively using such tools in the safety evaluations of novel drug candidates, food additives, environmental contaminants and consumer products. We will begin by providing a basic introduction to various in silico tools, specifically predictive toxicology and metabolism platforms, and how their algorithms compute results and influence the decision process. A composed set of didactic lectures will be used to introduce the basic concepts and activities surrounding the use of in silico tools in ADME/Tox and safety studies. In follow-up participants will be provided with a brief summary of various platforms with practical tutorials of the computational toxicology platforms discussed.

The WHO/IPCS harmonized guidance document is the first compendium guidance document for risk assessment in toxicology. Immunotoxicity risk assessment of chemicals is an evaluation of the potential for unintended effects of chemical exposure on the immune system. These effects manifest as four principal types of immunotoxicity which are categorized as immunosuppression and stimulation, autoimmunity, and sensitization. We will provide an overview of the methods used to detect and characterize immunotoxicity and the potential consequences of unintended immunomodulation. It is well established that xenobiotic-related immunomodulation can lead to reduced resistance to infections and certain neoplastic diseases. Exposure to xenobiotics has been shown to be associated with development or worsening of autoimmune disease. It has been established that xenobiotics can
elicit hypersensitivity responses directly as an allergen, or they can enhance the in-duction or severity of allergic sensitization to pollen or dust mites. The determina-tion of risk associated with immunostimulation may be more difficult, but unex-pected stimulation should not be disregarded as it may result in nonspecific inflammation or the skewing of normally protective immune responses to favor in-duction or exacerbation of autoimmunity and hypersensitivity. The fundamental concepts of risk assessment as they apply to the evaluation of immunotoxicity as well as the application of the guidance will be highlighted. We will begin by re-viewing case studies which include data that focuses on different areas of immuno-toxicity—suppression, sensitization, and autoimmunity. The studies will demon-strate application of the guidance, particularly the development of weight of evidence conclusions from the available data. Finally, we will illustrate that risk as-sessment for a given chemical should consider the full range of immune effects for that chemical, and data should be evaluated separately for evidence of suppression, stimulation, autoimmunity, and sensitization.

7 STEM CELLS IN TOXICOLOGY.
E. J. Tokar and M. P. Waalkes, NIEHS, Research Triangle Park, NC.

Stem cells are revolutionizing toxicological research and remain an area with tremendous potential. Recently, research on stem cells has generated tremendous public and professional interest. However, some areas of toxicological research have lagged behind in the integration of stem cells as a concept in toxicant-induced disease etiology. We will describe the utility and suitability of the assorted types of stem cell models (i.e. embryonic, fetal, progenitor, induced pluripotent, immortal-ized stem cell lines, etc.) for various research purposes, including disease modeling, drug discovery, and toxicity testing in order to describe the potential applications of stem cells in toxicological research. This important overview of stem cells will high-light their nomenclature, properties, and their roles in the genesis of various dis-eases.

8 CONCEPTS OF GREEN CHEMISTRY AND ITS ROLE IN THE IDENTIFICATION AND DESIGN OF SAFER CHEMICALS AND PRODUCTS.
P. J. Spencer1 and J. Warner2, 1DuPont Chemical Company, Midland, MI and 2Warner Babcock Institute for Green Chemistry, Wilmington, MA.

Hazard identification, dose-response characterization, and exposure potential are the underpinning of product safety assessments. These basic principles help regula-tory agencies, manufacturers, and formulators determine the conditions for safe use of chemicals, raw materials, and products for a given application to reduce adverse impacts to human health and the environment. Today, as a part of the growing in-terest in green chemistry, the pendulum is shifting. The large number of companies engaging in sustainability initiatives coupled with increased consumer demand for greener products is driving a new process where impacts of chemical products and processes are included as design criteria. Reducing intrinsic chemical hazards up front is a strategy used in developing safer alternatives to existing chemicals. Thus, green chemistry is raising the bar for chemical safety assessments. Our panel of ex-perts will begin with a background of green chemistry, its basic principles, why it is useful and highlight key certification programs/tools used to identify safer alterna-tives including their methods and criteria with specific emphasis on the Green Screen for Safer Chemicals alternatives assessment tool. There are unique opportu-nities for toxicologists to assist molecular designers in reducing the intrinsic hazards of their molecules by providing insight into toxicological mechanisms and data that support the application of green chemistry principles in the design of new chemi-cals and products. To underscore the importance of this issue, we will illustrate how principles of green chemistry are applied in a consumer products and a chemical company. The caveats and challenges will be addressed by using case studies. The exploration of this topical area will provide an understanding of green chemistry, awareness of the tools and programs immediately available and how to access and use them as well as an appreciation for some of the practical challenges associated with implementing principles of green chemistry into product development and as-sessments of safer alternatives.

9 INNATE IMMUNITY AND ITS RELEVANCE TO TOXICOLOGY.
W. J. Freebern1 and J. M. Shenton2, 1Immunotoxicology, Bristol-Myers Squibb, North Brunswick, NJ and 2MedImmune, Inc., Cambridge, United Kingdom.

The innate immune system is the host’s first line of defense against infection. Thus, knowing the what, why, how, and when of innate immune function assessment in toxicology evaluations is important. This course will introduce the components of the innate immune system and its role in host defense, discuss clinical observations resulting from inhibition or stimulation of innate immune function in non-clinical species, provide case examples where understanding intentional or inadvertent ef-fects on the innate immune system has had utility in toxicity testing, and explain the what and how of innate immune measurements and the gaps in capabilities thereof. Innate immunity assessments to be discussed include bacterial killing assays and an array of macrophage, neutrophil, and natural killer cell activity assessments which will be described within the context of various target organs, animal models, and toxicity programs. In addition, investigating innate immune function on a mole-cular level through evaluating cell signaling molecules and regulated expression of anti-microbial peptides, chemokines, and cytokines will be discussed. In closing, the application of innate immunity testing in the clinic and translatability of non-clinical findings to the clinic will be examined. This course should be of broad in-te rest to Toxicologists with a desire to learn about the complex innate system and how innate immune evaluations can be applied to toxicology testing. In addition, the course will appeal to scientists who are interested in learning methodologies of innate immune function testing and applicability thereof.

10 MICRORNAS IN BIOLOGY AND TOXICOLOGY.
N. Aluru1 and C. J. Marsili2, 1Biology, Woods Hole Oceanographic Institution, Woods Hole, MA and 2Department of Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH.

MicroRNAs (miRNAs) constitute a critically important class of non-coding, small RNA molecules which post-transcriptionally regulate gene expression. miRNAs, approxi-mately 18-24 nucleotides (nt) in length, regulate gene expression by binding to 3’untranslated regions (UTR), coding sequences or 5’UTR of target messenger RNAs (mRNAs), and leading to inhibition of translation or mRNA degradation. It is estimated that miRNAs regulate approximately 30% of the human protein-coding genome. miRNAs control the expression of genes involved in several biological processes, including apoptosis, proliferation, differentiation, and metastasis. Given the prominent role miRNAs play in organismal function, it is not surprising that the aberrant expression of miRNAs can lead to a wide range of human diseases and disorders, including cancer, neurodegenerative diseases, diabetes and a variety of cardiovascular and hepatic disorders. In addition to contributing to the underlying cause of a particular disease, miRNAs can also represent potential therapeutic tar-gets and diagnostic biomarkers. The recently discovered of circulating miRNAs are promising biomarker candidates since they can be detected from readily attainable blood samples. Because of the critical role that miRNAs play in biological function and the diverse range of applications in which miRNA analysis is of value, signifi-cant effort has been invested over the past decade to develop new detection meth-ods. We will provide an overview of existing and emerging tools for miRNA analy-sis, with particular emphasis placed on the current state of the art and important developments in this emerging field.

11 REGULATORY SCIENCES: PRECLINICAL DRUG DEVELOPMENT FROM SMALL MOLECULES TO BIOLOGICS.
T. Wang1 and W. McGuinness2, 1Preclinical Safety, Novartis Pharmaceuticals, Emerpixelle, CA and 2US FDA, Silver Spring, MD.

Drug development is a highly regulated but science-driven process from early dis-cover to marketing. Once the drug candidate has been discovered, preclinical safety evaluations are required to ensure the safety of the drug during clinical trials, ultimately bridging the gap between drug discovery and marketing. The preclinical development of four types of drugs, small molecular-weight drugs, biologics, oligonucleotide-based therapeutic drugs and antibody drug conjugates (ADCs), will be illustrated to emphasize the cross-functional nature of regulatory sciences. In exploration of this important topic, we will begin with a focus on small molecular-weight drug candidates, which require a sliding scale for the degree of development from relatively minimal regulatory requirements for oncology drug development to the much more stringent requirements for the development of drugs for non-life-threatenning conditions and chronic treatment. Next the focus will shift to large molecule biologics and will provide illustrations of the unique challenges in regula-tory safety assessment and clinical development that biologic drug candidates pres-ent. Our panel of experts will then focus on oligonucleotide-based therapeutics since many of the overarching oligonucleotide class-based properties have been well estab-lished, but unique considerations remain for each subclass of oligonucleotide. This talk will discuss the preclinical development of oligonucleotide-based therapeu-tic drugs, including antisense, siRNA, immunostimulatory and aptamer applica-tions. At last this course will also cover ADCs, which are comprised of mono-clonal antibodies (biologics) conjugated with drugs or cytotoxins (small molecules). Standard approaches for preclinical safety evaluation of each of the individual com-
in utero and postnatal development is uncertainty regarding the actual exposure in the target subpopulation. We will demonstrate the value of PBPK modeling in quantitative health risk assessments for infants and children by providing a scientifically sound tool to predict the target tissue dose in the young. A thorough understanding of dynamic changes in physiological and biochemical factors is essential to predict the target tissue exposure during development. Factors that influence the kinetic behavior of chemicals in early life include ontogeny in metabolizing enzymes, changes in transporter expression, maturation of biological barriers such as the blood brain barrier, differential growth of tissues, and distinct exposure patterns compared to adults. PBPK modeling provides a means to integrate these factors in the proper context and thus reduce uncertainty in conducting risk/safety assessment for early life. The presentations will provide an overview of pharmacokinetic factors affecting early life sensitivity and two case studies of PBPK approaches for gestation/lactation and childhood exposures, plus a demonstration of how PBPK modeling of development can be used to evaluate neonatal epidemiological results. The course participants will get an in-depth understanding of the value of PBPK modeling in addressing issues of potential sensitivity in infants and children and the possible application scenarios of this valuable tool.

**15 DIETARY SUPPLEMENT ADULTERATION–A CLINICIAN’S PERSPECTIVE.**

A 12-year-old child develops bleeding from his gums and a diffuse rash. A 30-year-old man presents to the hospital with a new onset seizure that is resistant to therapy. A 77-year-old man is found in cardiac arrest after taking an herbal medication for his shortness of breath. What do all of these cases have in common? Each of these patients was using a dietary supplement that contained a toxic ingredient, though in each case the intent was markedly different. Herbal or cultural products may be intentionally adulterated with conventional medications known to be therapeutic for a given disorder in an effort to assure effectiveness. An example is the inclusion of an analgesic for a pain syndrome, Indomethacin and phenylbutazone are just two examples of nonsteroidal anti-inflammatory drugs that have been implicated in many adverse clinical outcomes. Herbal medications may contain a small quantity of a known toxic principle added for a purported benefit that has a historical, not scientific, basis. True to the tenet that “dose makes the poison” these compounds are themselves directly toxic following more substantial exposures. Due to the relatively poor quality control standards required of largely unregulated dietary supplements, dangerous exposures may occur. Examples include the use of mercury in Chinese herbs or lead in Ayurvedic (Indian) medications. Furthermore, excessive exposure to a pharmacologically active ingredient from a plant may result in an unanticipated side effect. An example is exposure to diethylene glycol from Digitalis plants or aconitine from Monkshood (Aconitum sp.), both used in the practice of classical herbal medicine and both associated with cardiac arrhythmias. These examples highlight the potential risks in the use of poorly regulated dietary supplements, and should focus efforts on the amelioration of the conditions that allow this dangerous situation to persist.

**16 DIETARY SUPPLEMENT ADULTERATION: CANADIAN REGULATOR’S PERSPECTIVE.**

In the age of a global economy, and the widespread international movement of products, poor quality ingredients manufactured in one country can impact on a multitude of finished products elsewhere in the world. The intentional manufacture of adulterated dietary supplements has become a significant global problem which now only creates risks to the health of consumers, but also consumer uncertainty and suspicion directed towards dietary supplements. Proper quality control and ingredient testing by manufacturers plays a crucial role in protecting the public from adulterated dietary supplements. Another key activity in the protection against adulterated products is the surveillance of adverse reactions (ARS) reported to domestically available products. It is also useful to monitor the activities of foreign regulatory agencies, to detect issues of product adulteration in other countries, which may only become relevant if consumers import these products or if they are sold in Canada. Health Canada carries out routine monitoring of both the domestic and international situations, and informs the Canadian public as necessary. ARs are reported to Health Canada through the Canada Vigilance program. Issues of product adulteration have been detected during the monitoring of AR information. In these situations, suspicion of adulteration may lead to the collection of the product in question, and analysis by Health Canada. Examples where domestic adverse reactions actions have led to the detection of product quality issues include adulteration of sexual enhancement products (sildenafil/analogaues), sleeping aid products (estazolam), and anti-inflammatory/arthritis products (dexmethasone). In these situations, Health Canada issues risk communications to inform the public, and to reduce the risk associated with use of these products. Health Canada also actively monitors risk communications issued by foreign regulatory agencies, related to adulterated products.
US REGULATORY PERSPECTIVES ON THE INTENTIONAL ADULTERATION OF DIETARY SUPPLEMENTS.

FDA has, since 2008 identified almost 300 tainted products marketed as "dietary supplements" that contain undeclared or mislabeled drugs or other chemicals. The hidden ingredients include various combinations of prescription drugs and analogues, controlled substances, drugs withdrawn for safety reasons, IND drugs, foreign drugs not approved in the US and other untested chemicals. FDA has received numerous reports of serious injury and even deaths associated with these products. As announced in April, 2011, more than half of all Americans take a dietary supplement. Thus the potential for a large scale public health catastrophe with intentionally adulterated products is significant. The agency is using tools at its disposal to address the issue and developing new targeted strategies and techniques to prevent further intentional adulteration that places public health at risk.

QUALITY STANDARDS: SPECIFICATIONS ON PURITY AND AUTHENTICITY.

J. C. Griffiths, Global Services, US Pharmacopeia, Rockville, MD.

Quality standards or compendial standards provide an independent, science-based measure of criteria regarding purity and authenticity to industry, the regulators and by extension, the consumers. An international compendium of quality specifications for dietary supplement ingredients and dosage forms in commerce would support current Good Manufacturing Practices (cGMP) initiatives, and supply a neutral measure of authenticity, purity, strength of these frequently adulterated products. Compendial standards are comprised of relevant acceptance criteria defining the authenticity, appropriate analytical methods to verify these criteria, and in many cases, authenticated physical reference standards to verify the appropriate execution of the test method. A compendium providing all three components to everyone involved in the supply chain of dietary supplements, will enhance product safety through a predictable and stable supply chain of verifiable authentic products to everyone involved in the supply chain of dietary supplements, will enhance product safety through a predictable and stable supply chain of verifiable authentic materials to an industry that ultimately aims at producing healthy and safe products to consumers. One such example, the Dietary Supplements Compendium (DSC) prepared and published by the United States Pharmacopeia (USP) will be detailed, demonstrating the information provided and the processes by which additional dietary ingredients and dietary supplement dosage forms are added.

DNA DAMAGE RESPONSES AND REPAIR.

R. S. Paules1 and L. D. Samson2, 1NIEHS, Research Triangle Park, NC and 2Massachusetts Institute of Technology, Cambridge, MA.

Exposure to agents that have the potential to damage DNA occurs every day and is in fact a normal part of life. As a consequence, extremely efficient processes have developed that protect the genome from deleterious alterations by recognizing DNA damage in what is referred to as the DNA Damage Response (DDR) and initiating a series of cellular signal transduction pathway responses that lead to a coordination of regulation of cell cycle proliferation and repair of DNA lesions, if possible, or to the initiation of a cell death process, if appropriate repair is not possible. DNA damage can arise from both endogenous and exogenous sources, and, if not repaired properly, may lead to mutations, development of diseases such as cancer, cellular, or tissue toxicity, or ultimately to the death of the organism. Activation of the DDR results in the activation of the DNA damage response sensors ATM and ATR, which can then initiate an inhibition of cell cycle progression through the activation of a DNA damage checkpoint, in order to allow time for the repair of DNA lesions and to prevent the transmission of damaged or incompletely replicated genetic material. By repair of the DNA damage and restoration of the integrity of the DNA duplex, genomic stability can be maintained. DNA repair mechanisms that function to maintain genomic stability and to avoid toxicity include base excision repair, nucleotide excision repair, double-strand break repair, as well as translesion DNA synthesis. We will present important updates on the progress made in elucidating the consequences of genetic and pharmacological modifications of the levels and functions of DNA repair and response genes on both toxicities of exposures, as well as exciting possible new therapeutic approaches. We will focus on recent advances in understanding the molecular mechanisms of the DDR and DNA repair, both to provide molecular insight into toxicity and disease processes, and also potentially to provide novel targets for therapeutic strategies for treating individuals with certain diseases such as cancers.

IDENTIFYING TRANSLATIONAL COMPONENTS OF THE DNA DAMAGE RESPONSE.

T. Begley1, J. Aguirre-Ghiso1, P. Dedon1, M. Soledad Sosa2, U. Begley3, C. Chan4, M. Dyavahla5, Y. Estrada2, A. Patil6, A. Avivar-Valderas7 and K. Taghizadeh1, 1College of NanoScale Science and Engineering, University at Albany, SUNY, Albany, NY, 2Division of Hematology and Oncology, Mount Sinai School of Medicine, New York, NY, 3Department of Chemistry, Massachusetts Institute of Technology, Cambridge, MA, 4Department of Biomedical Engineering, Columbia University, New York, NY, and 5Laboratory of Structural Biology, NIEHS/NIH, Research Triangle Park, NC.

Transcriptional and post-translational signals are known mechanisms which promote efficient responses to DNA damage. Using high throughput screening and small molecule analysis approaches we have identified translational components of the DNA damage response, which operate through the modification of RNA. Our data indicates that enzyme catalyzed modification of RNA can be dynamically regulated after exposure to DNA damaging agents and we have developed and tested computational models to demonstrate their signaling role. Specifically we have shown that mRNA methylation of chromosome 9 (Trm9) from budding yeast and humans enhances the translation of transcripts over-represented with specific arginine and glutamic acid codons. In budding yeast, we have shown that translation of the DNA damage response transcripts ribonucleotide reductase 1 & 3, which are over-represented with specific arginine and glutamic acid codons, is dependent on Trm9 catalyzed RNA modifications. In human systems we demonstrate that Trm9 optimizes codon-specific translation and plays important roles in stress signaling, preventing toxicant-induced cell death and responding to environmental conditions. In addition we demonstrate that Human Trm9 is epigenetically silenced in colorectal cancer and that reactivating this gene by responding stress signaling. Ultimately our studies highlight a translation-associated mechanism that regulates gene expression during times of cellular stress and DNA damage.

COMPLEX RESPONSES OF MICE TO ALKYLATION AND INFLAMMATION-INDUCED TOXICITY.

L. D. Samson, Biological Engineering Department and Biology Department, Center for Environmental Health Sciences, MIT, Cambridge, MA.

In the last few years we have been characterizing the effects of modulating the level of DNA base repair enzymes on the sensitivity of various tissues to the effects of model alkylating agents, to inflammation. Human and rodent cells exposed to such agents from a variety of endogenous and exogenous sources, and we have simulated such exposures in knockout and transgenic mouse models. Surprisingly, we find that for wild type mice, specific cells in some tissues (for example certain postmitotic neurons in the retina and the brain) are extremely sensitive to alkylination-induced damage, while the same cells are completely resistant in animals that are knocked out for repair mediated by the Aag DNA repair glycosylase. Moreover, we find that the same is true for specific cells in other tissues that are undergoing an inflammatory response as a result of ischemia and reperfusion. These counter-intuitive findings are supported by the fact that these cells in Aag-transgenic mice, expressing higher than wild type levels of Aag, become super-sensitive to induced damage. We will discuss these findings in the context of the large inter-individual differences in AAG levels in human populations.
23 DAMAGE-SPECIFIC PATHWAYS FOR THE REGULATION OF POSTREPLICATION REPAIR.

Postreplication repair (PRR) pathways play important roles in restarting stalled replication forks and regulating mutagenesis. In yeast, Rad5-mediated damage avoidance and Rad18-mediated translesion synthesis (TLS) are two forms of PRR. Rad18 promotes PCNA monoubiquitination and the recruitment of TLS polymerases, while Rad5 forms lysine 63-linked ubiquitin chains on monoubiquitinated PCNA to promote damage avoidance through an unknown process. In mammalian cells, PCNA is also ubiquitinated in a Rad18-dependent manner, and two Rad5-related proteins, SHPRH and HLTF, have also been identified. However, the specific functions of these two proteins in response to DNA damage have not been clearly addressed. We have been investigating the roles of SHPRH and HLTF in PRR. Surprisingly, we find that SHPRH and HLTF act in non-redundant, damage-specific ways to suppress mutagenesis. SHPRH suppresses mutagenesis induced by MMS treatment, while HLTF suppresses mutagenesis induced by UV treatment.

These findings suggest that SHPRH and HLTF can discriminate between different types of DNA damage at a stalled replication fork. Our data also suggest that SHPRH and HLTF specifically recruit distinct, damage-specific TLS polymerases to stalled forks. The use of SHPRH versus HLTF appears to be regulated, at least in part, by a switch between Rad18-HLTF and Rad18-SHPRH complexes that is induced by DNA damage and the damage-specific degradation of HLTF. We therefore propose that different types of DNA damage specify the recruitment of the most appropriate TLS polymerase(s) by controlling the relative abundance of the different Rad18-Rad5 complexes at the fork. We will discuss this work and more recent findings about the mechanisms underlying damage-specific regulation of HLTF and SHPRH. Our work may have important implications for damage-specific mutagenesis and may also provide insight into how mutations in HLTF and SHPRH may influence cancer progression and treatment.

24 REDUNDANCY AND CROSS-TALK IN PATHWAYS AND FUNCTIONS IN DNA DAMAGE RESPONSES TO THE HIGHLY TOXIC DNA DOUBLE-STRAND BREAK.
R. S. Paules1, S. S. Paliit2, Y. Cui1, J. E. Hesse1, C. L. Innes1 and B. P. Sleckman2.
Environmental Stress & Cancer Group, Laboratory of Toxicology & Pharmacology, NIEHS, NIH, Research Triangle Park, NC and 2Department of Pathology & Immunology, Washington University School of Medicine, St. Louis, MO.

DNA double strand breaks (DSBs) are the most lethal form of DNA damage and can be generated by both endogenous and exogenous sources. In the DNA damage response (DDR), most cells have the capacity to activate a cell cycle checkpoint response to delay proliferation in order to allow time for repair of the DNA lesions or to activate a programmed cell death process. We and others have demonstrated substantial cross-talk between DDR pathways mediated by members of the PI3 kinase family, i.e. ATM, ATR, and DNA-PKcs. Using lentiviral expression of shRNAs, we have generated normal human mammary epithelial cell lines that have either stable or inducible knockdown of ATM, ATR and CHK1. As expected, depletion of either ATM, ATR or CHK1 by more than 90% results in impaired G2 checkpoint control and lower viability. Interestingly, CHK1 deficiency also results in enhanced phosphorylation of multiple DNA damage proteins following IR-treatment, most notably phosphorylation of CHK2 on Thr68, and this effect is modulated by both ATM and DNA-PKcs. Furthermore, these cell lines have allowed us to investigate a negative feedback from CHK1 to the ATM kinase involving protein phosphatases and potentially regulation by microRNAs. The results of these studies could be exploited to enhance the efficacy of therapeutic regimens for certain cancers. In addition, our genomic studies with mouse pre-B cells that DSBs, generated by physiologically relevant sources, arrest not only DDR pathways but also lymphocyte developmental pathways, a finding that could help to explain the immunotoxic effects of certain genotoxic agents.

This research was supported by the Intramural Research Program of the NIH, National Institute of Environmental Health Sciences.

25 THE THICK AND THIN OF NUCLEAR RECEPTORS IN DIABETES AND OBESITY.
A. L. Slitt, Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

Xenobiotic nuclear receptors, such as CAR, PXR, AHR, FXR, and NRF2 are best known for transcription regulation and induction of Phase I and Phase II biotransformation enzymes, as well as transporters. These receptor pathways are of interest because they are activated by diverse chemicals—drugs, chemicals of environmental exposure, as well as endogenous chemicals such as hormones and bile acids. It is well established that there are chemical-receptor interactions—especially in the liver, which lead to transcriptional upregulation of gene batteries and result in coordinate regulation of metabolism and transport. However, recent evidence points to nuclear receptors and the role for these receptors in diseases related to metabolic syndrome, dyslipidemia, and glucose homeostasis. As the incidence of obesity and obesity-related diseases, which culminate in metabolic syndrome, increase worldwide, understanding the mechanisms of obesity is of high interest for human health. As these receptors are targeted by drugs and environmental chemicals, it is of importance to understand how activators of these xenobiotic receptors affect aspects of adipocyte differentiation, adiposity, and pancreatic function in adults, as well as sensitivity variations, specifically pregnant women and children. Our findings will be presented for various receptor-mediated pathways with regard to various obesity and diabetes models. Presentations will cover nuclear receptor-mediated gene induction and research findings related to nuclear receptors with regard to obesity and diabetes. Finally, findings will be presented regarding what is currently known regarding nuclear receptor function in caloric restriction, the practice most recommended to combat obesity and obesity-related disorders. The information presented will be useful to those interested in nuclear receptors, aspects of metabolic syndrome, mouse models of obesity and diabetes, aspects of metabolic syndrome and drug interactions, therapeutic drug targets, and environment-obesogen effects.

26 A NOVEL FUNCTION OF THE XENOBIOTIC RECEPTOR CAR IN OBESITY AND TYPE 2 DIABETES.
W. Xie. Department of Pharmaceutical Sciences, University of Pittsburgh School of Pharmacy, Pittsburgh, PA.

The constitutive androstane receptor (CAR) was initially characterized as a xenobiotic receptor. We have recently uncovered an unexpected endobiotic role of CAR in preventing obesity and alleviating type II diabetes. We showed that treatment of wild type mice with the CAR agonist TCPOBOP efficiently prevented diet-induced obesity from happening or reversed pre-induced obesity. Treatment with TCPOBOP improved insulin sensitivity in diabetic mice. In contrast, CAR null mice maintained on chow diet showed spontaneous insulin insensitivity. The metabolic benefits of CAR activation may have resulted from the combined effect of inhibition of lipogenesis, VLDL secretion and export of triglycerides, gluconeogenesis, and increases in brown adipose tissue energy expenditure and peripheral fat mobilization. In summary, our results have revealed an important metabolic function of CAR and may establish this “xenobiotic receptor” as a novel therapeutic target for the prevention and treatment of obesity and type II diabetes.

27 PARADOXICAL ROLES OF NRF2 ACTIVATION IN ARSENIC-INDUCED PANCREATIC ß-CELL DYSFUNCTION AND INSULIN RESISTANCE.
L. Pi. The Hammer Institute, Research Triangle Park, NC.

There is growing evidence that chronic exposure of humans to inorganic arsenic (iAs), a potent environmental oxidative stressor, is associated with the incidence of Type 2 Diabetes (T2D). Nuclear factor E2-related factor 2 (Nrf2) is a CNC-bZIP transcription factor that is well established as a master regulator in the cellular adaptive response to oxidative stress. Although cytosolic, reactive oxygen species (ROS) also function as important intracellular signaling molecules to activate cellular responses to a variety of physiological stimuli, including glucose-stimulated insulin secretion (GSIS) in pancreatic β-cells and insulin action in insulin responsive cells. Therefore, we propose that Nrf2-mediated antioxidant response plays paradoxical roles in β-cell function and insulin signaling transcription: (1) It protects the cells from oxidative damage and possible cell death, thus minimizing oxidative damage-related impairment in insulin secretion and action; (2) Since ROS signaling triggered by glucose could be an important component involved in insulin secretion and action, the induction of endogenous antioxidants in the presence of oxidative stress may blunt the signals, resulting in reduced GSIS and insulin resistance. iAs and its methylated trivial metabolites are potent oxidative stressors and robustly activate Nrf2-mediated antioxidant response, but at the levels typically observed in human exposures, they are not likely to reach cytosolic concentrations sufficient to cause overt oxidative damage, especially when endogenous antioxidant enzymes can be actively induced. Therefore, blockade of ROS signaling in pre-mice is potentially more relevant to the etiology of T2D in the context of low-level environmental iAs exposure, whereas premice 1 might be associated with protecting cells from acute toxicity induced by high doses of arsenic.
Bile acids play an important role in maintaining lipid, glucose and energy homeostasis. Our recent study shows that transgenic mice overexpressing Cyp7a1 are resistant to western high fat diet-induced obesity and diabetes. Bile acid signaling may activate insulin signaling to maintain glucose and lipid homeostasis. In diabetes, hyperglycemia stimulated CYP7A1 gene expression by epigenetic mechanisms and increased bile acid bile acid pool and serum bile acid concentrations. Bile acid derivatives may be potential therapeutics for diabetes, fatty liver diseases, and obesity.

Evolving, previously approved drugs are now serendipitously being found to have coepigenetics is still relatively young. As greater understanding of the epigenome is developed, therapeutic intervention in these disease areas have been identified. While pharmaceutical mechanisms have become more extensively characterized, new opportunities for epigenetic interventions have emerged. These include: (1) using small molecules to reverse epigenetic changes and (2) using pharmacological intervention in these epigenetic changes to modulate gene expression.

In recent years, epigenetic factors have been implicated in the etiology of various disorders. This talk will provide an overview of published studies that focus on the role of the above presented nuclear receptors in mediating processes involved in weight loss. Given the emerging role for the Nrf2-Keap1 pathway regarding diabetes and obesity, targeting the Nrf2-Keap1 pathway may be of therapeutic benefit to promote weight loss or augment weight loss during caloric restriction (CR). Studies have been conducted to evaluate the effect of CR on Nrf2 expression and activation in lean and obese mouse models. Overall, findings will be presented from CR studies carried out using Nrf2-null, Keap1-Knockdown, and transgenic ARE-hPAP reporter mice. Overall the findings will summarize use of these transgenic/knockout models to address the role of Nrf2-Keap1 in weight loss, gluconeogenesis, glucose tolerance, and insulin sensitivity. The talk will conclude with discussion about the potential for targeting nuclear receptors as weight loss therapies.

Methylation at the 5-position of DNA-cytosine (5mC), the histone code and non-coding RNAs contribute to epigenetic regulation. Additionally, a sixth DNA base, 5-hydroxymethylcytosine (5hmC) was identified recently. It is generated by the Ten-eleven Transcription Location (Tet) family of proteins through oxidation of 5mC. Thus, Tet modules DNA methylation levels. Furthermore, Tet exhibits a dual function in that these proteins can also play a role in regulating transcription. Additionally, components of the core promoter recognition complex change in a cell-specific fashion to turn on transcriptional program while turning off others; this provides a novel epigenetic mechanism. Interest in understanding the extent to which epigenetic changes might underlie toxicity/disease (as a causative or susceptibility factor), including adverse transgenerational effects, is increasing. This will provide a basis for discussing issues to contemplate when considering epigenetics and safety assessments, (e.g., parameters to be evaluated, genomic region(s) to monitor, methodological (ies), biological endpoint(s),) and what tools and model systems might be employed? Attention should be paid to fundamental principles of toxicology, (e.g., dose-response, criteria for a maximum dose, normal variability, and change vs. an adverse effect). Might some alterations be beneficial? Additionally, the background provided will facilitate conversations regarding identification of epigenetic "targets" that might be amenable to pharmacological manipulation.

Bile acids play an important role in maintaining lipid, glucose and energy homeostasis. Our recent study shows that transgenic mice overexpressing Cyp7a1 are resistant to western high fat diet-induced obesity and diabetes. Bile acid signaling may activate insulin signaling to maintain glucose and lipid homeostasis. Multiple signaling pathways contribute to the regulation of hepatobiliary transporter expression and function. Altered expression of uptake and efflux transporters influences hepatic drug disposition and susceptibility to chemical-induced toxicity. In response to hyperglycemia, the Nrf2 transcription factor mediates up-regulation of ABC efflux transporters in livers of mice. Induction of these transporters is in part regulated by hepatocyte proliferation. Interestingly, up-regulation of ABC efflux transporters during diabetes is attenuated in mice in response to pregnancy, likely through disrupted FXR-Shop signaling. In this presentation, the physiological and transcriptional pathways regulating ABC transporter expression during diabetes and pregnancy, as well as the implications for drug therapy and xenobiotic toxicity, will be discussed.

Methylation at the 5-position of DNA-cytosine (5mC), the histone code and non-coding RNAs contribute to epigenetic regulation. Additionally, a sixth DNA base, 5-hydroxymethylcytosine (5hmC) was identified recently. It is generated by the Ten-eleven Transcription Location (Tet) family of proteins through oxidation of 5mC. Thus, Tet modules DNA methylation levels. Furthermore, Tet exhibits a dual function in that these proteins can also play a role in regulating transcription. The talk will conclude with discussion about the potential for targeting nuclear receptors as weight loss therapies.

In recent years, epigenetic factors have been implicated in the etiology of various diseases including cancers, psychiatric disorders, and diabetes/obesity. As epigenetic mechanisms have become more extensively characterized, new opportunities for therapeutic intervention in these disease areas have been identified. While pharmaceutical inhibitors of epigenetic targets such as histone deacetylases and DNA methyltransferases have recently gained regulatory approval, the field of pharmacoeigenetics is still relatively young. As greater understanding of the epigenome is evolving, previously approved drugs are now serendipitously being found to have epigenetic modulatory properties and are currently under evaluation for new indications. With the rapid emergence of multiple novel epigenetic targets for pharmacological inhibition, new considerations for the field of pharmacoeigenetics are becoming apparent as well. In order to address the potential toxicological consequences associated with pharmacological inhibition of potential therapeutic epigenetic targets, toxicologists are addressing the need for new models and endpoints to be considered in the safety assessment of epigenetic targets. These important toxicological issues, which may be unique to epigenetic targets, will be addressed.

Epigenetics refers to heritable mechanisms superimposed on DNA base sequence that regulate gene expression (thus, the term epi- (Greek: over, above) genetics). Methylation at the 5-position of DNA-cytosine (5mC), the histone code and non-coding RNAs contribute to epigenetic regulation. Additionally, a sixth DNA base, 5-hydroxymethylcytosine (5hmC) was identified recently. It is generated by the Ten-eleven Transcription Location (Tet) family of proteins through oxidation of 5mC. Thus, Tet modules DNA methylation levels. Furthermore, Tet exhibits a dual function in that these proteins can also play a role in regulating transcription. Additionally, components of the core promoter recognition complex change in a cell-specific fashion to turn on transcriptional program while turning off others; this provides a novel epigenetic mechanism. Interest in understanding the extent to which epigenetic changes might underlie toxicity/disease (as a causative or susceptibility factor), including adverse transgenerational effects, is increasing. This will provide a basis for discussing issues to contemplate when considering epigenetics and safety assessments, (e.g., parameters to be evaluated, genomic region(s) to monitor, methodological (ies), biological endpoint(s),) and what tools and model systems might be employed? Attention should be paid to fundamental principles of toxicology, (e.g., dose-response, criteria for a maximum dose, normal variability, and change vs. an adverse effect). Might some alterations be beneficial? Additionally, the background provided will facilitate conversations regarding identification of epigenetic "targets" that might be amenable to pharmacological manipulation.
The epigenome can be passed through the germ line to influence transgenerational inheritance. Recent studies suggested that chemical exposure of pregnant rodents can cause epigenetic changes in the (F1) concepts, which can be inherited by subsequent generations. To further explore this phenomenon, groups of 25 pregnant F0 CD-1 mice were administered diethylstilbestrol or estradiol from gestation day 9 to lactation day 20. Offspring were mated for two additional generations, with F1-F3 offspring evaluated for uterotrophic effects and vaginal patency, and a subset of animals evaluated at 18 months for uterine tumor incidence. This presentation provides an overview of our, and others, transgenerational epigenetic data for areas of concordance and discordance, as well as provides thoughts on how these findings are placed within the context of product safety assessment.
will provide a single unified data repository and analysis system that compiles available information on a substance, including: chemical structures and properties, regulatory records, toxicity studies, biological screening assays, (QSAR) models and application programming interfaces (APIs) to commercial (QSAR) tools. In cases where no information is available for a particular substance, CERES provides tools to identify potential safety concerns by applying mode-of-action-driven (QSAR) prediction models, computer models using structural alerts and, in the future, modified TTC categories, and for identification and analysis of data on structural and biological analogs (read-across). The presentation will describe the use of (QSAR) tools at OFAS and the future directions of (QSAR) within OFAS through the CERES system.

W 42 APPLICATION OF IN SILICO APPROACHES IN COSMETICS—JUNIPER BERRY OIL.
T. Re L’Oréal, Clark, NJ.

Natural, plant-derived botanical ingredients are increasingly being used in cosmetic and personal care products. Safety evaluation of these complex mixtures is a challenge due to factors such as a high degree of variability in composition. Where direct evidence of safety does not exist, it may be necessary to use Threshold of Toxicological Concern (TTC) and a weight-of-evidence (WoE) approach to evaluate safety. The first step in the safety evaluation of natural ingredients is to obtain a complete as possible characterization of chemical constituents. For each component, its maximum known concentration, its molecular weight, and LogP are used to estimate skin penetration potential and to estimate a maximal daily systemic exposure. Nominal exposure values are then compared with their respective TTC class, known NOAELs and/or food intake values of “no safety concern.” In cases where systemic exposure exceeds these values, additional in silico evaluation may be done. Read across using procedures such as the JECFA congeneric model and/or computer modeling to identify similar structures with known toxicity data may be used. In addition, potential structural alerts of individual components can be evaluated using commercially available databases – DEREK, OECD toolbox, Lead Scope, etc.). Therefore, a weight-of-evidence approach based on available toxicology data, extrapolated NOELs, and/or predictive in silico data can be used to evaluate the safe cosmetic use of complex plant-derived materials.

W 43 HIGH-THROUGHPUT IN VITRO TOXICITY TESTING: A MIDDLE-COURSE ASSESSMENT OF PREDICTIVE ACCURACY FOR IN VIVO ENDPOINTS AND USE IN DECISION-MAKING.
R. S. Thomas1 and W. D. Pennie,1 The Hamner Institutes for Health Sciences, Research Triangle Park, NC, and2 Pfizer, Inc., Groton, CT.

Over the past five years there has been a broad-based discussion on the future direction of toxicology and how safety testing is performed. This discussion has spawned multiple research efforts looking to use high- and medium-throughput in vitro screening data in identifying chemical hazards. For industrial and agricultural chemicals, research efforts in United States and Europe have characterized the in vitro biological activity of chemicals using multiple in vitro assays and technologies to predict in vivo toxicity and prioritize compounds for conventional toxicity testing. For pharmaceuticals, high-throughput in vitro screening assays have been integrated early into preclinical drug development to identify toxic components and guide medicinal chemistry efforts. In both cases, the application of in vitro toxicity screening for prioritization and hazard identification relies on its ability to accurately predict the results of in vivo laboratory animal studies and humans. The efforts in the United States and Europe are now several years old and a significant amount of data has been collected to provide an evaluation of the strengths and limitations of the using high- and medium-throughput screening for predicting in vivo animal responses. This session will be of broad interest to investigators and regulators looking to use in vitro assays for toxicological testing and safety assessment of environmental, industrial, and pharmaceutical chemicals.

W 44 A COMPREHENSIVE STATISTICAL ANALYSIS OF THE IN VITRO-TO-IN VIVO PREDICTIVE CAPACITY OF HIGH-THROUGHPUT TOXICITY SCREENS.
R. D. Wolfinger, SAS Institute Inc., Cary, NC.

The release of the US Environmental Protection Agency’s ToxCast Phase 1 dataset has provided an excellent opportunity to evaluate the ability of high-throughput in vitro screening assays to predict in vivo toxic endpoints. A broad-based statistical classification analysis was performed using a suite of different predictive modeling methods. The predictors include the results from the nearly 400 in vitro cell-based and biochemical assays and structural chemical descriptors. The in vitro effects to be predicted include hundreds of endpoints from the ToxRef database. Analysis of the results demonstrated that the in vitro cell-based and biochemical assays provided similar predictive performance compared with the structural chemical descriptors across the majority of the in vivo endpoints. The combination of in vitro cell-based and biochemical assays and structural chemical descriptors provided increased predictive performance over either type of data alone. For the in vitro cell-based and biochemical assays themselves, broad evaluation of predictive performance showed limited sensitivity, but high specificity for predicting the in vivo effects. These results offer mid-course insights for their utility in toxicity testing and decision making.

W 45 FEASIBILITY OF PREDICTING IN VIVO MODE OF ACTION USING PATHWAY-BASED IN VITRO SCREENS.
R. S. Judson, National Center for Computational Toxicology, US EPA, Research Triangle Park, NC.

The US EPA is carrying out a large scale project called ToxCast, one goal of which is to build toxicity signatures. These are intended to be predictive models that link in vitro assay results for chemicals with whole animal in vivo toxicity outcomes. From Phase I of ToxCast (309 data rich chemicals), we have developed signatures for several cancer endpoints (e.g., liver and thyroid), reproductive fitness and developmental toxicity endpoints. Phase II data (700 chemicals combing data rich and data poor subsets) is allowing us to test the forward predictive power of the original signatures and to make further refinements. This talk will describe signature development approaches including hurdles to successful development of highly predictive models. These issues include multiplicity of modes of action (e.g. for cancer) leading to statistical power issues; problems with lack of metabolism in most in vitro assays; the need for pharmacokinetic modeling; inherent noise in in vitro assays; and the lack of realistically organotypic cell systems. Despite these inherent limitations, we have examples of useful signatures that link specific key molecular events that can be probing in vitro assays to predict in vivo modes of action. We illustrate this linkage using the example of pathways that help drive angiogenesis, which play roles in both chemically-driven developmental defects and cancer progression.

W 46 EVALUATING THE EFFECT OF DOSIMETRY ON THE IN VITRO-TO-IN VIVO PREDICTIVE CAPACITY AND RELATIVE SENSITIVITY OF THE TOXCAST SCREENS.
B. A. Wetmore, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

The current ToxCast Phase I project has evaluated 309 chemicals across 500 in vitro cell-based and biochemical assays. The results from the assays have been summarized based on the half-maximal activity concentration (AC50) or lowest effective concentration (LEC) which characterizes the responses based on nominal chemical concentrations in the well. The AC50 and LEC summary values are being used to predict the in vivo toxic endpoints; however, the use of nominal chemical concentrations does not account for pharmacokinetic factors in predicting in vivo toxicity and no overall evaluation has been performed to assess the relative sensitivity of the in vitro assays compared to in vivo responses. In this study, metabolic clearance was measured in rat primary hepatocytes and plasma protein binding was measured in rat plasma for a subset of 59 ToxCast chemicals. Computational in vitro-to-in vivo extrapolation methods and reverse dosimetry were then used to estimate rat oral equivalent doses required to produce steady state in vivo concentrations equivalent to in vitro AC50 and LEC values in each of the ToxCast assays. For each chemical, the rat oral equivalent dose from the most sensitive in vitro assay was compared with the low effect level from the most sensitive endpoint in the in vivo studies in the ToxRef database. The results suggest that the most sensitive in vitro assay is 10- to 15-fold more sensitive than the apical responses in vivo. When the oral equivalent doses for all the in vitro assays were used in a partition tree classification model to predict the in vivo endpoints, an increase in model performance based on the area under the curve (AUC) of the ROC curve was observed for more than half of the endpoints. However, the increase in the AUC was relatively small suggesting the gain in performance was minimal. Inherent pharmacodynamic differences between the in vivo human bioactivities and in vivo rat endpoints assessed are being explored as factors that may be compromising the analyses.

W 47 PREDICTING IN VIVO TOXICITY USING IN VITRO ASSAYS AND CHEMICAL PROPERTIES IN PRECLINICAL DRUG DEVELOPMENT.

The incorporation of predictive toxicity approaches in early preclinical drug development will be important for reducing the attrition rate within the industry. To identify potential toxic compounds and guide medicinal chemistry efforts, targeted
in vitro assays have been integrated with structure activity-relationship rules and physicochemical properties to predict in vivo effects. The results have demonstrated that selecting appropriate cell systems that predict the mechanisms of toxicity are key factors that determine the successful prediction of in vivo effects while predicting organ-specific toxicity remains a challenge. In profiling drug-like molecules, we have considered multiple mechanistic endpoints (cell death, apoptosis, promiscuity against secondary targets, microchimeric endpoints, etc.) in cell lines of different tissue origins (e.g. transformed cell line of hepatic or cardiac origin, or using stem cell derived specific cell lineages). In these experiments, we have established not only the technical performance of mechanistic cell-based assays, but also the impact of cellular background on predictivity. In building predictive models particular challenges exist in the careful annotation of the training data set and building data bases of well annotated and accessible data. Finally, the need to balance an understanding of transporter interactions, metabolism and intended dose of the compound are all shown to have an effect on predictive model performance. In this regard, we have built computational models that incorporate dose prediction as well as chemical properties in an attempt to guide early medicinal chemistry to safer chemical space.

W 48 USING IN VITRO MODELS TO PREDICT REPRODUCTIVE AND DEVELOPMENTAL TOXICITY: A MIDCOURSE ASSESSMENT OF THE EUROPEAN REPROTECT PROGRAM.

M. Schwarz, Institute of Experimental and Clinical Pharmacology and Toxicology, University of Tuebingen, Tuebingen, Germany. Sponsor: R. Thomas.

An integrated project called ReProTect (www.reprotect.eu) was run from 2004 to the end of 2009, which was funded by the European Commission within the 6th Framework Program for research. The project assembled 33 European partners from academia, small and medium-sized enterprises, governmental institutions and industries. The aim of ReProTect was to develop or improve in vitro assays for their integration into a testing strategy suited to provide detailed information on the hazard of compounds to the mammalian reproductive cycle. At the end of the project more than 20 different tests were developed, predicting effects on spermatogenesis, folliculogenesis, germ cell maturation and fertilization, steroidogenesis, the endocrine system, the pre-implantation embryo, placentaion, uterus function, and embryonic development. Standard operating procedures for each of the tests have been produced and more than 150 peer-reviewed reproducitive toxicants have been tested. In the final year of the project, a ring trial, termed the “Feasibility Study”, was conducted in order to challenge the in vitro tests of ReProTect. A set of 10 test chemicals were investigated under blinded conditions by the participants of the Feasibility Study in their respective assays. The outcome of the study revealed that this preliminary test battery was able to correctly predict most of the in vitro effects on fertility and embryonic development, while only few predictions were incorrect for explainable reasons. The Feasibility Study of ReProTect has constituted a paradigm of alternative testing batteries and will guide future approaches in this field. Its success is a major step towards reduction and replacement of animal experiments and portrays the main achievements of the EU project.

W 49 THE EPIDIDYMIS, THE FORGOTTEN TARGET OF TOXICANTS.

D. Cry1 and R. E. Chapin2, Institute Armand-Frappier, INRS, Laval, QC, Canada and Drug and Safety Development, Pfizer, Groton, CT.

The epididymis is the major component of the testicular excurrent duct system. Testicular input to the tissue is conveyed via the efferent ducts, which anastomose to form a single, highly convoluted epididymal duct. The epididymis can be divided into two main compartments: the epithelium and the lumen. In the lumen, the contents of sperm that are bathed in luminal fluid whose composition varies markedly along the tissue. The blood-epididymis barrier, formed by epithelial principal cells, regulates this luminal environment and distinguishes it from blood. Functional sperm maturation in the epididymis is the result of their exposure to this luminal environment. Thus, the ability of the epididymis to provide the appropriate milieu for sperm maturation is critical. This is created by several processes, most notably the highly absorptive and secretory activities of the epithelial cells that line the duct. Many epididymal functions are either androgen or estrogen-dependent. The critical functions of the epididymis for sperm maturation and its reliance on hormonal regulation make it a prime target for toxic action. Several studies have shown that endocrine-disrupting chemicals, such as phthalates, can alter the development of the epididymis, and, in extreme cases, lead to its absence. Other chemicals, such as dioxins, affect sperm maturation via alterations to epididymal functions. However, epididymis frequently is ignored in toxicity studies. Yet, posttesticular and idiopathic male infertility represents a significant problem, suggesting that alterations in epididymal sperm maturation may have greater significance than previously thought. This session will provide an overview of epididymal functions and regulation and show examples of how environmental toxicants may alter male fertility by targeting the epididymis.
The final stages of sperm maturation occur in the epididymis, where sperm acquire the ability to swim and fertilize. Since sperm are transcriptionally inert, they must rely on the epididymis for protection from chemical insult. This is accomplished in part by an extensive blood-tissue barrier that limits the passage of molecules between cells and the epididymal lumen. The blood-epididymis barrier is composed of occludin and claudins, which form tight junctions between adjacent principal cells of the epididymal epithelium. The barrier is, however, more complex involving a series of chemical and ionic transporters that permit creation of specific microenvironments, required for sperm maturation, within the lumen, along the length of epididymis. In addition to these transporters, specific pores formed by claudins within the tight junction allow rapid and selective passage of ions across the tight junction. The barrier also contains transporters that can protect sperm from chemical toxicity. Alkylphenol ethoxylates, such as octylphenol (OP) have been reported to exert toxicity on sperm motility at high concentrations. We have shown that, at environmentally relevant doses, octylphenol does not accumulate in either the testis or epididymis, and is in fact rapidly eliminated, suggesting an active transport mechanism. We have shown the presence of a functional ABC-B1 transporter in the epididymis, which is induced by octylphenol and may be responsible for preventing (OP) accumulation in the epididymis. Surprisingly, we also observed that during epididymal transit, sperm acquire a functional ABC-B1 transporter critical to the detoxification process protecting sperm from chemical insult. Thus the blood-epididymis barrier is not only critical to epididymal physiology but acts as an essential structure for protecting maturing spermatozoa from chemical insult. Supported by CIHR and NSERC.

In evaluating the risk of neoplasia posed by selective immunomodulatory drugs, preclinical models, by providing data on hazard identification and characterization, can play an important role in a weight of evidence-based approach to risk assessment. However, their predictive value in quantitative risk assessment is limited. This is particularly true for genetically deficient animals and studies conducted with surrogate molecules. This presentation will focus on the available preclinical models and discuss their utility in informing risk assessment of immunomodulation and cancer.

Risk assessment for carcinogenic potential of selective immunomodulatory drugs requires a strategy based on a weight-of-evidence approach. This presentation will describe how a Product Specific Assessment (PSA) is formulated, including a review of relevant data from a variety of sources, such as published data, information on class effects, target biology and mechanism of action, as well as in vitro, chronic toxicity, and clinical data. In some cases, the available information may be insufficient to address carcinogenic potential and inform clinical risk without additional nonclinical studies, while in other cases the sponsor should design a strategy to address the potential hazard, which may include additional studies that could mitigate the mechanism-based concern or the PSA may be used to communicate risk and provide input to the risk management plan along with labeling proposals, clinical monitoring, postmarketing surveillance, or a combination of these approaches.

Communication of risk of potential carcinogenicity of a drug product is a key component to any product label. Regulatory agency’s and product innovators are challenged to provide useful and understandable information to the clinician. This presentation will discuss the product labeling for several US FDA-approved immunomodulatory compounds and how the existing clinical and nonclinical information ultimately impacted the final product labeling and discuss how a detailed product-specific assessment could impact future drug product labeling.
60 IMAGING-BASED MULTISCALE MODELS OF THE RESPIRATORY SYSTEM THAT ACCOUNT FOR REGIONAL HETEROGENEITY IN HEALTH AND DISEASE.

D. R. Einstein, R. E. Jacob, S. Kabilan, A. P. Kuprat, J. P. Carson, K. R. Minard and R. A. Corley, Pacific Northwest National Laboratory, Richland, WA.

Historically, computational fluid dynamic (CFD) models of the respiratory system have been unable to account for mechanical variation in the lung. However, local deviations from nominal heterogeneity and compliance in disease states such as emphysema and fibrosis have both important clinical and pathological implications. Moreover, by altering site-specific flow, these deviations are likely to influence the dosimetry and responses to drugs, gases or particulates. To investigate the influence of regional heterogeneity and compliance on airflow, multiscale CFD models of the respiratory airways of control and elastase treated rats were constructed from high-resolution computed tomography (CT) images. Time-dependent CT images were acquired in live, mechanically-ventilated Sprague-Dawley rats at eleven time points over the breathing cycle. Three-dimensional (3D) deformation fields were calculated for each set of images by non-linearly warping each image to a reference image. From these deformation maps, 3D volumetric strain was computed by solving for non-linear strain based on a finite-element discretization. Model geometries were derived from high-resolution CT images of post-mortem lung casts. Lower-dimensional models of distal lung mechanics, including resistance, inductance and compliance were parameterized from the live and cast images and bi-directionally coupled to each CFD outlet. Boundary conditions for the multiscale models consisted of atmospheric pressure at the nose and time dependent regionally specific volumetric strain – ventilation – at the terminus of each lower-dimensional model. Compared to the control models, predications from the elastase-derived models indicated that disease specific mechanics profoundly altered flow. These models are the first to our knowledge to incorporate detailed mechanics of the parenchyma and form the basis for an investigation of airway toxicity in health and disease. Funded by NHLBI R01 HL073598.

61 AN IN SILICO MODEL OF ENDOTOXIC SHOCK MEDIATORS.

M. K. Makley, E. Hack and J. M. Gehrart, 711 HPW@RHHP, Henry M. Jackson Foundation—Wright-Patterson AFB, Dayton, OH.

Biologically-based in silico models of pathogen-host interactions are being designed in our lab to predict the time-course of pathogenic infection in humans. Macrophages respond to lipopolysaccharides (LPS), including the release of potent lipid autacoids, causing a cascade of events leading to endotox shock. However, animals have been shown to vary in response and susceptibility to E. coli endotox: guinea pig > hamster > mouse. To establish a sound basis for interspecies extrapolation, a pathogenesis model is being extended to encompass endotox shock. Exposing experimental animals to aerosols of LPS elicits bronchoconstriction, activation of alveolar macrophages, and recruitment of inflammatory cells into airways. These effects have been attributed to a potent lipid autacoid, platelet-activating factor (PAF). Species differences in the biomodulatory effects and mechanisms of PAF are similar to those seen with endotoxin. In guinea pigs, PAF (2 ug/kg IV) causes bronchoconstriction and hypotension in seconds and lethality within 25 minutes. In rats, however, 3 ug/kg of PAF had a negligible impact on heart rate. Therefore, a dynamic model for PAF was developed to link a pathogen’s kinetics and host response. The current model focuses on kinetics and receptor binding of PAF and its antagonist ginkgolide B (GB). The kinetic models include plasma, red blood cell, lung, heart, and rapidly and slowly perfused tissues, with IV and inhalation exposure routes, and pathways for binding and elimination of PAF. Kinetic parameters were from the literature. The model was used to simulate experimental exposures to PAF and GB, revealing potential explanations for species differences in sensitivity to PAF. Internal dose metrics were generated and correlated with observed signs of infection and lethality in an attempt to identify the most appropriate metrics for predicting adverse effects. This model of pathogen kinetics and these dose metrics help to elucidate mechanisms of host response dynamics and improve cross-species extrapolation of data.

62 COMPARATIVE EXPOSURE ASSESSMENT: USE OF PBPK MODELING FOR THE ESSENTIAL ELEMENT MANGANESE.

R. Gentry1, A. Santamaria1, S. Sulsky1, A. Shipp1, C. Van Landingham1, W. Fuller2, K. Fast2, M. Taylor3 and J. Roper3, ENVIRON International Corporation, Monre, LA and 4Aton Chemical Corporation, Richmond, VA.

Most methods for exposure and risk assessment cannot capture the typical biophysical response of an essential element. Investigations have been conducted to assess the potential for adverse health impacts from exposure to Mn present in air from occupational sources. These analyses have not considered the essentiality of Mn and its function in key biological processes. Furthermore, the lack of an integration of Mn-specific kinetic and experimental data has resulted in the application of uncertainty factors that may not be necessary for the derivation of a ‘safe’ inhalation exposure level. PBPK models were applied to determine target tissue concentrations of Mn following occupational and measured ambient environmental exposures. These data were then compared to determine margins of safety and to evaluate the biological plausibility of applying uncertainty factors to derive acceptable air concentrations. Blood concentrations reported in the occupational studies allowed for human verification of the PBPK models, increasing confidence in the estimates. The results of modeling considering both dietary and inhalation intake of Mn suggested that marginal exposure levels only when exposure is to levels of Mn in ambient air far higher than those currently measured in Canada or the United States. Margins of Safety were greater than three orders of magnitude, indicating how much of an increase in the ambient levels would be required to produce the target tissue level at or below which no subclinical neurotoxicological effect would be expected. This application of PBPK modeling for an essential element, such as Mn, clearly demonstrates that the application of default factors to “convert” an occupational exposure to a continuous environmental exposure, followed by the application of uncertainty factors is not scientifically defensible in the case of Mn. It also suggests a maximum uncertainty factor on the order of 10, rather than several orders of magnitude.

63 TRANSLATIONAL PHARMACOKINETIC-PHARMACODYNAMIC MODELING OF QTc EFFECTS IN DOG AND HUMAN.

J. Parkinson1, P. Jarvis2, S. Visser3, C. E. Pollard4, J. Yates4, H. Southworth5, J. P. Valentin4 and L. Ewart6, Safety Pharmacology, AstraZeneca, Alderley Park, United Kingdom, 2Discovery Enabling Capabilities & Science, AZ, AP, United Kingdom, 3Global DMPK Centre of Excellence, AstraZeneca, Södertälje, Sweden, 4DMPK, AstraZeneca, AP United Kingdom and 5Global Clinical Development, AstraZeneca, AP, United Kingdom.

Prolongation of the QT interval is used as a biomarker for the arrhythmia Torxsdes de Pointes. In contrast, less is known about safety implications of QT shortening despite a recent increase preclinically in the number of drugs with this effect (1). A pre-clinical assessment of the relationship between concentration and QT change is therefore crucial to assure drug safety. The aim of this investigation was to perform a retrospective pharmacokinetic-pharmacodynamic (PKPD) analysis of dog and man data and compare the effects of 2 proprietary small-molecules, one increasing and one decreasing the heart-rate corrected QT interval (QTc) in both species. The preclinical data were collected in a conscious dog telemetry model while the clinical data were collected during Phase I trials in healthy volunteers. 2 or 3 compartmental models were used to describe the PK of drugs in dog and man, respectively. Final PK parameter estimates were then used as an input for the PKPD model. An effect compartment was introduced to derive the concentration-effect relationships. The QTc response from dog and man at matching free concentrations were then plotted against each other. The initial plot showed a clear translational relationship between dog and man QTc response, confirming that the conscious dog model is effective for predictions of drug-dependent QTc effects in man. To confirm our findings, we have included PKPD data for known QT prolongers (moxifloxacin & dofetilide). The resulting plot closely matched initial results and had a slope of 1.3 ms. Based on this relationship, QTc change of ~7 ms in dog would correspond to 10 ms change in man. Such relationships could be therefore useful to predict the clinical outcome on QTc interval change using preclinical dog data and will thus improve future decision-making. 64 DEVELOPMENT OF A HUMAN GESTATION PHYSIOLOGICALLY-BASED PHARMACOKINETIC/PBPK MODEL FOR COEXPOSURE OF POLYCHLORINATED BIPHENYLS (PCBS).

M. Ray1, P. Ruiz2, S. Li2, M. Mumtaz3 and J. Fishb4, Division of Toxicology and Environmental Medicine, CDC, ATSDR, Atlanta, GA, 2Medical College of Georgia, Augusta, GA, 3University of South Carolina, Columbia, SC and 4National Center for Toxicological Research, US FDA, Jefferson, SC.

Exposure of pregnant women to persistent organic pollutants such as PCBs can lead to toxic effects in mothers and fetuses via blood transfer through the placenta. Concentrations of PCBs measured in human biomonitoring data from expectant mothers exposed to background levels of PCBs, and the transfer of PCBs from mother to fetus were assessed using PBPK modeling. A human gestation PBPK model for the coexposure of PCBs was developed to simulate the disposition of a
maximum of ten PCB congeners within a pregnant mother and fetus throughout the entire 40 week gestational period. A five compartment maternal model, and four compartment sub-model was used to describe the pharmacokinetics of PCBs in the mother and fetus, respectively. Quantitative Structure Activity Relationships were applied to calculate the chemical-specific parameters, while the physiological parameters were taken from the literature. Model evaluation was performed by comparing estimated daily intakes and tissue concentrations of PCBs from published literature with the model predicted tissue concentrations. The model was capable of simulating the pharmacokinetics of PCBs during pregnancy in a sample of NHANES biomonitoring during 1999-2000 and 2001-2002. The model correlation coefficients values were 0.87, 0.81, and 0.85 for the first, second and third trimester, respectively. Hence, this model can be used as a screening tool that can provide useful information for mothers and the in utero exposure of PCBs.

Physiologically-based pharmacokinetic (PBPK) models are compartmental models that describe the uptake and distribution of drugs and chemicals throughout the body. They can be structured so that model parameters (i.e., physiological and chemical-specific) reflect biological characteristics. Bayesian methods can be used to combine prior information derived from the literature (e.g., mean values, chemical structure, and in vitro data) in the form of probability distributions on PBPK model parameters with new information from in vivo data to determine parameter estimates and model uncertainties. These methods can also be used to evaluate and refine biological modeling assumptions underlying PBPK models. Using a PBPK model developed for permethrin in rats, we combine prior information from the literature on several of the PBPK model parameters (e.g., blood flows, partition coefficients, chemical-specific parameters) with measured concentrations of both the cis- and trans-isomers of permethrin in various tissues for uncertainty analysis and model evaluation. We evaluate biological assumptions used to describe partition coefficients via Schmitt's predictive model (2008) by comparing the model fits of two different permethrin PBPK models. In the first version of the model, partitioning is characterized by the explicit use of standard tissue-specific partition coefficients as PBPK model parameters. In version two of the permethrin PBPK model, we use Schmitt's 2008 model based on tissue composition, solubilities, and binding properties to compute the partition coefficients for each tissue or compartment within the permethrin PBPK model. We illustrate how Bayesian methods provide a useful statistical framework in which to determine how well the underlying biological assumptions used to model partitioning describe the distribution kinetics of permethrin. This abstract does not necessarily reflect US EPA policy.

There has been considerable interest in the development of in vitro tests for the characterisation of chemical allergens, such as cytokine production by dendritic cell (DC)-like cell lines. These methods are often limited by toxicity and delivery of lipophilic chemical allergens in culture and lack of dynamic range. We have measured IL-8 production following 24h culture of the human monocytic THP-1 cell line with various allergens or with nonsensitising irritants. Treatment of THP-1 cells with a range of water soluble and lipophilic allergens of diverse chemistries (dinitrohalobenzenes, potassium dichromate, resorcinol and aminophenol) resulted in increased IL-8 expression. Although the concentrations at which cytokine secretion was stimulated spanned a relatively narrow range (generally doses that caused 10-30% decrease in cell viability), IL-8 production was selective for allergens, such that culture with a number of irritants (at doses causing equivalent levels of cell death) failed to upregulate this cytokine. Furthermore, an impressive dynamic range was revealed for THP-1 cell IL-8 expression. Thus, the reference lipophilic allergen dinitrochlorobenzene (DNCB) stimulated the production of 1-4ng/ml (equating to a 15-fold increase in IL-8 compared with background levels). Its water soluble analog, dinitrobenzenesulfonic acid (DNBS), induced levels of 12ng/ml. In addition, analysis of IL-8 expression in both supernatants and cell lysates revealed that allergens (but not irritants) stimulated increases in both secreted and intracellular levels of this cytokine. These data suggest that analysis of the production of IL-8 by THP-1 cells may provide a useful tool in the identification of chemical allergens, possibly involving a metric where total (secreted and intracellular) IL-8 is measured.
The production of cytokines such as interleukin (IL)-8 by cultured dendritic cell (DC)-like cells has been suggested as a potential endpoint for the in vitro identification of chemical allergens. It is of some interest that allergen-induced IL-8 production appears to be related to cell injury and cell death. We have demonstrated that for several cell types (including the HaCaT keratinocyte cell line), allergen-induced IL-8 production is closely associated with the profile of toxicity (with only subtoxic doses stimulating IL-8). However, the induction of cell death by other means, including osmolality-induced lysis or culture with a number of different chemical irritants (e.g. sodium lauryl sulfate, Tween 20 and benzene sulfonic acid), did not show the same relationship between cellular toxicity and IL-8 expression. Furthermore, this relationship was observed only for IL-8 expression, and not for other cytokines (IL-6 or IL-1β). Other cytokine inducing reagents (reactive oxygen species [ROS] activators) that provoke activation of the inflammatory immune system have also been examined. The ROS activators uric acid, aluminium hydroxide, ATP and silica had little effect on cell viability and provoked relatively modest increases in IL-8 but vigorous production of IL-1β. Hydrogen peroxide did cause marked cell death, but IL-8 expression was recorded even at doses at which >50% cell death was observed. Thus ROS activating agents also stimulate a very different pattern of cytokine expression, and show a very different relationship to cell death compared with that observed for the chemical allergens. The impact of diphenylethenoclonium chloride (DPI), an inhibitor of nicotinamide adenine dinucleotide phosphate-oxidases, on IL-8 expression and show a very different relationship to cell death compared with that observed for the chemical allergens. The inhibition of dienophylenedononium chloride (DPI), an inhibitor of nicotinamide adenine dinucleotide phosphate-oxidases, on cytokine production was examined. The inhibitor had some impact on IL-8 production induced by allergen, but was unable to completely block cytokine production. These data suggest that ROS generation is playing a partial role in IL-8 production, at least by some types of allergen.

The production of cytokines such as interleukin (IL)-8 by cultured dendritic cell (DC)-like cells has been suggested as a potential endpoint for the in vitro identification of chemical allergens. It is of some interest that allergen-induced IL-8 production appears to be related to cell injury and cell death. We have demonstrated that for several cell types (including the HaCaT keratinocyte cell line), allergen-induced IL-8 production is closely associated with the profile of toxicity (with only subtoxic doses stimulating IL-8). These data suggest that ROS generation is playing a partial role in IL-8 production, at least by some types of allergen.
donor with the allergic reaction are incubated with the suspected drug and cytokines (IL-2, IL-5, IL-7, IL-10, IFNgamma) and green fluorescent protein (GFP) reporter transgenic liver supernatant. The objective of these studies was to evaluate incubation times and the ability of the mLTT to reproducibly detect positive responses against sulfamethoxazole (SM) with cryopreserved PBMC from an SM allergic donor. In addition, specificity was determined by evaluating the cytokine responses of PBMC from the SM allergic donor when incubated with an irrelevant drug (amoxicillin). Peak levels of IL-2, IL-5, IL-13, IFNgamma, and granzyme B were observed between days 3 to 7. Experiment-to-experiment variability for IL-2, IL-5, IL-13, IFNgamma, and granzyme B release was high but the mLTT was able to detect a positive response in 83% of 12 separate experiments (a positive is defined as 3 out of 5 endpoints having at least 2-fold higher signal with SM treatment than the signal with no drug experiment (stimulation index)). The specificity of the response was 90% since only 1 of 10 experiments gave a positive response with amoxicillin exclusion. In conclusion, the mLTT assay performance appears to be robust based on repeated experiments with PBMC from one SM allergic donor. Further evaluation of assay performance is needed using samples from additional donors with allergic reactions to different drugs.

74 DEVELOPMENT OF A DELAYED-TYPE HYPERSENSITIVITY ASSAY TO CANDIDA ALBICANS IN JUVENILE RATS: COMPARISON OF IN VIVO AND EX VIVO METHODS.

Delayed-type hypersensitivity (DTH) is a memory T cell-mediated, antibody-independent immune response that may be used for immunotoxicity testing in non-clinical species. However, a number of current DTH assays are confounded by the production of antibodies to the antigen. We are currently modifying a DTH model, previously established in mouse, for use in juvenile rats to assess the effect of immunosuppressive drugs on the developing rat immune system. The assay measures footpad swelling induced by subcutaneous footpad injection of *Candida albicans* (*C. albicans*) chitosan in rats previously immunized with *C. albicans*. Antibodies to chitosan are not produced in this model. Large inter-animal variability inherent in the footpad swelling assay makes it difficult to precisely quantify the magnitude of the immune response and inhibition by immunosuppressants. We have developed an *ex vivo* assay to assess DTH in rats using IFN-gamma production by splenocytes of rats previously sensitized with *C. albicans* as the quantifiable measure of DTH response. Rats dosed with dexamethasone, a known immunosuppressive compound, exhibited immunosuppression as evidenced by a reduction in IFN-gamma production in response to *C. albicans* chitosan. Current data indicate that the in vitro based DTH assay is more sensitive than the conventional footpad swelling assay due to lower background response and smaller variability. Our *ex vivo* based rat DTH assay offers a highly sensitive and quantitative alternative to the footpad swelling assay, and may be used to assess the immunosuppressive properties of drugs. The increased sensitivity of the *ex vivo* DTH assay may be useful for identifying smaller changes in response to immunosuppressive drugs, and also for studying the responses in juvenile rats that do not yet have a fully functional immune system.

75 SPECIFICITY PROTEINS LINK ONCOPICENMICRORNAMIRB14 SIGNALING AXIS TO EZH2 REGULATION.
K. Kim and S. Safe, Center for Environmental Health and Genetic Medicine, Texas A&M Health Science Center, Houston, TX.

The Enhancer of Zeste 2 (EZH2) protein is a histone methyltransferase that mediates epigenetic silencing through chromatin remodeling. EZH2 plays a pivotal role in cell self-renewal and tumorigenesis and is frequently overexpressed in many cancers. Thus, it is important to identify pathways that regulate EZH2 expression and to develop strategies to target EZH2. Oncogenic microRNAs (miRs), including miR-106b and miR-93, target ZBTB4 which functions as a specificity protein (Sp) repressor through competitive binding to GC-rich sequences. Increased ZBTB4 expression by oncogenic miR depletion resulted in downregulation of Sp1, Sp3 and Sp4 proteins and Sp-dependent oncogenes, including survivin, VEGF and Wnt5a, suggesting a tumor suppressive role for ZBTB4. Bioinformatics analysis further revealed that EZH2 is a downstream target of ZBTB4 and in fact, ZBTB4 overexpression repressed EZH2 expression through downregulation of Sp5 proteins in MCF-7 and MDA-MB-231 breast cancer cells. Sp1, Sp3 and Sp4 knockdown by RNA interference decreased EZH2, indicating that Sp proteins are necessary for EZH2 expression. Chromatin immunoprecipitation and gel shift assays confirmed that Sp proteins bond GC-Rich Sp binding sites on the EZH2 promoter and ZBTB4 compete Sp protein binding at these sites. Furthermore, transfection of miR-106b antagonir increased ZBTB4 and decreased EZH2 expression and this was accompanied by enhanced ZBTB4 binding to the GC-rich sites in the EZH2 gene promoter. Moreover, betulinic acid (BA), a phytochemically previously reported to downregulate Sp proteins in various cancer cell lines also decreased EZH2 expression by modulating the oncogenic miR/ZBTB4 axis. These results underscore Sp proteins as “non-oncogene addiction” proteins essential to maintain oncogenic function and cancer phenotype during tumorigenesis. Furthermore, this is the first study showing that Sp proteins connect the oncogenic miR-ZBTB4 pathway to EZH2 regulation and that inhibition of Sp proteins by BA will be a novel therapeutic approach that targets EZH2.

76 METHYLESELENOCYSTINE RESETS CIRCADIAN RHYTHM IN MAMMARY EPITHELIAL CELLS BY ENHANCING NAD+-DEPENDENT SIRT1 ACTIVITY.
M. Fang, W. Guo, C. Lewis and H. Zarbl, Environmental Occupational Medicine, University of Medicine and Dentistry of New Jersey, Piscataway, NJ.

We previously demonstrated that a chemopreventive regimen of dietary methyleselenocysteine (MSC) can reset and enhance the circadian expression of major clock genes (Per2) and circadian-controlled genes (CCGs) persistently disrupted by carcinogenic N-methyl-N-nitrosourea (NMU) during early stages of mammary tumorigenesis in rat. Here we show that dietary MSC significantly enhanced the intracellular circadian oscillations in the NAD+/NADH ratio, an indicator of REDOX status, with a peak value occurring at Zeitgeber Time (ZT8), resulting in an increased NAD+-dependent Sirt1 activity in the mammary glands of rats at ZT12. Moreover, dietary MSC specifically decreased acetylation of the Bmal1 (AcBmal1) transcription factor associated with E-box element within the promoter of the Per2 gene between ZT12 and ZT16, which negatively corresponded to the transcriptional phase of Per2 gene. The increase of NAD+/NADH and Sirt1 activity was also temporally correlated with significantly increased oscillations in the acetylation of lysine 9 in the histone 3 proteins (AcH3K9) associated with both E-box and Eson1 sequences within Per2 promoter regions in mammary glands of rats. The activating effect of MSC on NAD+-dependent Sirt1 activity was also observed *in vivo* when normal mammary epithelial cells (MCF10A) exposed to carcinogen were treated with MSC for 72 hrs. As was the case in vivo, the increased intracellular NAD+/NADH and increased Sirt1 histone deacetylation in vitro might be responsible, at least partially, for the increased cellular AcH3K9 level observed in mammary epithelial cells. These results suggested that MSC-enhanced circadian cycling of intracellular redox status increases the Sirt1 activity *in vitro* and *in vivo*. Moreover, these findings indicated that the resulting decrease in AcBmal1 and increase in AcH3K9 at E-box contributes to the induction of carcinogenic Per2 expression during chemoprevention. (Supported by NIH Grants: U19ES011387, P080ES05022, P30ES007083)

77 EPIGENETIC ALTERATIONS UNDERLIE THE MECHANISM OF N, N-DIETHYLITRITOSAMINE AND CARBON TETRACHLORIDE CARCINOGENESIS IN THE MOUSE LIVER.
T. Uehara1, K. Kutanzi2, I. Koturbash3, I. P. Pogribny3 and I. Rusov3, 1Department of Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC and 2Department for Biochemical Toxicology, National Center for Toxicological Research, Jefferson, AR.

Human hepatocellular carcinoma (HCC), which develops mostly under conditions of liver fibrosis and cirrhosis, has been linked to changes in the cellular epigenome. However, despite the large body of evidence demonstrating profound cancer-linked epigenetic abnormalities in HCC, the role of these epigenetic changes may play in hepatocarcinogenesis is less understood. This study used a mouse model of genotoxic carcinogenesis in a fibrotic liver to test the hypothesis that epigenetic events play a role in liver carcinogenesis. Male B6C3F1 mice were injected intraperitoneally (i.p.) with either N,N-diethylitritosamine (DEN, single dose of 1 mg/kg) or PBS vehicle at 15 days of age. Carbon tetrachloride (CCL4) treatment (0.2 ml/kg, i.p.; 2/week) was initiated at 8 weeks of age and continued for 9 or 14 weeks. Treatment with DEN alone resulted in few histopathological changes, whereas treatment with CCl4 led to a severe bridging fibrosis and the development of liver adenomas and carcinomas. In the DEN+CCl4 group, a strong synergistic effect was observed, as evidenced by a marked increase in liver tumor incidence. Histomorphological changes in livers of mice from CCl4 and DEN+CCl4 groups were accompanied by the loss of global and repetitive element DNA methylation. Hypermethylation of the Cdkn2a, Mgmt, Socs1, Cdh1, and Riz1 gene promoters was also found in non-tumorous liver tissue in these groups; however, only hyper-
methyltransferase of Riz1 was associated with gene silencing. Changes in DNA methylation were associated with a decrease in histone H3 lysine 9 trimethylation, which may be a subsequent effect of epigenetically-induced inhibition of the Riz1 gene expression. The latter correlated with tumor incidence. These findings suggest that liver fibrosis is acting as a tumor promoter and is also affecting the cellular epigenome during genotoxic-induced liver carcinogenesis in the mouse.

Data from the National Lung Screening Trial (NLST) have suggested that computed tomography (CT) annual screening of at-risk patients can decrease lung cancer mortality by 20%. Concerns remain regarding the long term effects of radiation exposure to the damaged lung cells of heavy smokers and ex-smokers. We previously reported that exposure of transgenic mice expressing a mutant Ki-ras⁶¹G12 gene to multiple whole-body CT doses approximating the NLST screening protocol had a significant (p<0.01) 43% increase in tumor multiplicity. Using Affymetrix gene chip expression profiling followed by gene ontology analysis, we identified clusters of genes under the categories “immune response” and “oxidative phosphorylation” that were significantly up- and down-regulated, respectively, in mutant Ki-ras⁶¹G12 expressing mice 10 min after exposure to a single 50 mGy dose of CT radiation compared to controls. We now confirm these findings in mice treated at 8 weeks of age with 4-(methylthio)acetophenone-1-(3-pyridyl)-1-butanone (NNK) followed one week later by 4 weekly doses of 0, 10, 30, or 50 mGy of whole-body CT radiation. Eight months after the last fraction of radiation, mice treated with NNK and exposed to radiation exhibited significant 1.5 to 2-fold increases in radiation-induced tumors compared to mice treated with NNK alone. Treatment of female mice with 0.7% N-acetylcysteine in the diet starting 3 days prior to the first CT exposure and continuing for a total of 5 weeks inhibited the CT-induced increases in lung tumor multiplicity back to levels seen in NNK treated, unirradiated mice (p<0.05; one tailed t-test). Our data indicate that: 1) exposure to CT radiation in sensitive populations increases the risk of tumorogenesis, 2) this effect may be mediated by immune response and oxidative stress mechanisms, and 3) pre-treatment with an anti-oxidant may prevent the long term carcinogenic effects of low dose radiation exposure. (Supported by NIH grant CA136910)

**80 EXPRESSION OF PROTO-ONCOGENE CFMS IN LUNG SQAMOUS CELL CARCINOMA AND ADENOCARCINOMA.**

S. Kakiuchi-Kiyota¹, C. Heintz¹, P. Lapointe¹, A. W. Robertson¹, F. Voigt¹, C. Tyő¹, R. E. Huynh¹, A. M. Ryan¹ and N. Mathialagan¹. ¹Drug Safety Research and Development, Pfizer Inc., Groton, CT and ²Drug Safety Research and Development, Pfizer Inc., La Jolla, CA.

cFMS proto-oncogene encodes the tyrosine kinase receptor for macrophage colony-stimulating factor 1 (CSF-1). Previous studies have shown that CSF-1 and cFMS are co-expressed in tumor cells and tumor-associated stromal cells in gynecological cancers and are involved in invasiveness and metastasis through autocrine and paracrine mechanisms. It was also reported that glucocorticoids induced cFMS expression in the choriocarcinoma cell line through glucocorticoid receptor (GR). Although CSF-1 level increased in the serum and tumor cells of patients with non-small lung carcinomas, little is known about the expression of cFMS and GR in patients with lung cancers. We postulated that cFMS expression is increased in lung cancers through GR, an action that may promote tumor progression. To test our hypothesis, we performed immunohistochemistry for cFMS on tissue microarrays (TMA)s of human normal lung, lung squamous cell carcinoma (SSC) and adenocarcinoma (Ade) by using a validated anti-human cFMS specific antibody. cFMS was uniquely stained in tumor stromal cells but not stromal cells in normal lung tissue, normal epithelium or tumor epithelium. Evaluation of lung SCC (n=63) and Ade (n=71) samples revealed stromal cell cFMS staining in approximately 59% (37 out of 63) and 37% (26 out of 71) of the tumor samples, respectively. To investigate whether stromal cFMS expression in lung cancers was associated with glucocorticoid signaling, GR distribution was investigated in human lung SCC and Ade TMA's by immunohistochemistry. Stromal cell GR staining was observed only in 18% (2 out of 11) of lung SSC and 6% (1 out of 17) of lung Ade samples. These results suggest that: 1) cFMS expression is elevated in patients with lung cancers, 2) cFMS expression is localized to stromal cells rather than tumor cells, and 3) cFMS expression is not likely to be mediated by glucocorticoids due to the absence of GR staining in tumor stromal cells.

**81 THE ROLE OF PPARγ IN MAMMARY SECRETORY EPITHELIAL CELLS DURING DBMA-INDUCED BREAST TUMOURIGENESIS.**

A. J. Apostoli¹, G. Skelhorne-Gross¹, R. Rubino¹, M. Schneider¹, S. SenGupta¹ and C. Nicol¹,². ¹Pathology & Molecular Medicine, Queen's University, CRI, Kingston, ON, Canada and ²Division Of Cancer Biology & Genetics, Queen's University, CRI, Kingston, ON, Canada.

Previously, we showed PPARγ normally suppresses 7,12-dimethylbenz(a)anthracene (DBMA)-induced breast tumour progression. We are now clarifying which cell types and mechanisms are involved. Mammary secretory epithelial (MSE) cells rapidly proliferate before pregnancy, and apoptose and/or transdifferentiate into adipocytes following pregnancy. Given PPARγ plays a critical role in fat cell differentiation, we hypothesized that deleting MSE-specific PPARγ enhances DBMA-mediated breast tumourigenesis. MSE-specific PPARγ knockout (MSE KO) mice were generated, and 12-week-old post-lactational female MSE KO and congenic wildtype (WT) controls were treated p.o. once/week for 6 weeks with 1mg DMBA. At week 7, mice were randomized to continue on a normal chow diet (DMBA Only: WT, n=15; MSE KO, n=25) or one supplemented with a PPARγ activating drug rosiglitazone (ROS, 4mg/kg/day; DMBA+ROS: WT, n=17; MSE KO, n=24) for 25 weeks. Compared to DMBA Only-treated WT mice, MSE KO had a significant decrease in median survival (>25 vs 17 weeks respectively, p<0.05), and significantly earlier median onset of mammary tumours (20 vs 15 weeks respectively, p<0.01). Compared to DMBA Only-treatment, DMBA+ROS-treated mice in either group had a modest increase in median survival and a 4-fold decrease in mammary tumour volumes. Further, DMBA+ROS-treated MSE KO had delayed mean mammary tumour onset versus DMBA Only-treated mice. Breast tumour analyses suggest MSE-specific PPARγ signaling stops mammary tumour growth, in part, by decreasing cyclin D1 expression. MSE cells lacking PPARγ express decreased Bax protein, which may provide a cell survival advantage after tumorigenic initiation. Together, these studies are the first to highlight...
The protective role of M-se-specific PPARγ expression and signaling in breast tu-
mourigenesis, and add support for a chemopreventive role of PPARγ activation in
breast cancer treatment.

**PL 82** COMPREHENSIVE MAPPING OF TRANSCRIPTIONAL AND EPIGENETIC PERTURBATIONS IN VITRO IDENTIFIES NONCODING RNAs AS NOVEL BIOMARKERS FOR LIVER TUMOR PROMOTION.

F. Bolognani1, H. Lempainen1,2, M. Arne1, C. Philippe1, V. Dubost1, R. Luiser2,3, J. Thomson2, E. Unterberger2, E. Hahne1, S. Braas2, T. Zollinger3, M. Marcellini1, J. Marlowe4, E. Oakley1, D. Schube1, M. Schwarz1, R. Mehan3, H. Ellinger-Ziegelbauer1,1, R. Wolf1, D. Theil1, D. Heard1, P. Moulin1, O. Grenet1, J. Moggs1,2 and R. Terranova2,3. 1Novartis Institute for Biomedical Research, Basel, Switzerland and 2IMI MARCAR Consortium, EU, Switzerland.

The temporal events leading to tumorigenesis are still poorly understood. Long-
lasting epigenetic perturbations in gene regulation may take place at the earliest
stages of nongenotoxic carcinogenesis and their characterization will help to iden-
tify early mechanisms-based biomarkers with great impact for biomedical research.

We have used genome-wide transcriptional, microRNA, DNA methylation, chromo-
atin modification and phosphoprotein profiling approaches anchored to histopathological analyses to characterize the dynamics of molecular perturbations in a 7 time-point in vivo study using a well characterized rodent liver tumor pro-
motion model (phenobarbital (PB) treatment of B6C3F1 mice). We observed dy-
namic and progressive changes in the transcriptome and DNA methylation that highlight temporal perturbations of biological pathways at early stages of tumor promotion. Transcriptomic and DNA methylation perturbations show only limited cor-
relations, whereas chromatin modification perturbations were strongly corre-
lated with transcriptional changes and showed specificity to drug metabolism genes. This integrated profiling approach has revealed a progressive increase in liver expression levels of long noncoding RNAs (ncRNA) and microRNAs that have pre-
viously been associated with stem cell pluripotency in mice and various neoplasms
in humans. We show that the expression of selected liver ncRNA biomarkers is de-
pendent both on the constitutive androstanone receptor and beta-catenin pathways
and is maintained in PB promoted liver tumors. Investigation of the cell-type speci-
ficity and functions of these novel ncRNA biomarkers is ongoing, together with an
assessment of their potential perturbation by rodent nongenotoxic carcinogens
with distinct modes of action.

**PL 83** NANOMATERIAL (NM) BIOACTIVITY PROFILING BY TOXCAST HIGH-THROUGHPUT SCREENING (HTS).

A. Wang1, E. L. Berg1, M. Polokoff2, J. Yang1, D. Reif1, N. Kleinsteuber1, S. Marinakis5, A. Badreddy4, S. Gangwal1, C. Matson3,5, M. Wiesner3,4 and K. Houch1. 1NCCT, US EPA, Research Triangle Park, NC, 2BioSeek LLC, San Francisco, CA, 3CEINT, Duke University, Durham, NC, 4Civil & Environmental Engineering Department, Duke University, Durham, NC, and 5Environmental Science, Baylor University, Waco, TX.

Rapidly increasing numbers of new NMs and their uses demand efficient tests of
NM bioactivity for safety assessment. The EPA ToxCast program uses HTS assays to
 prioritize for targeted testing, identify biological pathways affected, and aid in
 linking NM properties and potential in vivo effects. NMs (Au, Ag, CeO2, CNT, CuO, TiO2, SiO2, or ZnO core) and their ion and micro counterparts were tested for
cytotoxicity in various cell types, for transcription factor (TF) activation in
 HepG2 cells, and by protein expression in 8 BioMAP® human primary cell sys-
tems. Tested concentrations were from below the in vitro equivalents of the MMPD model–predicted lung retention (mass/surface area) after 24h exposure to reported
NM concentrations in air to about the equivalent of 45yr exposure. Assay/cell sen-
tivity and specificity was assessed for characterization of toxicity. Signific-
tant differences were observed with effects (10-12 in vitro) of AgNPs after 24h exposure in HepG2 cells. Mitochondrial toxicity was observed in HepG2 cells and A549
cells (AgNP) in a concentration-dependent manner.

**PL 84** BIOAVAILABILITY AND TOXICITY OF SILVER NANOPARTICLES AFTER TWENTY-EIGHT-DAY ORAL EXPOSURE IN RATS.

We investigated whether silver nanoparticles (AgNPs) can pass the intestines, accu-
mulate in tissues and induce toxicity. For this, rats (n=5) were exposed to ~20 nm,
non-coated or ~15 nm PVP-coated AgNPs ([Ag]=20 mg/kg bw) for 28 days. Since -
10% of the Ag in the AgNP solutions is present in an ionic form, a third group
obtained Ag ions (AgNO3) equal to this fraction. As negative control, rats obtained
the carrier solution. Dissection was either at day 29 or for studying the wash-out at
day 36 or 84. Ag measurements by AAS demonstrated presence of Ag in all organs
examined with highest levels in the liver and spleen for each of the three treatments.

The Ag content was decreased at day 84 in most organs but remarkably not in the
brain and testis. The AgNP- and Ag ion-treated groups had equal tissue Ag con-
tents, indicating that in AgNP exposed rats mainly dissolved Ag+ and to a much
lesser extent AgNPs passed the intestines. SP-ICPM was used to detect AgNPs in
gastro-intestinal (GI) tract, liver, spleen, kidney, lungs and bones. Remarkably,
AgNPs were not only found in the GI tract and liver of AgNP exposed rats, but also
in the Ag ion exposed rats, demonstrating formation of AgNPs from Ag+ in vivo.

To test this, CD1 male mice were injected of vehicle and 1 mg/kg spherical AgNPs of 10nm diameter via the tail vein every 3 days, five times, beginning at postnatal day 45.

**PL 85** INTRAVENOUS ADMINISTRATION OF SILVER NANOPARTICLES IN MALE MICE ALTERs LEYDIG CELL FUNCTION AND INCREASES SERUM TESTOSTERONE, BUT DOES NOT PERTURB SPERMATOGENESIS.

T. García1, G. M. Costa2, L. R. França2 and M. Hofmann1. 1Comparative Bioscience, University of Illinois at Urbana-Champaign, Urbana, IL and 2Morphology, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.

Spermatogenic stem cells (SSCs) provide the foundation for spermatogenesis and
are vital for the perpetuation of species. Previous studies from our lab examined the
in vitro effects of silver nanoparticles (AgNPs) on an SSC cell line. Our data showed
that AgNPs interfered with SSC proliferation in a dose and size-dependent manner
and that AgNPs disrupted components of the GDNF signaling pathway, a pathway
critical for self-renewal of SSCs in vivo. If AgNPs were to induce a similar effect in
vivo, spermatogenesis and fertility would be severely impaired. To test this, CD1 male mice were given injections of vehicle and 1 mg/kg spherical AgNPs of 10nm diameter via the tail vein every 3 days, five times, beginning at postnatal day 45.

This in vitro dose is roughly equivalent to the lowest in vivo dose with effects (10
gg/ml) from our previous studies, and ~2,000 times greater than that found in the
blood in a previous AgNP inhalation study. Body and testis weights were unaffected
at 15, 60, and 120-days post-injection trial. Although serum levels of LH, FSH, and
Inhibin B were unaffected at 15, 60, and 120 days, testosterone was signifi-
cantly increased, and significant changes in Leydig cell nucleus and individual size
(morphology) were observed at 15 and 60 days. Sperm analyses demonstrated no
changes in cauda epididymal sperm/ml and all sperm motility parameters were
unaffected in AgNP mice at 15, 60, and 120 days. Likewise, the pregnancy rate and
delivery success of female mice, which mated with treated males for 1 week beginning
at 15 and 60 days, did not differ from those that mated with controls. Taken to-
gether, these results demonstrate that AgNPs do not perturb SSCs in vivo as seen in our
previous in vitro studies, and despite a significant increase in testosterone, sperm quantity and quality, and the overall fertility of male mice was unaltered
under the experimental conditions. Supported by T32ES007326.
Molecular Toxicology, Oregon State University, Corvallis, OR and 2Chemistry, Laboratory FA8650-05-1-5041. Nanoparticles can interact with and perturb developmental progression. This research demonstrates that exposures to 1.5 nm TMAT AuNPs impair vertebrate eye development, inducing apoptosis and reducing pigmentation, indicating that specific nanoparticles can interact with and perturb developmental progression. The results demonstrate that monolayers of 1.5 nm TMAT AuNPs grown on coverslips or in transwell chambers. Microscopy (confocal, TEM) indicated that nanoparticles translocate through barrier cells at different rates (30 min - 3 hr) without disrupting their tight junctions. Changes in transcellular electrical resistance (TERS) indicated that surface coating (PVP-citrate) and small aggregate size (10 nm-75 nm) facilitated this movement (15-30 min). Reporter genes (AP-1, ARE), translocated into RBC4 cells were significantly stimulated by 10 nm PVP-capped nanoparticles. The genomic response of the cells to each nanoparticle was also examined using Illumina BeadChips. PCA analysis indicated that the number and types of transcripts activated by 10nm PVP were significantly distinct from the other experimental treatment. Bioinformatic analysis (KEGG analysis, IPA) indicated that pathways activated by 10nm PVP 10 nm nanoparticles were associated with endocytosis, bio-energetics and oxidative stress-mediated neurodegenerative (SLCA21) diseases. Future experiments will examine the relationship of nanoparticle's physical properties and genomic events in brain cells (e.g., microglia, neurons) that are potential targets. (This abstract has been reviewed by NIEHS and does not necessarily reflect EPA policy.)

GOLD NANOPARTICLES DISRUPT ZEBRAFISH EYE DEVELOPMENT AND PIGMENTATION.

K. Kim1, T. Zaikova2, J. Hutchison2, B. Tanay2. 1Environmental and Molecular Toxicology, Oregon State University, Corvallis, OR and 2Chemistry, University of Oregon, Eugene, OR.

The concerns regarding the potential toxicity of engineered nanoparticles (NPs) is gaining greater attention. The zebrafish embryos exposed to citicomic-functionalized, N,N,N trimethylammoniumethanethiol (TMAT), gold nanoparticles (AuNPs) with 1.5nm core size develop smaller and pale grey eyes (i.e., microphthalia). To determine the apoptosis resulted from AuNPs exposure, acidine orange staining, TUNEL and flow cytometry analysis of DNA content were conducted using embryonic BeadChips. PCA analysis indicated that the number and types of transcripts activated by 10 nm PVP were significantly distinct from the other experimental treatment. Bioinformatic analysis (KEGG analysis, IPA) indicated that pathways activated by 10 nm nanoparticles were associated with endocytosis, bioenergetics and oxidative stress-mediated neurodegenerative (SLCA21) diseases. Future experiments will examine the relationship of nanoparticle's physical properties and genomic events in brain cells (e.g., microglia, neurons) that are potential targets. (This abstract has been reviewed by NIEHS and does not necessarily reflect EPA policy.)

USE OF AN INTESTINAL CO-CULTURE MODEL TO STUDY THE EFFECTS OF Ag AND TiO2 NANOPARTICLES: MUCUS PROTECTIVE ROLE AND SIZE DEPENDENT EFFECTS.

A. Georgantzopoulou1, M. Kruetzewski2, A. Lankoff3, M. Dusinska1, J. Audinot3, L. Hoffmann4 and A. C. Gurleb1. 1EVA, Centre de Recherche Public—Gabriel Lippmann, Belvaux, Luxembourg. 2SAM, Centre de Recherche Public—Gabriel Lippmann, Belvaux, Luxembourg. 3Centre for Radiobiology and Biological Dosimetry, Warrsaw, Poland and 4Norwegian Institute for Air Research, Kjeller, Norway. Sponsor: B. Blomcke.

Nanoparticles (NPs) have hundreds of applications, from medicine to personal care products. The increasing production and use of NPs will unavoidably lead to their release in the environment with the potential of unpredictable effects. The aim of this study was to establish a more relevant intestinal co-culture model with the use of Caco-2 and HT29-MTX (mucus secreting) cell lines and employ the model for the evaluation of the effects of Ag (20 and 200 nm) and TiO2 (21 nm) NPs and Ag ions. In addition, their uptake was evaluated with Nanoscale Secondary Ion Mass Spectrometry (NanoSIMS 50). After 14 days the mucus layer completely covered the monolayer of differentiated cells seeded at a ratio of 90:10 (Caco-2:HT29-MTX). An overall higher metabolic activity compared to the untreated control was observed during this period; however the particles showed a continuous increase in adsorbed protein beginning after approximately 2 hours of incubation. PEG coated particles were also administered via tail-vein injection to ICR mice and the total gold content in the blood, liver, and spleen were monitored over 48h after the dose. Approximately 2h after dosing, the concentration of gold in the bloodstream began to decrease while the tissue concentrations began to increase, paralleling the protein binding behavior of the particles. Taken together, these results suggest that after approximately 2h, the PEG coating has degraded to a point at which it is no longer effective at resisting protein adsorption. Although still well dispersed, once this layer of protection has been lost, the particles can be readily recognized by the body and removed from circulation by the liver and spleen.

IN VITRO BIODISTRIBUTION OF SILVER NANOPARTICLES IN ISOLATED PERFUSED PORCINE SKIN FLAPS.

T.L. Leavens1, N.A. Monteiro-Riviere1, A.O. Inman1, J.D. Brooks1, S.J. Oldenburg1 and J.E. Rieke2. 1Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC and 2NanoComposite, San Diego, CA.

Nanomaterials are increasingly playing a role in society for uses ranging from bio-medicine to microelectronics; however, pharmacokinetic studies, which will be necessary for human health risk assessments are limited. Currently, the most widely used nanoparticle in consumer products is silver (Ag). The objective of this study was to quantify the biodistribution of two types of Ag nanoparticles, Ag-citrate and Ag-silica, in the ex vivo tissue perfusion system, the isolated perfused porcine skin flap (IPPSF). IPPSFs were perfused for 4hr with 0.84μg/ml Ag-citrate or 0.48μg/ml Ag-silica followed by a 4hr perfusion with media only during a washout phase. Arterial and venous concentrations of Ag were measured in the media by ICP-MS. The normalized volumes of distribution estimated from the noncompartmental analysis of the venous concentrations indicated distribution of Ag greater than the vascular space, however since total Ag was measured, the extravascular distribution could be due to Ag ions diffusing across the media. The estimated clearance for both types of Ag nanoparticles was 1 ml/min, which was equal to the flow perfusion rate indicating that there was no detectable elimination of Ag from the system. Venous concentrations of Ag for both types of nanoparticles were best fit with a two-compartment model in which estimated rates of distribution between the central and peripheral compartment were similar but slower than clearance from the central compartment due to the media flow. By 4 hrs following infusion of the Ag nanoparticles, the recovery of Ag in the venous effluent was 90 ± 5.0% and 87 ± 2.2% of the infused Ag for Ag-citrate and Ag-silica, respectively. PROTEIN ADSORPTION BEHAVIOR OF PEG-COATED GOLD NANOPARTICLES IN HUMAN PLASMA.

P.L. Carpinone1, K. W. Powers2, D.S. Barber1 and S.M. Roberts1. 1CEETH, University of Florida, Gainesville, FL and 2PERC, University of Florida, Gainesville, FL.

Colloidal gold has generated a significant amount of interest as a vehicle for in vivo therapeutic and diagnostic applications. Like most nanomaterials, gold particles must be stabilized prior to parenteral administration to prevent rapid agglomeration and adsorption of opsonins. Suspension stability and surface passivation are typically achieved via polymer coatings, most often involving polyelectrolyte glycol (PEG). Stability of the polymer coating is a critical determinant of the efficacy and fate of the particles as a therapeutic or diagnostic agent. In this study, the stability of the PEG coating on colloidal gold particles and its relationship to protein binding, particle stability, and particle uptake is examined. It was hypothesized that clearance of these particles was mediated by agglomeration and/or degradation of the protective PEG coating, allowing for opsonization and uptake from the bloodstream. PEG coated particles were incubated in human plasma over a 48h period and analyzed for total adsorbed protein and particle size. No agglomeration was observed during this period; however the particles showed a continuous increase in adsorbed protein beginning after approximately 2 hours of incubation. PEG coated particles were also administered via tail-vein injection to ICR mice and the total gold content in the blood, liver, and spleen were monitored over 48h after the dose. Approximately 2h after dosing, the concentration of gold in the bloodstream began to decrease while the tissue concentrations began to increase, paralleling the protein binding behavior of the particles. Taken together, these results suggest that after approximately 2h, the PEG coating has degraded to a point at which it is no longer effective at resisting protein adsorption. Although still well dispersed, once this layer of protection has been lost, the particles can be readily recognized by the body and removed from circulation by the liver and spleen.
found in the co-culture for all particles. The co-culture system showed a significantly lower response to reactive oxygen species (ROS) formation upon exposure to Ag 200 nm. In conclusion, the co-culture model could be more relevant as the mucus layer potentially traps and prevents NPs from reaching the epithelium. An overall protective effect against oxidative stress and metabolic activity decrease was observed. Ag NPs induced size-dependent effects on IL 8 release that could not be attributed solely to ions. Furthermore, the NanoSIMS 50 could be a useful tool for NP uptake evaluation and intracellular localisation.

ACUTE VASCULAR EFFECTS OF NANOPARTICLE INFUSION IN ISOLATED PERFUSED SKIN.

L. E. Riviere, T. L. Leaveng, J. D. Brooks and N. A. Monteiro-Riviere, Center for Chemical Toxicology Research and Pharmacokinetics, North Carolina State University, Raleigh, NC.

Engineered nanomaterials are widely used in various biological and industrial applications. Their safety profile has largely been defined by in vitro inhalational exposures or using various in vitro cell-based techniques. Some concern has arisen to their potential adverse effects in the vascular system as evidenced by endothelial cell toxicity or deposition of particles in endothelial cell walls. In the process of conducting biodistribution studies in the ex vivo isolated perfused porcine skin flap (IPPSF) with arterial infusion of nC60, quantum dots (QD), citrate or silica coated spicules, biodistribution studies in the vasculature were performed. Biodistribution profiles during perfusion and skin flap weights prior to and following perfusion have been collected on all 3,600 IPPSFs conducted over the past few decades, providing a robust database on which to assess vascular changes. The most pronounced and earliest effect of nanomaterial was an increase in arterial vascular resistance during perfusion. This was accompanied by increases in perfused skin flap weight, possibly indicative of edema or vascular congestion. These studies suggest that systemic exposure to a number of diverse nanomaterials may have adverse effects on the vascular physiology that merits further attention when conducting in vivo studies.

91 BIOLOGICAL EQUIVALENT-BASED RISK ASSESSMENT—THE CASE OF BPA AND HCHO.

D. A. Saripanishvili1,2 and S. P. Karakitsios1,2. 1Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece and 2Chemical Process Engineering Research Institute, Center for Research and Technology Hellas, Thessaly, Greece.

The work deals with the refinement of Risk Characterization Ratio (RCR) calculation for Bisphenol-A and HCHO by employing the concept of Biological Equivalents (BEs). To utilize the concept of BEs, the appropriate internal dose modeling was employed. The models developed were a multi-compartmental mother-fetus PBPK model for BPA, while the corresponding PBPK model for HCHO describes the formation of DPH (an HCHO-DNA adduct) in the nasopharyngeal cavity. The BE for BPA was estimated (equal to 0.16 μg/L) by calculating the steady-state concentration of free-plasma BPA for a typical adult, receiving orally an amount equal to the one suggested by EFSA TDI (~82% of the overall variance). Cluster analysis with the principal components indicated that 744 and 502 duodenal and 1021 and 167 jejunal genes exhibiting sigmoidal dose-response profiles at 8 and 91 days, respectively. At 8 days, the interquartile EC50 range overlapped between duodenum and jejunum, but the median EC50 was -10 times lower in duodenum (5 μg/L) compared to jejunum (52 μg/L). At 91 days, the median EC50 values were comparable between duodenum (49 μg/L SDD) and jejunum (59 μg/L SDD). Functional annotation identified differential expression associated with oxidative stress, cell cycle, cell death and immune response, consistent with changes in oxidative stress and inflammatory markers. QRT-PCR confirmed induction of oxidative stress genes, including Gpx2 and Gclc. Genes involved in dietary iron absorption/transport were also repressed, suggesting SDD may interfere with iron homeostasis. These results indicate that, like the mouse, the rat intestinal epithelium is responsive to Cr(VI). Comparisons of gene expression changes in rats and mice should inform the mode of action underlying the different tumor outcomes in the small intestine. Funded by the ACC Cr(VI) Panel.

94 ASSESSMENT OF GENOTOXIC POTENTIAL OF CR(VI) IN THE MOUSE DUODENUM VIA TOXICOGENOMIC PROFILING.

C. M. Thompson1, J. G. Hixon2, A. K. Kopeć3, M. A. Harris1, D. M. Proctor1 and L. C. Haw2. 1ToxStrategies, Katy, TX, 2ToxStrategies, Austin, TX, 3Michigan State University, East Lansing, MI and 4ToxStrategies, Rancho Santa Margarita, CA.

Chronic exposure to hexavalent chromium [Cr(VI)] as sodium dichromate dihydrate (SDD) leads to intestinal tumors in mice, and oral cancers and mild hypoperfusia in rats. In this study, the dose-dependent gene expression effects of SDD (0.3-520 mg/L) were evaluated in female Fischer rat duodenal and jejunal epithelia following 7 and 90 days of exposure in drinking water. Agilent 4x44K whole-genome microarrays identified 3269 and 1815 duodenal, and 4557 and 1534 jejunal differentially expressed genes (fold change>1.5, P<0.009) at days 8 and 91, respectively. Comparisons at day 8 showed significant overlap (2312 genes) between duodenum and jejunal gene expression, with the former exhibiting greater ef-ficacy (i.e. maximum fold change). The overlap was ~50% lower at day 91 with comparable fold inductions in both tissues. Automated analysis identified 744 and 310 duodenal and 1021 and 167 jejunal genes exhibiting sigmoidal dose-response profiles at 8 and 91 days, respectively. At 8 days, the interquartile EC50 range overlapped between duodenum and jejunum, but the median EC50 was -10 times lower in duodenum (5 μg/L) compared to jejunum (52 μg/L). At 91 days, the median EC50 values were comparable between duodenum (49 μg/L SDD) and jejunum (59 μg/L SDD). Functional annotation identified differential expression associated with oxidative stress, cell cycle, cell death and immune response, consistent with changes in oxidative stress and inflammatory markers. QRT-PCR confirmed induction of oxidative stress genes, including Gpx2 and Gclc. Genes involved in dietary iron absorption/transport were also repressed, suggesting SDD may interfere with iron homeostasis. These results indicate that, like the mouse, the rat intestinal epithelium is responsive to Cr(VI). Comparisons of gene expression changes in rats and mice should inform the mode of action underlying the different tumor outcomes in the small intestine. Funded by the ACC Cr(VI) Panel.

95 COMPARATIVE TOXICOGENOMIC ANALYSIS OF CR(VI) EFFECTS IN RAT AND MOUSE SMALL INTESTINE.

A. K. Kopeć1, A. L. Forgas3, S. Kim1, C. M. Thompson1 and T. R. Zacharewski1. 1Biochemistry & Molecular Biology, Center for Integrative Toxicology, Michigan State University, East Lansing, MI and 2ToxStrategies, Inc., Katy, TX.

Continuous drinking water exposure to hexavalent chromium [Cr(VI)] as sodium dichromate dihydrate (SDD) is linked to intestinal tumor development in mice but not rats. In this study, the dose-dependent gene expression effects of SDD (0.3-
520 mg/L) were evaluated in female Fischer rat and B6C3F1 mouse duodenal (Duod) and jejunal (Jej) epithelia following 7 and 90 days of drinking water exposure. Using HolomoGeneID, 13899 orthologs were identified as represented across the mouse and rat whole-genome 4x44K Agilent microarrays. At day 8, comparative analysis (fold change > 1.5, P < 0.099) identified 5013 differentially expressed mouse orthologs compared to 2790 rat orthologs in the Duod, with comparable numbers of orthologs (rat 3782, mouse 3334) in the Jej. Ortholog comparisons at day 91 suggest mouse Duo (3484) and Jej (3620) are ~2.5 times more responsive to Cr(VI) compared to rat Duo (1504) and Jej (1305). Automated dose-response modeling suggests the mouse had more orthologs exhibiting a sigmoidal dose-response compared to the rat, although the median EC50s were over comparable (39-55 mg/L SDD). Functional annotation identified differentially expressed orthologs associated with oxidative stress, cell cycle, cell death and immune response, consistent with changes in GSH/GSSG levels, hyperplasia, apoptosis and inflammation. Several differentially expressed orthologs exhibited species-specific expression that was verified by QRT-PCR. For example, genes associated with inflammation (C2l2q: Mouse, C3: Rat, T. g. house, transport (S.25a2: T. r. mouse) and growth (Arg1: T. mouse, I. r. rat) exhibited divergent expression. Implications of these analyses for the mode of action for Cr(VI)-induced intestinal carcinogenesis will be discussed. Funded by the ACC Cr(VI) Panel.

96 MODE OF ACTION FOR INTESTINAL CARCINOGENESIS OF INGESTED HEXAVALENT CHROMIUM IN MICE.

Chronic ingestion of hexavalent chromium (Cr(VI)) has been shown to cause small intestinal tumors in mice at concentrations ≥ 60 mg/L of sodium dichromate dihydrate (SDD). To assess the mode of action (MOA) for carcinogenesis in rodents and relevance to humans, we conducted 90-day drinking water studies in both rats and mice, with collection of histopathological, biochemical, toxicogenomic, and pharmacokinetic data, as well as measures of DNA modification at concentrations of 0.3-520 mg/L SDD. These studies were designed to assess whether intestinal tumors are initiated through a mutagenic or non-mutagenic MOA. After 7 days of exposure, change in redox status (decreased GSH/GSSG) occurred ≥60 mg/L in the mouse duodenum; cytotoxicity in the villi and apoptosis in the crypt were observed at ≥ 170 mg/L and crypt hyperplasia was observed at 520 mg/L. At day 91, these effects progressed, each occurring at lower doses, with changes in redox status starting at 14 mg/L. Cytogenetic examinations of intestinal crypts revealed apoptosis at the highest two concentrations, but no increase in micronuclei. Toxicogenomic studies of intestinal crypts revealed apoptosis at day 8 at the highest two concentrations, but no increase in micronuclei. Several differentially expressed orthologs exhibited species-specific expression that was verified by QRT-PCR. For example, genes associated with inflammation (C2l2q: Mouse, C3: Rat, T. g. house, transport (S.25a2: T. r. mouse) and growth (Arg1: T. mouse, I. r. rat) exhibited divergent expression. Implications of these analyses for the mode of action for Cr(VI)-induced intestinal carcinogenesis will be discussed. Funded by the ACC Cr(VI) Panel.

98 DEVELOPMENT OF A UNIT RISK FACTOR FOR NICKEL AND INORGANIC NICKEL COMPOUNDS BASED ON AN UPDATED CARCINOGENIC TOXICITY ASSESSMENT.

It is important for the TCEQ to conduct up-to-date assessments of all carcinogens (including nickel) emitted in Texas based on the latest scientific data and analyses. For nickel, because there are industrial emission sources in Texas which may increase air concentrations in neighboring communities and the expected nickel species exposure profile from Texas sources is different than that of nickel refinery workers, it was important to use studies with more environmentally-relevant exposures to help ensure generalizability to the Texas public (i.e., the most predictive toxicity factor possible). Consequently, the TCEQ has developed an inhalation unit risk factor (URF) for nickel based on excess lung cancer in two epidemiological studies of nickel refinery workers with nickel species exposure profiles most similar to emissions expected in Texas (i.e., low in sulfide nickel). One of the studies (Enterline and Marsh 1982) was used in the 1986 USEPA assessment, while the other (Grimsrud et al. 2003) is an update to an earlier study (Magnus et al. 1982) used by USEPA but not known to have been used previously to derive URF estimates. The linear multiplicative relative risk model with Poisson regression modeling was used to obtain maximum likelihood estimates and asymptotic variances for cancer potency factors (β) using cumulative nickel exposure levels versus observed and expected lung cancer mortality (Enterline and Marsh 1982) or lung cancer incidence cases (Grimsrud et al. 2003). Life-table analyses were used to develop URFs for inhalation exposure to the two studies, which were then combined using weighting factors relevant to confidence to derive the final URF for nickel of 1.7E-04 per μg/m3. The de minimis air concentration corresponding to a 1 in 100,000 extra lung cancer risk level is 0.059 μg/m3. The TCEQ will use this conservative value to protect the general public in Texas against the potential carcinogenic effects from chronic exposure to nickel.

99 THE USE OF SURROGATE DATA AND CHEMICAL ESTIMATION METHODS IN THE DEVELOPMENT OF A UNIT RISK VALUE FOR CUMENE (1-METHYLBENZENE).

Chemune (1-methylnaphthalene) has demonstrated clear carcinogenicity in mice and rats (NTD 2009) and is based on kidney lesions, body weight, stunting, xenyle and benzene. Like other alkylbenzenes cumene may undergo side chain or ring oxidation via cytochrome P450. Likely metabolites would include 4-isopropylphenol and the corresponding catechol, dimethylphenylcarbinol, quinone methide, and 4-isopropylquinone. Although no PBPK model for cumene was identified in the published literature, models for ethylbenzene and related aromatics (α-xylene, toluene, benzene) have been published. In order to assess internal dosimetry of cumene in the rodent bioassays our approach was to use ethylbenzene metabolic parameters as a surrogate for cumene in a PBPK model and derive chemical parameters for cumene with chemical estimation methods. We then compared PBPK-derived internal dose metrics with applied dose to fit the quantal tumor incidence data. The metabolic parameters for ethylbenzene were Vmax = 7.6 mg/hr/kg/74 and Km = 0.1mg/L. Four sets of cumene partition coefficients were developed using different estimation methods and evaluated in mouse and rat PBPK models. The modeled dosimetry (metabolized dose) gave superior fits to the most sensitive site tumor data for female mice (lung) compared to the applied dose. For alveolar and bronchiolar adenomas and carcinomas combined the best estimate benchmark dose and fit statistics were BMD10 = 11.2, BMDL10 = 7.2 mg/kg-d; X2 = 0.25, and P = 0.62. The slope factors for mice and humans were 0.014 and 0.084 mg/kg-d, respectively. The latter value would correspond to a unit risk value of approximately 0.012/mg/m3 assuming a default low dose uptake of 50%. Potency values obtained through PBPK modeling were about twice the values based on applied doses. Several of the parameter sets gave similar values indicating the robustness of the approach.
100 CARCINOGENIC RISK ASSESSMENT FOR THE USE OF METHYLENE BLUE IN DAIRY COWS.

T. Zhou, K. Gaido, J. Qiu, J. Oriani and K. Ekelman. Center for Veterinary Medicine, University of California Davis, Davis, CA.

Methylene blue (MB), though not approved as an animal drug by FDA, is used as a food-animal antidote for nitrate poisoning because there is no viable alternative. CVM recommended in 1990s a 180-day slaughter withdrawal period in ruminants. Since then, new information has emerged including total residue data and a 2008 NTP study report. Therefore, the purpose of this evaluation was to determine if the previously recommended 180-day withdrawal time for both edible tissue and milk could be reduced. To achieve such a goal, we followed a step-by-step approach. First, the NTP report (NTP TR 540) was evaluated and we concurred with the finding that MB is genotoxic and carcinogenic. Second, we calculated the concentration of total residue of carcinogenic concern of the test compound in the total diet of test animals that corresponds to a maximum lifetime risk of cancer in the test animals of 1 in 1 million. We allocated 70% and 30% of the So to tissue and milk, respectively. Third, we used the allocated So to derive Sm, the permitted concentration of residues of carcinogenic concern in a specific edible product. Fourth, we reviewed the available residue data for MB in tissues and milk, and found that neither the depletion rate of MB in tissues down to Sm concentration nor the depletion rate of MB in milk could be established. Based on the above assessment of the carcinogenic concern of MB and residue information, we conclude that (1) the available residue data are not sufficient to allow a shorter than 180-day withdrawal time for both tissue and milk, (2) a depletion study for total residues (typically 14C-radiolabel) with adequate sampling times and number of animals is needed in order to determine the depletion profile of MB in tissues and milk, and (3) the Food Animal Residue Avoidance & Depletion Program (FARAD) recommended 14-day withdrawal period for edible tissues and 4-day milk discard time for MB is not supported by the information available to CVM.

101 CONSIDERING MODE OF ACTION IN ESTIMATING A NSRL FOR 3-MCPD

P. Sheehan, K. Bogen, B. Brotho and S. Holm. 1Exponent, Oakland, CA, 2ToxStrategies, Vallejo, CA and 3Georgia Pacific LLC, Atlanta, GA.

Pursuant to California’s Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65), 3-monochloronorpropene-1,2-diol (3-MCPD) was listed as a carcinogen on October 8, 2010. As neither California EPA nor U.S. EPA has developed a cancer potency estimate (i.e., slope factor [SF*]) for 3-MCPD that could serve as a basis for a non-significance-risk level (NSRL), an independent risk assessment was conducted. SF* for 3-MCPD were estimated using available experimental bioassay data for male and female Fischer 344 and Sprague-Dawley rats administered 3-MCPD for 2 years via drinking water. A multistage cancer risk extrapolation model was implemented by using a bootstrap Monte Carlo procedure to the 14C-radiolabeled) with adequate sampling times and number of animals is needed in order to determine the depletion profile of MB in tissues and milk, and (3) the Food Animal Residue Avoidance & Depletion Program (FARAD) recom mendation of 14-day withdrawal period for edible tissues and 4-day milk discard time for MB is not supported by the information available to CVM.

103 A QUANTITATIVE RISK ASSESSMENT OF 2, 3-PENTANEDIONE, BASED ON PRELIMINARY DATA.

D. A. Dankovic1 and D. L. Morgan. 1Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH and 2Respiratory Toxicology, NIEHS, Research Triangle Park, NC.

Only preliminary (pilot study) toxicity data are currently available for the food flavoring 2,3-pentanedione (PD). However, it is possible to compare the pilot study data for PD to similar data for diacetyl and derive an estimate of the relative toxicities of PD and diacetyl in mice. PD data were taken from a study described by Morgan et al. [2010] (Toxicologist 114(1):316) and compared to a diacetyl pilot study, Morgan et al. [2008] (Toxicologist 103 A QUANTITATIVE RISK ASSESSMENT OF 2, 3-PENTANEDIONE, BASED ON PRELIMINARY DATA.

D. A. Dankovic1 and D. L. Morgan. 1Risk Evaluation Branch, CDC/NIOSH, Cincinnati, OH and 2Respiratory Toxicology, NIEHS, Research Triangle Park, NC.

Only preliminary (pilot study) toxicity data are currently available for the food flavoring 2,3-pentanedione (PD). However, it is possible to compare the pilot study data for PD to similar data for diacetyl and derive an estimate of the relative toxicities of PD and diacetyl in mice. PD data were taken from a study described by Morgan et al. [2010] (Toxicologist 114(1):316) and compared to a diacetyl pilot study, Morgan et al. [2008] (Toxicologist 114(1):316). Male and female Fischer 344 rats and mice (6/dose group) were exposed to 0, 50, 100, or 200 ppm for 2 weeks + 2 days. In the diacetyl study, male C57Bl6 mice (5/dose group) were exposed to 0, 25, 50, or 100 ppm for either 6 or 12 weeks. The pathology produced by both chemicals was very similar, affecting nasal tissue most severely but also the trachea, larynx, and bronchi. Benchmark dose analysis compared the BMD50s for nasal suppurrative exudate in male mice, and for bronchial inflammation in male mice for diacetyl and female mice for PD. Comparing the PD data to the 6-week diacetyl data for the nasal suppurrative exudate endpoint, PD appears to be 73% (95% CI 30-177%) as potent as diacetyl. Comparing the PD data to the 6-week diacylal data for the bronchial inflammation endpoint, PD appears to be 53% (95% CI 18-158%) as potent as diacetyl. Comparisons to the combined 6 + 12-week diacetyl data yield toxicity ratios of 67% (95% CI 32-141%) for the nasal endpoint, and 58% (95% CI 22-153%) for the bronchial endpoint. Although the central estimates suggest that PD may be somewhat less potent than diacetyl for the endpoints in question, given the wide confidence limits equipotency of PD and diacetyl cannot be ruled out based on the current data. The findings and conclusions in this report are those of the authors and do not necessarily represent the view of the National Institute for Occupational Safety and Health or the National Institute of Environmental Health Sciences.

104 US EPA’S PROPOSED TOXICITY VALUES FOR TCDD: IMPLICATIONS FOR DECISION-MAKING REGARDING THE SAFETY OF FOODS IN THE UNITED STATES.

L. Hayes, I. Fitzgerald, K. Burkhalter, M. Harris and D. WikoFF. ToxStrategies, Austin, TX.

USEPA recently released a draft RfD (0.7 pg/kg-d) and oral CSF (0.001 pg/kg-d) for 2,3,7,8-TCDD. The CSF equates to intakes of 0.1–0.001 pg TEQ/kg-d1 at 10-4-10-6 risk levels, respectively. These intakes are substantially lower than tolerable daily intakes (TDIs) developed by other regulatory and public health agencies (eg, JECFA has established a provisional tolerable intake equivalent to 2.3 pg/kg-d), as well as considerably below estimated breastmilk intakes (242 pg/kg-d). Our objective was to compare intakes of dioxin-like compounds (DLCs) from US foods to intakes associated with the USEPA draft toxicity values as a means of assessing the implications of these values. Daily intakes were based on USDA estimates of average total dietary intakes of DLCs, which were calculated using data from the Total Diet Study and consumption data from USDA. Risk and hazard were estimated using standard equations and exposure factors for child, adolescent, adult and age-adjusted scenarios. Daily intakes from food greatly exceeded the intakes associated with the CSF at all risk levels for all age groups. Daily intakes also exceeded the RfD for a number of infant, child and adolescent age groups. The cancer risk associated with lifetime dietary DLC exposure (3x10-4 to 9x10-4) was above USEPA’s acceptable risk range. The noncancer hazard estimates were found to exceed the USEPA’s target HQ of 1 for infants (1.4-4.9), children (2.5-12.4), and adults (3.4). The 1.3 when the full value of the detection limit was imputed for non-detects (NDs). In contrast, when intakes were compared to the JECFA value, which is protective of
both cancer and noncancer, results indicated that daily intakes are below the level of concern for all age groups regardless of the value imputed for NDs. Collectively, these data indicate that different conclusions about the toxicity of TCDD lead to substantially different conclusions regarding the safety of foods, and demonstrate the importance of using best available science rather than simply relying on precautionary approaches.

105 ASSESSMENT OF RISKS TO CHILDREN EXPOSED TO HYDROCARBON CONSTITUENTS FROM THE GULF OF MEXICO OIL SPILL.

A. Pawlisz, CRA, Dallas, TX.

On April 20, 2010, an oil exploration platform, DeepWater Horizon, located approximately 41 miles off the Louisiana coast, failed causing a release of crude oil at the depth of 5,000 feet. This event has been defined as the largest offshore oil spill in US history. By July 4, 2010, surface oil came onto populated shorelines of Louisiana, Mississippi, Alabama, and Florida. On July 15, 2010, the leak was stopped and the well was officially sealed on September 19, 2010. However, approximately 185 million gallons (MG) of crude oil was released into the Gulf of Mexico. Moreover, a total of 1.8 MG of dispersant was sprayed onto or injected into the water column as part of the spill response activities. Questions about the toxicity of spilled oil/dispersant to human health and the environment linger given the state of current knowledge. The presentation focuses on the assessment of health risks to children who may be exposed to the spill constituents while playing/recreational activities. Extensive data collection activities were undertaken by various agencies resulting in a vast explosion media database on air, water, and sand concentrations of hydrocarbons. These data, after screening for adequacy and applicability to the beach exposure scenario, were adopted in the current study to populate an exposure model for a young child directly exposed to all three media. The results of exposure modeling and toxicity assessment for a range of tested constituents on GOM beaches of Louisiana, Mississippi, Alabama, and Florida are tabulated and discussed relative to the magnitude of worst-case, average, and most likely risks.

106 RISK-BENEFIT ASSESSMENT OF FLAME-RETARDANT CHEMICALS.

A. Blum,1,2, V. Babrauskas,3, R. Fuoco2 and L. Birnbaum,4 Chemistry, University of California Berkeley, Berkeley, CA; 2Green Science Policy Institute, Berkeley, CA; 3Fire Science and Technology Inc., Issaquah, WA and 4National Cancer Institute, National Institute of Environmental Health Sciences, Research Triangle Park, NC.

As a basis for regulation of flame retardant (FR) chemicals, both potential health risks and fire safety benefits should be evaluated. Using an integrated risk assessment, we evaluate the use of organohalogen FRs to comply with California furniture flammability standard Technical Bulletin 117 (TB117). Pentabrominated diphenylether was the main FR chemical used to comply with this standard from the 1980s until 2004, when it was banned and production ceased. Major replacements include tris(1,3-dichloro-2-propyl) phosphate, removed from children’s sleepwear in 1978 due to mutagenicity concerns, and Firemaster 550, a proprietary mixture containing brominated retardants. Our fire safety evaluation, based on the fire science literature, found that (1) TB117 foam compared to non-FR foam covered in identical fire retardant, (2) differences observed between identically-constructed furniture with non-FR foam and furniture made with foam complying with TB117 are within the normal data scatter. Our human health evaluation, based on the toxicological and epidemiological literature, found that (1) previous and current FRs used for TB117 compliance are found in human body fluids and (2) carcinogenic and/or neurological, reproductive, endocrine, and developmental harm are associated with exposure to some flame retardants.

Approval does not signify that the contents necessarily reflect the views of the Agency, nor does the mention of trade names or commercial products constitute endorsement or recommendation for use.

107 ANALYSIS OF HEALTH RISKS TO SURGICAL PATIENTS FROM INSTRUMENTS CONTAMINATED WITH USED HYDRAULIC FLUID.

D. G. Dodge1, B. D. Beck2, M. T. BenKinney2 and P. D. Boehm3, 1Gradient, Bend, OR; 2Gradient, Cambridge, MA and 3Exponent, Maynard, MA.

Over the course of 1-2 months in 2004, certain processing errors led to the inadvertent use of used hydraulic fluid (HF) in place of detergent in one step of a multi-step cleaning and sterilization process of surgical instruments at a US hospital system. Several thousand patients may have had surgery or minor bedside procedures performed using the instruments in question. We evaluated the presence of and amounts of residual fluid and individual constituents potentially remaining on instruments after they were exposed to HF, and conducted a screening-level risk analysis to address the potential hazards posed by their use during surgical procedures. Residual fluid was extracted from HF-exposed instruments in both saline- and solvent-extracted experiments. Of 40 organic analytes, as well as numerous polycyclic aromatic hydrocarbon (PAH) and total petroleum hydrocarbon (TPH) analytes, chemicals of interest (COIs) were identified if they were detected in either experiment. To estimate acute and chronic exposure doses, we used conservative assumptions regarding the number of instruments used during surgery and the amount of transfer of residual HF on instruments to the patient during surgery. We examined toxicity using both whole-mixture and individual-constituent approaches, and we assessed cancer and non-cancer risks using a margin-of-exposure (MOE) approach comparing acute and chronic toxicity effect levels and dietary intake levels to estimates of exposure. We also made an adjustment to oral toxic equivalents (OETs) to ensure the additional potential of greater non-cancer risks of ester exposures. MOEs for acute and chronic non-cancer effects were greater than 100 for all COIs, indicative of negligible toxicological concern. MOEs for cancer effects were greater than 1 for all carcinogenic COIs, indicative of less than 1 in a million cancer-risk. We conclude that there were no appreciable non-cancer or cancer risks to patients who underwent surgery using the HF-exposed instruments.

108 NATURAL GAS EXPLORATION AND PRODUCTION IN THE BARNETT SHALE: ASSESSMENT OF EXPOSURES TO VOLATILE ORGANIC COMPOUNDS (VOCs).

C. S. Perry, A. Tachovsky, M. Ke, J. D. Urban and L. C. Haws, TexStrategies, Inc., Austin, TX.

There are an estimated 13,500 producing natural gas wells in the Barnett Shale (BS) formation, which spans approximately 24 counties in north central Texas (TX). Since 2002, natural gas production in the BS region has substantially increased, and the region contains the largest onshore gas fields in the US. The Texas Commission on Environmental Quality (TCEQ) has over 20 monitors in the region, 8 of which are in relatively close proximity to natural gas exploration and production operations (six AutoGCs analyzing 46-64 VOCs and two canister monitors analyzing 105 VOCs). Maximum 1-hour AutoGC and 24-hour canister data were compared to available federal and state acute health-based toxicity values. Annual average concentrations were compared to available federal and state chronic health-based toxicity values. The measured concentrations were also compared to typical US and TX-specific background concentrations, as well as to TCEQ odor-based values. While there were a few acute exceedances of odor-based values, our analyses showed that none of the 1-hour or 24-hour concentrations exceeded any of the acute health-based toxicity values. For the annual average concentrations, there were exceedances of some federal chronic health-based values for benzene and 1,3-butadiene at all six AutoGCs, but these levels were all below TCEQ chronic health-based values and typical US or TX-specific background concentrations. In terms of the canister monitors, the annual average concentrations of 16 chemicals exceeded some federal health-based toxicity values. However, with the exception of 1,2-dibromoethane and methyl butyl ketone, all of the annual average concentrations were below the TCEQ chronic health-based values. Importantly, all measurements for 1,2-dibromoethane and methyl butyl ketone were non-detected, and the exceedances are solely the result of conservatively assuming that these chemicals were present at a concentration equal to ½ DL. Collectively, these data do not indicate any concern regarding potential exposures to VOCs associated with these types of operations.

109 INHALATION TOXICITY OF PARTICULATE MATTER FROM MIDDLE EASTERN BASES IN RATS EXPOSED FOR TWO WEEKS.

P. A. Ortiz1, K. C. Roberts2, C. U. Parkinson2, V. Mokashi and B. A. Wong1,2, 1Naval Medical Research Unit, Wright-Patterson AFB, Dayton, OH and 2The Hammer Institute for Health Sciences, Research Triangle Park, NC.

Personnel deployed in the Middle East are exposed to particulate matter (PM) that may have suspected toxicological properties from various sources. Deployment locations in the Middle East have been examined in some in vitro cell culture screening studies that have indicated differences in the potential toxicity between locations. For example, PM from Iraq (Talil), as compared with PM from other locations (Camp Victory), showed increased lactate dehydrogenase (LDH) and decreased production of MTT, indicators of cellular toxicity. An in vivo inhalation study was conducted by exposing male and female Sprague-Dawley rats via whole body inhalation to an aerosol of PM from Afghanistan or Iraq at 1 mg/m3 or clean air for 20 h/d, 7 d/wk for 2 weeks. After exposures, one set of animals from each exposure
group was necropsied immediately while a second set was held for a 3-week recovery period. At necropsy, bronchial alveolar lavage (BAL) fluid was collected and clinical chemistry and hematology were conducted on blood samples. Group average body weights were not significantly different for the two PM. There were some statistically significant differences in clinical chemistry and hematology results; however, differences were small and there was no overall pattern to indicate organ damage or other biochemical dysfunction. There was no significant difference in the LDH or total protein concentrations in BAL fluid. Also in BAL fluid, concentrations of inflammatory cytokines, MIP-1?, IL-1?, IL-6, and TNF-? were below limits of detection. Finally, histopathology did not identify any PM in the lung tissue and there were no findings that were considered to be induced by the test material. While in vitro studies are useful for initial screening and identified PM with potential toxicity, this two week in vivo inhalation study under conditions more relevant to military personnel deployment showed no toxicity under the conditions of this study.

110 HEALTH IMPLICATIONS OF COAL TAR AND BITUMEN COATINGS IN CAST IRON WATER MAINS.

C. M. de Jongh1, B. M. van de Ven2, G. Mesman3 and M. Blokker3.
1KWR Watercycle Research Institute, Utrecht, the Netherlands and 2National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands. Sponsor: M. Heringa.

Between 1900 and 1990 cast iron water mains have been laid which are coated on the inside by coal tar and bitumen. Although the purpose of this coating is minimizing corrosion, the linings themselves can deteriorate over time. In 2009 one of the Dutch water companies received odor and taste complaints after maintenance in a cast iron distribution network. The complaints could be traced back to the presence of poly cyclic aromatic hydrocarbons (PAHs) in the drinking water. PAHs were presumed to originate from the coal tar or bitumen coating in the cast iron mains. As in the Netherlands normally hardly any PAHs are found in drinking water, the question arose how often and under which circumstances increased PAH levels can occur and whether human health effects may be expected as PAHs have known or suspected genotoxic potential. In a nationwide study, the Dutch water companies took samples in cast iron distribution networks at 120 locations under various conditions such as undisturbed operation, during flushing and after a mains repair. The samples were analyzed for PAHs and the health risk associated with an exposure scenario over a lifetime period was estimated. During flushing high PAH levels may occur in drinking water, sometimes even above the drinking water guideline levels, but after flushing these levels drop rapidly. After the removal of part of the coated cast iron main, increased PAH levels were found in drinking water up to 40 days after repair. Risk assessment showed that despite of exceeding drinking water guideline values, the cumulative excess cancer risk of exposure to PAHs through drinking water remained below the negligible risk of 1 in a million lifetime exposed individuals under the test conditions at the 120 measurement locations. Although no human health effects are expected, presence of PAHs in drinking water is undesired as this may lead to taste and odor problems. The drinking water companies are advised to monitor PAH levels in drinking water after interventions on cast iron mains.

111 MOE-BASED RISK ASSESSMENT OF GENOTOXIC AND CARCINOGENIC INGREDIENTS IN PLANT FOOD SUPPLEMENTS.

S. van den Berg1, P. Restani2, M. Boersma1, L. Delmulle3 and I. Rietjens1.
1Department of Pharmacological Sciences, Università degli Studi di Milano, Milan, Italy and 2Division of Toxicology, Wageningen University, Wageningen, Netherlands and 3Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

PAHs are a class of chemicals common in the environment. Benzo(a)pyrene (BaP) is a well-studied PAH and a known human carcinogen. Current regulatory risk assessment practices do not account for the risk of in utero chemical exposures, thus regulatory guidelines are missing a susceptible timeframe for exposure. Here, we utilized umbilical cord blood measurements of BaP-DNA adducts to generate an estimate for cancer risk posed by prenatal exposure to BaP. Cord blood was collected at delivery from a cohort of mothers and newborns in New York City. DNA was isolated from white blood cells and BaP-DNA adducts were measured in 380 newborns. Traditional quantitative cancer risk assessment calculations were adapted to generate a cancer risk due to prenatal exposure of BaP. We used a slope factor relating BaP-DNA adducts to tumor incidence from a previously published toxicology study. Some simplifications and assumptions were made in our cancer risk estimation related to extrapolating the conditions of the toxicology study to those in humans, the pharmacokinetics of BaP-DNA adducts, and susceptibility during developmental stages. Based on our analysis, we estimate that prenatal exposure to BaP results in an average excess lifetime cancer risk of 9.3x10^-3; this is unmodified by any age-dependent adjustment factor. These results will be compared to excess lifetime cancer risk estimations in two additional cohorts: where environmental PAH exposure is typically higher. Prenatal exposures should be considered in regulatory risk assessments. We provide here an estimate of excess cancer risk posed by prenatal BaP exposure as an example of how molecular epidemiologic data may be used in risk assessments. There are gaps in this field that need to be addressed through additional research that examines the pharmacokinetics of DNA adduction and cancer risk in a prenatal exposure model, but doing so would allow utilization of cord blood-based biomarkers in risk assessments for prenatal exposures.

112 QUANTITATIVE CANCER RISK POSED BY PRENATAL EXPOSURE TO BA P.

S. Iyer1, M. Fox2, D. Tang1 and F. Perera1.
1Environmental Health Sciences, Columbia University—Mailman School of Public Health, New York, NY and 2Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

The frontline drug for tuberculosis treatment, isoniazid (INH), is known to cause mild elevations in alanine aminotransferase (ALT). A subset of patients (<1%) will experience rare, life-threatening liver toxicity. Mechanistic understanding of the INH hepatotoxic reaction has been limited due to a lack of animal models. In this study, a genetically diverse population of mice, or mouse diversity panel (MDP), was utilized to better understand the toxicity and to identify targets of effect in susceptible individuals. Thirty-four mouse strains were exposed for three days to isoniazid (100 mg/kg/day, i.g.) or vehicle. The primary histological finding was microvesicular steatosis in the liver which was strain-dependent in incidence and severity. To uncover the molecular mechanisms of the response, the transcriptome of the liver was evaluated using Affymetrix microarrays. Not unexpectedly, the majority of transcript changes (15,483) were significant for the mouse strain tested and not affected by treatment, a consideration that is important when selecting mouse strains for toxicity assessment. Analysis was focused instead on the 5,371 major transcript changes (15,483) that were different between the MDP and the strain tested (i.e. genotype of the individual) as these changes are the most informative for assessing the mechanisms of toxicity susceptibility. Consistent with the finding of microvesicular steatosis, the primary pathways affected were the methyleneol, safrole or ?-asarone might raise a potential concern for human health and would be of high priority for risk management. ©2011 Scientific Research Publishing, Inc. The research leading to these results has received funding from the European Community’s 7th Framework Programme (FP7/2007-2013) under grant agreement n° 245199. It has been carried out within the PlantLIBRA project (www.plantlibra.eu). This report does not necessarily reflect the Commission’s views or its future policy on this areas.

113 POPULATION-BASED TOXICITY ASSESSMENT IMPLICATES MITOCHONDRIAL DYSFUNCTION AS AN EARLY EVENT IN ISONIAZID-INDUCED LIVER INJURY.

J. S. Eaddy1, C. L. Kurtz1, H. Wu1, K. Adkins2, P. B. Watkins2 and A. H. Harrell2.
1The Hamner Institutes, Research Triangle Park, NC and 2Pfizer Inc., Groton, CT.

The frontline drug for tuberculosis treatment, isoniazid (INH), is known to cause mild elevations in alanine aminotransferase (ALT). A subset of patients (<1%) will experience rare, life-threatening liver toxicity. Mechanistic understanding of the INH hepatotoxic reaction has been limited due to a lack of animal models. In this study, a genetically diverse population of mice, or mouse diversity panel (MDP), was utilized to better understand the toxicity and to identify targets of effect in susceptible individuals. Thirty-four mouse strains were exposed for three days to isoniazid (100 mg/kg/day, i.g.) or vehicle. The primary histological finding was microvesicular steatosis in the liver which was strain-dependent in incidence and severity. To uncover the molecular mechanisms of the response, the transcriptome of the liver was evaluated using Affymetrix microarrays. Not unexpectedly, the majority of transcript changes (15,483) were significant for the mouse strain tested and not affected by treatment, a consideration that is important when selecting mouse strains for toxicity assessment. Analysis was focused instead on the 5,371 transcripts for which expression changed with treatment, and the level of change differed by the strain tested (i.e. genotype of the individual) as these changes are the most informative for assessing the mechanisms of toxicity susceptibility. Consistent with the finding of microvesicular steatosis, the primary pathways affected were the
mitochondrial dysfunction and oxidative phosphorylation pathways. These data support the hypothesis that the steatosis observed in these studies has a mitochondrial basis, as transcript changes occurred in genes that are an integral part of many components of the electron transport chain, including genes from Complexes I to V and all subunits of Complex II. Taken together, these data suggest broad disruption of mitochondrial gene expression due to INH treatment, and highlight the value of using a MDP to investigate mechanisms of toxicity.

114 HEALTH ASSESSMENT OF METHANOL USED IN HYDRAULIC FRACTURING FLUIDS.

Hydraulic fracturing (“fracking”) is a method of inducing manmade fractures in low-permeability rocks, so that trapped natural gas can flow from the rock, into the fractures, and into a natural gas well. The volume of fluids used in a fracking job can be as much as 2 to 8 million gallons per well, with water and sand typically constituting about 99.5% of the fracturing fluids. Methanol is used as a chemical additive in fracturing fluids for corrosion resistance, friction reduction, and flowback enhancement. Concerns have been raised about the use of methanol in fracking operations and the potential for impacts on human health. This study evaluated the potential health risks associated with exposure to methanol through consumption of groundwater impacted by methanol-containing fracturing fluids, and incidental ingestion of river and stream waters that received treated flowback. Modeled concentrations of methanol in groundwater and surface water were evaluated in the context of health-based screening levels developed specifically for these exposure scenarios, background dietary intake of methanol, and endogenous methanol production. Based on a high-end methanol concentration in groundwater of 0.6 mg/L, the estimated methanol intake from consumption of groundwater is 0.017 mg/kg body weight per day, corresponding to a hazard index of 0.03, and is more than 40 times less than the estimated dietary intake from fruit juice and wine. A high-end modeled methanol surface water concentration of 0.0000047 mg/L is 9 orders of magnitude below the health-based level derived for protection of incidental water ingestion during recreational activities. The results of this study indicate that, based on current practices, there is little risk to human health from the release of methanol into water as a result of hydraulic fracturing operations.

115 HEALTH RISK ASSESSMENT ON OCCUPATIONAL HAZARDS EXPOSURE AMONG WORKERS INVOLVED IN JASMINE’S AGRICULTURE.

S. Chakliang1, P. Suggaravat2 and L. Charenthanyakar1. 1Environmental Health Science, Faculty of Public Health, Khon Kaen University, Muang Khon Kaen, Thailand and 2Epidemiology, Faculty of Public Health, Khon Kaen University, Muang Khon Kaen, Thailand.

Many previous studies reported that the agricultural worksite is one source of health hazards to farmers. This survey study aimed to determine the potential health risk of exposure to occupational hazards among workers in a jasmine’s agricultural area, Sila sub-district, Khon Kaen, Thailand. Data were collected by an in-depth interview, observations and personal air samplings. Farmers almost used methyl carbamate and carbendazim to control the pests in the jasmine’s field. Three types of work-related jasmine’s field were jasmine farmers (n=16), jasmine collectors (n=16), and villagers who made garlands (n=22). The qualitative health risk assessment on exposure to occupational hazards was performed by considering of working procedures of those workers and possible types of hazards. Risk characterization identified that jasmine farmers had the highest risk of pesticide exposure through skin contact (40.0%), followed by inhalation exposure (26.7%). Both jasmine collectors and villagers who made garlands had the highest risk of awkward postures and repetitive works, followed by pesticide exposure through skin contact. The maximum concentration of methomyl in the breathing zone of workers (n=24) was 1.12 mg/m3 (range 0.1-12.1 mg/m3), however, carbendazim was not found. Comparison to the standard regulation on the ambient concentration of methomyl, i.e. TLV-TWA of 2.5 mg/m3 (ACGIH) or PEL-TWA of 2.5 mg/m3 (NIOSH), the results of this study did not exceed the regulation. The estimation of inhalation exposure to methomyl among workers was 0.08 mg/kg-d. The result of hazard quotient (HQ=3.24) indicated the potential health risk of jasmine farmers to the long term exposure to methomyl. Therefore, farmers in a jasmine’s agriculture and people should be aware of occupational hazards, particularly using the pesticide by better protection, continuous monitoring, and occupational health surveillance for safe working and living.

116 PROVISIONAL ADVISORY LEVEL (PAL) DEVELOPMENT FOR METHACRYLONITRILE.

C. Bast1, M. McClanahan2, P. McGinnis3 and F. Adeshina4. 1Oak Ridge National Laboratory, Oak Ridge, TN, 2CDC, Retired, Lilburn, GA, 3Syracuse Research Corporation, North Syracuse, NY and 4US EPA, Washington, DC.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hr, 30-d, and 2-yr durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALs have not been promulgated nor have they been formally issued as regulatory guidance. They are intended to be used at the discretion of risk managers in emergency situations when site specific risk assessments are not available. Application of PAL protocols has been performed for methacrylonitrile to estimate oral and inhalation exposure limits. Following oral and inhalation exposure, methacrylonitrile is readily absorbed and widely distributed. Toxicity is due to formation of epoxide intermediates, depletion of tissue glutathione, and metabolic release of cyanide. Oral and inhalation PALs were based on clinical signs consistent with cyanide poisoning or lethality. Oral PAL 1, 2, and 3 values are NR, 0.88, and 20 mg/L for 24-hr; NR, 0.63, and 15 mg/L for 30-d/90-d and 2-yr. Inhalation PAL 1 is 0.077 ppm for 24-hr, 0.063 ppm for 30-d/90-d and NR for 2-yr. Inhalation PAL 2 is 0.20 ppm for 24-hr/30-d/90-d and NR for 2-yr. Inhalation PAL 3 is 1.1 ppm for 24-hr, 0.31 ppm for 30-d/90-d and NR for 2-yr.

117 ORAL RISK ASSESSMENT OF DIACETONE ALCOHOL: USE OF METHYL ISOBUTYL KETONE DATA TO ADDRESS DATA GAPS.

The general population may be orally exposed to diacetone alcohol (DAA) through food and drinking water, since it is used as an indirect food additive and as a solvent in applications with potable water contact. Exposure to DAA may also occur through the various industrial applications for methyl isobutyl ketone (MIBK), since DAA is the primary metabolite of MIBK. Although the longest-term oral study for DAA was a 54-day reproductive/developmental toxicity screen by gavage, the database for MIBK is robust and the spectrum of toxicity is very similar between the two substances when evaluated in single or repeated-dose oral or inhalation studies and in genotoxicity assays. Since toxicokinetic studies confirm rapid metabolism and clearance of MIBK to the more persistent DAA, the majority of the internal exposure to DAA in both oral and inhalation studies with MIBK. The kidney is a target organ after oral exposure to DAA based on hyaline droplet nephropathy in male rats and renal tubular lesions in female rats. Slight changes in reproductive performance and pup viability at high gavage DAA doses may have been secondary to maternal toxicity. The point of departure for risk assessment of DAA was considered exacerbated chronic progressive nephropathy (CPN) after chronic inhalation of MIBK in female F344 rats. Based on 59% systemic absorption inferred from studies in human volunteers and a 20 m3/day inhalation rate, the benchmark concentration (BMCL10) of 25 mg/m3 for exacerbated CPN corresponded to an internal MIBK dose of 0.042 mmol/kg/day. The internal MIBK dose was adjusted to an internal DAA dose based on 79% of the area under the plasma concentration curve (AUC) being associated with DAA and 20% with the parent compound. The internal DAA dose corresponds to an ingested DAA dose of 3.9 mg/kg/day assuming 100% gastrointestinal absorption. Using a 30x uncertainty factor to account for intraspecies variability as well as limited data to compare the AUC after MIBK inhalation to that after oral DAA intake, a Reference Dose (RfD) of 0.1 mg/kg-day was determined for DAA.

118 THE WEIGHT OF EVIDENCE DOES NOT SUPPORT ENDOCRINE DISRUPTION AS THE CRITICAL EFFECT OF BENZOPHENONE.

The general population may be exposed to benzophenone through food and drinking water due to its use as a direct and indirect food additive and as an UV stabilizer in some coatings with water contact. Although some benzophenone derivatives are suspected endocrine disruptors, the weight of evidence does not support a hormonally-mediated mode of action for benzophenone. Decreases in mammary tumors
and thyroid hyperplasia in female rats chronically fed benzophenone were likely secondary to reduced body weight rather than ‘weak endocrine’ activity of the major metabolite, p-hydroxybenzophenone. In the uterotrophic assay, the benzophenone doses achieving comparable responses to 17-β-estradiol were more than three orders of magnitude greater. Putative estrogenic responses achieved in vivo suggested a potency ranging from one to four orders of magnitude weaker than the positive control depending on the assay. Results from the reproduction research study also do not support endocrine disruption or adverse reproductive effects. The modest, non-dose-related decrease in anogenital distance in F1 female rats occurred without other evidence of an androgenic mode of action. The critical effect for human health risk assessment is considered bile duct hyperplasia in female rats. A cytotoxicity-mediated mode of action is plausible in the liver and bile duct due to enterohepatic recirculation, altered bile acid transport and/or cholestasis. The toxic moiety is unclear and there were insufficient data to construct a model describing the disposition of benzophenone or its metabolites in blood or target tissue for use as an internal dose metric. Since a reliable benchmark dose (BMD) for bile duct hyperplasia could not be estimated, the Reference Dose (RfD) of 0.04 mg/kg-day was based on the human equivalent LOAEL of 4 mg/kg-day, which corresponds to a Total Allowable Concentration of 0.3 mg/L in drinking water. A short-term exposure level (STEL) of 2 mg/L was derived based on a human equivalent BMDL_{1,2} of 5 mg/kg-day for renal tubule dilation in F1 adult female rats from the two-generation study.

119 IS SULFUR DIOXIDE A REPRODUCTIVE AND DEVELOPMENTAL TOXICANT?
M. Seeley and J. E. Goodman. Graduate, Cambridge, MA.

Sulfur dioxide (SO2) is regulated as a criteria air pollutant by the US Environmental Protection Agency on the basis of respiratory effects, such as asthma. In addition to respiratory effects, effects on developmental and reproductive endpoints have been observed in some studies. Based on these effects, California’s Office of Environmental Health Hazard Assessment (OEHHA) recently added SO2 as a Proposition 65 developmental toxicant, specifically citing evidence regarding reduced fecundity in males and both pre-term birth and fetal growth effects in women. We evaluated the weight of evidence regarding these effects, focusing primarily on results from epidemiology studies, along with supporting evidence from animal and in vitro studies. OEHHA’s conclusion regarding reduced fecundity is based primarily on results from a single study conducted in a highly industrialized district of the Czech Republic, while related studies do not provide robust evidence to support this association. For both pre-term delivery and fetal growth restriction, there is inconsistency among studies with respect to the critical exposure window associated with these outcomes that cannot be fully explained biologically; some studies show associations for exposure throughout pregnancy, some show associations only in either early or late pregnancy, and others show no association at all. For all three adverse outcomes, there is uncertainty regarding whether the observed associations were due to SO2 or other factors that are also associated with adverse birth outcomes, such as differences in socioeconomic status and birth season. Inadequate control of other factors associated with adverse birth outcomes may confound the observed associations with SO2, particularly if these factors are also associated with SO2 levels. In addition, OEHHA proposed biological plausibility assessments, which SO2 might cause these effects are oxidant by existing data. We conclude that the weight of evidence does not support listing SO2 as a developmental toxicant.

120 ACUTE EFFECTS OF EXPOSURE TO VAPORS OF HYDROGEN PEROXIDE IN HUMANS.
L. Ernstgård, B. Sjögren and G. Johanson. Work Environmental Toxicology, Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden.

Hydrogen peroxide (H2O2) is a colorless, reaction unstable chemical with pungent odor. It is mainly used in chemical industrial processes, in paper industry for bleaching, as a disinfectant, for water treatment and bleaching hair. The use of H2O2 has increased in Sweden. The critical effect of H2O2 is considered to be irritation of mucous membranes and airways, however, scarce data available makes it difficult to assess effect levels and thus to set safe exposure limits. The aim of the study was to investigate effects in humans of inhaled H2O2 vapors. Six female and five male healthy volunteers were exposed blinded in a balanced order to clean air, 0.4 ppm and 2 ppm H2O2 for 2 h at rest. Symptoms related to irritation and effects on the central nervous system were rated on Visual Analogue Scales (VAS). The ratings were analysed with a nonparametric test (Friedman) whereas the objective effect measurements were analyzed with repeated measures ANOVA and Students t-test. The VAS ratings were generally low although they varied considerably. The sensory irritation scores were all statistically significant (p=0.09) and nasal and throat irritation (p=0.06) showed borderline tendencies to increase during exposure to 2 ppm H2O2 compared to 0.4 ppm and control exposure. Nasal airway resistance increased after exposure to 2 ppm H2O2 (p=0.04) but not after 0.4 ppm or clean air. No significant exposure-related effects on pulmonary function, nasal swelling, breathing frequency and blinking frequency were found. Furthermore, no clear effects were seen on markers of inflammation and coagulation in blood (C-reactive protein, interleukin-6, serum amyloid A, fibrinogen, factor VIII, von Willebrand-factor and Clara cell protein), although there were some scattered tendencies to increase after exposure to H2O2 compared to clean air. In conclusion, our study suggests that short-term exposure to H2O2 is slightly irritating at 2 ppm, but not at 0.4 ppm. These data should be considered when setting occupational exposure limits.

121 DRAFT REFERENCE EXPOSURE LEVELS FOR CARBONYL SULFIDE—A NERVOUS SYSTEM TOXICANT.
J. F. Collins and A. G. Salmon. OEHHA, Cal/EPA, Oakland, CA.

Carbonyl sulfide (COS), a chemical intermediate and a byproduct of oil refining, has been proposed as a grain fumigant to replace methyl bromide, which is being phased out due to its ozone depleting ability, and to supplement phosphogas, which is experiencing increased insect resistance. Morgan et al. (Toxicol Appl Pharmacol 200:131–145, 2004) exposed groups of male F344 rats to 0, 75, 150, 300, or 600 ppm COS for 6 h once and then held them for 2 weeks. Adverse effects were noted at 600 ppm in the respiratory system and the central nervous system. Thus 600 ppm was a LOAEL and 300 ppm was a NOAEL for acute effects. Morgan also exposed F344 rats to 0, 75, 150, 200, 300, 400, 500, or 600 ppm COS 6 h per day, 5 days per week for up to 12 weeks. After 12 weeks at 400 ppm, the predominant lesions were necrosis in parietal cortex area 1 and neuronal loss, microgliosis, and hemorrhage in the posterior colliculus; occasional necrosis was seen in the putamen, thalamus, and anterior olivary nucleus. Thus 400 ppm was a LOAEL and 300 ppm a NOAEL for subchronic effects. Based on these reports we have estimated a draft acute (1-hour) Reference Exposure Level (REL) of 2.7 ppm and a draft chronic REL of 90 ppb for COS based on effects on the rat nervous system. Although derived by approved methodology, the RELs for carbonyl sulfide have not undergone external peer review.

122 DERIVATION OF DRAFT CHRONIC REFERENCE EXPOSURE LEVELS FOR BOTH DIOXIN-LIKE AND NONDIOXIN-LIKE PCB CONGENERS.
J. Yang, A. G. Salmon and M. A. Marty. OEHHA, Cal/EPA, Oakland, CA.

Polychlorinated biphenyls (PCBs) are ubiquitous global contaminants with important toxic effects, although their production was banned nearly 3 decades ago. Health risk assessment for this class of chemicals is complex, since exposure occurs to mixtures of many PCB congeners in differing proportions. Therefore, toxicological and exposure data for individual PCB congeners are most relevant to health risk assessment. Five PCB congeners were selected based on toxicity and exposure information, which cover both dioxin-like (DL) and non-dioxin-like (NDL) PCBs as previously described in our publication of TEF_{v} values. Although extensive experimental data are available on PCB toxicities, investigators have used different methods, and measured different biomarkers, with variable results, complicating study-to-study comparison. To overcome this difficulty, we compared several similar subchronic studies that investigated health effects of dietary exposure to these congeners in rats. Among several biomarkers, we find that thyroid hormone is one of the most consistently sensitive biomarkers for these PCB congeners. We then determined the no-observed-adverse-effect levels (NOAELs) for PCBs 28, 77, 118, 126, and 153; these are 36, 8.7, 17, 0.01, and 34 μg/kg-day, respectively. By setting occupational exposure limits.
123 PROVISIONAL ADVISORY LEVELS (PALS) FOR CARBON DISULFIDE.
S. Milanese1, D. Dorman2, G. McConnell3 and E. Adeshina1, 1Environmental Sciences Division, Oak Ridge National Laboratory, Oak Ridge, TN, 2College of Veterinary Medicine, North Carolina State University, Raleigh, NC, 3ToxPath Inc., Raleigh, NC and 4US EPA, Washington, DC.

PAL values developed for hazardous materials by the US EPA represent general public emergency exposure limits for oral and inhalation exposures corresponding to three different severity levels (1, 2, and 3) for 24-hour, 30-day, and 2-year durations. PAL 1 represents the threshold for mild effects; PAL 2 represents the threshold for serious, irreversible or escape-impairing effects; PAL 3 represents the threshold for lethal effects. PALS have not been promulgated nor have they been formally issued as regulatory guidance, but are intended for use at the discretion of risk managers in emergency situations when site-specific risk assessments are not available. PALS are developed using standard protocols with appropriate human and animal data. Carbon disulfide (CS2) is a colorless liquid with a high vapor pressure that has been used in manufacturing cellulose rayon by the viscose process since the early 1900s, and is also used to produce carbon tetrachloride, cellophane, and other sulfur compounds. Large amounts are made commercially (>10^7 tons in 2002). Carbon disulfide is fat-soluble and concentrates in lipid-rich tissues, especially the nervous system, which is the primary target organ (CNS and PNS) in humans and animals. Chronic occupational exposure has also been associated with blood lipid changes and heart disease. Oral PALS were derived using a rabbit developmental study: PAL 2 and PAL 3 values were 29 and 88 mg/L, respectively, for 24 hours and for 30 days. Oral PAL values were not derived due to insufficient data. Inhalation PALS were derived using human and animal data. The PAL 1, 2, and 3 were, respectively, 1.7, 5.3, and 7.5 ppm for 24 hours; 0.89, 4.1, and 5.4 ppm for 30 days; 0.71, 4.1, and 5.4 ppm for 90 days, and 0.38, 0.79, and 3.2 ppm for 2 years. These values were approved by the Expert Consultation Panel for Provisional Advisory Levels in July 2011.

124 INTERSPECIES ADJUSTMENTS TO RODENT-DERIVED DIOXIN TOXIC EQUIVALENCY FACTORS ARE NECESSARY FOR PCBs.
E. Carbon1, C. H. Sutter2 and T. R. Sutter3, 1General Electric Company, Niskayuna, NY and 2University of Memphis, Memphis, TN.

The World Health Organization Toxic Equivalency Factor (TEF) scheme is used to estimate the combined human health risk of complex mixtures containing dioxins and “dioxin-like” compounds. Individual TEF values are primarily based upon toxicity data from rodent feeding studies. The literature now abounds with human-specific relative potency (REP) estimates, derived from in vitro system studies, which question the relevancy of rodent-derived TEFs for human health risk assessment. For instance, human-derived REP estimates for the most potent “dioxin-like” poly-chlorinated biphenyl (PCB) congener, PCB 126, are approximately 40-fold lower than its assigned TEF of 0.1. This species difference is robust, repeatable, and significant. Since both PCB 126 and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD; the reference compound) exhibit similar in vitro pharmacokinetics and rodent-derived PCB126 REPs are invariant between in vitro and in vivo studies, the human-specific in vitro REP estimate for PCB 126 can serve as a direct replacement to the current TEF. Although pharmacokinetic issues may cloud the direct applicability of in vitro REP estimates for PCB congeners other than PCB 126 in adjusting TEFs representing oral intake, studies using human cells have determined that these congeners exhibit either very weak (i.e., partial agonism) or undetectable “dioxin-like” activity. Overall, from this information we have developed interspecies adjustments to the current TEF values for PCBs. Following a weight-of-evidence approach, in vitro human data indicate that most PCB congeners should be removed from the TEF scheme entirely. In addition, the in vitro sensitivities of human cells to “dioxin-like” PCBs also calls into question current Aroclor risk values, where the critical effects are mainly due to the “dioxin-like” toxicity of PCB congeners observed in ultra-sensitive animal models (i.e., rats and rheas monkeys).

125 SUBCHRONIC TOXICITY OF BENZYL ACETONE IN RATS.
C. Letizia, V. Polizano and A. Api, Human Health, RJF, Woodcliff Lake, NJ.

The subchronic toxicity of benzyl acetone, a widely used fragrance ingredient, was evaluated in a 13-week oral toxicity study in Sprague Dawley rats with a 4-week recovery period. Male and female rats (10/sex/dose) were dosed via gavage at dose levels of 0 (control), 55, 165, 250 or 500 mg/kg/day. Corticosterone in urine was monitored with the vehicle, corn oil. An additional 5 rats/sex were treated with 0 and 500 mg/kg/day and were maintained for a 4-week recovery period. Observations included clinical observations, food consumption, body weights, functional observa- tional liver histopathology, hematology, plasma chemistry, urinalysis, estrous cycling, sperm analysis, gross necropsy and histopathology. One female at 55 mg/kg, 1 male at 165 mg/kg and 1 female at 500 mg/kg were found dead. Reasons for these deaths could not be established. Mean hemoglobin values were re- duced in females during week 7 and in males and females during week 14. Kidney weights were significantly increased in males at 500 mg/kg, but this finding had re- solved with recovery. Liver weights were significantly increased in both sexes at 165, 250 and 500 mg/kg; this effect was also reversible with recovery. Histopathological findings included reversible hepatocellular hypertrophy in livers from males at 250 mg/kg and in males and females at 500 mg/kg, reversible thyroid follicular cell hyper- trophy in males at 500 mg/kg and tubular lesions in male kidneys at 250 and 500 mg/kg which were associated with an increase in hyaline droplet formation. This finding was compatible with the diagnosis of alpha-2-micro-globulin nephropathy and was not considered relevant. Based on these results, the NOAEL was concluded to be 165 mg/kg.

126 A RAPID PROCESS FOR SETTING TOXICOLOGICAL LIMITS IN SUPPORT OF EQUIPMENT CLEANING IN A CONTRACT DRUG MANUFACTURING FACILITY.
E. Hope1, S. C. Gordon1, A. M. Kote1 and L. Harrison1, 1Medical Department, 3M, Saint Paul, MN and 2Drug Delivery Systems, 3M, Saint Paul, MN.

In drug manufacture, production equipment is cleaned to assure that there is minimal carryover of residual chemicals from one drug product run to the next. Validation of these cleaning methods is a critical step in assuring the safety and quality of the drug products, and includes setting Toxicological Limits (TLs), amounts of residual chemicals that can safely be carried over to the next product. Industry practices to set TLs are evolving away from default X-fold reduction in drug substance, to chemical-specific, health-based risk assessments. Also, assessment has expanded to include intentional and unintentional additives as well as the drug substance. In a contract manufacturing plant new drug products are constantly added, demanding a rapid method to set TLs. We report a tiered process to efficiently set TLs. Whenever available, published health-based human exposure limits or minimum recommended therapeutic doses, are used as the bases for setting TLs. In the ab- 2

127 CUMULATIVE RISK ASSESSMENT OF THREE ALDEHYDES PRESENT IN TOBACCO SMOKE: USING MARGIN-OF-EXPOSURE (MOE) AND MODE-OF-ACTION (MOA) EVALUATIONS.
F. H. Cunningham, S. Fiebelkorn and C. Meredith, Group R&D, British American Tobacco, Southampton, United Kingdom.

There has been significant interest in further characterising tobacco smoke toxicants both from the perspective of future regulatory frameworks aimed at monitoring or lowering toxicant levels and from the perspective of tobacco product development focused on selective toxicant reduction as part of broader harm reduction initiatives. We have previously described the use of the Margin of Exposure (MOE) model as part of a quantitative risk assessment paradigm for tobacco smoke toxicants, in conjunction with the preparation of mode of action (MOA) reviews. To generate a combined MOE assessment two assumptions are made: 1) the compounds are structurally similar and 2) that they share similar toxicological proper- ties. The generation of MOAs reduces the number of assumptions made in combined MOE assessments by ensuring similar toxicological properties and lesion types are seen. In this example, three structurally similar aldehydes found in tobacco smoke have had MOE and MOA assessments completed. The aldehydes investigated were acetaldehyde, formaldehyde and propionaldehyde. Multiple MOEs for each toxicant were generated from data available in the literature. The MOA reviews identified the same four key events associated with the carcinogenic potential of all three of these aldehydes. For each of the four key events, the lowest generated MOEs have been combined, using the following formula: MOEcombined = 1 / [1/MOE1 + 1/MOE2 + 1/MOE3 + 1/MOE4]. The cumulative MOEs generated were: Genotoxicity – 0.13; Cytotoxicity – 80.55; Hyperplasia / Metaplasia – 7.42; Tumours – 74.38. In all instances, the MOEs are lower than 100 suggesting that these toxicants are of a very high prior- ity for risk reduction research (Cunningham et al., Food Chem Tox, doi:10.1016/j.fct.2011.07.019). This is the first attempt at generating a combined MOE assessment for a group of toxicants found in tobacco smoke, based on the
However, screening (HTS) assays in the determination of chemical testing priorities. Momentum has been growing in Toxicology to assess the utility of high-throughput assays. This daily dose was then compared to human exposure estimates to aid in prioritization. Unlike the Phase I set, comprised primarily of food-use, data-rich pesticides, the -700 chemicals in Phase II are much more diverse structurally and in their usage and exposures. In vitro hepatic clearance and plasma protein binding assay data generated for Phase II chemicals indicate similar distributions to those observed with the Phase I set. The majority of chemicals are highly bound to plasma proteins, with median and upper quartile values at -3 and -20% unbound, respectively, for both sets. In vitro hepatic metabolic clearance values are also similar, with median and upper quartile values at -8 and -18 μL/min/106 cells, respectively, for both. In contrast to the Phase I chemicals, review of USEPA and CDC documents revealed that human exposure estimates are available for <10% of the Phase II chemicals. Our data indicate that the PK behavior of Phase II chemicals is similar to that of the Phase I set. Strategies to provide human exposure estimations, in part through EPA's ExpoCast project, are being explored to compensate for the limited information available for these chemicals. This abstract does not necessarily reflect EPA policy.

A modified Joint Director Laboratories (JDL) data fusion (DF) framework was developed to integrate data from disparate sources to estimate risks associated with potential exposure to a petroleum hydrocarbon mixture. The framework was used to detect patterns and integrate various toxicological datasets from the F1 group of hydrocarbons. F1 toxicological data were fused where available. The main objective of our case study was to demonstrate the applicability of the DF-based approach in risk assessment and management projects. For chemical mixture risk assessment, the problem formulation was defined using an illustrative example of a contaminated site. Traditionally, health risk assessments of mixtures are evaluated using a surrogate of chemical mixture data (e.g., current practice of F1 hydrocarbons assessment) or through component data. For neurotoxicity response analysis, neurotoxic metabolites toxicological data were fused with predictive toxicological data and then probability-boxes (p boxes) were developed to represent the toxicity of each compound. The neurotoxic response was given a rating of "low," "medium" or "high". These responses were then weighted by the percent composition in the illustrative F1 hydrocarbon mixture. The resulting p-boxes were fused according to Dempster-Shafer Mixture rule of combination. The fused p-boxes were fused again with toxicity data for n-hexane. We analyzed system biology curated n-hexane datasets. These types of dataset integration exercises from various disparate sources may help contaminated sites risk assessment and risk management project where a key risk management decision may be required based on site specific exposure analysis, operable exposure pathways and toxicity assessment. Part of the work was presented at the Alliance for Risk Assessment workshops. Currently we are exploring data fusion applications in remediation risk management and predictive toxicology tools.

The NRC (2009) Science and Decisions report discusses methods for assessing noncancer risks using linear extrapolation procedures similar to those used to assess risks posed by exposures to carcinogens. As part of the Alliance for Risk Assessment...
workshop series, this study was conducted to demonstrate four potential approaches to extrapolating risks below the point of departure, identified using an extension of the Benchmark Dose (BMD) method that allows the development of risk values at doses above the Reference Dose (RfD). The use of an internal measure of dose (blood methylmercury concentration), rather than external concentrations, was also considered in the risk evaluation by incorporating data from the National Health and Nutrition Examination Survey (NHANES). Methylmercury provides an unusual case in which the available BMD/BMDLs (USEPA 2001) are not only based on human responses, but were also estimated based on biomarkers (i.e., levels in hair and cord blood) measured in individuals as part of the evaluation for potential health effects. Both simple and more complex PBPK models are also available that allow the risk assessor to estimate external exposure rates associated with internal biomarkers. The dose-response conducted here addressed multiple issues raised by the NRC (2009) report including the impact of human variability, sensitive subpopulations, and method of extrapolation above and below the BMD/BMDL and RfD. The results demonstrate that depending on the assumptions used to estimate risks at exposures above the RfD, very different fractions of the population would be expected to have adverse events. This could have significant impacts on decision making in the risk assessment process. This case study exhibits how risk assessments using biomonitoring data for both dose-response and exposure helps to reduce uncertainty in the risk assessment process.

133 APPLYING THE “SCIENCE AND DECISIONS” CONCEPTUAL MODELS (CMS) TO DIOXIN.
T. Simon1, M. Stephens2, Y. Yang3, R. Manning4, L. Bowlands2 and R.A. Budinsky5. 1Tied Simon LLC, Winston, GA, 2John Hopkins Center for Alternatives to Animal Testing, Baltimore, MD, 3The Hamner Institute, Research Triangle Park, NC, 4Georgia Department of Natural Resources, Athens, GA and 5The Dow Chemical Company, Midland, MI.

The Alliance for Risk Assessment provided the opportunity to conduct this case study and compare the three CMSs for dose-response from the NRC 2009 report Science and Decisions: Advancing Risk Assessment. This exercise profits our understanding the strengths and weaknesses of applying these models. Dose-response assessments for TCDD were conducted with all three CMSs for the endpoints of hepatic and bile duct tumors in rats. Recently, an expert panel considering the aryl hydrocarbon receptor (AHR) concluded that sustained AHR activation was a pivotal key event in the mode of action (MOA) of rodent liver tumorigenesis. We use a biomarker of AHR activation as a dose metric for species extrapolation. The median dose at 10% risk from linear CM1 was 1 ppm/kg-d, that from nonlinear CM2 was 300 ppm/kg-d, and that from linear CM3 was 6 ppm/kg-d. These results show the differences and potential uncertainty for decisions using risk estimates based on policy versus those based on scientific evidence.

134 ASSESSING EXPOSURE DOSE EQUIVALENT OF VINYL CHLORIDE IN DRINKING WATER FROM SHOWERING AND BATHING ACTIVITIES USING PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING.
A. Nong1, P. Hamel2, R. Chatton3 and M. Deveau3. 1Environmental Health Science and Research Bureau, Health Canada, Ottawa, ON, Canada and 2Water, Air, and Climate Change Bureau, Health Canada, Ottawa, ON, Canada.

Historically, safety evaluation of chemicals in drinking water accounted only for exposures via the ingestion route. Recently, however, performing chemical risk assessments for drinking water have begun to account for the different routes of exposure where daily intake are calculated as equivalent dose using chemical data and average daily exposure assumptions. With more available information such as pharmacokinetic and toxicity data, the multiroute dose closely related to the target response can be estimated using a physiologically-based pharmacokinetic (PBPK) model. The objective of this study was to investigate these methods in a proposed tiered analysis within a drinking water exposure assessment framework. A PBPK model was derived to determine the human dose equivalent of vinyl chloride in drinking water following a shower exposure scenario. For an average shower exposure, a dermal and inhaled point of departure in humans was extrapolated from a rodent PBPK model and target liver metabolism dose-response relationship. The resulting model dose estimates were transformed to an oral dose equivalent (L-eq) for vinyl chloride in drinking water, and compared with values calculated using the tiered approach. The modeled dose estimates (inhaled 0.5 and dermal 2.0 L-eq) were as conservative as the L-eq values that were generated using chemical exposure data (inhaled 1.0 and dermal 3.0 L-eq). A tiered analysis framework based on available data using the different computational techniques is a scientifically meaningful approach supporting risk assessment practices of chemicals and contaminants in drinking water.

135 DISCREPANCIES AMONG ACUTE GUIDELINE VALUES FOR EMERGENCY RESPONSE.

Acute guideline values are tools for public health risk assessment and management during planning, preparedness and response related to sudden airborne release of hazardous chemicals, for example after an industrial accident or terrorist attack. A comparison of the two most frequently used set of values, i.e. the Acute Exposure Guideline Levels (AEGL) and the Emergency Response Planning Guidelines (ERPG), reveals that the individual values diverge by a factor of 3 or more for almost 40% of the 88 investigated substances, including many of high production volume. These deviations can be explained by differences in selection of critical effect or critical study and in a few cases differences in interpretation of the same critical study. The issue of astatistics was investigated in more detail, as this as a potentially susceptible subpopulation of considerable size. It is stated in the AEGL Standing Operating Procedures that astatistics are considered as a susceptible group, still 67% of the AEGL chemicals do not include any data or comments on astatistics. Moreover, only 6% of the AEGL chemicals include references to experimental data from human volunteers with astatistics and many of these references do not appear in nine other sets of acute reference values that we examined (covering guidelines for emergency response as well as short-term occupational exposure limit). Thus, there seems to be a significant lack of data related to the susceptibility of astatistics and where data are present they are frequently unknown or disregarded. In conclusion, there is a need for international harmonization in the area of acute guideline values. Key factors for broad international acceptance include transparency in the key documentation and the decision process as well as agreement on definitions of toxicological tiers and susceptible target populations such as astatistics. Lack of harmonization and transparency may interfere with trufstful and efficient communication and management during preparedness and response to sudden chemical releases.

136 COMPARATIVE STUDY ON THE UTILITIES OF ANIMAL EXPERIMENTAL DATA FOR RISK ASSESSMENT OF INHALATION EXPOSURE TO CHEMICALS.
Y. Aoki1, Y. Matsumoto2 and M. Matsumoto3. 1Center for Environmental Risk Research, National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan and 2Institute of Statistical Mathematics, Tachikawa, Tokyo, Japan.

Health risk assessment of chemicals in ambient air should be evaluated using the information obtained from epidemiological studies first in Japan, but toxicity data derived from epidemiological studies are often limited to the cases of occupational exposure. As preventive measures against exposure have been progressed in recent years, the cases toxicity expression due to high dose will be expected as quite rare. In future health risk will be assessed mainly on the basis of animal study instead of epidemiological study. However, there are species differences between human and animals. We intended to confirm whether the extrapolation of species difference using uncertainty factor and other is appropriate. Already, air quality standards or guideline values for air are established in Japan on the basis of epidemiological study. We re-evaluated cancer risk of vinyl chloride (VC) and 1,3-butadiene (1,3-BD) on the basis of animal study and compared with the result of assessment based on epidemiological study. Guideline values for air of VC and 1,3-BD in Japan was already established as 10 and 2.5 mg/cubic meter, respectively, which was evaluated from cancer risk level at 1 in 100,000 based on epidemiological studies. Cancer risk level of VC and 1,3-BD at 1 in 100,000 evaluated on the basis of animal inhalation studies was 1.7 - 19 and 0.6 - 7.2 mg/cubic meter, respectively; the guideline value for air of these chemicals were in the ranges of risk levels evaluated from animal studies. Usefulness of animal experiment data for health risk assessment will be discussed.

137 EFFECTS OF ACUTE EXPOSURE OF HUMAN PRECISION-CUT LUNG SLICES TO CHEMICALS.
L. Launertsen1, S. Switala1, F. Prenzler2, C. Förster2, O. Pfennig2, E. Corsini3, N. Krug1, A. Brain1 and K. Sewald1. 1Immunologie, Allergologie und Immunotoxikologie, Fraunhofer ITEM, Hannover, Germany, 2HRV-Klinikum Nordstadt, Hannover, Germany and 3Laboratory of Toxicology, University of Milan, Milan, Italy.

Introduction: A number of low-molecular weight (LMW) chemicals at workplaces are involved in the development of occupational asthma, one of the most common lung diseases in developed countries. Risk assessment is performed in animal experiments, however, in the context of REACH and the principle of 3Rs there is an increasing public demand for alternative methods. Human precision cut
lung slices (PCLS) is an *ex vivo* approach in which all relevant cell types of lung tissue are present in their natural position. The aim of the study was to establish PCLS as a relevant toxicity model for LMW chemicals.

Methods: Human PCLS were prepared from peripheral tumor-free tissue from resected lung lobes of cancer patients. PCLS were incubated with 20 industrial chemicals in serum-free DMEM under standard submerged cell culture conditions. PCLS without test substances were incubated as controls. After 24 hours incubation, induced toxicity was assessed by vitality staining and determination of enzymatic activity using WST-1 assay. The concentrations of chemicals resulting in toxicity very closely and also correlates with LD50 values from in vivo studies. Thus, conclusions can be made.

Results: Concentration dependent toxicity could be shown for all tested chemicals with EC25 ranging from 0.051 μg/mL to 1895 μg/mL. Individual EC25 values correlated significantly with data published for in vitro approaches with THP-1 and NCTC cell lines (r = 0.87 and 0.83, respectively). Furthermore EC25 of human PCLS correlated with LD50 data published for in vivo rat inhalation toxicity with r of 0.53 (p value of 0.08).

Conclusion: The toxicity of chemicals in human PCLS resembles the in vitro situation very closely and also correlates with LD50 values from in vivo studies. Thus, PCLS can be regarded as an *ex vivo* primary tissue toxicity model, displaying toxicity on all relevant cell types of lung tissue and excluding abnormal characteristics of cell lines.

138 ARE OELS AND DNELS THE SAME THING? A QUANTITATIVE COMPARISON OF THE EUROPEAN INDICATIVE OCCUPATIONAL EXPOSURE LIMITS AND THE DERIVED NO-EFFECT LEVELS FOR WORKERS UNDER REACH.

G. Johansson1 and L. Schenk2, 1Work Environment Toxicology, Karolinska Institute, Stockholm, Sweden and 2Division of Philosophy, Royal Institute of Technology, Stockholm, Sweden.

The new European Union (EU) REACH legislation requires Derived No-Effect Levels (DNEL) to be calculated for substances produced in quantities >10 tonnes/year. Meanwhile, the setting of occupational exposure limits (OEL) continues both at the member state and the EU level. Most OELs established at the EU level are not binding for the Member States (Innovative OEL Values, IOELV). The IOELVs are implemented by the European Commission as an EU Directive following proposals from the Scientific Committee for Occupational Exposure Limits (SCOEL). Although the DNELs and IOELVs thus belong to different sets of legislation and serve different purposes, the latter may, according to REACH, under certain circumstances be used as worker-DNELs. On the other hand, worker-DNELs will be derived for several thousand substances, far more than the roughly 100 substances for which IOELVs have been established. Thus, the procedure to set health-based OELs may become influential on that of DNELs and vice versa. In this study, we compare the safety margins of 88 SCOEL recommendations with those of the corresponding worker-DNELs. The latter were derived according to the interpretation of the REACH guidance document. Overall, the REACH safety margins were approximately six times higher than those derived from the SCOEL documentation but varied widely with REACH/SCOEL safety margin ratios ranging by two orders of magnitude, from 0.5 to 58 (n=88). The discrepancies may create confusion in terms of legal compliance, risk management and risk communication. We also found that the REACH guidance document, although encompassing detailed advice on many issues, including default assessment factors for species and route extrapolation, gives no quantitative guidance on when and how to depart from defaults.

139 DERIVATION OF SURROGATE ACUTE EMERGENCY GUIDANCE LEVELS (AEGLS) BY STATISTICAL CROSS-EXTRAPOLATION WITHIN AND ACROSS SEVERITY THRESHOLDS.

AEGLS are comprehensively peer-reviewed protective action criteria for assessing the risk of hazardous chemical inhalation exposures in emergency response situations. They are developed for three severity thresholds (AEGL-1: discomfort, AEGL-2: disabling, AEGL-3: lethal) at five exposure durations (1/6, 1/2, 1, 4, and 8 hours). Currently, only 66 compounds have finalised AEGLS, 192 interim, and 12 proposed. And of those, 12% are missing AEGLs for certain exposure durations and threshold levels, with 10% found in the AEGL-1 threshold (n=420). Statistical analysis of AEGL pairs across different thresholds and exposure durations showed high linear correlations between them (0.62 < R² < 1.0, log-scale). Within a threshold, AEGLS were most similar to their adjacent upper exposure duration value (i.e. 8-hr, R > 0.85). The threshold analysis of AEGLs-1 showed highest correlations with the 8-hr AEGLs of the other thresholds (0.91 < R² < 0.98). Interestingly, cross-threshold analysis of AEGLs-2 (and also AEGLs-3) showed that they were most correlated with the 1/6-hr AEGLs of the other thresholds (0.81 < R² < 0.97, respectively). From these analyses two high-correlation and time-specific extrapolation methods for estimating missing AEGLs were deduced. Since most missing AEGL data were from AEGL-1 threshold, the analysis suggested that for each compound, these values can be confidently cross-extrapolated within and across thresholds using scaling coefficients derived by the orthogonal least-squares regression. AEGL data at adjacent upper exposure duration were observed to be lower than LD50, perhaps due to a lesser time-scaling factor applied. In the future, structure-activity relationships, time-scaling relationships, and biological relevance of AEGL compounds will be investigated, which may explain the high correlations across exposure durations and severity threshold levels established in the present study.

140 STATISTICAL ANALYSIS OF THE ATSDR DATABASE OF CHEMICAL HEALTH GUIDANCE VALUES (HGVS).

E. Demchuk and Y. Tie. ATSDR/CDC, Atlanta, GA. Sponsor: B. Fowler.

Minimal risk levels are developed by ATSDR to be used as HGVs for populations exposed to hazardous chemical substances. However, HGVs are currently available for only a small number of substances. A goal of this work is to develop QSAR (Quantitative Structure Activity Relationship) models using toxicological information that has been rigorously peer-reviewed by responsible agencies, and then apply these models to estimate provisional HGVs (pHGVs) for other toxic chemicals that have not been yet reviewed. The development of a robust database of trustworthy toxicological information is the key component on this path; at present, the ATSDR oral toxicity database contains 678 data records for 548 unique pure chemicals. The data were collected with an emphasis on organic compounds. For each substance, the database record contains the following information: HGV, uncertainty factors for its derivation, LOAEL (lowest-observed-adverse-effect-level), NOAEL (no-observed-adverse-effect-level), POD (point-of-departure), exposure duration, and other experimental details about toxicity studies. Descriptive statistics analyses were performed for each toxicity category. Multivariate relationships were explored using the principle component analysis. Bivariate analysis was applied to relate NOAELs at intermediate to chronic exposure durations, and the NOAELs to LOAELs. The fitted ratios were 2 ± 0.5 (95% confidence level) and 4.5 ± 1.1, for intermediate-to-chronic LOAEL and LOAEL-to-NOAEL extrapolations, respectively. Both were within the 10-fold range, which is commonly used as a default uncertainty factor in HGV derivation. Using the new knowledge extracted from the ATSDR database, more chemicals within the feature domain of the database will be collected to expand the coverage of the chemical space available for a QSAR model. A QSAR model will be used to enhance the database coverage. A robust QSAR pHGV model will benefit public health by improving the assessment of toxicity risks caused by individual chemicals and mixtures.

141 MODELING OF FUROSEMIDE IN DILISYM™ REVEALS TESTABLE HYPOTHESES ABOUT HEPATOTOXICITY MECHANISMS.

S. Q. Siller1, D. J. Antoing2, B. A. Howell1, J. L. Woodhead1, B. Park2, and P. B. Watkins1. 1The Hamner-University of North Carolina Institute for Drug Safety Sciences, Research Triangle Park, NC and 2University of Liverpool Center for Drug Safety Sciences, Liverpool, United Kingdom.

A predictive, quantitative, mathematical model (DILISym™) is under development as a public-private initiative based on the physiological processes involved in drug-induced liver injury. The model includes multiple scales, ranging from molecular/cellular interactions to organ-tissue level considerations. Simulated mice, rats, and humans accurately reproduce the hepatotoxic responses to acetaminophen and methotrexate, providing validation of the DILISym™ model for reactive metabolite mediated toxicity. Furosemide (FS) hepatotoxicity is also thought to be reactive metabolite mediated, but with some mechanistic differences. FS was also recently included in the DILISym™ model, simulating the quantitative aspects of drug metabolism, covalent binding, glutathione, and ATP levels that are described in the literature and from unpublished experiments in mice dosed with 400 mg/kg. ALT levels were accurately predicted based on these inputs, and multiple hypotheses for the ATP reductions were tested with additional modeling and simulations. Dose-dependent necrosis and associated increases in ALT levels do not appear to be de-
dependent upon mitochondrial toxicity. Rather, simulations that included substantial (4x) increases in cellular energy expenditure or decreases (75%) in mitochondrial ATP production due to substrate limitations were more consistent with the experimental hepatotoxic responses. Specific laboratory experiments that will test these hypotheses were identified and are currently underway, including providing glycolytic substrate to sustain ATP production and levels in mice treated with FS. Incorporating FS into the DILIsym™ model provided an increased understanding of the mechanisms associated with FS hepatotoxicity, identified gaps in knowledge, and suggested multiple testable hypotheses to close these gaps.

A chloracne-like response in rhesus monkeys (Macaca mulatta) serves as the critical endpoint for the Aroclor 1254 reference dose (RfD). An interspecies uncertainty factor of 3 was used in the derivation of the Aroclor 1254 RfD, despite the fact that rhesus display an ultra-sensitive response to polychlorinated biphenyls (PCBs), including lethality. Since the establishment of this RfD in the mid-1990s, much has been learned regarding the mechanisms behind “dioxin-like” responses such as lethality. Since the establishment of this RfD in the mid-1990s, much has been learned regarding the mechanisms behind “dioxin-like” responses such as lethality. Furthermore, our laboratory and others have demonstrated that human cells are relatively insensitive to the “dioxin-like” effects of PCBs. Building upon our earlier studies using fresh hepatocytes in vitro, we have examined the potency of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), the “dioxin-like” congener PCB 126, and Aroclor 1254 to induce Cytochrome P450 1A1 (CYP1A1) gene expression in keratinocytes derived from human donors and rhesus monkey. Both PCB 126 and Aroclor 1254 were at least 2 orders of magnitude more potent inducers of CYP1A1 in rhesus keratinocytes compared to human keratinocytes, similar to that observed previously for hepatocytes. Interestingly, Aroclor 1254 failed to induce CYP1A1 beyond 1% of the maximal response level achieved by TCDD in human keratinocytes. The current observation of a clear species difference in sensitivity to PCBs between human and laboratory animal cells has been independently replicated in numerous studies and involves species differences in the arylhydrocarbon receptor pathway. From our quantitative data, we have calculated a data-derived extrapolation factor (DDEF) to account for interspecies differences in toxicodynamics and applied this DDEF to estimate a range of possible Aroclor 1254 RfDs. The proposed RfD estimates, utilizing the best available science, may explain why real-world exposure to PCBs have not resulted in “dioxin-like” toxicity in humans.

PS 142 THE AROCLOL 1254 REFERENCE DOSE AS A CASE STUDY FOR THE DEVELOPMENT OF DATA-DERIVED EXTRAPOLATION FACTORS TO REPLACE THE INTERSPECIES UNCERTAINTY FACTOR.
J. D. Schell1, E. Carlson1, J. B. Silkworth2, S. Bodreiddigari3, T. R. Sutter2 and C. H. Sutter4
1, 2, 3University of Memphis, Memphis, TN.

A chloracne-like response in rhesus monkeys (Macaca mulatta) serves as the critical endpoint for the Aroclor 1254 reference dose (RfD). An interspecies uncertainty factor of 3 was used in the derivation of the Aroclor 1254 RfD, despite the fact that rhesus display an ultra-sensitive response to polychlorinated biphenyls (PCBs), including lethality. Since the establishment of this RfD in the mid-1990s, much has been learned regarding the mechanisms behind “dioxin-like” responses such as lethality. Furthermore, our laboratory and others have demonstrated that human cells are relatively insensitive to the “dioxin-like” effects of PCBs. Building upon our earlier studies using fresh hepatocytes in vitro, we have examined the potency of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), the “dioxin-like” congener PCB 126, and Aroclor 1254 to induce Cytochrome P450 1A1 (CYP1A1) gene expression in keratinocytes derived from human donors and rhesus monkey. Both PCB 126 and Aroclor 1254 were at least 2 orders of magnitude more potent inducers of CYP1A1 in rhesus keratinocytes compared to human keratinocytes, similar to that observed previously for hepatocytes. Interestingly, Aroclor 1254 failed to induce CYP1A1 beyond 1% of the maximal response level achieved by TCDD in human keratinocytes. The current observation of a clear species difference in sensitivity to PCBs between human and laboratory animal cells has been independently replicated in numerous studies and involves species differences in the arylhydrocarbon receptor pathway. From our quantitative data, we have calculated a data-derived extrapolation factor (DDEF) to account for interspecies differences in toxicodynamics and applied this DDEF to estimate a range of possible Aroclor 1254 RfDs. The proposed RfD estimates, utilizing the best available science, may explain why real-world exposure to PCBs have not resulted in “dioxin-like” toxicity in humans.

PS 143 DIFFERENTIATING ALCOHOL SOURCES IN A DRAM SHOPPE CASE—A NOVEL MASS-BALANCE MODELING APPROACH.
M. Dulaney, Dulaney Toxicology Inc., Tallahassee, FL.

Multiple alcohol sources in Dram Shoppe cases are commonplace and it is difficult to scientifically differentiate between law-abiding establishments and other uncontrolled alcohol sources. This can lead to unfortunate liability as usually only a single Blood Alcohol Concentration (BAC) is collected after an accident and many times it is not uncommon for all alcohol sources to be considered contributory. To address just such a problem, a time-based, mass-balance model, based on the standard Widmark Equation combined with Monte Carlo simulation, was developed. The model requires only five input parameters: amount of ethanol consumed per hour at each source, body weight; Widmark “r” factor; Widmark “β” factors and the total time from beginning of the drinking episode to the accident. At least one BAC, taken after the accident, is also required to validate the input variables selected for the model. The mass balance of each alcohol source is calculated at hourly intervals. The alcohol mass-balance calculation is applied to the input parameters “r” and “β”. The full range of Widmark “r” and “β” values from the literature were utilized in the calculations. The mass balance calculations are used to determine the relative contribution of the alcohol remaining in the body for each hour. Remaining alcohol is added to the next hour’s alcohol consumption. The model calculates each source’s contribution to the hourly BAC, over time and defines when a particular source’s contribution to the total BAC is eliminated. While this situation only evaluates two-time consuming cases, the model can easily accommodate three to four alcohol sources if the drinking scenario lasts for at least 12 to 14 hours. The type of alcohol is irrelevant to the model and the drinking episode can be discontinuous as long as a measurable BAC is still present. This model was able to determine when Source A’s alcohol liability ended while confirming that Source B’s alcohol was solely contributory to the accident.

PS 144 ASSESSING THE IMPACT OF CHILD/ADULT DIFFERENCE IN PRESYSTEMIC CLEARANCE ON THE HUMAN KINETIC ADJUSTMENT FACTOR (HKAF) FOR INGESTED TOXICANTS.
M. Vakilli1, 2 and K. Krishnan1, 1Service Environnementale et Santé au Travail, Université de Montréal, Montréal, QC, Canada and 2Institut National de Santé Publique du Québec, Montréal, QC, Canada.

HKAF, as developed by IPCS/WHO, is aimed at replacing the 3.2-fold default value used for human variability in noncancer risk assessment. The value of chemical-specific HKAF has been reported by several authors based on child/adult differences in systemic clearance, without accounting for the additional impact of the presystemic clearance or first-pass effect (FPE) which is critically important for the oral route. The objective of this study was to evaluate the impact of child/adult differences in FPE on the magnitude of HKAF for ingested toxicants. Steady-state equations (SSE) that account for presystemic and systemic clearance were validated by PBPK modeling and were used to compute two dose metrics (arterial blood concentrations (Cass) and rates of metabolism (RAMs)) for oral exposures to 1 μg/kg/d in neonates (0-30 d), infants (1-12 mo), toddlers (1-3 y), and adults. The required physiological parameters were computed on the basis of body weight (BW) and height (H), whereas distributions of BW, H and hepatic enzyme content were derived from the literature. Simulations were compared with Monte Carlo simulations in each subpopulation for hypothetical CYP2E1 and CYP1A2 substrates exhibiting a range of blood:air partition coefficients (Pb: 1–10,000) and hepatic extraction ratios for the average adult (E: 0.01–0.99). Adjustment of the catalytic turnover as a function of the hepatic enzyme ontogeny could, in some cases, reduce significantly the magnitude of the FPE in children. HKAF was computed as the ratio of the 95th percentile value of dose metrics in children over the 50th percentile value in adults. HKAF > 3.2 were observed only based on Cass for various Pb values, in neonates when E ≥ 0.3 for CYP2E1 substrates (max.: 6.3) and in both neonates and infants when E ≥ 0.1 and 0.7 respectively, for CYP1A2 substrates (max.: 28.3).

Overall, this study showed that child/adult differences in presystemic clearance influence the variability of Cass and the resulting HKAF.

PS 145 A SYSTEMS BIOLOGY ANALYSIS TO INFORM HUMAN HEALTH RISK ASSESSMENT OF BENZENE.

Benzene is a ubiquitous environmental hematotoxicant. Benzene causes acute myeloid leukemia (AML) and myelodysplastic syndromes and has been associated with lymphoproliferative disorders including childhood lymphoblastic leukemia. Through its metabolites, benzene induces multiple alterations that likely contribute to the leukemogenic process. Biological plausibility for a causal role of benzene in these diseases comes from benzene’s genotoxic effects and toxicity to hematopoietic stem cells or progenitor cells, from which leukemias arise. This is manifested as lowered blood counts (hematotoxicity), even in individuals occupationally exposed to low levels of benzene. This effort explores a systems biology approach, encompassing endpoints that are relevant to the leukemogenic process and observed at low workplace benzene exposures. The analyses utilized samples from low occupational exposures to examine the dose-response relationship for blood cell counts, biochemical pathways, and expression of genes in the AML pathway. Multiple statistical analyses, including both parametric and non-parametric models that make minimal assumptions about model structure, were explored. The findings revealed dose-dependent responses below 1 ppm for the AML pathway genes, at both the pathway and gene expression level. In addition, the pattern of response appears to change around the 1 ppm region. These responses are considered in view of hypothesized pathways of metabolism that may only be operative below this level. In all, these analyses aid in elucidating: 1) the adverse effects of benzene at low exposures on pathways and mechanisms relevant to hematotoxicity and leukemia; 2) susceptible populations; and 3) quantitative approaches to estimate the low-dose human health risks of benzene exposure. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the US EPA.
from a component. Monte Carlo analysis was used to characterize the uncertainty in HI and MHQ that arises from the uncertainties in the components’ human health standards. Probabilistic models of the uncertainty in HI and MHQ values were created for 3,099 mixtures of 81 plant protection products (PPPs), previously analyzed in Price and Han (2011). Different sets of MCR values were obtained based on different levels of conservativeness (50th, 95th, and 97.5th percentiles) in estimating HI and MHQ. These HI and MCR values were compared to values set using actual (deterministic) PPP standards. The models treat the concentration data and Points of Departure in the standards as point estimates while sampling values for the uncertainty factors (e.g., animal-to-human extrapolation) from probability distributions taken from the literature. The deterministic standards on average fell at the 6th percentile of the standards’ uncertainty distributions while the deterministic values of HI and MHQ on average fell between the 95th and 97.5th percentiles of the uncertainty distributions. The averages of MCR values of the mixtures based on the 50th (MLE), 95th and 97.5th percentiles of HI and MHQ were 3.0, 1.5 and 1.4 respectively. The average MCR value based on the deterministic standards was 1.8. These indicated that compared to treating the uncertainty factors deterministically (i.e., point estimation) for setting the PPP standards, using MLE of PPP toxicity can generate larger values of MCR. However, increased conservativeness (95th and 97.5th percentiles of HI and MHQ) results in smaller MCR values and implies less need for CRAs.

There are a vast number of possible combinations of chemicals to which individuals are exposed and risk assessment of these exposures are of resource-intensive nature. A decision tree for the assessment of cumulative chemical risks has been developed by Cefic based on WHO and EU guidance and industry-sponsored research on the Maximum Cumulative Ratio MCR. The MCR is a tool to determine whether risk assessment of a mixture and the MCR is a practical, conservative and robust tool. Its application to the cumulative assessment of the risks from constituents in this formulation demonstrates the potential value of the MCR for characterizing the need for cumulative risk assessments.

There is considerable experimental support for the hypothesis that interactive effects are not likely to occur among components of a mixture when the constituents are present at concentrations below their respective NOAEL values. Nevertheless, greater-than-additive effects can occur when the components of the mixture are present at their NOAELs, especially for compounds with the same mode of action. This study evaluated the potential for interactions to occur between components of a binary mixture (saline extracts of BUNA rubber and nitrile rubber) that are toxicologically similar, but do not necessarily have the same mode or mechanism of action. Interactive effects of the mixture components were evaluated at the respective NOAEL of each component of the binary mixture, and at concentrations just below (1/3 of NOAEL), or well below (1/10 of NOAEL) their NOAEL values. Interactive effects were evaluated using in vitro hemolysis of bovine erythrocytes as the endpoint. Greater-than-additive interactive effects were observed when the mixture components were present at the NOAEL, but not when one of the mixture constituents was present at 1/3 or 1/10 the NOAEL and the other was present at the NOAEL, or when both were below the NOAEL. These results lend support to...
the hypothesis that interactive toxicological effects can occur when the components of a toxicological mixture are present at their respective NOAELs, but are not likely at concentrations below their NOAELs, at least in this test system. From a regulatory perspective, such findings are important for assessing the potential for toxicological interactions to occur in low-dose exposure scenarios.

151 THE IMPACT OF MIXTURE COMPOSITION, MIXING RATIO AND DOSE ON THE INTERACTIONS AMONG THE FOUR TRICHLOROMETHANES (THMs) REGULATED IN DRINKING WATER.

J. Simmons1, C. A. Dingus2, L. K. Teuscher3, G. E. Rice1, Y. M. Sey1 and A. McDonald. 1NHEERL, US EPA, Research Triangle Park, NC, 2Battelle, Columbus, OH and 3NCEA, US EPA, Cincinnati, OH.

Oxidizing disinfectants reduce microbial contamination but react with organic and inorganic materials in water forming disinfection byproducts (DBPs). The U.S. EPA regulates 4 THM DBPs (chloroform, CHCl3; bromodichloromethane, BDCM; chlorodibromomethane, CDBM; bromoform, CHBr3) as a group. Our objective was assessment, under an assumption of dose addition, of hepatotoxicity (serum sorbitol dehydrogenase, alanine aminotransferase, aspartate aminotransferase) of the 6 binary combinations of the 4 THMs. Individual THMs and mixtures were tested in female CD-1 mice (14 days of daily gavage) across a dose range that included no/low and overt response (0.1 – 3.0 mmol/kg/day). DBPs were compared at equimolar ratios (EQ) and at ratios representing disinfection by chlorine (Cl). Dose additivity models consistent with Benzbrium’s definition of additivity were developed with individual THM data. Toxicity increased significantly with dose for each individual THM and endpoint. The overall test for departure from dose additivity was significant (p<0.02 – p<0.001) for each mixture containing CHBr3 (the least prevalent THM in chlorinated water); with Hochberg’s correction applied (alpha=0.05), less-than-additive (antagonistic) toxicity was observed at the highest dose level of the EQ (CHCl3:CHBr3, BDCM:CHBr3) or the Cl (CDBM:CHBr3) mixtures. Deviation from additivity was not detected at the lower dose levels of the CHBr3 containing mixtures. Toxicity of the CHCl3:BDCM, CHCl3:CDBM and BDCM:DBCM mixtures was generally consistent with dose additivity. In summary, these data emphasize the importance of careful consideration of mixture composition and mixing ratio as well as the need for dose-response assessment that includes both the low dose and the overt response region when evaluating the health risks from exposure to mixtures present in the environment at low levels. (This abstract may not reflect EPA policy.)

152 IN VIVO TOXICOKINETIC INTERACTIONS BETWEEN THREE MEDICINAL DRUGS AND TRICHLOROETHYLENE IN RAT.

M. Cheikh-Rouhou1, G. Charest-Tardif1 and S. Haddad. 1Environmental and Occupational Health, IRSPUM, Université de Montréal, Montréal, QC, Canada and 2Biological Sciences, TOXEN, UQÀM, Montréal, QC, Canada.

We recently demonstrated that some pharmaceuticals can modulate the in vivo metabolism of trichloroethylene (TCE) in rats and humans. The objective of this study was to assess the in vivo significance of observed interactions between TCE and three selected drugs, i.e., valproic acid (VA), salicylic acid (SA) and naproxen (NAP). All groups of rats were exposed by inhalation to TCE (50 ppm; 6 h) in inhalation chambers. Groups co-treated with one of the drug were also given an oral dose (10 times the recommended daily dose, mg/kg) just an hour before of TCE exposure. Blood, urine and various tissue samples were collected at different time points and analyzed by headspace-GC coupled to an electron capture detector to determine the levels of TCE and metabolites (i.e., trichloroethanol [TCOH] and trichloroacetate [TCA]). Results show that NAP significantly increases free and total TCOH levels in the blood (i.e., up to 50%). This modulation was found to be significant up to 90 minutes after the end of exposure (p<0.05 for free TCOH, p<0.001 for total TCOH). This increase in blood TCOH can be explained by an inhibition of glucuronidation. VA and SA coexposures, revealed a significant increase (i.e., up to 50%) in blood levels of TCE (p<0.05). For VA, the peak interaction occurs at 30 and 60 minutes, while for SA this occurs at 120 minutes after the end of exposure. It can also be observed that these two drugs behave differently on TCOH levels. VA has no significant effect on blood TCOH levels, but is responsible of a significant increase in urine TCOH (p<0.05). SA, on the other hand, induced an increase of total TCOH levels in blood at 30 and 60 minutes after the end of exposure (p<0.05). Only NAP had a significant (p<0.05) impact on TCA levels in the liver (increase). The results of this study confirm that these drugs may interfere with TCE kinetics in vivo. Future efforts should be directed at evaluating how chronically medicated populations have greater health risks related to TCE exposure.

153 THE OXIDATIVE METABOLITES OF MEHP INHIBIT TESTOSTERONE PRODUCTION IN A RAT TUMOR CELL LINE ASSAY.

J. Campbell1, P. Balbuena2, R. Clewell2, M. E. Andersen2 and H. Clewell1. 1Center for Human Health Assessment, The Hamner Institutes, Research Triangle Park, NC and 2Institute for Chemical Safety Sciences, The Hamner Institutes, Research Triangle Park, NC.

Phthalate esters have been shown to disrupt sexual development in the male rat after gestational exposure, which is at least partially due to reduced testosterone synthesis in the fetal Leydig cell. While human exposure is primarily to the diester, rapid hydrolysis to the monoester occurs in the gut, blood and liver via side chain cleavage from the phthalic acid backbone. We previously developed a rat Leydig cell (R2C) assay to test antiantiandrogenic activity of the PE's in vitro. In agreement with in vivo studies, T synthesis in R2C cells was inhibited by monoethoxyl (MEHP) and monobutyl (MBP), but not monochlor phthalate. In vivo, MBP is primarily cleared by glutathione conjugation and excretion in urine and feces. However, MEHP undergoes extensive oxidative metabolism resulting in hydroxy, oxo and carboxyl metabolites. The oxidative metabolism occurs primarily on carbons 2 and 5 of the side chain. In this study, we have exposed R2C cells in monolayer culture to four metabolites of MEHP (5-hydroxy, 5-oxo, 5-carboxy and 2-carboxy MEHP) to ascertain whether or not these metabolites may contribute to the overall in vivo potency of MEHP. Compared to MEHP, the 5-oxo metabolite was approximately 5 times more potent at reducing testosterone. The remaining metabolites exhibited potencies below that of MEHP; however, all were able to reduce testosterone production in R2C cells. The order of potency was 5-hydroxy>MEHP>5-oxo>5-carboxy-2-carboxy. The toxic equivalents for the four metabolites compared to MEHP were approximately 5, 0.8, 0.6 and 0.35 for 5-hydroxy, 5-oxo, 5-carboxy and 2-carboxy, respectively. Thus, these oxidative products should be considered when determining the contribution of DEHP to cumulative risk from phthalate exposures.

154 IMPLEMENTATION OF THE HAZARD INDEX APPROACH IN FIELD ASSESSMENT OF CHEMICAL MIXTURES.

M. Murray1, P. Bourdillon1, P. Ruiz2 and D. Mellard3. 1Division of Toxicology and Environmental Medicine, CDC ATSDR, Atlanta, GA and 2Division of Health Assessment and Consultation, CDC/AISDR, Atlanta, GA.

The issue “Do chemical mixtures pose added risk?” has been a long time concern of health assessors. Three basic data driven approaches with some variations are part of various federal agency guidance. Of these, when exposure data are available, the hazard index (HI) approach is used most often. A recent review of 80 record of decision documents (ROD) revealed the following breakdown for the HI values: 0 to <1 (19%); 1 to <10 (36%); 10 to <100 (30%), and100 to 2,523 (15%). In the RODs, HI values can be found for various age, gender and life stages of a human population. A HI > 135 for neurological effects and HI > 52 for hepatic effects was calculated in an ATSDR health assessment of the Conrail site, where high level exposures occurred to trichloroethylene and carbon tetrachloride. Thus, when data are available effect specific HIs are calculated that can help in decision making. In this case, portable water was provided to the population as an alternative source. Because HIs are based on the principle of dose or response addition chemical interactions such as synergism and antagonism should also be considered when using HI values. Palmerton, a zinc smelter site, had high soil levels of zinc, lead, and substantial levels of other metals. These pollutants can potentially cause neurological, hematological, hepatic and testicular toxicities. The issue at this site was can the soil cleanup-goals for lead be relaxed because of zinc inhibition of other toxicities. The recommendation for this site was that additional joint toxicity data for testicular toxicity were needed and until then the clean-up levels could not be lowered. It is important to understand the advantages and limitations of a method before its implementation. Even though this is the most often used approach, HI values have several uncertainties associated with them. They can be fine-tuned for specific use and can provide insight to the risk characterization and risk communication.

155 MIXTURES OF ENDOCRINE DISRUPTORS: HOW SIMILAR MUST MECHANISMS BE FOR CONCENTRATION ADDITION TO APPLY?

T. Webster, Department of Environmental Health, Boston University School of Public Health, Boston, MA.

Rationale: Must molecular mechanisms be the same for concentration addition or is it sufficient to affect similar pathways and common outcomes? Does concentration addition provide a closer approximation to observations than alternative models such as effect summation? Suppose effects are mediated by hormone A through several uncertainties associated with them. They can be fine-tuned for specific use and can provide insight to the risk characterization and risk communication.
Results: Under concentration addition, the isolates must be negatively sloped straight lines. We show that linearity of the isolobes depends crucially on $g(B)$. The mixture is concentration additive if $g'(B)$, the second derivative of $g(B)$ with respect to $B$, is zero. It is supra-additive if $g'(B)$ is positive and sub-additive if $g'(B)$ is negative. We describe functions $g(B)$ that lead to all three cases as well as one that is supra-additive in some regions and sub-additive in others.

Discussion: At least in this simple model, concentration addition cannot be assumed based on action on a common hormone: mixtures of competitive antagonists and compounds that alter hormone synthesis can lead to results that are concentration additive, supra-additive or sub-addative. Nevertheless, concentration addition provides a closer approximation to the mechanistic model than effect summation. Care needs to be taken in extrapolating from the model used here to other situations, but analysis of simple mechanistic models appears to be a useful strategy.

156 DISCRIMINATORY POWER OF STANDARD TOXICITY ASSAYS USED TO EVALUATE CIGARETTES.

M. Oldham1, H. Hausmann2, W. Gomm3, L. T. Rimmer4, M. J. Morton1 and W. J. McKinney1. 1Altria Client Services, Richmond, VA. 2Toxicology Consultant, Roericht, Germany and 3GommCavalli, Roericht, Germany.

Toxicological acceptability of materials or products are typically based upon results from a battery of in vitro and in vivo assays. In most cases decisions are based on absence or presence of biological activity. In some cases, however, the tested product is biologically active in toxicity assays (e.g., cigaretes). In these cases it is difficult to a-priori determine the assays statistical discriminatory power. A large experimental dataset from a multi-year program of cigarette ingredient testing performed at two separate laboratories using similar methods was used to determine discriminatory power for chemical-analytical testing. Salmonella mutagenicity, cytotoxicity and 90-day rodent inhalation assays. Discriminatory power was measured using the minimum detectable difference (MDD) statistical method, which is the smallest difference that could reliably be detected assuming a defined sample size, significance level (p<0.05), power (80%) and variability. The MDD of 37 different cigarette mainstream smoke constituents ranged from 6-29% of the average yield. MDDs for the in vitro Salmonella mutagenicity and cytotoxicity tests ranged from 20-81% and 18-49% of the average activity, respectively. In the 90-day nose-only inhalation studies MDDs were: 30-40% for body weight; 6-43% for organ weights; 20-81% and 18-49% of the average activity, respectively. In the 90-day nose-only inhalation studies MDDs were: 30-40% for body weight; 6-43% for organ weights; 20-81% and 18-49% of the average activity, respectively. In the 90-day nose-only inhalation studies MDDs were: 30-40% for body weight; 6-43% for organ weights; 20-81% and 18-49% of the average activity, respectively.

157 THE PHOSPHORYLATION PATTERN OF HSP27 REVEALS THAT THE TOXICITY PATHWAY OF OKADIC ACID PREDOMINATES OVER THAT OF PALTOTOXIN IN HUMAN CELLS EXPOSED TO THE TOXIN MIXTURE.

G. Rossiini, G. Sala and M. Bellocchi. Scienze Biomediche, Università di Modena e Reggio Emilia, Modena, Italy.

Toxicity pathways (TP) and their interactions in biological systems have been studied by analysis of proteomes of cultured human cells exposed to toxins and toxin mixtures. When MCF-7 cells were exposed to either okadac acid (OA) or paltotoxin (PTX), two algal toxins possessing different molecular mechanisms of action, concomitant modifications of stress response proteins marked their cytotoxic effect (Sala et al., Chem. Res. Toxicol; 22, 2009, 1077-1085 and 2009-2016). The phosphorylation of the Hsp27 protein, in particular, was affected, and isoforms phosphorylated in Ser82 were found in cells exposed to either OA or PTX. Based on these observations, we have analyzed the effects mixtures of OA and PTX on the cellular protein phosphorylation patterns in MCF-7 cells, to probe possible crosstalks between the TP's of these toxins. Immunoblotting analyses of cell extracts using antibodies recognizing the total Hsp27 protein pool and several residue-specific phosphorylations confirmed our previous data on Ser82, and showed that a prominent increase in phosphorylation at Ser15 of Hsp27 in response to OA but via different specific mechanisms. Are combinations of B and C concentration additive? Methods: We used simple mechanistic, pharmacodynamic models, deriving mathematical models using equilibrium binding and mass balance. Assume A binds the receptor at one site R with effects proportion of AR. Let C act as a competitive antagonist via the Gaddum equation. Let B affect synthesis of A via a function describing the joint response surface of B and C, and a function describing its isolobes.

Discussion: At least in this simple model, concentration addition cannot be assumed based on action on a common hormone: mixtures of competitive antagonists and compounds that alter hormone synthesis can lead to results that are concentration additive, supra-additive or sub-addative. Nevertheless, concentration addition provides a closer approximation to the mechanistic model than effect summation. Care needs to be taken in extrapolating from the model used here to other situations, but analysis of simple mechanistic models appears to be a useful strategy.

158 EVALUATION OF MIXTURE EFFECTS AT DOES RELEVANT FOR HUMAN SAFETY.

M. Heneweer1 and T. Eeecto1. 1Taskforce on Mixture Effects, ECETOC, Brussels, Belgium and 2Shell Health, Shell International BV, the Hague, Netherlands.

Mixture toxicity has been a topic of interest for many years, with thousands of studies being conducted. Currently, the European Commission is looking at ways to include mixture toxicity in existing legislation. The focus should however remain on effects of mixtures which reflect real-life exposures, where each chemical is likely to be present below its threshold of toxicity. An ECETOC Taskforce has reviewed the evidence for unexpected effects, when each component in a mixture is at a dose below its threshold of toxicity. A survey of literature revealed that in over 500 papers was conducted with strict criteria for papers to be accepted as relevant for the review. Considered relevant were studies where the combinations of chemicals were the) tested at doses close to (but below) the NOAEL of each component, b) tested at doses well below the NOAEL of each component, or c) real or simulated environmental mixtures. The task force aimed to evaluate a) whether the evidence on interactions at environmentally or human-relevant doses demonstrates toxicologically relevant effects and determine whether there are any associations with specific modes of action, e.g. endocrine disruption, b) whether it is appropriate to assume dose additivity for substances with common modes of action and c) the adequacy of current human safety risk assessment practice in light of the conclusions of the above. From the high number of included studies, a relatively low number discussed effects at or well below NOAEL. The majority of these described additivity while only a limited number of studies reported deviation from additivity (both antagonism and synergy); the majority of which was observed in in vitro studies. Occasionally, the nature of the interaction could not be determined, whilst a small number of studies showed no effects at all. These findings indicate that current legislation (based on single chemicals) with a modification to accommodate for additivity when appropriate, is sufficiently protective against mixture effects on human health.

159 MOTORCYCLE EXHAUST INDUCES BEHAVIORAL TOXICITY IN FEMALE RATS AND OFFSPRING.

H. Yu, T. Li and T. Ueng. National Taiwan University, Taipei, Taiwan.

Emissions from two-stroke motorcycles create a major environmental burden in urban areas where motorcycles are a popular means of transportation. Motorcycle exhaust (ME) has higher levels of benzene and butadiene than exhausts from diesel and gasoline passenger cars. Particulate matters of ME contain carcinogenic aromatic hydrocarbons including benz(a)pyrene and benz(a)anthracene. The major purpose of the present study was to determine the behavior effects of ME exposure on female rats and maternal ME exposure on rat offspring. Female rats were exposed to 1:10 diluted ME by inhalation one hour each in the morning and afternoon daily and Monday through Friday for eight weeks. Control rats were exposed to clean air. The results of forced swim, light-dark transition, and tail-flick tests showed that ME produced depression-, anxiety-, and antinociception-like behavioral effects in female rats, respectively. At twelve weeks after cessation of ME exposure, depression-like behavioral effect persisted in female rats exposed to ME; in contrast, anxiety- and antinociception-like effects were not detected. At the end of ME exposure, control and ME-exposed female rats were mated with untreated male rats for two weeks. Behavior tests were done using offspring rats on postnatal day 56. Maternal ME exposure produced depression-like behavior, but not anxiety-like behavior, in male and female offspring. The maternal exposure produced antinociception-like effect in male offspring, but not in females. These results show that ME inhalation exposure induces depression-, anxiety-, and antinociception-like behavior in female rats and maternal ME exposure produces a depression-like effect in offspring. The underlying basis for the variable reversibility and developmental effect in ME behavior toxicity remains to be investigated.
Motor gasoline is manufactured by blending naphtha, i.e., refinery feedstocks composed of hydrocarbon constituents suitable for use in gasoline. The types of hydrocarbons found in naphtha are normal-, iso- and cyclo-paraffins as well as aromatics with carbon numbers in the range of approximately C4-C10. Heavy straight run naphtha (HSRN, CAS number 64741-41-9) has higher levels of cyclic-paraffins than other naphthas, and was tested as a “worst case” example. HSRN was tested in a combined repeated dose/reproductive toxicity test (OECD 422) to assess the potential for systemic toxicity, neurotoxicity, and for reproductive and developmental effects. Rats were exposed by inhalation at levels of 100, 500 or 3000 ppm, 6 h/day. Exposures started 2 weeks prior to mating and then through a 2 week habitation period. Rats taken for assessment of subchronic toxicity were sacrificed after approximately 30 days of exposure. In the reproductive toxicity study, exposures continued until gestational day 19; the rats were then held without exposure to final sacrifice on post-natal day 4. All animals survived the treatment period.

Principal systemic effects were increased liver weights in males and females, attributed to increased metabolic demands; increased kidney weights in males, attributed to an α2u-globulin-mediated process; and histological changes in the thyroid, judged by the pathologist to be secondary to liver enzyme induction. None of these were considered to be toxicologically important. There were no treatment-related effects in functional observation tests or in the assessment of motor activity. There were no significant reductions in fertility, no significant changes in other reproductive parameters, and no evidence of developmental toxicity. The overall no observed adverse effect concentration was 3000 ppm.

### PS 160 TOXICOLOGICAL ASSESSMENT OF HEAVY STRAIGHT RUN NAPHTHA

R. H. McKee1, D. Steun2, C. Schreiner3, R. White4 and L. A. Malley5, 1Toxicology and Environmental Sciences, ExxonMobil Biomedical Sciences, Inc., Annandale, NJ, 2Shell International, Houston, TX, 3C&C Consulting in Toxicology, Middelharnis, PA, 4American Petroleum Institute, Washington, DC and 5E. I. Du Pont de Nemours and Company, Newark, DE.

We have previously demonstrated using A549 cells that exposures to ozone in a photochemically aged air mixture induces greater toxicity than exposure to ozone alone. This study is an extension of these studies, aimed at comparing adverse effects in different human-derived cell cultures to understand potential differences. Commerically available EpAirway 3-D human-derived tracheal/bronchial epithelial cells from MatTek Corporation and A549 human alveolar epithelial cells were used. In vitro cultures were exposed to clean chamber air (sham), 400ppb of ozone, 100ppb of NOx, 400ppb of NOx and 100ppb of ozone, 400ppb of NOx and 500ppb of ozone, 100ppb of NOx and 900ppb of ozone, or 400ppb of ozone and 900ppb of ozone. After 24 hours of exposure, the cell cultures were fixed, stained, and observed using an inverted fluorescence microscope. Cell viability was determined using the MTT assay. Cell morphology was assessed using phase-contrast microscopy. The results of this study suggest that ozone and NOx have a synergistic effect on cell viability, and that the combination of ozone and NOx is more toxic than either gas alone.
Basolateral supernatants, apical washes, and RNA were collected at 0, 9, and 24 hours post-exposure. Cytotoxicity was assessed via lactate dehydrogenase (LDH), IL-6 and IL-8 were measured to determine the inflammatory response, and heme oxygenase-1 (HO-1) levels were used to determine oxidative stress. Analysis of A549 LDH levels demonstrates that a photochemically aged urban mixture does induce greater toxicity than exposure to ozone alone. However, this effect is not observed in the EpiAirway LDH levels detected. Similarly, IL-6 trends were observed in the A549 cells, but not the EpiAirway cells. Although EpiAirway cells produced much higher levels of IL-6 compared to A549, no exposure trends can be observed due to the high variability in expression. These findings indicate that type and magnitude of responses induced by air pollution mixtures may be cell culture model dependent. Therefore, it is important to understand the limitations of each in vitro model and critical to identify appropriate endpoints for each model.

Petroleum coke (CAS number 67471-79-3), the material remaining after thermal decomposition of petroleum streams, is primarily inorganic carbon but also contains some entrained volatile hydrocarbon material, sulfur, and trace metals. Previous studies have shown that in rats, repeated exposure to petroleum coke dust by inhalation results in dust accumulation in the lungs and inflammatory changes but does not cause tumors or produce other systemic effects. As part of the petroleum industry response to the USEPA High Production Volume (HPV) challenge program, the potential reproductive effects of respirable coke dust (3.3 micron MMAD) were assessed in a subchronic toxicity/reproductive toxicity screening test in rats (OECD 421). The repeated-dose portion of the study in which male rats were exposed 6/day, 7 days/week for at least 4 weeks, provided further evidence for petroleum coke dust accumulation and inflammatory responses in rats exposed to 100 mg/m3 and 300 mg/m3. But there was no evidence of systemic toxicity. The low exposure level (30 mg/m3) was a no observed effect concentration for all endpoints. Therefore, it is important to understand the limitations of each in vitro model and critical to identify appropriate endpoints for each model.

The study aims at the development of a computational framework for assessing mechanistically the risks imposed by major components of ETS, by assimilating biomonitoring data, internal dose modeling and Biology Based Dose Response (BBDR) modeling for three organic contaminants, namely 4-(N-nitrosomethylamino)-1-(3-pyridyl)-1-butanone, benzene and formaldehyde, related to lung cancer, leukemia and nasopharyngeal cancer respectively. A nicotine-cotinine PBPK model was developed, allowing the use of biomarkers such as urinary cotinine and nail nicotine for short and long term exposure assessment through reverse modeling. Reconstructed exposure scenarios are fed forward to BBDR models coupling PBPK/D with mechanistic pathology models for each carcinogenic contaminant. Genetic polymorphisms linking variation of human susceptibility to xenobiotics were explicitly accounted for. Extrapolation to the wider population through hierarchical population modeling incorporated all variabilities and uncertainties governing exposure and response to xenobiotics from ETS. Individual risks estimated for lung cancer, leukemia and nasopharyngeal cancer ranged within values of order 10-5, 10-7 and 10-9 respectively under the typical urinary cotinine-driven exposure scenarios. Exposure duration had a non-linear effect on lung cancer, while the limited variability of formaldehyde exposure was compensated by the strongly non-linear mechanism governing formaldehyde-DNA adduct formation. Considering that benzene toxicity relies upon the presence of its toxic metabolites, polymorphism variability among gene variants of CYP2E1 and NQO1 was found to be determinant for overall risk assessment. A multi-tiered approach is proposed here as a valid alternative to classic epidemiological approaches, since cancer risk is estimated using models with strong biological underpinning.
CRUDE OIL FROM VARIOUS SOURCES YIELDS DIFFERENT ACUTE TOXICITY OUTCOMES IN RATS: CORRELATION WITH ‘H-NMR AND EPR SPECTRA.

S. A. Meyer1, S. Lajigoma2 and K. A. El Sayed1. 1Toxicology, University of Louisiana at Monroe, Monroe, LA and 2Basic Pharmaceutical Science, University of Louisiana at Monroe, Monroe, LA.

Crude oil is a mixture of alkanes, simple and polyyclic aromatics, nitrogen, sulfur and condensed PAH asphaltene with traces of porphyrin nickel and vanadium that varies with source. We previously identified several adverse effects with acute, oral exposure of rats to Louisiana sweet crude oil and here extend those observations to Nigerian (Qua Iboe) sweet and Iraq high sulfur oils (ONTA, Inc., Toronto, Canada). Chemical fingerprinting of the oils by 'H-NMR and EPR has been used to correlate constituent contents with toxicological effects. Female Sprague-Dawley rats were orally gavaged with 2 daily doses of 2.5 and 5 mg/kg of oil, 0.5 ml/kg benzene or vehicle (0.5% DMSO in corn oil). After 48 h, rats were euthanized, blood was taken for hematology and clinical chemistry and femur bone marrow cells assayed for myeloid progenitor cells (CFU-GMs). All oils elevated serum alkaline phosphatase (ALP) with LA oil being the least potent and effective. BUN was increased 40% by high dose of Iraqi oil. Granulocytes were increased 1.5-2 fold by high dose of LA and Iraqi oil. Liver weights increased 25-75% with both doses of all oils with LA oil being least effective. Spleen weights decreased 30% with high doses of Iraqi and Nigerian oil. CFU-GMs were decreased only with high dose of all oils with LA oil being least effective. Spleen weights decreased 30% with high doses of Iraqi and Nigerian oil. CFU-GMs were decreased only with high dose of LA oil (40%). Benzene decreased spleen weight by 20%, but was without effect on other endpoints. 'H-NMR spectra exhibited qualitatively similar alkane peaks for all oils, but some differing aromatic peaks. Benzene peak (7.38 ppm) of Iraqi oil was less intense than that of the other oils. EPR spectra of all oils exhibited the asphaltene free radical peak with intensity greatest for Iraqi oil. Vanadium porphyrin was detected in Iraqi oil, but not the others. Summarizing, LA sweet crude oil was uniquely myelosuppressive and with no or lesser effect on spleen and liver weights and BUN. Elevated BUN was uniquely associated with Iraqi oil, the source richest in asphaltene free radical and vanadium porphyrin and lowest in benzene. (LA Board of Regents)

CYTOTOXICITY PROFILING: A NOVEL METHOD FOR ENVIRONMENTAL CONTAMINANT ASSESSMENT.

D. Y. Huang1, S. Gabos2, W. Zhang1 and D. W. Kinniburgh1. 1Institute of Computer Science, Martin Luther University, Halle/Saale, Germany, and 2Department of Environmental Science, University of California Davis, Davis, CA.

The traditional method of assessing the toxicity of environmental contaminants is to use animal studies to determine the toxicity, but concerns over the use of animals has driven the search for alternative in vitro methods. We have developed an alternative system for measuring in vitro toxicity utilizing a real time impedance based cytotoxicity system. Using an array of cell lines derived from major organs, we are able to produce a cytotoxicity profile, or toxicological fingerprint, for a number of environmental samples. Unique profiles were derived for the chemicals that potentially can be used to identify the mechanism of action for the chemical in question and estimate the toxicity. In order to apply this technique to a “real world” samples we conducted experiments to determine any matrix effect of natural water. Using cell lines from different organ origins (CNS, liver, lung, kidney), we tested water samples from ground water (well), and surface water (lake) and compared these results to the chemical testing. The current work demonstrates 1) the feasibility of using the impedance based cytotoxicity assay to test environmental water samples without sample cleanup and concentration, 2) the agreement between the impedance based cytotoxicity testing and chemical results, and 3) the proof of concept for cytotoxicity profiling using impedance based cytotoxicity testing.

ARE IN VITRO EFFECTS OF METAL MIXTURES PREDICTABLE FROM THE RESPONSES TO THE SINGLE COMPONENTS?

F. Glahn1, Q. D. Nguyen1, J. Wiese1, J. G. Heneghan1, I. Grose1 and H. W. Forth1. 1Institute of Environmental Toxicology, Martin Luther University, Halle/Saale, Saxony-Anhalt, Germany, 2Institute of Computer Science, Martin Luther University, Halle/Saale, Saxony-Anhalt, Germany and 3JALdo, Leibniz Research Centre for Working Environment and Human Factors, Technical University, Dortmund, North Rhine-Westphalia, Germany.

At occupational settings people are often exposed to mixtures of metals, which increases complexity of toxicological risk assessment. For example in battery manufacturing or recycling of electronic devices workers can simultaneously be exposed to Cd, Co and Pb. To gain more insight into the effects of Cd(II), Co(II) and Pb(II) in single or combined application we conducted experiments with the human lung tumor cell line H322 and primary cultures of normal human bronchial epithelial cells (NHBEBC). Incubation of H322 with Cd (2.5 μM) for 24h reduced viability to 87%, as measured by MTT-assay. Whereas treatment of H322 with Co (≥ 20 μM) or Pb (≥ 30 μM) was not cytotoxic, simultaneous treatment with Cd, Co and Pb was not more toxic than Cd alone. When induction of ROS was analysed by DCF-assay, significant inductions where detected at following concentrations: Cd (0.13 μM; 134%), Co (0.5 μM; 129%), Pb (2.65 μM; 159%). If metals where applied in these concentrations simultaneously, ROS-induction was 150%. To understand cellular responses to low doses of Cd (0.13 μM), Co (0.42 μM) and Pb (2.65 μM), a gene array study was conducted with NHBEBC. Different algorithms for the analysis of the raw data were compared in order to find the procedure most suitable to detect differentially expressed genes. Moreover applying a newly developed processing setup with pre-processing by GCRMA and data analysis by shrinkage generalized interaction t-test, it was possible to detect genes reacting in a cooperative manner to combined metal exposure. The top five of these genes are: GOS1, TOR1AIP1, ARL1, SDF2L1 and DHCR7. These experiments demonstrate that a thorough analysis of the mechanism of action - beyond tests on cytotoxicity or induction of ROS - could be useful for predicting the effects of metals on human lung cells.

HIGHLY SENSITIVE AND RESPONSIVE SPECIES-SPECIFIC AH RECEPTOR-BASED CALUX CELL LINES FOR HIGH-THROUGHPUT CHEMICAL SCREENING AND SPECIES COMPARISONS.

J. Brennan1, G. He1, T. Tsutsumi2, P. Magaizis3 and M. Denison1. 1Environmental Toxicology, University of California Davis, Davis, CA, 2Division of Foods, National Institute of Health Sciences, Tokyo, Japan and 3Pharmacy, University of Athens, Athens, Greece.

The CALUX (chemically-activated luciferase expression) cell bioassay is the most widely used Ah receptor (AhR)-based technique for screening of environmental, biological and food samples for the presence of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and related chemicals. Recently, the AhR-CALUX bioassay has been used for high-throughput screening of chemical libraries in order to identify AhR agonists/antagonists for use in therapeutic applications. We previously developed several CALUX cell lines for large scale high-throughput screening applications, but these cell lines are not sensitive or responsive enough for such purposes. Accordingly, stable transfection of mouse, rat, human and guinea pig cell lines with a luciferase reporter plasmid in which the number of AhR-responsive DNA binding sites has been increased to 20, produced a series of species-specific recombinant cell lines with significantly improved sensitivity (minimum detection limits for TCDD in these cell lines range from 10 fM to 30 pM TCDD) and dramatically increased induction of luciferase activity. The significantly enhanced induction response in the cells has allowed the bioassay to be utilized in a 1500-well microplate format for high-throughput screening of chemical libraries for AhR agonists. Comparison of a series of natural products and extracts in these cell lines has revealed dramatic species specific differences in AhR response, with indirubin being selectively more potent in human cells than that of other species and extracts of Polygonum seeds activating the AhR in rat, guinea pig and human cells, but antagonizing that in mouse cells. These more sensitive and responsive cell lines not only improve use of the CALUX bioassay for large scale screening purposes, but provides novel systems to study species differences in AhR response. (ES00469, ES007685,ES012498)

STABLE REPORTER CELL LINES FOR THE IDENTIFICATION AND CHARACTERIZATION OF SUBTYPE-SELECTIVE ESTROGENIC LIGAND.

E. K. Sharle and W. Xu. Oncology, Molecular and Environmental Toxicology, University of Wisconsin-Madison, Madison, WI.

Estrogen signaling is mediated by two estrogen receptors (ERs), ERα and ERβ, which have unique roles in the regulation of breast cancer cell proliferation. ERα mediates proliferation in response to estrogen and ERβ inhibits proliferation in breast cancer cells, suggesting ERβ selective ligands may be beneficial for promoting the anti-proliferative action of ERα. Identification and characterization of subtype selective ligands can be achieved using transcriptional assays, but cell lines in which ERα or ERβ are independently expressed are required. Of the available reporter cell lines, none have been generated in breast cancer cells. Here we describe the generation of two isogenic breast cancer cell lines, Hs578T/ERELuc and...
H578T-ERβLuc, with stable integration of an estrogen responsive luciferase reporter gene and characterization the subtype selectivity of two natural phytoestrogens, cosminin and liriquitin. H578T-ERαLuc and H578T-ERβLuc cell lines are highly sensitive to estrogenic chemicals and ER subtype selective ligands, providing a tool to characterize the transcriptional potencies and subtype selectivity of estrogenic ligands in the context of breast cancer cells. In addition to measuring reporter activity, ERβ target gene expression and growth inhibitory effects of ERβ selective ligands were determined as biological endpoints. These cell lines are valuable tools for characterizing estrogenic ligands, and the data support the anti-proliferative role for ERβ in breast cancer.

RECEPTOR AND LIGAND-DEPENDENT FUNCTIONS OF PPARα/β and PPARγ ON CELL PROLIFERATION IN THE A431 HUMAN CARCINOMA CELL LINE.

M. G. Borland1, C. Lee1, P. S. Allreuc1, B. Zhu1, T. S. Lahoti1, E. L. Gonzalez2 and M. P. Peters1. 1Chemistry and Biochemistry, Bloomsburg University of Pennsylvania, Bloomsburg, PA, 2Veterinary and Biomedical Science, Penn State University, University Park, PA and 3Laboratory of Metabolism, NCI, Bethesda, MD.

The peroxisome proliferator-activated receptor (PPAR) isoforms (PPARα, PPARβ/δ, and PPARγ) are known to modulate proliferation in skin tumorigenesis models. To examine the functional role of PPARα/β and PPARγ in skin cells with greater detail, the Migr1 retinoviral system was used to generate stable expression of each receptor in the A431 human carcinoma cell line. As compared to controls, the expression of a known PPAR target gene was greatly enhanced in response to PPARα/β or PPARγ ligands in A431 cells over-expressing these receptors. Over-expression of either PPARα/β or PPARγ did not alter A431 cell growth under normal cell culture conditions. Administration of PPARγ ligands in A431 cells over-expressing PPARγ reduced cell growth; however, similar alterations in cell growth were not observed with ligand activation of PPARα/β. In contrast, anchorage-independent cell growth was not influenced by either over-expression or ligand activation of PPARα/β or PPARγ. Over-expression of PPARα/β modestly inhibited clonogenicity, but ligand activation of PPARα/β markedly inhibited clonogenicity as compared to controls. Over-expression of PPARα/β did not influence clonogenicity, but ligand activation of PPARα/β in A431 cells over-expressing PPARα/β resulted in reduced clonogenicity. Over-expression of PPARα/β or PPARγ markedly reduced tumor volume in ectopic xenografts, but PPAR ligands had no further influence on tumor volume. Collectively, these studies demonstrate that stable over-expression of PPARα/β or PPARγ in A431 cells increased the efficacy of ligand activation and reduced A431 cell growth. Importantly, over-expression of receptor did not modulate normal cell growth, but increased PPAR expression or ligand activation had major impacts on clonogenicity and/or tumor volume. This model will be a valuable tool to dissect the functions of PPARα/β and PPARγ in human skin tumorigenesis.

FUNCTION AND EXPRESSION OF TRPA1 IN RESPONSE TO ENVIRONMENTAL IRITANT EXPOSURE IN VITRO.

J. J. Pellman1,2, P. E. Kunkler1,2, J. H. Hurley1,2 and G. S. Oxford1, 1Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN, 2Stark Neuroscience Research Institute, Indiana University School of Medicine, Indianapolis, IN and 3Biochemistry, Indiana University School of Medicine, Indianapolis, IN.

Headaches are the most common symptom reported after exposure to both indoor and outdoor air pollution. Many of these headaches are attributed to Multiple Chemical Sensitivity (MCS), an acquired chronic disorder estimated to affect 15% of the US population. The induction of MCS is often due to low level exposure to air pollution and industrial chemicals such as acrolein. Acrolein and other environmental irritants have been shown to activate transient receptor potential A1 (TRPA1) channels in trigeminal neurons. Trigeminal neurons are the sensory neurons of the head and are activated in migraine headaches. TRPA1 channels are excitatory calcium generating ion channels expressed in a subset of sensory neurons. Activated TRPA1 channels have been shown to cause release of neuropeptides such as calcitonin gene-related peptide (CGRP). We have shown that 30μM acrolein application results in a 6-fold increase over baseline of CGRP release in trigeminal neurons in vitro. CGRP release is associated with pain, inflammation, and headache. Our work uses primary cultures of trigeminal neurons as well as transfected cell lines incubated with low levels (1-10μM) of environmental irritants for multiple days in vitro to simulate chronic exposure. We examine changes in expression using quantitative PCR. Function of TRPA1 channels is examined using Fluoro-4 AM calcium imaging and radioimmunoassays to measure CGRP release from neurons. As MCS has emerged as a global public health concern, understanding the mechanism of MCS is a very important and relevant question with regard to public health and workplace safety. The objective of these studies is to describe the impact of low levels of environmental irritants on TRPA1 expression and function.

ACTIVATION OF THE AH RECEPTOR SIGNALING PATHWAY BY SHEAR STRESS: GENERATION OF ENDGENOUS LIGANDS AND/OR EXPERIMENTAL ARTIFACT?

M. S. Deisenroth1, A. Gojova1, J. E. Bohonowycz1, J. Morgan1, G. He1, A. Baraket2 and B. Zhao3. 1Department of Environmental Toxicology, University of California Davis, Davis, CA, 2Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing, China and 3Department of Mechanical and Aerospace Engineering, University of California Davis, Davis, CA.

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor that mediates the toxic effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). AhR regulates the expression of hundreds of genes including TCDD-inducible poly(ADP-ribose) polymerase (TiPARP, PARP7). TiPARP is a member of the PARP superfamily, which is an enzyme family that mediates poly(ADP-ribose)ylation of protein targets. Poly(ADP-ribose)lation is post-translational modification associated with a number of biological functions including DNA repair, transcription, and apoptosis. TiPARP contains a C-terminal PARP catalytic domain, a conserved WWE (tryptophan-tryptophan-glutamate) domain and a zinc-finger domain. However, the biological role of TiPARP and whether TiPARP modulates AhR action is unknown. The aim of the present study was to investigate modulation of TCDD-induced AhR activity by TiPARP. We investigated the effects of loss and overexpression of TiPARP on TCDD-induced cytochrome P450 1A1 (CYP1A1) and CYP1B1 gene expression in T47D human breast carcinoma and HuH7 hepatoma cell lines. RNA-mediated knockdown of TiPARP significantly increased TCDD-induced CYP1A1 and CYP1B1 expression. TiPARP knockdown also reduced TCDD-induced AhR protein degradation following 24 h treatment. TiPARP overexpression decreased TCDD-induced CYP1A1- and CYP1B1-regulated reporter activity in a dose-dependent manner. Interaction studies demonstrated that overexpressed GFP-tagged TiPARP co-localized and co-immunoprecipitated with AhR. TiPARP truncations and point mutants revealed TCDD-induced inhibition required the zinc-finger and catalytic function. Catalytic assays demonstrated TiPARP possesses mono-ADP-ribosyltransferase (mART) activity rather than poly(ADP-ribose)lation activity. Auto-mART activity required both the catalytic domain and central portion (residues 275-328). Collectively, these results demonstrate TiPARP as a mART and a negative regulator of AhR signalling.

ACTIVATION OF THE Ah RECEPTOR SIGNALING PATHWAY BY SHEAR STRESS: GENERATION OF ENDGENOUS LIGANDS AND/OR EXPERIMENTAL ARTIFACT?

M. S. Deisenroth1, A. Gojova1, J. E. Bohonowycz1, J. Morgan1, G. He1, A. Baraket2 and B. Zhao3. 1Department of Environmental Toxicology, University of California Davis, Davis, CA, 2Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing, China and 3Department of Mechanical and Aerospace Engineering, University of California Davis, Davis, CA.

The Ah receptor (AhR) is a ligand-dependent transcription factor that can be activated by structurally diverse synthetic and natural chemicals. Endogenous activators of the AhR have been proposed, but few have been identified that are active at physiological concentrations. The role of AhR in cardiovascular and vascular development and disease and AhR activation in endothelial and hematopoietic cells suggests the existence of endogenous AhR activators. Incubation of endothelial cells or cell lines in fluid-flow, arterial shear-stress conditions activates the AhR-dependent gene expression, suggesting that vascular shear-stress produces an AhR agonist(s). While production of this AhR activator was serum-dependent and suggested to be a shear-stress modified low density lipoprotein, the actual source of the shear-stress dependent AhR ligand is unclear. Using a closed-loop laminar flow shear-stress system we demonstrated a rapid and flow-dependent transient activation of AhR-dependent gene expression in stably transfected mouse hepatoma cells; there was no induction in the absence of serum. This suggests that shear stress generates AhR agonist from serum, but subjecting serum to comparable shear forces by other methods did not generate AhR agonists. Since AhR agonists are present in rubber and plastic products (components of the flow chambers and tubing), we examined whether these might be a source of AhR agonists. Serum, but not media, could...
readily extract AhR agonist activity from rubber tubing and gaskets used in the flow cell system. Our studies demonstrate that the binding of the AhR in flow cell systems is predominantly an artifact derived from the experimental system rather than shear stress generation of endogenous AhR agonists from serum. (ES004699;ES007685)

PS 178 CAN THE BINDING BY STRUCTURALLY DIVERSE AGONISTS ALTER THE NUCLEOTIDE SPECIFICITY OF AH RECEPTOR DNA BINDING?
D. E. DeGroot and M. S. Denison, Environmental Toxicology, University of California Davis, Davis, CA.

The aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor belonging to the basic-helix-loop-helix-PAS family of regulatory proteins. It is best characterized for its role in mediating the toxic and biological responses resulting from exposures to halogenated aromatic hydrocarbons, such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and related compounds. The AhR resides in the cytosol until ligand binding promotes nuclear translocation and heterodimerization with the aryl hydrocarbon receptor nuclear translocator protein (ARNT) after which binding of the ligand:AhR:ARNT complex to its specific DNA binding site (the dioxin responsive element (DRE)) stimulates transcription of downstream genes. While the sequence of the DRE is well defined, several reports have suggested that the nucleotide specificity of AhR DNA binding may be ligand-dependent. To examine whether ligand-dependent nucleotide specificity of AhR DNA binding can occur we have used PCR-assisted binding site selection analysis to examine DNA binding of the guinea pig hepatic AhR complex activated by structurally diverse agonists. Ligand activated AhR complexes were incubated with oligonucleotides containing a 15-base variable region (all nucleotides represented at each position), ligand:AhR:ARNT:oligonucleotide complexes were isolated by immunoprecipitation, and the DNA was PCR amplified and used in the next round of selection. Following four rounds of selection, sequence analysis of the isolated oligonucleotides did not reveal any major differences in the nucleotide specificity of the DRE for the compounds tested. While some minor single base variations were observed in the established DRE consensus sequence, these sequence variations did not alter the DNA binding of AhR complexes activated by any tested agonist. Our results are consistent with the established role of the canonical DRE sequence as the only AhR DNA binding site and that the binding of structurally diverse agonists to the AhR does not alter its nucleotide specificity of DNA binding. (R01ES012498)

PS 179 FUNCTIONAL ANALYSIS OF THE SV23, SV24, AND SV25 SPICE VARIANTS OF HUMAN CONSTITUTIVE ANDROSTANE RECEPTOR (CAR): COMPARISON OF GINKGO BILOBA EXTRACT WITH OTHER KNOWN ACTIVATORS OF CAR.
A. Lau, G. Yang and J. K. Chang, Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada.

Ginkgo biloba extract has several biological activities, including protection against neurotoxicity and oxidative stress. Constitutive androstanoid receptor (CAR) controls the transcription of genes involved in a broad array of biological functions, including bioactivation and detoxification of toxicants. Naturally-occurring splice variants of human CAR (hCAR) exist, including hCAR-SV23 (insertion of amino acids SPTV), hCAR-SV24 (APYLT), and hCAR-SV25 (SPTV and APYLT). G. biloba extract was reported to activate hCAR-SV24 and the wild-type (hCAR-WT). However, it is not known whether it selectively affects hCAR splice variants and how it activates hCAR isoforms. We evaluated the impact of G. biloba extract on the functionality of CAR-SV23, hCAR-SV24, hCAR-SV25, and hCAR-WT, and compared it to that of phenobarbital, di-2-ethylhexyl phthalate (DEHP), 6-(4-chlorophenyl)-imidazo[2,1-b][1,3]thiazole-5-carboxaldehyde O-(3,4-dichlorobenzyl) oxime (CITCO), and 1,4-bis-[3,5-dichloropyridyl]oxo]benzene (TCPPOB) in cell-based reporter gene assays. Among the hCAR splice variants investigated, only hCAR-SV25 was activated by G. biloba extract and this in vivo-activated form required co-transfection of a retinoid X receptor-β (RXRβ) expression plasmid. The extract activated CAR-SV23 to a lesser extent than hCAR-WT. CITCO activated hCAR-SV3, hCAR-SV24, and hCAR-WT, whereas phenobarbital activated hCAR-WT, and DEHP activated hCAR-SV23, hCAR-SV24, and hCAR-WT. TCPPOB did not affect the activity of any of the isoforms. G. biloba extract and phenobarbital did not bind or recruit coactivators to the ligand-binding domains of hCAR-WT and hCAR-SV23, whereas positive results were obtained with the controls (CITCO for hCAR-WT and DEHP for hCAR-SV23). In conclusion, G. biloba extract activates hCAR in an isoform-selective manner, and hCAR-SV23, hCAR-SV24, and hCAR-WT have overlapping but distinct sets of ligands. (Supported by Canadian Institutes of Health Research)

PS 180 ANALYSIS OF THE MECHANISMS OF LIGAND-DEPENDENT TRANSFORMATION OF THE AH RECEPTOR INTO ITS DNA BINDING FORM.
A. Soshilov and M. S. Denison, Environmental Toxicology, University of California Davis, Davis, CA.

The aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that mediates toxic and biological effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) and related compounds. AhR-mediated biological responses demonstrate dramatic interspecies differences which may occur in part during ligand-dependent conversion of the AhR into its high affinity DNA binding form. This process is termed AhR transformation and its mechanism is not fully understood. Instances of decreased transformation efficiency (measured as the ratio of total AhR (determined by ligand binding) to the amount that binds to DNA in a ligand-dependent manner) were analyzed and the underlying mechanisms determined. Unlike guinea pig, rat or CH mouse hepatic cytosolic AhR, mouse C57BL cytosolic AhR demonstrated decreased transformation efficiency and this appeared to result from insufficient levels of ARNT in the cytosolic extract. Similarly, while TCDD binding to the C57BL mouse AhR was reversible (i.e., TCDD could dissociate from the AhR), TCDD binding to other cytosolic AhRs was irreversible. Further analysis of in vitro synthesized C57BL mouse AhR revealed that a decrease in transformation efficiency occurred in the presence of sodium molybdate (an agent that stabilizes the association of the AhR with Hsp90) as well as with insertion of selected point mutations within the AhR. Of these mutations, D371A was found to negatively affect the initiation of AhR dimerization with ARNT, while that of R217A affected the ligand-dependent conformational change of the AhR. Additionally, evidence to support the hypothesis that the binding of ARNT results in a progressive displacement of Hsp90 from the AhR was obtained from the detection of a transient molybdate-stabilized hsp90:AhR:ARNT complex. Together, these findings provide further insights in the mechanisms of ligand-dependent transformation of the AhR into its DNA binding form and demonstrate that AhR transformation is a multi-step progressive process with several defined intermediate steps. Triclocarban (3,4,4’-trichlorocarbanilide, TCC) is used as a broad-based antimicrobial agent that is commonly added to personal hygiene products. Because of its extensive use in the health care industry and resistance to degradation in sewage treatment processes, TCC has become a significant waste product that is found in numerous environmental compartments. While TCC has been linked to a range of negative health and environmental issues, few studies have been conducted to examine the impact of exposure to TCC and the underlying mechanisms linked to the negative responses. In this study, experiments were initiated to investigate the role of TCC exposure towards activation of xenobiotic metabolism through regulation by the nuclear xenobiotic receptors (XRs). TCC treatment to humanized CYP2B6 (α) mice resulted in the induction of the liver Cyp2b10 gene. These observations demonstrated that TCC be classified as an endocrine disruptor, we also demonstrated that it activates the estrogen receptor-alpha (ERα) leading to induction of Cyp1b1 gene in female ovaries. Activation of ERα by TCC in receptor-based assays also promotes induction of the human UGT1A1 gene. Through the use of reverse genetics, this induction was shown to be dependent upon the constitutive androstane receptor (CAR) since no induction occurred in hUGT1A1/cArγ mice. Induction of the UGT1A genes by TCC also corresponded with induction of Gsp2b10, another CAR target gene. TCC was demonstrated to be a phenobarbital-like agonist of CAR in receptor-based assays. While it has been suggested that TCC be classified as an endocrine disruptor, we also demonstrated that it activates the estrogen receptor-alpha (ERα) leading to induction of Cyp1b1 gene in female ovaries. Activation of ERα by TCC in receptor-based assays also promotes induction of the human UGT1A1 gene. These observations demonstrate that TCC activates XRs CAR and ERα both in vivo and in vitro. Activation of these xenobiotic-sensing receptors amplifies gene expression profiles that might represent a mechanistic base for potential human health effects from exposure to TCC. (Supported by USPHS Grants ES010337 and ES004699).
Remarkably little is known about how TCDD causes toxicity. AHR cross-talks with multiple signaling pathways and hundreds of genes have been found to be activated by TCDD in an AHR-dependent manner. Still, a unifying mechanism of dioxin toxicity is lacking that can explain the multitude of developmental consequences from exposure during early life, tumor promotion and modulation of immune cell development. Over a long period it has been claimed that structurally diverse compounds can act as AHR agonists although they show low binding affinity. This has led to the prevailing view of a promiscuous ligand-binding specificity of the AHR and lowered the interest in finding an endogenous high affinity ligand. We claim that the physiological functions of the AHR are activated by an endogenous ligand with hormone/vitamin like properties. Our ongoing chemical and biological characterization of 6-formylindolo[3,2-b]carbazole (FICZ), which we have suggested to be the enigmatic endogenous AHR ligand, shows that this signal substance has very interesting biological properties. It has the highest affinity for binding to the AHR of all compounds tested so far and it is also an ideal substrate for the CYP1 enzymes. We have documented effects of FICZ, on cell cycle regulation at femtomolar concentrations. Also, new studies by others e.g. those reporting effects of FICZ at low concentrations on the function of various cells of the immune system support its physiological importance. FICZ seems to be ubiquitously present in bio-logic materials that contain the amino acid tryptophan, such as cell culture media. Thus, the presence of FICZ may have erroneously influenced the interpretation of earlier studies like those that describe ligand-independent activation of the AHR. We propose that the endogenous ligand for the AHR is considerably more important than previously thought. We also propose that deficiency as well as excess of FICZ may explain toxicity by TCDD and other agents that induce or inhibit its metabolic clearance and thereby disrupt FICZ-dependent homeostatic processes.

Several polyphenols have been shown to activate the aryl hydrocarbon receptor (AHR) in spite of the fact that they bind to the receptor with low affinity. The aim of this study was to investigate if quercetin, curcumin and resveratrol activate the AHR indirectly by interfering with the metabolic degradation of a high affinity AHR ligand FICZ. Especially, we wanted to test the ability of some polyphenols to interfere independently with the metabolic degradation of a high affinity AHR ligand FICZ. We propose that the endogenous ligand for the AHR is considerably more important than previously thought. We also propose that deficiency as well as excess of FICZ may explain toxicity by TCDD and other agents that induce or inhibit its metabolic clearance and thereby disrupt FICZ-dependent homeostatic processes.

Constitutive androstane receptor (CAR, NR1:3), a member of the nuclear receptor superfamily, plays an important role in the transcriptional activation of multiple metabolizing enzymes such as cytochrome P450 (CYP). CAR can also be induced in a time and dose dependent manner when added together with FICZ. Furthermore, recombinant human CYP1A1 enzyme and clearance of FICZ, recombinant human CYP1A1 enzyme and metabolism of FICZ, recombinant human CYP1A1 enzyme and CYP1A1 transcription and enzyme activity were up-regulated by all three compounds and the effects were only observed in the commercial DME medium. Quercetin, curcumin and resveratrol prolonged CYP1A1 induction in a time and dose dependent manner when added together with FICZ. To investigate the inhibitory effects of polyphenols on CYP1A1 enzyme activity and metabolic clearance of FICZ, recombinant human CYP1A1 enzyme and CYP1A1 enzyme and metabolite studies were used. The intracellular levels of FICZ in cells co-treated with FICZ and polyphenols were quantified by HPLC. The CYP1A1 enzyme activity and clearance of FICZ were inhibited in a dose-dependent manner by polyphenols. Our finding demonstrates the following: i) quercetin, curcumin and resveratrol do not activate the AHR without trace levels of FICZ being present in the culture medium, ii) polyphenols seem to induce CYP1A1 through inhibition of metabolic degradation of FICZ. The balance of differentiation of multipotent mesenchymal stromal cells (MSC) between osteogenesis and adipogenesis is a central element of bone homeostasis. Peroxisome proliferator activated receptor γ (PPARγ) sits at the crossroad, promoting adipogenesis and suppressing osteogenesis. Adipocyte differentiation in bone marrow is potentially deleterious to both bone integrity and lymphopoiesis. Because organotins are dual ligands for PPARγ and its heterodimerization partner, the retinoid X receptors (RXRs), we hypothesized that tributyltin (TBT) and triphenyltin (TPhT) would have similar yet distinct effects on MSC differentiation from either a PPARγ agonist (Rosiglitazone; Rosi) or RXR (Bexarotene; Bex) agonist. While TBT, TPhT, Rosi, and Bex all shared the ability to suppress osteogenesis (alkaline phosphatase activity, nodule number, mineralization) in primary bone marrow cultures, only TBT, TPhT and Rosi induced adipogenesis. Gene expression studies support our hypothesis that the organotin-induced transcriptional program is distinct. TBT and Rosi strongly induced the expression of PPARγ, its gene target FABP4 and a terminal adipocyte marker adipins and suppressed expression of Runx2, its gene target osteocalcin and an osteoblast maker alkaline phosphatase. Intriguingly, only TBT and Bex upregulated the expression of the liver X receptor gene target ABCA1. In vivo exposure to TBT and Rosi altered a serum marker of bone turnover (PINP), decreased cortical thickness (μCT) and increased marrow adiposity (histology). Surprisingly, only TBT increased the expression of markers of both adipogenesis (FABP4, adipin) and osteogenesis (intercal) in bone. TBT alone upregulated ABCA1 expression in bone. These data suggest that RXR and PPARγ may contribute independently to TBT-induced adipogenesis and reduction in osteogenesis and that TBT alters bone homeostasis leading to bone loss in vivo.

The Ah receptor (AHR) is rapidly degraded both in vivo and in vitro following binding to ligands typified by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). The AHR is also degraded after cells are exposed to compounds such as geldanamycin.
The aryl hydrocarbon receptor (AHR) is a ligand-activated transcription factor that is regulated by the lipid soluble environmental toxicant 2,3,7,8 tetrachlorodibenzo-p-dioxin (TCDD). TCDD activation of the AHR induces the transcription of several genes that are important for xenobiotic metabolism. Obesity is a risk factor for several types of cancers and identifying molecular mechanisms that influence the interactions between adipose tissue and cancerous epithelial cells will be important for developing new cancer therapies given the current increases in obesity in the United States. Adipocytes mediate this risk through multiple mechanisms involving several adipocyte derived signaling molecules which stimulate tumor growth directly or indirectly by promoting angiogenesis and inflammation. We have discovered that pharmaceutical AHR antagonists inhibit adipocyte-supported growth of human breast cancer cells. However, the mechanisms by which the AHR potentially mediates adipocyte regulated breast cancer cell growth are not clear. To further understand the role of the AHR in mediating the effects of adipocyte derived signaling molecules on breast cancer cell growth, short interfering RNA against the AHR, a p-dioxin (TCDD). Inhalation exposure to environmental particulate air pollutants (PM) is correlated with a number of specific adverse health effects in humans. However, the molecular “sensors” that detect PM and initiate deleterious responses that may culminate as compromised health are not known. Recently, TRPA1 was shown to be activated by diesel exhaust particle (DEP), but the molecular consequences of this phenomenon have not been demonstrated. The hypothesis of this study was that activation of TRPA1 by DEP would cause pneumotoxicity. Studies in vitro indicate that the activation of TRPA1 by DEP is selective and it is the electrophilic components of DEP that activate TRPA1. Mutation of the electrophilic binding site had no effect. DEP induced calcium flux in isolated mouse sensory neurons overlapped with responsiveness to the prototype TRPA1 agonist AITC and were abolished by co-treatment with the TRPA1 antagonist HC-030031. Mice instilled with DEP exhibited a reduction in lung compliance and increased expression of a number of pro-inflammatory and ER stress-associated genes. Both changes in lung compliance and the pro-apoptotic ER stress response gene GADD153 were attenuated by HC-030031 co-treatment implicating TRPA1 as the mediator of these processes in vivo. This study identified TRPA1 as a specific molecular sensor for specific chemical components of DEP and suggests that activation of TRPA1 in airway cells may be a critical first-step in DEP-induced pneumotoxicities including irritation, inflammation, and tissue injury. This work was supported by the 2011 Colgate-Palmolive Postdoctoral Fellowship and NIH grant ES017431.

191  GNFS1 DIMINISHES ARYL HYDROCARBON RECEPTOR OCCUPANCY AT THE IL-6 PROMOTER CONTRIBUTING TO MODULATION OF INFLAMMATORY PHENOTYPE IN FHS-RA CELLS.

T. S. Lahoti1, I. A. Murray1, K. John2 and G. H. Peredel1, 1Veterinary Sciences, Penn State University, University Park, PA and 2DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE.

Rheumatoid Arthritis (RA) is a chronic inflammatory disease of unknown etiology which manifests itself, in part, as inflamed human fibroblast-like synoviocytes (HFLS). Upon inflammation, FLS, in RA aggressively proliferate to form a pannus, leading to expression of inflammatory mediators. Epidemiological studies have identified a positive correlation between cigarette smoking, a source of agonistic aryl hydrocarbon receptor (AHR) ligands, and development of rheumatoid arthritis. To test whether AHR activation in the myocardium reproduces cardiac toxicity, we expressed it under the control of a myocardium specific promoter in zebrafish. AHR activation produced pericardial edema and altered heart looping; however, the cardiovascular defects seen following TCDD exposure. Notably, myocardial edema was abolished by co-treatment with the TRPA1 antagonist HC-030031. Mice instilled with DEP exhibited a reduction in lung compliance and increased expression of a number of pro-inflammatory and ER stress-associated genes. Both changes in lung compliance and the pro-apoptotic ER stress response gene GADD153 were attenuated by HC-030031 co-treatment implicating TRPA1 as the mediator of these processes in vivo. This study identified TRPA1 as a specific molecular sensor for specific chemical components of DEP and suggests that activation of TRPA1 in airway cells may be a critical first-step in DEP-induced pneumotoxicities including irritation, inflammation, and tissue injury. This work was supported by the 2011 Colgate-Palmolive Postdoctoral Fellowship and NIH grant ES017431.

192  CONSTITUTIVE AHR ACTIVATION IN CARDIAC MYOCYTES INDUCES HEART MALFORMATION IN ZEBRAFISH.

K. Lanham1, R. E. Peterson1, 2 and W. Heidenreich1, 2, 3. 1Department of Biomolecular Chemistry, University of Wisconsin-Madison, Madison, WI, 2Molecular and Environmental Toxicology Center, University of Wisconsin-Madison, Madison, WI and 3School of Pharmacy, University of Wisconsin-Madison, Madison, WI.

Exposure of zebrafish embryos to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) activates the zebrafish aryl hydrocarbon receptor 2 (Ahr2) to produce multiple developmental defects, particularly within the cardiovascular system. These defects include un looping of the heart, pericardial and yolk sac edema, reduction of cardiac output, decreased peripheral blood flow, disruption of bulbus arteriosus formation, and impaired common cardinal vein regression. The gene targets responsible for these developmental defects following AHR activation remain unknown. A primary difficulty in unraveling the target genes is a lack of understanding regarding the site of action of TCDD and how that contributes to specific endpoints of toxicity. Cardiac toxicity could be the result of TCDD acting directly on myocardial cells or it could be secondary to AHR activation in endothelial cells or at other distal sites. To test whether AHR activation in the myocardium reproduces cardiac endpoints of TCDD toxicity we constructed a constitutively active AHR and expressed it under the control of a myocardium specific promoter in zebrafish. AHR activation within the myocardium was sufficient to reproduce some, but not all, of the cardiovascular defects seen following TCDD exposure. Notably, myocardial AHR activation produced pericardial edema and altered heart looping; however, bulbus arteriosus formation and common cardinal vein regression occurred normally. These results link specific endpoints of TCDD cardiac toxicity to AHR activation within cardiac myocytes and demonstrates that these endpoints are not secondary to AHR activation within other cell types. (Supported by NIEHS, NIH Grants RO1 ES012716 and T32 ES007015)

193  ROLE OF TRPA1 IN DIESEL EXHAUST PARTICLE-INDUCED PNEUMOTOXICITY.

C. Deering-Rice, S. Darien, E. G. Romero, J. M. Veranth, G. S. Yost and C. A. Reilly, Pharmacology/Toxicology, University of Utah, Salt Lake City, UT.

Inhalation exposure to environmental particulate air pollutants (PM) is correlated with a number of specific adverse health effects in humans. However, the molecular "sensors" that detect PM and initiate deleterious responses that may culminate as compromised health are not known. Recently, TRPA1 was shown to be activated by diesel exhaust particle (DEP), but the molecular consequences of this phenomenon have not been demonstrated. The hypothesis of this study was that activation of TRPA1 by DEP would cause pneumotoxicity. Studies in vitro indicate that the activation of TRPA1 by DEP is selective and it is the electrophilic components of DEP that activate TRPA1. Mutation of the electrophilic binding site had no effect. DEP induced calcium flux in isolated mouse sensory neurons overlapped with responsiveness to the prototype TRPA1 agonist AITC and were abolished by co-treatment with the TRPA1 antagonist HC-030031. Mice instilled with DEP exhibited a reduction in lung compliance and increased expression of a number of pro-inflammatory and ER stress-associated genes. Both changes in lung compliance and the pro-apoptotic ER stress response gene GADD153 were attenuated by HC-030031 co-treatment implicating TRPA1 as the mediator of these processes in vivo. This study identified TRPA1 as a specific molecular sensor for specific chemical components of DEP and suggests that activation of TRPA1 in airway cells may be a critical first-step in DEP-induced pneumotoxicities including irritation, inflammation, and tissue injury. This work was supported by the 2011 Colgate-Palmolive Postdoctoral Fellowship and NIH grant ES017431.
threat to human health, the molecular mechanisms through which it causes adverse effects is not well defined. A hypothesis of the laboratory is that TRPV1, V2, V4, M2, or M8. Several chemical components of WSPM were also assayed, revealing new TRPA1 agonists. Differential activation of TRPA1, as a function of particle size, demonstrated that PM<10 μm were most potent. The mechanism of TRPA1 activation by WSPM largely involved the electrophile/oxidant sensitive domain of TRPA1, but ongoing studies suggest that the menthol binding site of TRPA1 also is a target for non-electrophilic WSPM components. WSPM also potently activated TRPA1 in isolated sensory neurons which was associated with changes in the expression of mRNA for the stress marker c-fos, the pro-inflammatory neuropeptides substance P and neurokinin A, as well as TRP channels. This study identifies TRPA1 as a molecular sensor for WSPM in airway sensory neurons which is hypothesized to be a critical step in elucidating the precise mechanisms by which WSPM causes respiratory toxicities. Support: NIH ES017431 and The University of Utah Biotechnology Undergraduate (BioURP) program.

**A NOVEL ROLE OF THE CONSTITUTIVE ANDROSTANE RECEPTOR IN HUMAN Hepatic DIFFERENTIATION.**

E. Chen, S. M. Zamule, D. M. Csto and C. J. Omiecinski. Center for Molecular Toxicology and Carcinogenesis, University Park, PA.

The constitutive androstanone receptor (CAR) is an orphan receptor that regulates the expression of genes involved in hepatic metabolism and clearance of xenogenous and endogenous substances. Recent studies have indicated detection of CAR expression in fetal livers of mouse, rat and human. Coupled with our findings demonstrating that CAR is significantly increased in hepatic-like cells derived from human embryonic stem cells (hESCs) [CBI 190: 62, 2011], we hypothesized that CAR plays an important functional role in hepatic differentiation. Over-expression of CAR in hESCs transduced by a lentiviral vector enhanced mRNA expression of hepatic-specific markers, including transcription factors (C/EBPα, HNF1α, and HNF4α), plasma proteins (α1-antitrypsin and albumin), transcriptional enhancers (CYP2B6, CYP3A4 and CYP3A7), and metabolic enzymes (HMGCS2 and PEPCK). In particular, CYP3A4 and CYP3A7 expression were 39- and 30-fold elevated, respectively, in the CAR transduced hepatic-like cells compared with non-transduced cells after 20 days of differentiation. The transduction of CAR also accelerated maturation of hepatic-like cells, with CAR-over-expressing cells exhibiting a 2.5-fold increase in albumin secretion at day 20. Inducible activity of CYP3A7 by 5μM CITCO in CAR-over-expressing cells was also significantly higher than that of non-transduced cells. Further, knockdown of CAR mRNA via siRNA attenuated the differentiation-dependent increase in hepatic marker expression, including CAR, C/EBPα, HNF1α, HNF4α, FOXA1, and e-tetraoctoate. In contrast, expression of the pregnane X receptor (PXR), another nuclear receptor, was extremely low in fetal liver tissue and not increased during the differentiation process. In addition, over-expression of PXR in hepatic hESCs did not result in enhanced expression of genes involved in hepatic differentiation/maturation. These data suggest that CAR, but not PXR, contributes importantly to hepatic lineage commitment.

**IDENTIFICATION OF STANNIOCALCIN 2 AS A NOVEL TRANSCRIPTIONAL TARGET OF THE ARYL HYDROCARBON RECEPTOR.**

T. Harper and C. J. Elferink. Pharmacology & Toxicology, University of Texas Medical Branch, Galveston, TX.

The aryl hydrocarbon receptor (AhR) is a ligand-activated member of the Per-ARNT-Sim (PAS) superfamily of transcription factors. The AhR is traditionally recognized for its role in the adaptive metabolism of polycyclic and halogenated aromatic hydrocarbons. However, current AhR research has focused on the understanding of normal AhR biology and physiological activities due to the generation of the AhR knockout mouse. Recent reports from our lab and others suggest the AhR has a role in regulating cell survival and death. These newly recognized roles along with traditional AhR activities have steered our laboratory in the direction of identifying AhR target genes in the absence of an exogenous ligand. Using primarily hepatocytes isolated from AhR−/− mice, we are able to generate AhR null hepatocytes through introduction of Cre recombinase using an adenoviral expression system. This model allows us to monitor changes in the transcriptome that occur immediately after the loss of the AhR. In order to assess AhR transcriptional control in relation to apoptosis we performed qRT-PCR using SYBR arrays containing 84 key genes involved in cell death. However, no significant changes were identified leading us to perform a comprehensive DNA microarray analysis. Stanniocalcin 2 (Stc2) was consistently down regulated with the loss of the AhR in both the microarray screen and SYBR validation. In silico analysis of the Stc2 promoter region identified 9 putative AhR binding elements (XRE) within 1 kb of the Stc2 transcriptional start site. Further analysis of AhR dependent Stc2 induction reveals Stc2 as a new AhR target gene induced in ER stress responses. As a result we are now in position to characterize the AhR-Stc2 relationship that ultimately leads to cell survival, a mechanism consistent with normal AhR biology and physiological function. [ESO12018, ES017254, ES006676]

**198 ATMOSPHERIC BEHAVIOR, DEPOSITION, AND BUDGET OF RADIOACTIVE MATERIALS FROM THE FUKUSHIMA DAIICHI NUCLEAR POWER PLANT IN MARCH 2011.**

To understand the atmospheric behavior of radioactive materials emitted from the Fukushima Daiichi nuclear power plant after the nuclear accident that accompanied the great Tohoku earthquake and tsunami on 11 March 2011, we simulated the transport and deposition of iodine-131 and cesium-137 using a chemical transport model. The model roughly reproduced the observed temporal and spatial variations of deposition rates over 15 Japanese prefectures (60-400 km from the plant), including Tokyo, although there were some discrepancies between the simulated and observed rates. These discrepancies were likely due to uncertainties in the simulation of emission, transport, and deposition processes in the model. A budget analysis indicated that approximately 13% of iodine-131 and 22% of cesium-137 were deposited over land in Japan, and the rest was deposited over the ocean or transported out of the model domain (700 × 700 km2). Radioactivity budgets are sensitive to temporal emission patterns. Accurate estimation of emissions to the air is important for estimation of the atmospheric behavior of radionuclides and their subsequent behavior in land water, soil, vegetation, and the ocean.

**199 HUMAN HEALTH RISK ASSESSMENT FOLLOWING THE FUKUSHIMA NUCLEAR POWER PLANT ACCIDENT.**

A. Trischler, P. Verger, M. Perez and E. Perkins-van Deventer. World Health Organization, Geneva, Switzerland.

Following the accident at the Japanese nuclear power plant in Fukushima, as consequence of the severe earthquake and tsunami, WHO has been working with other international partners to advise countries on potential health implications. WHO is now engaged in an international effort to assess the human health risk of radiation exposure due to this incident for the population globally. Different scenarios have been defined regarding exposed population within and outside Japan and different age groups (adult, 10y child, 1-2y child). As a first step, together with FAO and IAEA, WHO has established an international expert group for the initial evaluation of total radiation exposure, considering internal exposure from ingestion (food and drinking water) and inhalation, and external exposure. Total dose assessments will be available by the end of 2011, these will feed into the work of another expert panel to estimate the potential health risks. Primary input data for the oral exposure assessments are monitoring results rather than modelling results, focussing on the first four months after the accident. Inhalation doses will be estimated both for Japan and the rest of the world on the basis of atmospheric dispersion modelling. External dose estimates will be based on atmospheric dispersion modelling and on data on ground deposition levels and on gamma dose rates. The outcome of the preliminary dose assessments will feed into estimates for dose response relationships between effective doses and total cancer, effective dose and all solid cancers or leukemia; and between thyroid dose and risk of thyroid cancer.

**200 AIRBORNE RADIATION MONITORING IN CALIFORNIA FOLLOWING THE 2011 FUKUSHIMA DISASTER.**

S. B. DuTeaux, Office of Emergency Response, California Air Resources Board, Sacramento, CA.

Shortly after the March 11, 2011 earthquake and tsunami, concerns rose about the threat of a radioactive plume reaching the US from the destabilized Fukushima Daiichi reactors. California officials tried to access the most reliable model predictions from the National Atmospheric Release Advisory Center (NARAC) and the Defense Threat Reduction Agency (DTRA). Unfortunately, those models were not available to agencies responsible for radiation monitoring in California. In their absence, models from the Comprehensive Nuclear Test Ban Treaty Organization and
the Norwegian Institute for Air Research quickly spread through the internet and media outlets. Both emphasized extremely minor consequences; however, the plume images themselves fueled fear and speculation and resulted in a deluge of public inquiries. Thankfully, California has robust radiation monitoring capabilities, including a filter-based program operated by the California Department of Public Health (CDPH) and 11 near-real time radiation monitors operated by the California Air Resources Board (ARB) and local air districts on behalf of the Environmental Protection Agency’s (EPA) RadNet Program. From March 12-20, gross beta and gamma counts were not significantly different from data prior to the Fukushima disaster. Not until the first filters were analyzed was it clear that gaseous iodine-131 (I131) and cesium-137 (Cs137) particulates — isotopes of greatest concern following a nuclear power accident — arrived in California. Concentrations were far below any public health concern. However, the fact that I131 and Cs137 were detected catapulted state and local agencies into a tremendous risk communication effort. ARB executives launched a consolidated web portal for California-specific data and joined efforts with others in a multi-agency coordination group to focus the work of technical specialists and to develop consistent messages. Airborne radiation quickly returned to background, but the “failure” resulted in many lessons learned for California’s emergency response and public health agencies.

Environmental risk assessment and risk communication were of eminent importance after meltdown of the FDNP nuclear reactors caused by the devastating tsunami attack. After release of half a million tera Bq of radionuclides, approximately 10% of that of Chernoyyl disaster, environmental radiation monitoring and risk communication by Japanese Government was failure in the early stages. The governmental spokesman, one of Cabinet member, simply announced measurement data of air space radiation and claiming safety, even though he was not reliable authority of the academy. After six months of the event, I conducted questionnaires survey among the participants after risk communication seminars about radiation and food safety in the neighboring communities from Fukushima prefecture. The result showed that announcement of environmental radiation monitoring data rather increased their anxieties and suspicion about the government’s concealment of the catastrophic damage. They have been looking for information about margin of safety and risk. As my conclusion, simple and clear messages about risk and basic knowledge of radiation toxicology shall be given to the inhabitants with environmental measurement data sets.

The health effects of low doses of radiation (LDR) are not fully understood, and few have considered the role of background radiation in gene-environment interactions. Radiation leakage at Fukushima and the concern over intentional release of radioactive materials by terrorists have heightened public awareness of this issue. The Pacific Northwest National Laboratory’s (PNNL) low dose radiation systems biology program is investigating the consequences of low dose radiation exposures in experimental human organotypic skin culture. Skin is the 4th most sensitive site in atomic bomb survivors, exhibits dose-dependent transitions for radiation carcinogenesis and is the most advanced human organotypic model system. Our approach combines genomic, proteomic and metabolomic platforms to interrogate tissue radiation responses and exploits advanced bioinformatics and computational modeling resources developed at PNNL to interpret complex data sets. Many signaling networks are activated by low doses of radiation, including p38 MAPK pathway, IGF1 pathway and cell proliferation/apoptosis. Further, advanced imaging capabilities have led to the discovery of new LDR sensitivities in molecular feedback control processes that regulate major signaling networks (e.g. ERK). Our objective is to understand the consequences of LDR on cellular homeostasis and how this impacts tissue response to subsequent challenges. We are currently developing radioresistant engineered tissue model systems as contrast to normal tissue responses to LDR. The long term goal is to determine scenarios where LDR effects might modulate human health or modify subsequent challenges induced by a second insult, (e.g. in the case of a radiological incident wound healing, physical trauma or burns.)

Biological modeling has helped improve our understanding of how radiocative contaminants distribute in the body after an intake, as well as how radiation interacts with the body to cause acute damage. For example, application of a detailed inhalation model together with physiological models for internalized Cs-137 and Am-241 has improved radiation dose estimations. Modeling of the treatment of these nuclides by Prussian Blue and DTPA further enables the evaluation of the efficacy of treatment at different times after exposure and for different treatment durations. The resulting knowledge improves the risk assessment for both acute effects, as well as long-term health risks. Physiological models for Cs-137 and Am-241 and their treatment will be presented along with practical examples of their application. Another useful application of biological modeling employs a systems biology approach to examine how radiation interacts with acute injury (e.g. burn or trauma) to provide valuable information concerning common mechanistic interactions between the two different injury types (e.g. radiation together with burn). This modeling effort provides a more accurate understanding of the pathophysiology of combined injury and can improve estimation of the outcomes anticipated after major radiological events like the Chernobyl accident. Thus, biological modeling can help better predict health consequences of radiological hazards from nuclear accidents, and therefore provide valuable information that can be used to minimize the impact of radiological incidents.

Prolonged genomic changes after radiation exposure are stochastic and thus cannot be identified on the basis of common gene expression in hematopoietic stem/progenitor cells. Changes, if available, may be radiation-effect-related changes in stromal/niche functions; however, little evidence has been reported to date. Recent progress in functional research on hematopoietic stem/progenitor cells has suggested that their changes seem to be due to oxidative stresses caused by stromal/niche alterations. According to our collaborator’s recent report, surveying the stromal capability of lineage(-)c-kit(+)SCA1(+) (LKS) cells in lethally irradiated and repopulated mice, monitored by the Ly5.1 isotype for 270 days after transplantation (Otsuka et al. Exp Hematol, 2010), each bone marrow niche/stromal cell maintained stem/progenitor compartment, such as the LKS fraction or various colony forming units, respectively were found to be functionally different. Specifically, the LKS fraction was likely to be unable to differentiate and migrate to peripheral blood after 270 days when the recipient stroma was irradiated. Presumably, although primitive (possibly osteoblastic) niches were found to be radiosensitive, intermediate (possibly vascular) niches seemed to be moderately radiosensitive and promoted progenitor cells to proliferate and differentiate, and the general type of stromal cells was less sensitive to radiation and promoted mature blood cells to migrate to peripheral blood. Each stromal cell component or detailed regulating gene repertoire is not yet identified. The findings of this study suggest that each stromal cell compartment was functionally separated along with the hematopoietic cell differentiation from primitive stem cells via various progenitor cells to mature blood cells.

ACUTE RADIATION SYNDROME: HEMATOPOIETIC CHARACTERIZATION OF A NONRODENT MODEL.

Current regulations require evaluation of radiomimetic drug candidate efficacy and safety in a rodent and a nonrodent model prior to approval under the FDA Animal Rule. Cell blood counts were obtained from 120 Rhesus monkeys for 12 to
60 days after whole body radiation using a Cobalt-60 at radiation dose levels ranging from 400 to 1210 Gy. The blood cell counts and proportions of these blood cells were observed approximately on Day 26 at doses of 400, 600 and 634 cGy. Neutrophil counts also showed a progressive decrease after irradiation and reached earlier and lower nadirs with higher irradiation doses. Severe neutropenia (≤ 0.5 X 10^9/L) was first observed on Day 8 at 400 cGy while it was first noted on Day 5 at irradiation doses of 600 cGy and higher. The number of days of severe neutropenia was 10, 13 and 15 at radiation doses of 400, 600 and 634 cGy. Lymphocyte counts on Day 2 post-TBI were significantly decreased from baseline with a severity that was irradiation dose-dependent. Lymphocyte count recovery was initially observed approximately on Day 18 but remained lower than baseline levels throughout of monitoring period at all irradiation doses. Severe thrombocytopenia was first observed on Days 16, 11 and 10 at radiation doses of 400, 600 and 634 cGy, respectively. Platelet nadirs were observed earlier at higher irradiation doses and the recovery was comparable at irradiation doses of 400, 600 and 634 cGy. Mean platelet volume decreased parallel to platelet counts. At 634 cGy, mean platelet volume reached a minimum (≤20% from baseline) on Day 12 post-TBI. The hematology profiles obtained in this nonrodent acute radiation syndrome model were comparable to radiation exposed humans and confirm the value of this nonrodent model for drug development.

206 RADIATION EXPOSURE EXACERBATES LETHALITY AND LUNG PATHOLOGY FOLLOWING A SUBSEQUENT INFLUENZA A VIRUS INFECTION.

C. M. Manning1, C. J. Johnston1,2, B. Lawrence1, J. P. Williams1 and J. N. Finkelsten1,2,3

Since 2001, there has been increased concern with the possibility of a radiological or nuclear dispersion event. Exposed individuals that survive the acute radiation syndrome will be at risk for complications resulting from radiation injury in late-responding tissues, such as the lung. The lung’s constant contact with the outside environment also makes it susceptible to other noxious agents, such as pathogens. It is unknown whether irradiation will affect the lung’s ability to defend against a subsequent challenge. In this study, we hypothesized that irradiation will affect the lung’s response to an Influenza A virus infection. Adult, C57BL/6J mice were whole lung irradiated with 6.5, 10 or 15 Gy α-γ-radiation and infected with virus ten weeks later. Mortality, immune cell recruitment, viral titer, lung structure and lung function were assessed. Mortality after infection was increased in 10 and 15 Gy irradiated animals. Surviving 15 Gy irradiated animals failed to regain body weight lost during infection. The peak T cell response was attenuated in the 15 Gy irradiated infected animals; however, viral clearance still occurred. Irradiated infected animals also displayed persistent pulmonary edema. We further investigated the effect of irradiation on exacerbation of radiation-induced lung injury, which begins to appear at 26 weeks post-15 Gy lung irradiation. In 15 Gy irradiated infected animals, lung pathology, which included increased collagen deposition, inflammation and edema, was observed at 17 weeks post-irradiation. Consistent with pathological observations, the animals also displayed reduced pulmonary function. To determine if this contribution to the lung injury was mediated by an increase in the lung inflammatory response, the animals were treated with the anti-inflammatory drug, dexamethasone. In this study, it was concluded that irradiation can increase lethality and impair the restoration of normal lung structure and function following a virus infection. Furthermore, this effect was dependent on the lung radiation dose. Funded by NIAID U19 AI091036-01, ES-01247, ES T32 07026.

207 NEONATAL IRRADIATION SENSITIZES MICE TO ADULT PULMONARY INFLUENZA CHALLENGE.

C. J. Johnston1,2,3, C. M. Manning1,2,4, J. P. Williams1, T. D. Randall1,3, J. Rangel-Moreno1, E. Hernandy1 and J. N. Finkelsten1,2,3,4

Rationale: Significant differences exist between the physiology of the immature, neonatal lung compared to the adult, which may affect acute and late response to irradiation. Identifying these differences would be critical in developing successful mitigation strategies for this special population. Our current hypothesis suggests that radiation during this critical period is likely to alter developmental processes resulting in long-term consequences including altered susceptibility to secondary inflammatory challenge. Methods: C57BL/6J mice, 4 days of age, received total body irradiation of 5.0 Gy prior to influenza A virus challenge at 3, 6 or 11 mont post irradiation (PI). At these times mice were intra-nasally infected with 120 HAU of influenza A virus. Body weight and survival were monitored. Pulmonary response was determined by lavage and histological examination. Analysis of epithelial and inflammatory marker binding expression were done by immunohistochemical and mRNA analysis. Results: Following influenza infection, irradiated animals lost significantly more weight at 6 and 11 months post-irradiation and had reduced survival compared to the unirradiated but infected controls with a greater effect seen at 11 months post radiation. Irradiated animals had a reduced percent of lymphocytes re-cruited to the lung following infection compared to shams. Conclusions: These results demonstrate that early life radiation injury may affect the lung’s response to a subsequent challenge and further suggests that this effect may be dependent on the time post-irradiation that the challenge occurs.Funded By: NIAID U19 AI-067733-0551, U19 AI-091036-P30 ES-01247, ES T32 07026 and EPA Star PM Center R827354.

208 FETAL RADIATION EXPOSURE INDUCES TESTICULAR CANCER.

G. Sherry1, P. B. Comish1, C. C. Weng2, A. Martin3 and M. I. Meistrich4

Fetal exposures to environmental factors have been cited as the cause of the steady 3% annual increase in testicular cancer in humans. Since testicular cancers are derived from primordial germ cells (PGCs), the increase has been attributed to maternal/fetal exposures to environmental factors. We examined the effects of an estrogen (diethylstilbestrol, DES), an antiandrogen (flutamide), or radiation on the incidence of testicular germ cell tumors in a genetically predisposed mouse strain, 129.MOLF-L1 (L1) congenic mice. L1 mice were mated and vaginal-plug positive females were exposed to the agents at days 10.5 and 11.5 of pregnancy. The testes from male offspring were examined for the presence of teratoma by morphology and histology at 4 weeks of age. Neither flutamide nor DES produced noticeable increases in cancer incidence. In contrast, two doses of 0.8-Gy radiation increased the incidence of testicular teratoma from 45% to 100% in the offspring. The percentage of mice with bilateral tumors, weights of testes with teratoma, and the percentage of tumors with multiple dermal origins were higher in the irradiated mice than in controls, indicating that irradiation induced more aggressive tumors and/or more foci of initiation sites in each testis. This radiation dose did not disrupt spermatogenesis, which was qualitatively normal in tumor-free testes although they were reduced in size. Since the radiation is given at a stage when extensive DNA demethylation and chromatin remodeling is occurring as the PGCs are losing their pluripotent capacity, we suggest that the DNA repair response is interfering the epigenetic program at this critical stage. Also this is the first proof of induction of testicular cancer by an environmental agent and suggests that the male fetus of women exposed to radiation at about 5-6 weeks of pregnancy might have an increased risk of developing testicular cancer.

209 IONIZING RADIATION AND ENVIROMENTAL TOXICANTS CAN INTERACT DURING BRAIN DEVELOPMENT TO EXACERBATE COGNITIVE DEFECTS IN MICE.

P. Eriksson1, B. Stenerlow2, A. Fredriksson1, S. Buratovic1, H. Viberg1 and S. Sundell-Bergman1,1 Department of Environmental Toxicology, Uppsala University, Uppsala, Sweden,2 Department of Radiology, Oncology and Radiation Science, Uppsala University, Uppsala, Sweden and3 Department of Soil and Environment, Swedish University of Agricultural Sciences, Uppsala, Sweden.

There is lack of knowledge and increasing concern about low dose exposure to ionizing radiation (IR) and induction of non-cancer effects. We are indirectly or directly exposed to persistent environmental toxicants and IR. It is therefore important to integrate different environmental agents which might act synergistically to exacerbate developmental toxic effects and thereby also change the dose-response curve. Foetuses and neonates are known to be high-risk groups for exposure to toxic agents. Epidemiological studies indicate that exposure to environmental toxicants, including IR, during early human development can have deleterious effects on cognitive development in childhood. By using the mouse as an animal model we can study the effect of a single toxic agent given directly to the neonatal animal during different stages of the rapid brain growth spurt, and also to study the combination of environmental agents in a controlled manner. In these studies we have observed that IR, and the environmental toxicants like MeHg, PCBs and PBDEs, can induce behavioural disturbances such as deranged spontaneous behaviour and habituation, learning and memory defects and reduced cognitive functions, together with altered function of the cholinergic system, when the exposure occurs during a critical phase of neonatal brain development (PND 10). In recent studies we have observed
that the effects after co-exposure to IR (0.05 – 1.5 Gy) and environmental toxicants (e.g. Methyl 0.08 – 4.0 mg/kg bw, PBDE 99 0.8 mg/kg bw) on PND 10 significantly enhance the developmental neurotoxic effects at doses where neither compound nor the IR caused any developmental defects. Furthermore, the dose of IR is down to a single exposure of just 0.1 Gy. This indicates a change in the dose-response curve of IR that can have implications for risk-estimates of non-cancerous effects.

210 LOW-DOSE IONIZING RADIATION ALTERS THE FETAL EPIGENOME OF THE AVY MOUSE.

A. Bernal1, D. Huang1, D. G. Dolinoy2 and R. L. Jirtle3, 1 Radiation Oncology, Duke University Medical Center, Durham, NC and 2 and 3 Environmental Health Sciences, University of Michigan School of Public Health, Ann Arbor, MI.

Low-dose (<10.0 centigray (cGy)) radiation exposure in man-made sources, such as diagnostic imaging, predominates in the US population and now comprises nearly 50% of the average individual’s yearly radiation exposure. Besides the acute effects of radiation exposure, there are concerns for long-term epigenetic aberrations. Such aberrations can disrupt normal development and are involved in the occurrence and progression of numerous diseases, including cancer. To date, analyses of high doses of radiation have shown that epigenetic disruption occurs and is necessary for the persistence of radiation-induced genomic instability; however epigenetic changes in response to low-dose ionizing radiation (LDH) in vivo have not yet been fully defined.

In order to characterize the dose-dependent epigenetic responses to low-dose ionizing radiation, we utilized the Agouti viable yellow (Avy) mouse model. This is a unique biological model that functions as a biosensor for developmental exposures that alter the epigenome.

Here we show that LDIR exposure in utero induces epigenetic changes in the Avy mouse in a dose-dependent and sex-specific manner. Acute exposure to 1.2, 2.5, 5.0 or 10.0 cGy X-ray irradiation significantly shifts offspring coat color distribution to pseudoagouti (ChiSquare: p = 0.019; p = 0.022, p = 0.0028, and p = 0.045, respectively). To assess low-dose radiation’s effect on the epigenome of Avy/a off-spring, DNA methylation levels at 11 CpG sites in and near the genetic promoter region of the Avy IAP were measured by bisulfite treatment and Sequenom analysis. Acute exposure to 2.5 or 5.0 cGy significantly increases methylation at multiple CpG sites in the Avy metastable epiallele in male offspring, but not female offspring (Repeaated Measures ANOVA, p<0.0001). Our results demonstrate that relevant, low doses of radiation can elicit epigenetic changes that lead to a persistent phenotype.

211 IS NEUROGENESIS ALTERED AFTER CHRONIC INTERNAL CONTAMINATION OF URANIUM DURING BRAIN DEVELOPMENT?

The objective of this study was to analyze the effects of depleted uranium (DU) on neurogenesis at different stages of brain development in an in utero model of internal contamination. Female rats have been exposed to DU (40 or 120mg/L) during gestation and lactation. Two time points of analysis have been chosen: embryonic day 13 and post natal day 21. In this work, we examined: 1) if contamination modified proliferation of cells in neurogenic zones by using BrDU immunostaining, 2) if cells from contaminated animals retained their multipotential properties using in vitro neurosphere and differentiation assay and 3) if neurite growth is affected by DU contamination using Golgi staining.

Preliminary results did not reveal any qualitative difference on cell proliferation in subgranular zone in contaminated rats compared to sham animals at P21. Moreover, no macroscopic morphological difference was observed on neurites of granular cells between exposed and non exposed animals. Finally, cells from the tenecephalic zone at E13 and cells from subventricular zone at P21 of exposed rats retained their capacities to form neurospheres and kept their multipotential properties as cells from non exposed rats did.

These first data suggest that chronic contamination of low dose of uranium has no effect on developmental neurogenesis at early stages. To complete these results, we have started experiments to determine if the proportion of cells implicated in neurogenesis is modified after internal contamination. We are also performing behavioral tests on animals exposed to DU to determine cognitive changes. Together, these results will provide a first view of internal contamination effects by uranium on neurogenesis during brain development.

212 URANIUM OLFACTORY ROUTE: A NASAL INSTILLATION MODEL TO STUDY BIOLOGICAL MECHANISMS INVOLVED IN THE TRANSFER TO THE BRAIN.

C. Ibanez1, P. Lestaev1, O. Delissen2, I. Dublineau1 and P. Gourmelon1, 1DRPH/SRE/IIRTOX, IRSN, Fontenay aux roses, France and 2DRPH/SRE/IIRTOX, IRSN, Pierrelatte, France. Sponsor: M. Pallardy.

The first evidence that uranium could reach the brain via the olfactory compartment has raised new concerns in terms of radioprotection of nuclear workers potentially exposed to particles inhalation. A recent study suggested that neurons located in the nasal cavity are directly involved in uranium transfer to the brain, representing a probable new contamination mode (Tournier et al., 1999). A feature of this uranium pathway seems to be a specific accumulation in the anterior part of the brain. Indeed, this is not observed when uranium is injected since its concentration is more homogenous throughout the brain.

In the light of these results, we developed a model of uranium nasal instillation to test this hypothesis, the interest being that pharmacological association with other agents and cellular localisation would be easier. A solution of uranyl nitrate at different concentrations (ranging from 0.01 to 10mg.ml-1) was instilled in the nasal cavity of 12 week old male rats. Tissue dissections: olfactory epithelium and bulbs, frontal cortex, hippocampus, cerebellum, lung-trachea and kidneys were performed 4 hours later. Uranium concentrations were measured by mass spectrometry. The results show that instilled uranium accumulates in the olfactory bulbs and is measured in the other cerebral structures but at lower concentrations. Instilled uranium was also found in lungs-trachea and kidneys. This frontal accumulation of uranium in the brain is in accordance with previous inhalation experiments (Tournier et al., 1999).

It appears that the nasal instillation model strengthen the hypothesis relying on a uranium axonal route via neurons of the nasal cavity. Future experiments will be performed to define the type of transport using lesion models or combining uranium with pharmacological agents involved in transporters, ion channels function.

213 GENETIC ALTERATIONS AND FUNCTIONAL CONSEQUENCES OF EMBRYONIC IONIZING RADIATION EXPOSURE IN ZEBRAFISH.

L. L. Freeman, A. Funk, S. Peterson, G. Weber and L. H. Nie, Health Sciences, Purdue University, West Lafayette, IN.

The relationship and genetic mechanisms associated with ionizing radiation (IR) exposure and carcinogenesis has long been established, but recently the association between IR exposure and other diseases is starting to be recognized. Currently, there is limited information on the genetic mechanisms governing the role of IR exposure in non-cancer related adverse health effects. To begin to elucidate radiation induced genetic and functional alterations associated with non-carcinogenic diseases, zebrafish embryos were exposed to a range of IR doses (0, 1, 2, 5, and 10 Gy) at 24 hours post fertilization (hpf). No significant increase in mortality or hatching rate was observed at any dose at any developmental time point through 120 hpf. A significant decrease in body and head length and eye diameter was observed in the 10 Gy dose at 120 hpf. Genomic microarray analysis was subsequently conducted at 120 hpf to compare gene expression profiles between the control and highest IR dose at 120 hpf. No significant differences were observed in gross morphological measurements (5 Gy). In this analysis, 251 genes with a well-established function or orthology to human genes were identified as significantly altered. Gene ontology and molecular network analysis revealed enrichment of genes associated with cardiovascular and neurological development and function. As recent literature has suggested a link between IR exposure and cardiovascular alterations, expression of a subset of gene targets was assessed using qPCR with individuals exposed to 0, 1, 2, or 5 Gy to identify a potential low threshold of effects on the cardiovascular associated gene targets. Moreover, heart rate was analyzed through 120 hpf following IR dosing at 24 hpf. A significant decrease in heart rate was observed at 10 Gy, while a significant increase in heart rate was observed at 1, 2, and 5 Gy. Overall these findings indicate IR exposure at doses below those that induce gross morphological changes alters heart rate and expression of genes associated with cardiovascular and neurological functions.

214 IODIDE PROPHYLAXIS FOLLOWING NUCLEAR ACCIDENTS: PROTECTING CHILDREN.

J. Fisher1 and C. Harris2, 1US FDA, Jefferson, AR and 2University of Georgia, Athens, GA.

After the Chernobyl nuclear accident a significant increase in thyroid cancer incidence was observed in many children exposed to low doses of 131I exposure. Protecting the fetal thyroid after week 12 of gestation, the thyroid glands of new-
The possibility of a radiation disaster from a nuclear detonation or accident has existed for over 50 years and spawned much of the basic research in radiobiology in the 1950-60s. The recent Fukushima accident was yet another reminder that there remains a dire need to develop novel therapies against radiation-induced toxicities. Here we report on the development of two novel radiation countermeasure therapies: Yel001 and Yel002. These small, biologically active, drug-like molecules were uncovered in the DEL high throughput assay reducing radiation-induced cytotoxicity and genotoxicity in yeast. Radiation-modulating activity was further confirmed in yeast plate-based DEL Assay; addition of either Yel001 or Yel002 to irradiated cultures reduced cell death and genomic instability. Further, Yel compounds reduce lethality to an average of 25% in vivo following an LD100/30 dose of ionizing radiation (IR) with the first therapeutic injection administered 24 hours post exposure followed by injections at 48,72,96, and 120 hours. Additionally, treatment with Yel001 and Yel002 compounds reduces radiation-induced leukemia from 90% to 50% and 40% respectively. Of note, treatment with either Yel001 or Yel002 reduced spontaneous leukemia rate from 10% to 0%. Treatment with Yel002 following IR accelerates the recovery of the hematopoietic system after sub-lethal exposures. Toxicity has not been observed in neither in vitro or in vivo administrations. Overall, Yel compounds have much potential as stockpile therapies for radiation-induced lethality and cancer: they are highly effective when administered up to 24 hours post exposure, they reduce radiation-induced sequelae such as leukemia, and appear to have an acceptable toxicity profile.

218 ISMTR-283 PROTECTS HUMAN BONE MARROW PROGENITORS FROM THE LETHAL EFFECTS OF IONIZING RADIATION.

E. Clarke1 and A. Traynor-Kaplan2, 1ReachBio LLC, Seattle, WA and 2ISM Therapeutics, Inc., Seattle, WA.

Bone marrow (BM), comprising stem and progenitor cells (CFC) as well as marrow stromal/ mesenchymal cells (CFU-F), is extremely susceptible to radiation damage. BM from matched donors is often used to “rescue” patients following medical radiation for leukemia. However, in the event of accidental/environmental radiation exposure, the ability to identify appropriate donors in a timely manner is rarely possible. We initially evaluated a small molecule compound (ISMTR-283) on human BM CFC. BM cells were treated with 0.1 – 0.4 μM ISMTR-283 for 2 hours and then subjected to 2 or 4 Gy ionizing radiation using a RS 2000 Biologic X-Ray Irradiator (Rad Source). Cells were mixed with ColonyGel™ methylcellulose-based media to support CFC growth and plated in 35 mm dishes (n=5), cultured for 14 days in a humidified incubator and then scored microscopically. At 0.4 μM, ISMTR-283 demonstrated a protective effect of CFC proliferation following 2 Gy. Results (mean +/- s.d): No irradiation: 32 +/- 4 CFC, 2 Gy: 3 +/- 1 CFC; ISMTR-283 + 2 Gy: 27 +/- 4 CFC. The study was extended to evaluate the effect of ISMTR-283 on CFU-F proliferation prior to and following radiation. BM cells were treated with 0.1 – 2 μM ISMTR-283 for 2 hours and then subjected to 2 or 4 Gy. Cells were cultured for 12 days, fixed, stained and scored macroscopically. Results: No irradiation: 170 +/- 9 CFU-F; 2 Gy: 109 +/- 3 CFU-F; 4 Gy: 49 +/- 5 CFU-F; ISMTR-283 + 2 Gy: 138 +/- 4 CFU-F; ISMTR-283 + 4 Gy: 72 +/- 4 CFU-F. Additionally, BM cells were subjected to 2 or 4 Gy and 24 hours later were treated with ISMTR-283. When ISMTR-283 was added 24 hours following 4 Gy, all concentrations demonstrated a protective effect on CFU-F proliferation. Results: 4 Gy + 16 +/- 2 CFU-F; ISMTR-283 + 4 Gy: 27 +/- 4 CFU-F. The data show that ISMTR-283 can protect BM stem and progenitor cells from the lethal effects of ionizing radiation.
Antibiotic overloading into the environment and the subsequent emergence and transfer of antibiotic resistance genes poses both ecosystem and human health risks. Traditional methods to quantify resistance genes in the environment rely on PCR-based approaches that target specific resistance genes and organisms. The rapid advancement of metagenomics in tandem with next generation sequencing technologies now allows for more high-throughput genomic approaches to environmental public health monitoring and can provide community-level profiling of environmental resistance. This study is profiling the prevalence and distribution of antibiotic resistance determinants in bacterial communities in Puget Sound, WA. Metagenomic DNA was collected at six sites in Puget Sound in addition to one wastewater treatment plant (WWTP) that discharges into the Sound and pyrosequenced. A total of approximately 1.4 million sequence reads (~550 Mbp) were obtained and assembled. Bioinformatic analysis of antibiotic resistance determinants was performed at the gene, protein motif and subsystem levels. Overall, the resistance profiles across the open Sound, nearshore and WWTP samples were similar. While known and previously cultured antibiotic resistance genes had a low prevalence in all samples, there was a significant difference in the number of resistance genes across the open Sound, nearshore and WWTP samples. The protein motif and subsystem analyses showed further evidence of differential resistance determinant prevalence across the three sample types. Taxonomic differences may be responsible for the variation in resistance profiles, for example increased Actinobacteria in the WWTP sample. Variability may also be a function of environmental or anthropogenic impacts. This environmental metagenomic approach allows for a more high-throughput survey of potential resistance determinants in natural environments that can be used to guide initial public health monitoring and more targeted and functionally-based investigations.

**220 EXPOSURE TO ARSENIC AND FLUORIDE IN CHIHUAHUA, MÉXICO.**

Combined exposure to arsenic (As) and fluoride (F) are frequent because both these minerals are known groundwater contaminants from geological sources. This study focused on evaluation of the relationship between As and F in well-water and human urine collected in Chihuahua, Mexico, where As exposure has been associated with adverse health effects. Notably, Chihuahua residents exposed to high As concentrations are also exposed to high levels of F. Here, we analyzed associations between As and F levels in urine of 600 study subjects who drink well water. The concentration of As in water was determined by hydride generation (HG)-atomic fluorescence spectrometry and As species in urine were analyzed by HG-cryotrap-atomic absorption spectrometry. The concentrations of F in water and urine were measured by potentiometry, using a selective fluoride-ion electrode. The As concentrations in water and urine ranged from 0.1 to 419 μg/L and 5 to 426 μg/L, respectively. The concentrations of F ranged from 0.01-9.9 mg/L in water and from 0.06 to 18.08 mg/L in urine. A positive significant correlation between urinary As and water As (r=0.2000; p<0.0001), and between urinary F and water F (r=0.0878; p=0.035) were obtained. Moreover, a statistically significant positive correlation was found between As and F concentrations in well water (r=0.8212; p<0.0001) but lower relationship between sum of As species and F level in urine (r=0.1675, p=0.0001), suggesting that sources other than drinking water may contribute to As or F exposure in this population. Further examination will focus on associations between the exposures to As and F and disease (diabetes and skin lesion) prevalence in the Chihuahua group.

**221 BIOLOGICAL ACTIVITY AND THE SURGING OF BERGING GLACIER.**

The Bering Glacier field program typically starts in early June and runs through the end of August. The field camp is located near the base of the glacier on Vitus Lake, on a former terminal moraine adjacent to the Glacier Syntaxis. Since 2008 we have been using this field laboratory to investigate the cause and effect relationships of glacier dynamics on the local ecosystem. The specific objective of the 2011 voyage was to obtain real time data on Bering Glacier land cover, Bering Glacier terminus characterization; and Vitus Lake turbidity mapping. The specific task for our group was to determine the degree of movement and behavior of the glaciers at Vitus Lake since our last visit in 2008. We have been mapping terminus retreat using remote sensing images and we have determined that the terminus is retreating approximately 0.38 km per year. The data obtained from the 2011 voyage will be used to provide a more precise picture of surging in this region of the Bering Glacier.

**222 COMPARATIVE INHALATION TOXICITY OF ORGANIC NAPARTICLES AND LARGER PARTICLES OF THE SAME CHEMICAL IDENTITY.**

K. Wiencz1, L. Ma-Hock1, V. Strauss1, M. Ray Moreno1, W. Wohlleben1, B. van Ravenzwaay1 and R. Landsiedel21 Experimental Toxicology and Ecology, BASF SE, Ludwigshafen am Rhein, Germany, 2Polymer Physics, BASF SE, Ludwigshafen am Rhein, Germany and 3Product Safety, BASF SE, Ludwigshafen am Rhein, Germany.

Several anorganic nanoparticles (NP) caused higher inhalation toxicity than the corresponding coarse particles (Oberdoerster et al. 2005). We examined an organic pigment and a polymer dispersion each as nanomaterial and as the chemical identical coarse material in short-term inhalation studies in malers.

The polymer was an anionic acrylic ester polymer containing free carboxylic groups, the different particle sizes were synthesized by varying polymerization conditions: 12, 80 or 250 nm. Although polymeric acrylic ester was reported to be irritating to the respiratory tract at 3 mg/m3, all three tested polymers - including the NP (12 and 80 nm) - did not cause any changes in lavage fluid and in histopathology at 10 mg/m3. The organic pigment was a poorly soluble pyrrol with an intense orange color. The NP (10 to 50 nm width and 30 to 400 nm length) and the coarse pigments (70 to 200 nm width and 0.3 to 3 μm length) are both needle-like. They were tested at 1, 3, 10 and 30 mg/m3 for the NP and 3, 10 and 30 mg/m3 for the coarse materials. Mild and partly reversible morphological changes were observed in lung and lymph nodes at the highest concentrations, but the more pronounced effect was found in rats exposed to the coarse material. Likewise there was an increase of lavage parameters in rats exposed to thecoarse material but not to the NP. These data demonstrate that inhalation of finer NP is not necessarily associated with higher toxicity compared to the coarse material. The results were obtained with two organic particles of rather different size and composition but are in contrast to the more severe effects seen with several anorganic NP when compared to the corresponding coarse particles.

**223 HUMAN EXPOSURE TO ROADWAY TRAFFIC PARTICLES PRODUCES RESPIRATORY OXIDATIVE STRESS.**

H. M. Kipen1, 2, R. J. Laumbach1, 2, Z. Fan1, 2, P. Ohman-Strickland3, 4, K. Kelly-McNeil1, 2, S. Ko4, C. Cepeda4 and A. Gore41 Environmental & Occupational Health Sciences Institute (EOHSI), Piscataway, NJ, 2University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Piscataway, NJ, 3University of Medicine and Dentistry of New Jersey-School of Public Health, Piscataway, NJ, and 4School of Pharmacy, Rutgers University, Piscataway, NJ.

Rationale: Epidemiologic studies show that cardiorespiratory events, including MI, occur within hours to minutes of roadway traffic-related air pollution (TRAP) increases. Induction of oxidative stress is a commonly invoked mechanism, but there is little direct human evidence of acute increases in oxidative stress following TRAP
exposure. We hypothesized that acute exposure to traffic particles increases nitrite and nitrate in exhaled breath condensate (EBC) and that the effect will be dependent on the level of reactive oxygen species (ROS) and oxidative potential (OP) in the inhaled particles. Methods: 20 healthy subjects volunteered for a fasting, 2-hr, double-blind, randomized cross-over protocol to ride in rush hour on the NJ Turnpike while breathing either unfiltered or HEPA-filtered vehicle cabin air (FA) delivered by a powered air-purifying respirator. Particle count and mass concentrations were measured inside and outside of the respirator. EBC was collected before, immediately after, and 6 and 24 hours after each ride. NO2-/NO3- increased significantly by 31% and 104% respectively, immediately after the ride (p=0.02 and p=0.035), with no persistence at 6 or 24 h post exposure. Ongoing analyses will determine the levels of ROS and OP in the TRAP.

The results were compared with FA, NO2- and NO3- increased significantly by 31% and 104% respectively, immediately after the ride (p=0.02 and p=0.035), with no persistence at 6 or 24h post exposure. Ongoing analyses will determine the levels of ROS and OP in the TRAP.

Cardiovascular diseases have been associated with situations in which enhanced activity of renin-angiotensin system (RAS) overrides cardioprotective effects of kallikrein-kinin system (KKS). The lung is the target organ of exposure to airborne particulates (PM), and it is where angiotensin is activated and bradikinin deac- vated, modulating homeostasis of the cardiovascular system. By using RT-PCR we examined changes in the induction of lung and heart RAS, angiotensin type 1 (AT1R) and 2 (AT2R) receptors, angiotensin converting enzyme (ACE), bradikinin type 1 (B1R) and 2 (B2R) receptors and kallikrein (KLK1), and how they may mediate expression of heart gene reprogramming markers like t-skeletal actin (Acta1) and procollagen-III (Col3a1). Male Sprague-Dawley rats were exposed acutely - 3 days and subchronically - 8 weeks to coarse (C), fine (F) and ultrafine (UF) particulates and filtered air, with an inertial particle separator (VACES). We observed increased expression of AT1R, AT2R and KLK1 in the lung after acute exposure to F, and AT1R, B2R and ACE to UE Subchronic exposures to F and UF increased the expression of AT1R without KKS changes. Acute exposure did not induce heart gene reprogramming, although induction of B1R after C, F and UF exposures, KLK1 after F and UF exposures, AT1R after F exposures, and ACE after C and UF exposures, were observed. After subchronic exposures, heart gene reprogramming was observed, expression of Col3a1 and Acta1, in F and UF with an up-regulation of AT1R and a down-regulation of AT2R with UE, and the induction of KLK1 with F exposures. Overexpression of RAS components accompanied by a reduced expression of KKS in the lung and heart after exposure to F and UF suggests heart gene reprogramming modulated by AT1R, thus its over-expression may be an important mechanism to explain some cardiovascular system adverse effects of PM exposure. More gentle washing using pressure differential. In this study, we collected the BAL fluid (BALF) using both injection/suction (Manual) and 2) differential pressure retrieval (Pressure), from cigarette smoke-exposed rats and mice. The goals were: 1) to standardize and assess if there is qualitative/quantitative difference between the two methods and 2) to evaluate the inflammatory parameters between rats and mice following subacute cigarette smoke exposure. Animals were exposed up to 1000 μg/L WTPM, varying daily exposure duration, for 5 wk (6-10 animals/group). A total of 6 was washing performed and for both methods, the 1st and (2nd to 6th) BALF were separately collected. The supernatant from the 1st wash was analyzed for LDH, GGT, and ALP while all 6 washes were used for total cell counts and differential. In control, the BALF parameters and their variability were overall comparable between the methods. The smoke-exposed animals had increased neutrophils and lymphocytes above the control, which tended to be retrieved slightly higher by the Manual method. Interestingly, the relative retrieval of different leukocytes between 1st and (2nd to 6th) wash varied between the methods. In smoke-exposed rats, all BALF enzymes increased in a dose-related manner, while only LDH increased in mice. While both methods under the employed condition were acceptable for BAL cell and enzyme parameters, a consistent use of a selected method is recommended to minimize variability.

Cardiovascular diseases have been associated with situations in which enhanced activity of renin-angiotensin system (RAS) overrides cardioprotective effects of kallikrein-kinin system (KKS). The lung is the target organ of exposure to airborne particulates (PM), and it is where angiotensin is activated and bradikinin deactivated, modulating homeostasis of the cardiovascular system. By using RT-PCR we examined changes in the induction of lung and heart RAS, angiotensin type 1 (AT1R) and 2 (AT2R) receptors, angiotensin converting enzyme (ACE), bradikinin type 1 (B1R) and 2 (B2R) receptors and kallikrein (KLK1), and how they may mediate expression of heart gene reprogramming markers like t-skeletal actin (Acta1) and procollagen-III (Col3a1). Male Sprague-Dawley rats were exposed acutely - 3 days and subchronically - 8 weeks to coarse (C), fine (F) and ultrafine (UF) particulates and filtered air, with an inertial particle separator (VACES). We observed increased expression of AT1R, AT2R and KLK1 in the lung after acute exposure to F, and AT1R, B2R and ACE to UE. Subchronic exposures to F and UF increased the expression of AT1R without KKS changes. Acute exposure did not induce heart gene reprogramming, although induction of B1R after C, F and UF exposures, KLK1 after F and UF exposures, AT1R after F exposures, and ACE after C and UF exposures, were observed. After subchronic exposures, heart gene reprogramming was observed, expression of Col3a1 and Acta1, in F and UF with an up-regulation of AT1R and a down-regulation of AT2R with UE, and the induction of KLK1 with F exposures. Overexpression of RAS components accompanied by a reduced expression of KKS in the lung and heart after exposure to F and UF suggests heart gene reprogramming modulated by AT1R, thus its over-expression may be an important mechanism to explain some cardiovascular system adverse effects of PM exposure.

soluble particle extract. Longer carbon chain fatty acids are present in the B20 while shorter carbon chains are detectable in the B0 extract. Aldehydes were identified in the B0, B20 and B100 extract. The current data suggests B0 and B3 blends, and PD extracts induce alterations in endothelial cell antioxidant responses. A NOVEL HYPOXIA STRESS TEST DEMONSTRATES CARDIOVASCULAR AND PULMONARY SUSCEPTIBILITY TO ACREOLIN GAS IN HYPERTENSIVE RATS.

High levels of air pollution increase the risk of cardiovascular morbidity and mortality, especially in susceptible populations including those with hypertension. Stress tests are useful for manifesting latent effects of exposure, particularly at low concentrations, often when no overt effects are evident. The goal of this study was to develop a hypoxia stress test to illuminate susceptibility to environmental pollu-
tants in a rodent model of hypertension. We hypothesized that acrolein exposure would increase sensitivity to hypoxia, particularly in hypertensive rats. Acreolin is an unsaturated aldehyde found in diesel exhaust and is a known environmental toxicant and potent pulmonary irritant. Spontaneously hypertensive (SH) and Wistar Kyoto (WKY; rats with normal blood pressure) rats, implanted with biopotential icant and potent pulmonary irritant. Spontaneously hypertensive (SH) and Wistar of Kentucky, Lexington, KY and 2Pharmaceutical Sciences, Wayne State University, Detroit, MI.

Ozone (O3), and tobacco smoke (TS) are pulmonary irritants and known risk factors in the development of chronic lung disease. This study was performed to de-
terminate if sequential exposures of rats to O3 and TS will produce lung injury greater than that produced by either pollutant. Adult Sprague Dawley (SD) male rats were exposed for a single 3 hour period to 1) Air (control) 2) O3 or 3) O3 followed by TS (O3/TS). At 12 hrs post-exposure, bronchoalveolar lavage (BAL) was performed, and lung tissues were isolated. These samples from the controls and exposure groups were analyzed for lung injury, airway permeability and antioxidant activity. Data revealed a significant increase in total antioxidant capacity in the BAL in the O3 group compared to that in the control, showing a development of a pro-
tective mechanism for oxidative stress damage from O3. A subsequent exposure to TS attenuated the levels of total antioxidant capacity, but the reduction was not sta-
tistically significant in comparison to that after O3-alone exposure. A significant in-
sues were processed for light microscopic examination and morphometric analysis. RESULTS: ND and HFD rats exposed to O3 or O3/CAPs, but not control ND rats exposed to filtered air alone, had an acute rhinitis with marked hyperplasia of nasal epithelium (NE). HFD rats, but not ND rats, exposed to CAPs also had an acute rhinitis but no epithelial hyperplasia. The severity of the inflammatory cell re-
sponse (numeric density of neutrophils) was not different among the rats with rhinitis. Of all the air pollutant-exposed groups, the HFD rats coexposed to O3/CAPs had the greatest numeric cellular density of NE (54, 45, 12 and 12% greater than CAPs-alone HFD, air-exposed HFD, O3/CAPs-alone ND, and O3-ex-
posed HFD rats, respectively). Though we have previously reported that repeated O3 exposure will cause rhinitis with nasal epithelial hyperplasia, this is the first re-
port of a diet-related enhancement of air pollutant-induced nasal toxicity. Underlying mechanisms responsible for HFH enhancement of O3- and/or CAPs-
induced nasal epithelial or inflammatory lesions are yet to be determined. Funded by USEPA RD5479701.

EFFECTS OF HIGH-FRUCTOSE DIET ON NASAL EPITHELIAL AND INFLAMMATORY RESPONSES TO INHALED OZONE AND AMBIENT FINE PARTICLES IN RATS.

Ozone (O3), and tobacco smoke (TS) are pulmonary irritants and known risk factors in the development of chronic lung disease. This study was performed to de-
terminate if sequential exposures of rats to O3 and TS will produce lung injury greater than that produced by either pollutant. Adult Sprague Dawley (SD) male rats were exposed for a single 3 hour period to 1) Air (control) 2) O3 or 3) O3 fol-
lowed by TS (O3/TS). At 12 hrs post-exposure, bronchoalveolar lavage (BAL) was performed, and lung tissues were isolated. These samples from the controls and exposure groups were analyzed for lung injury, airway permeability and antioxidant activity. Data revealed a significant increase in total antioxidant capacity in the BAL in the O3 group compared to that in the control, showing a development of a pro-
tective mechanism for oxidative stress damage from O3. A subsequent exposure to TS attenuated the levels of total antioxidant capacity, but the reduction was not sta-
tistically significant in comparison to that after O3-alone exposure. A significant in-

ONE VERSUS FIVE DAYS OF EXPOSURE TO VARYING CONCENTRATIONS OF B100 SOYA BIODIESEL EXHAUST REVEALS A THRESHOLD CONCENTRATION FOR INCREASED SENSITIVITY TO ACONITINE-INDUCED ARRHYTHMIA.

Although biodiesel (BD) is rapidly being considered as an alternative to diesel fuel, its health effects have not been thoroughly characterized. We previously used the aconitine challenge test to demonstrate that a single exposure to petroleum diesel exhaust (DE) increases the risk of arrhythmia being triggered in hypertensive rats. Here we hypothesized that inhalation of biodiesel exhaust (BDE) increases the risk of arrhythmia, particularly with repeated exposures. Spontaneously hypertensive rats surgically implanted with radioelemelems were exposed for one or five days to 50, 150 or 500 μg/m3 of B100 soya BDE or filtered air (FA) (4 hours). Arrhythmogenesis was assessed 24hrs after the last exposure in urethane-anesthetized animals by continuous intravenous infusion of aconitine while heart rate (HR) and electrocardiogram (ECG) were monitored. Rats exposed to BDE had lower HR when compared to air-exposed animals but no ECG changes when com-
pared to controls. Sensitivity to arrhythmia was measured as the threshold dose of aconitine required to produce ventricular premature beats (VPB), ventricular tachycardia (VT), and ventricular fibrillation (VF). There was no effect of 50 μg/m3 BDE. Rats exposed to five days of 150 μg/m3 BDE successively developed VPBs, VT, and VF at significantly lower doses of aconitine than FA, however a single 
gle exposure had no effect. Both one and five days of 500 μg/m3 BDE significantly, and comparably, increased sensitivity to aconitine-induced arrhythmia when com-
pared to FA. These findings suggest that below a certain concentration, exposure to BDE does not increase arrhythmogenic sensitivity. Furthermore, given the effects of 500 μg/m3 BDE were still lower than 150 μg/m3 DE, BDE might be a safer alter-
native, particularly if exhaust levels are kept below a certain threshold concentra-
tion. (This abstract does not reflect EPA policy.)
increase in BAL albumin in O3 group compared to that in the control was observed, and a subsequent non-significant reduction was similar to that in total antioxidant levels in the O3/TS group. Lung tissue protein analysis further showed a significant reduction of extracellular superoxide dismutase (EC-SOD) and catalase in the O3 and O3/TS groups compared to the control levels, but their expression was not significantly different between O3 and O3/TS groups. None of the exposures produced any effect on the expression of manganese-SOD or copper/zinc-SOD. Overall, the results show that the increase in total antioxidants after O3 exposure does not block airway injury/penetrability. Sequenical exposures to O3 and TS decrease some antioxidant enzymes, suggesting limited cross-tolerance following such exposures. The results do not support synergistic toxic effects predicted for O3 and TS. Supported in part by funding from OVP-WSU.

232 TRANSCRIPTOMIC ANALYSIS OF LUNGS AND PERIPHERAL BLOOD OF SILICA-EXPOSED RATS.

Non-invasive or minimally invasive surrogate approaches to detect/predict target organ toxicity have significant practical applications in occupational toxicology. Presently, using a rat model, we have investigated the potential application of peripheral blood transcriptomics as a practical approach to determine silica-induced pulmonary toxicity. Rats were exposed to crystalline silica (15 mg/m³, 6-hours/day, 5 days/week). Pulmonary toxicity and global gene expression profiles of lungs and peripheral blood were determined in the control and silica exposed rats 32-weeks post-exposure period. A significant elevation in bronchoalveolar lavage fluid LDH activity and a decrease in histopathological changes in the lungs, including tumor, fibroplasia, indicated silica-induced pulmonary toxicity in the rats. Similarly, significant infiltration of neutrophils and elevated MCP1 activity in the lungs suggested silica-induced pulmonary inflammation in the rats. Microarray analysis of global gene expression profiles identified significant differential expression (>1.5 fold change and FDR <0.001) of 520 and 537 genes, respectively, in the lungs and blood of the silica exposed rats. Bioinformatics analysis of the differentially expressed genes demonstrated significant similarity in the biological processes, molecular networks, and canonical pathways enriched by silica exposure in the lungs and blood of the rats. Several genes involved in functions relevant to silica-induced pulmonary toxicity such as inflammation, cancer, oxidative stress, fibrosis, etc., were found significantly differentially expressed in the lungs and blood of the silica-exposed rats. The results of this study, in addition to providing molecular insights into the mechanisms underlying silica-induced pulmonary toxicity, further confirm the potential application of peripheral blood gene expression profiling as a toxicologically relevant, minimally invasive surrogate approach to study silica-induced pulmonary toxicity.

233 EXPOSURES TO EMISSIONS FROM COMBUSTION OF BIODIESEL FUELS (B100/B20) ELICIT DIFFERENTIAL RESPONSES IN REDOX-SENSITIVE PATHWAYS.

Fukagawa1. 1Medicine, University of Vermont, Burlington, VT; 2Civil and Environmental Engineering, University of Vermont, Burlington, VT and 3Epidemiology, NHEERL, US EPA, Research Triangle Park, NC.

Exposure to airborne particulate matter (PM) is associated with higher risk for cardiopulmonary diseases but mechanisms for the effects remain unknown. Combustion of biodiesel fuels (BD) is associated with lower emission of PM but questions remain if BD combustion is consistently better for health. To examine the potential applications of complementary research methods, we conducted a study to test the hypothesis that BD combustion has a lower impact on redox-sensitive pathways. PM samples were collected from an experimental facility that fired pure BD versus the presence of petrodiesel in the B20 blend in producing the differential responses, both of which would affect particle size and composition. (This abstract does not represent US EPA policy).

234 BIOINFORMATICS OF GENE EXPRESSION PROFILING DATA PROVIDE MECHANISTIC UNDERSTANDING OF ACUTE OZONE-INDUCED LUNG INJURY.

Acute ozone-induced pulmonary injury and inflammation are well characterized. A few studies have used gene expression profiling to determine the types of changes induced by ozone; however the pathways involved are less well understood. We presume that robust bioinformatics of the transcriptional data will allow us to better understand mechanisms of pulmonary injury caused by acute ozone exposure. Male Wistar Kyoto rats (10-12 wk) were exposed to air, or ozone (0.25, 0.5 or 1.0 ppm) and pulmonary injury and inflammation were assessed 4 and 20 h later and lung gene expression profiling was assessed 4 h later (air and 1.0 ppm ozone). At 20 h BAL fluid protein and neutrophils increased at 1 ppm ozone. Numerous genes involved in acute inflammatory response were upregulated along with changes in genes regulating processes such as cell adhesion and migration, steroid metabolism, apoptosis, cell cycle control and cell growth. The NFKB (Rela), SP1 and TP3 transcription factors were identified to be mediating activation of genes for these processes. Upstream signaling involving ErbB, toll-like receptors, Wnt, TGF-β, NOD-like receptor and others were predicted based on downstream changes in expression. Because many of these genes regulating various inflammatory and repair processes are also involved in cancer, this pathway was also identified as being significantly changed by ozone. Remarkable changes in genes regulating endocytosis and glucocorticoid receptor activities (as evident by KEGG pathway analysis) provide the insight that ozone-induced injury might be initiated from cell membrane alterations and oxidatively modified lung lining lipids and proteins. Thus, gene expression profiling data could predict mechanisms of ozone-induced lung injury. Different cellular processes such as endocytosis, cell signaling, and transcription factor activation leading to cytokines release, cell migration, apoptosis, and growth could orchestrate the inflammatory and repair processes in the lung. (Does not reflect the US EPA policy).

235 METABOLIC CHANGES FROM HIGH-FRUCTOSE FEEDING ARE ALTERED BY AIR POLLUTANT EXPOSURE.

K. Allen1, A. K. Kopes1, T. B. Zacharewski1, J. G. Wagner1, M. Morishita1,2, T. T. Dvonch1,2 and J. R. Harkema4,3,4. Michigan State University, East Lansing, MI; 2Biochemistry, Michigan State University, East Lansing, MI; 3Pathobiology, Michigan State University, East Lansing, MI and 4School of Public Health, University of Michigan, Ann Arbor, MI.

People with diet-induced metabolic maladies may be more susceptible to the adverse effects of air pollution (AP). The present study evaluated the effect of AP on facets of diet-induced metabolic dysfunction. Mature male Sprague Dawley rats were fed normal chow (NC) or a high fructose diet (HF) for 8 weeks prior to and during AP exposure. Inhalation exposures to ozone (O3; 0.5 ppm) and/or concentration-ambient fine particles (CAPs, 400 μg/m³) were conducted in a mobile air re- search laboratory located in an industrial area of Dearborn, MI during summer 2011. Rats were exposed for 9 days, 8 h/day (4-5 days/week). Rats were sacrificed 24h after the end of exposure. Prior to sacrifice, blood was collected for homeostatic model assessment–insulin resistance (HOMA-IR) analysis. At necropsy, hepatic tissues were collected for light microscopy and gene expression analyses using qRT-PCR and whole-genome arrays. Through HF feeding did not induce obesity, HOMA-IR was increased concurrent with peripheral steatosis. HF-induced gene expression of stearoyl-Coenzyme A desaturase (Scd1) was potentiated after exposure to O3, CAPs and O3/CAPS (~21-fold) relative to filtered air/HF group (~14-fold). Scd1 expression was repressed by O3 (~3.4-fold) and O3/CAPS (~2.5-fold) in rats fed NC. Low density lipoprotein receptor (Ldlr) was also induced in HF-fed rats that were exposed to O3 and O3/CAPS (~1.6-fold) compared to filtered air-exposed NC and HF rats. In contrast, HF feeding caused a significant decrease in phosphoepinephrine pyruvate dehydrogenase 1 (Pck1), suggesting inhibition of gluconeogenesis. Furthermore, CAP’s exposure down-regulated Pck1 in NC-fed rats (~1.7-fold) and further suppressed Pck1 on a HF diet (~6-fold). Collectively, these data suggest that acute AP exposure may exacerbate facets of the metabolic syndrome. Funded by USAEPA R83479701.
SPD is a collectin important in limiting pulmonary inflammatory responses. SPD-/− mice develop progressive lung pathology culminating in emphysema. O3 inhalation (0.8 ppm, 3 hr) resulted in increases in lung MPs were observed in old SPD-/- but not WT mice. This correlated with structural alterations suggestive of chronic inflammation and emphysema. O3 inhalation (0.8 ppm, 3 hr) resulted in increases in lung MP levels in both young and old SPD-/- mice. Activated MPs have been implicated in pulmonary disease pathogenesis; however, their role depends on their phenotype. Two groups are classically activated cytoplasmic/proinflammatory iNOS+ MPs (CAM) and alternatively activated anti-inflammatory/profibrotic YM-1+ MPs (AAM). In old WT mice, O3 inhalation increased AAM after 72 hr. Increases in AAM were also observed in lungs of air-exposed young SPD-/- mice, while in old SPD-/- mice, both CAM and AAM were present. Whereas in young SP-D-/− mice, O3 caused increases in CAM, with no change AAM, in old SPD-/- mice, AAM increased and CAM decreased. We next determined if these changes were associated with alterations in lung function. Age-related increases in resistance (Rn) and decreases in tissue damping (G) were observed in WT and SPD-/- mice, indicating effects on airways and parenchyma. In young, but not old WT and SPD-/- mice, O3 inhalation altered central airway mechanics, as shown by increased responsiveness of Rn to recruitment, but not G. Additionally, alterations in tissue mechanics were observed in old SPD-/- but not WT mice after O3, suggesting that SPD is important in maintaining lung resistive properties. These results indicate that SPD regulates MP phenotype during inflammatory responses of the elderly to inhaled irritants; moreover this leads to increased lung functional alterations. **Enhancement of platelet activity and plasma homocysteine level by intratracheal instillation of carbon black.**

H. Kim1, S. Kim2, K. Park3 and M. Lee1.1 Dongguk University College of Pharmacy, Goyang, Gyeonggi-do, Republic of Korea, 2 Chungnam National University College of Pharmacy, Daejeon, Republic of Korea and 3 Dongguk Women's University College of Pharmacy, Seoul, Republic of Korea. Sponsor: J. Chung.

Carbon black is an industrial chemical with the high potential of occupational exposure. Although the relationship between exposure to particulate matters and cardiovascular diseases is well established, the cardiovascular risk of carbon black has not been characterized clearly. Here, we designed and performed this study to investigate the cardiovascular effect of carbon black and to identify the target tissues and the potential biomarker. Carbon blacks with distinct particle size, N330 (ultrafine particle) and N990 (fine particle) were intratracheally instilled to rats. After 24 hrs and 1 week, we evaluated the thrombotic activities such as platelets aggregability and plasma coagulability, and analyzed the homocysteine levels in blood plasma, along with the cardiac functions and the inflammatory response. Exposure to N330 resulted in the acceleration of platelet-dependent blood clotting at 10 mg/kg, the highest exposure tested, while N990 exhibited minimal effect, suggesting that carbon black can enhance thrombotic risk. Unexpectedly, both carbon blacks led to the prolongation of activated partial thromboplastin time (aPTT), although it was not dose-dependent. N990, but not N330, significantly elevated the plasma homocysteine, a well established etiological factor for cardiovascular diseases. Although both of carbon blacks induced mild but apparent inflammation in lungs, it did not spill over into systemic inflammation, and none of them caused cardiac symptom detectable with electrocardiography. These results suggest that carbon black exposure may induce cardiovascular risk by the induction of hyperhomocysteinemia and the exaggeration of platelet activity. Homocysteine in blood plasma may be a potential biomarker for cardiovascular toxicity following carbon black exposure.

**L-menthol inhibits respiratory irritation by cigarette smoke irritants targeting diverse chemosensory receptors.**

M. A. Ha1, B. Liu2, S. Jordt2 and L. B. Morris1.1 Toxicology Program, University of Connecticut, Storrs, CT and 2Department of Pharmacology, Yale University School of Medicine, New Haven, CT.

Stimulation of chemosensory nerves in the respiratory tract results in irritation responses which in humans can include the sensation of tickling or pain and the urge to cough. In mice stimulation of trigeminal chemosensory nerves results in reduced breathing frequencies due to extension of the duration of braking (DB) at the onset of each expiration. L-menthol, the cooling terpene in peppermint, has analgesic properties and may inhibit respiratory irritation in smokers of mentholated cigarettes. L-menthol activates the cold/menthol receptor, Transient Receptor Potential Melastatin 8 (TRPM8) and other sensory TRP ion channels, such as TRPA1 or TRPV1. Using female C57Bl/6j mouse as the experimental model, the DB response was measured during exposure to L-menthol (6, 12, 18 or 32 ppm) in combination with either 2 ppm acrolein or 1500 ppm cyclohexanone, two cigarette smoke irritants. Whereas acrolein is an agonist of the irritant receptor, TRPA1, fluorescent Ca2+ imaging experiments in cultured murine sensory neurons identified cyclohexanone as a specific agonist of TRPV1, the capsaicin receptor. L-menthol significantly reduced the irritation response to acrolein, with an EC50 of less than 6 ppm. This effect was diminished by AMTB, an antagonist of TRPM8. The inhibitory action of L-menthol on respiratory irritation was maintained in Trpa1-/- mice. L-menthol significantly reduced the irritation response to cyclohexanone, but the EC50 was approximately 20 ppm.

These results show that L-menthol inhibits respiratory irritation responses to smoke irritants targeting diverse chemosensory receptors (TRPA1 or TRPV1) expressed in different populations of sensory neurons. The cold/menthol receptor, TRPM8, is a crucial mediator of this inhibitory effect. The potency of counter irritation by menthol may depend on the nerve population being stimulated by the irritant. Supported by R01HL105635.

**Dry powder inhalation exposures of single rat lungs to fluticasone furoate: Control of dose, substance consumption and pharmacokinetics.**

Inhalation exposures of rats to respirable particles is an important part of air pollution studies and the development of new inhalation therapies. One problem with such studies is the availability of methods allowing controlled inhalation exposures to respirable particles using only small amounts of study material. The purpose of the current study was to evaluate the dosing precision, substance consumption, and resulting pharmacokinetics when using the Dustgun exposure platform to expose both the isolated, perfused rat lung (IPL) and endotracheally intubated rats (EIR). Using female C57Bl/6j mouse as the experimental model, the DB response was measured during exposure to L-menthol (6, 12, 18 or 32 ppm) in combination with either 2 ppm acrolein or 1500 ppm cyclohexanone, two cigarette smoke irritants. Whereas acrolein is an agonist of the irritant receptor, TRPA1, fluorescent Ca2+ imaging experiments in cultured murine sensory neurons identified cyclohexanone as a specific agonist of TRPV1, the capsaicin receptor. L-menthol significantly reduced the irritation response to acrolein, with an EC50 of less than 6 ppm. This effect was diminished by AMTB, an antagonist of TRPM8. The inhibitory action of L-menthol on respiratory irritation was maintained in Trpa1-/- mice. L-menthol significantly reduced the irritation response to cyclohexanone, but the EC50 was approximately 20 ppm.

The resulting PK of FF demonstrated a similar pulmonary absorption rate of this sparingly soluble steroid in the IPL and the EIR. Together were 18 lungs exposed and the total substance consumption was 55 mg, including determination of particle size distribution and preparative filter tests. Results indicated the usefulness of the IPL for predicting the pulmonary absorption of particulate solutes in rats in vivo, provided that similar sized aerosols and ventilation patterns were used during the exposures. Inhalation exposures of EIR to respirable dry powder aerosols can be performed as an alternative to intratracheal instillation of liquid-suspended materials using a similar animal treatment protocol.
Ozone (O3) is an air pollutant that is associated with cardiovascular and respiratory diseases. The aged population is considered to be more sensitive to pollutants such as O3; however, relatively few studies have demonstrated increased susceptibility in aged or senescent animal models. We employed a subchronic, intermittent O3 exposure protocol to study the susceptibility in young and aged Brown Norway (BN) rats. In one study, young adult (4 m) and aged (20 m) rats were exposed to 0 or 0.8 ppm O3 for 6 hr/d, 1 d/wk for 17 wks. Respiratory parameters assessed by unrestrained plethysmography the day after exposure revealed that O3 led to airway flow limitation (i.e. increased PenH). Young rats exhibited a greater rise in PenH over the 17 wk exposure. Bronchoalveolar fluid macrophages were reduced in aged rats and neutrophils increased in young rats. Age affected 20 of 58 serum analytes, including C-reactive protein, interferon, and macrophage inflammatory protein-2 (MIP-2). O3 affected 6 analytes, including fibroblast growth factor (basic), MIP-2, leukemia inhibitor factor, and haptoglobin. In another study, core temperature (Tc) and heart rate (HR) were monitored by telemetry in 8 and 20 m BN rats exposed for 6 hr/d, 2 consecutive d/wk to 0 or 1.0 ppm O3 for 12 wk. Aged rats were less responsive to aconitine-induced arrhythmia formation in a manner similar to 0.8 ppm O3, suggesting a latent O3-in-dependent autonomic modulation of cardiac function in rats. Rats implanted with a chronic indwelling cannula were exposed to O3 for a possible underrepresentation of chemical classes) a TTC value of 10 μg/kg for a possible underrepresentation of chemical classes) a TTC value of 10 μg/kg bw/d for maternal as well as developmental endpoints. DEVELOPMENT OF A NEW NONCANCER TTC DATABASE FOR COSMETICS INGREDIENTS: A COLLABORATIVE PROJECT BETWEEN THE EC, COLIPA, AND ILSI EUROPE.

K. Jacobs², K. Arvidson², K. Cronin², S. Enoch², S. Felter², E. Fioravando³, J. Madden², M. Pavan², A. Richard³, R. Safford³, A. Worth³, C. Yang³ and G. ILSI Expert⁴.

The Seventh Amendment of the Cosmetics Directive foresees a deadline in 2013 for the replacement of animal testing of cosmetic products for repeated dose/reproductive toxicity and toxicokinetics. Currently, there are no accepted alternative methods for the regulatory assessment of repeated dose toxicity. As part of the research initiative to address the knowledge and technology gap, the European Commission (EC) and COLIPA jointly funded the COSMOS consortium.

The Threshold of Toxicological Concern (TTC) approach is being considered as one of the alternatives for the safety assessment of cosmetics ingredients. To improve the applicability of the TTC approach to cosmetics ingredients, COSMOS partners established two expert working groups in collaboration with ILSI Europe. The first expert group supports the development of a new noncancer TTC database for cosmetics ingredients, whereas the second group addresses the oral-to-dermal extrapolation. We report on a new noncancer TTC database (~650 cosmetics ingredients) compiled from various data sources. Also reported is the method to normalize the critical NOAELs from different study types. Cosmetics ingredients were defined as chemicals found in the EU COSING and US PCPC lists. About 90% of the non-cosmetics in the Munro dataset belonged to Cramer class III (high concern), whereas <50% of the cosmetics ingredients were in class III. Although preliminary, our results indicate that currently accepted TTC values may be adequately protective for cosmetics ingredients. The COSMOS noncancer database will comprise the single largest compilation of NOEL values in the public domain, and will serve as a sound basis for developing alternative methods for repeated dose toxicity. This abstract does not necessarily reflect the official position of US FDA, JRC, or EC.

COLIPA PROGRAM ON OPTIMIZATION AND VALIDATION OF HPLC-BIO-ANALYTICAL ASSAY TO EXPAND APPLICABILITY DOMAIN OF IN VITRO EYE IRRITATION RHT TEST METHODS FOR DYES.

In vitro eye irritation assays using Human Reconstructed Tissue (RHT) test systems (SkinEthic™ HCE & EpiOcular™ EIT) are currently undergoing EVAM validation for detection of GHS irritants/non-irritants. In these test methods, irritation potential of a test chemical is determined by measuring cell viability in treated tissues by colorimetric MTT reduction assay. Cell viability is determined by enzymatic reduction of a yellow MTT tetrazolium salt to blue formazan. It is quantified photometrically with results expressed as % viability in the test chemical treated tissues relative to the negative control. Decrease in MTT reduction capacity is used to identify potential irritancy of test chemicals. A known limitation of the MTT test is possible interference of dye with absorbance measurement of formazan. The European Cosmetics Industry Association (Colipa) is conducting a program to address this limitation. The aims of the program are to: 1) optimize the preliminary analytical approach using High Performance Liquid Chromatography (HPLC) to quantitatively separate formazan from intrinsically coloured test chemical; 2) demonstrate application of the HPLC analytical method to evaluate dyes in RHT test methods; 3) demonstrate within and between laboratory reproducibility. Results presented describe validation using the FDA guideline for bioanalytical method and the multi-centric study (6 chemicals tested in 3 labs). This work has supported development of a Standard Operating Procedure that can be applied to extend the applicability domain of RHT test methods.

METAIBOILICS IN VIVO—APPLICATION FOR FORMING CHEMICAL CATEGORIES.

H. Kamp¹, D. Althborey-Dicker², S. Bade³, E. Fabian¹, M. Ferrieks¹, S. Germer¹, M. Herold¹, G. Krennrich¹, R. Looser¹, W. Mellert¹, A. Prokoudine², V. Straus¹, T. Walk¹, J. Wiemer² and B. van Ravenzwaay¹. ¹BASF SE, Ludwigshafen, Germany and ²Metanomics GmbH, Berlin, Germany. Sponsor: T. Landsiedel.

BASF SE and metanomics GmbH have developed a metabolomics data base (MetaMap®Tox) containing more than 500 data rich chemicals, agrochemicals and drugs. This metabolome database is based on 28 day studies in rats with blood sampling and metabolic profiling after 7, 14 and 28 days of test substance treatment. More than 100 patterns (i.e., set of changed metabolic levels) have been established for different toxicological modes of action. With these patterns early detection of toxicological effects becomes possible and will help to accelerate development of new compounds with a better toxicological profile with a reduced number of animal studies. Thus this technology contributes to animal welfare by reduction through refinement. Following the requirements of the new European chemicals legislation REACH, a high number of animal studies has to be performed. On the other hand, REACH demands the conduct of animal experiments only when no alternative exists to fill a data gap. Amongst the most promising methods to reduce the number of animal experiments are “read-across” and “grouping”, i.e., forming of categories of compounds based on information justifying that these chemicals will have a similar toxicological profile. Structural similarity or QSAR models are often used to define such chemical groups, however, with known limitations. Omics technologies (e.g., metabolomics) can optimize the chemical grouping process by providing biological information for equivalence. In case of MetaMap®Tox, this is based on the recognition of modes of action through specific metabolome patterns and by comparing the entire metabolome of a chemical with those of the reference compounds available in the MetaMap®Tox database. Therewith, metabolomics provides a powerful tool for going from QSR to QBAR (quantitative biological activity relationship) through biology based grouping of chemicals.

PHARMACOKINETIC, TISSUE DISTRIBUTION, AND EXCRETION BALANCE OF PARABENS AFTER TOPICAL SKIN APPLICATION IN RATS.

N. Aubert, T. Ameller, R. Forster and J. Legrand. CIToxLab France, Evence, France.

Parabens (PB) are preservatives widely used in topically applied drugs and personal care products. Our study compared the ADME profiles of radiolabelled methyl-, butyl- and propyl-PB following single oral, dermal or subcutaneous administration to Sprague-Dawley rats. PBs were administered in ethanol at a dose of 100 mg/kg. Blood total radioactivity Cmax and AUC were at least 10-fold higher when parabens were administered by the oral route when compared with those after other administration routes; Tmax was from 1 (oral gavage) to 8 hours (dermal application) after dosing. Methylparaben produced approximately 2x higher levels of radioactivity in all pharmacokinetic compartments when compared with other tested parabens. Whatever the administration route, no chromatographic peak of any paraben was detected in plasma samples; all radioactivity co-eluted as a single peak corresponding to that of para-hydroxybenzoic acid (PHBA). Following oral or subcutaneous administration, urinary excretion was predominant (>70 %, mainly during the first 24 hours), less than 4% were eliminated in the feces, and 2% were retained in the tissues and/or carcasses. Following dermal application, near to 50% of the dose was not absorbed, 14 to 27% and <2% were respectively excreted in the urine and feces, and <2% retained in the dissected tissues, whilst >20% of radioactivity was recovered in the remaining carcasses, likely located in the fur, paws or muzzle. These results suggest that parabens are partially absorbed through rat skin, extensively metabolized to PHBA, and rapidly excreted, mainly through the urine, with low retention in tissues.

REFINING ACUTE INHALATION TOXICITY TESTING: THE FIXED CONCENTRATION PROCEDURE.

S. Creton. NC3Rs, London, United Kingdom. Sponsor: T. Gant.

Acute toxicity testing is required under many regulatory frameworks. Acute studies are intended to support protection of human health, but are among the most criticized of regulatory toxicity studies for scientific and animal welfare reasons. A refinement method for acute inhalation toxicity has been proposed: the Fixed Concentration Procedure (FCP). The FCP avoids deaths as an endpoint by relying on ‘evident toxicity’, i.e. clear signs of toxicity such that it can be predicted that death or severe toxicity would occur if animals were exposed to a higher concentra-
tion. Testing at higher concentrations and the predicted severe effects can thus be avoided. Progress of the FCP through the OECD Test Guideline programme was suspended while work to address concerns raised by some member countries on three key points was initiated: The performance of the method in comparison with existing methods; the potential for sex differences in sensitivity to inhalation toxicity (as the FCP proposed testing females only); and, the perception that evident toxicity decision more transparent and consistent.

A mathematical objective system for recording clinical signs in acute inhalation studies has been developed to reduce the levels of certain tobacco leaf constituents.

The Globally Harmonized System of Classification and Labeling of Chemicals (GHS) represents an international approach to standardize the classification and communication of hazards for materials. One of the hazards addressed by GHS is serious eye damage and eye irritation. Institutional cleaning products, due to their surface-active chemistries, commonly have serious eye damage or irritation as a suspected health hazard. To support proper GHS classification, one approach is to conduct ocular testing. Current GHS criteria for classifying this endpoint is based primarily on interpreting in vivo data. However, due to animal welfare concerns, there is a shift in testing emphasis from in vivo to in vitro assays. Significant progress has been made in developing alternative ocular test methods. One such assay is the EpiOcular assay. EpiOcular is a corneal model consisting of human-derived epithelial keratinocytes cultured to form a stratified, squamous epithelium similar to the cornea. Two institutional cleaning products were evaluated using both in vivo and in vitro assays for eye irritation potential and subsequent GHS classification. For in vivo testing, the products were tested following OECD Test Guideline 405 and individual irritation scores were used to assign a GHS classification. EpiOcular served as the in vitro assay with tissue viability, cytokine release and histology evaluated. Tissue viability measured against time of exposure was used to determine the exposure time required to reduce viability to 50% of controls (FT50). The FT50, along with consideration of cytokine release and histology results, was used to assign a GHS classification. The in vivo data supported a GHS 2B classification (i.e., mild irritant) for both products. In contrast, the in vitro data for both products supported GHS 2A classifications (i.e., irritant). For this preliminary study, the in vitro assay provided a more conservative GHS classification for eye effects relative to in vivo testing; however, the limited number of test articles prevents drawing definitive conclusions.

As a person ages, the human body changes, and the efficiency of functions that ensure homeostasis is reduced. Altered function conditions (e.g., pharmacokinetics, pharmacodynamics) are physiologically and may have serious consequences on the capacity of detoxification and control of homeostasis, which reduces workers’ abilities to handle chemical stressors. Therefore, it is reasonable to expect that the impact on the ability of older workers to manage stress might be different in comparison to younger workers. The objective of this work was to analyze changes in physiological parameters that may influence the responses of older workers to chemical exposures from the perspectives of prevention, integration, and keeping them in their jobs regardless of their ages. For this project, we conducted a comprehensive literature review, using research tools such as MEDLINE, TOXNET, and other specialized medical books and reference volumes. We proposed grouping workers by stratum to compare different age groups (people aged between 18 and 70 years). This approach fills the gaps where there are sensitivities that reduce the body’s ability to handle chemical exposures. The results suggest that many physiological changes change with age. For example, the gastrointestinal tract transit decreases with age, thereby increasing the residence time of drugs and possibly the amount absorbed. This higher absorption can increase the interaction with a chemical product. A decrease in liver perfusion with age can increase the half-life of chemical reactivity; however, it does not seem that cytochrome P450 changes with age. A decrease in hepatic drug metabolism observed with age might be related to a reduction of the organ mass. Using this approach, the level of physiological and biochemical parameters are extracted, compiled, and compared. This research targets workers exposed to chemicals. Physicians and toxicologists in occupational health may use the results to identify constraints for aging workers with a perspective view for prevention.

Proteins and amino acids have been reported to be precursors for a number of potentially toxic constituents of tobacco smoke, including 2-aminonaphthalene, 4-aminobiphenyl and mutagenic heterocyclic amines. Therefore, a novel process has been developed to reduce the levels of proteins in cut tobacco. This process resulted in significant reductions in protein and total nitrogen (59% and 31% respectively) in tobacco leaf, which were associated with significant reductions (p<0.01) in tar normalised mainstream smoke yields of both nitrosamine containing and phenolic toxicants. In order to evaluate the biological effect of the treatment, test cigarettes containing up to a maximum of 80% of treated tobacco were compared against non-treated tobacco control product in a test battery of in vitro studies, and a 90-day subchronic nose-only rodent inhalation study. Cigarette smoke particular matter (PM) was tested in a Neutral Red uptake cytotoxicity assay, the Ames test, mouse lymphoma assay, and the micronucleus assay. Whilst toxicity was observed in all of these studies for all samples, there were no consistent qualitative differences between them. However, PM produced from cigarettes containing 80% treated tobacco demonstrated significantly lower mutagenic potencies (p<0.05) in Ames strain TA98 in the presence of S9.
In the inhalation study, the overall responses of the rats exposed to mainstream tobacco smoke from all cigarettes were found to be similar, although smoke from the test cigarettes showed reduced histopathology at one anatomical site (nasal 1) when compared to the control. In isolation, this limited change was considered minor rather than being indicative of a major biological effect.

The results of this test battery demonstrated that whilst the use of a tobacco containing reduced levels of proteins and polyphenols did reduce the genotoxicity associated with the presence of heterocyclic amines, it did not ameliorate any of the other biological endpoints (either in vitro or in vivo) investigated in these studies, when compared to an untreated tobacco control product.

253 A DECISION TREE APPROACH FOR THE SAFETY ASSESSMENT OF BOTANICAL COSMETIC INGREDIENTS.

E. Antignac1, T. Re2, R. Persaud1, J. Clouezat1 and Y. Srinivasan2, 1L’Oreal Research and Innovation, Amières, France and 2L’Oreal Research and Innovation, Clark, NJ.

Natural and organic cosmetic and personal care products are becoming increasingly popular with consumers worldwide. Many of the new botanical ingredients being used in these topically applied products are novel to the industry and require a more rigorous safety evaluation. We present a decision tree approach to guide risk assessments for various botanical ingredients. A straight forward pathway can be followed for materials commonly ingested. The focus here is to first assure there is sufficient safety data to move to a cosmetic use and to then assess local tolerance, i.e., irritation potential, phototoxicity/phoroallergy, and Type IV sensitization risk. For materials found to closely resemble food or known herbal medicines the pathway to topical tolerance may be based on detailed characterization and should be supported by reliable data including in vitro, in vivo, in silico, or human data. However, other botanicals must first be characterized by: taxonomy, cultivar, content of macro and micronutrients, chemical markers, known naturally occurring toxicants, etc. Since extracts of botanical materials can differ based on extraction procedures, etc. they may require chemical fingerprinting or more detailed structural analysis to allow the use of ‘in silico’ tools such as FTYC, SAR, and metabolic profiling. For a chemical compound of known toxicity or for which a tailed structural analysis to allow the use of such tools; TTC, SAR, and in vitro testing may be required to complement in silico assessments and arrive at an adequate human safety assessment. A decision tree approach for botanical ingredient safety assessment is presented in this poster.

254 EVALUATION OF SUBACUTE BTAT TOXICITY IN RATS AND IN VITRO GENOTOXICITY.

V. H. Adams1, J. L. Williams1, L. R. Beall1, R. L. Kibby2, M. L. Thompson2 and W. S. Eck1, 1Toxicology-Health Effects Research Program, Army Institute of Public Health, Aberdeen Proving Ground, MD and 2Toxicology-Toxicity Evaluation Program, Army Institute of Public Health, Aberdeen Proving Ground, MD.

The sustainability of military training ranges is a necessary component of operational readiness. The development of new energetics for military use is ongoing with one of the objectives for a successful product being minimal or low negative environmental and human health effects. The elimination of compounds that are appreciably harmful to the environment and/or human health can provide significant economic savings associated with potential future clean-up and health costs. BTAT (Bis(2,2,2-trinitroethyl)-3,6-diaminotetrazine) is under consideration as a new energetic replacement for RDX. The AIPH initial health assessment investigations included an in vitro mutagenicity assay and an oral acute/subacute 14-day bioassay in rats. In a modified Ames microplate assay (Salmonella typhimurium test strains TA98, 100, 1535, 1537, E. coli test strains pKM101 and uvrA), BTAT was found to be not mutagenic in all strains (with S-9 activation) at concentrations below its water solubility limit of 100 μg BTAT/mL. Without S-9 activation, BTAT was mutagenic at ≥9 μg BTAT/mL to test strain TA100. In female rats, the acute oral LD₅₀ for BTAT was ≥2000 mg/kg body weight. Male rats were used in the subacute 14-day study. The subacute LC₅₀ was ≥1000 mg/kg/day. Statistically significant findings included effects on several blood chemistry and hematology parameters in dose groups ≥293 mg BTAT/kg/day, increased spleen weights at 1000 mg BTAT/kg-day, decreased kidney and liver weights and decreased food consumption at 1000 mg BTAT/kg-day, and decreased thymus weights and body weights at 500 and 1000 mg BTAT/kg-day. In summary, except for test strain TA100, BTAT was not mutagenic in the Ames assay. Acute BTAT toxicity was found to be low (LD₅₀ >2g/kg) and subacute toxicity was consistent with anemia and methemoglobinemia.

255 MUTAGENICITY AND SUBACUTE TOXICITY TO FEMALE RATS OF GUANIDINIUM 3, 4-DINITROPYRAZOLO (GDNP)*.

Sustainable use of training ranges requires the development of compounds that have a minimal impact to the environment when used in a weapon system. A new energetic, GDNP, has been developed that may have efficacy in specific systems. To ensure the health of potentially exposed personnel and the environment, initial toxicity investigations were conducted and the results compared with another widely used energetic (hexahydro-1,3,5-trinitro-1,3,5-triazine; RDX). In a microplate Ames assay, GDNP is not cytotoxic to Ames bacteria at concentrations less than 100 μg/mL. However, GDNP is mutagenic to 4 out of 5 bacterial strains, both with and without 39 metabolic incubation, at concentrations as low as 0.8 μg/mL. The mutagenicity of GDNP is likely due to the 3,4-dinitropyrazole component. Unlike RDX, GDNP did not have an affinity for the GABA receptor convulsant site, and was predicted to not induce seizure. After oral acute dosing in female rats, GDNP had toxicity similar to that reported for guanidine hydrochloride, i.e., at concentrations above 750 mg/kg. GDNP induced progressive sedation culminating in bradycardia, reduced lial histopathology (ALD) for both sexes was 5000 mg/kg. A 14-day toxicity study in rats was conducted with 4A2NT in the feed at concentrations of 0, 125, 250, 500, 1000, and 2000 ppm. The 2000 ppm concentration was selected as highest concentration for subsequent 90-day study. An oral 90-day subchronic toxicity study in rats was conducted with concentrations of 0, 500, 1000 and 2000 ppm of 4A2NT in the feed. The calculated consumed doses of 4A2NT in the feed were 0, 27, 52 and 115 mg/kg-day for males and 0, 32, 65, and 138 mg/kg-day for females. A no observed adverse effect levels (NOAEL) was not determined. The low observed adverse effect levels (LOAEL) was 27 mg/kg/day for males and 32 mg/kg/day for female rats based upon adverse histopathology of the liver (cytoplasmic vacuoles) and body weight decreases. Testicular atrophy (hypospermatia) was also observed in male rats at dose of 52 and 115 mg/kg. The toxicity data developed can be used to develop oral RD kinetics that can be useful for human health risk assessment.

256 TOXICITY ASSESSMENT OF 4-AMINO-2-NITROTOLUENE.

2, 4-Dinitrotoluene (2,4-DNT) is used in the manufacture of dyes, in munitions and in military explosive composition. It degrades into a number of nitro reductive products, including 4-amino-2-nitrotoluene (4A2NT) (CAS:119-32-4) through in vivo metabolism and in vitro bacterial systems. 4A2NT is also an environmental degradation product of 2, 4-DNT and is detected in soil and ground water at some ammunition plant manufacturing and disposal facilities. The toxicity data on 4A2NT is limited. Therefore, we developed acute, sub acute and subchronic toxicity data in rats to assess environmental and human health effects from exposures. The intraperitoneal lethal dose (LD₅₀) for both sexes was 5000 mg/kg. A 14-day toxicity study in rats was conducted with 4A2NT in the feed at concentrations of 0, 125, 250, 500, 1000, and 2000 ppm. The 2000 ppm concentration was selected as highest concentration for subsequent 90-day study. An oral 90-day subchronic toxicity study in rats was conducted with concentrations of 0, 500, 1000 and 2000 ppm of 4A2NT in the feed. The calculated consumed doses of 4A2NT in the feed were 0, 27, 52 and 115 mg/kg-day for males and 0, 32, 65, and 138 mg/kg-day for females. A no observed adverse effect levels (NOAEL) was not determined. The low observed adverse effect levels (LOAEL) was 27 mg/kg/day for males and 32 mg/kg/day for female rats based upon adverse histopathology of the liver (cytoplasmic vacuoles) and body weight decreases. Testicular atrophy (hypospermatia) was also observed in male rats at dose of 52 and 115 mg/kg. The toxicity data developed can be used to develop oral RD kinetics that can be useful for human health risk assessment.

257 ACUTE TOXICITY STUDY OF LIPOSOMAL ANTIOXIDANT FORMULATIONS CONTAINING N-ACETYLSCYSTEINE, α-TOCOPHEROL, AND γ-TOCOpherol IN RATS.

Z. E. Suntrra1, K. Pucaj2, M. Alipour3 and M. Smith1, 1Medical Sciences Division, Northern Ontario School of Medicine, Thunder Bay, ON, Canada, 2Nucro-Technics, Toronto, ON, Canada and 3Amexox Ltd., Melbourne, FL.

The acute toxicity of a single dose of intravenously administered liposomal antioxidant formulation containing N-acetylcysteine (NAC) without or with tocopherol (α-T) or γ-tocopherol (γ-T) in rats was examined. Each group consisted of 5 male and 5 female Sprague-Dawley rats with a control group receiving empty DPPC liposomes (660 mg/kg DPPC, EL), and test groups receiving liposomes prepared from DPPC lipids with δ NAC (200 mg/kg NAC [L-NAC]), δ NAC and α-T (200 mg/kg NAC [L-NAC] and 83.3 mg/kg α-T [L-α-T]), δ NAC and γ-T (200 mg/kg NAC [L-NAC] and 71.4 mg/kg γ-T [L-γ-T]). These dose levels were determined from dose-range finding study and considered to be the Maximum Feasible Dose levels,
based on the volume of 10 mL/kg and physical properties/viscosity of the test articles that could be safely administered to rats by an I.V. injection. Two weeks after treatment (Day 15), all animals were sacrificed and submitted for gross necropsy, clinical pathology investigations (haematology, coagulation, clinical chemistry and urinalysis) with a comprehensive range of organs submitted for histopathological evaluations. The rats in the control group (EL) and three test groups exhibited no clinical signs of toxicity during the dosing period or during the 14-day post-treatment period. Weight gain and food consumption in all animals was appropriate for the age and sex of animals. Clinical pathology findings were unremarkable in all rats and in all groups. However, WBC counts in male rats treated with L-tyr-NAC formulation were below the lower end of the normal range although gross necropsy and histopathological observations were not of any toxicological significance. In conclusion, the results of this study showed no drug/treatment related toxicity in rats at the maximum feasible dose level by a single bolus intravenous administration. This work was funded by a grant (W81XWH-06-2-0044) from the Department of Defence, USA.

258 PLATELET COUNTING IN ANIMALS—BACK TO BASICS.

Rationale and scope: Platelet clumping is an important and common problem in laboratory animal species, particularly in Mini-pigs. In addition to reducing platelet counts, clumping may result in inaccurate gating of erythrocytes and leukocytes, pseudoleukocytosis, or trapping of leukocytes and erythrocytes. Our objective was to investigate the effects of pre-analytical variables on platelet counts, and the relevance of platelet clump flags generated by an automated hematology analyzer. Experimental procedures: In a study of Mini-pigs, blood was collected into tubes containing EDTA or CTAD and stored at -80°C. Three different experimental conditions were investigated. The Advia 120 analyzer was used to measure the platelet count (PLT) and the ‘Clump count’ (CC). May Grunwald/Giemsstained blood films were used to assess platelet morphology. EDTA samples were also investigated in dog, sheep and rabbit. Summary of results: In Mini-pigs the use of CTAD anticoagulated tubes resulted in higher PLT and lower CC when compared to EDTA. For EDTA and CTAD, storage at 4°C reduced the PLT by 10%, but had no effect on the CC; mixing (inversion or rotary mixer) had no effect on PLT or CC. The PLT was stable for 4 hours at room temperature. Blood smear examination confirmed the presence of platelet aggregates when the CC was elevated. Conclusions: In Mini-pigs, the use of CTAD as an anticoagulant results in fewer CC flags with lower CC and higher PLT than EDTA. In our hands, the CC flag was a useful alert regarding clumped platelets.

259 FLUOROALKYL METHACRYLATE COPOLYMER AQUEOUS DISPERSION: SUBCHRONIC TOXICITY EVALUATION IN RODENTS.

B. Singh1, S. S. Anand1, R. C. Buck2, J. M. Lewis1, S. R. Frame1, T. L. Sera5, G. P. Sykes1 and S. E. Loveless1. DuPont Haskell Global Centers for Health and Environmental Sciences, Newark, DE and 2DuPont Chemicals and Fluoroproducts, Wilmington, DE.

A fluoralkyl methacrylate copolymer aqueous dispersion comprised of a short-chain methacrylate monomer, 2-chloroethyl methacrylate, a medium-chain methacrylate monomer F(CF2)6(CH2CH2OC(CH3))=CH2, was evaluated in one-gen reproto and repeated-dose toxicity studies. Four groups of young adult male and female Crl:CD(SD) rats were daily administered test substance by oral gavage that contained 0, 100, 500 or 1000 mg/kg/day of test substance for approximately 90 days. No primary test substance-related effects on mortality, clinical signs, neurobehavioral assessment, body weight, nutritional parameters or clinical pathology were observed at any dose. Treatment related adverse nasal lesions consistent with regurgitation rhinitis were observed in males and females at ≥100 mg/kg/day. Clearance of test substance and complete resolution of the associated inflammatory response did not occur following a 1-month or 3-month recovery period. Since posterior nasal regions were most affected, with foreign material present within the inflammatory exudates, reflux and retrograde aspiration of irritant material (possibly stomach contents with test formulation) into the nasal cavity were suspected. Therefore, nasal lesions are likely secondary to gavage reflux rather than primary target organ toxicity or gavage error. The underlying cause of the apparent reflux is uncertain. Nasal lesions similar to the repeat dose study were also observed in a one-generation reproductive study where P1 rats were administered test substance (25/sex/group) daily at 0, 20, 100, 500, or 1000 mg/kg/day for at least 109 days. In the one generation reproductive study, the NOAEL based on nasal lesions was 20 mg/kg/day in males and 100 mg/kg/day in females. No effects on reproductive endpoints at any dose were observed at any dose. The test substance is not a selective reproductive toxicant. Therefore, taking both studies together, the NOAEL for rats based on these type of nasal lesions was > 20 and < 100 mg/kg/day.

260 SUBCHRONIC INHALATION EXPOSURE OF RATS TO LIBBY AMPHIBOLE AND AMOSITE ASBESTOS.

Exposure to Libby amphibole (LA) is associated with significant increases in asbestos, lung cancer, and mesothelioma. To support biological potency assessment and dosimetry model development, a subchronic nose-only inhalation exposure study (6 h/d, 5/ wk, 13 wk) was conducted in male F344 rats. Rats were exposed to air (control), LA (LO, MED, HI; 1.01, 3.33, 10.08 mg/m3 gravimetric concentration: 43, 171, 280 particles/cc by APS, respectively), or amosite (AM; 3.35 mg/m3; 404 particles/cc). No clinical findings were observed during the exposures though average body weights were 4% lower than controls in the AM group for weeks 2-14. One day after final exposure, significant increases in BAL LDH (2-2.5x) and total protein (1.5-1.7x) were found in MED and HI LA groups, but no significant changes were found in the AM group at the same mass exposure as MED LA. BAL ALP and NAG concentrations were similar in all exposure groups including the control. Changes observed in BAL cells were significant decreases in percentages of macrophages (59% vs. 90%) and increases in percentages of lymphocytes (1.4x) and neutrophils (4x) in HI LA vs. control. Histopathological examination of the lung found a minimal increase in alveolus inflammation, interstitial fibrosis, bronchiolization, and foreign body presence in all rats (8/8) in LO LA, MED LA, and AM groups compared to controls. Alveolus inflammation was more severe (6/8) in HI LA rats. The HI LA group showed increasing bronchiolar epithelial hyperplasia (8/8 were minimal grade). Other groups of rats were necropsied 1 and 3 months post-exposure (also 8/group), with the final necropsy planned for 18 months post-exposure (50/group). Tissue fiber burdens are being determined to support dosimetry model development. Results show comparable inflammatory and fibrogenic responses 1 day after subchronic exposure of rats to LA and AM asbestos. (This abstract does not represent US EPA policy.)

261 UTILIZING A COMPREHENSIVE APPROACH FOR SAFETY ASSESSMENT OF COSMETIC INGREDIENTS: A CASE STUDY.

F. Liu, V. Tu and M. D. Helman. Revlon Research Center, Edison, NJ.

Safety assessment of cosmetic ingredients is a critical part of cosmetic product safety review. Conventional safety assessment largely relies on toxicological data from animal testing. Due to recent European Union regulations and public support to stop testing cosmetic ingredients on animals, toxicologists face challenges of conducting safety assessment of new chemicals without employing animal testing. There are only a limited number of validated in vitro methods are available for risk assessment. In particular, lack of animal subchronic/chronic data prevents toxicologists from conducting the traditional Margin-of-Safety (MoS) based risk assessment. To address the challenges, we present here a comprehensive approach that combines investigative data with predictive toxicology to conduct risk assessment on a model chemical, diglycerin. Data on acute toxicity, skin and eye irritation, skin sensitization, and mutagenicity were obtained from investigatory studies. To fill the data gap of subchronic/chronic toxicity, an in silico approach was applied. The chemical was screened by DEREK and OECD QSAR Toolbox for structural alerts, and by US EPA T.E.S.T. and Acetelon's OSIRIS Property Explorer for potential reproto/developmental toxicity. In addition, three structurally similar analogues were identified by using the OECD QSAR Toolbox and US EPA AIM programs. The analogues’ subchronic/chronic and reproductive/developmental toxicity data were reviewed. The lowest no observed adverse effect level (NOAEL) among these studies was conservatively used as the point of departure in risk assessment. Exposure assessment was conducted to obtain systemic exposure dose by taking the actual skin penetration into account. Based on the calculation of MoS and the application of an additional uncertainty factor, we concluded that diglycerin is safe to use for the target product types and use levels. The framework proposed in this report represents a feasible approach to fulfill safety assessment in the absence of relevant systemic toxicological data.

262 EVALUATION OF STRAIGHT CHAIN UNSATURATED ALDEHYDES IN A LOCAL LYMPH NODE ASSAY.

J. Scognamiglio, J. Lalka and A. Api. Research Institute for Fragrance Materials, Woodcliff Lake, NJ.

Local lymph node assays (LLNA) were conducted on hexen-2-al, 2-octenal, trans-2-nonenal, and 2-tridecenal to determine their potential to induce dermal sensitization. These materials are all straight chain unsaturated aldehydes with a variety of
uses which include application in fragrances. The materials tested have limited sen-
sitation data available and are all expected to have similar chemical reactivity; the
only difference between the materials is their carbon chain length (6, 8, 9, and 13
carbons, respectively). The variation in chain length can affect the potential for sen-
sitation as shorter carbon chains would be expected to have an increased volatility,
decreasing the amount of material available for absorption under non-occlusive
conditions. Each material was tested according to OECD guideline 429 in female
CBA/CA mice (5/group) at 5 concentrations ranging from 0.5 – 50% w/v in 1:3
ethanol/diethyl phthalate using on the standard LLNA dosing regimen. The auricu-
lary lymph nodes were excised and pooled for each experimental group and incorpo-
ration of 3HThdR was measured by β-scintillation counting and expressed as de-
niturations per minute (dpm) per lymph node for each experimental group. The
stimulation index (SI) values were calculated for each dose level, with values ≥3
considered a positive response. The estimated concentration (EC3) required to el-
icit a positive response was calculated and taken as a measure of relative potency.
The EC3 values for hexen-2-al, 2-octenal, trans-2-nonenal, and 2-tridecenal were
calculated to be 2.6%, 5.6%, 2.1%, and 3.8%, respectively. Based on these values,
chain length does not seem to have an effect on the LLNA results, as all the materi-
als tested were found to be weak sensitisers with very similar EC3 values.

263 ESTIMATION OF THE CONSUMER INHALATION RISK OF WATERPROOFING SPRAYS.
C. Dassenbrock, M. Fischer, W. Koch and H. Windt. Fraunhofer Institute for
Toxicology and Experimental Medicine, Hannover, Germany.

Waterproofing sprays are widely used consumer products containing for example
fluorinated polymers or silicon based compounds dissolved in alcohols or volatile
petroleum distillates. There have been repeated reports on cases of severe acute res-
piratory disorders following inhalation exposure when using these products for the
first time. It is hypothesized that impairment of the pulmonary surfactant by deposition of in-
haled volatile particles of the active compound is one of the main causes of the
acute lung injury. Since the inhalation toxicity cannot be predicted a priori based on
the physical and chemical properties of the formulation, proper test strategies
are required to ensure consumer safety.

We propose to combine screening tests addressing both, exposure and acute lung
toxicity. The exposure potential of the spray product is characterized by determin-
ing the release fraction of the active compound in the respirable particle size range
under conditions relevant for the product application. This is carried out by spray-
ing defined quantities of the product into a control volume and measuring the con-
centrations of health related size fractions. This procedure takes into account spray
ageing, especially size reduction of the droplets due to solvent evaporation.
The isolated perfused lung is used as a model for testing acute toxicity. Ventilated
rat lungs are exposed to aged aerosols with proper particle size of approximately 1
μm MMAD generated from the liquid spray formulation. Lung compliance and
lung resistance are continuously monitored during exposure. Dose dependent devi-
ations from the normal values (without exposure) are used as read-out parameters.
Using the combined procedure, different sprays could be ranked according to their
realistic exposure risk and, most importantly, sprays with known lung toxicity could
be uniquely distinguished from those that have been shown to be safe. In its current
stage of development the simple test method is recommended for screening of sub-
stances only.

264 TOXICITY ASSESSMENT OF THE INSECTICIDAL PROTEIN Vip3Aa20, PRESENT IN GENETICALLY
MODIFIED MIR162 MAIZE PLANTS.
Syngenta Crop Protection, LLC, Greensboro, NC.

The Bacillus thuringiensis-derived Vip3Aa20 protein has insecticidal activity against several lepidopteran species and is expressed by Event MIR162 genetically
modified maize for the biological control of agricultural pests. As part of an overall
safety assessment, bioinformatics homology searches for amino acid sequence simi-
larities between Vip3Aa20 and known toxins, in vitro digestibility studies, and in
vivo toxicity studies were conducted. There was no significant sequence similarity
between Vip3Aa20 and any proteins known or putatively known to be toxic to
mammals. Vip3Aa20 was readily digested after incubation in simulated gastric fluid
containing pepsin, as assessed by SDS-PAGE and Western blot analyses. Vip3Aa20
was administered as a single oral dose via gavage to groups of 5 male and 5 female
mice at 0 or 1250 mg /kg body weight (BW) to assess the toxic potential of
Vip3Aa20. Animals were observed for 14 days following dosing. There were no
deaths or treatment-related effects on body weight, food consumption, clinical ob-
servations, clinical pathology, select organ weights, gross necropsy findings or
histopathological findings. Therefore the NOAEL for this acute oral toxicity study
was > 1250 mg/kg BW. Additionally, this protein was tested for potential toxicity
when administered repeatedly for a period of 28 days. Vip3Aa20 was administered
via gavage to female rats at dosages of 0, 5, 50, and 500 mg/kg BW per day. An additional group was administered bovine serum albumin to con-
roll for any effects of dosing a high concentration of non-toxic protein at levels
matched to the highest dose level of Vip3Aa20. There were no deaths or treatment-
related effects on body weight, food consumption, clinical observations, hematol-
omy, clinical chemistry, select organ weights, or gross necropsy findings. These data
support the conclusion that Vip3Aa20 is nontoxic to mammals and that Event
MIR162 maize is safe for use as food or feed.

265 TOXICOLOGY ASSESSMENT OF ORTHO-
PHTHALALDEHYDE (OPA) FOLLOWING 90 DAYS OF
INHALATION EXPOSURE IN MICE AND RATS.
S. A. Thakur1, G. L. Baker1, J. H. Roycroft1, L. M. Stask2, J. A. Dil1, D. B.
Bau1, G. S. Travlos1, D. R. Gerrnolds1 and M. E. Wyde2. 1Division of National
Toxicology Program, NIEHS, NIH, Research Triangle Park, NC. ; 2Batelle Toxicology
Northwest, Richland, WA and 3Integrated Laboratory Systems Inc. , Research Triangle
Park, NC.

Ortho-phthalaldehyde (OPA) is a chemical sterilizer used on heat-sensitive medical
devices and surgical instruments. Despite the rising popularity of OPA as a poten-
tial alternative to glutaraldehyde, very little is known about its toxicity profile.
Studies at NIOSH indicate that OPA concentrations in air samples from hospital
sterilizing units range from 0.001 to 0.0135 ppm. Occupational exposure to the
marketed concentrate of OPA (5.75%) is also not uncommon among healthcare
workers. The objective of this study was to characterize the potential toxicity of
OPA following inhalation exposure. B6C3F1 mice and Harlan Sprague-Dawley
rats (of both sexes) were exposed to 0.44, 0.88, 1.75, 3.5 and 7.0 ppm of OPA for 6 hours/ day, 5 days/ week for 90 days. Endpoints evaluated included body and organ weights, hematological assessment, and
histopathology. Following 90 days of treatment, there were dose-related decreases in
body weight and decreased survival in the mice and rats exposed to ≥ 3.5 ppm
OPA. Relative lung weights were significantly increased in both mice and rats ex-
posed to ≥ 1.75 ppm OPA. The spectrum of lesions noted following OPA exposure
included inflammation and necrosis of the cornea, nose, larynx, trachea and
bronchus. A NOAEL for the nose in either sex/species was not identified. Additional lesions included inflammation and epidermal hyperplasia in the skin.
Hematological analyses in mice exposed to 1.75 ppm OPA indicated de-
creased red cell mass suggesting a suppression of erythropoiesis. These studies
demonstrate that subchronic exposure of mice and rats to OPA leads to inflamma-
ition of the respiratory system with the most severe effects being in the upper respi-
ratory tract. These are preliminary results that have not yet been peer-reviewed by
the NTP.

266 6:2 FLUOROTOLEUMER ALCOHOL: FOUR WEEK
INHALATION TOXICITY STUDY.
T. L. Serex, C. Morris, R. C. Buck, S. E. Loveless and M. P. Delorme. DuPont
Haskell Laboratories, Newark, DE.

6:2 Fluorotolem Alcohol (CAS# 647-42-7, 1-Octanol-3,4,5,6,7,8,8,8
tracecycliclururo,-6.2 FTOH) is a raw material used for manufacturing surfactant and
polymeric surface protection products. Inhalation of the 6.2 FTOH vapor phase is
a potential route of human exposure for toxicity determination. In this 4-wk study,
four groups male and female Crl:CD(SD) rats were exposed whole body 6 hr/day,
5 days week to 0 ≥ 0, 1.0 ± 0.0087, 10. ± 0.057 or 100 ± 0.02 ppm 6.2 FTOH for
a total of 22 exposures (mean ± SD). Exposure to 6.2 FTOH demonstrated no
adverse effects on body weight, body weight gains, food consumption or food effi-
ciency. No test substance-related or adverse clinical signs of toxicity were observed
on the course of this study. Male and female rats exposed to 100 ppm 6:2 FTOH
demonstrated increased mean serum bilirubin levels when compared to the control
group and several females at this exposure level exhibited increased alanine amino-
transferase (ALT). All animals exposed to 100 ppm 6.2 FTOH demonstrated in-
creased mean absolute liver weights as well as increased mean liver weight relative
to body and brain weight. Male rats exposed to 100 ppm 6:2 FTOH also demon-
strated decreased motor activity during the 4th week of exposure. Changes in
bilirubin, ALT, liver weights and motoractivity in animals exposed to 100 ppm re-
solved following a 4-week recovery period. Microscopic findings were limited to the
incisor teeth of male and female rats exposed to 100 ppm 6.2 FTOH observed as
basophilic striations within the inner dentin. This change is a common finding in
rats following exposure to fluorescence-containing compounds, was not associated with
changes in odontogenic epithelium and was considered non-adverse. Therefore,
derunder the conditions of this study, the NOAEL for 6.2 FTOH is 10 ppm. These
findings correlate well with the great weight effects observed in oral studies with 6:2
FTOH and indicate a lack of a route of entry effect. Therefore, route-to-route ex-
trapolation for systemic effects is appropriate for risk assessment of this material.

SOT 2012 ANNUAL MEETING
56
Exciptents are pharmaceutically inactive compounds in drug products that serve different functions, such as, diluent, binder, coating agent. Various excipients are used based on the medication form and route of administration. Polyoxyethylene sorbitan fatty acid esters (polysorbates) are widely used in cosmetics, food products, oral, parenteral, and topical pharmaceutical formulations. Polysorbate 80 is a commonly used excipient in parenteral formulations as an emulsifier, solubilizer, and to stabilize aqueous formulations of medications. Formulations intended for intravenous administration are typically qualified for use using an in vitro hemolysis assessment. The hemolytic potential of polysorbate 80 concentrations in routinely used vehicles was assessed with rat and human blood. Briefly, mixtures containing blood substrate (blood diluted to give an absorbance value of 0.8 - 1.2 upon complete hemolysis) and each vehicle were diluted and incubated under static conditions for 30 minutes at 37°C. A hemolytic index for each vehicle formulation was determined by comparing the optical density determined spectrophotometrically in the test article samples to a scale between 0 and 100% hemolysis. Polysorbate 80 has been used at 0.1% in intravenous formulations for humans. The hemolysis assay performed with vehicles containing 0.1% polysorbate 80 caused severe hemolysis of rat blood. Subsequent titration experiments showed that the vehicle mixtures containing less than 0.006% polysorbate 80 were non-hemolytic to rat blood. Also, addition of rat plasma to the assay mix with 0.1% polysorbate 80 vehicle mixtures reduced the hemolytic potential suggesting partial binding to polysorbate 80 may limit the hemolytic potential. In contrast, vehicles containing polysorbate 80 failed to induce lysis of red blood cells obtained from human donors at concentrations up to 2.5% polysorbate 80. It will be useful to understand the hemolytic potential of polysorbate 80, a commonly used intravenous excipient, in other animal species to determine limits for use in preclinical studies.
in contrast to publically available assessments that suggest preservatives are prima-
arily used in adult-intended products. Results of animal studies conducted to deter-
mine the developmental effects of parabens suggest that this group of substances
may have developmental and reproductive effects when used in sensitive popu-
lations. Further studies suggested that parabens may also cause sensitization reac-
tions. Results of toxicology studies conducted using the preservatives MCI and/or MI
suggest that they may be acutely toxic via the oral and dermal routes of expos-
ure. Using the results of these studies and exposure scenarios developed by our
group, we analyzed the margins of safety for use of these preservatives in children’s
products. Our analysis suggests that these preservatives are often present in child-
intended products at levels that exceed their safe level for use. The results of our
studies suggest that several preservatives found in child-intended consumer prod-
ucts have the potential to be a safety concern following foreseeable (mis)use and
emphasize the need for realistic exposure considerations for these types of products.

272 GENETIC TOXICOLOGY DATA PLAY AN INTEGRAL ROLE IN THE SAFETY ASSESSMENT OF DIETARY SUPPLEMENTS CONTAINING NEW DIETARY INGREDIENT(S).
N. Anyangwe1, D. Levy2, R. Gudi2, A. Abdel-Rahman2, E. Enongene2 and D. Fabricant3. 1Oak Ridge Institute for Science and Education Fellowship Program, Division of Dietary Supplement Programs, Center for Food Safety and Applied Nutrition, US FDA, College Park, MD and 2Division of Dietary Supplement Programs, Center for Food Safety and Applied Nutrition, US FDA, College Park, MD.

Dietary Supplement Health and Education Act (DSHEA) of October 15, 1994
mandates the submission of a pre-market safety notification for dietary supplement
products containing new dietary ingredients (NDI). Other evidence of safety
includes published literature and unpublished toxicological studies including
genetic toxicity studies. The genetic toxicology data concerning the NDI can be
evaluated and interpreted in the context of documented history of safe use, if pro-
vided, and the proposed conditions of use. For example, if a botanical that is widely
used as a conventional food is positive in an in vitro genetic toxicity assay, using
the weight of evidence approach, its long history of safe use can balance the
signal. On the other hand, negative in vitro and in vivo genetic toxicity data on a test
substance derived from the root of a plant may be of questionable relevance for an
NDI derived from leaf because the two likely differ in their chemical composition.
Furthermore, a negative Ames test is of limited relevance for the safety assessment
of a botanical which contains methylleugenol and estragole that have been shown to
cause cancer in rodents but are also known to be negative in Ames and/or other
short-term studies. In general, these case studies indicate that genetic toxicology
data play an integral role in the safety assessment of a dietary supplement contain-
ning NDIs. In the draft New Dietary Ingredient Guidance for industry, the FDA
proposed genetic toxicity testing for some but not all NDIs.

273 IS DERMAL SENSITIZATION FOR 1, 2-
BENZISOTHIAZOLIN-3-ONE [BIT] IN CONSUMER
PRODUCTS A CAUSE FOR CONCERN?

1,2-Benzisothiazolin-3-one (BIT, CAS # 2634-33-5) is a preservative in widely
used consumer products, such as sunscreen, laundry and dish detergents, and hard
surface spray cleaners. Dermal exposure to BIT is known to cause skin sensitization
and allergic contact dermatitis in animal and susceptible humans following specific
doses. In general, once an individual is sensitized (e.g., receives an induction dose),
the excitation of a skin reaction may occur at lower exposures (e.g., μg/cm²). The
purpose of this study was to identify the concentration of BIT in various consumer
products where skin sensitization is unlikely to occur during normal use. It is well
established that the potential for skin sensitization is based on the mass of product
applied per unit area of skin (mg/gm²). In this study, the BIT exposure which was
thought to not pose a sensitization hazard (to those sensitized or not sensitized) was
estimated by dividing the NOEL for induction by a safety factor. Published data
from human patch test studies reported that the no expected sensitization induc-
tion level was 45 μg/ cm². We then assigned and applied safety factors for sunscreen
(300) and cleansing products (100) based on interindividual differences, the matri-
ces, and the product use. The amount of product applied to the skin (mg/cm²) and
the estimated “safe doses” were used to calculate the concentration of BIT for sun-
screen lotion, laundry detergent, dish detergent, and spray cleaner that would be
unlikely to induce skin sensitization in any consumer. Our quantitative risk assess-
ment results were compared to the BIT content in these consumer products to de-
termine if they are likely to be safe for a majority of users.

274 LOCAL TOLERANCE OF SUBCUTANEOUSLY
ADMINISTERED 2-HYDROXYPROPYL-β- CYCLODEXTRIN (HPβCD).
B. L. Soldo1, B. T. Walker1, J. Janusz1, L. Smith1, M. Luksic2, J. Daniels2 and K. Peters1. 1Akeliah Therapeutics, Cincinnati, OH and 2Intrinsic Health Sciences Inc., Mississauga, ON, Canada.

Cyclodextrins (CDs) interact with drug molecules to increase solubility and stabil-
ity by forming inclusion complexes, thereby making CDs useful excipients for
pharmaceutical dosing. The nonclinical use of HPβCD has shown increased solu-
bilità and greater systemic safety relative to other CDs (primarily oral and IV data),
although data by the subcutaneous (SC) route are lacking in the literature. Local
tolerations to SC injection can be a challenge due to local high concentrations and/or
volumes of the drug and vehicle excipient. In acute local tolerances studies
using Sprague-Dawley rats, SC injection of HPβCD or other excipient vehicles (in-
cluding PEG400 and Poloxamer) resulted in injection site microscopic findings at-
tributed largely to the vehicle, volume of vehicle, and/or the trauma caused by the
injection procedure. In contrast to control vehicles (0.9% Saline, 5% Dextrose)
with findings limited largely to subacute inflammation, SC injection of the excip-
ient vehicle formulations resulted in varying incidence and severity of inflammation,
necrosis, and congestion at the injection sites. Adverse effects were most prominent
with SC injection of formulations in Poloxamer or PEG400. For HPβCD formula-
tions (25%, β2−HOH), SC injection was clinically well tolerated, while the severity
of inflammation and necrosis was slightly increased with higher concentrations of
cyclohextrin. The severity and extent of local findings were also greater at larger injec-
tion volumes (3.5 mL/kg) relative to lower volumes (1 mL/kg). Repeat-dose toxi-
cology studies in Sprague-Dawley rats and Beagle dogs confirmed the minor
injection site findings observed with 10% HPβCD at 1 mL/kg in local toleration
studies. Following drug-free recovery periods, inflammation and fibrosis persisted
at decreased severity whereas necrosis was absent at the injection sites. In conclu-
sion, a 10% HPβCD formulation was well-tolerated locally and systemically fol-
lowing repeated SC administration at a dose volume of up to approximately 1
mL/kg in rats and dogs.

275 POLYMERIC FLAME RETARDANTS: POSSIBLE LESS
HAZARDOUS ALTERNATIVES TO DECBROMODIPHENYL ETHER?
C. Williams1, D. Krause1 and R. Freeman2. 1Environ International, Tampa, FL and 2Freeman Consulting, Inc., Tallahassee, FL.

Damages from the approximately 12 million fires per year in the United States,
Europe and China amount to nearly $317 billion. One contributing factor to the
increased incidence of fires is the widespread use of flammable plastics in electrical
and electronic devices found in residential and industrial products. Use of flame
 retardants (FRs) in plastics reduces the incidence of fire with the added benefit of re-
ducing potentially toxic smoke emissions from fires that do occur – e.g., PAHs,
PCBs, PCDs and PCDFs. Owing to health and environmental concerns, exten-
sively-used halogenated FRs such as decabromodiphenyl ether, or decBDE, are
being phased-out of commerce in the United States by 2013. As a consequence, FR
manufacturers have been considering alternatives to decBDE. An approach to for-
mulating newer and more environmentally-friendly brominated FRs is to produce
large molecular weight compounds – polymeric FRs – that are limited in their abil-
ity to cross biologic membranes and interact with cellular macromolecules. We re-
viewed the health and environmental effects of polymeric FRs, relying principally
on published data in the scientific literature. If information in the public realm was
lacking and/or available from industry sources – e.g., FR producers or suppliers – health
and environmental effects data were supplemented with such ‘in-house’ data where appropriate. Health effects studies reviewed included acute toxicity, sub-
chronic and chronic toxicity, mutagenicity/genotoxicity, and carcinogenicity. Environ-
mental effects studies reviewed included aquatic toxicity, environmental fate/transport, and environmental persistence/bioaccumulation. All health and en-
vironmental effects data for the polymeric FRs were compared to the corresponding
data for decBDE. Results of the analysis indicated that, by most measures, the
polymeric FRs displayed a more favorable health and environmental profile
than decBDE and thus may be a considered viable alternatives to decBDE in
consumer and industrial products that require FRs.
276 SAFETY ASSESSMENT OF CYTOSOL+™ BOTANICAL METABOLITES AS AN ANTIDIARRHEAL AGENT.
S. B. Patel1,2, C. Chen3 and G. Wai4, 1Product Solutions Research, Davis, CA, 2Animal Science, University of California Davis, Davis, CA, 3Animal Technology Institute Taiwan, Niaoli, Taiwan and 4LiveLeaf Bioscience Corporation, San Carlos, CA.
Botanical polyphenols are one of the largest and most ubiquitous groups of secondary metabolites that are an integral part of the human diet. Clinical studies shown that polyphenol intake is associated with a reduced risk of cancers and cardiovascular and neurodegenerative diseases. Cytosol+™ comprised primarily of green tea and pomegranate polyphenolic extracts, demonstrated significant gastrointestinal health benefits and a broad-spectrum microbial inhibitory effect with very low daily intake. An E. coli 0149:K88 challenge study in pigs showed a significant reduction in the severity and duration of pathogen induced diarrhea, reduced fecal shedding, and increased proliferation of mucosal cells as evidenced by histometry. Increased villi crypt depth in treated animals also suggests direct protective effects on mucosal tissue. To evaluate the safety of Cytosol+™, a 28-day toxicity effect in weaned SPF piglets was investigated. Piglets (n=10) were randomly divided into three groups and orally inoculated either with water (control), or 50x or 500x of daily treatment dosage of Cytosol+™. Clinical disposition, blood chemistry, and histopathology were examined. Cytosol+™ did not show toxic effects at either dose levels after 28 days chronic use. No significant difference in histological analysis of the major organs was found. The safety and tolerability of oral administration of Cytosol+™ was further evaluated in a clinical trial in patients with infectious diarrhea. No adverse effects were observed in test subjects and results also indicated that Cytosol+™ is more effective than conventional anti-diarrheal pharmaceutical agents such as loperamide, anti-emetics and antibiotics. This study concluded that Cytosol+™ had no toxicological effect up to 500 times the daily treatment dosage and may serve as a safe and effective therapeutic alternative for gastrointestinal distress.

277 EFFECTS OF EXPOSURE TO ETHYL TERTIARY BUTYL ETHER AT LOW CONCENTRATIONS IN ALDH2 KNOCKOUT MICE.
Ethyl Tertiary Butyl Ether (ETBE) is used by mixing with gasoline for vehicles. ETBE is low toxicity and it’s No Observed Adverse Effect Level was thought to be 500 ppm in experimental animals. In our previous study, we found that in Aldh2 knockout mice, ETBE could induce damages in chromosomes and reproductive system even at 500 ppm. The present study was aimed at clarifying if ETBE has any effect on reproductive and other systems in mice at low concentrations. METHODS: Male C57BL/6 strain (WT), Aldh2+/+ (HT) and Aldh2-/- (KO) at 8 weeks were exposed to ETBE at 0, 50, 200 and 500 ppm, 6 hr/day and 5 days/week, for 9 weeks. Blood, liver, testes, epididymides and vasa deferentia were sampled 20 hr after the last exposure. Sperm from the cauda epididymides, and vas deferentia were released into a medium, and sperm motion was analyzed. RESULTS: There was no effect of ETBE exposure on the ratio of liver to body weight, and neither any change in the hematology in any exposure group. As for the reproductive system, the ratio of testes or epididymides to the body weight was not observed for any genotypes of mice. In WT mice, ETBE exposure did not affect the motility of sperm. In HT mice, there was a significant decrease in the motile percentage and sperm count. No adverse effects were observed in HT mice. The present study was aimed at clarifying if ETBE has any effect on the ratio of liver to body weight, and neither any change in the hematology in any exposure group. As for the reproductive system, the ratio of testes or epididymides to the body weight was not observed for any genotypes of mice. In WT mice, ETBE exposure did not affect the motility of sperm. In HT mice, there was a significant decrease in the motile percentage and sperm count.

278 HAZARD EVALUATION OF A SHORT-CHAIN FLUOROROTELOMER ALCOHOL PHOSPHATE MIXTURE.
S. S. Anand1, T. L. Seres1, R. A. Hoke2, R. C. Buck2, C. Carpenter1, M. Donner1 and S. E. Lovelace1, 1Haskell, DuPont, Newark, DE and 2Chemicals and Fluoroproducts, DuPont, Wilmington, DE.
The toxicity profile of a short-chain fluorotelomer alcohol phosphate mixture was evaluated. This substance has low acute toxicity potential by the oral and dermal routes (LD50 >5000 mg/kg), is not an irritant to the eye or skin, and did not cause skin sensitization in the LLNA assay. It was not mutagenic in the Ames test or in the in vitro chromosomal aberration assay. The 96-hour LC50 in fathead minnows was > 120 mg/L, 96-hour LC50 in zebra fish was > 150 mg/L, 48-hour EC50 in Daphnid was 16.2 mg/L, and 72-hour EC50 in algae was > 120 mg/L. The 21-day no-observed-effect-concentration (NOEC) in Daphnid was 0.409 mg/L. The repeated dose toxicity potential was assessed by administering 0, 5, 25, and 125 mg/kg/day via oral gavage to SD rats for 28 days. Main study animals (10 rats/sex/group) were sacrificed at the end of the dosing period. One-Month Recovery (5/sex/group) and toxicokinetic (5/sex in the 5 mg/kg/day group) animals were sacrificed approximately one month after the dosing period. The toxic compo-

279 EFFECTS OF SUBCHRONIC ADMINISTRATION OF THE ETHANOLIC EXTRACT OF CARPOLOBIA ALBA STEM ON SOME HAEMATOLOGICAL AND SERUM LIPID PARAMETERS IN RATS.
The high cost of the potent antimalarials, artesminin combined therapies, coupled with the resistance of P. falciparum to other conventionally used antimalarials has left the poor masses of the tropical regions of the world heavily reliant on herbal preparations for the treatment of the devastating disease, without considering the possible toxic effects. This study was aimed at evaluating the effect of subchronic administration of the ethanolic extract of Carpolobia alba stem, an antimalarial herbal remedy in Southwestern Nigeria, on some haematological and serum lipid parameters that could serve as cardiovascular disease indices in albino rats. Twenty-five (25) albino rats were randomly divided into five groups (A, B, C, D and E) of five rats each. Ethanolic extract of Carpolobia alba stem was administered to rats in groups A, B, C and D at the doses of 31.25, 62.5, 125 and 250 mg/Kg body weight respectively for twenty-one days while group E, which served as the control, received the appropriate volume of the vehicle (5% DMSO solution). At the end of the experimental period, venous blood was collected from the animals and full blood count coupled with serum concentrations of HDL-cholesterol, LDL-cholesterol, triglycerides, and total-cholesterol were determined. Also the atherogenic index was calculated. The extract did not cause any significant alteration (P>0.05) in the red blood cell indices, white blood cell indices and serum concentrations of HDL-cholesterol, LDL-cholesterol, total-cholesterol and the atherogenic index at all doses administered compared to controls while it significantly increased (P<0.05) serum triacylglycerol concentration at the dose of 250 mg/kg body weight compared to controls. The results of this study suggest that Carpolobia alba stem extract may not predispose subjects to cardiovascular diseases when administered below 250mg/kg body weight.

280 TOXICOLOGICAL ASSESSMENT OF A PEDIATRIC ORAL REHYDRATION SOLUTION (PEDIAONE™).
S. B. Patel1,2, S. Z. Stone1, D. R. Hattem and K. Shah1, 1Product Solutions Research, Davis, CA, 2Animal Science, University California Davis, Davis, CA, 1H2O Innovations, LLC, Birmingham, MI and 2Allergy and Immunology, Pediatrics Division, Mayo Clinic, Rochester, MN.
Diarrhea is a common illness in children, resulting in at least 200,000 U.S. hospitalizations and hundreds of deaths per year. UNICEF and WHO recommends pediatric oral rehydration solutions (ORS) for therapeutic treatment of dehydration as well as zinc supplementation. PediaONE™ is a safe and effective zinc-supplemented ORS which also provides a recommended percent daily value of vitamins and minerals typically lost during dehydration: Vitamin C, calcium, Vitamin B3, Vitamin B5, Vitamin B6, and Vitamin B12. To demonstrate the safety of PediaONE™, we conducted a series of toxicity tests at a GLP compliance laboratory. Acute oral and acute dermal toxicity tests were conducted in rats to determine the potential for PediaONE™ to produce toxicity from a single dose via the oral route and topical application. Under the conditions of these studies, the acute oral LD50 of PediaONE™ is <5,000 mg/kg, and acute dermal LD50 of PediaONE™ is <2,000 mg/kg. In a Primary Eye Irritation toxicity study in rabbits,
minimal conjunctivitis was observed 1 hr after instillation, however irritation decreased thereafter. The Maximum Mean Total Score of PediaONE™ 1.0 and was classified as minimally irritating to the eye. In a Primary Skin Irritation study in rabbits, very slight erythema was observed within 1 hr of patch removal, however severity of irritation decreased thereafter. The Primary Dermal Irritation Index for PediaONE™ is 0.2 and classified as slightly irritating to the skin. All animals were free of eye and dermal irritation by 48 hours. Throughout the studies all animals appeared healthy and there were no other signs of gross toxicity, adverse pharmacologic effects, or abnormal behavior. These studies demonstrate the safety of PediaONE™, a novel pediatric oral rehydration solution.

281 SUBACUTE EFFECTS OF ORAL LEAD ACETATE ON BLOOD PARAMETERS AND GI MICROBIAL ANTIBIOTIC RESISTANCE IN JUVENILE CHICKENS.
'Department of Anatomy and Radiology, University of Georgia, Athens, GA, 'Savannah River Ecology Laboratory, University of Georgia, Savannah, GA and 'Population Health, Poultry Diagnostic Research Center, University of Georgia, Athens, GA.

Lead (Pb) is a common heavy metal contaminant released into the environment and can result in growth inhibition, reproductive retardation, immune suppression, metabolic alteration, and impaired neurological function in chickens. Chickens are an important animal model due to their close association with humans through food production and consumption. Preliminary in vitro studies showed an unexpected increase in antimicrobial resistance in bacteria cultured with low levels of Pb. This study was conducted to determine if sub-acute oral exposure to Pb may similarly alter microbial antibiotic resistance in gut bacteria of white Leghorn chickens. Positive data would suggest increased difficulty managing pathogen outbreaks in flocks exposed to Pb. Fifty specific pathogen free Leghorn chickens (2 week old, male and female) were administered 0.0, 0.01, 0.1, 1.0, or 10.0 mM Pb acetate through drinking water for 14 days. Birds were bled and weighed, and cloacal swab samples were taken on day 0, 7, and 14. Birds were euthanized on day 14 and sections of the liver, spleen, kidney, and brain were collected. Blood physiologic parameters were not changed by Pb exposure with the exception of delta aminolevulinic acid dehydratase (d-ALAD) activity, which was suppressed by Pb. Unlike the in vitro results, no alteration in gut bacteria antibiotic resistance was observed in the Pb-exposed birds. This difference from the in vitro results could be due to the type (pathogen free) and age of the bird, the duration of Pb exposure, the form of Pb administered, or differences between in vitro culture and in vivo environments of the tested bacteria.

282 SOLVING THE DATA INTEGRATION PROBLEM FOR A SUPERFUND RESEARCH PROGRAM CENTER.
'Pacific Northwest National Laboratory, Richland, WA and 'Oregon State University, Corvallis, OR.

Superfund Research Programs (SRPs) are multi-disciplinary and multi-institutional to leverage the best science and solve complex environmental health issues. Success depends on the center's ability to effectively integrate data across all research projects and cores. Our SRP Center has developed a system that integrates environmental monitoring data with the analytical core operational data and downstream bioinformatics/statistics to enable complete ‘source to outcome’ data modeling. The system incorporates commercial software for operational laboratory management (LIMS) and sample management in addition to custom software for bioinformatics, experimental data management and a web-store for sharing chemical standards to all researchers in the program. By creating a pipeline that integrates these systems together into a seamless workflow, we are able to use one set of identifiers throughout the workflow and keep data replication at a minimum. One successful example, the chemical standards repository web-store, uses the LIMS database to keep track of chemical inventory but maintains a separate data store for current requests and processing. For this workflow we’ve segregated the processing of sample IDs and chemical inventory so that we can easily incorporate other systems as necessary or easily replace any part of the workflow without rewriting the integration code. Through this and other data integrations we have been able to generate more repeatable and comparable results between projects while maintaining privacy and quality assurance compliance. We’ve also created a tool set that easily reports statistics and status to our collaborators and grantors through the web. These successes stretch our grant dollars by improving center efficiency and enhance collaboration between cores and projects at OSU and PNNL as well as case proposal collaboration with other organizations and governmental agencies. Supported by NIEHS grants P42ES016465 and P30ES00210.

283 CHEMICAL EFFECTS IN BIOLOGICAL SYSTEMS: A TOXICOLOGICAL DATABASE.
L. A. Hall1, H. Gong2, A. Pajela2, A. Rashid2 and J. M. Fostel1, 1DNTP, National Institute of Environmental Health Sciences, Research Triangle Park, NC and 2NTP Computer and User Support, Team Vistronix, National Institute of Environmental Health Sciences, Research Triangle Park, NC. Sponsor: C. Smith.

The Chemical Effects in Biological Systems (CEBS) is a toxicological database with a flexible design that can accommodate a wide variety of data types. CEBS houses toxicological study data from the Division of the National Toxicology Program (NTP), National Institute of Environmental Health Sciences and other government laboratories, pharmaceutical companies, and academic laboratories. NTP carcinogenicity and toxicology, genetic toxicology, immunotoxicology, as well as some reproductive and developmental toxicology study data are all available in CEBS. Also housed are the chemogenomics database DrugMatrix® data, microarray study data, and phase I high throughput screening Tox21 data. CEBS is designed and modified to accommodate new data and to meet the needs of the scientists in viewing, downloading, and searching data. CEBS stores raw data and contextual information — such as protocol information, dosing regimen, and subject characteristics — on each of the studies. The user interface allows a user to browse through the list of studies, view studies, download data, and search for studies or subjects across the database that meet personally chosen criteria. CEBS allows a user to gather animal data from different studies together for analysis. The number and diversity of study types together with its searching capabilities makes CEBS different than most other scientific databases. One of the advantages of CEBS is that the raw data from studies is accessible to users. Raw data from toxicological studies can be viewed, extracted, and downloaded, permitting custom meta-analysis. CEBS also allows statistical meta-analyses on housed normalized data. As the NTP expands into different research areas such as epigenetics, genomics, and new technologies such as next-generation sequencing, designed flexibility will permit integration of these data within CEBS and continue to make CEBS a valuable tool for toxicologists.

284 USING CTD TO DISCOVER AND PREDICT MOLECULAR CONNECTIONS BETWEEN ENVIRONMENTAL CHEMICALS AND HUMAN HEALTH.
C. G. Murphy, A. P. Davis, C. A. Saraceni-Richards, M. C. Rosenstein, T. C. Wieggers and C. J. Mattingly, MDIBL, Salisbury Cove, ME.

The Comparative Toxicogenomics Database (CTD: http://ctdbase.org/) is a freely available resource (funded by the National Institutes of Environmental Health Sciences) that promotes understanding about the effects of environmental chemicals on human health. Biocurators manually curate three types of data from the scientific literature: chemical (C)-gene (G) interactions, chemical (C)-disease (D) relationships, and gene (G)-disease (D) relationships. These data are then internally integrated as well as externally combined with Gene Ontology (GO) and Pathway (P) annotations to infer possible connections between all five components (C, G, D, GO, and P). CTD has greatly expanded its curated content, in part, as a result of a collaboration with Pfizer, Inc., involving the curation within one year of over 50,000 additional toxicity publications selected for four disease targets (cardiovascular, renal, hepatic, and neurological defects). These data are now integrated and freely available to all CTD users. To help navigate and analyze this vast information, CTD provides statistical, analytical, and visualization tools that allow users to retrieve, explore, and maximize the utility of the data, including a new feature called “DiseaseComps” which complements our existing “ChemComps” and “GeneComps” by identifying similar diseases, chemicals, and genes based upon shared toxicogenomic profiles, respectively. We are also in the development phase of curating and integrating phenotype (non-disease) and exposure data. Collectively, CTD’s wealth of information, data integration strategy, and unique analysis tools make it an unparalleled and flexible resource for understanding toxicology and developing hypotheses about the molecular mechanisms underlying environmental diseases.

285 TOXML, A COMMON DATA EXCHANGE STANDARD FOR TOXICOLOGY.
M. L. Patel1, M. A. Ali1, D. Wilkinson1, P. N. Judson2, K. P. Cross3 and D. A. Bowser4, 1Junas Limited, Leeds, United Kingdom, 2Judson Consulting Service, Harrogate, United Kingdom and 3Leadscope Incorporated, Columbus, OH. Sponsor: C. Marchant.

With rapid scientific advances in toxicology and changing regulatory requirements, the number of toxicity datasets available for those wishing to share and communicate knowledge, or to use for data mining and modelling is continually expanding.
The challenge with this ever-growing amount of data is that it exists in a multitude of different formats, depending on its source and original purpose. Different databases covering the same endpoint may omit or use widely differing conventions to structure and represent the same information. The issues of comparing or combining disparate data apply both to public and proprietary sources, and both historical and newly generated data. It is often laborious for individuals and groups to restructure their datasets in order to supply them to different investigators. The ToxML project addresses the need for a common data exchange standard that allows the representation and communication of this data in a well-structured electronic format to the user community. ToxML is an open standard based on the Extensible Markup Language (XML) format. We describe the utility of ToxML as a common data exchange standard for toxicology information, the mechanism for its dissemination and its community-based development in the future. An example of how ToxML is currently implemented and used in transactions involving large quantities of repeat-dose study data is described. The standard is open and maintained by a curation team overseen by the ToxML organisation. The standard is published on a website together with tools to view, edit and download it.

PS 286 EXTENDING THE DEREK-METEOR WORKFLOW TO PREDICT CHEMICAL-TOXICITY SPACE IMPACTED BY METABOLISM: APPLICATION TO TOXCAST AND TOX21 CHEMICAL INVENTORIES.

P. Volarath, M. Martin and A. Richard. US EPA, Research Triangle Park, NC.

A central aim of EPA's ToxCast project is to use in vitro high-throughput screening (HTS) profiles to build predictive models of in vivo toxicity. Where assays lack metabolizable capability, such efforts may need to incorporate the role of metabolic activation (or deactivation). A workflow combining two structure-based expert systems – Meteor (predicts bio-transformations) and Derek (predicts in vivo toxicity) – was previously developed and applied to identify ToxCast Phase I chemicals likely to require metabolic activation for rat carcinogenicity (Rat Carc). Positive and Negative Derek predictions for the parent structures [P+, P-] and for the Meteor-generated metabolites [M+, M-] were compared and validated using rat chronic study results from ToxRefDB. In cases where Derek has implicit knowledge of metabolic activation requirements associated with a structural alert (SA), the parent chemicals and associated metabolites are both predicted as rat carcinogens [P+/M+]. However, because the Derek knowledge-base is incomplete, some compounds trigger a positive Derek prediction only after the parent compound is metabolically transformed by Meteor, (i.e., [P-/M+]). We extended the workflow to combine metabolic activation-related knowledge implicitly contained in Derek SAs (through review of SA narratives) with that implied by the [P-, M+] outcomes of the Meteor-Derek workflow. In principle, the extended workflow enables the extraction of a set of meta-bolism (or deactivation) structural features in association with any Derek toxicity endpoint. This cheminformatics workflow is being applied to the full ToxCast Phase 1 & II (10,600 unique chemicals) and Tox21 (>8,600 chemicals) inventories to identify regions of chemical HTS space where in vitro to in vivo Rat Carc associations are more likely to be impacted by metabolism. These results will be used to inform future predictive modeling efforts. This abstract does not necessarily represent US EPA policy.

PS 287 REVISITING THE TTC APPROACH FOR CANCER ASSESSMENT: PART OF A ROAD MAP OF COMPUTATIONAL METHODS AT US FDA CFSAN OFAS.

J. Augst1, K. Arvidson1, D. Rua2, D. Hristosov1, B. Muga1, E. Matthews1, A. McCarthy1, C. Yang1 and M. A. Cheeseman1. 1CFSAN/OFS, US FDA, College Park, MD, 2CFSAN/OCA, US FDA, College Park, MD and 3Astatina LLC, Columbus, OH.

Alternative methods in risk assessment workflows are attracting attention due to international legislation on providing safety data for large numbers of chemicals. The Threshold of Toxicological Concern (TTC) is one method of interest and was developed based on the Threshold of Regulation (T0R) policy of US FDA Center for Food Safety and Application (CFSAN). TTC provides a mechanism for assessing the safety of low-exposure food-contact materials. The goal of this project is to aid regulatory risk assessment procedures by refining the TTC process. The first refinement is providing a cancer TTC dataset based on regulatory study review criteria. This process helps gain better regulatory acceptance and supports building a high-quality training set for other computational methods. The Carcinogenicity Potency Database (CDPB) was integrated into the Chemical Evaluation and Risk Estimation System (CERES) database at CFSAN. Study details and TD50 values were selected for the cancer TTC dataset only from studies in the CDPB that were in accordance with defined regulatory criteria (e.g., test substance administration routes, duration and sample size). To address gaps in available data, a first refinement is to incorporate known genotoxic mechanisms into the TTC decision tree. Positive and negative Ames assay data were curated from various databases. These data were then incorporated into and analyzed as part of the cancer TTC dataset. This analysis shows Ames positive carcinogens to be much more potent than Ames negative carcinogens. This analysis has two additional benefits. (1) The qualification of data through regulatory screening criteria increases the regulatory applicability and acceptance of TTC methods. (2) Our methodology provides a mechanism for incorporation of alternative and in vitro test methods into a regulatory risk assessment.

PS 288 CASE ULTRA: A NEW IN SILICO TOOL FOR QUANTITATIVE PREDICTION OF BIOLOGICAL ACTIVITY.

S. Chakravart1, R. D. Saiakhow1, M. A. Fuller1 and G. Klopman1, 2, 1MultiCASE Inc., Beachwood, OH and 2Department of Chemistry, Case Western Reserve University, Cleveland, OH.

Purpose of this study was to demonstrate a novel approach to build quantitative structure-activity relationships from diverse chemical structures with continuous biological activity data in a fully automated fashion. This in silico tool can be successfully used for assessment of potential toxicity or beneficial therapeutic effects of new drug candidates, impurities and metabolites. Case Ultra is a computer program that uses an algorithm to find structure-activity knowledge and can be used as both chemists and DRDBs completely automatically. Traditionally we have successfully used Case Ultra mainly in predicting binary activity outcomes (e.g. active/inactive or toxic/non toxic). Recently we have added a novel algorithm to Case Ultra to extend its capabilities to predict activity/toxicity on the continuous scale. This immediately makes the program equally useful in computational toxicology as well as in drug design discovery. The algorithm does not need any prior knowledge of different structural classes present in the training set and automatically divides the training set into representative classes and builds predictive QSARs for each class. We have applied Case Ultra to build predictive QSARs on very different benchmark datasets namely PTP1B inhibition, Daphnia LC50, DHFR inhibition, Estrogen Binders, COX2 Inhibitors etc. Besides being predictive Case Ultra also gives a very clear explanation of its predictions so that they are easily interpretable by chemists and toxicologists. The predictive performance and details of the QSAR models for different end points (e.g. PTP1B inhibition, Daphnia LC50, DHFR inhibition, Estrogen Binders, COX2 Inhibitors) are demonstrated. Various cross validation of the models shows a solid performance. For example average cross validated r2 of PTP1B (132 chemicals) and DHFR (397 chemicals) models are 0.66 and 0.52 respectively. Different chemical structural classes within each end point were also successfully identified.

PS 289 OPEN SOURCE PLUG’N PLAY PREDICTIVE MODELING METHODS USEFUL IN TOXICOLOGY.

L. Carlsson1, E. Ahlberg2, M. Ekblund1, 2, O. Spjuth2 and S. Bayr3. 1Computational Toxicology, AstraZeneca, Malmö, Sweden and 3Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden.

There is a wide range of different tools that can be used to create and use predictive models for toxicology related endpoints. For someone new to modeling and with an interest in applying models to her or his own data it might be quite time consuming to find which method and tools that are most adequate. Some of the existing tools are also quite costly and it is often not clear if there is any additional benefit with the increased costs. Furthermore, legislation like REACH demands a transparency which can be hard to fulfill for some of the commercial alternatives. We have developed a method to assess chemical liability of compounds based on data provided by the user of the system or by community models from for example OpenTox, which is called BioClipseDS. The method was implemented in BioClipse, using the Chemistry Development Kit, the Signature descriptor and libsvm. BioClipseDS has undergone more enhancements and can now be used as a plug’n play modeling and prediction platform, freely available to anyone with an open source that can be adapted to individual needs. The enhancements allow models to be built very quickly when datasets are provided in the SD-file format. Models can easily be built with thousands of compounds and based on different endpoints. When used for predictions, BioClipseDS shows an improved view and an overall assessment for all models. In an internal benchmark activity at AstraZeneca the method described here was the best in five out of ten cases. It was also the only method that could build a model on a data set with almost 100 000 compounds. Additionally, in this case this method also reduced the root mean square error on an external test set by almost 20% compared to the second best method. A selection of public datasets has been evaluated and the results are reviewed so that comparisons can be made of the performance of this method with other commonly-used modeling and prediction tools.
Male reproductive toxicants, manifest as testicular toxicants, and are among the top 6 target organ systems that result in project delays during the preclinical phases of drug development at AstraZeneca. Testicular toxicants are often not detected until pivotal 1 month studies are run during the preclinical phase and as a consequence, failures tend to be expensive, especially if the issue identified is related to the chemical scaffold of the development candidate. As such, there is a clear incentive to develop both in vitro and modeling methods to identify risks of testicular toxicity at a much earlier stage. For this purpose, we have developed a warning system aimed at testicular risk identification and mitigation. The warning system integrates data text mined from both public and internal sources via the PharmaConnect Knowledgebase. Using the knowledge base, compounds from public sources that relate to testicular toxicity were identified and integrated with internal reports (see poster on this method from Clark et al.). From these data, structural features that correlated with testicular toxicity were identified and form one part of the warning system as structural alerts. The second part is a predictive model of the in vitro RARa antagonist activity. RARa antagonism has been linked to testicular degeneration and can be used as an early marker for potential in vivo issues. The model is built on internal data and performance is in line with the experimental error in the range 65-80% correct classifications with sensitivity being in the lower range. In this study we present novel structural alerts related to testicular toxicity and show how these are used together with the QSAR model for risk assessment. We present performance statistics based on internal data and the application of a weight-of-evidence approach to give overall risk assessments.

**290 IDENTIFICATION OF TESTICULAR TOXICITY-RELATED RISKS IN EARLY DISCOVERY.**

Humans are exposed to chemicals based on the activities they perform. While the relationship between activities and near-field exposures have been greatly studied, an individual's near field exposures are difficult to ascertain because they vary based on that individual's personal product space. Key to understanding the relationship between activities and near-field chemical exposures is knowing which chemicals are in common household products. To achieve this goal, a workflow for quickly populating and curating a “personal chemical exposure” database linking products with their specific chemical components and ingredients was developed based on a large repository of publicly available Material Safety Data Sheets (MSDS) from a major retail chain (11,800 product MSDS). The resulting workflow utilizes Optical Character Recognition (OCR), chemical name and CAS identification software, and finally manually inspection through a straightforward multi-screen graphical user interface (GUI) to provide highly accurate identification of a products chemical components. Used in conjunction with ubiquitous computing (i.e. smartphone technology), 2D QR matrix codes, and bar-code scanner apps we demonstrate how a product chemical ingredient database can be used to inform an individual of the “Personal chemical exposure” by scanning real-life household/everyday products through the Augmented Reality for Exposure Awareness (AREA) tool. The workflow and tools are freely available allowing other to use the same techniques to create their own consumer product chemical database. The database, the first freely available and chemically searchable consumer product database, has been integrated into the Environment Protection Agency’s (US EPA) ACToR database for facile query by the public. This abstract has been cleared by the US EPA but solely expresses the view of the authors.

**291 CASE ULTRA: PREDICTIVE PERFORMANCE IN ASSESSING THE POTENTIAL CARCINOGENICITY, GENOTOXICITY, DEVELOPMENTAL TOXICITY AND ADVERSE IMPURITIES AND METABOLITES OF NEW DRUG CANDIDATES.**

M. A. Fuller, R. D. Saiakhov, S. Chakravarti and G. Klopman. MultiCASE Inc., Beachwood, OH.

The purpose of this study was to apply novel approaches in the creation of a superior data driven expert system for in silico toxicology capable of dealing with large sets of diverse chemicals with variable structural complexity without the necessity for additional animal testing. Such a system could be used for the assessment of the potential carcinogenicity, genotoxicity, developmental toxicity and adverse effects of new drug candidates, impurities and metabolites. CASE Ultra advances the MCASE fragment based approach, which breaks training set molecules into fragments with a predefined number of atoms and a predefined branching pattern. CASE Ultra uses a proprietary algorithm that automatically identifies substructures relevant to toxicity without having any limitation on their size or branching pattern. This results in increased exploratory capabilities and predictive performance of the models. The non-proprietary training data used to build the models were available through a Research Collaboration Agreement entitled “Enhancement of In Silico Decision Support Tools for the Evaluation of Drug Safety” between MultiCASE Inc and The US Food and Drug Administration’s Center for Drug Evaluation and Research. The models within each expert system were grouped to represent assays recommended by regulatory guidelines. Validation experiments were performed for each model individually and for groups of related models using standard leave-group-out and y-scrambling methods. The predictive performance of CASE Ultra carcinogenicity, genotoxicity, developmental toxicity and adverse effects expert systems is demonstrated. The results of our validations demonstrate a solid predictive performance with more balanced sensitivity and specificity than MC4PC, including overall concordance for Salmonella mutagenicity prediction above 75%.

**292 PARTNERING PREDICTIVE TOXICOLOGY WITH MEDICINAL CHEMISTRY FOR STRATEGIC DRUG DISCOVERY.**

L. L. McIntosh and C. Fishburn. Exponent Inc., Menlo Park, CA.

Translational research involves targeted drug design to address specific clinical challenges, and avoids the screening of large compound libraries. Improved in silico capabilities enable optimization of chemical structures by allowing prediction of likely toxicities, sometimes replacing or supplementing early screening of compounds, and increasing efficiency.

A risk characterization framework to classify nanomaterials based on their physical or chemical properties as well as their biological impacts is necessary to reduce the uncertainty around potential nanomaterial hazards. Structure-property relationships that can be used to predict nanomaterial impacts in lieu of empirical data can provide significant support for the nanotech industry in developing safer nanomaterials. Knowledge on the governing principles of nanomaterial-biological interactions can more effectively be utilized once computational tools are available for data integration and consensus analysis. The Nanomaterial-Biological Interactions (NBI) knowledgebase was developed to consolidate and integrate disparate data on
Today, drug discovery and development programs involve the generation of large amounts of in vitro and in vivo data, with the goal to ensure that potential drug candidates meet all the requirements needed to become new medicines. A significant part of the produced data comes from Non-Clinical Safety (NCS) organizations, whose efforts are aimed at ensuring that selected clinical candidates possess a suitable safety profile.

In modern drug discovery and analysis, knowledge generation, interpretation of results and hypothesis assessment are crucial. While in vitro data can be easily made accessible by a number of available IT solutions, the interaction with and the visualization of in vivo data generated by non-clinical safety (NCS) studies represent a real challenge. On one hand, each in vivo NCS study generates a number of specific data types, which are separately stored in independent Laboratory Information Management Systems (LIMS). Roche decided to commit to the Safety Data Integration (SDI) project with the clear goal to provide NCS experts with an application permitting rapid and easy access to all relevant in vivo NCS data, seamlessly integrated from active and decommissioned safety applications adopted in pertinent Roche sites worldwide.

The deployment of the SDI system to Roche scientists allowed them to have complete access to more than 3,500 in house in vivo studies and to perform highly complex queries such as: “Which compounds showed a 200% increase in Aspartate transaminase AND a 30% increase in liver weight AND necrosis in liver?” Roche, together with its partners, developed a fully integrated platform, which is currently unique in the non-clinical safety framework and represents the gold standard for in vivo NCS data repository, visualization and analysis.

The quality of environmental data collected and analyzed at a contaminated site is crucial in assessing risks to human health and the environment, as well as establishing cleanup levels. Data quality management should be implemented in all stages of a remedial investigation (RI), including field investigation, data evaluation and validation, database development and management, and data usability for risk assessment and other data users. Poor data quality used in risk assessments will result in expensive re-sampling, costly delays to remedial efforts, or worst yet, unnecessary remedial actions. Starting from the field investigation, a FORMS II Lite or Scribe software is used to minimize errors and shorten the sample documentation process. In addition, environmental data management software, such as Scribe and Environmental Quality Information System (EQuIS), provides automation for electronic data deliverable checks and submissions, including data verification of field parameters and validation of analytical data. Using these softwares and working closely with engineers, geologists, chemists, and other project team members throughout an entire RI will minimize errors and reduce costs. A case study demonstrates that an effective data management program has resulted in a significant cost saving. Most importantly, an effective data management in all stages of a RI ensures the high quality of data used in risk assessments; consequently, it provides technically sound and legally defensible risk management decisions.

The Department of Homeland Security (DHS) is mandated to develop and implement a capability for providing chemical threat awareness and assessment as applied to homeland security issues. The Chemical Security Analysis Center (CSAC), a knowledge management center under the DHS, was established to meet these needs. One area of focus for the CSAC is science and technology based assessments of specific hazards. The CSAC develops toxicologically informed comprehensive hazard assessments to determine expected public health impacts of the release of toxic chemicals. As part of the hazard assessment, the CSAC uses a series of computer modeling and dispersion tools to develop plausible scenarios that provide a realistic appraisal of acute public health consequences following the release of chemicals at various locations. Models predict population exposure and toxic effects for a given chemical, location, dissemination method, route of exposure, and amount of chemical released, in the presence or absence of effective countermeasures. Key modeling parameters are identified for each scenario that, when adjusted, produce larger or smaller numbers of exposures. Taking into account physical properties, mechanism of action, toxicity, environmental persistence, diagnostic and detection capabilities, and treatment options for each chemical, results of the consequence modeling are analyzed and used to guide medical mitigation decisions. This presentation will discuss a number of models the CSAC utilizes to develop scenarios such as release of chemicals in transportation hubs, office buildings, chemical production facilities, transportation vehicles, and in food or water. Models include the US Department of Defense (DoD) Hazard Prediction Assessment Capability model, the DoD Consequence Assessment Tool Set, the Sandia National Laboratories Facilities Weapons of Mass Destruction Decision Analysis Capability model, and the Los Alamos National Laboratory Quick Urban and Industrial Complex Dispersion Modeling System.
for the many thousands of environmental chemicals lacking comprehensive toxicological data and/or human health risk assessment (e.g., species, sex, endpoint, range of doses/concentrations, duration of study, etc.) associated with the >700 chemicals with derived US or California EPA human health toxicity values (e.g., cancer potencies, reference doses and concentrations). Second, the availability of additional in vivo and animal in vivo data for the same compounds was examined. The greatest overlap (~50-70%) was found to exist with databases of rat LD50, Ames genotoxicity, and in vitro cytotoxicity screening conducted by the National Toxicology Program. Next, we used the latter data as independent variables to develop both chemical structure-based and hybrid (chemical structure and in vivo and in vitro data) models for predicting toxicity values. We posit that values derived through such models can not only aid prioritization of yet untested compounds for additional study, but may support decision-making for environmental contaminants. As additional toxicological data are generated, their ability to refine provisional estimates can be evaluated in a value-of-information approach. Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the US or California EPA.

300 NANOMATERIAL TOXICITY SCREENING IN DEVELOPING ZEBRAFISH EMBRYOS.

To assess nanomaterial vertebrate toxicity, a high-content screening assay was created using developing zebrafish, Danio rerio. This included a diverse group of nano-materials (n=42 total) ranging from metallic (Ag, Au) and metal oxide (CeO2, CuO, TiO2, ZnO) nanoparticles, to non-metallic nanomaterials (SiO2, nanoparticle and carbon nanotubes), as well as micro and ion counterparts. Overt toxicity (lethality, dysmorphology, and hatching) was assessed via visual inspection and/or high-content imaging analysis. At 5-7 hours post fertilization, individual embryos were treated in a 96-well plate with the testing material (8 doses, semi-log spacing, 3±3 at each dose). Solutions were renewed daily until 5 days post fertilization (dpf) when the larvae were placed into embryo rearing solution. A total of 6 dpf, dysmorphology was assessed via visual inspection. Following visual inspection, fish were euthanized and positioned, and images were recorded and analyzed on the ArrayScan IV automated microscopy system using the Zebrotix V3 bioscillation. Results showed little to no overt toxicity, with a few exceptions: some of the nano-Ag and nano-CuO compounds produced dose-related overt toxicity. This result was also seen in the Ag and Cu ions; however, in general, metal salts were more toxic than their corresponding nanoparticles at the same metal mass concentration. Also, nano-ZnO and ZnCl2 did not typically cause lethality or dysmorphology, but did delay hatching. By employing few larvae per dose, we were able to assess toxicity for a relatively large number of different materials, demonstrating the utility of high-content screening of whole organisms as a valuable platform for nanomaterial or other chemical toxicity screening. These results will be combined with data from other ToxicityScan screening assays for nanomaterials to more fully characterize bioactivity and toxicity. This abstract does not necessarily reflect US EPA policy.

301 PHOTOTOXICITY OF TITANIUM DIOXIDE NANO PARTICLES (NANO-TiO2) TO DAPHNIA MAGNA IS DEPENDENT ON SOLAR UV SPECTRUM.

H. Ma, A. Brennan and S. A. Diamond. Mid-Continent Ecology Division, US EPA, Duluth, MN.

Phototoxicity of nano-TiO2 has become an important concern as the material can be photocatalyzed under environmental UV radiation and generate reactive oxygen species (ROS). In this study, we investigated photocatalytic ROS production and phototoxicity of nano-TiO2 to Daphnia magna under simulated solar radiation (SSR). Our hypotheses were that: i) phototoxicity of nano-TiO2 is ROS mediated and will be correlated to photocatalytic ROS production by the material; ii) photocatalytic ROS production and phototoxicity of nano-TiO2 is dependent on the UV spectrum within SSR (i.e., only certain wavelengths are able to photocatalyze nano-TiO2). D. magna was exposed to nano-TiO2 under different solar UV spectrum by applying a series of spectral filters (i.e., standard window glass (SWG), acrylic glass (AG), 345 nm, 360 nm, and 400 nm cutoff filters) within SSR. Photocatalytic ROS production was measured by AFS [3’ (p-aminophenyl) fluorescein] assay, a fluorescence-based ROS assay with great specificity to OH. Phototoxicity was evaluated by immobilization of D. magna. Intracellular ROS production was determined by H2DCFDA assay. Greatest phototoxicity occurred when no spectral filter was applied, with a 48-h LC50 of 180 µg TiO2/L. Immobilization of D. magna by nano-TiO2 at 500 µg/L under different spectral filters showed the following order (standardized to no filter): SWG(92%) > 345 nm(57%) > 360 nm(69%) > AG(6%) > 400 nm (0%). Photocatalytic ROS production by nano-TiO2 showed similar order (standardized to no filter): SWG(100%) > 345 nm(92%) > 360 nm(69%) > AG(6%) > 400 nm (0%). An excellent correlation (r = 0.94, p<0.001) was found between the immobilization of D. magna and ROS production. Intracellular ROS production was consistent with D. magna immobilization, strongly suggesting oxidative stress was involved in the phototoxicity. Our findings demonstrate that phototoxicity of nano-TiO2 can occur under natural solar radiation. We have also identified the activating wavelength for nano-TiO2 photoactivation – a critical component of risk assessment for TiO2.

320 ECOTOXICITY TEST PROTOCOLS FOR REPRESENTATIVE NANOMATERIALS—THE PROSPECT RESULTS FOR ZINC OXIDE.

D.卡尔德, K. Wieden1, R. Tanner1, T. Galloway3 and S. Friedrichi2.1Product Safety, BASF SE, Ludwigshafen, Germany, 2Nanotechnology Industries Association, Brussels, Belgium, 3National Physical Laboratory, Teddington, United Kingdom and 4University of Exeter, Exeter, United Kingdom.

The OECD’s Working Party on Manufactured Nanomaterials has a Sponsorship Programme, where 13 nanomaterials are to be tested for a number of human health and environmental safety endpoints. PROSPECT (Ecotoxicity Test Protocols for Representative Nanomaterials in Support of the OECD Sponsorship Programme) is a public-private-partnership to generate data by addressing gaps in the current knowledge of physical-chemical and ecotoxicological properties of zinc oxide (ZnO). The PROSPECT data for four types of ZnO from the EU repository. ZnO was characterized as delivered and used in the test systems for the following properties: Agglomeration/aggregation, Water Solubility/Dispersibility, Crystalline phase, Dustiness, Crystallite size, Representative Electron Microscope picture(s), Particle size distribution, Specific surface area, Surface chemistry, Photocatalytic activity, Pour density, Porosity, Redox potential and Radical formation potential. To guarantee reliable results a harmonized handling procedure was established. ZnO was tested comparing different standardised preparation and dispersion protocols alongside bulk and soluble formulations. Exposure test was conducted with zebras (Danio rerio), rainbow trout (Oncorhynchus mykiss), the crustacean Daphnia magna and the sediment dwelling amphipod Corophium volutator. Bio-accumulation and uptake were measured using stable isotope fingerprinting and elemental analysis, combined with Transmission Electron Microscope and Coherent Anti-Stokes Raman Spectroscopy for label-free imaging of particles. Sublethal effects were explored across different levels of biological organisation, combining unbiased screening of the metabolome with more focused, functional studies of targeted pathways. Results highlight in particular subtle effects of ZnO on mechanisms of feeding rate and behaviour, with metal formulation a more relevant predictor of toxicity than size or aggregation.

302 EMBRYOLARVAL EXPOSURE TO TITANIUM DIOXIDE NANO PARTICIPANTS IN THE PBP RANGE PRODUCES PHOTO-DEPENDENT TOXICITY.

O. Bar-Ilan1, 2, C. Chuang1, D. J. Schwahn1, R. Hamers2, J. Pedersen3, R. E. Petersen1 and W. Heideman1, 2. 1Division of Pharmaceutical Sciences, University of Wisconsin-Madison, Madison, WI and 2NSEC, University of Wisconsin-Madison, Madison, WI.

Titanium dioxide nanoparticles (TiO2NPs) are able to absorb photons to produce electron-hole pairs that react with O2 and H2O to form reactive oxygen species (ROS). We found that exposure to 100-1000 µg/ml TiO2NPs when illuminated over a 5 d period resulted in mortality and sublethal morphological malformations as a result of photo-induced oxidative stress. In this study, we exposed embryonic zebrafish to environmentally relevant concentrations of two commercial brands of TiO2NPs for 23 d during metamorphosis. We show that a long-term, low-dose (0.001-10 µg/ml) exposure of embryos to photoactivated TiO2NPs increases toxicity in zebrafish larvae, whereas the same particles are relatively inert in the absence of light. Larvae were assessed for various endpoints of toxicity at 12 and 23 days post-fertilization (dpf). Exposures to illuminated particles produced dose- and photodependent mortality and delays in the metamorphic development process. Furthermore, exposures to both brands of particles led to increased levels of an oxidative stress marker in 12 and 23 dpf larvae when illuminated. Histopathological examination of the larvae demonstrated that illuminated TiO2NP exposures cause proliferative and necrotic branchiitis in the gills, as well as skin and hepatic necrosis.
Both brands of TiO₂ NPs were taken up into the developing larvae and were found most consistently in the liver, gut, and gills. Interestingly, we show that depuration of TiO₂ NPs is possible as Ti levels return to baseline, survival rates stabilize, and oxidative stress is reduced when larvae are placed into nanoparticle-free H₂O for 7 d following the 23 d exposure period. To our knowledge, this is the first study to show a photo-dependent toxic response to low doses of TiO₂ NPs during the metamorphic, exposed larval period. Our study reveals that the potency of TiO₂ NPs is much higher than previously shown and that the phototoxic effect is inherent to TiO₂ NPs regardless of the brand (Funded by NSEC).

TIO₂ nanoparticles (NPs) are used in a wide range of applications and concern has increased about the potential hazard of these particles to humans and the environment. At present, little information is available about the possible risks of exposure to TiO₂ NPs. We have investigated the effect of particle size on the toxicity of TiO₂ NPs in the zebrafish embryo. Three different sizes of citrate-coated TiO₂ NPs (primary particle size = 5, 12 and 19 nm) were used. Embryos (4-120 hpf) were exposed to graded concentrations of these citrate-coated TiO₂ NPs under either simulated sunlight illumination or in the dark. Citrate-coated TiO₂ NPs of all three sizes caused photo-dependent toxicity. Embryos exposed to 5 nm particles under illumination exhibited higher mortality than those exposed to 12 or 19 nm particles. To gain insight into the mechanism, we measured the hydrodynamic size of citrate-coated TiO₂ NPs aggregates and compared Ti uptake in the embryos. After 24 h the hydrodynamic diameters of TiO₂ NPs aggregates, measured by dynamic light scattering, increased from 28 to 63 nm (12 nm NPs) and from 22 to 111 nm (19 nm NPs). In contrast, the hydrodynamic diameter of aggregates of 5 nm NPs increased to a much smaller extent (from 15 to 23 nm). Ti body burden, measured by ICP-OES, in embryos exposed to 19 nm NPs appeared to be higher than the Ti levels in embryos exposed to smaller NPs when compared at the same particle number concentration, but was not different at the same citrate-coated TiO₂ NPs mass concentration. Aggregation can affect the degree of toxicity and uptake. Therefore further research is required on the correlation between aggregate size and toxicity. Our results indicate a photo-dependent toxicity of citrate-coated TiO₂ NPs to zebrafish embryos with the smaller particle being more toxic than the larger particle. This work was supported by NSEC (NSF grant No. DMR-0425880) and EPA Star Program (RD-8338601-0).

**307 Uptake of Quantum Dots in Fathead Minnows, Pimephales promelas, Ovarian Explant Cultures.**

The need for understanding the interactions of nanomaterials (NMs) with biological systems is evident, as their use in a variety of applications including cosmetics, electronics, and biomedicine is increasing. Of specific importance is the biological fate of NMs in aquatic organisms, particularly in fish, for which much is not yet understood. Previous research has shown that particle characteristics such as size and surface chemistry (including plasma protein coatings) influence biological fate and ultimately the overall effects. One class of NMs of interest are quantum dots (QD) which are structurally composed of a semiconductor core and shell that can be modified by the addition of different functional groups. The goal of this study was to determine what particle surface characteristics and physiological conditions allow QD uptake of QDs into developing oocytes or their follicle cells in vitro. Oocytes were collected from mature female fathead minnows (FHMs) and transferred to a 12-well plate with approximately even numbers of oocytes in each well. Assay conditions and supplementation was methodically varied in regards to the presence of carp pituitary extract, bCG (25 U/well), QDs (80 nM, a plasma containing exposure) and QD-coated nanoparticles (60 nM, OC-E10, colloidal cysteine, may cause direct toxicity to the oocyte or perturb the functions of the follicle cells.
308 MULTIGENERATIONAL IMPACTS OF CARBON NANOMATERIAL EXPOSURE ON THE MODEL ORGANISM DAPHNIA MAGNA.

D. A. Arndt and R. Klaper. School of Freshwater Sciences, University of Wisconsin Milwaukee, Milwaukee, WI.

We examined how carbon nanomaterial core structure and surface chemistry influence the toxicity of these materials to the progeny of an exposed F₀ generation of Daphnia magna. F₁ daphnids were exposed to various types of carbon nanomaterials with different core structures and functionalizations. Chronic toxicity was measured on the parent population by evaluating mortality and reproductive parameters over a 21-day period. In addition, the impact of carbon nanomaterials in the presence of additional environmental stressors was evaluated by running experiments under ideal population conditions or highly dense population conditions. The neonates produced by the F₁ generation were raised for an additional 21-day period over a 21-day period. In addition, the impact of carbon nanomaterials in the parent population by evaluating mortality and reproductive parameters was constant in the two cell lines. These results indicate that different dispersants affect MWCNT uptake into cells, and that cytotoxicity depends on the exposed dosage such as IC₅₀ value. It suggests a possible correlation that toxicity appears depending on time even if the exposure of MWCNTs is the low concentration because MWCNTs are biopersistent.

309 THE BIOLOGICAL RESPONSE OF MULTIVALLED CARBON NANOTUBES IN DIFFERENT DISPERSANTS.

H. Hanai¹, N. Saito², Y. Matsuda³, Y. Kim⁴, K. Park⁵, T. Tsukahara⁶, Y. Usui⁷, K. Aoki⁵, M. Shimizu⁶, N. Oghara⁵, K. Hara⁵, S. Takahashi⁶, M. Okamoto⁵ and H. Kato¹. ¹Institute of Carbon Science and Technology, Shinshu University, Matsumoto, Japan, ²School of Health Sciences, Shinshu University, Matsumoto, Japan, ³Clinical Pharmacology Educational Center, Nihon Pharmaceutical University, Ina-shi, Japan, ⁴Faculty of Engineering, Shinshu University, Naganoshi, Japan, ⁵School of Medicine, Shinshu University, Matsumoto, Japan and ⁶Research Center for Exotic Nanocarbons, Shinshu University, Matsumoto, Japan.

To date, there are many reports about the cytotoxicity of multi-walled carbon nanotubes (MWCNTs). However, the results are still controversial. As the one reason, various dispersants are used in each research. Therefore, we clarified influence of the dispersants of MWCNTs on the cellular uptake and the cytotoxicity. First, we examined the cytotoxicity, MWCNTs uptake and cytokine secretion to MWCNTs in three different dispersants (gelatin, carboxymethyl cellulose and 1,2-Dipalmitoyl-sn-glycer-3-phosphocholine) on human bronchial epithelial cells (BEAS-2B). Cytotoxicity was measured by alamar blue assay and cellular uptake of MWCNTs and cytokine secretion were analyzed using flow cytometry. Next, we researched that the relationship between the cellular uptake of MWCNTs and cytotoxicity using different two cell lines, BEAS-2B and human malignant pleural mesothelioma cells. We found that the cellular uptake of MWCNTs was different for each of the three dispersants and that the level of cytotoxicity and inflammatory response was dependent manner. It is also possible that cationic nanoparticles can interfere with the receptor assembly on lipid rafts, thereby disrupting cellular signaling.

310 THE IN VITRO EFFECTS OF SILICA NANOPARTICLES ON MOUSE MACROPHAGE MORPHOLOGY AND FUNCTION.

Silica (SiO₂) nanoparticles (NPs) are hard core, durable NPs that are being proposed as drug delivery devices for cancer therapy. SiO₂ NPs accumulate in macrophages of clearance organs after systemic administration and may not be fully cleared after administration. We determined if accumulation of SiO₂ NPs (7 nm) in mouse macrophages impact their morphology and function in vitro. RAW 264.7 and J774.A cells were exposed to SiO₂ NPs (0.001 g/L - 0.1 g/L) for variable time periods (24h - 72h) and their viability, proliferation, and function were evaluated. Our results show that exposure to high concentrations (0.01-0.1 g/L) of SiO₂ NP induced cell death as measured by plate based and flow cytometry viability assays. Lower concentrations (0.001 to 0.005 g/L) of SiO₂ NPs significantly reduced cell proliferation by ~ 4 fold as compared to control cells as shown by Coulter counter measurements. Interestingly, SiO₂ NPs induced a heterogeneous cell size distribution in RAW cells. Exposure of RAW cells to 0.005 g/L SiO₂ NPs also induced a 2 fold increase in the number of macrophages larger than 20 μm as measured by Coulter counter. The SiO₂ NP induced cell size increase was also confirmed by confocal microscopy. Cell surface activation markers (CD40, CD80 and CD86) did not show significant changes in expression when dosed with SiO₂ NP (0.0025 to 0.01 g/L). Phagocytosis assays in SiO₂ NP-treated macrophages were performed using fluorochrome conjugated E.coli. Bacterial uptake was assayed by flow cytometry and results show that SiO₂ NPs did not impair phagocytosis at 0.01 g/L. The results indicate that SiO₂ NP exposure can impact macrophage cell morphology and proliferation in vitro, but does not appear to impact activation markers and phagocytosis as indicators of macrophage function.

311 MODULATION OF IL-8 ACTIVITY UPON LIPID RAFT DISRUPTION AND NANOPARTICLE EXPOSURE.

C. Thach and J. N. Finkelson. Environmental Medicine, University of Rochester, Rochester, NY.

With the increase in production of engineered nanomaterials, researchers are discovering that there is a direct impact of these nanomaterials on the cell membranes. The cell membrane contains many different types of lipids and proteins responsible for numerous cell functions. The assembly of cholesterol and sphingolipids within the membrane forms microdomain structures known as lipid rafts. Lipid rafts contain many receptors that are involved in regulating cytokine production. Studies have shown that engineered nanomaterials can erode the membrane and create holes. We hypothesized that nanoparticles can interfere with cellular signaling by inhibiting the assembly of receptors on lipid rafts. Using two different cell lines containing an Interleukin-8 promoter Luciferase construct, we were able to evaluate the ability of charged nanoparticles to alter cytokine gene expression elicited by a secondary stimulus. We exposed cells to charged nanoparticles, followed with stimulation of the IL-8 promoter with the proinflammatory cytokine tumor necrosis factor-α (TNF-α). We then used endocytic inhibitors and cholesterol depleters to determine if the nanoparticles rely on endocytosis and membrane cholesterol to alter the TNF-α stimulated IL-8 promoter. Cell lysis products were collected to assess for intracellular proteins and IL-8 promoter expression. Additionally, cells were exposed to nanoparticles after adding TNF-α to determine if the nanoparticles can disrupt cellular signaling upon receptor activation. We found that cationic nanoparticles are able to reduce the IL-8 promoter activity despite exposure to the endocytic inhibitors. When membrane cholesterol is removed from the cells, all the effects of the nanoparticles disappeared. Furthermore, these nanoparticles can only disrupt signaling prior to receptor activation with TNF-α. Our studies demonstrated that cationic nanoparticles can disrupt cellular signaling in a cholesterol dependent manner. It is also possible that cationic nanoparticles can interfere with the receptor assembly on lipid rafts, thereby disrupting cellular signaling.

312 EVALUATION OF OXIDATIVE STRESS AND APOPTOSIS IN THE LIVER FOLLOWING A SINGLE INTRATRACHEAL INSTITUTION OF CEERIUM OXIDE NANOPARTICLES IN MALE SPRAGUE DAWLEY RATS.

S. Nalabotu¹,², N. Manne³,², M. Kolli³,², G. Nandyala³,², R. Para³,², M. Valentovski¹,², J. Ma³ and E. Blough³,². ¹Department of Pharmacology, Physiology, and Toxicology, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV, ²CDN, Marshall University, Huntington, WV and ³HELD, NIOSH, Morgantown, WV.

Cerium oxide (CeO₂) nanoparticles appear to exhibit antioxidant properties which have led some to suggest that these particles may be used to treat medical conditions that are associated with increases in oxidative stress. Conversely, other in vitro and in vivo work has suggested that exposure to CeO₂ nanoparticles can, at least under certain conditions, lead to increases in oxidative stress. Herein we attempt to explore the underlying mechanism of this finding. To this end, 7-week old male Sprague Dawley rats (n=72) were randomized to one of two groups: CeO₂ nanoparticle (20 nm diameter) instillation (7 mg/kg in 300 μl normal saline) or age-matched saline control (300 μl normal saline) or age-matched saline control (300 μl normal saline). After instillation, animals were sacrificed at 1, 3, 14, 28, 56 and 90 days (n=6/group). Compared to saline-control animals, the concentration of malondialdehyde (MDA) per gram of liver tissue in CeO₂ exposed animals was 25%, 31% and 20% higher at days 1, 3 and 90 post exposure (P<0.05) while the ratio of Bax to Bcl-2 was 55%, 62%, and 47% lower at days 14, 28 and 56 (P<0.05). Compared to saline-control, the levels of cleaved caspase-3 (17 kDa and 19 kDa fragments) were by 32% higher and 49%
higher (P< 0.05) at days 1 and 3 before being decreased by 35%, 25%, 20%, and 7% at days 14, 28, 56, and 90 respectively. These data suggest that the initial response of the liver to intratracheal instillation of CeO2 nanoparticles is characterized by increased oxidative stress and caspase-3 activation at days 1 and 3 post exposure. Whether these events are associated with hepatic apoptosis and subsequent tissue remodeling is currently under investigation.

**Comparative Study on Antibacterial Efficiency and Cytotoxicity of Various Types of Ion-Doped Titanium Dioxide Nanoparticles.**

Visible light absorbing titanium dioxide (TiO2) has been widely accepted photosensitizer in harnessing solar energy for photocatalysis process. Doping TiO2 with non-metal or metal ions is one of the most efficient methods to shift the spectral response of TiO2 from UV to visible light region. Efficiency and safety of these materials are important selection criteria for further commercial uses. In this study, chromium (Cr-TiO2), nitrogen (N-TiO2) and carbon-doped TiO2 (C-TiO2) nanoparticles were investigated on their antibacterial efficacy in S. aureus and E. coli and their toxic effects in human skin epithelial (A431) cells. The nanoparticles were firstly subjected to physical and chemical characterizations such as light absorption by UV spectrophotometry, morphology by TEM, chemical composition by EDX, crystal structure by XRD, hydrodynamic diameter by DLS as well as photocatalytic activity by DPPH assay. The results showed that all types of ion-doped TiO2 nanoparticles can absorb both UV and visible light. N-TiO2 nanoparticles showed the highest photocatalytic activity in correlation to their antibacterial effects against S. aureus and E. coli under visible light followed by C-TiO2 and Cr-TiO2, respectively. Using CCK-8 and DCF assays, N-TiO2 and C-TiO2 demonstrated their ability to reduce cell viability and to generate ROS in A431 cells, respectively, in a concentration-dependent manner. The higher effects can be seen in Cr-TiO2. Beside their photocatalytic ability under visible light, it is interesting that non-metal-doped (N-TiO2 and C-TiO2) showed higher antibacterial efficiency but lower toxicity to A431 cells than metal-doped (Cr-TiO2) particles. The results from this study can be used as a selection guidance of ion-doped TiO2 nanoparticles for specific applications.

**Development of In Vitro Bioactivity Profiling of Alternative Sustainable Nanomaterials.**

Sustainable, environmentally benign nanomaterials (NMs) are being designed as alternatives based on functionality to conventional metal-based nanomaterials (NMs) in order to minimize potential risk to human health and the environment. Development of rapid methods to evaluate the potential hazard of alternatives before entering the marketplace is critical for informing material design and utilization. Cellular based high-throughput screening (HTS) assays, currently being utilized in the ToxCast chemical screening project, are valuable to evaluate the differences in the bioactivities of conventional NMs and their alternatives. Preliminary research has focused on development of nanoparticles (NPs) from natural biopolymer materials that will maintain integrity for intended applications and then rapidly degrade post-use. These NMs, infused with active components, would become inert after use and could serve as novel NM platforms in oral drug delivery or as environmental remediation. Biodegradable cellulose and lignin NPs have been synthesized by an environmentally-friendly water-based antisolvent precipitation process based on pH-jump. The hydroxypropyl methylcellulose phthalate NPs (~200-300 nm in diameter) dissolve above pH ~ 5.5 limiting their potential applications. However, the synthesized lignin NPs (~50-100 nm in diameter) have been stabilized up to pH ~ 9, allowing them to be viable in physiological conditions for their intended use and in the HTS assays (pH ~ 7.4). The next phase of research will focus on further characterizing lignin NPs and evaluating bioactivity of infused particles pre- and post-use using ToxCast assays. This research takes an innovative and
proactive approach to enhance the safety of materials, inform hazard assessment up-
stream, and move nanotechnology toward sustainability based on green chemistry
principles. This abstract may not necessarily reflect US EPA policy.

317 EFFECTS OF CERIUM OXIDE NANOPARTICLES ON
DIESEL EXHAUST PARTICLES—INDUCED
PULMONARY RESPONSES.
J. Y. Ma1, R. R. Mercer1, M. Barger1, J. K. Ma2 and Y. Castranova1, 1NIOSH,
Morgantown, WV and 2West Virginia University, Morgantown, WV

Diesel exhaust particles (DEP) are the major constituent of ambient particulate that
are known to induce lung inflammation and injury. When using cerium compo-
sounds as diesel engine catalyst to lower DEP emission, cerium oxide nanoparticles
(CeO2) were detected in the exhaust. Our previous studies have shown that CeO2
not only induces pulmonary inflammation, but also lung fibrosis. In this study, we
investigated the effects of CeO2, DEP and their combination on pulmonary re-
sponses pertaining to lung inflammation and fibrosis. Male Sprague Dawley rats
were exposed to DEP with or without CeO2 (20% w/w) by a single intratracheal
instillation and sacrificed at 1, 10 and 28 days after exposure. Bronchial alveolar
lavage (BAL) was performed; cellular and acellular fractions of BAL fluid were ob-
tained; and particle-induced lung inflammation, cellular toxicity, and alveolar
air/blood barrier damage were determined through monitoring PMN infiltration,
LDH activity, and albumin content in the first BAL fluid. The DEP-induced re-
sponses were acute and transient, peaked at 1-day after exposure, but significantly
decreased at 10- and 28-day post exposure. However, CeO2+DEP induced inflam-
matory responses were found persistent throughout the 28-day exposure period.
DEP-exposed alveolar macrophages induced oxidant and nitric oxide generation
and proinflammatory cytokine, TNF-α and IL-12, production. The presence of
CeO2 markedly reduced DEP-induced cellular responses. At 28 days post exposure,
CeO2- and CeO2+DEP-exposed lungs showed significantly induced phospholipi-
dosis and hydroxyproline content in lung tissues. Morphological analysis showed
that both DEP and CeO2+DEP demonstrated granulomatous lesions. However, there
were more cells and collagen in CeO2+DEP- than DEP-exposed lungs. These
results suggest that exposure of rats to CeO2+DEP induced sustained inflammatory
lung injury and enhanced fibrotic development compared to exposure to DEP
alone. These findings suggest potential health effects of CeO2 when used as diesel
engine catalyst are of concern.

318 COMPARISON OF THE GLOBAL GENE EXPRESSION
OF RAT LUNG INHALED MANUFACTURED
NANOMATERIALS: ULTRAFINE NICKEL OXIDE, C60
FULLERENE, AND CARBON NANOTUBES.
K. Fujita1,2, M. Fukuda1, Y. Morimoto1, A. Ogami1, T. Myojo1, I. Tanaka1,
M. Shimada1, W. Wang1, S. Endoh1, K. Uchida1, H. Fukui1, M. Shichiri1, M. Horie1
and H. Iwashashi1. 1National Institute of Advanced Industrial Science &
Technology, Tsukuba, Japan, 2Technical Research Association for Single Wall Carbon
Nanotubes, Tsukuba, Japan.

In this study, comparative analyses of gene expression profiling of the rat lung after
whole-body inhalation exposure to ultrafine nickel oxide (Uf-NiO), C60 fullerene,
multi or single walled carbon nanotubes (MWCNTs or SWCNTs) for 6 h, 4 days,
and 4 weeks were performed to gain insights into the influence of MNs on the pulmonary
system at a molecular level. DNA microarray analysis revealed that high expression
of genes associated with chemokines and response to oxidative stress were induced
by Uf-NiO at both 3 days and 1 month post-exposure. Mmp12 (macrophage met-
alloelastase) was significantly upregulated at both 3 days and 1 month post-expos-
ure. The results suggest that Uf-NiO lead to acute inflammation for the exposure
period, and the damaged tissues are repaired in the post-exposure period. Few genes
associated with chemokines were significantly higher than those of SWCNT or
C60 alone. These findings suggest potential health effects of CeO2 when used as diesel
engine catalyst are of concern.

319 LONG-TERM PHARMACOKINETICS AND
BIO DISTRIBUTION OF SILICA NANOPARTICLES
USING ACCELERATOR MASS SPECTROMETRY IN
VIVO.

Initiative, Battelle, Columbus, OH.

Nanoparticles and their use for commercial applications are continuing to increase,
especially for diagnostic and therapeutic purposes in the biomedical field. However,
to date, the toxicity and biological fate of nanoparticles have not been thoroughly
investigated; this information is critical for translation of nanoparticles for clinical
use. Silica nanoparticles are used for many biological applications including imag-
aging and as drug delivery vehicles. In this work, Accelerator Mass Spectrometry
(AMS), an ultra sensitive technique for quantifying long-lived radioisotopes, is used
to measure the long-term biodistribution and pharmacokinetic properties of silica
nanoparticles after administration in vivo. 14C-Labeled (t1/2=57.30 yrs) carbo-
ylated silica nanoparticles (33nm) were administered as a single bolus i.v. dose to
male mice. AMS was used to quantify the tissue distribution and pharmacokinetic parameters over an eight week period. Within eight hours after dosing, nanoparti-
cles were cleared rapidly from the bloodstream, but were retained in organs of the
reticuloendothelial system, including the liver, spleen, bone marrow and lymphatic
tissue. Small amounts of nanoparticles were also observed in other peripheral or-
gans and in excreta. These results demonstrate that silica nanoparticles can accu-
mulate in organs upon entering the blood stream and that AMS is a powerful tool
to assess the long-term pharmacokinetics and biodistribution of nanoparticles in
vivo. This work performed under the auspices of the U.S. Department of Energy by
Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344
and supported by LLNL CRADA No. PNNL/284.

320 TISSUE-SPECIFIC GENOTOXICITY OF TITANIUM
DIOXIDE NANOPARTICLES EVALUATED USING THE
IN VIVO COMET ASSAY.
W. Deng1, M. E. Bishop1, J. Yan1, G. White1, J. A. Bhilli1, R. Sadiq1, Y. Li1
and T. Chen1. 1Division of Genetic and Molecular Toxicology, US FDA/National
Center for Toxicological Research, Jefferson, AR and 2Toxicology Pathology Associates,
US FDA/National Center for Toxicological Research, Jefferson, AR.

Nanosized titanium dioxide (nanoTiO2) is one of the most widely used nanomate-
rials. Although TiO2 is chemically inert, it can cause lung cancer in rats. The International Agency for Research on Cancer (IARC) recently classified TiO2 as
possibly carcinogenic to humans (class 2B), based on sufficient evidence in experi-
mental animals. Considering that nanosized TiO2 materials are much more reac-
tive than its bulk materials, a genotoxic evaluation of nano-TiO2 is necessary be-
cause the genotoxicity data are required for the cancer risk assessment. In the
current study, we evaluated the tissue-specific genotoxicity of 10 nm TiO2
nanoparticles and the possible mechanisms for their genotoxicity using in vivo
Comet assay. B6C3F1 (1H) male mice were treated by intraperitoneal injection
with 50 mg TiO2 nanoparticles /kg body weight daily for three days and sacrificed
4 and 24 hr after the last treatment. Liver, bone marrow, spleen and lung were col-
lected for the evaluation. The standard Comet assay was performed to detect DNA
breaks induced by the nanoparticles; and the enzyme-modified Comet assays by ad-
dition of human 8-oxo-guanine DNA glycosylase (hOGG1) and endonuclease III
(Endo III) were conducted to measure the oxidative DNA adducts due to the treat-
ment. The study revealed that the treatment significantly resulted in DNA strand
breaks in liver at both the 4 and 24 hr sampling times and in spleen at the 4 hr time
point, but not in other tissues. Statistically significant (p≤0.05) increases of oxida-
tive DNA adducts were observed in all tissue samples at all time points. The results
suggest that the 10 nm TiO2 nanoparticles can induce DNA damage including
DNA single strand breaks and 8-oxo-guanine, which could be the possible mecha-
nism for the induction is the oxidative stress caused by the treatment of the
nanoparticles.
cerium oxide nanoparticles (CNP) released in the exhaust. Previous studies from our laboratory have shown that DEP and/or CNP induced lung inflammation, damage and fibrosis. This study focuses on the effects of DEP- and/or CNP-exposed rats on the susceptibility to endotoxin. Male Sprague-Dawley rats were treated with intratracheal (IT) instillation of DEP (5 mg/kg body weight) and/or CNP (1 mg/kg body weight). After 3 days, the rats were exposed to lipopolysaccharide (LPS) by IT instillation (1 mg/kg body weight) and then sacrificed after 3 additional days. CNP, DEP, CNP+DEP exposures induced neutrophilia, enlarged macrophages, and released inflammatory mediators, interleukin-12 (IL-12) and osteopontin (OPN), into the bronchial alveolar lavage (BAL) fluid. The exposure to LPS further increased neutrophilia, but did not affect particle-induced cytoxicity and air/capillary damage. LPS exposure did not affect IL-12 and OPN production in rats treated with DEP or CNP+DEP but significantly increased IL-12 and OPN in BAL fluid of CNP-treated rats. Increased transforming growth factor beta (TGF-β), an important mediator of fibrosis detected in alveolar macrophages isolated from all particle-exposed rats. TGF-β induction was further enhanced in response to injury. A significant increase of collagen type I was seen in BAL from CNP- and CNP+DEP-exposed rats. Tissue inhibitor of metalloproteinase 1 (TIMP-1), a MMP-9 inhibitor, was markedly increased in particle-exposed groups. LPS exposure did not significantly alter particles-induced MMP-9, but markedly enhanced TIMP-1 levels. These results suggest endotoxin exposure significantly increased TGF-β production, but lowered the MMP-9/TIMP-1 ratio. These changes may lead to extracellular matrix damage and fibrotic development, leading to health concerns.

**324 RAT OVARIAN STEROIDOGENESIS EX VIVO IS STIMULATED DIFFERENTIALLY UPON EXPOSURE TO LOW CONCENTRATIONS OF NANOPARTICLES.** L. Larson1, 2, M. J. Carvan III1, 2, 3, R. Klapier1, 2, and R. J. Hunt1, 2, 3, 4, 5 1Biological Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI, 2School of Freshwater Sciences, College of Natural Sciences and Mathematics, Milwaukee, WI, and 3NIEHS Children’s Environmental Health Sciences Core Center, University of Wisconsin-Milwaukee and Children’s Research Institute, Milwaukee, WI.

Gold nanoparticles (GNPs) have gained considerable attention for use in medicine, consumer goods, and industry due to their advantageous physicochemical properties. However, the effects of GNP exposure on female fertility remain unclear. The objectives of the present study were (1) to evaluate the effects of GNPs (primary diameter = 6.81 ± 1.25 nm; [Mean ± SD]) on testosterone (T) and estradiol-17β (E2) accumulation by rat ovaries in culture using radioimmunoassay; and (2) to identify the locus/loci whereby GNPs modulate ovarian steroidogenesis by our exploitation of multiple-reference gene quantitative real-time RT-PCR (qPCR) to evaluate expression of sterogenic (i.e., star, cyp11a1, hsd3b1, cyp17a1, and cyp19a1) and oxidative-stress (i.e., sod2 and bax) genes. We hypothesized that GNPs modulate P4 and E2 accumulation by affecting expression of one or more genes involved in steroidogenesis and/or oxidative stress. Ovaries were cultured under control or treatment conditions (31.7 pg/ml, 31.7 ppt, or 31.7 pg/gm GNPs) for either 12, 24, or 48 hours. Regression analyses indicated a positive relationship between either star (n=30 rats, p<0.05, r2= 0.278) or cyp11a1 (n=30 rats, p<0.001, r2= 0.366) expression and P4 accumulation upon exposure to 31.7 pg/gm GNPs, regardless of time. Additional analyses showed that E2 accumulation was positively repressed on hsd3b1 (n=24 rats, p<0.05, r2= 0.181) and cyp17a1 (n=23 rats, p<0.01, r2= 0.301) expression, independent of incubation period, upon exposure to 31.7 pg/ml and 31.7 pg/gm GNPs, respectively. These results suggest that GNPs stimulate differentially, depending upon concentration, rat ovarian steroidogenesis in our ex vivo model, via a complex mechanism that involves transcriptional regulation of star, cyp11a1, cyp17a1, and hsd3b1.

**325 EVALUATION OF THE APPLICATION OF STANDARD ASSAYS FOR ASSESSING GENOTOXICITY OF NANOMATERIALS.** T. Chen1, 2, 3, N. Mei1, 2, R. S. Woodruff1, 2, J. Yan1, Y. Chen1, W. Ding1, 2, J. A. Bhati1, R. Sadiq1, Y. Li1, 2, E. Rice1, Y. Zhang1, 2, A. S. Biris3, 2, P. C. Howard1, 2, T. Zhou1, 2, M. M. Moore1, 2, 3, 4, 5 1Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR, 2Division of Microbiology, Arkansas Regional Laboratory, US FDA, Jefferson, AR, 3Center for Food Safety and Applied Nutrition, US FDA, College Park, MD, 4Nanotechnology Core Facility, National Center for Toxicological Research, US FDA, Jefferson, AR, 5Nanotechnology Center, University of Arkansas at Little Rock, Little Rock, AR and 6Center for Veterinary Medicine, US FDA, Rockville, MD.

The unique properties of nanomaterials may cause adverse effects. It is very important to assure that the current genotoxicity tests are adequate to detect the potential genotoxicity of new nanomaterials. In this study, we evaluated whether the current genotoxicity assays were suitable for assessing the genotoxicity of nanomaterials. Genotoxicity of titanium dioxide nanoparticles (TiO2NPs) and silver nanoparticles...
(AgNPs) were evaluated using the Ames test, the in vivo and in vitro Comet assay, the mouse lymphoma gene mutation assay, the mouse Pgi-t mutation assay, and the in vivo and in vitro micronucleus assay. Mutagenic evaluation of 10 nm TiO2NPs and 5 nm AgNPs with the Ames test showed negative results. Five nm uncoated AgNPs induced mutations dose-dependently in mouse lymphoma cells via an oxidative stress mechanism. Micronuclei in TK6 cells were increased by AgNPs in a dose-, size- and surface coating-dependent manner. While 10 nm TiO2NPs were negative in the mouse lymphoma thymidine kinase mutation assay, the in vivo micronucleus assay, and the Pgi-t mutation assay, they induced DNA damage in TK6 cells, and in mouse liver, lung, spleen and bone marrow when measured using the Comet assay. Our results suggest that the Ames test may not be responsive to the treatment of nanoparticles while the Comet assay is very sensitive to the insults of the nanoparticles. More research, using a wider array of nanomaterials, is needed before drawing final conclusions as to the capability of the genetic toxicology assays for assessing the potential genotoxicity of nanomaterials.

### 326 HEMOPEXIN AS BIOMARKERS FOR ANALYZING THE BIOLOGICAL RESPONSES ASSOCIATED WITH EXPOSURE TO SILICA NANOPARTICLES.

K. Higashisaka1, Y. Yoshikawa1,2, T. Nagano1, A. Kunieda2, K. Nagano3, Y. Abe3, H. Kamada3, S. Tsuoda3, H. Nabeshi3, T. Yoshikawa1,2,3, and Y. Tsutsumi1,2,3.

Recently, practical uses of nanomaterials are rapidly spreading to a wide variety of fields, such as cosmetics, foods, and medicine. However, potential harmful effects of nanomaterials and concerns about the long-term effects that they possess novel properties different from materials with submicron size. In this regard, we have attempted to establish risk assessment system by using biomarkers that estimate or predict the safety and toxicity of nanomaterials. We recently showed that haptoglobin could be a useful biomarker for analyzing the biological responses associated with exposure to silica nanoparticles (nSP). Here, we attempted to identify novel biomarkers by proteomics analysis. Initially, to identify protein biomarkers in mice, we analyzed changes in the level of plasma proteins following treatment with nSP by two-dimensional differential in gel electrophoresis analysis. The quantitative analysis showed that 82 spots displayed increased or decreased expression levels in the plasma of nSP treated mice compared with that of saline treated control mice. LC/TOF/MS analysis of the spots subsequently identified 7 different proteins. Then, we focused on hemopexin, one of the acute phase proteins. ELISA analysis showed that the levels of hemopexin in the plasma increase as the silica particle size decreases. These results suggested that hemopexin could be an additional biomarker for analyzing the biological responses associated with exposure to nSP. We believe this study will enable us to establish the development of safe forms of nanomaterials.

### 327 THE EFFECT OF IN UTERO EXPOSURE TO AMORPHOUS NANOSILICA PARTICLES ON NEONATAL IMMUNE FUNCTION AND NEUROLOGICAL FUNCTION.

Y. Morishita1,2, Y. Yoshida1,2,3, K. Takao2,3, H. Sato2,3, N. Nojiri2,3, K. Nagano1, Y. Abe3, H. Kamada3, S. Tsuoda3, H. Nabeshi3, N. Itoh1, T. Yoshikawa1,2,3, M. Miyakawa1,2, and Y. Tsutsumi1,2,3.

1Laboratory of Toxicology and Safety Science, Graduate School of Pharmaceutical Sciences, Osaka University, Suita, Osaka, Japan, 2Laboratory of Biopharmaceutical Research, National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan, and 3Laboratory of Biomedical Research, National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan.

Nanomaterials (NMs) are increasingly being used for commercial purposes due to their unique properties, such as cosmetics, foods, and medicine. However, it is not understood sufficiently for their safety about potential risks to health. We have tried to establish safe assessment system of NMs by using predictable biomarkers for the development of safe NMs. Previously we identified some acute proteins as biomarkers of NMs by proteomic analysis. On the other hand, recent reports showed that microRNAs could be useful biomarkers for organ-specific injury and side effects of medicines. Here we attempted to examine the potential of microRNA as a safety biomarker of NMs. Because we already demonstrated that intravenous injection of silica nanoparticles with a diameter of 70 nm (nSP70) induced liver injury in mice, we focused on the liver-specific microRNA. Mice were intravenously injected with nSP70 and blood was collected at 4, 8, and 24 h after injection. Then, quantitative real-time RT-PCR analysis of microRNA was performed after the purification of small RNAs including microRNAs from plasmas. The expression level of liver-specific microRNA in nSP70 treated mice was higher than that of control mice. In addition, the sensitivity of the liver-specific microRNA was almost the same as the conventional hepatic injury biomarkers such as ALT and AST. These findings suggested that the liver-specific microRNA could be useful safety biomarkers of NMs in addition to ALT and AST. We are now trying to find other useful microRNAs as biomarkers of NMs. We believe that this study will provide useful information for the development of biomarkers of NMs.

### 328 MICRONRNA AS A BIOMARKER FOR THE SAFETY ANALYSIS OF NANOMATERIALS.

T. Nagano1,2,3, Y. Yoshikawa1,2,3, K. Higashisaka1,2, A. Kunieda1, K. Nagano3, Y. Abe3, H. Kamada3, S. Tsuoda3, H. Nabeshi3, T. Yoshikawa1,2,3, and Y. Tsutsumi1,2,3.

Although zinc oxide nanoparticles (ZnONPs) have been applied in nanotechnology, their kinetics and tissue distribution in vivo are unknown. Here we compared the kinetics and tissue distribution of 10 nm 65ZnONPs, 71 nm 65ZnONPs, and 65ZnONPs injected into mice after intravenous injection. The areas under curve and half-lives in the second compartment of 65ZnONPs were greater than those of 65ZnONPs, the kinetic parameters were similar for both 65ZnONPs. However, the tissue distributions of the three forms were different. ZnONPs preferentially accumulated in the liver and spleen at 24 hrs. At day 28, 65Zn concentration was the highest and in bone and the proportion of recovered 65Zn radioactivity was the highest in the carcass; these had the same ranking, 10 nm 65ZnONPs >71 nm 65ZnONPs >65ZnONPs. Although more than 80% of the 10 nm 65ZnONPs had been excreted by day 28, greater amounts of the 10 nm 65ZnONPs than 71 nm 65ZnONPs or 65ZnONPs had accumulated in other organs (brain, lung, heart and kidneys). Zn ions seem to have a longer half-life in the plasma, but ZnONPs show greater tissue accumulation. Although the size of ZnONPs had no obvious effect on the kinetics, nevertheless the smaller ZnONPs tended to accumulate preferentially in some organs.

### 329 KINETICS AND TISSUE DISTRIBUTION OF NEUTRON-ACTIVATED ZINC OXIDE NANOPARTICLES AND ZINC IN MICE: EFFECTS OF SIZE AND PARTICULATE NATURE.

P. Lin1, T. Yeh1, J. Chen1, M. Yang1,2, C. Yang1, C. Lin1 and F. Chou2.

1National Health Research Institutes, Zhunan, Taiwan and 2The Institute for Living Taiwan University, Hsinchu, Taiwan.

Quantum dots (QDs), promising luminescent nanoparticles, have great potential medical applications, with the persistence of safety concerns about the human medical applications, with the persistence of safety concerns about the human...
their genotoxic effects remain under-explored. This study aims to elucidate the toxicokinetics and biological responses and provide the possibility of prediction for cancer therapy by attractive nanomaterial QDs. In this study, CdSe/ZnS core/shell QDs-induced cell death type in A549 cells was evaluated via MTI, apoptosis, and LDH assay and analyzed differential mRNA levels involved in apoptosis with/without UVA/UVB irradiation. The genotoxic effect of CdSe/ZnS QDs was measured, for the first time by comet and micronucleus assay based on human cancer cell line, for the present study. The extent of cell death was the most severe in CdSe/ZnS QDs treatment under UVB irradiation group, which indicated the strong induction of photocytotoxicity by CdSe/ZnS QDs with UVB and it led to both apoptotic and necrotic cell death. In the induction of olve tail moment and micronucleus formation, significant increases were also investigated in CdSe/ZnS QDs under UVB irrad- iation group. Here, we estimated the genotoxic effect and mechanistic details on the CdSe/ZnS QD-induced cell death pathway and suggest, furthermore, it might be used to apply for cancer therapy using UVB radiation.

331 ROLE OF DOSE RATE ON NANO PARTICLE-INDUCED INFLAMMATORY RESPONSES IN VITRO.

B. L. Baisch, N. M. Corson, P. Wade-Mercer, R. Gelein, G. Oberdörster and A. Fidler, Environmental Medicine, University of Rochester Medical Center, Rochester, NY.

The increased production of nanomaterials has caused a corresponding increase in concern about human exposures in consumer and occupational settings. Numerous in vitro studies in rodents have evaluated dose-response relationships following respira- tory tract (RT) delivery of nanoparticles (NPs) in order to identify potential hazards. These studies often use high doses and bolus delivery methods that do not reflect real world scenarios. We hypothesized that the delivered dose rate is a key de- terminant of the induction of the inflammatory response in the RT. These studies aim to re-evaluate the predictive power of in vivo bolus delivery for NP hazard identifi- cation. F-344 rats (175-270 μg) were exposed to the same deposited dose (200 μg) of TiO2 (80% anatase, 20% rutile; 21 nm) by high dose rate (bolus) intratra- cheal instillation or by low dose rate (aerosol) whole body inhalation over 4 hrs. Controls were exposed to saline or filtered air. The impact of dose rate was also ex- amined in the context of repeated instillation and inhalation exposures (one quarter the dose on each of 4 consecutive days). The greatest post-exposure (24 hrs) in- creases in high dose rate (HDRV) neutrophils were observed. The TiO2 instillate (31.1% ± 2.6% (SD)) and repeated (16.8% ± 3.6%) bolus TiO2 NP exposures. Aerosol delivery resulted in lower inflammation (6.2% ± 1.5%, single; 1.6% ± 0.6%, repeated exposure). For both bolus and aerosol delivery, there was an atten- uation of the neutrophil response when the dose was delivered over 4 days. Similar trends were found for changes in BALF lactate dehydrogenase and β-glucuronidase activities. We conclude that high dose rate NP delivery elicits significantly greater inflammation compared to realistic low dose rate delivery and that bolus delivery overestimates the NP-associated hazard. This research was funded by NIH R01CA134218, P30ES012473, T23E007026, and 5R2CE0518741.

332 SILVER NANOPARTICLE TOXICITY TO RETINAL PIGMENT EPITHelial CELLS IN VITRO IS INFLUENCED BY PARTICLE SIZE AND COATING, BUT NOT UVA RADIATION.

Silver nanoparticles (AgNP) are used in textiles, medical devices, cleaning products and ocular devices because of their antibiotic properties. Because the retina is the only part of the nervous system exposed to light and because other nanoparticles have demonstrated photocytotoxicity, human retinal pigment epithelial cells (ARPE-19) were used to test the potential cytotoxicity and photocytotoxicity of PVP- and citrate-coated silver nanoparticles (Ag-PVP and Ag-CIT, respectively). ARPE-19 cells were grown to confluence in DMEM/F12 + 10% FBS and dosed with 0, 3, 10, 30, 55, 100, & 200 μg/ml of 10, 50, and 75nm Ag-PVP or Ag-CIT(nanoComposition). For phototoxicity tests, the cells were exposed to 2 hrs of either UVA, visible light, or no light exposure 24 hrs after dosing. Cell viability(calcinel A/M apopmpidu iodide) was measured either 24 hrs after dosing (cytotoxicity) or 24 hrs after dark/light/radiation exposure (phototoxicity). Flow cytometry showed dose-related increased side-scatter consistent with cellular uptake of AgNP; silver particles were observed in the cytoplasm of ARPE-19 cells under darkfield microscopy. The cyto- toxicity of nano-silver was dose-dependent, and inversely proportional to particle size. Nano Ag-PVP was more potent than equivalent-sized Ag-CIT for 50 or 75 nm particles. No differences in cytotoxicity were observed between 10 nm Ag-PVP and 10 nm Ag-CIT. No differences were observed between cells treated 10 nm Ag-PVP or 50 nm Ag-CIT and co-exposed to dark (400) visible light or UVA. Thus, the tox- icity of Ag nanoparticles was influenced by particle size and coatings, but no evi- dence of photocytotoxicity was observed. This abstract does not reflect EPA policy.

333 IN VITRO MODEL TO MIMIC THE LUNG EPITHELIAL BARRIER FOR NANO-TOXICOLOGY STUDIES.

R. Derk1, A. Mishra1, T. Stueckle1, S. Friend1, V. Castranova2, Y. Rojanasakul3, M. Chen4 and L. Wang1. 1Pathology and Physiology Research Branch, CDC/NIOSH, Morgantown, WV and 2School of Pharmacy, West Virginia University, Morgantown, WV.

Previous data have shown that upon alveolar deposition, dispersed carbon nanotubes (CNT) can penetrate into the interstitium or pleural area which may indi- cate a specific mechanism of CNT induced pulmonary toxicity. Our hypothesis is that physicochemical properties of CNT could play a key role in determining the penetration mechanism of CNT into deep lung tissue. However, this would be dif- ficult to determine in vivo. Lung epithelial cells typically form tight junctions which serve as a protective barrier against external particulates and can be moni- tored through resistance measurement in vitro. An experimental model was devel- oped using an immortalized human lung epithelial cell line (Calu-3 cells (HTB- 55), ATCC, Manassas, VA) and Transwell ® inserts (Costar 6.5 mm polysylymer membrane with 3.0 μm pores). Calu3 cells were cultured at 10, 20 or 50 x 104 per insert in Eagle’s Minimum Essential Medium (EMEM) containing 15% Fetal Bovine Serum (FBS). After two days, medium was changed to EMEM that contained 2, 5, 10, or 15% FBS to assess serum effects on tight junction formation. Resistance (ohms) of the cell monolayer was monitored every day from days 3 - 18 in culture using the Epithelial Voltomheter and STX2 electrode (World Precision Instruments). A subset of Transwell inserts were collected at various resistances and days in culture and tight junctions were immunofluorescence stained using the ZO-1 antibody. Light microscopy for light junctions was observed using an ophole the resistance reached 2000 ohms in all concentrations of FBS tested. Resistance reached and maintained > 4000 ohms in 5 days at 50k, in 12 days at 20k and 14 days at 10k cell density. Establishment of Calu3 cell monolayers with functional tight junctions is dependent on filter size, seeding density and serum concentration. The Transwell Calu-3 model represents a potential rapid assessment in vitro model to test the effects of nano-material exposure on cell tight junction integrity.

334 GENOTOXIC STRESS RESPONSE GENES ARE DYSREGULATED BY SILVER NANOPARTICLES IN TK6 CELLS.

Y. Chen, J. Yan, M. Moore and T. Chen. Division of Genetic and Molecular Toxicology, National Center for Toxicological Research, US FDA, Jefferson, AR.

Silver nanoparticles (AgNPs) are presently the most used engineered nanomaterials due to their antimicrobial nature. AgNPs have been used in dressings to reduce in- fections in burns, and as antimicrobials in air fresheners, water purifiers, food stor- age containers, and in coatings for clothing. However, their genotoxicity has not been well examined. In this study, 4 genes involved in the genotoxic stress response, p21, GADD45, ATF3, and DDB2, were used to evaluate the genotoxicity of AgNPs. Cells were treated in triplicate for 24 hours with different concentrations of 5 nm AgNPs coated with polyvinylpyrrolidone (PVP) or tannic acid (TA). The cyto- toxicity of AgNPs increased as dose and the doses causing relative cell counts 50% of the control cell count were about 3 ug/ml for PVP-AgNPs and 4 ug/ml for TA-AgNPs. There were dose-dependent increases in the expression of all 4 genes except for those at concentrations causing very high cytotoxicity. The fold changes induced by the AgNPs were small and the highest induction over the con- trol was 2.5-fold that occurred in the p21 gene. The gene expression was signifi- cantly altered by the treatment of the two types of AgNPs for at least one concentra- tion in all the 4 genes (p < 0.05). The response of these genotoxic stress genes to the AgNP treatment was correlated well with our other genotoxicity studies showing that AgNPs induced DNA adducts, DNA breaks, micronuclei and mutations in TK6 or mouse lymphoma cells.

335 CEREBROVASCULAR TOXICITY OF PCBs BOUND TO NANOPARTICLES IN THE EXPERIMENTAL STROKE MODEL.

B. Zhang1, 2, L. Chen2, B. Hennig1,3 and M. Toborek1,2. 1Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY; 2Department of Neurosurgery, University of Kentucky, Lexington, KY and 3College of Agriculture, University of Kentucky, Lexington, KY.

Polychlorinated biphenyls (PCBs) are among the most persistent and widespread environmental pollutants. Recent evidence suggests that exposure to PCBs may in- crease the incidence of stroke and worsen stroke outcomes. PCBs released from en- vironmental sources are capable of binding onto nanoparticles present in the envi- ronment and be taken up by humans. However, very little is known about the toxic effects of PCBs assembled onto nanoparticles. In the current study, we hypothesis
that binding to nanoparticles can potentiate PCB-induced vascular toxicity and brain damage in an experimental stroke model through activation of toll-like recep-
tor 4 (TLR4), followed by stimulation of inflammatory responses, and alterations of
tight junction protein expression in brain capillaries. To study this hypothesis, TLR4-deficient (C3H/HeJ) and control (C3H/HeOuJ) mice were exposed to
PCB153-bound to nanoparticles (PCB153-NPs), PCB153, nanoparticles (NPs)
alone, or vehicle (PBS). PCB153 was administered in the amount of 5 mg/kg body
weight. PCB153-NPs-induced stimulation of proinflammatory responses and NF-
κB nuclear translocation were attenuated in TLR4-deficient mice as compared to
control mice. TLR4-deficiency attenuated the decrease in tight junction protein ex-
pression in response to PCB153-NPs treatment in mouse brain capillaries. TLR4
inhibition also protected against PCB153-NPs-induced disruption of tight junc-
tion proteins in cultured human brain endothelial cells. Importantly, PCB153-
NPs-mediated enhancement of the brain injury in an experimental stroke model
was also less pronounced in TLR4-deficient mice than in control mice. The results of
present study indicate the importance of the TLR4-mediated signaling in cere-
brovascular pathology of PCBs and nanoparticles. These findings may also be ap-
licable to other neuropathological disorders where organic pollutants and
nanoparticles, and/or BBB integrity play crucial roles.

336 TOXICITY EVALUATION OF MULTIWALL CARBON NANOTUBES IN RATS AFTER TAIL VEIN ADMINISTRATION.

N. Kobayashi1, M. Kawabe2, F. Furukawa2, R. Kubota1, N. Sugimoto1, T. Nishimura1 and A. Hino1.
1National Institute of Health Sciences, Tokyo, Japan and 2DIMS Institute of Medical Science Inc., Aichi, Japan.

We have the limited knowledge about the chronic toxicity of nanomaterials,
whereas a growing number of studies have implicated the toxicological effects of
nanomaterials. Recently, some studies reported that maternally exposure to nanopar-
ticles may transfer to their fetuses and affect the development and function of the
central nervous systems. Further information is needed to clarify the potential for
chronic toxicity, particularly reproductive and developmental toxicity of nanomate-
rials. The aim of our study is to evaluate the biodistribution and reproductive and
developmental toxicity of nanomaterials via realistic exposure route (e.g., pul-
monary exposure). In prior to conduct above examinations, we need to develop the
sample preparation methods, and to determine dose and observation period. In
order to obtain the basic information for establishing above methods, we conducted
tail vein administration study of multi-wall carbon nanotubes (MWNTs) in fe-
male SD rats. MWNTs were added to blood serum obtained from female rats and
then ultrasonicated using an ultrasonic bath for 30 min. MWNTs were well dis-
persed into the serum. MWNT precipitation was not observed during injection.
The above MWNT suspensions were administered to two groups of five rats at
dose of 0.25 and 0.5 mg/kg bw. In both groups, body weight loss was observed at
1 day after administration. However, there are no other significant effects in these
groups. MWNT-related clinical signs of toxicity (e.g., abnormal behavior, irregu-
lar respiration, and pilorection) were not found in any groups of rats during the
observation period. Therefore, we have judged that 0.5 mg/kg bw is the allowable
dose for the ven administration of further examinations. Rats were dissected at 3
days after administration. MWNT deposition was not observed in the exami-
ned tissues (i.e., the heart, lungs, liver, kidneys, and spleen). In order to evaluate
biodistribution of MWNTs, we will perform light microscopic examinations of
MWNTs in rats.
suited in an increment of DNA damage in lung cells and especially in BAL cells which showed a 6-fold increase in comparison with the control group. However, CNTs induced no systemic genotoxic effects in peripheral leukocytes or bone marrow. An inflammatory effect, assessed by the number of neutrophils in BAL fluid and by immunohistopathological analyses, was seen in the same mice. Our findings suggest that long, needle-like CNTs induce both genotoxic and inflammatory effects in a murine model. In contrast, short CNTs induce only primary effects due to inflammation. (Funded by the Finnish Work Environment Fund)

### 340 GREEN TEA EXTRACT DIFFERENTIALLY AFFECTS ACETAMINOPHEN-INDUCED HEPATOTOXICITY BASED ON THE EXPOSURE PATTERN.

Green tea extract (GTE) is a widely used dietary supplement and has been promoted for a wide range of uses such as preventing cancer, aging, and weight loss. There are conflicting reports about the safety of GTE. Human studies suggest that GTE may have some short-term benefit in controlling obesity; but it has been also associated with clinical cases of hepatotoxicity. This study was conducted in B6C3F1 male mice to determine if GTE alters the toxicity of the widely-used over-the-counter analgesic acetaminophen (APAP). APAP was chosen since it is the leading cause of drug-induced acute liver failure in the US and certain conditions may increase its toxicity like chronic alcohol use or concurrent use of drugs or dietary supplements that induce cytochrome P450 activity. The first exposure scenario involved administering an oral dose of APAP (150 or 300 mg/kg) to mice followed by a single dose of GTE (500 or 1000 mg/kg) 6 hours later. The second exposure scenario involved administering once-daily oral doses of GTE (500 or 1000 mg/kg/day) for three days followed by an oral dose of APAP (300 mg/kg) on the 4th day. Hepatotoxicity was assessed 24h after the APAP dose in both scenarios. Based on serum ALT and AST levels, histopathology, and survival, GTE potentiated APAP-induced hepatotoxicity when administered 6h after the APAP dose. In contrast, GTE decreased APAP-induced hepatotoxicity when administered for 3 days prior to the APAP dose. These results and further mechanistic studies might help explain the wide-range of effects noted with GTE, and also highlight the potential for drug-dietary supplement interactions.

### 341 A SYSTEMS BIOLOGY APPROACH TO UNRAVEL MECHANISMS OF CYCLOSPORINE A-INDUCED HEPATOTOXICITY.

W. Van den Hof1, 4, A. Ruiz-Aracama2, 4, A. Van Summeren1, 4, D. Jennew1, 4, S. Gajj1, 4, W. Wodziesz1, 4, J. van Delft1, 4 and J. Kleijnan1, 4. 1Department of Toxicogenomics, Maastricht University, Maastricht, Netherlands, 2RIKILT-Institute of Food Safety, Wageningen University and Research Centre, Wageningen, Netherlands, 3Department of Clinical Chemistry, Maastricht University Medical Center, Maastricht, Netherlands and 4Netherlands Toxicogenomics Centre, Maastricht, Netherlands. Sponsor: H. van Loveren.

There is a need for a better understanding of the mechanisms behind drug-induced hepatotoxicity which shall improve preclinical testing and diminish the number of hepatotoxic compounds going into animal experiments and clinical trials. Although transcriptomics, proteomics and metabolomics all give valuable information about toxicological responses, separately they don’t give you the complete story. By combining these different techniques in one toxicogenomic analysis, we aim to further unravel the system wide response to a toxic compound. Therefore, we combined transcriptomic, proteomic and metabonomic profiling of HepG2 cells exposed to Cyclosporine A. HepG2 cells were exposed to different concentrations of Cyclosporine A and cells were investigated at several time points. The mRNA and miRNA expression levels were investigated using array technology. The changes in protein expressions were studied using quantitative 2-D Differential Gel Electrophoresis and a metabolomic investigation was done using 1H-Nuclear Magnetic Resonance spectroscopy. The transcriptomics, proteomics and metabolomics analyses demonstrated many dose- and time-dependent changes in Cyclosporine A-exposed HepG2 cells. Cyclosporine A may induce ER stress and disturb the ER-Golgi transport. Moreover, patterns seen after cyclosporine A treatment can be related to cholestatic mechanisms. Our findings indicate that a systems wide approach combining metabolomics, proteomics and transcriptomics with bioinformatics can lead to a better understanding of the underlying mechanisms of drug-induced cholestasis and may help to improve the assessment of novel compounds for cholestatic properties at an early stage in drug discovery.

### 342 A STRUCTURE-TOXICITY-RELATIONSHIP INVESTIGATION OF 2-PHENYLAMINOPHENYLACETIC ACID ANALOGS.

Y. Pang, M. Go and H. Hu. Pharmacy, National University of Singapore, Singapore, Singapore.

Diclofenac and lumiracoxib are NSAIDs possessing the 2-phenylaminophenylacetic acid backbone. Although structurally similar, they exhibit different pharmacological and toxicological profiles. Bioactivation of both drugs by Phase I and Phase II enzymes to reactive metabolites such as quinone imines and acyl glucuronides respectively have previously been studied and attributed to be the cause of hepatotoxicity associated with both drugs. However, the mechanistic differences in toxicity due to structural differences have not been previously studied. Therefore, the aim of this study was to investigate the effect of structural changes to the 2-phenylaminophenylacetic acid backbone on the cytotoxic profiles of the analogs. By substituting different alky groups and halogens at positions 5 and 2’6’ respectively, twenty-four analogs were synthesized. These analogs were tested for their cytotoxicity effects using TAMH, a metabolically-active mouse liver cell line and HuH-7, a human hepatoma cell line exhibiting low metabolic activity. The analogs were incubated at varying concentrations for 24 hours with the cells before carrying out the MTT assay to obtain IC50 values. Statistical analysis was carried out using one-way ANOVA. Results obtained showed that toxicity of the analogs were consistently greater in TAMH as compared to HuH-7, indicating that metabolism plays an important role in affecting cell viability. Increasing the size of the alky group at the position 5 resulted in an increase in cytotoxicity. It was also observed that a progressive increase in the size of the halogen at positions 2’6’ from fluorine to bromine resulted in an increase in cytotoxicity regardless of the substitution at the 5-position. These results demonstrate that structural changes at critical positions of the 2-phenylaminophenylacetic acid backbone exert significant effects on cytotoxicity. Further studies such as covalent adduction formation and metabolite profiling will provide mechanistic insights to allow design of safer analogs.

### 343 ACHATINA C-REACTION PROTEIN AMELIORATES LEAD-INDUCED TOXICITY IN RAT HEPATOCYTES.

S. Agarwal, S. Mukherjee, S. Chatterjee, S. Sarkar, S. Maitra and S. Bhattacharya. Environmental Toxicology Laboratory, Department of Zoology, Visva Bharati University, Santiniketan, India.

Lead is a ubiquitous toxic heavy metal having different sources of environmental exposure. Inhibition of the activity of several proteins through its binding to SH groups has been described as the major cause of lead toxicity (ATSDR, 1998). In the present study 20hM Pb(NO3)2, an environmentally relevant dose of exposure (Kansal and Singh, 1983), induced notable cytotoxicity in rat hepatocytes which was significantly ameliorated by treatments with individual subunits (60, 62, 90 and 110 kda) of C-reactive protein (CRP) isolated from a mollusc Achatina fulica. Isolated rat hepatocytes were incubated in vitro with Pb(NO3)2, Pb(NO3)2 plus each subunit (10tg/kg) for 4h maintaining a concurrent control. Cell viability was assessed by Trypan blue and MITT assay. Viability reduced significantly at 4h (78%) in Pb treated cells compared to control or cells pretreated with CRP subunits (92%). NBT and TBARS assays were performed to estimate O-2 and lipid peroxidation respectively. In TBARS assay microsomal fraction was heated with TBA- TCA-HCl and lipid peroxidation was measured at 535nm. GSH level was determined following the method of Sedlak and Lindsay (1968). In Pb treated cells there was a 26old increase in the rate of O-2 production and lipid peroxidation at 4h against control. Concomitantly GSH depleted rapidly (2old at 1h) in Pb treated cells. GSH depletion was found to be insignificant in rat hepatocytes pretreated with CRP subunits. Furthermore, reduced expression of HSP70 in CRP subunits treated cells clearly indicates amelioration of metal stress. Thus a new functional role of ACRP as a stress reducing agent in heavy metal toxicity in a vertebrate system emerges which warrants further research.

### 344 DIETARY FAT IS A PRIMARY SOURCE OF LIPIDS IN TCD2-ELICITED HEPATIC STEATOSIS.

M. M. Angriks1, 2, 3, A. D. Jones1, 2, D. B. Mets1 and T. R. Zacharewski2, 3. 1Genetics, Michigan State University, East Lansing, MI, 2Center for Integrative Toxicology, Michigan State University, East Lansing, MI, and 3Biochemistry & Molecular Biology, Michigan State University, East Lansing, MI.

Lead is a ubiquitous toxic heavy metal having different sources of environmental exposure. Inhibition of the activity of several proteins through its binding to SH groups has been described as the major cause of lead toxicity (ATSDR, 1998). In the present study 20hM Pb(NO3)2, an environmentally relevant dose of exposure (Kansal and Singh, 1983), induced notable cytotoxicity in rat hepatocytes which was significantly ameliorated by treatments with individual subunits (60, 62, 90 and 110 kda) of C-reactive protein (CRP) isolated from a mollusc Achatina fulica. Isolated rat hepatocytes were incubated in vitro with Pb(NO3)2, Pb(NO3)2 plus each subunit (10tg/kg) for 4h maintaining a concurrent control. Cell viability was assessed by Trypan blue and MITT assay. Viability reduced significantly at 4h (78%) in Pb treated cells compared to control or cells pretreated with CRP subunits (92%). Furthermore, reduced expression of HSP70 in CRP subunits treated cells clearly indicates amelioration of metal stress. Thus a new functional role of ACRP as a stress reducing agent in heavy metal toxicity in a vertebrate system emerges which warrants further research.

### SOT 2012 ANNUAL MEETING 73
50%, 60%, or 70% carbohydrate exhibited increased relative liver weights in all groups following gavage with 30 μg/kg TCDD for 168 h. Gas chromatography/mass spectrometry analysis of hepatic extracts identified a ~1.5-fold and ~2-fold FA increase in mice on the carbohydrate and fat diets, respectively. Interestingly, mice on the 5%, 10% and 15% fat diets exhibited a dose-dependent increase in the dietary essential FAs, linoleic acid (18:2n6) and linolenic acid (18:3n3). No dose-dependent increase in dietary FA increase was detected when comparing on-genotype TCDD-treated mice suggesting TCDD-induced steatosis is due to enhanced FA uptake rather than de novo lipogenesis. In Scd1 null C57BL/6 mice, that are incapable of desaturating stearate (18:0) to oleate (18:1n9), TCDD increased oleate 3-fold. This increase is also consistent with TCDD enhancing dietary FA uptake since oleate represents 81% of all monounsaturated FA in Harlan 79764 Teklad F6 rodent chow. Moreover, TCDD decreased serum C14 levels 1.7-fold, increased liver C14 levels 2-fold, and decreased parametral fat pad C14 content 3-fold, while having no effect on muscle C14 levels. Notably, C14 levels were >50-fold higher in TCDD-treated livers compared to other examined tissues. This is consistent with the induction of lipid transport genes Cd36 and Faslp in the intestine and G6D6, Vldlr, and Ldlr in the liver by TCDD. These results provide compelling evidence that increased uptake of dietary fat is a primary source of lipids in TCDD-elicited hepatic steatosis. Funded by SBRP P42ES04911.

345 TCCD-ELICITED EFFECTS ON LIVER, SERUM, AND ADIPOSE LIPID COMPOSITION IN SCDD+/+ AND SCDD−/− MICE.

Mouse studies have shown that the aryl hydrocarbon receptor (AhR)-mediated induction of stearoyl-CoA desaturase -1 (Scd1) alters hepatic lipid composition in 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-elicited steatosis. Comparative studies were conducted in fasted 4-week-old female Scdd+/+ and Scdd−/− mice treated with 30 μg/kg TCDD for 24, 72, and 168 h to investigate elicited changes in liver, serum and adipose lipid composition. Relative liver weights were increased in both Scdd+/+ and Scdd−/− mice at all time points while relative parametral fat pad weights decreased in Scdd+/+ (72 and 168 h) and Scdd−/− (72 and 168 h) mice. Mouse serum analysis identified a ~150% increase in total fatty acids (FAs) in both genotypes, and a 120%, 210%, and 135% increase in monounsaturated (MUFAs), saturated (SFAs), and polyunsaturated fatty acids (PUFAs), respectively, in Scdd+/+ mice. In hepatic lipid profile comparisons between genotypes, SFA and PUFA levels decreased 21% and 11%, respectively, while MUFA levels increased 234% in Scdd+/+ compared to Scdd−/− mice. Serum analysis identified a 7% and 11% decrease in absolute FAs in both Scdd+/+ and Scdd−/− mice, respectively. Serum lipid panels also revealed TCDD decreased total cholesterol and high-density lipoprotein particles by 25% at 168 h in both genotypes. GC/MS analysis of adipose EAMES at 168 h identified a TCDD-dependent 30% decrease in SFAs, MUFAs, and PUFAs in Scdd+/+ mice whereas SFAs and PUFAs increased 30% and MUFAs didn’t change in Scdd−/− mice. Adipose FA transporter, SCD2A1, was induced in both genotypes (3- to 7-fold) and AIPQ, involved in lipid catalysis, was increased 1.6-fold in wild-type mice. Collectively, these results suggest that, in addition to altered hepatic lipid composition, AhR mediates alterations in systemic lipid metabolism. Funded by SBRP P42ES04911.

346 A SURVEY OF MECHANISMS FOR DRUG-INDUCED LIVER INJURY.

V. Vijay and W. Tong.

Sponsor: W. Dekant.

Drug-induced liver injury (DILI) remains a major cause that results in termination of drug development programs or regulatory actions. Drugs that cause similar histopathological changes may induce DILI through similar mechanisms. Studying drugs that cause the same histological picture and performing comparative analysis of drugs with different histopathological manifestations could shed light on the mechanisms of toxicity and guide further research using emerging technologies. Currently, most histopathological terms used in the literature to describe DILI are free text, which has resulted in diverse histopathological terms being used to describe the same injury in clinical reports. This makes the analysis and interpretation of histopathological data difficult, especially for researchers without specialized training in pathology. We reviewed the histopathological terms used in the literature to describe various liver injury types associated with 115 drugs that were either withdrawn from the market due to hepatotoxicity or had indications of DILI in FDA-approved drug labeling. These terms were subsequently analyzed against the morphological abnormality terms in Systematized Nomenclature of Medicine (SNOMED), which resulted in a histopathological DILI ontology. The ontology characterizes different DILI types in humans with a controlled vocabulary (i.e., standard histopathological term) and the logical relationships (i.e., hierarchical tree) among them. We then mapped 115 drugs into the ontology terms. For each term, we determined the genomic signatures based on the drugs with the gene expression data available from Japanese Toxicogenomics database using ArrayTrack™. The implications of genomic signatures were interpreted through pathway analysis using KEGG and IPA. This ontology driven gene expression analysis linking to different levels of characterization of histopathology in DILI provides a new way to discern mechanisms of different DILI types. The preliminary results from this study will be discussed.
mation to 4'- and 5-hydroxy-Dcl, consistent with down-regulation of various Cyp550s (e.g. Cyp550C11) as evidenced by qRT-PCR. Hepatic gene expression analysis suggested activation of NFκB and MAPK pathways and up-regulation of co-stimulatory molecules (IL-1β, TNF-α, CINC-1) by LPS/Dcl and PIC/Dcl, but also down-regulation of protective factors (HSPr, SOD2). However, only LPS/Dcl lead to extensive release of pro-inflammatory cytokines (IL-1β, IL-6, IFN-γ, TNF-α) and factors thought to constitute danger signals (HMGB1, CINC-1). Our results show that cellular stress mediated by LPS but not by PIC or BSO reduce the threshold of diclofenac hepatotoxicity.

Organic halides have been used for syntheses of many drugs. In the present study, hepatotoxic effects of two brominated compounds, benzyl bromide and ethyl bromide, and their conjugation with glutathione (GSH) were compared in male Sprague Dawley rats. Animals were treated orally with benzyl bromide at 500 and 1,000 mg/kg in corn oil once or treated orally with ethyl bromide at 1,000 and 1,500 mg/kg for 24 hr. S-Benzyl GSH and S-ethyl GSH were identified in livers treated with benzyl bromide and ethyl bromide, respectively, by liquid chromatography-electrospray ionization tandem mass spectrometry. At the doses used, benzyl bromide showed increased activities of serum alanine aminotransferase and aspartate aminotransferase. Meanwhile, ethyl bromide was not hepatotoxic at the doses tested in the present study. Hepatic GSH levels were almost completely depleted by the treatment with benzyl bromide. However, the decrease in GSH by ethyl bromide was relatively marginal. The present results suggest that the decreased level of hepatic GSH, due to the formation of GSH conjugates, might be a critical process for the toxicity induced by low molecular weight brominated compounds. [Supported by a grant (2010-00266220) from National Research Foundation of Korea.]

**349 INTERSTRAIN DIFFERENCES IN SUSCEPTIBILITY TO LIVER INJURY INDUCED BY METHYL DEFICIENCY IS ASSOCIATED WITH PPARα EXPRESSION.**

Nonalcoholic fatty liver disease (NAFLD) is a major health problem and the leading cause of chronic liver disease in the United States and developed countries. In humans, genetic factors greatly influence individual susceptibility to NAFLD. Elucidating the molecular basis for these individual differences to disease susceptibility is critical in human patient care. In our own previous study, we demonstrated that Pparα expression is an important factor in determining individual susceptibility to NAFLD and one of the key mechanisms in protecting liver from injury induced by the methyl-deficiency.

**350 N-ACETYL-META-AMINOPHENOL, THE ALLURED NON-TOXIC ISOER OF ACETAMINOPHEN, IS TOXIC IN BOTH RAT AND HUMAN PRECISION-CUT LIVER SLICES.**

M. Hadi1, B. Herpers2, S. Dragovic3, R. van Swelm2, E. Russel4, J. Commandeur5, B. van de Water2 and G. Groothuis1. 1Pharmacokinetica, Toxicology and Targeting, GRIP, University of Groningen, Groningen, Netherlands, 2Toxicology, LACDR, Leiden, Netherlands, 3Molecular Toxicology, LACDR, VU Amsterdam, Amsterdam, Netherlands and 4Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

N-acetyl-meta-aminophenol (AMAP) is generally considered as a non-toxic region-of-the well-known hepatotoxic acetaminophen (APAP). However, so far AMAP has only been shown to be non-toxic in mice and hamsters. To investigate whether AMAP could also be used as non-toxic analog of APAP in studies in rat and human, the toxicity of APAP and AMAP was tested ex vivo in precision-cut liver slices (PCLS) of mouse, rat and human. Based on ATP content and histomorphology, APAP was most toxic in mouse and least toxic in human PCLS. Surprisingly, although AMAP showed a much lower toxicity than APAP in mouse PCLS, AMAP was more toxic than APAP at all concentrations tested in both rat and human PCLS. In HepG2 cells, AMAP caused similar apoptosis and induced a higher Nrf2-mediated oxidative stress signal than APAP. The protein profile in the medium of AMAP-treated rat PCLS was similar to that of APAP, whereas in the medium of mouse PCLS it was similar to the control. Metabolite profiling indicated that mouse PCLS produced the highest amount of glutathione conjugate of APAP, while no glutathione conjugate of AMAP was detected in all three species. Mouse also produced ten times more hydroquinone metabolites of AMAP than rat or human. The marked species differences in APAP and AMAP toxicity and metabolism underline the importance of using human tissues for better prediction of toxicity in man.

**351 IDENTIFICATION OF GLUTATHIONE CONJUGATES OF BENZYL AND ETHYL BROMIDE IN MALE SPRAGUE DAWLEY RATS.**

T. Jeong1, S. Lee1, M. Kang1, D. Oh1, K. Lee1 and H. Jeong1. 1Pharmacy, Yeungnam University, Gyeongsan, Gyeongbuk, Republic of Korea, 2Pharmacy, Kyungpook National University, Daegu, Republic of Korea, 3Pharmacy, Chonnam National University, Gwangju, Republic of Korea and 4Pharmacy, Chugung National University, Daejeon, Republic of Korea.

Acetaminophen (APAP) is a commonly consumed drug. Overdose results in acute liver failure in humans and in experimental animal models. The role of complement activation in APAP-induced hepatotoxicity has not been evaluated. Complement comprises more than 30 proteins that can participate in tissue injury and/or repair. Treatment of male, C57Bl/6j mice with APAP (200-400 mg/kg) resulted in liver injury as evidenced by increased activity of alanine aminotransferase (ALT) in plasma, hepatic necrosis and neutrophil infiltration in liver. C3 is a central component of the complement pathway. C3 concentration in plasma was significantly reduced by 6h after treatment with APAP. Immunostaining with anti-C3b antibody revealed accumulation of C3b around the centrilobular, necrotic areas. These results suggest activation of complement components by APAP treatment. Cobra venom factor (CVF) was used to deplete complement components. Pretreatment with CVF (15 U/mouse) abolished APAP-mediated C3b accumulation, and this was accompanied by a reduction at 24 h in plasma ALT activity, hepatic necrosis, hepatic neutrophil infiltration and expression of inflammatory genes (IL-6, IL-10 and PAI-1) relative to mice treated with APAP alone. Loss of hepato-cellular glutathione was similar in APAP-treated mice pretreated with saline or CVF, suggesting that CVF pretreatment did not affect APAP bioactivation. Mice deficient in C3 had reduced ALT activity in plasma 6 and 12 h after APAP administration compared to wild-type animals. These data implicate a key role for complement activation in hepatic inflammation and progression of injury during the pathogenesis of APAP-induced hepatotoxicity. [Supported by NIH grant R01DK087886]
was to evaluate S-S-adenosyl-L-methionine (SAMe) protection of APAP induced subcellular post-translation modification of proteins and polyamine homeostasis. The hypothesis was that S-adenosyl-L-methionine (SAMe) may prevent oxidative stress and protect polyamine pathways. Mice were divided into vehicle (VEH, 15 ml/kg water ip), SAMe (1.25 mmol/kg 5 ml/kg/ip), APAP (250 mg/kg/ip), SAMe and APAP (SAMe administered one hour before APAP) and livers were collected 2, 4, and 6 hours following APAP. Western analysis of hepatic subcellular fractions evaluated 4-Hydroxyenonal posttranslational modifications occurring after APAP treatment. APAP at 4h induced 4-hydroxyenonal (4HNE) adduction of carboxyl phosphate synthetase-1 (CPS-1). 3-Nitrotyrosine (3-NT) adduction of mitochondrial proteins was significantly increased 2 and 4h following APAP compared to VEH. The APAP associated rise in 3-NT adduction within mitochondrial fractions was reduced by SAMe at 4h post APAP. APAP depressed spermine (Spm) at 4 and 6h, while SAMe increased Spm levels, when given after APAP. In conclusion, we have identified novel protection mechanisms of SAMe against APAP toxicity. (Supported by NIH Grants INBRE 5P20RR016477-05S4 and 5P20RR016477 to the West Virginia Idea Network for Biomedical Research Excellence).

**354 PEROXYNITRITE IS CENTRAL TO INCREASED HEPATIC LEPTIN RESISTANCE IN XENOBIOTIC METABOLISM OF CYP2E1-INDUCED NASH.**

S. Chatterjee1, E. J. Tokar1, M. Kadiiska1, M. Waalkes2 and R. P Mason1, 1Laboratory of Toxicology and Pharmacology, NIEHS, Research Triangle Park, NC and 2National Toxicology Program, NIEHS, Research Triangle Park, NC.

We hypothesized that xenobiotic metabolism by CYP2E1 induced steatohepatitis of obesity increases circulating leptin and down regulates both OB-Ra and OB-Rb forms of leptin receptor through peroxynitrite mediated free radical mechanisms. Results indicated that steatohepatitis progression by cytochrome P450 was associated with increased bioactivation of CYP2E1 increased serum leptin levels significantly (48ng/ml in diet induced obese mice (DIO)) to 132 mg/ml in DIO mice with steatohepatitis. This was also associated with reduced stress in steatohepatitic livers, inhibitable by either, or NADPH oxidase inhibitor apocynin or iNOS inhibitor 1400W and in NADPH oxidase or iNOS KO mice. Macrophage depleted DIO mice had significantly decreased oxidative stress suggesting that resident macrophages were the seat of free radical induced inflammation. Since absence of both forms of leptin receptors OB-Ra and OB-rb has been shown in the liver, we explored the expression patterns of these receptors in the steatohepatitis model. OB-Ra and OB-Rb mRNA expression was significantly reduced in steatohepatitis of obesity (16% and 44% respectively) when compared mice with no steatohepatitis. Administration of FeTPPS alone increased the expression OB-Ra and OB-Rb(12 fold and 21fold respectively) while administration of apocynin or 1400W increased it 3 and 5 folds respectively when compared to steatohepatitic mice. Finally mice that were depleted for resident macrophages had increased expression of both OB-Ra and OB-Rb. Further FeTPPS induced increases in both OB-Ra and OB-Rb isoforms of the leptin receptor had a significant correlation with improved progression in steatohepatitis as evidenced by lesser tissue damage. Thus our data for the first time show that peroxynitrite mediated free radical mechanisms are key to induction of increased leptin resistance and steatohepatitic lesions in obesity following xenobiotic metabolism of CYP2E1.

**355 DEVELOPMENT OF A TOXICITY PROFILE FOR THE HEPATOCARCINOCGENIC CONAZOLES: CYPROCONAZOLE, EPOXICONAZOLE, AND PROPICONAZOLE.**

S. Neuang1, T. Moore2, W. Padgett3, L. Murphy3, C. Wood3 and D. S. Hester, 1Systems Biology Branch, US EPA, Durham, NC, 2Cancer Biology Branch, US EPA, Durham, NC and 3Research Cores Unit, US EPA, Durham, NC.

Conazole are fungicides used in farming as pesticides and in medicine as Pharma- ceutical agents. The mechanism of conazole-liver carcinogenesis in mice has been the subject of intensive investigations. The motivation for this study was to apply toxicological and transcriptomic approaches to develop a toxicity profile for hepatocarcinogenic conazoles using cyproconazole, epoxiconazole and propiconazole. In the current study, male CD-1 mice were fed dietary levels of cyproconazole (0, 50, 100, or 200 ppm), epoxiconazole (0, 50, 200, or 500 ppm) or propiconazole (0, 500, 1250 or 2500 ppm) for 30 d. Each conazole induced hepatoemalgenesis and hepato- cytotoxic hypertrophy, decreased serum cholesterol and hepatic levels of all-trans retinoic acid, and increased hepatic cell proliferation. Microarray-based transcriptional analysis revealed 330 differentially expressed probesets common among these conazoles, including strong dose-dependent responses for CYPs, glutathione S-transferases, and markers of oxidative stress. Further analyses identified an 80 gene subset common to the three conazoles that were functionally related to cancer. Within these genes were pathways associated with xenobiotic metabolism, oxidative stress, cell signaling, and cell proliferation. A common TGF-α-centric gene signaling pathway was identified that may be the mechanism produced by these tumorigenic conazoles. (This abstract does not reflect EPA policy and mention of trade names is not an endorsement for any product).

**356 EFFECT OF DIETARY FAT/CARBOHYDRATE RATIO ON PROGRESSION OF ALCOHOLIC LIVER INJURY AND BONE LOSS IN RATS FED VIA TOTAL ENTERAL NUTRITION (TEN).**

M. Roni1,2, K. Mercer1,2, L. Suzu1, B. Badeau1, M. Ferguson1, W. Hogue3, N. Sharma1 and T. Badger1,4, 1Arkansas Children’s Nutrition Center, University of Arkansas for Medical Sciences, Little Rock, AR, 2Pharmacology & Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR, 3Orthopedic Surgery, University of Arkansas for Medical Sciences, Little Rock, AR and 4Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR.

Diet is an important factor in the development of alcoholic liver injury. However, few studies have examined the effects of diet on the dynamics of injury progression or on alcohol-induced bone loss. In the current study, 300 g male Sprague-Dawley rats (N = 10/group) were intragastrically infused isocaloric liquid diets via TEN where fat content was either 5% (high carbohydrate, HC) or 45% (high fat) with or without ethanol (EtOH) substitution for carbohydrate calories to a final level of 13 g/kg/d. After TEN feeding for 14, 28 or 67 d, rats were sacrificed and liver and tib- bone analyzed. HC rats gained more weight and had larger fat pads than HF rats with or without EtOH (P<0.05), whereas blood/urine EtOH values did not differ. Steatosis developed more rapidly in EtOH/HC rats than EtOH/HF rats (P<0.05) accompanied by increases in mRNAs encoding genes involved in fatty acid (FA) synthesis (FASN, ACC1). However, over time control rats also developed steatosis associated with increased expression of FA transporter, CD36. Genes related to FA degradation were elevated by EtOH-independent of diet (P<0.05), but no ef- fects were observed on genes associated with VLDL synthesis. Despite higher levels of steatosis, HC/EtOH rats had no increase in lipid peroxidation until day 67 and no increases in necrosis related to controls. In contrast HF/EtOH rats had in- creased lipid peroxidation from day 28 and increased necrosis over controls and higher expression of CYP2E1 and CYP4A1 enzymes over HC/EtOH rats by day 67. In contrast, no dietary differences were observed on EtOH-induced loss of bone mineral density or strength. Supported in part by R01 AA08645 (TMB), R01 AA018282 (MR).

**357 THE ROLE OF SERINE/THREONINE KINASE (STK) IN LIVER MACROPHAGE ACTIVATION FOLLOWING ACETAMINOPHEN (APAP) INTOXICATION.**

C. R. Gordon1, V. Mishin2, P. Haskel3, L. D. Lukin4 and D. L. Lukin5, 1Baugher University, Piscataway, NJ, 2University of Medicine and Dentistry New Jersey/Robert Wood Johnson Medical School, Piscataway, NJ and 3Penn State University, University Park, PA.

Classically activated macrophages and mediators they release play an important role in promoting APAP hepatotoxicity, while, alternatively activated macrophages are involved in wound repair. Hepatocyte-derived macrophage stimulating protein functions to promote alternative macrophage activation by binding to its receptor, STK. STK--/-- mice were used to analyze the role of this protein in regulating alter- native macrophage activation following APAP intoxication. STK--/-- mice were signifi- cantly more sensitive to APAP than wild type (WT) mice. Thus, while adminis- tration of APAP (300 mg/kg, ip) to WT mice resulted in 8% mortality at 24 h, in STK--/-- mice, mortality was 44%. Surviving STK--/-- mice exhibited severe hemor- rhagic cirrhotic hepatic necrosis with injury extending into the midzonal and portal regions of the liver, a response which was not evident in WT mice. This was accompanied by significantly greater increases in serum transaminase which were apparent within 6 h of APAP intoxication. Increased hepatotoxicity was not due to differences in APAP metabolism, as measured by serum levels of free APAP and APAP-glucuronide. However, a persistent depletion of hepatic glutathione was noted in livers of STK--/-- mice when compared to WT mice. This was correlated with increased expression of heme-oxygenase-1, a marker of oxidative stress. In WT mice, APAP intoxication resulted in a time related increase in expression of macrophage chemoattractant protein-1 (MCP-1) and tumor necrosis factor-α (TNFα), which are known to be important in recruiting alternatively activated macrophages into the liver and initiating tissue repair. Expression of these mediators was signific- antly reduced in STK--/-- mice. These data demonstrate that STK plays an impor- tant role in regulating alternative macrophage activation and tissue repair in the liver following APAP intoxication. Cocaine is a local anesthetic and well known to be one of major abuse drugs. It is known that cocaine mediates organ toxicities including injury to the liver. We thus investigated a protective effect of auranofin against hepatic injury induced by cocaine. Cocaine (75 mg/kg) markedly increased serum alanine amino transferase (ALT) (4,130 IU/L) and aspartate amino transferase (AST) (1,730 IU/L) activities at 16 h after treatment, and induced hepatic necrosis surrounding central veins in mice. Concurrently, overexpression of HO-1 was identified at the edges of cocaine-mediated necrotic area. Auranofin (10 mg/mL, i.p.) significantly induced hepatic HO-1 protein in mice from 12 h after treatment. Interestingly, pretreatment with auranofin resulted in the prevention of the increase of serum ALT and AST activities in a dose-dependent manner. On the other hand, although cocaine increased tumor necrosis factor α (TNFα) gene expression in mouse livers, cocaine-induced liver injury was observed in TNFα deficient mice as well as wild-type mice. Auranofin-induced HO-1 gene expression was observed in human primary hepatocytes but not in mouse primary hepatocytes. The present findings suggest that auranofin is effective in preventing cocaine-induced hepatic injury, and HO-1 may contribute to protect against chemically-induced cytotoxicity.

EXACERBATION OF ACETAMINOEPHEN-INduced HEPATOTOXICITY BY THE ANTHELMINTIC DRUG FENBENDAZOLE.

D. L. Laskin¹, V. Mishin¹, J. D. Laskin² and C. R. Gardner. ¹Rutgers University, Piscataway, NJ and ²University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Piscataway, NJ.

Fenbendazole (methyl 5-(phenylthio)-2-benzimidazole, Fen) is a broad spectrum anthelmintic agent commonly added to laboratory rodent feed to prevent or treat pinworm infestation. Potential interactions between Fen and hepatotoxins are unknown. In the present studies, we examined the interaction between Fen and acetaminophen (APAP). Mice were fed a control diet or a diet containing Fen (8-12 mg/day) for 7 days prior to APAP intoxication (300 mg/kg). We found that mice fed the Fen-containing diet were significantly more sensitive to APAP than mice on the control diet. Thus mice on the Fen diet exhibited exaggerated centrilobular hepatocellular necrosis and increased serum transaminase levels when compared to animals fed a control diet. Moreover, administration of APAP to mice on the Fen diet resulted in 63% mortality by 24 h compared to no mortality in mice fed a control diet. The Fen-containing diet alone caused no hepatotoxicity. Analysis of liver microsomal cytochrome P450s (cyp) revealed that Fen had no effect on the activities of cyp2e1 and cyp3a, the major enzymes mediating the first and second phase metabolism of the toxic APAP metabolite, NAPQI. In contrast, cyp2e1 activity was suppressed. A prolonged suppression in hepatic glutathione (GSH) was also noted in APAP-treated mice fed the Fen diet when compared to the control diet. These data demonstrate that Fen exacerbates the hepatotoxicity of APAP, an effect which is related to GSH depletion. These findings suggest a potential drug-drug interaction that should be considered in rodent colonies treated with Fen. Supported by NIH grants ES-009649, ES-019487, and DK-081461.

AURANOIN PROTECTS AGAINST COCAINE-INduced HEPATIC INJURY THROUGH INDUCTION OF HEME OXYGENASE-1.

T. Ashino¹, J. Suguchi¹, J. Uehara¹, Y. Naito-Yamamoto¹, S. Kenmotsu¹, Y. Iwakura¹, S. Shioda¹, S. Numazawa² and T. Yoshida. ¹Biochemical Toxicology, Shonan Institute of Medical Science, University of Tokyo, Tokyo, Japan and ²Anatomy, Shonan University, Tokyo, Japan.

Auranofin, a disease-modifying gold compound, has been empirically applied to the management of rheumatoid arthritis. It is reported in vitro that auranofin suppresses the release of inflammatory cytokines from immune cells; moreover, the drug has an ability to induce heme oxygenase-1 (HO-1), a rate-limiting enzyme for heme degradation and an oxidative stress responsive protein. However, action of auranofin and effect against chemically-induced hepatic injury are obscure. Auranofin is a local anesthetic and well known to be one of major abuse drugs. It is known that cocaine mediates organ toxicities including injury to the liver. We thus investigated a protective effect of auranofin against hepatic injury induced by cocaine. Auranofin (75 mg/kg) markedly increased serum alanine amino transferase (ALT) (1,130 IU/L) and aspartate amino transferase (AST) (1,730 IU/L) activities at 16 h after treatment, and induced hepatic necrosis surrounding central veins in mice. Concurrently, overexpression of HO-1 was identified at the edges of cocaine-mediated necrotic area. Auranofin (10 mg/mL, i.p.) significantly induced hepatic HO-1 protein in mice from 12 h after treatment. Interestingly, pretreatment with auranofin resulted in the prevention of the increase of serum ALT and AST activities in a dose-dependent manner. On the other hand, although cocaine increased tumor necrosis factor α (TNFα) gene expression in mouse livers, cocaine-induced liver injury was observed in TNFα deficient mice as well as wild-type mice. Auranofin-induced HO-1 gene expression was observed in human primary hepatocytes, but not in mouse primary hepatocytes. The present findings suggest that auranofin is effective in preventing cocaine-induced hepatic injury, and HO-1 may contribute to protect against chemically-induced cytotoxicity.
Acid synthesis. Conversely, terpinelione-induced SREBP-1c activity was inhibited by rapamycin pre-treatment. These data provide evidence that terpinelione can cause fatty liver disease mediated by activating fatty acid synthesis regulated by SREBP-1c.

**Increased Susceptibility to Drug-Induced Toxicity in Nonalcoholic Steatohepatitis.**

R. N. Hardwick, A. D. Lake, M. J. Canet, M. D. Merrell and N. J. Cherrington. *Pharmacology and Toxicology, University of Arizona, Tucson, AZ.*

Adverse drug reactions (ADRs) often arise from inter-individual variation in drug metabolism and disposition, and resulted in 82,724 deaths in 2010. Hepatic drug metabolizing enzymes and transporters play a crucial role in determining the fate of most drugs. Alterations in these processes can place individual patients at greater risk for ADRs. We have shown that nonalcoholic steatohepatitis (NASH), the most severe form of nonalcoholic fatty liver disease (NAFLD), leads to increased systemic retention of acetaminophen and ezetimibe due to elevated expression of sinusoidal transporters and disrupted localization of canalicular transporters. These transporters (Abcc1, 2, 3, 4, Abcg1, and Abcg2) are responsible for the disposition of numerous drugs such as methotrexate, which has significant toxicity that varies between patients. The purpose of the current study was to determine the effect of NASH on the disposition and toxicity of MTX. Sprague-Dawley rats were fed either a control or methionine-choline deficient diet for 8 weeks to induce NASH, followed by administration of a single i.p. dose of vehicle, 10, 40, or 100mg/kg MTX. Blood, urine, and fecal samples were collected up to 96 hours, followed by tissue terminal collection. At the onset of MTX dosing, Abcc1, 2, 3, 4, Abcg1, and Abcg2 were elevated in NASH livers, whereas Abcc2 and Abcg1 appeared to be removed from the canalicular membrane. Importantly, 40 and 100mg/kg doses of MTX resulted in hepatocellular damage followed by initiation of repair (as evidenced by positive PCNA staining) only in NASH animals. Control livers, regardless of MTX dose, did not exhibit significant hepatocellular damage and repair. In contrast, intestinal toxicity in NASH animals tended to be less severe, possibly due to altered MTX hepatobiliary disposition. These data suggest that the hepatobiliary disposition of MTX, governed by expression and localization of efflux transporters, may be altered in NASH, resulting in increased susceptibility to MTX hepatotoxicity.

**L-Serine Attenuates Steatosis by Suppression of Hyperhomocysteinemia.**

W. Sim1, H. Choi1, H. Yin1, H. Koo2, S. Kim2 and B. Lee3. 1College of Pharmacy, Seoul National University, Seoul, Republic of Korea and 2College of Pharmacy, Chunnan National University, Daejeon, Republic of Korea.

Increasing evidence showed that hyperhomocysteinemia plays an important role in the development of steatosis. In this study we evaluated the effects of L-serine (L-ser) on the ethanol-induced steatosis and elucidated the possible mechanisms of action in terms of the inhibition of the maturation of SREBP-1c through suppression of hyperhomocysteinemia. In *vitro* studies showed that treatment of AML-12 murine hepatocytes with methionine and homocysteine increased the intracellular homocysteine levels and triglyceride contents, whereas cotreatment with L-ser decreased the homocysteine and triglyceride accumulation. L-ser treatment increased the expression of insulin-induced gene-1 (INSIG-1) and inhibited the maturation and translocation of SREBP-1c to the nucleus. Transfection of the cells with siRNA for betaine homocysteine S-methyltransferase (BHMT) or cystathionine beta-synthase (CBS) increased cellular homocysteine and triglyceride level possibly due to the increase in the activation of SREBP-1. L-ser treatment reversed the SREBP-1 activation and triglyceride accumulation in BHMT siRNA-transfected cells, but not in CBS siRNA-transfected cells. Male C57BL/6 mice received ethanol (5g/kg body weight) by gavage every 12 hours for a total 3 times. L-ser (200mg/kg body weight) was administrated by gavage for the last two ethanol treatment. L-ser treatment significantly attenuated hyperhomocysteinemia. Ethanol-induced activation of SREBP-1 and accumulation of triglyceride in the liver were reversed by L-ser. These results demonstrate that L-ser inhibits hyperhomocysteinemia by accelerating the conversion of homocysteine to cystathionine which results in the amelioration of SREBP-1 activation and fatty liver.

**LYSOSOMAL DIVERGENT METAL TRANSPORTER 1 (DMT-1)-MEDIATED IRON RELEASE CONTRIBUTES TO ISCHEMIA-REFPERUSION INJURY IN RAT HEPATOCYTES.**

X. Zhang, J. Schwartz and J. Lemasters. Center for Cell Death, Injury & Regeneration, Department of Pharmaceutical Sciences, Medical University of South Carolina, Charleston, SC.

Translocation of chelatable iron from lysosomes to mitochondria plays a key role in ischemia-reperfusion (IR) injury of rat hepatocytes. However, the mechanism of iron release from lysosome during ischemia remains unknown. Divergent Metal Transporter 1 (DMT-1) is a cation transporter that mediates translocation of Fe" across lysosomal membranes. Accordingly, our AIM was to investigate the role of DMT-1 in IR-induced lysosomal iron release and iron-dependent oxidative injury in rat primary hepatocytes. Methods: Overnight cultured hepatocytes were incubated anaerobically at pH 6.2 for 4 h and re-oxygenated at pH 7.4 to simulate IR. Chelatable Fe" and mitochondrial membrane potential were monitored by confocal fluorescence microscopy of calcein and tetramethylrhodamine methyl ester (TMRM). ROS generation and cell killing were assessed by chloromethyl dichlorofluorescein (cmDCF) and propidium iodide fluorescence. Results: Lysosome-induced quenching of cytosolic calcein was blocked by pretreatment with ebselen (20 μM), an inhibitor of DMT-1, whereas the antioxidant N-Acetyl-Cysteine (NAC, 0.5 mM) and the lipid radical scavenger DPPD (1 μM) had no inhibitory effect. Ferristatin (50 μM), another inhibitor of DMT-1, also suppressed quenching of cytosolic calcein produced by ischemia. In addition, ebselen and ferristatin inhibited quenching of calcein loaded into mitochondria, indicating that inhibition of DMT-1 blocked mitochondrial iron uptake. Importantly, ebselen and ferristatin added before ischemia attenuated ROS formation, opening of mitochondrial permeability transition pores and cell killing after reperfusion. Conclusions: Taken together, the results indicate that DMT-1 mediates lysosomal iron release into the cytosol during ischemia. Lysosome-derived iron then enters mitochondria and contributes to iron-dependent oxidative injury and cell killing after reperfusion. Thus, DMT-1 is a potential therapeutic target against IR-induced hepatotoxicity.

**Interstrain Differences in Oxidative Stress-Induced by a Lipotrope Methyl-Deficient Diet in Mice.**

I. Koturbash1, S. Melnyk2, B. Montgomery1, S. Shtromonak1, L. Collins1, L. Busyn1, F. A. Beland1 and I. P. Pogribny1. 1Biochemical Toxicology, National Center for Toxicological Research, Jefferson, AR, 2University of Arkansas for Medical Sciences, Little Rock, AR and 3University of North Carolina at Chapel Hill, Chapel Hill, NC.

Nonalcoholic fatty liver disease (NAFLD), the most common cause of chronic liver disease in the US, includes a range of liver injury from steatosis to steatohepatitis, fibrosis, and cirrhosis, and can result in development of hepatocellular carcinoma. Although major research efforts have been put toward understanding the pathophysiological and molecular processes underlying NAFLD, the mechanisms of individual susceptibility to NAFLD remain largely unknown. It is widely-accepted that oxidative stress is one of the earliest events in pathogenesis of both human and rodent NAFLD. In this study, we used a panel of genetically diverse inbred mice (A/J, C57BL/6, C3H/HeJ, 129S1/SvImJ, CAST/Eij, PWK/PhJ, and WSB/Eij) to investigate the strain-specific differences in oxidative stress after being fed a methyl-deficient diet (MDD), a human relevant mouse model rodent NAFLD. Feeding MDD for 12 weeks resulted in the induction of oxidative stress in livers of mice in all seven strains, as evidenced by the decreased levels of reduced glutathione (GSH), increased levels of oxidized glutathione (GSGS), and a decreased GSH/GSSG ratio. Mice fed the MDD also have an increased expression of Gpx3 gene, a sensitive marker of oxidative stress. These changes were accompanied by an altered expression of genes involved in DNA base excision repair, a predominant pathway for repair of oxidative DNA lesions. The magnitude of oxidative stress differed significantly among the individual mouse strains; with the extent of oxidative damage being greatest in WSB/Eij mice and least in A/J mice. These results suggest that the individual susceptibility to NAFLD may be linked to the extent of oxidative stress-associated alterations in the livers.

**Sulforaphane Prevents Liver Injury Caused by High-Fat Diet and Olanzapine.**

R. Schmidt1, 2, M. Tan1, 2, X. Ding1, 2, H. Zhong1, 2 and G. Artech1, 2. 1Pharmacology & Toxicology, University of Louisville, Louisville, KY and 2Alcohol Research Center, University of Louisville, Louisville, KY. Sponsor: C. States.

Olanzapine (OLZ), an atypical antipsychotic, is a first-line treatment for psychosis and mood disorders. The major side effects of OLZ use are weight gain and metabolic syndrome, including the hepatic manifestation of this disease (i.e., NAFLD).
It is now understood that obesity is a major risk factor for drug-induced liver injury. Although OLZ has been known to cause obesity, the effect of diet-induced obesity on OLZ-induced liver damage has not been tested experimentally. This gap in our knowledge is especially important to fill, as the obesity incidence in the psychiatric population is even higher than in the US population as a whole. The purpose of the current study was to test the hypothesis that obesity enhances OLZ-induced hepatic injury, and to test the potential protective effect of anti-oxidant supplementation. Eight-week-old mice were fed either high-fat diet (HFD) or control diet for 4 weeks. Mice also received either OLZ (8 mg/kg/d) or vehicle via osmotic minipumps. Some mice were co-treated with SFN (90 mg/kg/d, i.g.), an isothiocyanate that confers indirect protection by activating intrinsic ROS defenses. HFD caused weight gain and hepatic steatosis, as expected in this model. OLZ exacerbated body weight gain in the HFD group and doubled plasma transaminase release. Hepatic triglyceride accumulation caused by HFD was exacerbated by OLZ co-administration. HFD moderately impaired glucose uptake and utilization; this effect of HFD was exacerbated in the OLZ group. SN partially blunted the biochemical changes caused by HFD, which was blocked in the combination of OLZ and HFD treatment. Taken together, these data show that OLZ dysregulates glucose and lipid metabolism and exacerbates hepatic changes caused by HFD. These data therefore suggest that underlying obesity may be a risk factor for OLZ-induced liver injury. Activating intrinsic antioxidant defenses with SFN can partially prevent these effects of OLZ and may represent a useful strategy to protect against liver injury in the clinics.

**368 POLYCHLORINATED BIPHENYL 153 WORSENS NONALCOHOLIC FATTY LIVER DISEASE IN C57BL/6 MICE.**

1 Ergebnisse von Medizin2Ge, University of Louisville, Louisville, KY and 2Louisville VAMC, Louisville, KY.

Introduction: Exposure to polychlorinated biphenyls (PCBs) including the ubiquitous PCB153 has been shown to increase odds ratio for serum alanine aminotransferase elevation, indicative of nonalcoholic fatty liver disease (NAFLD). To determine if PCB153 plays a causal role in the development of NAFLD, we undertook a study to examine if PCB153 either caused NAFLD by itself or worsened NAFLD induced by a high fat diet (HFD). Methods: C57BL/6 mice were fed either a normal chow or HFD (43% milk fat) for 12 weeks with or without PCB153 co-exposure (50 mg/kg i.p. X4). Liver and fat samples were taken for immunohistochemistry, RT-PCR, metabolomics and lipid analysis. Results: PCB153 treatment increased body weight for animals fed with HFD. PCB153 treatment caused micro-vesicular steatosis and worsened HFD-induced macro-vesicular steatosis. Serum adipokines were increased with HFD and this was augmented by PCB153 co-treatment. The adiponectin/leptin ratio was reduced in both HFD and PCB153 groups. The adiponectin mRNA level decreased in the HFD+PCB153 group. PCB153 treatment increased adipocyte area, liver triglycerides and cholesterol levels in HFD fed animals. Metabolomic analysis identified alterations in approximately 70 metabolites between HFD and HFD+PCB153 groups. These differences included reduced levels of glutathione and the spontaneous glutathione conjugate, S-(hydroxymethyl) glutathione, by 84% and 74% respectively, in the HFD+PCB153 group. In contrast, erythronic acid levels increased 30-fold. Conclusions: PCB153 treatment worsened diet induced obesity by acting synergistically with HFD. In concert, the metabolomics results suggested that PCB153 caused weight gain, adipocyte area increase, liver triglycerides and cholesterol levels in HFD fed animals. Metabolomic analysis identified alterations in approximately 70 metabolites between HFD and HFD+PCB153 groups. These differences included reduced levels of glutathione and the spontaneous glutathione conjugate, S-(hydroxymethyl) glutathione, by 84% and 74% respectively, in the HFD+PCB153 group. In contrast, erythronic acid levels increased 30-fold. Conclusions: PCB153 treatment worsened diet induced obesity by acting synergistically with HFD. In concert, the metabolomics results suggested that PCB153 may exacerbate oxidative stress within the cell. Funding sources: This research was funded by NIH grants from NCCR (SP2ORR024489), the NIAAA (K23AA18399, P101AA17103) and the NIEHS (P30ES01443-T35ES014559).

**369 INVESTIGATION OF DRUG-DRUG INTERACTIONS CAUSED BY HUMAN PREGNANE X RECEPTOR- MEDIATED INDUCTION OF CYTOCHROME P450 3A4 AND 2C SUBFAMILIES IN PBX-MICE.**

M. Kakuni1, M. Hasegawa2, H. Tabara2, R. Inoue1, J. Ushiki2 and C. Tateno1.

1Department of Medicine/GI, University of Louisville, Louisville, KY and 2Louisville VAMC, Louisville, KY.

The induction of cytochrome P450 3A4 (CYP3A) enzymes is one of the risk factors for drug-drug interactions (DDIs). Two major CYP enzymes of CYP3A4 and CYP3A subfamilies are known to be upregulated by the human pregnane X receptor (PXR) regulation, and the DDIs via the enzyme induction of CYP3A4 and/or CYP3A2 subfamilies have been reported to have a major impact in the clinical treatments. The purpose of this study was to examine the DDI between a model human PXR ligand, bupropion (PBX-mice®) and PXR agonists, (S)-warfarin (CYP2C9), and (S)-mephenytoin (CYP2C19). The induction of several drug metabolizing enzymes and transporters in the liver was also examined by measuring the enzyme activity and mRNA expression levels. Significant reductions in the plasma exposure levels of triazolam, pioglitazone, and (S)-mephenytoin were observed in PXB-mice, and the microsomal activity of CYP3A4, CYP2C8 and CYP2C19 were confirmed to be increased in in vitro study. In contrast to the other three CYP isoenzymes, the plasma exposure levels of (S)-warfarin did not decrease, although the microsomal activity of CYP2C9 was elevated after the rifampicin treatment. The discrepancy in the (S)-warfarin results between the in vivo and in vitro studies may be due to the relatively small contribution of CYP2C9 to (S)-warfarin elimination. In summary, the PXB-mice are a useful animal model to examine DDIs caused by PXR-mediated induction of CYP3A2 and CYP3A4.

**370 ISOFORM-SPECIFIC ALT MEASUREMENT CAN DISTINGUISH HEPATIC FROM EXTRA-HEPATIC INJURY IN HUMANS.**

Serum alanine aminotransferase (ALT) is used as a clinical marker to detect hepatic damage and hepatoxicity. Two isoforms of ALT have been identified, ALT1 and ALT2. Increased plasma ALT activities are detected and measured in human serum/plasma using classical clinical chemical assays. Differences exist in the expression patterns of the ALT1 and ALT2 proteins in different organs, which suggest changes in the proportion of ALT1 and ALT2 in plasma could arise and reflect damage to different organs in man. This has, however, not been previously studied due to the lack of a selective methodology that can quantitatively both ALT1 and ALT2 protein and ALT activity in the total serum/plasma samples. Here we show, for the first time, that during three clinically different liver injuries (fatty liver disease, hepatitis C and direct liver surgery) the leakage of ALT1 activity into plasma greatly exceeds that of ALT2. In contrast, during skeletal muscle injury, induced in volunteers experiencing physical exertion, leakage of ALT2 exceeds that of ALT1 and the proportion of ALT isoforms changes accordingly. These results show that the measurement of ALT activity in plasma may offer an opportunity to define whether extra-hepatic injury is occurring in cases where these may falsely have been interpreted as liver injury only.

**371 HCV CORE PROTEIN EXPRESSION AND ACETAMINOPHEN-INDUCED LIVER INJURY.**

A. Ramachandran, M. Lebofsky, S. A. Weinman and H. Iserchoe, Pharmacology, Toxicology & Therapeutics, University of Kansas Medical Center, Kansas City, KS.

The Hepatitis C virus (HCV) is a hepatotropic pathogen of significant importance to public health. Chronic HCV infection pre-disposes patients to a variety of liver diseases and it has also been shown that hepatitis C infection was a predictor of acute liver injury among hospitalizations for acetaminophen overdose in the United States. Acetaminophen (APAP) overdose is the leading cause of acute liver failure in the United States and we used transgenic mice expressing the HCV core protein to explore if this increased susceptibility of animals to APAP induced liver injury. Treatment of C57BL/6 mice with APAP (200 mg/kg body weight) resulted in moderate liver injury at 6 h as indicated by elevated ALT levels, focal centrilobular necrosis and nuclear DNA fragmentation. HCV core protein over-expressing mice showed a variable response, with approximately half the animals showing significant exacerbation of all parameters of liver injury while the other half were protected. These effects were not mediated by changes in APAP metabolism, since neither cytochrome P450 protein levels nor early depletion of glutathione was affected in the HCV transgenic mice. Animals showing protection against liver injury had a substantial increase in liver glutathione content at 6 hours when compared to wild type animals, accompanied by protection against mitochondrial oxidative stress and prevention of mitochondrial AIF release. This was accompanied by an elevation in glutathione S transferase mRNA levels and activity, which suggests that an efficient clearance of the reactive intermediate is the mechanism of protection against APAP hepatotoxicity in these mice. In the case of animals showing exacerbation of liver injury, a substantial decrease in liver glutathione at 6 hours, elevated mitochondrial oxidative stress, and enhanced release of AIF from the mitochondria were observed. This was accompanied by induction of the ER stress response, which probably resulted in amplification of the mitochondrial oxidative stress and downstream cellular injury.
Hepatotoxicity from acetaminophen (APAP) overdose is the leading cause of acute liver failure in the United States. APAP-protein adducts are detectable in plasma, and quantification of these adducts represents a valuable tool for studying APAP-induced hepatotoxicity. The elderly population is of particular interest with respect to such toxicity since older patients have a high incidence of chronic APAP usage; however, the effect of age on plasma protein adduct concentrations has not been evaluated. The present study explored the possibility of age-dependent differences in plasma protein adduct concentrations in a mouse model. Male C57Bl6/J mice, 4 or 22 months of age, were treated with 0, 75, 150 or 300 mg/kg APAP, i.p., in saline vehicle. Plasma and liver tissue were collected at 2, 6, 12 or 24 h post-injection. HPLC-MS/MS quantification of plasma APAP-protein adducts revealed higher concentrations in 4-month-old mice compared to 22-month-old mice for the 300 mg/kg dose at 2 and 24 h. At 24 h, this coincided with more severe hepatic necrosis in 4-month-old mice than in 22-month-old mice, as determined by histology. To explore the origin of these differences, liver tissue was collected from non-treated mice of the same ages, and in vitro enzyme activity for major APAP-related metabolic reactions was assessed. APAP glucuronidation and sulfation rates were lower in 4-month-old mice compared to 22-month-old mice, which may have contributed to the observed accumulation of plasma protein adducts in young mice. In conclusion, age-dependent differences in plasma APAP-protein adduct concentrations were evident and could be attributed to altered APAP metabolism. Age is an important consideration for future work that utilizes plasma protein adducts to study APAP-induced hepatotoxicity. Supported by a grant from the University of Utah on Aging. Mice were obtained from the National Institute on Aging and reared colony strains.

L-FABP MEDIATES IMPAIRED LIPID UPTAKE AND TRAFFICKING IN A RODENT MODEL OF EARLY ALCOHOLIC LIVER DISEASE.

L. R. Smathers1, J. J. Galligan1, K. N. Maclean2, C. T. Shearn1, K. S. Fritz1 and D. R. Petersen1. 1Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado Anschutz Medical Campus, Aurora, CO and 2Pediatrics, University of Colorado Anschutz Medical Campus, Aurora, CO.

Chronic ethanol consumption is a prominent cause of liver disease throughout the Western world. Among the predictable and prominent histologic abnormalities resulting from ethanol ingestion is hepatosteatosis (fatty liver). Utilizing a modified Lieber-DeCarli liquid feeding regimen, male C57Bl6/J mice were fed for a period of 6 weeks. To assess the extent of liver damage, standard biochemical assays revealed increases in serum and liver triglycerides, increased ALT activity and increased immunohistochemical staining for the reactive aldehyde, 4-hydroxyxenonale (4-HNE). Gene array analysis revealed significant alterations in the expression of genes involved with lipid trafficking and metabolism, including liver fatty acid-binding protein (L-FABP), peroxisome proliferator activated receptor-alpha (PPAR-α), carnitine palmitoyltransferase 1a (CPT-1a), and sterol carrier protein 2 (SCP-2). A significant decrease in the cytosolic and nuclear expression of L-FABP was observed, as well as expression and activity of PPAR-α. Immunohistochemical evaluation of liver sections also revealed considerable changes in lobular expression and localization of L-FABP. Protein-protein interactions between L-FABP and PPAR-α/CPT-1a were also investigated utilizing co-immunoprecipitations. Collectively, these data demonstrate dramatic effects of ethanol consumption on L-FABP at the gene and protein level. L-FABP is responsible for activating PPAR-α, and subsequent transcription of FA metabolism genes like L-FABP and CPT-1a. An alteration in the expression of L-FABP suggests a cyclic demolition of the regulatory events of changes in lipid trafficking. The observed alteration in L-FABP expression provides mechanistic insight into the dysregulation of lipid homeostasis in the pathogenesis of ALD. (R37 NIH/NIAAA009300; NIH/NIAAA F31 AA18898-03)

EVALUATION OF HEPATIC FLAVIN-CONTAINING MONOOXYGENASE 3 (FMO3) GENE REGULATION, PROTEIN EXPRESSION, AND ENZYME ACTIVITY IN RESPONSE TO ACETAMINOPHEN TOXICITY.

S. Rudraiah and J. E. Manautou. University of Connecticut, Storrs, CT.

Flavin-containing monooxygenase 3 (Fmo3) catalyzes the NADPH-dependent oxygenation of nitrogen, sulfur, and phosphorus-containing xenobiotics in human liver. Members of the Fmo family of genes have distinct gender, development- and tissue-specific expression patterns in mice. Until recently Fmo3 was thought to be noninducible. We have previously shown that toxic acetaminophen (APAP) or alpha-naphthylisothiocyanate treatment, as well as bile duct ligation in mice markedly increase Fmo3 gene expression. The purpose of this study was to evaluate if the pronounced changes in Fmo3 mRNA levels by APAP treatment translate into increases in protein expression and functional activity of the enzyme. Hepatic Fmo3 mRNA, protein expression, and enzyme activity were quantitated at 48 h in male mice treated with APAP (400 mg/kg). This treatment resulted in mild hepatic necrosis as evidenced by plasma ALT values of 237.9 IU/L. Fmo3 mRNA levels increased significantly by 25-fold while protein levels increased just 2- to 3-fold. Liver microsomes from APAP and control treated mice were generated and assayed for oxygenation of methimazole (MIM), a selective functional substrate for Fmo3. The Kcat value for liver microsomes from APAP treated mice increased from 486.2 to 610.6 (nM min-1-mg-1), although this difference was not significant. The Kd value for microsomal samples from APAP mice decreased from 51.2 to 25.9 µM, which causes a statistically significant 2-fold increase in the catalytic efficiency (Kcat/Kd 23.6 10-3min-1uM-1) of Fmo3 for MIM. In summary, the profound increase in Fmo3 gene expression produced by APAP treatment was not accompanied by changes in protein and functional activity of a corresponding magnitude. The reason for this disparity in gene, protein expression and function is currently being investigated. Supported by NIH DK069557.

PROTECTION AGAINST ACETAMINOPHEN CYTOTOXICITY BY PPARα AND RXR AGONISTS: DETERMINING THE ROLE OF CHANGES IN VANIN-1 mRNA EXPRESSION.

D. W. Ferri2, K. Flores-Saez1 and J. E. Manautou1. 1Department of Pharmaceutical Sciences, University of Connecticut, Storrs, CT and 2Department of Biology, University of Puerto Rico, Mayaguez, Puerto Rico.

Activation of the peroxisome proliferator-activated receptor alpha (PPARα) prevents acetaminophen (APAP) hepatotoxicity in mice. A gene array analysis of livers from mice resistant to APAP toxicity by clofibrate (CFFB) treatment identified Vanin-1 (Vnn1) as a potential gene contributing to this protection. Vnn1 is as a cytoprotective gene responsible for the production of the antioxidant cysteine. We previously analyzed the susceptibility of Vnn1 knockout mice to APAP toxicity. As predicted, mice lacking Vnn1 were more susceptible to APAP hepatotoxicity. The current study aimed at developing a strategy to protect mice from APAP toxicity through the use of a protective agent with an in vivo role of protecting against APAP toxicity using the human hepatocyte cell line HC04. Treatment of HC04 cells with APAP resulted in dose-dependent cytotoxicity. Exposure of HC04 cells to 1.0µM CFFB resulted in a ten-fold increase in VNN1 mRNA expression. However, considerable cytotoxicity occurred at this CFFB concentration. By contrast, treatment with the peroxisome proliferator Wy-14,643 (100µM) resulted in a four-fold induction of VNN1 mRNA levels in the absence of noticeable cytotoxicity. Treatment with Wy-14,643 conferred partial protection against APAP cytotoxicity as shown by a 25% reduction in lactate dehydrogenase (LDH) leakage into media in comparison to cells treated with APAP alone. Due to cooperative interaction of PPARα and the retinoid x receptor (RXR) in gene transcription, we tested the ability of hexareten (Bex), a RXR activator, to protect against APAP cytotoxicity and upregulate VNN1 expression. Treatment of HC04 cells with Bex (1.0µM) alone or in combination with Wy-14,643 resulted in virtually the same magnitude of protection from APAP toxicity. Interestingly, Bex by itself did not change VNN1 mRNA expression. In conclusion, these results document the utility of the bex in vivo system for studying the mechanistic role of VNN1 as a cytoprotect gene.

LYSOSOMAL IRON RELEASE PROMOTES HEMORRHAGE/RESUSCITATION-INDUCED LIVER INJURY.

A. Khomukhamedov1, X. Zhang2, J. Schwartz3 and J. L. Lemasters1,2. 1Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC and 2Biochemistry & Molecular Biology, Medical University of South Carolina, Charleston, SC.

Background: Despite recovery of hemodynamics by fluid resuscitation, liver, and other organs may progress after hemorrhage to develop multiple organ dysfunction syndrome. Recently, we showed that minocycline and doxycycline block iron uptake by mitochondria. Here, our aim was to determine whether iron plays a role in H/R-induced liver injury. Methods: Under anesthesia, C57BL6 mice were hemorrhaged to 30 mm Hg for 3 h and then resuscitated with shed blood plus half the volume of Ringer’s solution containing tetracycline, minocycline, doxycycline or vehicle. In some experiments, desferal and starch-desferal were administered intraperitoneally 1h before H/R. Serum alanine aminotransferase (ALT), liver...
10993-1 Biological Evaluation of Medical Devices - Part 1: Evaluation and Testing within a Risk Management Process. A completed semi-quantitative extractable studies on colorants as part of the safety assessment. The challenges and successes in demonstrating the safety of the colorants used in a short-term blood-contacting catheter are presented here. A color elution study was conducted on a stent delivery system catheter to demonstrate the potential bioavailability of the colorants. The sample devices were reflushed for up to 24 hours in acetone. These aggressive extraction conditions maximized the potential to extract colorant and were not intended to represent clinical use. Results were quantitated using UV-VIS spectroscopy against a five point calibration curve for each of five colorants. The estimated maximum amounts of extracted colorant ranged from 0.25 μg/ml (0.5 μg/device) to 5.0 μg/ml (10 μg/device). These values were used as reasonable “worst case” estimates in the safety assessment. Poor process spike recovery results and baseline noise caused by extracted polymer materials contributed to uncertainty in the reported results. The safety assessment was conducted following ISO 10993-17: Establishment of allowable limits for leachable substances. The history of clinical use, existing toxicology and biological safety data were included in the risk assessment. The threshold of toxicological concern (TTC) was applied for colorants with insufficient toxicological data. We concluded that the colorants used in this short-term BSC catheter were eluted from the device at toxicologically insignificant amounts when extrapolated to the clinical exposure.

377 CYTOTOXICITY STUDIES IN A549 CELLS CULTURED ON 2-METHACRYLOYLOXYETHYL PHOSPHORYLCHOLINE POLYMERS.

2-Methacryloyloxyethyl phosphorylcholine (MPC) polymer has a phospholipid polar group that mimics a biomembrane, and has been used in medical science, biotechnology, pharmaceutical industry, and environmental technology. In medical devices, MPC polymer shows good biocompatibility with the reduction of protein adsorption, and it is used as surface ornamentation agents with artificial organs, blood-contact medical tubes, catheters, and contact lenses. In this study, we compared the cytotoxicity of chemical materials in human lung-derived epithelial-like cell line A549 cells and Chinese hamster lung fibroblast (CHL) cells. A549 and CHL cells were cultured on the MPC polymer-coated plate (MPC plate) and a control plate, and examined in the cytotoxicity and genotoxicity test. On MPC plate, CHL cells formed spheroid and the growth rate was almost the same as control plate during the small spheroid. On the other hand, A549 cells gathered and grew up with a grape-like shape and the growth rate was less than half of the control. The genotoxicity test was carried out with the micronucleus test and no remarkable difference was observed. As a result of the cytotoxicity test for CdSO4 and ZnO (nano size) using a 96-well MPC plate, the cytotoxicity of CdSO4 in CHL cells was weaker on MPC plate compared with control, and the cytotoxicity of ZnO in A549 cells was stronger on MPC plate compared with control. This result was considered that the morphology of cells affected on the sensitivity for the chemical materials. Further molecular level analysis would help the better understanding of the living body/material interactions and the mechanism of biocompatibility.

378 BIOCOMPATIBILITY EVALUATION OF A SILICONE-COATED SURGICAL NEEDLE COMPRISED OF A NOVEL TUNGSTEN-RHENIUM ALLOY.
K. George’ 1, T. Buite1, T. A. Barthel1 and J. W. Oldham1. ‘Predilinc Research, Edison, Inc., Somerville, NJ and T.A.B Consulting, Alamosordo, NM.
A new surgical needle for cardiovascular surgery was developed to provide improved mechanical performance and reduced penetration force over current surgical needles. This needle was manufactured using a novel Tungsten-Rhenium alloy with a new silicone-based lubricious coating. The biocompatibility of this needle was evaluated by conducting cytotoxicity, intracutaneous reactivity, sensitization, acute systemic toxicity, pyrogenicity, and hemocompatibility studies in accordance with ISO 10993 guidelines. Headspace analysis using Gas Chromatography-Mass Spectroscopy was conducted to determine if residual organic solvents from the coating process remained on the needle. The results of this program of biocompatibility studies indicated that this silicone-coated Tungsten-Rhenium alloy surgical needle was non-cytotoxic, non-irritating, not a sensitizer, non-acutely toxic, non-pyrogenic, and hemocompatible, and residual solvents were not detectable. Overall, this biocompatibility assessment demonstrates that the new coated surgical needle is biocompatible and does not represent any safety concerns for patients.

379 CHALLENGES IN CONDUCTING SAFETY ASSESSMENTS OF COLORANTS USED IN MEDICAL DEVICES.
E. K. Hsu and H. J. Beckord. Corporate Toxicology and Biocompatibility Services, Boston Scientific, Maple Grove, MN.
The medical device industry has recently experienced an increase in questions and concerns from the FDA regarding color additives (i.e., colorants) in many categories of devices. In response to the FDA questions and to be compliant with ISO 10993 guidelines, companies have been asked to perform safety assessments on colorants used in medical devices. These assessments are complex and require expertise in toxicology, pharmacology, and materials science. The challenges in performing these assessments include identifying the appropriate test methods, determining the appropriate dose levels, and interpreting the results in the context of the intended use of the device. In addition, there are regulatory requirements that must be met, such as establishing allowable limits for leachable substances. Despite these challenges, companies are working to meet the regulatory requirements and ensure the safety of colorants used in medical devices.
a rate of 1 μL/hr can be conducted. In our laboratory, we validated the iPrecio soft-
ware and the accuracy of the delivery of the micro-infusion pumps, to allow its use on regulatory compliant studies. Three infusion pumps were programmed to de-
liver 1 or 30 μL/hr for 30 minutes, and 2, 4, 8, 12, 24 and 48 hours, with several planned interruptions of the infusion over the course of the given period. Our vali-
dation study demonstrated the successful implantation of iPrecio® pumps, the ability to use these pumps in a number of dosing schemes, and that the software ac-
curately programmed the infusion pumps to deliver 1 or 30 μL/hr for 4-48 hours with an accuracy of +/- 15% of the intended volume. In conclusion, the iPrecio® implantable pumps were shown to be a suitable alternative for use on regulatory compliant studies when very low rates of infusion are required.

**382 EVALUATION OF AN IN VITRO HUMAN SKIN IRRITATION TEST FOR USE WITH MEDICAL DEVICE EXTRACTS.**

K. Coleman1, G. Lewerenz1, E. Rankin1, J. Willoughby2, L. Blakeman1 and J. McKim1. ‘Medtronic, Inc., Minneapolis, MN and ‘CerTos, Inc., Kalamaazoo, MI.

In accordance with ISO 10993, the rabbit skin irritation test is used to assess med-
ical device biocompatibility, however, this method is time-consuming and expen-
sive. Our study’s goal was to determine if the Epiderm™ reconstructed human skin model (MatTek Corp.) could be an acceptable alternative. To that end, eleven medical device polymers and adhesives were selected for testing. Four extracts were prepared per test article, two each with saline and sesame oil as vehicles, resulting in 44 total matrices. Half of the extracts were spiked with known amounts of two R-
38 dermal irritants (lactic and heptanoic acid). A range-finding study determined the lowest concentrations that would produce skin irritation (LOAEL). Tissues were exposed for 24 hours. Cell viability was assessed by MTT and IL-1β release was measured by ELISA. The positive control (5% SDS) reduced cell viability to 8.5% of the negative control (PBS) and increased the release of IL-1β to 8.5% of the negative control (PBS) and increased the release of IL-1β to 8.5% of the negative control (PBS) and increased the release of IL-1β.

**384 RISK ASSESSMENT OF BISPHENOL A FROM BISGMA-
BASED COMPOSITE DENTAL MATERIALS.**

J. K. Dahms1 and L. H. Moilanen2. ‘3M ESPE Dental Products, 3M, St. Paul, MN and ‘Medical Department, 3M, St. Paul, MN.

Bisphenol A glycidyl methacrylate (BisGMA) is an important resin monomer that has been used in composite dental products for over forty years. BisGMA provides essential properties of mechanical strength, rapid polymerization, and low shrink-
age, and is currently used in more than 70% of all dental composites. Recently, the safety of BisGMA has been questioned in regard to its potential to release Bisphenol A (BPA), but data-based risk assessments on this topic are scarce. A quantitative risk assessment of BPA release from dental composites was performed to address this gap. BisGMA is manufactured from BPA in a multi-step process, and low residual levels of BPA may remain in the BisGMA used in dental products. Published infor-
mation from several sources indicates that BisGMA contains < 2 ppm of residual BPA. Polymerized BisGMA is not subject to oral enzymatic degradation; therefore, the only likely source of BPA from BisGMA is leaching of residual monomer. The following exposure assumptions were used in the assessment scenario: 1) 2 ppm of residual BPA is present; 2) the product contains a maximum of 15% BisGMA (w/w); 3) applied product weight is sufficient to restore 3 large molars in an adult or 1 large molar in a 10 year old child and 4) any leached BPA is completely ab-
sorbed by the dental patient. Dental composites are likely to remain in the mouth for more than 10 years; therefore, BPA exposure via leaching into saliva was calcu-
lated both on a worst-case short-term basis and a more clinically relevant long-term basis and these estimates were compared to authoritative BPA toxicity reference va-
ues. The resulting margins of exposure (MOE) for an adult patient were greater than 10,000 on an acute basis and greater than 320,000 on a chronic basis. The re-
sulting margins of exposure (MOE) for a pediatric patient were greater than 20,000 on an acute basis and greater than 500,000 on a chronic basis. These MOE values confirm the safety of BisGMA-based dental composites with respect to potential BPA exposure and support their continued use in adult and pediatric dentistry.

**385 MEDICAL SURVEILLANCE OPTIONS FOR PERSONS WITH ELEVATED COBALT-CHROMIUM LEVELS FROM HIP IMPLANTS.**

M. Fedoruk1, L. Hong2, L. Israel1 and S. Hardy1. ‘University of California Irvine, Irvine, CA and ‘Exponent, Irvine, CA.

Background: Persons with metal-on-metal (MoM) total hip arthroplasties can de-
velop elevated blood and urine cobalt (Co) and chromium (Cr) levels. Epidemiologic studies evaluating long-term effects of elevated Co and Cr levels in persons with MoM implants are lacking and sale blood and urine levels are not de-
defined. Rare cases of cobaltosis, characterized by hypothyroidism, cardiomyopathy, peripheral neuropathy, blindness, and deafness, have occurred, generally after mas-
ive joint deterioration. Hypersensitivity reactions leading to localized symptoms in-
cluding progressive osteolysis have been reported. Case description: A 69-year-old fe-
male with bilateral MoM hip prostheses implanted 6 and 7 years ago was consid-
ering implant removal because of toxicological concerns associated with ele-
vated blood Co (22.1 ug/L) and serum Cr (11.3 ug/L) levels. Ophthalmological as-
essment, echocardiography, hemoglobin, and thyroid, renal and hepatic function did not reveal findings of Co or Cr toxicity. Hip replacement surgery was not ad-
vised for toxicological indications. Rather periodic surveillance evaluations to de-
tect early manifestations of Co and Cr toxicity were recommended. Case discus-
sion: This case provides evidence for lack of systemic toxicity in a person with bil-
ateral MoM hip replacements and increased blood Co and Cr levels. Conclusions: The lack of an established no effect Co or Cr levels may result in per-
sions unnecessarily undergoing revision surgery for toxicological concerns even though MoM implant removal has not demonstrated to be of benefit in asympto-
matic persons. Medical conditions associated with Co toxicity can be caused by other conditions, especially in elderly populations, and need to be considered in any clinical evaluation. Medical evaluations for early manifestations of systemic toxicity coupled with ongoing monitoring of blood Co and Cr levels can be per-
fomed for persons considering MoM hip implant removal for systemic toxicologi-
cal concerns. Subsequent epidemiological studies of populations with MoM hip implants will provide data on health risks and management options.
**386 IN SILICO MUTAGENICITY PREDICTION FOR LEACHABLE COMPONENTS OF DENTAL DEVICES.**

In silico predictive toxicology models are routinely used for screening or predicting the hazards of pharmaceutical and industrial chemicals. The applicability of these tools to leachable components of medical devices is an increasing topic of discussion as regulatory agencies begin to consider the addition of in silico prediction tools to the suite of chemical evaluation procedures. The usefulness of any predictive model depends on the underlying chemicals in the dataset and their relevance to the components of interest. Mutagenicity potential is one critical endpoint for the evaluation of medical devices with prolonged or permanent contact. Eighty-two chemicals were reported in the literature as potential leachables from dental devices with prolonged or permanent contact. These chemicals were specifically identified and evaluated for their predicted mutagenicity potential in the bacterial reverse mutation assay using several commercially or publicly available in silico predictive tools including TOPKAT, Admet Predictor and USEPA TEST. The bacterial reverse mutation assay was selected as the appropriate test for comparison of predictions based on its feasibility of applying the TTC approach to safety assessment of polymers. The results of this exercise confirm the potential utility of the TTC approach for compounds classified as sensitizers.

**387 APPLICATION OF THE THRESHOLD OF TOXICOLOGICAL CONCERN APPROACH TO EVALUATION OF LEACHABLE COMPONENTS FROM POLYMER DENTAL DEVICES.**

L. H. Moilanen and B. D. Bagley. Medical Department, 3M, St. Paul, MN.

The Threshold of Toxicological Concern (TTC) is a proposed approach for assessing the human health risk of leachable medical device components when toxicological data are not available. Currently, there are no published accounts of applying TTC in the safety assessment of medical devices to inform the use of this approach. The feasibility of applying the TTC approach to safety assessment of polymers was considered necessary for its relevance for regulatory assessment of medical devices. The resulting predictions were compared across the models and to the available test data on the identified chemicals. The specificity and sensitivity of each model were calculated and compared. Preliminary results indicate a general concordance of predicted results among the three models, with a lack of agreement for some compounds. The chemicals were specifically identified and evaluated for their predicted mutagenicity potential in the bacterial reverse mutation assay using several commercially or publicly available in silico predictive tools including TOPKAT, Admet Predictor and USEPA TEST. The bacterial reverse mutation assay was selected as the appropriate test for comparison of predictions based on its feasibility of applying the TTC approach to safety assessment of polymers. The potential for conflicting predictions when estimating the toxicological hazards of a medical device ingredient and the advantage of using multiple predictive models.

**388 ASSOCIATION BETWEEN PAH EMISSION AND LUNG CANCER RATES AROUND THE WORLD.**

O. Motoronyi, J. Molitor, and S. Simonich. 1Department of Chemistry, Oregon State University, Corvallis, OR, 2College of Health and Human Sciences, Oregon State University, Corvallis, OR and 3Department of Environmental Molecular and Toxicology, Oregon State University, Corvallis, OR.

Polycyclic aromatic hydrocarbons (PAH) are products of incomplete fuel combustion. Some of them (e.g. benzo(a)pyrene) have carcinogenic properties. Because of this, it is important to be able to measure and estimate human exposure to PAHs. Although other factors, such as cigarette smoking, can lead to lung cancer, PAH emissions also contribute to lung cancer rates. A multiple linear regression model was developed to investigate the potential contribution of gross domestic product (GDP), smoking rates, cigarette price, population and PAH emissions on the number of lung cancer deaths (NLCD) around the world. These data were collected from the World Health Organization, the International Agency for Research on Cancer, and other sources. Diagnostic procedures suggested general log transformation of the data, followed by use of a Poisson distribution. The indicator variables were used to investigate the contribution of PAH emissions on NLCD for seven major parts of the world. After accounting for smoking rates, GDP, cigarette price and geography, we found that PAH emissions contributed significantly to the number of lung cancer deaths and that this contribution varies for different parts of the world. In North America and Europe, a 10% increase in PAH emission was associated with a 5.6% and 2.9% increase in median NLCD, respectively. On average worldwide, a 10% increase in smoking rates was associated with a 5.7% increase in median NLCD. While a 10% increase in cigarette price was associated with a 4.7% decrease in median NLCD.

**389 INFLUENCE OF TRAFFIC-RELATED AIR POLLUTION ON EXHALED NITRIC OXIDE IN HEALTHY ADULTS: A SEASONAL FOLLOW-UP.**

S. De Prin, G. Koppens, K. Cox, V. Nelen, F. Fiersens, K. Constandt, T. Navròt and G. Schoeters. 1Environmental Risk and Health Unit, Flemish Institute for Technological Research (VITO), Mol, Belgium, 2Faculty of Pharmaceutical, Biomedical and Veterinary Sciences, University of Antwerp, Belgium, 3Centre for Environmental Sciences, Hasselt University, Diepenbeek, Belgium, 4Environmental and Health Unit, Provincial Institute of Hygiene, Antwerp, Belgium, 5Belgian Interregional Environment Agency (IRCEL), Brussels, Belgium and 6Environment & Health Unit, Department of Environment Nature & Energy, Flemish Government, Brussels, Belgium. Sponsor: P. Hoet.

Ambient air quality is a major concern in Belgium due to the high degree of urbanization and dense traffic networks. It is known that exposure to traffic-related air pollution is associated with adverse respiratory effects. We investigated whether traffic-related air pollutants are associated with exhaled nitric oxide (eNO) in healthy adults. The study population consisted of 48 healthy non-smoking adults (25 men, age 16-65 years). eNO was analyzed in winter and summer using a portable Niox Mino device. Exposure to traffic-related air pollution was assessed for all subjects in both seasons by interpolated NO2, PM2.5, PM10 and O3 concentrations at the home address for various exposure windows before eNO measurement and by using geographical information. Associations between exposure parameters and eNO were tested using a multiple mixed-effects regression model with age, sex, and inflammation in the week before eNO analysis as covariates. Various short-term NO2, PM2.5 and PM10 exposure windows (2-10 day lagged averages) were significantly associated with eNO (p<0.05). eNO in winter and summer were highly correlated (Pearson r=0.68, p<0.000001) and eNO was higher in men compared to women (17.4 vs. 24.5 ppb, t-test, p<0.001). Exposure to ambient NO2 and PM10 at the home address was associated with eNO indicative for lower airway inflammation in healthy adults. This study was financed by the Flemish Government (Department of Environment Nature & Energy, Environment & Health unit), and the EU-FP6 project INTARESE.

**390 CUMULATIVE RISK MODEL FOR PM and O3 IN AMBIENT AIR.**

D. A. Sarigiannis, A. Gotti and S. P. Karakitsios. 1Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece and 2Chemical Process Engineering Research Institute, Centre for Research and Technology Hellas, Thessali, Greece.

The study deals with the assessment of air pollution attributed short-term cardiovascular and respiratory morbidity and mortality in Athens in 2003-2005. The data used included the daily number of hospital admissions and deaths due to cardiovascular and respiratory causes, hourly mean concentrations of O3 and PM and meteorological data from several monitoring stations from the area of study. The relations among these variables were analysed using Generalized Linear Models (GLMs) and Artificial Neural Networks (ANNs). Using GLMs, causal links between PM-O3 levels and respiratory mortality were identified (an increase of 10 μg/m3 in both PM and O3 corresponds to an increase in morbidity equal to 4.49%). No statistically significant association was obtained for cardiovascular mortality. An increase of 10 μg/m3 for PM and O3 corresponds to an increase in cardiovascular morbidity equal to 1.84%, while respiratory morbidity seems to be more sensitive to these changes (4.96%). The ANN model attributed slightly
higher Relative Risk values. To validate the derived models, the RR values were val-

idated against independent data for different years. Daily morbidity data were bet-

ter predicted than mortality data suggesting that other causes than air pollution in-
fluence significantly mortality. ANN models perform better than GLMs in predicting daily morbidity: Pearson coefficients are 0.734 and 0.717 respectively for respiratory and cardiovascular morbidity using ANN compared to 0.519 and 0.429 obtained with GLM. Concerning daily mortality the two models produced similar results with a Pearson coefficient of 0.29 for ANN and 0.31 for GLM. ANN models tended to perform better than GLMs in predicting daily morbidity and mortality. Comparison of the two methods indicated that the flexibility and the adaptation of the ANN's models provides several advantages when assessing non-linear problems, such as the u-shaped temperature effect, in predicting daily mortality.

**393 NEUROBEHAVIORAL EXPOSURE-EFFECT GRADIENT IN SCHOOLCHILDREN CHRONICALLY EXPOSED TO PESTICIDES.**

F. Yoram¹, A. Opahir²-³, E. Doinsch¹, U. Warmser², M. Aschner⁴ and E. D. Richet³, ¹Neurology and Toxicology Service and Unit, Shear Zedek Medical Center, Jerusalem, Israel, ²Institute of Drug Research, School of Pharmacy, Hebrew University, Jerusalem, Israel, ³Peditrics, Vanderbilt University Medical Center, Nashville, TN and ⁴Department of Occupational and Environmental Medicine, Faculty of Medicine, Hebrew University, Jerusalem, Israel.

Our group previously showed in-season reversible neurobehavioral effects of low-
level chronic exposure to pesticides in residents in rural communities in Israel. This study assessed the neurobehavioral effects in 8-12 years-old schoolchildren in these communities. Eighty-four percent of these schoolchildren are the second genera-
tion exposed to pesticides, given that at least one of their parents has been residing in this rural area for at least three decades and chronically exposed to pesticides. The studied group included two sub-groups: 51 children who reside and attend school in an exposed valley; and 45 children residing on the hills around the valley and attend school in the valley. The control group included 40 age- and sex-matched children residing in a different rural area in which the use of pesticides is restricted for decades. Parents' questionnaire included exposure assessment and Inattention Hyperactivity. Neurobehavioral tests included Digit Cancellation, arithmetic, Diamond and Trail Making Tests A and B; and Purdue Pegboard.

The performance of all of these tests showed pesticides exposure-effect gradient. The parents' Questionnaires indicated a similar gradient between children's exposure to pesticides and their inattention and hyperactivity. Neurotoxic effects of chronic exposure of children to pesticides were manifested in their executive skills, first and foremost in their attention span, visual scanning and execution speed. There may be environmental-susceptibility interactions and epige-
netic effects expediting the occurrence of ADHD.

This work was partially supported by grants from EHF, No. RGA0903; Israel Ministry of Environmental Protection, No. 7-2-1.

**394 PERFLUOROOCTANOATE, PERFLUOROOCtANESULFONATE, AND CHRONIC KIDNEY DISEASE: CLEARANCE COMES BEFORE CAUSATION.**

J. L. Butenhoff, G. W. Olsen and L. R. Zobel. Medical Department, 3M Company, St. Paul, MN.

A previous cross-sectional (C-S) study based on NHANES data reported a de-

creased estimated glomerular filtration rate (eGFR) and 2-fold increased risk in chronic kidney disease (CKD) associated with serum perfluorooctanoate (PFOA) and perfluorooctanesulfonate (PFOS) (mean ~5 and 25 ng/mL, respectively). These authors suggested biological plausibility based on a 28-day gavage study in which microscopic changes in the rat kidney were observed at 20 mg/kg PFOA or PFOS (a 100% lethal dose for PFOA by day 26) and not observed at 5 mg/kg dose, at which serum mean PFOA and PFOS concentrations were 39,000 and 72,000 ng/mL, respectively. To further examine this association, a C-S study was done of 506 male 3M Co. workers in a 2000 medical surveillance program prior to the 3M purchase of Intercontinental. Median PFOA and PFOS concentrations were 1.097 mg/L (range 7-92.025) and 716 mg/L (range 24-6241), respec-
tively. Discordant covariates were adjusted for by ANCOVA and logistic regression. Median eGFR was 75.3 mL/min/1.73 m² (range 24.6–130.2). The adjusted mean differences between the eGFR in the 1st and 10th deciles of PFOA (median values 57 ng/mL and 4,941 ng/mL) and PFOS (median values 107 ng/mL and 3,069 ng/mL) were an insignificant increase of 1.7 mL/min/1.73 m² (95% CI -1.0, 4.4) and 2.0 mL/min/1.73 m² (95% CI 0.8, 4.8), respectively. The odds ratios for CKD were 2.107 (95% CI 0.60, 1.91) and 0.66 (95% CI 0.35, 1.17), respectively. There was no evidence for a decreased trend in eGFR or increased risk for CKD in this C-

S study. This suggests that the likely correct interpretation of the NHANES data is
that lower eGFR leads to higher serum PFOA and PFOS based strictly on physiological factors and is non-causal. This may explain other perfluoroalkyl associations with renal-cleared compounds, including C-reactive protein and uric acid.

**395 A LONGITUDINAL OCCUPATIONAL ASSESSMENT OF THE POTENTIAL ASSOCIATION OF CHANGES BETWEEN SERUM CONCENTRATIONS OF PERFLUOROOCANOATE AND PERFLUOROOCTANESULFONATE AND NON-HIGH-DENSITY-LIPOPROTEIN ChOLESTEROL.**

D. I. Friesman, L. L. Butenhoff, S. Chang and G. W. Olsen. Medical Department, 3M Company, St. Paul, MN.

Introduction: Cross-sectional studies of general, environmentally-exposed populations have observed a positive association between serum concentrations of perfluoroocanoate (PFOA) and perfluorooctanesulfonate (PFOS) with serum non-high-density-lipoprotein (non-HDL) cholesterol. The strength of these associations has been paradoxically not observed in occupational studies. Toxicological and mechanistic studies have demonstrated that PFOA and PFOS would be expected to reduce serum cholesterol; therefore, a causal basis for the associations observed in cross-sectional studies has been questioned. Cross-sectional studies cannot be used to infer causality. The study reported herein represents the first longitudinal assessment of these potential associations among individuals whose initial concentrations were at general population levels. Objective: To examine in a longitudinal occupational assessment whether changes in the serum concentrations of PFOA and PFOS are positively associated with non-HDL cholesterol. Methods: Baseline and end-of-project PFOA, PFOS, lipid and hepatic clinical chemistries were measured in 204 workers involved with the demolition of former perfluoropolyalkyl manufacturing facilities. Of interest were 130 workers whose PFOA and PFOS baseline concentrations were at general population (ng/mL) levels. Results: Among the 130 workers, their mean matched pair changes included: PFOA 46 ng/mL (p < 0.0001); PFOS 4.3 ng/mL (p < 0.0001); and non-HDL cholesterol -0.3 mg/dL (p < 0.0001). Non-HDL cholesterol and hepatic clinical chemistries were not positively associated with PFOA or PFOS in linear regression analyses. Conclusion: In a longitudinal assessment, significant positive associations were not observed between changes in PFOA, PFOS, non-HDL cholesterol and hepatic clinical chemistries. Therefore, the associations observed in cross-sectional studies likely have a non-causal basis.

**396 NEGATIVE ASSOCIATION OF ENVIRONMENTAL EXPOSURE OF BLOOD LEAD AND BLOOD CADMIUM WITH DIABETES IN THE NHANES 1999–2006.**

F. Scinicariello1 and K. A. Thayer2. 1Division of Toxicology and Environmental Medicine, CDC ATSDR, Atlanta, GA and 2Office of Health Assessment and Translation, NIEHS/NIH; Morrisville, NC. Sponsor: M. Munnar.

Background: There have been reports suggesting an association of blood lead and blood cadmium with diabetes type 2. The objective of this study was to evaluate whether environmental blood lead level (BLL) and blood cadmium level (BCL) were associated with diabetes in the adult U.S. population.

Methods: We analyzed data from NHANES 1999–2006 participants aged 20 years and older for levels of blood cadmium and blood in relation to the prevalence of diabetes. Diabetes (n = 2121) was defined as self-reported, currently taking insulin, or diabetic pills to lower blood sugar or glycated hemoglobin (A1C) >6.5%. Blood lead and blood cadmium were categorized by weighted distribution in tertiles. Logistic regression models were adjusted for age, education, alcohol intake, smoking status, BMI, hypertension and serum creatinine (as a marker of kidney function).

Results: A significant negative association was found between BLL, BCL and diabetes. Individuals with BLL in the second (BLL = 1.11 – 1.90 μg/dL) and third (BLL >1.91 μg/dL) tertiles had significant adjusted ORs (0.67, 95% CI: 0.56 – 0.80; and 0.46, 95% CI: 0.37 – 0.56, respectively) to have diabetes compared to those in the first tertile. Individuals with blood cadmium in the second (BCL = 0.21 – 0.44 μg/L) and third (BCL >0.45 μg/L) tertiles compared to those in the first tertile had significant adjusted ORs (0.78, 95% CI: 0.64 – 0.94; and 0.69, 95% CI: 0.56 – 0.85, respectively). Analyses of lead and cadmium mixture found that individuals in the second and third tertiles of both BLL and BCL had a significant negative adjusted OR (0.50, 95% CI: 0.37 – 0.67; and 0.30, 95% CI: 0.21 – 0.42).

Conclusions: The findings, which are inconsistent with several previous reports, suggest that a potential role of blood lead and blood cadmium in the pathogenesis of diabetes is still unclear. Because of the cross sectional nature of the NHANES data further prospective studies are need to address these findings.

**397 EXPOSURE-BASED ESTIMATION OF THE GLOBAL FOODBORNE BURDEN OF DISEASE FROM CADMIUM EXPOSURE.**

Foodborne diseases constitute a serious worldwide public health threat. The World Health Organization (WHO) has launched an initiative to estimate the global burden of foodborne diseases, the Foodborne Disease Burden Epidemiology Reference Group (FERG). Cadmium (Cd) is a toxic element that is widely distributed in foods, and is one of FERG’s priority chemicals. Weight of evidence analysis was performed based on a thorough literature search and review. Renal and skeletal effects were identified as having a cause-effect association with Cd exposure. Urinary cadmium (U-Cd) was used as the indicator of chronic Cd exposure and assumed to follow a log-normal distribution. Next, dose-response relationships were modelled by fitting dichotomous models to selected epidemiological data. Disease prevalence rates were estimated based on the published U-Cd ranges in different WHO regions and the derived dose-response relationship. The Cd-attributable disease prevalence was estimated by subtracting the base prevalence of each endpoint. The estimated Cd-attributable disease prevalence was 0.25-6.6/1000 for microalbuminuria and 0.20-2.1/1000 for osteoporosis in different WHO regions. In areas close to industrial sites, the Cd-attributable disease prevalence was 12.0-33.7/1000 for microalbuminuria and 15.9-28.5/1000 for osteoporosis. While certain seafood and animal offal can accumulate high levels of Cd, the assessment of data from populations with high concentrations of seafood or animal offal did not show a large increase in Cd-attributable diseases. Therefore, Cd exposure from grains and vegetables grown on contaminated soil from industrial sites is a more significant contribution to Cd related burden of disease.

**398 IS SSRl ANTIDEPRESSANT USE IN PREGNANCY PROTECTIVE FOR RISKY ALCOHOL CONSUMPTION?**

H. S. Feldman1, K. L. Jones1 and C. Chambers1,2. 1Pediatric, University of California San Diego, La Jolla, CA and 2Family and Preventive Medicine, University of California San Diego, La Jolla, CA. Sponsor: S. Harris.

Background: Women who drink heavily in pregnancy have been shown to exhibit higher levels of depressive symptoms than women who do not. Selective serotonin reuptake inhibitors (SSRIs) are the most commonly prescribed antidepressants. A Finnish study reported that mothers of children with Fetal Alcohol Syndrome (FAS) were seven times more likely to have taken SSRIs during pregnancy than mothers of normal children. The purpose of this study was to examine the association between alcohol consumption and SSRI exposure. Methods: Data were collected from 992 women who enrolled in the California Teratogen Information Service and Clinical Research Program (CTIS) cohort study between 1978 and 2005. For this analysis, women were selected who reported any alcohol consumption. Alcohol exposure categories included average daily volume, number of binge episodes, and greatest number of drinks in one occasion during each half of the first trimester and each trimester. The exposure of interest was reported SSRI drug use (citalopram, escitalopram, fluoxetine, paroxetine, and sertraline) any time in pregnancy. Results: SSRI exposure in pregnancy was significantly negatively associated with prenatal alcohol exposure. Specifically, SSRI exposure in pregnancy was associated with significantly lower number of average daily drinks during the second half of the first trimester (β =−0.34, p<0.01) and significantly lower number of binge episodes during each half of the first trimester and the second trimester (p<0.05). In addition, SSRI exposure was associated with significantly lower maximum number of drinks in one episode during the second half of the first trimester (β =−0.61, p<0.01). Conclusion: We did not have the data to examine severity of the depressive symptoms. However, our analyses suggest that women with major depression who are appropriately treated with antidepressants may reduce alcohol consumption during pregnancy. Future analyses should include examining alcohol consumption and timing of SSRI exposure.

**399 DRINKING WATER ARSENIC LEVELS PREDICT PLASMA LEVELS OF OXIDIZED LDL CHOLESTEROL (OXLDL) IN NAVAJO POPULATIONS EXPOSED TO URANIUM-CONTAMINATED MINING SITES.**

Numerous abandoned mines within the Navajo Nation contribute uranium, arsenic, radium and other heavy metals to the soil and groundwater. Environmental exposure to heavy metal contaminants may promote or exacerbate cardiovascular...
disease. To assess the potential impact of these contaminants of cardiovascular health of exposed individuals, we have begun to examine (IL-6, CRP) and novel (oxLDL and its receptor LOX-1) plasma biomarkers in a large community of the Navajo Nation. Samples and data were obtained through a culturally appropriate community-based participatory approach, incorporating data collection and outreach by Navajo community staff. Biomarker and self-report data were then linked to geospatial data on contamination sites using traditional linear regression and Bayesian models. Proximity to abandoned uranium mines was not a significant predictor of oxLDL or LOX-1. However, when we used a binary model for uranium and arsenic drinking water levels, we observed that the estimated annual intake of arsenic was a significant predictor of the logarithm of ox-LDL, and therefore of ox-LDL itself. Age, the occupational exposure score, and the distance-environmental exposure score are also significant predictors. However, a binary variable derived from the arsenic intake, with the three other predictors named, is a better predictor. It has more significance in its model, and its model fits the oxLDL data better. Neither metal was a significant predictor for LOX-1. These results indicate that arsenic intake may increase markers of cardiovascular risk. While still preliminary, these findings highlight the potential risks of using water with high levels of arsenic contamination. Ongoing work will help us understand the level of risk incurred by arsenic, providing the Navajo community and health practitioners with a more informed basis for decision-making.

**400 INCREASED LEVEL OF URINARY 8-HYDROXYDEOXYGUANOSINE RELATED TO ALDH2 POLYMORPHISMS IN WORKERS OCCUPATIONALLY EXPOSED TO STYRENE.**

1Japan National Institute of Occupational Safety and Health, Kawasaki, Japan, 2Beijing Fengtai Health Inspection Institute, Beijing, China, 3Beijing Guandi Zhongyi Hospital, Beijing, China, 4National Institute of Occupational Health and Poison Control, Beijing, China and 5Division of Biochemical Toxicology, National Center for Toxicological Research, Jefferson, AR. Sponsor: M. Lan.

In this study, we examined the effect of occupational exposure to styrene on the level of urinary 8-hydroxydeoxyguanosine (8-OH-dG), which is a good indicator of oxidative stress in vivo, in 329 styrene-exposed workers and 152 unexposed healthy individuals in a reinforced plastic factory. In addition, we also analyzed the modifying effect of genetic polymorphisms of ALDH2 on styrene-induced oxidative stress. Urinary 8-OH-dG was measured by an automated high-performance liquid chromatography-electrochemical detector system and is normalized to creatinine concentration. Results showed that the level of urinary 8-OH-dG was significantly increased in styrene-exposed workers than unexposed individuals. We observed that there was a positive correlation between the level of urinary 8-OH-dG and years of employment in workers exposed to styrene. Individuals carrying variant allele ALDH2*2 showed significantly higher level of urinary 8-OH-dG than wild-type ALDH2*1/*1 in styrene-exposed workers, but not in unexposed healthy individuals. These data indicated that occupational exposure to styrene seems to induce oxidative stress in vivo, and this oxidative stress may be modulated by the activity of ALDH2.

**401 PULMONARY FUNCTION TESTING IN UTILITY WORKERS.**

Environmental and Occupational Health, University of South Florida—College of Public Health, Tampa, FL.

Utility workers may be exposed to petroleum combustion by-products, insulation chemicals, and other pulmonary toxics in the workplace that may affect pulmonary function (PF) and may require use of respiratory protection. This investigation used occupational health monitoring examination data to characterize PF in a population currently employed as utility workers in the state of Florida. PF tests for male workers (n = 227) who required health examinations to ensure fitness for continued respirator use were compared to NHANES III Raw Spirometry subjects (n = 5,866) to determine if decreased PF was associated with employment as a utility worker. Mean FVC and FEV1 values were determined and multivariate regression was used to evaluate the impact of utility worker status on PF after adjusting for confounders. Workers produced a higher mean FVC of 4.84L (95%CI 4.72-4.96) compared to a mean NHANES III subject value of 4.70L (95% CI 4.68-4.73) (p = 0.0023). No significant difference was detected between the worker FEV1 mean of 3.81L (95%CI 3.72-3.90) and the mean NHANES III subject value of 3.71 L (95% CI 3.69-3.73) (p = 0.0560). No significant differences were found between mean pulmonary function test values of workers and NHANES III study subjects when stratified by age, height, and smoking status except among older utility workers, who demonstrated modestly better pulmonary function values compared to their NHANES III counterparts. Multivariate regression analysis demonstrated significant predictors of FEV1 included age, height, pack-years of smoking, and utility worker status (all p-values < 0.0001). Significant predictors of FVC also included age, height, pack-years of smoking, and utility worker status (all p-values < 0.02). The direction of effect for utility worker status was beneficial for lung function (parameter estimates 0.17 L FEV1 and 0.12 L FVC). The modest increase in PF observed in utility workers in multivariate analysis is likely due to a combination of effective exposure controls in the workplace and the healthy worker effect among aging workers.

**402 ENVIRONMENTAL FACTORS ASSOCIATED WITH THE DEVELOPMENT OF BREAST AND CERVICAL CANCER IN WOMEN FROM NAYARIT, MEXICO.**

L. Ortega1, E. A. Rojas1, M. L. Robledol, B. Barrón1, I. Gíron1, F. López1, A. Carrillo1, A. Rodríguez2, A. Jauregui1 and L. M. Medina1.

1Secretaria de Investigación y Piongreso, Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico, 2Centro Estatal de Cancerología de Nayarit, Secretaría de Salud, Tepic, Nayarit, Mexico and 3Hospital Civil Antonio González Guevara, Secretaría de Salud, Tepic, Nayarit, Mexico.

The incidence of breast and cervical cancer varies widely among countries. In Mexico, for several years (1955-2005) cervical cancer mortality used to surpass breast cancer mortality in women. In 2006, however, the incidence of breast cancer increased and went ahead cervical cancer. The same year, the state of Nayarit occupied one of the first places having high incidence of cervical and breast cancer. The aim of this study was to analyze whether some environmental factors are associated with the development of cancer, as well as to describe the current trends of morbidity for breast and cervical cancer in women who attended the Cancer Center of Nayarit, Mexico during 2006-2010. The preliminary results show that the prevalence of cervical cancer is high in the poorest and most marginalized regions where woman start sexuality at an early age. Patients with breast cancer had a family history of cancer (45%) early menarche (11-13 years), advanced age of menopause (50-54 years), smoking and drinking habits (9 and 6%, respectively). The etiology of cancer is multifactorial from which 95% is environmental and hormonal. Environmental estrogens include polyyclic aromatic hydrocarbons which appear to be carcinogenic by genotoxic mechanisms and are found in tobacco smoke. Studies are in progress to explore the association between environmental factors and the incidence of both types of cancer.

**403 HEART RATE VARIABILITY (HRV)-BASED ASSESSMENT OF AUTONOMIC FUNCTION DISTURBANCES USING A RODENT TELEMETRY MODEL.**

M. R. Mota1, T. J. Vidmar2 and P. R. Atkinson1.

1WILL Research Laboratories, Ashland, OH and 2BioSTAT Consultants, Portage, MI.

While heart rate variability (HRV) is widely recognized as an adequate marker for cardiovascular or autonomic function, it is not often considered for the preclinical evaluation of cardiovascular risk. In the present study we explored the use of HRV for the preclinical evaluation of drugs for potential disturbances in autonomic function. Five groups of 4 male Sprague Dawley rats surgically implanted with DSI T1L1N2-C50-PXT radiotelemetry transmitters for collection of blood pressure and heart rate were administered either autonomic system blockers (5 mg/kg Phentolamine; 1 mg/kg Atenolol; 0.5 mg/kg Atropine; and a combination of Phentolamine and Atenolol) or physiological saline by intravenous injection, and cardiovascular data collected continuously predose and for 24 hours postdose. HRV analysis was performed with Kubios analysis software, developed by the University of Kuopio, Finland. Variations in heart rate induced by reference compounds were calculated using the methods outlined by the North American Society of Pacing and Electrophysiology Task Force (1996) and encompassed time domain (statistical and geometric), frequency domain, and nonlinear methods. Results obtained with each method were analyzed statistically (one-way analysis of variance with a repeated measures model) focusing on either short term (one hour) or long term (24 hours) changes in HRV. For each method used, statistically significant changes were identified and a set of variables with potential as autonomic function marker were selected and discussed. The results support the use of a selected set of HRV endpoints to assess autonomic function in a rodent preclinical model.
**STUDIES OF THE QT PROLONGATION RELATIONSHIP IN GUINEA PIG, RABBIT, AND BEAGLE DOG IN THE QTc ASSESSMENT.**

QT interval prolongation of the electrocardiogram has been associated with the occurrence of life-threatening fatal ventricular arrhythmias. The recent withdrawal from marketing of several drugs due to potential drug-related cardiac arrhythmias has greatly increased concern about drug-related changes on the QT interval. To avoid the QT prolongation as to increase the safety margin of new drug candidates during new drug discovery and development, use of much rigorous methodology is critical to evaluate the potential of QT prolongation liability. To exploring the relationship between preclinical cardiac conduct assessments relatively to the clinical outcome, measurements of QT Prolongation by Sotalol in Guinea pig, Rabbit, and Beagle dog were conducted using standard 12-lead ECG. The results display a linear relationship of ΔQTc versus body weight in three testing animals. Interestingly, extending the relationship with the literature human data revealed that ΔQTc is better fitted with the body surface area. Additionally, crude extracts of several Traditional Chinese Medicines, which respectively consist of potential cardiotoxic alkaloids, dipterter lactone, and cardiac glycosides, were studied using this system. Most ΔQTc is linear fit with the body weights of Guinea pig, Rabbit, and Beagle dog. Those results are discussed.

**QT CORRECTION METHODS: CAN WE FURTHER OPTIMIZE METHODS IN CYNOMOLGUS MONKEYS, BEAGLE DOGS AND GOTTINGEN MINIGUS?**

A. Stein*, S. Author†-‡, A. Ascha*, M. Pouliot*, R. Forster* and E. Troncy‡,

1Stein Consulting, LLC, San Diego, CA.
2CiT oxLAB, Laval, QC, Canada and
3Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, QC, Canada.

Correction of QT interval for heart rate is common practice in safety pharmacology. While standard correction methods are widely used, these methods suffer from species specific but also individual variations of the QT/RR relationship. Electrocardiographic data obtained from implanted and jacketed telemetry was used for analysis. A comparison of standard correction formulas and an individual correction method was conducted in Beagle dogs, cynomolgus monkeys and Göttingen minipigs. In all species, an individual correction method (QTca) provided the most stable QT values as a function of heart rate. When comparing standard methods, QT was optimally corrected with the Fridericia’s method (QTcF) in minipig, the Bazett (QTcB) in monkeys and QTcF or the Van De Water’s method (QTcV) for Beagle dogs. When using jacketed telemetry data, the mean slope of QTc as a function of heart rate in cynomolgus monkeys was 0.179 ± 0.232 msec/bpm for QTcF, 0.467 ± 0.070 msec/bpm for QTcB and 0.020 ± 0.010 msec/bpm for QTcV. The interval between calculations of QTc correction parameters for each animal may represent a success factor when using this method. Our results strongly highlight the beneficial impact of an individual correction method to improve the correction slope in all species but also to decrease variation of individual data within the same species, therefore increasing sensitivity of the models to detect QTc prolongation or shortening.

**RELIABILITY OF QT MEASUREMENTS COLLECTED FROM ROUTINE 28-DAY REPEAT-DOSE TOXICITY STUDIES.**

R. Irwin, E. N. Luca, K. Willard, B. S. Wahle and D. S. Dandekar, Xenometrics, LLC, Stilwell, KS.

There is a growing demand to include safety pharmacology parameters as a part of nonclinical toxicity studies. To meet this demand, various options such as jacket ECG monitoring or a subset of surgically implanted telemetryed dogs has been explored. Measurement of surface ECGs from limb leads I, II and III during a standard 28-day repeat dose canine toxicity study has been an ongoing practice for several years. However, due to study-related manipulations during study conduct, reliability and additive value of surface ECGs measured during toxicity studies is still unclear. In this case study, we have compared the ECG data (QT interval) obtained from dog telemetry studies (CV studies) to that of ECGs obtained from toxicology studies (TOX studies).

For comparison, vehicle control data (QT and RR interval) from three canine TOX studies and vehicle control data (QT and RR interval) from three canine CV studies were compared following Day 1, 2 or 3 postdose intervals. To assess the effect of handling/study-related manipulations during toxicity studies, pre-study surface ECG data (Day 1) was also compared with post-study data (Day 28).

The QT duration for beagle dogs from CV studies was 250 – 300 milliseconds (ms) and for the dogs from TOX studies was 215 – 240 ms (Day 1 and Day 2). The QT duration for dogs from CV studies was significantly greater than the QT duration for the dogs from TOX studies at all the time points however; the data were still within our laboratory historical range for CV or TOX study type and all the data obtained from the TOX studies from Day 1 and Day 28 were very consistent (within 215-240 ms). These results suggest that the surface ECG data following daily handling or study related manipulations of the animals did not affect the QT interval data. This comparison also shows that the surface ECG measurements should provide a reliable snap shot of potential QT effects following repeat dose administration without utilizing special (jacketed or telemeterized) dogs. Further investigations on the sensitivity of surface ECG measurement is ongoing.

**OPTIONS FOR BLOOD PRESSURE DETERMINATION IN EITHER DRF, MTD, OR REPEATED-DOSE TOXICITY STUDIES IN CYNOMOLGUS MONKEYS.**

B. Niggemann and M. Nickhoff, Covance Laboratories GmbH, Muenster, Germany.

Sponsor: E.Vogel

Introduction: Various methods are available for determination of blood pressure in cynomolgus monkeys. Animal restraint is required for standard oscillometry (OSC) as well as High Definition Oscillometry (HDO), whereas animals are allowed to freely move in their homecage during data collection for both minimal invasive(MI) and full implant (FI) telemetry. In this study we compared the above blood pressure determination approaches in the cynomolgus monkey model when applied to different study designs. Methods: Blood pressure measurements were performed under different conditions and various methodologies as follows: OSC: Cardell; Veterinary Monitor; HDO: S+B medVet Memo Diagnostic; MI: PA-C10-TOX implant, FI: Koenigsberg T27F-2B. Results: For OSC the systolic pressure range was 143±22 (mean±SD), diastolic 90±25, and MAP 116±24 mmHg, for HDO the ranges were 138±21 mmHg for systole, 73±12 mmHg for diastole, and 96±13 for MAP on conscious, untreated animals. For the FI, systolic pressure range was 118±3, diastolic 86±3, and MAP 100±4. Overall, it has to be noted, that for both restraint procedures, the standard deviation is higher when compared to invasive approaches. Although non-invasive OSC and HDO indicate overall reliable results, detection of hypertension becomes difficult because of excitement and manually elevated base pressure values. The introduction of an implanted system with regard to detection of hypertension was clearly shown in animals after treatment with Torcetrapib (FI), and with Effortil (MI). However, it certainly needs to be considered that invasive approaches might be accompanied by unexpected side effects (e.g. micro infarts), but our data indicate only local irritations like intima thickening. Conclusion: The data suggest that especially for drug induced hypertensive effects, the use of either full implants (FI) or minimal invasive (MI) telemetry implants should be considered since data collection is feasible in conscious, unrestrained animals and can be collected for significantly prolonged periods.

**JACKETED EXTERNAL TELEMETRY IN GUINEA PIGS: A SCREENING TOOL FOR EVALUATION OF CARDIO-RESPIRATORY FUNCTION IN EARLY DRUG DEVELOPMENT.**

The guinea-pig is a well established animal model for the evaluation of QT lengthening. The guinea pig is routinely used as anesthetised model or as a conscious model using implanted telemetry. Implantation of telemetry devices in guinea pigs requires surgical intervention that is time consuming and expensive. Therefore, the purpose of the present study was to evaluate a newly established jacketed external telemetry model in freely moving guinea pigs. Female guinea-pigs were equipped with jacketed external telemetry external telemetry using DSI transmitters and placed in plethysmography chambers allowing simultaneous recording of ECG and respiratory parameters. To evaluate the sensitivity of the model, effects of low dose of sotalol (10 mg/kg) or vehicle (0.5% methylcellulose) on ECG were investigated in freely moving guinea pigs (6 animals per group). In addition, effects of clonidine (5 mg/kg) on respiratory parameters were investigated. Drug treatments were performed by the oral route and all parameters were recorded one hour before and for a minimum of 4 hours after treatment. Although a low dose-level was used in the present study, significant increases in QT and QTT (Bazett’s correction) were observed after administration of sotalol. When compared to the vehicle, clonidine produced significant decreases in tidal volume and increases in respiratory rate. The present study demonstrates that the jacketed external telemetry model allows for a reliable screening tool for the potential risk assessment of new chemical entities, biologics or anti-cancer drugs on cardio-respiratory function in early drug development process.
409 METHOD VALIDATION OF CARDIOVASCULAR AND RESPIRATORY SAFETY ASSESSMENT IN CYMONOLUS MONKEYS AND BEAGLE DOGS.

This study validates the methods of cardiovascular and respiratory safety assessment in cynomolgus monkeys and beagle dogs using telemetry system and respiratory flow system at Pharmaron’s Laboratory. The cardiovascular effects of moxifloxacin and xylazine were investigated in cynomolgus monkeys and beagle dogs implanted with telemetry transmitters. The respiratory effects of methacholine, 8% CO2 and buprenorphine were evaluated in conditioned cynomolgus monkeys with helmet and beagle dogs with face mask connecting to respiratory flow system.

Moxifloxacin significantly prolonged QTc intervals and increased QT and R-R wave intervals in the telemetered cynomolgus monkeys (given 50 mg/kg) and beagle dogs (given 60 mg/kg). Xylazine increased both the diastolic and systolic pressures immediately after dosing in telemetered beagle dogs (given 2 mg/kg). Methacholine (8 μg/kg) significantly increased respiratory rate and minute volume (MV) in beagle dogs. CO2 at 8% significantly increased tide volume (TV), MV and respiratory rate in cynomolgus monkeys. Buprenorphine significantly decreased TV and MV in beagle dogs (given 16 μg/kg) and decreased MV and respiratory rate in cynomolgus monkeys. The changes observed cardiovascular and respiratory effects are similar and/or comparable to the results reported in the literature [1-8].

In conclusion, the cardiovascular effects of moxifloxacin and xylazine and the respiratory effects of methacholine, 8% CO2 and buprenorphine reported in the literature were reproducible in Pharmaron’s laboratory.

410 IMPACT OF A NOVEL DENOISING ALGORITHM ON ECG ANALYSIS.

M. Miyamoto1 and M. Brockway2,3,1Huntingdon Life Sciences, E. Millstone, NJ, 2VisaQuant, St. Paul, MN and 3University of Minnesota, St. Paul, MN, Sponsor: R. Hamlin.

Noise and artifact in ECGs collected from ambulatory preclinical subjects has been an obstacle to accurate and efficient automated analysis of ECG intervals. Most troublesome is noise that is within the bandwidth of the ECG signal (e.g., in-band noise) because it cannot be removed by traditional filtering techniques without distorting the ECG. In-band noise is most often caused by EMG and movement artifact. A new technology, Multi-Domain Signal Processing (MDSP denoising), has been shown to reduce the amplitude of in-band noise by up to 90% without distorting ECG morphology. In this work, the impact of MDSP denoising on analysis of ambulatory telemetered preclinical subjects using the EMKA ECGauto is evaluated. Five 24-hour recordings obtained using DSI D70-PCTs and Dataquest were analyzed by an experienced operator using EMKA ECGauto before and after MDSP denoising. Analysis results show that denoising using MDSP reduces the number of cardiac cycles rejected by the EMKA system due to excessive noise by > 90%. These results demonstrate that denoising of ECG recordings using MDSP prior to analysis with EMKA ECGauto can provide a significant increase in the number of cardiac cycles that can be automatically analyzed using the EMKA system, and may reduce the amount of labor required to review and edit results, especially when continuous beat-to-beat evaluation is required.

411 STATISTICAL SIMULATION FOR SENSITIVITY OF THE JACKETED EXTERNAL TELEMETRY ASSAY FOR DETECTING CHANGES IN ELECTROCARDIOGRAM AND BLOOD PRESSURE.

M. Marker, K. Soper, M. Santora, Y. Dhulipala and H. Miyazaki, Merck & Co., West Point, PA.

A statistical simulation was performed to assess the sensitivity of the canine jacketed external telemetry assay incorporated to a toxicity study for detecting drug-induced changes in electrocardiogram (ECG) and blood pressure (BP). Two studies were conducted: 0.5% methylcellulose and dl-sotalol at 1, 3, and 10 mg/kg (p.o.). The dl-sotalol study had a 3-period fixed sequence design with 4 dogs; each received vehicle (period 1) followed by two different doses (period 2 and 3). The vehicle study had 4 dogs; each received 0.5% methylcellulose over several periods. The sensitivity/power was simulated for 3-period fixed sequence (n=3/seq. 2 or 3), parallel groups (n=6/group or 3) and 4x4 Latin square (n=1/seq.) designs. The simulations assumed a true effect profile and variability from the two studies. The data were 5 min. averages, every 5 mins. for 24 hours. Data were summarized via AUC[0 to 6 hrs] and analyzed using repeated measures ANOVA. The simulation results for the 3-period fixed sequence design (n=2/seq.) showed that the test system was capable of detecting significant (p-value <0.05) changes of 10-14%, 37-46%, 21-28%, 13-16% and 9-13% in BP, HR, PR, QRS, and QTc with 80-90% power, respectively. The sensitivity was improved by increasing the number of dogs to n=3/seq. (5.3-6.6% in QTc with 80-90% power in n=3/seq.) and changing study design to a 4x4 Latin square (5%-6% change in QTc with 80-90% power with n=1/seq.) or a parallel design with n=6 or 8 per group (3.6-4.2% in QTc with 80-90% power in n=6/seq.; 3.2-3.5% in QTc with 80-90% power in n=8/seq.). In the dl-sotalol study, the expected pharmacological changes (dose-response and time-course changes) were accurately detected; effects as small as a 14% decrease in HR, 8% increase in PR and 9% increase in QTc were detected. In conclusion, the canine jacketed external telemetry assay incorporated to toxicity studies, was able to detect small changes in ECG or BP and was considered acceptable as a cardiovascular model in the preclinical testing.

412 ASSESSMENT OF BOVINE SERUM ALBUMIN ADDED TO MODIFIED KREBS HENSELIEF BUFFER EFFECTS ON ECG, LEFT VENTRICULAR MECHANICS, AND CORONARY BLOOD FLOW IN THE GUINEA PIG ISOLATED HEART.

The Langendorf isolated heart perfusion assay is valuable in determining the effects of pharmaceutical compounds on changes in cardiac electrical conductivity and cardiac contractility. Perfusion of the isolated heart with protein-free solution may result in myocardial tissue edema which would alter hemodynamic function. Bovine Serum Albumin (BSA) is commonly used in preparations of Krebs Henseleit Buffer (KHB) to prevent tissue edema. The added protein increases oncotic pressure by drawing fluid into the circulatory system, mimicking conditions found in the in vivo considering albumin in blood is responsible for 79% of the total capillary oncotic pressure. The aim of this study was to determine the effects of 1% BSA added to the KHB in retrograde perfusion on the isolated guinea pig heart. Measurements of ECG, left ventricular mechanics, and coronary flow were compared for KHB solution alone, against KHB with 1% BSA added. Additionally, in increasing concentrations of terfenadine, a known QT prolonging agent, parameters were assessed utilizing the 1% BSA in KHB. Hearts perfused with 1% BSA demonstrated an increase in coronary flow rates over time while hearts perfused with KHB alone decreased. Effect of BSA on ECG was minimal between the two groups. The increasing concentrations of terfenadine caused reduced contractility parameters as well as QT prolongation in the presence of BSA. In conclusion, the isolated hearts perfused with 1% BSA demonstrated greater stability in the measured contractility parameters over time as compared to hearts perfused with KHB alone. The effects of terfenadine where similar in this preparation.

413 THE TELL-TALE HEART: WHAT CAN THE ISOLATED HEART TELL US ABOUT DRUG-INDUCED CARDIAC INJURY?

K. A. Henderson1, B. R. Borders1, B. J. Ross1, H. Theresa3, J. Amir4, E. Gonzalez2, S. Armentrout2 and B. Brian2. 1Science and Technology, Battelle Memorial Institute, Columbus, OH, 2Safety Pharmacology, Battelle Memorial Institute, Columbus, OH, 3Batelle Eastern Science and Technology Center, Battelle Memorial Institute, Akron, MD and 4Medicine, Ohio State University, Columbus, OH.

Pharmaceutical drug attrition and failures after FDA approval remains an issue for the pharmaceutical industry and public safety. 30% of post approval drug failures are due to cardiac toxicity with 12% from arrhythmias and 18% due to compromised contractility. There is a need to engage in earlier, rigorous, preclinical cardiac testing. A cardiac toxicity assay should be cost effective, balanced specific and sensitive, translatable and predictive of acute and latent cardiac dysfunction and damage. The Langendorf model appears to meet most of these requirements. Our goal was to demonstrate the power and viability of the Langendorf model for predicting drug induced defects in cardiac contractility by combining multiple analysis end points including ECG, contractility, energetics, and biomarkers of injury. Male Sprague-Dawley rats were anesthetized with 50 mg/kg Nembutal, intratracheal, intravascular, and hearts were removed, placed in a cardiopulmonary solution for < 10 min, cannulated via the aorta, and perfused with Modified Henseleit Krebs solution at 37°C. A balloon was inserted into the left ventricle to measure left ventricular pressure (LVP) and electrodes were placed on the heart to measure ECGs. After equilibration, a baseline was measured followed by escalating doses of each class of drug for 20 minutes each dose. ECG and LVP were recorded continuously and effluent was collected from the heart at the end of each dosing period for analysis of biomarkers indicative of injury. Energy status of the heart was assessed by measuring high energy 31phos-
Cardiac toxicity is one of the leading causes of drug failures over the past two decades; withdrawals occurring during both development and after approval. Up to 30% of patients (children and adults) receiving chemotherapies such as Doxorubicin experience latent cardiac toxicity up to 15 years after initial treatment. The need to employ predictive, specific, sensitive, and cost-effective safety assays earlier in drug development and at times to retro test withdrawn drugs to determine mechanisms of unexpected toxicities has resulted in the necessity to not only extrapolate pharmacokinetic (PK) data between preclinical species, but also in vivo to in vitro studies. Data generated by traditional PK models apply only to the conditions and species from which the data was generated. This limitation has been most apparent in risk assessment analysis of environmental and industrial toxicants where human data is not usually available and Physiologically Based Pharmacokinetic (PBPK) models are used for species to species extrapolation of data from animal to human model based on physiological differences. Our goal was to apply this technique in the pharmaceutical drug arena to determine clinically relevant doses for potential cardiac toxicity assessment in the Langendorff Rat isolated heart model. Using Berkley Madonna™ software we developed PBPK models, human to rat species extrapolations, to determine clinically relevant doses associated with cardiac acute and latent toxicity for Doxorubicin, Sunitinib, Erlotinib, and 5-fluorouracil. We also extrapolated rat in vivo dosing to rat Langendorff concentrations, to determine relevant doses for acute cardiac injury for Isoproterenol, Verapamil, Carbonyl cyanide 4-(trifluoromethoxy)phenylhydrazone (FCCP), and Caffeine. The doses determined will be used to induce both acute cardiac toxicity and mimic conditions shown to cause latent toxicity in the Langendorff preparation.

The hERG channel assay is routinely used to evaluate the effects of new chemical entities on the delayed rectifier potassium current (IKr). Although the methodology of such assay is quite standardized, the experiments are not systematically conducted at physiological temperature. However, some test substances can display different properties or potencies at physiological temperature versus room temperature. The aim of this work was to evaluate the influence of the temperature on the hERG channel blockade induced by erythromycin or terfenadine.

Whole-cell patch clamp method was used to record the sodium current (INa) encoded by hNav1.5 in stably transfected HEK293 cells (n=6 to 7 cells/group). Experiments were performed at either near-physiological (35°C) or ambient (22-24°C) temperature. At physiological temperature, erythromycin (from 30 to 900 μM) concentration-dependently decreased the amplitude of IKr (-70.3 ± 4.9% at 900 μM, IC50 = 211.1 ± 51.54 μM). In contrast, at ambient temperature, erythromycin (900 μM) only slightly decreased the amplitude of IKr (-17.0 ± 4.0%).

Terfenadine (from 0.01 to 10 μM) similarly decreased the amplitude of IKr whatever the temperature used (IC50 = 0.27 ± 0.02 μM at ambient temperature versus 0.17 ± 0.05 μM at physiological temperature, NS). These findings suggest that the hERG Channel blockade induced by erythromycin was greater at physiological temperature than at room temperature. Therefore, the highest sensitivity of the model at 35°C should allow detecting proarrhythmic risk of a substance at lower concentrations. Although all substrates are not temperature-sensitive, the use of physiological temperature in the hERG Channel Test should be recommended for screening or safety pharmacology studies.

A novel heart slice model was used to compare the responses of human and rat to the following cardiotoxic drugs: isoproterenol, a β-adrenergic agonist known to induce cardiac ischemia and hypertrophy, and etomoxir, an inhibitor of mitochondrial long-chain fatty acid oxidation that can cause cardiac hypertrophy. Gene and
protein expression patterns were analyzed to compare activated pathways in the two species. Heart slices (1-200 μm thickness) from human donors or adult male Sprague-Dawley rats were cultured for 24 hr with isoproterenol (0-1000 μM) or etomoxir (0-500 μM). Both drugs effected human and rat slice energy (ATP) levels, which were measured as an indicator of tissue viability. Human heart slices treated with isoproterenol or etomoxir caused changes in gene expression associated with cardiac hypertrophy (Keg, Reg30), mitochondrial function (Idh2-3, Sdhα), and stress response (Hyp/A), as well as inflammatory (IL-6) and remodeling (TIMP 2, 4) protein biomarkers. Rat heart slices showed changes in genes related to stress response (Hyp/A) and cardiac hypertrophy (Reg3β). Additionally, etomoxir altered gene expression of the fatty acid oxidation pathway (Acot, Acox) in human and rat, consistent with its mechanism of action. In summary, heart slices responded to the known cardiotoxic agents isoproterenol and etomoxir. The mechanism of toxicity of these drugs can be examined using gene and protein expression in combination with pathway analysis. This model will be useful to provide insight into the effects of drugs with unknown mechanisms of toxicity.

419 MULTIPLEX BIOMARKER APPROACH FOR DETERMINING DRUG-INDUCED VASCULAR INJURY (DIVI) IN RAT.

Vascular injury is a common finding during the pre-clinical safety study of drugs. A lack of understanding of mechanisms of drug-induced vascular injury (DIVI) in animals, the absence of accepted specific and sensitive biomarkers have become significant barriers in the development of new therapeutics. A number of promising biomarker candidates have been nominated with the need for further validation and evaluation. However, the lack of qualified high-throughput assays has imposed a hurdle to the progress in this area.

Based on Lumines® MAP® technology, we developed multiplexed immunoassays for a panel of nine DIVI biomarker candidates in rat. The biomarker candidates included Alpha-2 Macroglobulin, Alpha-1 Acid Glycoprotein, Cavolin-1, CINC-1/GRO, Connective Tissue Growth Factor, Haptoglobin, Tissue Inhibitor of Metalloproteinase-1, Vascular Cell Adhesion Molecule 1, and Von Willebrand Factor.

To establish the sensitivity and specificity of the rat DIVI biomarker multiplex assay, serum and plasma samples from fenoldopam mesylate (FM) induced rat DIVI models were analyzed with the assay and the levels of the nine biomarker candidates were quantified simultaneously. To induce vascular injury, rats were treated with the vasodilator compound fenoldopam mesylate (FM). FM was administered by continuous intravenous infusion with a dose of 6 mg/kg/h over 24h. Subsequently to the infusion, three rats were sacrificed and serum and plasma was collected at day 1, 3, and 7 each. Sterile 0.9% saline was used in the vehicle control cohorts. Separately, a group of animals were IP-injected with FM. Serum and plasma samples were collected 6 hour, 24 hour and 5 days post-injection. Significant blood level elevations of several candidate biomarkers were observed in the fenoldopam-treated animals compared to the vehicle-treated cohorts. The degree of biomarker elevation in blood correlated to the dose and time of FM treatment. Overall, these results demonstrate the feasibility of using the multiplex biomarker approach to determine the onset and severity of DIVI in pre-clinical drug safety studies.

420 CHARACTERIZATION AND UTILIZATION OF INDUCED PLURIPOTENT STEM CELL-DERIVED CARDIOMYOCYTES IN IDENTIFYING NOVEL MECHANISMS OF CARDIOTOXICITY.

D. Puppala, V. Bonato, Y. Will, B. Anson, M. Pletcher and S. Engle.

Cardiotoxicity is one of the leading causes of early and late stage drug attrition which has significant impact on patients welfare and in particular for cancer patients. Current in vitro models insufficiently predict cardiotoxicity and there is a definite need for alternate physiologically relevant in vitro models. Induced pluripotent stem cells offer the promise for development of tissue specific in vitro models. In here, we describe the use of induced pluripotent stem cell-derived cardiomyocytes (iCell CM) for identifying novel molecular mechanisms of cardiotoxicity. Towards this end, we characterized iCell CM using gene expression analyses over a 42 day period post thaw in culture. Based on our initial analyses iCell CM express relevant cardiac markers such as ion channels (SCN5A, KCNQ2, KCNQ1 and KCNQ3), cardiac tissue markers(MYH6, MYLFP, MYBPC3, DES, TNNI3, TNN2 and TNN3), cardiac transcription factors (NKKX2.5, GATA4 and GATA6) and lacked the expression of stem cell markers(FoxD3, GROX2, NANOG, POU5F1, SOX2, and ZFP42). We then selected ten in vivo structural cardiotoxicants which were not flagged by our current in vitro assays and generated gene expression data in response to these compounds in both iCell CM and rat heart derived cell line H9C2. To further evaluate the data, we used our internal Casual Reasoning Engine (CRE) platform, which analyzes experimental gene expression data, in the context of prior biological knowledge to generate testable upstream molecular hypotheses. Based on our initial analyses across all compounds, iCell CM exhibited increases in structural cardiotoxicity injury signals, inflammation signals and TGFB beta signaling pathways whereas H9C2 cells exhibited increase in muscle injury signals, decreases in both TGFB gene and inflammation signals. In conclusion, iCell CM appear to represent a better in vitro cardiomyocyte model for understanding cardiotoxicity mechanisms and further validation will be performed to confirm these findings.

421 MURINE-SPECIFIC VASCULAR TOXICITY OF A VITRONECTIN RECEPTOR ANTAGONIST: MECHANISTIC STUDIES.

D. A. Dalmas, M. S. Scicchitano and D. W. Morel.1 Department of Pharmaceutical Sciences, University of the Sciences in Philadelphia, Philadelphia, PA and 2Safety Assessment, GlaxoSmithKline, King of Prussia, PA.

In previous studies, a potent, orally-active, non-peptide vitronectin (tvfβ3, tvfβ5) receptor antagonist (SB-273005) induced unique vascular lesions in mice, but not other species pharmacologically responsive to SB-273005 or other antagonists. Vascular smooth muscle cell (VSMC) necrosis was observed in the aorta of mice approximately 6 hours after dosing, followed by VSMC loss with adaptive VSMC hypertrophy but no endothelial damage. The lesions were non-progressive, as aortic changes were similar in mice treated for 4 days or 3 months, and were irreversible with no evidence of regeneration observed after drug-withdrawal. Since drug-induced direct chemical vascular toxicity is uncommon, especially in mice, involvement of VSMC–endothelial cell (EC) interactions in development of the toxicity was hypothesized. To explore this possibility, in vivo model systems of strain-specific primary murine aortic VSMC and EC were established and utilized to investigate the potential mechanism of cellular toxicity using both monocultures and VSMC/EC cocultures. Incubation of monocultures and cocultures with SB-273005 within a dose range and timeframe comparable to the in vivo studies showed a concentration-dependent decrease in viability, with subsequent increases in cytotoxicity, for both VSMC and EC monocultures and VSMC/EC co-cultures; however, VSMC monocultures responded at lower doses (were most sensitive), suggesting a direct effect on VSMC. EC are less susceptible than VSMC to the toxic action of SB-273005, and do not markedly affect VSMC toxicity. Further studies using VSMC monocultures revealed increases in Caspase 3 & 7 activity as early as 1 hr following treatment with SB-273005. These data suggest VSMC apoptosis is the primary mechanism of toxicity responsible for the murine-specific vascular lesions.

422 COENZYME Q10 RESCUES ENDOTHELIAL CELLS FROM NRTI-INDUCED MITOCHONDRIAL DAMAGE AND MITOPHAGY.

V. Y. Hebert, S. Xue and T. Dupas. Pharmacology, Toxicology, and Neuroscience, Louisiana State University Health Sciences Center in Shreveport, Shreveport, LA.

Long-term use of nucleoside reverse transcriptase inhibitors (NRTI) is known to induce mitochondrial damage in endothelial cells, culminating in endothelial dysfunction, an initiating event in the pathogenesis of atherosclerosis. Though the mechanism of NRTI-induced effects on endothelial cells is not well understood, prior work suggests that a mitochondrially-compartmentalized oxidative stress may be involved. We thus investigated the potential of adjunct utilization of the antioxidant coenzyme Q10 (CoQ10) to combat NRTI-induced endothelial toxicity and further characterized the mechanism of acute NRTI toxicity in endothelial cells. Co-treatment of human umbilical vein endothelial cells (HUVEC) with CoQ10 was found to rescue cells from increases in ROS levels and decreases in ATP production and oxygen consumption induced by NRTI treatment alone. In addition, we found that NRTI increased levels of endothelin-1, a marker for endothelial cell activation, but this effect was also reversed by CoQ10 co-treatment. Finally, treatment of HUVEC with the NRTI zidovudine (AZT) induced selective mitochondria...
ial autophagy, or mitophagy, AZT treatment for 6-8 h increased lysosomal activity, while 8 h treatment resulted in increased mitophagy with lysosomes, an indicator of mitophagy. The LC3-II/LC3-I ratio, a marker of autophagosomal activity, was also increased in treated cells. These findings suggest that NRTI-induced autophagic degradation of mitochondria may be involved in NRTI-induced endothelial dysfunction, and that this damage likely results from oxidative injury. NHLBI R01 HL082472.

423 TEMPOL AND TEMPOL-H PROTECT CARDIOMYOCYTES FROM NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITOR (NRTI)-INDUCED MITOCHONDRIAL TOXICITY.
Y. Liu1, P. Nguyen1, A. Gibbons1, J. B. Mitchell2 and M. C. Poirier1, 1Carcinogen-DNA Interactions Section, National Cancer Institute, Bethesda, MD and 2Tumor Biology Section, RBB, National Cancer Institute, Bethesda, MD.
NRTIs are essential components of the successful antiretroviral combination therapies used for treatment of HIV-1. However, during long-term therapy NRTIs may damage heart mitochondria, thus limiting clinical use of these drugs. Consequently, reducing NRTI-induced mitochondrial toxicity may benefit HIV-1-infected patients. Using H9c2 rat cardiomyocyte cultures exposed long-term to Zidovudine (AZT) or AZT plus Didanosine (ddI) we demonstrated NRTI-induced mitochondrial damage. In an attempt to protect mitochondria from this damage we have used the stable free radical Tempol and its metabolite Tempol-H, cyclic nitroxides with antioxidant properties. H9c2 cells were exposed to 50 μM AZT plus 50 μM ddI for 15 passages (P15) in the presence and absence of 150 μM Tempol or 150 μM Tempol-H. The AZT/ddI combination caused moderate growth inhibition (< 30 %), and co-exposure with Tempol or Tempol-H did not restore cell survival. Mitochondrial oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) were measured using the Seahorse XF24 analyzer. As seen previously, AZT/ddI reduced maximal FCCP-uncoupled OCR. However co-exposure with Tempol and Tempol-H stimulated OCR, restoring the AZT/ddI-reduced uncoupled OCR by 22-91 %. Similarly, the uncoupled ECAR levels were increased by 15-46 % with Tempol or Tempol-H. Preliminary Western blot findings showed that Tempol and Tempol-H enhanced the expression of uncoupling protein-2 (UCP-2). Therefore Tempol and Tempol-H may protect cardiomyocytes from mitochondrial compromise induced by the NRTI combination AZT/ddI, and UCP-2 may play a role through mild uncoupling. We are currently evaluating potential mechanisms by which these compounds may act as mitochondrial protective agents.

424 OVEREXPRESSION OF CAVEOLIN-1 PROMOTES ATHEROSCLEROSIS THROUGH INCREASED VASCULAR CELL ADHESION MOLECULE-1 EXPRESSION IN PRIMARY VASCULAR ENDOTHELIAL CELLS.
M. C. Petriello1 and B. Hennig2, 1Toxicology, University of Kentucky, Lexington, KY and 2Nutritional Sciences, University of Kentucky, Lexington, KY.
Persistent organic pollutants, such as polychlorinated biphenyls (PCBs), are well-known to cause toxicity in various cell types, including endothelial cells. Particularly detrimental, coplanar PCBs including PCB 77 and PCB 126 can activate the aryl hydrocarbon receptor (AhR) and subsequently induce oxidative stress and NF-κB activation. Increasing evidence has shown that lipid raft membrane microdomains, caveolae, may play an important role in the toxicity of coplanar PCBs. Caveolae are abundant in vascular endothelial cells and the cardiovascular system in general, which points to a possible major role for caveolae in inflammation and atherosclerosis. Our lab has reported previously that coplanar PCBs promote the up-regulation of genes related to the activation of endothelial cells and the initial stages of atherosclerosis. In this work we show evidence that the integral caveolae protein, caveolin-1 (Cav-1), may play an important role in PCB-induced activation of endothelial cells. In an effort to examine the impact of Cav-1 on the initiation of atherosclerosis, a Cav-1 gene overexpression vector was created and transfected into primary vascular endothelial cells. Vascular cell adhesion molecule-1 (VCAM-1) and Cav-1 protein levels were assessed using Western blot. The inducible vector system successfully promoted overexpression of Cav-1 in a positive dose dependent manner. It was determined that doubling the expression level of Cav-1 resulted in nearly a 3-fold increase in VCAM-1 protein expression. These results were consistent for both porcine and human endothelial cell lines. Increasing Cav-1 levels may alter cellular trafficking and or cellular signaling and subsequently promote the early stages of atherosclerosis. This work adds to the growing evidence that Cav-1 or functional caveolae may play an important role in endothelial cell activation and cellular dysfunction.

425 TYROSINE KINASE INHIBITOR SUNITINIB, INDUCED CARDIAC HYPERTROPHIC GENES THROUGH MITOGEN-ACTIVATED PROTEIN KINASES-DEPENDENT PATHWAY IN H9C2 CELLS.
H. A. Al-Suwayeh, S. A. Al-Bakheet and H. M. Korashy, Department of Pharmacology & Toxicology, College of Pharmacy, King Saud University, Riyadh, Saudi Arabia. Sponsor: A. El-Kadi.
Sunitinib (SUN) is a recently FDA-approved antitumor tyrosine kinase inhibitor for the treatment of renal cell carcinoma and gastrointestinal stromal tumors. Although SUN has improved survival rates in cancer patients, cardiotoxicity has been reported as a significant side effect. Several mechanisms have been proposed by which SUN causes cardiotoxicity. Yet, the potential effects of SUN on cardiac hypertrophic genes and the role of mitogen-activated protein kinases (MAPKs), including p38, ERK and JNK, signaling pathway have never been studied. Accordingly, we hypothesized that SUN induces cardiotoxicity by altering the expression cardiac hypertrophic genes through MAPK-dependent mechanism. To test our hypothesis, rat cardiomyocyte H9c2 cells were utilized as an in vitro model to a) determine the potential effect of SUN on the expression of cardiac hypertrophic genes, particularly α-MHC, β-MHC and BNP, at the mRNA and protein levels and b) explore the molecular roles of MAPKs' signaling pathways in SUN-induced cardiotoxicity using specific pharmacological inhibitors. At the mRNA levels, our results showed that SUN induced the mRNA expression of all the three hypertrophic genes in dose- and time-dependent manners. The mRNAs of hypertrophic genes were detectable as early as 6 h and remained elevated for at least 18 h after SUN treatment. Interestingly, pretreatment of H9c2 cells with p38 MAPK inhibitor, SB203580, significantly restored SUN-mediated effect, whereas neither inhibitors of ERK nor JNK inhibitors altered the mRNA expression. At the protein level, the induction of hypertrophic protein levels by SUN were gradually decreased by all MAPK inhibitors. In conclusion, our study clearly demonstrated that SUN induced hypertrophic genes at the mRNA and protein expression levels through MAPK-dependent signaling pathway.

426 SUNITINIB, TYROSINE KINASE INHIBITOR, INDUCES CYTOCHROME P450 1A1 GENE EXPRESSION IN RAT CARDIOMYOCYTE H9C2 CELLS: A POSSIBLE MECHANISM OF CARDIOTOXICITY.
Z. H. Maayah and H. M. Korashy, Pharmacology & Toxicology, College of Pharmacy, King Saud University, Riyadh, Riyadh, Saudi Arabia. Sponsor: A. El-Kadi.
Sunitinib (SUN) is a new multitargeted oral tyrosine kinase inhibitor that has both antiangiogenic and antitumor activity. Although sunitinib has improved survival rates in cancer patients, cardiotoxicity has been reported as a significant side effect. In this regard, several studies have demonstrated a direct correlation between the cytochrome P450 1A1 (CYP1A1) induction and cardiotoxicity. Taken together, the possibility that SUN induced cardiotoxicity through the induction of CYP1A1 has never been investigated yet. Therefore, we hypothesized that SUN induced cardiac hypertrophic genes through the induction of CYP1A1 gene expression. To test our hypothesis, we examined the capacity of SUN to induce the constitutive CYP1A1 gene expression and its correlation with two hypertrophic genes, atrial natriuretic peptide (ANP) and cardioprotein-1 (CT-1) mRNA levels in H9c2 cells. Our results showed that SUN induced CYP1A1 mRNA, protein, and activity levels in a concentration- and time-dependent manner in H9c2 cells. This induction was associated with proportional increase in the mRNA expression of hypertrophic ANP and CT-1 genes, suggesting a direct involvement of CYP1A1 in SUN-induced cardiotoxicity. Furthermore, the inability of SUN to bind to and activate AhR translocation, not only suggests an aryl hydrocarbon receptor (AhR)-independent mechanism is involved, but also to suggest that SUN is not an AhR ligand. On the other hand, Transfecting H9c2 cells with siRNA against CYP1A1, significantly restored SUN-induced ANP and CYP1A1 mRNA levels, implying the direct role of CYP1A1 in the induction of hypertrophic genes in response to SUN. In conclusion, this is the first demonstration that the SUN induces hypertrophic genes through the induction of CYP1A1 gene expression in H9c2 cells via an AhR-independent mechanism.

Rationale: Arsenic (As) contamination of groundwater is common throughout the world, and chronic ingestion of well water contaminated with inorganic As can produce toxic effects including blackfoot disease, various cancers, hyperpigmentation, and hyperkeratosis. Chronic As ingestion has also been epidemiologically associated with development of atherosclerosis and hypertension, yet cellular mechanisms by which both inorganic As and methylated As metabolites exert these toxic effects are not well elucidated. Scope: Both inorganic arsenite (iAs') and the human metabolite monomethylarsinous acid ('MMAs') are believed to affect the activity of the voltage-gated or 'L-type' calcium ion channel (LTCC), which is the most thoroughly characterized Ca2+ channel governing extravascular Ca2+ entry and a key facilitator of the development and maintenance of vascular smooth muscle (VSM) tone. Intracellular Ca2+ can regulate the activity of other classes of ion channels, including the large conductance Ca2+-activated potassium ion channel ('BK Ca'), a known modulator of cellular depolarization that has been recently implicated in the development of hypertension and restenosis disease. Experimental Procedures: The present study examined the effects of iAs and MMAs on expression and activities of LTCC and BKCa channels in acutely isolated and primary / tissue cultured rat thoracic aorta, as well as the experimental A7r5 rat thoracic aorta smooth muscle cell (SMC) line using whole-cell patch clamp, vascular contractility, real-time RT-QPCR, and fluorescence microscopy approaches. Data: Initial results indicate significant alterations in SMC morphology, viability, and responsiveness to phenylephrine-induced vasoconstriction upon acute and subchronic exposure to both iAs and MMAs. LTCC activity is also altered following iAs exposure. Conclusion: Exposure of VSM and SMCs to relevant concentrations of both iAs and MMAs affects tissue contractility, cell viability, and the activities of key ion channels governing the maintenance of VSM tone.

corporation into nanomaterials may increase bioavailability in unanticipated ways. Developing children and fetuses may be particularly vulnerable to toxins found in e-waste, and early epidemiological studies near informal e-waste recycling sites indicate potential developmental neurotoxicity. Understanding the hazards of e-waste, the impacts of its disposal, and the dangers of informal or careless recycling will help reduce or prevent disease outcomes associated with exposure to e-waste components.

**432 NIEHS CENTERS FOR NANOTECHNOLOGY HEALTH IMPLICATIONS RESEARCH: BUILDING THE SCIENTIFIC FOUNDATION FOR EVALUATING PUBLIC HEALTH IMPLICATIONS OF ENGINEERED NANOMATERIALS.**

J. G. Teguarden5, M. Philbert1, S. S. Nadadur1, G. Collman1, A. Ng2, T. L. Kavanaugh1 and T. R. Fennell2.

The NIEHS established the NIEHS Centers for Nanotechnology Health Implications Research (NCNHIR) consortium to gain a comprehensive understanding of how physical and chemical characteristics of engineered nanomaterials (ENMs) influence their molecular interactions with biological matrices and elicit biological responses. This consortium includes eight centers funded in 2010 through a multi-project cooperative agreement (U19) and research grant (U01) mechanisms, along with additional investigators supported by Nano-EHS research program at NIEHS. Together, the consortium and individual investigators are exploring a library of engineered nanomaterials selected by NCNHIR with an overarching research focus that integrates physical and chemical characteristics of ENMs with biological effects. The research projects at these centers are investigating how the physical and/and chemical characteristics of ENMs dictate biological interactions at the molecular and cellular level. This knowledge can be translated to predict biological responses in vivo such as absorption, distribution, metabolism, and elimination (ADME) as well as physiological and pathobiological events in target and secondary organs, using appropriate routes of exposure and dose metrics. This information can be used to develop and apply predictive models in hazard characterization and assessment due to accidental or incidental exposure to ENMs. This session will highlight some of the recent findings and efforts of the consortium and provide scientific leads for a better understanding of the potential adverse health effects associated with ENM exposure.

**433 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODEL FOR MICE, RATS, AND HUMANS ORALLY-EXPOSED TO CHROMIUM.**

C. R. Kirman1, S. M. Hays1, L. L. Aylward1, M. Suh2 and D. Proctor2. 1Summit Toxiloggy, LLL, Orange, OH and 2ToxStrategies, Rancho Santa Margarita, CA.

A multi-compartment physiologically based pharmacokinetic (PBPK) model was developed to describe the behavior of Cr(III) and Cr(VI) in mice, rats, and humans. Tissue compartments were included for gastrointestinal lumen, oral cavity, stomach, small intestines (duodenum, jejunum, ileum), blood, liver, kidney, bone, and a combined compartment for remaining tissues. Data from *ex vivo* reduction studies were used to characterize reduction of Cr(VI) in fed rodent gastric fluid as a second-order process. *Ex vivo* data for human stomach fluid were used to characterize reduction of Cr(VI) in humans as a pH-dependent process under fed and fasted conditions. Tissue time course data for total Cr were collected from rats and mice exposed to Cr(VI) in drinking water for 90 days at six concentrations ranging from 0.1 to 180 mg Cr(VI)/L. These data were used to supplement the tissue time course data collected by NTP for Cr(III) and Cr(VI). Clear species differences are identified for Cr delivery to the target tissue (small intestine), with higher concentrations achieved in mice, consistent with tumor formation upon chronic exposures, than rats, in which tumors were not observed. Plasma/RBC Cr ratios suggest that Cr(VI) entered portal circulation at 60 and 180 mg/L in rodents. Species differences were identified for distribution of Cr to the liver and kidney, with liver/kidney ratios higher in mice than in rats. Overall, the PBPK model provides a reasonable fit to the available data. Simulations in humans were conducted to evaluate diurnal variation in gastric pH, as a function of meal consumption, and its impact of Cr(VI) reduction. Additional simulations were conducted to address potentially sensitive subpopulations, including fasted individuals, individuals on proton pump inhibitor medication, and children. The predictions of internal dose using the PBPK model support dose-response assessments for cancer and noncancer endpoints and allow for interspecies extrapolations to humans at environmentally relevant exposure concentrations.

**434 GASTRIC REDUCTION OF Cr(VI) IN MICE, RATS AND HUMANS.**

S. M. Hays1, C. Kirman1, L. L. Aylward1, M. Suh2 and D. Proctor2. 1Summit Toxiloggy, Lyons, CO and 2ToxStrategies, Rancho Santa Margarita, CA.

The gastric reduction of Cr(VI) is a critical step in the proposed mode of action for the small intestinal tumors in mice. To investigate the kinetic mechanisms of gastric reduction of Cr(VI), stomach fluid was obtained from fed mice and rats and from fasted and fed human volunteers, including patients on proton pump inhibitors (PPIs). Studies were conducted to ascertain the kinetics (rates and capacity) of the various gastric fluids to reduce Cr(VI). The pH dependence of the various kinetic factors was also investigated. The reduction of Cr(VI) in fed mouse and rat gastric fluid followed second-order kinetics, with dependence upon both the Cr(VI) concentration and the concentration of reducing agents. Approximately 16 mg equivalents of reducing agent per liter of fed stomach fluid (which contains gastric secretion and food) was found to be adequate for both the mouse and rat. The second-order rate constant (k) was 0.005 and 0.003 min⁻¹ for rat and mouse, respectively. Species differences in gastric fluid production rates and water intakes indicated a higher Cr(VI) load per stomach fluid in mice compared to rats for a given Cr(VI) drinking water concentration. The amount of Cr(VI) emptying from the stomach into the duodenum was modeled in the stomach by accounting for competing rates of Cr(VI) loading via drinking water, emptying, reduction, and absorption. At doses that induce small intestinal tumors in mice, significant Cr(VI) emptying into the small intestine is predicted. Rate of reduction is faster in human gastric fluid at lower pH. The second-order rate constant for Cr(VI) reduction is higher in humans (0.6 – 0.1 min⁻¹ at pH 1-4, respectively) than rodents. Reduction capacity and rate are lower in humans taking PPIs compared to those not on PPIs. These data can be used in a PBPK model to support a risk assessment for humans exposed to Cr(VI).

**435 PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING OF POLYETHYLENE GLYCOL-COATED POLYACRYLAMIDE NANOPARTICLE IN RATS.**

D. Li1, 4, C. Fennold1, 3, G. Johnson4 and O. Jolliet1. 1Environmental Health Science, University of Michigan, Ann Arbor, MI, 2Environmental and Occupational Health, University of Montreal, Montreal, QC, Canada, 3BioSimulation Consulting Inc., Newark, DE and 4Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Though the use of engineered nanoparticles (NPs) has increased exponentially, studies of potential health hazards remain limited. In particular, little attention has been given to NP bioavailability and biodistribution. The aim of this study is to develop a physiologically-based pharmacokinetic (PBPK) model to explore the biodistribution of i.v. injected polyethylene glycol-coated polyacrylamide (PAA-peg) NPs in rats in order to advance the understanding of NP behavior in the body. The model consists of 8 tissue compartments (blood, liver, kidney, lungs, heart, brain, immune organs and carcass) interconnected via the systemic circulation. Each compartment is described as sub-compartment of macrophages (MPs) which may phagocytize NPs in a saturable process. All MPs are assumed to behave in the same way, only the number of MPs might differ between organs. The maximum capacity of phagocytosis and the number of MPs per organ were adjusted by visual optimization to experimentally observed data collected on 30nm PAA-peg NP (Wenger et al., 2011). The predicted time courses of NP and tissue distribution agree well with experimental data. According to the model, the NPs were quickly captured by the MPs, whereas the tissue levels stayed relatively constant. The MPs thus serve as the major reservoir of NPs in organs (storing 7% of the i.v. dose after 120 hr). The fitted MP parameters — number per tissue and maximum capacity — are consistent with what is known about NP behavior. To our knowledge, this is the first PBPK model that captures NP biodistribution with this degree of detail. Our model may easily be extended to other NPs or extrapolated to other species including human.

**436 ASSESSING THE RELATIVE POTENCY OF REACTIVE ALDEHYDES IN CIGARETTE SMOKE USING TRANSIENT CFD/PBPK MODELS OF THE RESPIRATORY SYSTEM.**

Computational fluid dynamic (CFD) models of the respiratory airways of the rat and human extending from the nose or mouth to the lung were coupled with physiologically based pharmacokinetic (PBPK) models to describe the uptake and tissue disposition of three reactive constituents of cigarette smoke: acrolein, acetaldehyde and...
Exposure Versus Internal Dose: Respiratory Tract Deposition Modeling of Inhaled Asbestos Fibers in Rats and Humans.

B. Agharian, O. T. Price, S. H. Gavett and A. M. Jarabek. 1ARA, Raleigh, NC and 1US EPA, Research Triangle Park, NC.

A dosimetry model to calculate deposited fractions (DF) in the upper and lower respiratory tract (URT and LRT) is the first step to a more comprehensive model addressing retained fiber burdens. We developed equations for external forces on fibers suspended in inhaled tidal air as a function of fiber dimensions and orientation. These equations were used to obtain fiber equivalent diameters, and replaced particle diameter in expressions for inhalability and deposition efficiency. Resultant local and regional DF were used to compute different dose(s) of inhaled fibers in the human and rat LRT for a monodisperse aerosol of 10 fibers/cc assuming a density of 3.0 g/cm3 and an aspect ratio (β) of 3, 5 or 10. Fiber diameter was a greater determinant of DF than fiber length. Deposited mass, surface area (SA), and number of fibers per LRT surface area was significantly lower in rats than in humans. By number, the fiber DF increased with decreasing physical diameter in the diffusion range, and in the impaction range reached a peak at 0.5 – 1 μm in rats and 2 – 5 μm in humans. The deposited mass and SA of fibers increased with physical diameter across the entire size range to reach a peak at ~2 – 3 μm in humans and ~0.6 μm for rats. LRT DF beyond these sizes dropped sharply to 0 due to URT filtering. The differences in DF with bivariate fiber distribution illustrate the value of dosimetry models to interpreting and translating data across species, and can be used to characterize the inherent uncertainty in risk assessments based on exposure versus internal dose. (The views expressed in this abstract are those of the authors and do not necessarily represent the views or policies of the U.S. Environmental Protection Agency.)
high body burden. These results indicate that our PBPK model, which was initially developed from animal studies, can be used to predict TCDD elimination in humans. Improvement of the model will require a systematic study with serial samples of maternal milk and blood across gestational and lactational stages. (This research was funded in part by the US Environmental Protection Agency [R82471], NIEHS [R01 ES07171], Regione Lombardia and Fondazione Lombardia Ambiente, Milan, Italy. This abstract does not necessarily reflect the views of these agencies.)

441 PHYSIOLOGICALLY-BASED PHARMACOKINETIC (PBPK) MODELING TO EXPLORE POTENTIAL METABOLIC PATHWAYS OF BROMOCHLOROMETHANE IN RATS.

1Pharmacokinetics Branch, US EPA, ORD, NIEH, ISTD, Research Triangle Park, NC; 2Math Department, Research Experience for Undergraduates (2011), North Carolina State University, Raleigh, NC and 3Math Department, North Carolina State University, Raleigh, NC.

Bromochloromethane (BCM) is a volatile organic compound and a by-product of disinfection of water by chlorination. Physiologically based pharmacokinetic (PBPK) models are used in risk assessment applications and a PBPK model for BCM, updated with F-344 specific input parameters, is used here for hypothesis testing to provide useful information for risk assessment of this compound. Inhalation vapor uptake data for F344 rats obtained from the literature were used for PBPK development. The initial chamber concentration ranged between 2000-4000 ppm to ensure that metabolic saturation was included in the experimental design. The two different metabolic hypotheses examined were: 1) a two-pathway model using both CYP2E1 and glutathione transferase systems, and 2) a two-binding site model where metabolism can occur via one enzyme, CYP2E1. Our computer simulations demonstrated that both metabolic hypotheses described the available experimental data in a similar manner. The two-pathway results were comparable to previously reported values (Vmax = 3.8 mg/hour, Km<0.35 mg/liter, and KGST=4.7/hr). The two-binding site results use Michaelis-Menten parameters to describe the first binding site, Vmax1 = 3.7 mg/hour and Km1=0.3 mg/liter, and KGST1=4.7/hr. The two-binding site results use Michaelis-Menten parameters to describe the first binding site, Vmax1 = 3.7 mg/hour and Km1=0.35 mg/liter, and a clearance rate to describe the second site, CL2 = 0.05 liter/hour. In addition, the sensitivity of different parameters for each model was explored using our obtained optimized values. At concentrations below 2000 ppm for both metabolic hypotheses, there was a peak in sensitivity towards Vmax measurement using liver concentration. In summary, the combination of PBPK modeling and sensitivity analysis is useful when studying different kinetic hypotheses using parameters optimized with closed chamber experimental data. (This abstract does not reflect EPA policy).

442 WHEN TO SAMPLE AND HOW TO INTERPRET BLOOD LEVELS IN THE OCCUPATIONAL SETTING: THE EXAMPLE OF STYRENE.

M. Verner1, R. McDougall2 and G. Johnson3.
1Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden and 2Ontario Institute of policy).

Styrene (C8H8) is a ubiquitous organic chemical produced at many plants and factories around the world. It is used, for example, to make polystyrene, a type of plastic. Styrene has been classified as a human carcinogen and epidemiologic studies have identified an association between occupational exposure to styrene and certain cancers, including breast cancer. However, further research is needed to understand the magnitude of this association and its underlying mechanisms. The purpose of this study was to create and test a physiologically based pharmacokinetic (PBPK) model of styrene that can be used to predict the toxicokinetics of styrene in humans, and to evaluate the impact of environmental and personal factors on styrene exposure and toxicokinetics. The PBPK model was developed using a systems biology approach that integrates biochemical pathways, transporters, and physiological parameters using public terminologies (e.g. GeneOntology, Foundational Model of Anatomy, Mouse Pathology Ontology, etc.). Using the model, we investigated the impact of various factors on styrene exposure and toxicokinetics, including workshift type, lunchtime break and one hour after the end of shift were, respectively, 0.10 mg/L (0.05-0.15) and 0.13 mg/L (0.07-0.19). The existing BEI was similar to the 5th percentile end of shift blood level (0.28 mg/L). Overall, this study supports the adequacy of the BEI put forward by the ACGIH, but proposes two new sampling times that might be more representative of the average and peak exposures with ranges of blood levels associated with a TWA exposure of 20 ppm.

443 ABSOLUTE AND RELATIVE ORGAN WEIGHT DISTRIBUTIONS FOR FISCHER 344 RATS.

D. J. Marino.
Conestoga-Rovers & Associates, Rochester, NY.

The Fischer 344 (F-344) rat is the standard rat strain used in toxicology studies conducted by the National Toxicology Program (NTP). While numerous reports have been published on growth, survival and tumor incidence, no overall compilation of organ weight data is available. Importantly, organ weight change is an endpoint used by regulatory agencies to develop toxicity values (TVs) for use in human health risk assessments. Furthermore, physiologically-based pharmacokinetic (PBPK) models, which utilize relative organ weights, are increasingly being used to develop TVs. Therefore, all available absolute and relative organ weight data for untreated control F-344 rats were collected from final NTP feed, drinking water and inhalation studies reported though September 2011 in order to develop organ weight distributions. Results show that organ weights were collected more frequently in NTP studies at 3-month (160 studies) than at other intervals and more frequently from feeding and inhalation than drinking water studies. Liver, right kidney, lung, heart, thymus, right testis, and brain weights were most frequently collected. Infrequently weighed organs included adrenals, pituitary gland, thyroid gland, spleen, pancreas, urinary bladder, and female and male reproductive organs other than the testis. From 3-month study results, the mean and standard deviation for absolute and relative organ weights were calculated for nearly 20 organs based on results from approximately 1,400 male and female F-344 rats. The results show greater variability in weights for small organs, and suggest a general variability trend in absolute organ weights of brain < right testis < right kidney < heart < liver < lung < thymus. Given the number of studies (160 studies), number of F-344 rats (nearly 1,400 males and females) and number of organs (nearly 20 organs) included in this evaluation, the resultant organ weight distributions are likely to be among the most comprehensive and robust available, and are useful as historical reference values, and for parameterization of probabilistic and Bayesian PBPK models.

444 VIRTUAL LIVER: AN IN SILICO FRAMEWORK FOR ANALYZING CHEMICAL-INDUCED HEPATOTOXICITY.

I. Shah1, J. Jack1, J. Wambaugh1, W. Setzer1, C. Corton1 and T. Knudsen2.
1National Center for Computational Toxicology, US EPA, Durham, NC and 2National Health and Environmental Effects Lab, US EPA, Durham, NC.

The US EPA Virtual Liver (v-LiverTM) is an in silico framework for the dose-dependent perturbation of normal hepatic functions by chemicals using in vitro data. The framework consists of a computable knowledge-base (KB) to infer putative pathways in hepatotoxicity and a cellular systems model to predict the dose-dependent effects of chemicals. We have synthesized diverse evidence about thousands of effects for 650 chemicals in the KB from ToxRefDB, DSSTox, -omics data and the literature using public terminologies (e.g. GeneOntology, Foundational Model of Anatomy, Mouse Pathology Ontology, etc.). Using the KB we related ToxCastTM in vitro bioactivity assay data on 68 rodent hepatotoxics (e.g. PFOA, Imazalil, Bisphenol A, Triclosan, Acetaminophen, Phenobarbital, WY-14643) to a putative network of events resulting in hepatocyte necrosis, apoptosis and proliferation, which were mediated by constitutive androstane receptor, aryl hydrocarbon receptor, pregnane X receptor, and p53/proliferator-activated receptors. In order to estimate the in vivo effects of these chemicals we encoded this network in a dynamic cell-agent based model that integrates micro-dosimetry, intracellular signaling and cell-cell interactions across the spatial extent of the hepatic lobule to predict histopathologic outcomes. We used experimental data on DNA synthesis following exposure to normal levels of growth factors and cytokines (e.g. Insulin, EGF and TNF-α) to calibrate the dynamics of cell cycle progression through S-phase. Next we used in vitro data (e.g. nuclear receptor activation, oxidative stress and c-Jun activation) to estimate key parameters required for simulating the dose- and time-dependent effects of 20 chemicals on hepatocyte proliferation, apoptosis and necrosis. We are using the v-Liver framework to analyze alternative mitogenic and cytotoxic pathways involved in non-genotoxic cancer. Abstract does not represent EPA policy.

445 ROLE OF THE ASIALOGLYCOPROTEIN RECEPTOR IN EXTRAPOLATING THE SYSTEMIC CLEARANCE OF ENB-0040 ACROSS SPECIES.

P. Poulin1, T. Tolomeo1, I. Lemire2, P. Leonard3, J. Marier4 and M. Beliveau5.

Traditional allometric scaling approaches focus on the relationship between body weight and clearance (CL) with minimal consideration for the mechanism behind protein CL itself. This can lead to differences between allometrically scaled predicted and actual values when scaling across species. For glycosylated proteins such
Biofuel blends of ethanol and gasoline are increasingly common in the USA. PBPK models were developed for ethanol-alone (Martin et al., 2011) and soy to inform studies of developmental effects of ethanol-gasoline blends. Following collection of tissue pharmacokinetic (PK) data from exposed dams (21K ppm ethanol/6.33h/gestation days (GD) 9-20) and fetuses (GD20), our earlier model was extended to pregnancy and lactation periods by including dynamic changes in maternal body composition and moving from a compartment model representing maternal, placental, and fetal compartments to a PBPK model to further refine predictions of humans CL of therapeutic proteins.

The PBPK model was adapted for pregnant women for potential use in the National Children's Study to assess and quantify prenatal exposure to stress through maternal hair samples and stress questionnaires.

To address concerns about potential health effects of exposure to nanomaterials during development, a PBPK model was developed that describes C60 disposition during gestation and lactation. A multiscale modeling approach was used, focusing on extrapolation of in vitro cell-based information to predict in vivo nanoparticle disposition. In this multiscale approach, a cellular kinetic model description of C60 kinetics in vitro is incorporated into the whole body PBPK model. Each tissue containing C60 was modeled as a series of sub-compartments representing specific subpopulations of cells, including entrainment in tissue macrophages, binding to proteins, and post-distributional aggregation, as identified by in vivo imaging data. The PBPK model was extended to pregnancy and lactation periods by including dynamic changes in physiology and transfers of C60 from the dam to offspring through placenta and milk. The model simulated C60 distribution agreed well with data from pregnant and lactating dams, placenta, and milk, as well as in pooled fetuses and tissues in pups 24 hr or 48 hr after the IV exposure on gestation day 15 or postnatal day 8, respectively. Our results indicate no substantial change in maternal C60 disposition during pregnancy or lactation in the rat, since the same cellular parameters for C60 kinetics could be used for different life stages. However, accumulation of C60 nanoparticles in the placenta, fetus and neonate following maternal IV dosing suggests the potential for developmental effects. This modeling strategy can be readily adaptable to other nanomaterials to contribute to developing a tool to assess potential risks of nanomaterial exposure in early life (This work was supported by NIH/NIEHS Award #U19ES019525, but solely expresses the view of the authors).

Polycyclic aromatic hydrocarbons (PAHs) are ubiquitous environmental contaminants generated by byproducts of natural and anthropogenic combustion processes. Dibenzo[def, p]chrysene (Dibenzo[def, p]chrysene (DBC) is a high molecular weight PAH classified as a 2B carcinogen by the International Agency for Research on Cancer (IARC) on the basis of sufficient evidence of carcinogenicity in animals. Notably, DBC has been shown to cross the placenta in exposed mice, causing carcinogenicity in offspring. Here, we present pharmacokinetic data of DBC in pregnant and non-pregnant mice. DBC (gestational day 17) and non-pregnant female B6129SF1/J mice were exposed to 15 mg/kg DBC in corn oil by oral gavage. Subgroups of mice were sacrificed over 48 hours post-dosing, and blood, excreta, and tissues analyzed for DBC and metabolites. The pharmacokinetics of DBC and its diol and tetroxol metabolites were significantly different in pregnant versus naïve mice, with elevated maximum concentrations of parent chemical and metabolites achieved in blood and other tissues. Using a pharmacologically-based pharmacokinetic (PBPK) model, we found that observed differences in pharmacokinetics could not be explained simply by changes in tissue volumes and blood flows that occur during pregnancy. Analysis of whole fetuses corroborated previous research indicating DBC and metabolites can move across the placenta. Concentrations of DBC in fetuses were generally one to two orders of magnitude below maternal blood concentrations, while metabolite concentrations closely resembled those observed in maternal blood. Supported by Award Number P42 ES016465 from the National Institute of Environmental Health Sciences.
Conflict results have been reported for associations between maternal exposure to perfluoralkyl acids (PFAAs) and human birth outcomes. Of particular interest are recent reports from epidemiological studies linking increased maternal blood concentrations of PFAAs with reduced infant size at birth and also a longer time to pregnancy for women who have higher serum PFAA levels. The purpose of this effort was to determine whether the observed epidemiological associations may be due to reverse causality, i.e., the relationships between plasma levels of PFAAs and various outcomes may be explained on the basis of pharmacokinetics rather than the chemicals exerting causal adverse effects. In order to understand how changing developmental physiology may affect the tissue distribution of a chemical in the mother, fetus, and neonate, we have developed physiologically-based pharmacokinetic (PBPK) models of pregnancy, perinatal, and postnatal life stages. In this work, the ability of the models to predict PFAA concentrations observed in epidemiological studies was examined using Monte Carlo analysis. We also evaluated whether the epidemiological associations noted above could be explained entirely by predictions made with the PBPK models. The models provided a good fit to observed PFAA concentrations in humans during pregnancy and lactation. The PBPK models predicted that plasma PFAA levels would be related to lower birth weight, and, among parous women, longer time-to-pregnancy, purely on the basis of physiological phenomena. Conflicting results have been reported for associations between maternal exposure to perfluoralkyl acids (PFAAs) and human birth outcomes. Of particular interest are recent reports from epidemiological studies linking increased maternal blood concentrations of PFAAs with reduced infant size at birth and also a longer time to pregnancy for women who have higher serum PFAA levels. The purpose of this effort was to determine whether the observed epidemiological associations may be due to reverse causality, i.e., the relationships between plasma levels of PFAAs and various outcomes may be explained on the basis of pharmacokinetics rather than the chemicals exerting causal adverse effects. In order to understand how changing developmental physiology may affect the tissue distribution of a chemical in the mother, fetus, and neonate, we have developed physiologically-based pharmacokinetic (PBPK) models of pregnancy, perinatal, and postnatal life stages. In this work, the ability of the models to predict PFAA concentrations observed in epidemiological studies was examined using Monte Carlo analysis. Reduced Acetaminophen-Induced Injury in LPR Mice Is Dependent on Increased Glutathione Synthesis and Enhanced Detoxification of Oxidant Stress

C. D. Williams, M. R. McGill, H. Yan and H. Jaszczuk, KUMC, Kansas City, KS.

Acetaminophen (APAP)-overdose is a classical model of hepatocellular necrosis, however, the mechanism of protection previously reported in Fas receptor-defective (LPR) mice remains unclear. Apoptosis has no role in the mouse model of APAP-overdose as demonstrated by the lack of morphological evidence and no observed protection by caspase inhibitors. From these findings it was unclear why preventing the signaling of an extrinsic apoptotic pathway could reduce APAP-induced injury. To better understand this mechanism of protection, LPR and C57BL/6 mice were treated with 300 mg/kg APAP for 0.5h, 6h and 24h. LPR mice showed a reduction in liver injury as measured by plasma ALT levels (~50% decrease) and reduced hepatic necrosis (~25% decrease) at both 6h and 24h. To eliminate the possibility of altered APAP metabolism, Cytochromes P450, protein expression, formation of APAP adducts and hepatic glutathione (GSH) depletion were compared demonstrating equivalent reactive metabolite generation. Isolated primary mouse hepatocytes from both strains showed equivalent GSH depletion and LDLH release after APAP treatment in vitro. Interestingly, in vivo post-APAP GSH recovery was higher in LPR than C57BL/6 (6h: 200% & 24h: 160% increase). Driving the increased GSH levels, mRNA induction and protein expression of glutathione-cysteine ligase (GCLC) were higher in LPR mice. The higher levels of GSH in LPR mice resulted in enhanced detoxification of reactive oxygen species measured by hepatic GSSG levels (6h: 165% & 24h: 600% of C57BL6 APAP-treated). Inducible nitric oxide synthase (iNOS) mRNA and protein levels at 6h were much lower in LPR mice, which correlated with greatly reduced nitrotyrosine staining at 6h. Conclusion: These data indicate the importance of non-parenchymal cells in the protection seen in LPR mice by stimulating hepatic GSH production and reducing peroxynitrite formation. These factors in combination result in the APAP-protected phenotype observed in LPR mice.

Tolerance of Robenacoxib Injectable and Tablets in 4 to 5-Month-Old Kittens

Robenacoxib (RXB) is a non-steroidal anti-inflammatory drug (Omnisar®) with approved indications in cats and dogs. A safety study of the interchangeable use of RXB tablets at 2.4 or 12 mg/kg (tablets) plus 2 or 10 mg/kg subcutaneous (SC) injection (each representing 1 and 5X the upper dose band for each route; the therapeutically guided dose for tablet and injection is 1.0 and 2.0 mg/kg, respectively). Male and female kittens (4-5 months old) were dosed by alternating 7-day tablet/3-day injection cycles for 37 days. Controls were given empty gelatin capsules or sterile saline SC (5X volume). On Day 16, one 5X group female showed constipation, thin body score, and behavioral changes that resolved with treatment within 7 days; this cat remained thin but healthy to the end of study. Injection site observations of all kittens included dose-dependent increases in edema, heat or erythema, resolving within 8 days, changes in preauricular lymph nodes close to injection sites, and/or scab formation. Body weight was reduced in each treated group despite unaffected therapeutic success, renal toxicity and hepatotoxicity have been reported in the clinic. Therefore, concern exists regarding the long term use of RXB. The goals of this study were to evaluate the molecular mechanism of TXD-induced toxicity in female BALB/c mice using an Affymetrix microarray and to correlate gene expression changes with plasma drug levels and other toxicology endpoints including clinical pathology and histopathology. TXD was orally administered by gavage daily for 91 days at 500 and 1000 mg/kg TID. Analysis of gene transcripts in the livers showed that Cdkn1a (p21, Cip1), a cyclin-dependent kinase inhibitor 1A, increased 3.7-fold compared with the controls on Day 92. The increase of Cdkn1a transcription level may have contributed to the inhibition of cell cycle progression at G1, causing cytomegaly in the liver. The kidneys from Day 92 TXD treated animals (1000 mg/kgTID) were histopathologically normal which was consistent with the microarray results which showed no significant differences in gene expression between the kidneys from TXD treated animals and the vehicle control animals on Day 92. Work supported by NIAID Contract N01-AL-70043.
food consumption. Electrocardiograms showed a slower heart rate and increased RR and QT interval in the 5X group compared to controls. Mild effects on some serum chemistries were seen most often in the 5X group, including increases in creatinine and amylase. Hematology and coagulation findings were unremarkable. Histopathology findings of injection sites in both treated groups included granulomatous changes and fibrosis. Renal vacuolation and degeneration of proximal tubules were seen in one 1X female and three 5X males. No treatment-related effects were observed in the liver, stomach, duodenum, jejunum, ileum, or colon. In conclusion, repeated administration of RXB tablets and injectable were well tolerated in 4-5 month old cats, with some treatment effects observed more often in the 5X dose group.

Serotonin (5-HT) and cannabinoid systems both direct neural circuit formation during brain development, and their dysfunction may underlie impaired social behavior in autism and other psychiatric disorders. Cannabinoid CB1 receptors are found on 5-HT neurons, and agonists such as WIN 55,212 inhibit 5-HT release. CB1 ligands and cannabinoid metabolites acutely alter murine social behavior, perhaps via direct 5-HT system interactions. We have found that in dorsal hippocampal, socially deficient BTBR mice have 40% higher 5-HT1A and CB1 receptor functional capacity than related 129S1/SvJm mice or more sociaizable C57 mice, as measured by agonist-stimulated [35S]GTPαS binding. However, CB1 receptor saturation binding (Bmax=958±117 fmol/mg protein) and affinity for [3H]A2A ligands and acetaminophen administration significantly increased levels of the endocannabinoid anandamide in the cingulate cortex of BTBR mice, but not in 129S mice, and so- aminophen administration significantly increased level of the endocannabinoid anandamide in the cingulate cortex of BTBR mice, but not in 129S mice, and so-ciability testing also increased this measure. These data support the hypothesis of anandamide in the cingulate cortex of BTBR mice, but not in 129S mice, and so-

The Wnt/β-catenin signaling pathway is one of the fundamental mechanisms that directly regulates cell proliferation, cell polarity and cell fate determination during embryonic development and tissue homeostasis. Abrupt activation of the Wnt/β-catenin signaling pathway is linked to a high frequency of numerous tumors. We screened the chemical library to develop the new drug for lung cancer therapy as a target protein of Wnt-2 using a cell-based reporter gene assay which was used to measure the transcriptional activity of β-catenin-TCP/LEF in A549/Wnt2 cells stably expressed wnt2. Among the screened compounds, we investigated one compound, GDK-100017, which was reduced to below 50% of the luciferase activity at IC50 concentration of the cell proliferation. GDK-100017 reduced the β-catenin-TCP/LEF dependent transcriptional activity in a dose-dependent manner with an IC50 value of about 10μM and decreased cell proliferation about 25% and 50% of IC50 values at 24, 48 and 72h, respectively, however, did not affect to human embryonic pulmonary cell lines, L132 cells. It was down-regulated the expressions of Wnt/β-catenin signaling pathway target genes, such as E2F and cyclin D1 which play critical roles in proliferation. FACs analysis showed that GDK-100017 significantly induced the G1 phase arrest in A549 cell lines and this G1 arrest seemed to correlate with inhibition of E2F and cyclin D1 expression. Altogether, these results showed that GDK-100017 possesses potential anti-cancer activity against lung cancer cells by inhibiting their proliferation and inducing cell cycle G1 arrest partly via the inhibition of Wnt/β-catenin pathway.

Aim of the present study was to investigate the effects of polyethylene glycol 400 (PEG 400) as a vehicle on the rat gastrointestinal tract. Crl: CD(SD) rats (5 males and 5 females in each group) orally received 0, 5, 50 or 100% of PEG 400 at a volume of 5 mL/kg/day for 15 days. After the 15 days, the whole parts of the gastrointestinal tract were examined histopathologically. The animals in the receive of 50 and 100% groups sometimes excreted loose stools during the 15 days. Although the fecal change had made us suspect some morpho-

The Wnt/β-catenin signaling pathway is one of the fundamental mechanisms that directly regulates cell proliferation, cell polarity and cell fate determination during embryonic development and tissue homeostasis. Abrupt activation of the Wnt/β-catenin signaling pathway is linked to a high frequency of numerous tumors. We screened the chemical library to develop the new drug for lung cancer therapy as a target protein of Wnt-2 using a cell-based reporter gene assay which was used to measure the transcriptional activity of β-catenin-TCP/LEF in A549/Wnt2 cells stably expressed wnt2. Among the screened compounds, we investigated one compound, GDK-100017, which was reduced to below 50% of the luciferase activity at IC50 concentration of the cell proliferation. GDK-100017 reduced the β-catenin-TCP/LEF dependent transcriptional activity in a dose-dependent manner with an IC50 value of about 10μM and decreased cell proliferation about 25% and 50% of IC50 values at 24, 48 and 72h, respectively, however, did not affect to human embryonic pulmonary cell lines, L132 cells. It was down-regulated the expressions of Wnt/β-catenin signaling pathway target genes, such as E2F and cyclin D1 which play critical roles in proliferation. FACs analysis showed that GDK-100017 significantly induced the G1 phase arrest in A549 cell lines and this G1 arrest seemed to correlate with inhibition of E2F and cyclin D1 expression. Altogether, these results showed that GDK-100017 possesses potential anti-cancer activity against lung cancer cells by inhibiting their proliferation and inducing cell cycle G1 arrest partly via the inhibition of Wnt/β-catenin pathway.

The Wnt/β-catenin signaling pathway is one of the fundamental mechanisms that directly regulates cell proliferation, cell polarity and cell fate determination during embryonic development and tissue homeostasis. Abrupt activation of the Wnt/β-catenin signaling pathway is linked to a high frequency of numerous tumors. We screened the chemical library to develop the new drug for lung cancer therapy as a target protein of Wnt-2 using a cell-based reporter gene assay which was used to measure the transcriptional activity of β-catenin-TCP/LEF in A549/Wnt2 cells stably expressed wnt2. The mitochondrial toxicity in vitro has been hampered by the reliance immortalised cell lines have on glycolysis for ATP production. Therefore, compounds that cause impairment of normal mitochondrial function can go undetected as blockage of oxidative phosphorylation does not lead to ATP depletion. The replacement of glucose by galactose within tissue culture media forces cells to become more reliant on oxidative phosphorylation, and therefore more sensitive to mitochondrial poisons. HepG2 cells cultured in glucose or galactose containing media were exposed to 8 mitochondrial toxins with known effects on specific complexes of the electron transport chain (ETC) and 11 compounds with no effect on mitochondrial function for 24 hours in a 96-well plate format. Intracellular ATP was measured and expressed relative to control levels. A ratio of the IC50 values observed in the glucose versus galactose cells was calculated to distinguish mitochondrial toxins (IC50 ratio > 2.5) from compounds that caused gross cytotoxicity or non-cytotoxic compounds (IC50 ratio < 2.5). The sensitivity of the screen was calculated as 75% with 100% specificity. Routine screening of AstraZeneca compounds revealed a hit rate (IC50 ratio > 2.5) of 7% across 1617 compounds. A subset of 29 compounds, 17 active in the mitochondrial toxicity screen and 12 inactive, were screened to identify inhibitors of complex I. 11/17 of the active compounds from the screen were Complex I inhibitors (inhibition > 50%) and 10/12 of the inactive compounds from the screen were inactive at this complex. Overall, the combination of the mitochondrial toxicity screen and the complex I inhibition assay are useful for detecting risk of mitochondrial toxicity in the early stages of drug discovery.

Cytokine production and expansion of T lymphocytes following antigen exposure are key components of the adaptive immune response. Monitoring compound-related effects on T-cell activation and proliferation may provide important information on the immunomodulatory potential of a compound. The purpose of this study was to develop methods to monitor antigen-specific T-cell responses in cynomolgus monkeys using peripheral blood mononuclear cells (PBMC). Two cynomolgus monkeys (1/sex) were immunized with hepatitis B specific antigen (HBsAg) (Engerix-B, GlaxoSmithKline) at 10 μg/animal intramuscularly on days 1 and 15. One male monkey was used as a non-immunized control. Beginning on day 26 and every week for 6 consecutive weeks, HBsAg-specific T-cell responses were monitored using flow cytometric evaluation of intracellular cytokine staining and ex vivo T-cell proliferation. After priming with hepatitis B antigen for 5 hours followed by co-incubation with Brefeldin A overnight, cytokines (IL-2, TNF-alpha, IFN-gamma) were detected mainly in CD3+CD4+ T-cells via intracellular cytokine staining procedure. Significant antigen-specific proliferation was detected for both CD3+CD4+ and CD3+CD8+ T-cells when stimulated with hepatitis B antigen for 96 hours. The percentage of CD3+CD4+IL-2+ cells correlated positively with proliferation for CD3+CD4+ and CD3+CD8+ T-cells (evaluated in a subsequent study). The results demonstrate that intracellular cytokine staining and ex vivo proliferation may be used to detect antigen-specific T-cell responses following hepatitis B vaccination in cynomolgus monkeys.

Molindone is an antipsychotic drug developed for treatment of schizophrenia. A 3-month rat study was conducted to evaluate toxicity and prolactin-mediated effects of molindone. Wistar rats (10/sex/group) were treated daily via oral gavage with molindone at 0 (control), 5, 20, and 60 mg/kg/day. Plasma samples for toxicokinetics and prolactin were obtained up to 6 timepoints over a 24-hr period postdose using 3 general anesthetics on Days 0 and 85. In males, there was a dose-dependent decrease in body weight gain of up to 35% that correlated with decrease in food consumption. The plasma concentrations of molindone were more than dose proportional with a 12-fold increase in dose resulting in a 49-fold increase in exposure. The exposure in females was generally higher than in males at Tmax between 0.5 to 1 hr. The prolactin concentrations on Days 0 and 85 peaked up to 265 ng/mL within 0.5 - 1 hr postdose compared to maximum predose value of 40 ng/mL. Historically, molindone-treated rats showed a dose dependent, pharmacologically mediated, mostly rodent specific changes known for this class of drugs, including increase in mammary hypertrophy and retention and enlargement of corpora lutea, disruption of estrus cycle, mucification of epithelia of reproductive tract, follicular atresia and uterine atrophy in females, and inflammation of prostate in males. There were no other major signs of general toxicity on clinical chemistry or anatomic pathology. Based on the known role of prolactin on hormonal homeostasis and reproductive physiology of rodents, the changes seen in this study demonstrate the pharmacologically mediated effects of molindone. Also these changes seem to be species-specific similar to those observed for other antipsychotics in this class. Since such changes have not been reported in humans at therapeutic doses (15 to 225 mg/day) with the use of molindone for many years, it is concluded that the changes reported in this study do not pose any significant risk.

Leflunomide (Arava®) is an oral disease modifying anti-rheumatic drug. While its safety profile in the clinic has been demonstrated it carries a black box warning for idiosyncratic liver toxicity, the mechanism of which is unknown. The active metabolite of leflunomide, teriflunomide, is being considered as a treatment for multiple sclerosis. It is not known if teriflunomide, leflunomide, or other minor metabolites are responsible for the hepatotoxicity. Recently multiple reports have been published establishing the important role of the mitochondria in idiosyncratic liver toxicity. We investigated the abilities of these two drugs to impair oxygen consumption in isolated mitochondria, and to cause cytotoxicity in various cell models. Leflunomide was found to be 10-fold more potent inhibitor of mitochondrial respiration and generation of ROS than teriflunomide. We also demonstrate that the P450 inhibitor SKF-525a potentiates the inhibitory effect of teriflunomide on mitochondrial respiration and the cytotoxicity of both compounds in isolated rat hepatocytes. However, metabolism studies with both compounds showed that SKF-525a has no effect on the metabolism of teriflunomide in rat hepatocytes, leading us to conclude that SKF-525 exerts its effect by potentiating the inhibitory effect on mitochondrial respiration. We further demonstrated the importance of mitochondrial respiration in the cytotoxicity of both compounds by showing that HepG2 cells reliant on oxidative phosphorylation are more susceptible to drug induced cytotoxicity, while HepG2 cells grown in glucose rich cell culture media are protected. In addition, Rho0 HeLa cells, which lack mitochondrial DNA, are found to be less sensitive to the cytotoxic effects of leflunomide than the wild-type HeLa cells. In conclusion, if mitochondrial toxicity is involved in the hepatotoxicity observed with leflunomide treatment, it is reasonable to believe that teriflunomide will have a better hepatic safety profile than leflunomide.
non compartmental analysis. Comparison of the two formulations showed that both formulations had similar Tmax (Dextran 10/insulin: 15 min, Exubera: 10 minutes), and Cmax (Dextran 10/insulin: 115 μU/mL, Exubera: 114 μU/mL). However, after dose normalization, the Dextran 10/insulin formulation resulted in a 13% higher relative bioavailability (determined from AUC0-last).

Latanoprost is used for the treatment of increased intraocular pressure to prevent the progression of glaucoma. Since the lack of compliance with topical ocular dosing may compromise efficacy, alternate methods of delivery are being sought. A 9-month study was conducted to assess the safety and tolerability of a latanoprost-containing biodegradable device. Dutch-belted rabbits were implanted subconjunctivally with up to 5 placebo or drug-containing devices containing from 50 to 190 μg of latanoprost per device. Study assessment consisted of irritation scoring, clinical signs, ophthalmic exams, electroretinography, and ocular histology of cohorts at 3 and 9 months post implantation. The implants were well tolerated, with the most severe clinical signs and irritation observed in the first few days of the study associated with the implantation procedure. Mild conjunctival congestion persisted through week 13 of the study and tended to correlate with the number of devices and presence of drug. Ophthalmic exams revealed no effects beyond the ocular surface irritation, including no effects on intraocular pressure, corneal thickness, or ERG parameters. Microscopically, implants at the 3-month necropsy were associated with cavities (containing the implants), fibrous encapsulation, and an infiltrate of macrophages, sometimes as multinucleate cells, into the implant cavity. Drug containing implants were often associated with additional inflammatory cell infiltrates within the implant subconjunctival cavities and adjacent to the implant sites. At the 9-month necropsy, neutrophils were no longer common among the inflammatory cell infiltrates, most implants were fragmented and disintegrating, and fibrovascular proliferation was present within implant luminal remnants. None of the findings were considered adverse. Overall, the study supports the safety of the latanoprost-containing subconjunctival device.

Lack of nephrotoxicity and myelosuppression following CMX001 administration in humans, rodents, and monkeys.

Introduction: CMX001 is an oral Lipid-Amantiviral-Conjugal (LAC) that delivers high intracellular levels of the active antiviral agent cidofovir-diphosphate. CMX001 is in development for prevention and treatment of CMV and adenovirus in transplant recipients and as a therapeutic countermeasure for smallpox. CMX001, a phospholipid covalently linked to cidofovir (CDV), was designed to take advantage of the broad-spectrum antiviral activity of CDV while eliminating the toxicities seen with MEKi. The Ras/Raf/MEK/ERK mitogen-activated protein kinase pathway mediates cellular responses to growth factors, cytokines, and growth-promoting oncogenes. It has been repeatedly substituted for propylene glycol or glycerin, liquids of similar appearance, in pharmaceutical preparations. Since diethylene glycol became commercially available in the late 1920’s, it has been repeatedly substituted for propylene glycol. Glycolic acid, with properties of similar appearance, in pharmaceutical preparations. This is done because diethylene glycol is much cheaper than either of the safe drug solvents. Many people have died after ingesting diethylene glycol contaminated pharmaceuticals. The countries where these deaths occurred are usually resource poor and cannot afford or do not have the technology for the expensive tests needed to determine if their raw ingredients are pure. Our objective is designing a simple and inexpensive enzyme-linked spectrophotometric assay to test for contamination of glycerin and propylene glycol. The assay measures the generation of NADH by the action of glycerol dehydrogenase (EC 1.1.1.6) employing the tetrazolium dye WST-1 (Dojindo Molecular Technologies, INC) to enhance sensitivity. Propylene glycol and glycerin are substrates for glycerol dehydrogenase and diethylene glycol is not. Thus solutions that are contaminated with diethylene glycol will show less absorbance. Linear absorbance versus concentration plots for propylene glycol (R2=0.9941) and glycerin (R2=0.9904) were generated. The absorbance with either substrate was diminished in a concentration dependent manner by added diethylene glycol. A preliminary estimate of the limit of detection for diethylene glycol contamination of propylene glycol was 6%. The values generated by the spectrophotometric assay were comparable to results obtained by gas chromatograph-mass spectroscopy determination using the same samples. The spectrophotometric assay described here has utility for alerting to potential diethylene glycol contamination of ingredients used in the fabrication pharmaceuticals.

A preclinical model for MEK inhibitor-induced retinopathy.

The Ras/Raf/MEK/ERK mitogen-activated protein kinase pathway mediates cellular responses to growth signals and is frequently activated in cancer. Several MEK inhibitors (MEKi) are currently in development. The most common dose-limiting toxicities seen with MEKi are: rash, diarrhea, nausea, vomiting, and less frequently but more troubling, central sensory retinopathy (CSR) and retinal vein occlusion (RVO). CSR is characterized by leakage of fluid under the neural retina of the mac-
ula resulting in the formation of a “blister” with detachment of the neural retina from the pigmented epithelium (PRE). This results in decreased visual acuity that may persist after the fluid has subsided. Similar findings have not been seen in any preclinical species with any MEKi tested to date making it difficult to select safer compounds for testing in humans. Using the Brown Norway Rat we assessed the ability of various MEKi to decrease the expression of MEK responsive RNAs (DUSP6 and Spry4) in the neural retina and PRE and correlated these effects with increased thickness of the photoreceptor layer as measured by Optical Coherence Tomography (OCT), free plasma concentrations and melanin binding. Toxicogenomic analyses also revealed that MEK inhibitors significantly decreased the expression of Tight-Junction mRNAs (Ocludins, Claudins and Junctional Adhesion Molecule) and related scaffold proteins (ZO-1, Actin, Rho PLA51, PAR6 and Cdc42) in the PRE. The data suggest that MEK alters the permeability PRE resulting in retinal fluid imbalance that causes CSR. Potential strategies to prevent MEKi induced CSR and the potential cause of RVO will also be discussed.

471 LONG-TERM EFFECTS OF PRENATAL ATRAZINE EXPOSURE ON PHYSIOLOGY, BODY COMPOSITION, AND STRESS REACTIVITY IN RATS.

C. E. Grace1, C. Aydin1, A. F. Johnston1, C. H. Gordon1 and J. M. Rogers1.

Low birth weight in humans is associated with increased risk of coronary heart disease, hypertension, and diabetes in adulthood. Experimental studies have also reported that undernutrition, stress or exposure to glucocorticoids during pregnancy is associated with hypertension, glucose intolerance, obesity, and altered stress reactivity. The mechanism(s) of these effects may be due to increased fetal exposure to maternal glucocorticoids. We hypothesized that environmental contaminants that increase maternal corticosterone (CORT) levels would elicit similar effects in offspring. Atrazine, a widely used herbicide, increases CORT in female rats. We exposed pregnant rats to 125 mg/kg/d atrazine, 0.1 mg/kg/d dexamethasone (DEX), or methyl cellulose vehicle from gestational day 14-20. Offspring were divided into 3 test groups: adult offspring were surgically implanted with radio transmitters for recording blood pressure (BP), core temperature, heart rate (HR), and activity during and without 1h restraint for 4 d (group 1); body composition was measured by magnetic resonance (Bruker) to determine percent body fat (group 2); and stress reactivity was measured by determining serum CORT levels prior to, during, and following 1h restraint (group 3). Baseline BP was increased in atrazine and DEX-treated animals, but differences were minimal during restraint. HR and temperature decreased daily during restraint, suggesting adaptation, but BP was elevated on subsequent days. Body fat was increased and lean mass decreased in DEX-treated female offspring. Prenatal atrazine treatment altered the adult offspring stress response to restraint: CORT levels were increased and did not return to control levels 2 h following restraint. These data indicate that exposure to chemicals that increase maternal CORT levels may lead to similar adult diseases as observed in maternal stress and undernutrition studies. Disclaimer: This is an abstraction of a proposed presentation and does not necessarily reflect EPA policy.
fetal testes were resistant to phthalate-induced suppression of steroidogenic gene expression across a range of doses. Based on these findings, we conclude that the human fetal tests is resistant to phthalate-induced androgen suppression, and developmental phthalate exposure is an unlikely contributor to the anti-androgenic related effects of TDS, namely hypospadias and cryptorchidism.

473 THE EFFECTS OF ENDOCRINE DISRUPTION ON THE DEVELOPING HUMAN FETAL PROSTATE.

C. Saffarini, S. J. Hall and K. Boekelheide. Pathology and Laboratory Medicine, Brown University, Providence, RI.

Prostate cancer is the most commonly diagnosed cancer and is the second highest cancer-related cause of death in men. This high incidence has led to speculation about the fetal origins of this adult disease and its etiology. Exposure to exogenous estrogens in pregnant women has been postulated to disturb the normal development of the human fetal prostate by disrupting the natural hormonal balance. Previous studies demonstrate that early life exposure to estrogens in rats can cause some degree of epithelial and stromal hyperplasia, inflammation, and prostatic intraepithelial neoplasia (PIN) lesions. The present study used a xenograft model to characterize the differentiation of human fetal prostate implants (gestation 12-22 weeks) exposed to either corn oil (control) or 250 ug/kg/body weight of 17β-estradiol 3-benzoate during an early acute exposure, as well as an additional later life exposure post-transplant. This xenograft model uses the renal subcapsular space as the site of implantation, thereby allowing for proper vascularization and growth of the implant. Characterization of the model included the expression of key immunohistochemical markers responsible for stromal and epithelial maturation, neuroendocrine cells, hormone receptors, cellular proliferation as well as apoptosis. As expected, the prostate implants grew and matured as seen in 7, 14, 30, 90, 200 and 400 days post-transplant xenografting. Interestingly, the human prostate xenografts exhibited marked differences in response to estrogen exposure compared to their endogenous rat prostate counterparts. Human prostate xenografts at 200 days post-transplant demonstrate basal cell hyperplasia shown by p63 staining, while the endogenous rat prostate exhibited atypical hyperplasia and the presence of cellular debris following estrogen exposure. This unique xenograft model provides insight on the growth and development of the human fetal prostate following developmental endocrine disruption.

474 GLUTAMATE CYSTEINE LIGASE MODIFIER SUBUNIT (GCLM) NULL MALE MICE ARE MORE SENSITIVE TO THE REPRODUCTIVE TOXICITY OF PRENATAL BENZO(A)PYRENE.

R. Patel1, L. Ortiz1, B. Nakamura1, Y. Hoang1, M. Cortes1, L. Muhair1, J. McConnachie1, T. Kavanagh1, and U. Luderer1. 1Medicine, University of California Irvine, Irvine, CA and 2Environmental and Occupational Health Sciences, University of Washington, Seattle, WA.

Benzo-a-pyrene (BaP), a ubiquitous environmental pollutant, is a testicular toxicant in fetus and adult. The tripeptide glutathione (GSH) is important in Phase II biotransformation of BaP and a major antioxidant. Mice null for the gene Gclm, which codes for the rate-limiting enzyme in GSH synthesis, have decreased GSH concentrations. We hypothesized that male Gclm-/- mice are more sensitive to the in utero reproductive toxicity of BaP than Gclm+/+ males. Female Gclm-/- mice were mated with Gclm+/+ males and were treated orally with 0 or 10 mg/kg/day BaP for Experiment 1 and 0 or 2 mg/kg/day BaP in Experiment 2 from gestation day 7-16. Male offspring were euthanized at 10 wks. In Experiment 1, tests weights, testicular sperm head counts, epididymal sperm counts, and epididymal sperm motility were significantly decreased by BaP exposure, and the effects of BaP were significantly greater in Gclm-/- males than Gclm+/+ males. In Experiment 2, testicular and epididymal sperm counts were slightly, significantly decreased by prenatal BaP exposure. There were inconsistent effects of Gclm genotype alone on cauda epididymal sperm counts and motility, with no effect in Experiment 1 and lower counts and motility in Gclm-/- males in Experiment 2. Prenatal BaP treatment increased the percentage of vacuolated seminiferous tubules in a dose-dependent manner. Cauda epididymal sperm morphology was assessed in Experiment 2: Percentages of sperm with abnormal heads and cytoplasmic droplets decreased with prenatal BaP exposure, and Gclm-/- males had increased percentages of sperm with abnormal heads. Serum testosterone was unaffected. These results show no effects of Gclm deletion alone on testicular spermatogenesis and inconsistent epididymal effects, but show increased sensitivity of Gclm-/- males to the transplacental testicular toxicity of BaP.

475 EFFECTS OF THE SMOKELESS TOBACCO PRODUCT, GUTKHA, ON REPRODUCTIVE AND DEVELOPMENTAL PARAMETERS IN PREGNANT MICE.

S. P. Doherty-Lyons1, C. Hoffman1, F. Ganey1 and J. T. Zelikoff2. 1Environmental Medicine, New York University School of Medicine, Tuxedo, NY and 2Memorial Sloan-Kettering Cancer Center, New York, NY.

Gutkha, an extremely popular herbal concoction made and sold throughout India, is exported worldwide. The product, a combination of tobacco, lime, betel nut, flavored, and catechu, is highly addictive and used by adults and children as a mild psychoactive drug. To assess the effects of Gutkha usage on gestational, developmental, and neonatal growth parameters, pregnant B6C3F1 mice were exposed daily to 21 mg of a water-soluble Gutkha solution beginning on gestational day (GD) 2 until parturition. The main objectives of this study were to: 1) develop an oral route of Gutkha administration that yielded relevant levels of serum and/or tissue cotinine; and, 2) determine whether Gutkha usage during pregnancy affected gestational outcomes. Female mice, paired with males for 2-4 nights prior to exposure, were painted with the Gutkha solution using a natural bristle paintbrush to coat the tongue and oral mucosa. Serum cotinine levels in the dams were measured weekly and ranged from 24-44 ng/ml. Cotinine was found in the amniotic fluid on GD 15 (16-22 ng/ml), and liver cotinine levels on the same GD were ~60% of those measured in serum (21-22 ng/ml). Dams were weighed daily throughout pregnancy; offspring were weighed from birth until weaning. Results demonstrated that Gutkha-exposed dams had a significantly longer duration of gestation than their control counterparts and gave birth on average 1.6 days later than control dams (p<0.05). In contrast, no effects of Gutkha were observed on pregnancy incidence, maternal weight gain, litter size, pup sex ratio, or offspring weight gain. In conclusion, a pregnant mouse model and relevant route of exposure has been developed for studying the toxic effects of smokeless tobacco. Findings from these studies demonstrate that nicotine, as its longer-lived metabolite cotinine, can reach the amniotic fluid and thus pose potential health risks to the fetus and/or growing neonate. Supported by NYU Cancer Institute.

476 ALZHEIMER’S DISEASE: TAU AND EARLY LIFE EXPOSURE TO PB IN PRIMATES.

S. W. Bihaqi and N. H. Zawia. Biomedical and Pharmaceutical Sciences, University of Rhode Island, Kingston, RI.

Late onset Alzheimer Disease (LOAD) constitutes the majority of AD cases (~90%) that have no clear genetic association. The differential susceptibility and course of illness, as well as the late age onset of the disease suggest that epigenetic and environmental components play a role in its etiology. Published reports from our lab showed that lead exposure occurring during brain development pre-determined the expression of AD-related genes such as the amyloid precursor protein (APP) later in life, influencing the course of amyloidogenesis and oxidative DNA damage via a process that involved DNA methylation and the transcription factor Sp1 (Basile et al. 2005; Wu et al. 2006; Bihaqi et al. 2011). In addition to an accumulation of β-amyloid (Aβ), deposition of another protein called tau in its hyperphosphorylated form is characteristic of the pathology of AD. Since Sp1 binding sites are present in the promoters of genes of APP as well as in tau, we hypothesized that early Pb exposure will also predetermine the expression of tau late in life. To test this hypothesis, we studied the brains of Cynomolgus monkeys, which were orally dosed in 1980-81 with 1.5 mg/kg/day of Pb- acetate from birth to 400 days of age and vehicle thereafter. The monkeys were sacrificed 23 years later. Here we present data on the protein expression of Tau46, Phospho tau (pSer199), cyclin dependent kinase-5 (cdk5) and F35/P25 in primate cerebral cortex that validate our hypotheses.

477 NEONATAL INFLAMMATION CONTRIBUTES TO FIBROTIC LUNG DISEASE IN ADULT MICE.

J. K. Rogers, R. D. Britt, K. M. Heyob, T. E. Tippie and M. Velsen. Center for Perinatal Research, The Research Institute at Nationwide Children’s Hospital, Ohio State University, Columbus, OH.

Maternally-derived inflammation contributes to prematurity and low birth weight. Preterm infants often develop respiratory insufficiency and are exposed to hyperoxia which elicits additional inflammatory responses. The long-term pulmonary consequences of multiple exposures during the neonatal period have not been ex-
tensively explored. In the present study, we tested the hypothesis that exposure to maternal inflammatory mediators neonatal hyperoxia alters lung physiology in the offspring at adulthood. Pregnant C3H/HeN mice at embryonic day (E)16 were injected with LPS (80 μg/kg) or saline (i.p.). Offspring were placed in room air (RA) or 85% O2 for 14 d and subsequently raised in RA. Pulmonary function tests (PFT), microCTs, and histological analyses were performed in the offspring at 8 wks and molecular analyses between E18 and 2 wks of age. PFT indicated decreased compliance and increased elastance in LPS/O2 mice. MicroCTs showed hyper-expanded lungs including patchy centrilobular areas of emphysema and higher tissue densities in the LPS/O2 group. Histological analyses revealed decreased alveolar numbers and increased lung collagen I and III protein levels (4- and 20-fold greater than control, respectively). In fetal lung tissues, IL-1β, TGF-β, and collagen I mRNA were increased on E18, following maternal LPS injection. Elevated levels of TNF-α, MCP-1, TGF-β, collagen I and collagen III mRNA and protein levels were sustained throughout hyperoxic exposure only in pups born to LPS injected dams. Early dysregulation of miR-29 expression coincided with changes in lung inflammation and proliferation. In mice, systemic maternal inflammation followed by neonatal hyperoxic exposure causes fibrotic lung disease in the offspring. These findings support the novel hypothesis that neonatal exposures contribute to the pathogenesis of adult pulmonary disease and suggest a need for similar studies in ex-preterm infants.

**478 ALTERATIONS IN NEUROBEHAVIOR AND HIPPOCAMPAL MORPHOLOGY FOLLOWING DEVELOPMENTAL EXPOSURE TO 3,3′, 4,4′-TETRACHLOROAZOBENZENE IN SPRAGUE DAWLEY RATS.**

A TRANSCRIPTOMICS APPROACH USING HBCD TO PRIORITIZE CHEMICALS AND MIXTURES FOR DEVELOPMENTAL NEUROTOXICITY RISK ASSESSMENT.

D. T. Szabo1, R. B. Shah1 and L. S. Birnbaum1

1. US EPA/ORISE, Washington, DC, 2SRA, Research Triangle Park, NC and 3NIEHS, Research Triangle Park, NC.

Omic presents a promising tool to identify mechanistic pathways associated with developmental neurotoxicity (DNT), with which to precise chemicals/mixtures with limited toxicity data. This approach can be used to mask low-dose toxicity not assessable by conventional testing, identify vulnerable developmental periods, test across species, and validate high throughput in vitro assays. Using this approach, we evaluated short-term disruptions to the developmental profile of genes in the hippocampus, a brain region involved in learning and memory, after exposure to hexabromocyclododecane (HBCD). HBCD is a flame-retardant mixture of 3 isomers (α, β, γ); γ dominates the mixture while α dominates in human blood/breast milk. In mice, infantile exposure to HBCD disrupts adult neurobehavioral function. Using a similar model, we examined hippocampal gene transcription following prenatal HBCD exposure on postnatal day 10 to the mixture, α, β or γ. Transcriptomic profiles differed between α, β, and the mixture (p-value <0.05 and fold change >1.5). α had the most robust changes in gene expression number, magnitude, and enrichment of canonical signaling pathways (α, 38; mixture, 18; and γ, 11 pathways). A top Ingenuity pathway identified as altered by all exposures was long-term potentiation (α, p=0.002; mixture, p=0.03; and γ, p=0.04), with an overall depression/delay in function. These data suggest developmental exposure to HBCD can alter the timing and possible structure of synaptogenesis, underlying the previously reported deficits in learning and memory. The different profiles generated with each compound suggest the necessity to assess the effects from the isomers as well as the mixture. We demonstrate the utility of an omics strategy to capture information on various aspects of brain development that can be altered with environmental exposures and to provide focus for further studies in determining possible modes of action. **480 PRENATAL CIGARETTE SMOKE EXPOSURE REPRODUCES FEATURES OF ADHD.**

C. Yochum1, S. Doherty-Leon2, L. T. Zelikoff3, C. Hoffman3 and J. R. Richardson1

1. Environmental and Occupational Medicine, Robert Wood Johnson Medical School, Piscataway, NJ and 2Nelson Institute of Environmental Medicine, New York University, Tucson, NY.

Attention-deficit hyperactivity disorder (ADHD) is a complex disorder with significant genetic contributions and numerous co-morbid conditions such as conduct disorder and oppositional defiant disorder. However, no single gene has been linked to a significant percentage of cases, suggesting that environmental factors or gene-environment interactions may play a role in ADHD of the unique environmental factors that have been found in epidemiological studies to increase risk of ADHD, maternal smoking has been the most extensively studied. However, the mechanism(s) by which maternal smoking leads to increased risk of ADHD are not clear. Here, we utilized an animal model of maternal smoking to determine the effects of prenatal cigarette smoke (CS) exposure on neurobehavioral development. Pregnant B6C3F1 mice were exposed whole body to either filtered air or mainstream CS from gestation day (GD) 4 to parturition. Exposures were conducted 4 h/d and 5 d/wk, with each exposure producing the equivalent of smoking <1 pack of cigarettes per day. Pups were weaned at postnatal day (PND) 21 and behavior assessed on PND30 and again at 6 months of age. Male, but not female, offspring of CS-exposed dams demonstrated a significant increase in locomotor activity (~40%) that was ameliorated by methylphenidate treatment. Additionally, male offspring exhibited increased aggression, as evidenced by a 125% increase in the number of fights in a resident intruder task. These behavioral abnormalities were accompanied by a 37% decrease in striatal dopamine and a 46% reduction in brain-derived neurotrophic factor (BDNF) mRNA. Taken in concert, these data demonstrate that prenatal exposure to CS produces neurobehavioral alterations in mice that are similar to those observed in epidemiological studies and suggest a role for dopaminergic and neurotrophic alterations in these effects. Supported in part by R01ES051991; ES050602; IFSH; ES000260.

**481 PRENATAL TCDD AND POSTNATAL LUPUS IN EARLY GERIATRIC C57BL/6 MICE.**

S. D. Holladay, A. Mustafa, E. Karpuzoglu and R. M. Gogal

Department of Anatomy and Radiology, University of Georgia, Athens, GA.

We recently reported an autoimmune profile in 24-week-old C57BL/6 mice that received a 2.5 or 5.0 μg/kg mid-gestation dose of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Clinical signs were consistent with a lupus-like syndrome and included: increased autoantibody levels, renal IgG and C3 immune complex deposition with associated inflammation, and increased peripheral Vβ+ T cells. No studies currently exist following the progression of such disease into middle or advanced ages, when human autoimmune disease manifests. Therefore in the present study, lettermates of mice from the previous 24 week prenatal TCDD study were allowed to age to 48 weeks, considered early geriatric in mice. Similarities and differences in the disease profile based on age and sex were observed. Peripheral autoimmune reactive T cells were increased only to 48 weeks, in contrast to males only to 24 weeks. Activated T cells from 48-week-old prenatal TCDD females over-produced the pro-inflammatory cytokine IFN-γ while males over-produced IL-10, effects again not seen at 24 weeks. Splenic transitional-2 B cells (CD21intCD24hi) were increased in males while transitional-1 B cells (CD21neg CD24neg) were increased in females at 48 weeks. Autoantibodies to cardiolipin and CD138+ spleen plasma cells were significantly increased in the aged males but not females. Anti-IgG and anti-C3 immune complex renal deposition were also significantly increased in the prenatal TCDD males but not females. These selective changes in the
Aged male mice may be noteworthy, in that the prevalence of SLE in humans shifts dramatically upward with aging. The collective findings suggest that prenatal TCDD permanently biases the postnatal immune response in aged C57BL/6 mice toward a sustained autoimmunity.

**Impact of Early Life BPA on Murine Cardiac Structure/Function.**

L. Chalifour and B. Patel. Lady Davis Institute, Montreal, QC, Canada.

Rationale: Bisphenol A (BPA), an endocrine disruptor used in the plastics industry, leaches out into the environment. Adult exposure is about 0.5 μg/kg/day with exposure in children about 10-fold higher. BPA can bind to estrogen receptors known to be present in fetal cardiomyocytes. We propose that BPA epigenetically reprograms early cardiac development to alter cardiac structure/function, DNA methylation and expression of proteins involved in calcium homeostasis.

Methods: BPA (BPA 0.5, 5, 200 μg/kg/day) or vehicle (VEH) was given orally to pregnant C57Bl/6 mice starting on gestation day 11. BPA200 pups received regular water at weaning. Cardiac function was measured by tail cuff blood pressure, echocardiography and electrocardiography. Physical parameters were measured monthly until 4M. Organ weights were collected at euthanasia. Protein expression was measured by immunoblotting.

Results: We report the impact of BPA on adult male progeny. Prostate, but not testes or seminal vesicle, weight was 1.5-fold increased in BPA5.0 mice. Kidney and abdominal fat was 2-fold increased in BPA5.0 mice. BPA200 had reduced blood pressure suggesting some hypotension. BPA5 had a longer PR interval suggesting a reduction in atria function. Echocardiography showed an increase in relative wall thickness in all BPA treated males suggesting cardiac hypertrophy. Fractional shortening, Vcf, pulmonary and ascending aorta VTI and cardiac output were similar suggesting no impact on ventricile function. SERCA2a and CASQ2 were increased >2-fold with no change in PLB or phosphorylated PLB at all BPA doses suggesting an increased ability to restore calcium and store calcium in the SER. PLB, LTCC, NCX1 expression was unaffected. DNMT3a was 2-fold increased at all BPA doses and DNMT3b was reduced suggesting altered DNA methylation activity.

Conclusions: Differences observed in cardiac function enable us to conclude that early life exposure to BPA, at BPA levels similar to those of childhood exposure, alters cardiac structure/function as well as cardiac gene expression in adult progeny, likely via changes in DNA methylation.

**Prediction of Drug-Induced Liver Injury by High-Content Analysis System Using HepG2 Cells: Detection of Reactive Oxygen Species.**

K. Yoshikawa, M. Ando, C. Aruga and Y. Iwas. Safety Research Laboratories, Mitsubishi Tanabe Pharma Corporation, Kasarazu, Chiba, Japan. Sponsor: L. Shinozuka.

Drug-induced liver injury (DILI) is a major reason for drug withdrawals from the market. It has been demonstrated that reactive oxygen species (ROS) are one of the primary causes of DILI. In this study, we examined the production of ROS (superoxide and peroxide) to predict DILI using a high content analysis system, namely, a high-throughput cell-based assay consisting of fluorescence microscopy and imaging data informatics. HepG2 cells from a human hepatoma cell line were seeded onto a 384-well plate and treated with test compounds for 1, 3, and 24 hr, and then triple-stained with dihydroethidium, CM-H2DCFDA, and Hoechst 33342 for detection of superoxide, peroxide, and cell loss, respectively. Then, the cells were analyzed by ArrayScan VTI and minimum effective concentrations for ROS production were calculated. At first, 7 compounds that induced oxidative stress were used to decide criteria for judgment in the multiplexed assay. Four of 7 compounds, hydrogen peroxide, menadione, L-buthionine sulfoximine, and blomycin, induced superoxide and/or peroxide at non-cytotoxic concentrations after 1, 3, and/or 24 hr-treatment. The remaining 3 compounds, mitomycin C, doxorubicin, and genticam, failed to detect superoxide and peroxide up to cytotoxic concentrations after 24 hr-treatment in HepG2 cells. Secondary, 9 hepatotoxicants and 6 non-hepatotoxins were tested to investigate the utility of the multiplexed assay as a screening system for hepatotoxic potential. As a result, all 9 hepatotoxicants induced superoxide and/or peroxide at non-cytotoxic concentrations (sensitivity = 100%), and 4 of 6 non-hepatotoxicants did not induce superoxide and peroxide up to cytotoxic concentrations (specificity = 66.7%). ROS5 production pattern, species and reactive time-point were revealed to be unique in some compounds. It is concluded that this high throughput multiplexed assay is a powerful tool to predict the DILI potential in the early phase of drug discovery.

**Enhancement of Proliferation in a Rat Hepatocyte Coculture Model After Mitogenic Stimulation.**

Primary mouse and rat hepatocyte cultures have long been the gold standard for assessment of cellular changes following chemical exposure. While helpful for assessing proliferative and responses in vitro, these cultures are limited to 1 or 2 days of incubation. Our motivation was to test whether extending the culture time beyond 3 days using micropatterned primary rat cultures coupled with quantitative high content imaging (HCI) technology could provide a more accurate assessment of the cell proliferative response after mitogenic stimulation. The HepatoPac® 96-well coculture system utilizes primary Sprague-Dawley hepatocytes seeded on micropatterned islands of collagen, surrounded by non-parenchymal murine fibroblasts. Following 8 days of stabilization, HepatoPac® cultures were incubated for 3, 5, and 7 days in serum-free media containing three mitogenic concentrations of Wyleh 14, 643 (WY) and Phenobarbital (PB) followed by parallel imaging analysis at 2 laboratories for Ki67 signal (a proliferation marker present in G1, S, G2, and mitosis, but not in G0). PB results showed an enhancement of Ki67 signal reported as % of control: 153%, 146%, and 83% at 3, 5, and 7 days respectively. WY results showed a similar trend: 140%, 108%, and 111% at 3, 5, and 7 days respectively. These results show an improvement of proliferative response with this hepatocyte model when compared to previous experiments using mono-layered primary rat cultures that produced a 5-10% hepatocyte proliferative response when held for 48hrs. These experiments suggest that the cellular environment & extended incubation capacity provided in the micropatterned cultures is a useful feature when testing compounds for mitogenic activity. (This abstract does not reflect US EPA policy and mention of trade names is not an endorsement for any product).

**Use of the HepaRG Cell Line to Assess Potential Human Hepatotoxicity of Toxcast Chemicals.**

G. Nelson1, M. Mennecozi2, G. Harris3, H. Rent1, W. Ward1, I. Shah1, J. Allen1, M. Whelan1 and C. Corron1. 1 US EPA, Research Triangle Park, NC and 2 JRC, Ispra, Italy.

The HepaRG cell line is a promising model system for predicting human hepatotoxicity in part because of the greater capacity to metabolize chemicals compared to other hepatocyte models. We hypothesized that this cell line would be a relevant model for toxicity testing of industrial chemicals. Gene expression profiles were used to predict changes in xenobiotic-activated transcription factors. Approximately 20 chemicals that have been evaluated in high throughput assays as part of the ToxCast screening program are under investigation. Initial studies examined the gene expression response to the fungicide vinclozolin, a rodent liver carcinogen. Three separate preparations of differentiated HepaRG cells were exposed for 72 hr with either DMSO or one of six concentrations of vinclozolin ranging from 7.8-250 μM. RNA expression was analyzed using Illumina Human HT-12v4 bead chips. The gene expression data were normalized by Illumina GenomeStudio, and differentially expressed genes were identified by CyberT. The doses of 250, 125 and 63 μM resulted in 404, 258, and 65 genes altered, respectively. No genes were significantly altered at doses below 63 μM. Ingenuity Pathways Analysis (IPA) indicated that a number of pathways were altered including metabolism of androgen/estrogen, xenobiotics and fatty acids. Genes associated with dose-dependent AHR (CYP1A1, CYP1A2, CYP1B1) and PPARα (ACADM, ACDVL1, CPT1A, ECH1) activation were identified. These findings overlap with changes observed after vinclozolin exposure in cell models as part of the ToxCast screening program including HepG2 transcription factor screening and nuclear receptor marker gene evaluation in human primary hepatocytes. Future research with additional ToxCast chemicals will allow more comprehensive baseline characterization of the HepaRG model and help to elucidate mode of action. (This abstract does not reflect EPA policy).
**486 A MULTIPLEX, AUTOMATED APPROACH TO SCREEN FOR MITOTOXICITY IN HUMAN HEPATOCYTES AND HEPG2 CELLS.**

T. Mödder1, T. Worzel2 and B. Larson3,1. 1Celis In Vitro Technologies, Halethorpe, MD, 2Promega Corporation, Madison, WI and 3Boston, Winnouski, VT. Sponsor: M. Xia.

Many drugs and environmental chemicals have been implicated in mitochondrial toxicity resulting in myopathies, hepatotoxicities, peripheral neuropathies and cardiovascular disorders. The mechanisms of mitotoxicities are complex due to multiple modes of action such as modulating mitochondrial replication and disruption of electron chain transport, and by organ-specific susceptibility. For example, the mitotostatin preferentially targets the liver over muscle due to metabolic activation in hepatocytes. Therefore, multiple approaches are needed to assess a chemical's mitochondrial liabilities in specific cellular systems. Herein, we present one approach to utilize two markers of cellular viability in an automated multiplexed format for high-throughput screening to monitor hepatotoxicity that can discriminate primary mitotoxicity from general cytotoxicity. Primary human hepatocytes and HepG2 cells were used in a 384-well suspension culture format in serum-free, glucose-free galactoside-containing medium for up to 6 hour exposure with cytotoxins in a 11-point response curve. ATP Detection Reagent and Cytotoxicity Reagent were used to measure ATP levels and cell membrane integrity, respectively. A mitotoxic effect was defined as a reduction of ATP relative to untreated control, with no or minor changes in cell membrane integrity. CCCP and antimycin were used as model compounds to disrupt mitochondrial activity. Digitonin cytotoxicity was caused by solubilizing the cell membrane, resulting in decreased ATP and loss of cell membrane integrity. Staurosporine and tamoxifen were also used as cytotoxins to validate the system. Similar results were observed between HepG2 and human hepatocytes except for antimycin where a Crabtree effect was implicated for the difference in its potency. In summary, the multiplex system provided a robust and informative platform to screen drugs and chemicals for hepatic mitotoxicity by measuring ATP and cell membrane integrity.

**488 AN RNA INTERFERENCE-BASED SCREENING IDENTIFIES THE SIGNALING NETWORK THAT DETERMINES DICLOFENAC-INDUCED LIVER CELL DEATH.**

Drug-induced liver injuries (DILI) are the leading cause of acute liver failure. DILI often involves a synergy between chemical-induced cell injury stress and immune-mediated cytokine signaling responses. So far the underlying signaling mechanisms in this interaction are unknown. We therefore applied a siRNA screening approach targeting all kinases and (de)ubiquitinas as well as cytokine signaling components. As a model we used diclofenac, a clinical relevant drug that can cause idiosyncratic DILI. Diclofenac-induced cell death of HepG2 cells is enhanced by the cytokine TNF-α and related to perturbation of the anti-apoptotic NF-κB pathway and activation of the pro-apoptotic caspase-8 pathway. Here we used a high-throughput siRNA screening approach to identify key signaling players in diclofenac/TNF-α-induced HepG2 cell death. HepG2 cells were transfected with Dharmacon smartpool siRNAs and thereafter treated with diclofenac for 8 hours followed by TNF-α challenge for 16 hours in the presence of annexin V-Alexa633. Cell death was assessed by measuring the relative annexin V fluorescence intensity per cell area at 8 and 24 hours. In total, 1596 genes were targeted. After automated image analysis 94 hits were selected with a Z-score cut-off of 2.0. The hits include those that increase or decrease diclofenac/TNF-α-induced cell death after 24h, that increase cell death induced by diclofenac alone at 8 hours, and knockdowns that cause cell death by TNF-α exposure at 24 hours. A deconvolution screen was then performed using 4 single siRNAs per target gene by our live apoptosis assay to assess the previously identified hits. This screen revealed key signaling molecules that define the sensitivity for diclofenac-induced hepatocyte killing. These genes are likely candidates in the predisposition for DILI in the patient population.

---

**487 AN IMAGING-BASED RNA-INTERFERENCE SCREEN IDENTIFIES MODULATORS OF TNF-MEDIATED NF-κB SIGNALING IN DRUG-INDUCED LIVER INJURY.**

Tumor necrosis factor-α (TNFα) is a cytokine that plays a dual role in the liver: TNFα can induce hepatocyte proliferation and liver regeneration, but it also affects cell death. TNFα has been implicated in various liver diseases as well as in drug-induced liver injuries (DILI). Thus, TNFα signaling enhances the diclofenac-induced cell killing of hepatocytes. The protective effect of TNFα is mediated by the timely nuclear translocation of NF-κB to activate its target gene transcription. Diclofenac negatively affects the frequency and amplitude of NF-κB oscillation in liver cells, thereby promoting synergistic pro-apoptotic responses. Here we performed a functional genomics screen to identify kinases and (de)ubiquitinases that are involved in the deregulation of the TNFα-induced NF-κB oscillatory responses caused by diclofenac. We used HepG2 cells expressing GFP-tagged p65/RelA (NF-κB subunit) in 96-well plates under control and drug-treatment (diclofenac) conditions and followed the GFP-p65 oscillation of ~200 cells per well for 6 hours using automated confocal laser scanning microscopy. The cell-specific NF-κB responses within a knockdown population were mapped using automated ImageJ-based algorithms. This work firstly uncovered distinct cell behaviors and population dynamics in the context of hepatotoxicant treatment in association with increased sensitivity towards apoptosis. Using a robust statistical analysis including several parameters, we selected 127 hits out of the 1596 genes screened. A validation deconvolution screen was then performed to confirm the functional role of the identified kinases and (de)ubiquitinases controlling the NF-κB response. Pathway analysis of the hits identified indicates that the activity of the NF-κB response is intricately linked to various stress responses, which, upon drug toxicity conditions, modulate the activity of the protective abilities of the NF-κB response. The identified candidate genes may play a critical role in modulating DILI responses.

**489 A HIGH-CONTENT IMAGING-BASED IN VITRO 3D MODEL FOR ASSESSMENT OF DRUG-INDUCED LIVER INJURY.**

S. Ramazanoglu1, B. Herpers1, J. Commandeur2, B. Van de Water1 and L. Price1, 1Department of Toxicology, Leiden University, Leiden, Netherlands and 2Department of Molecular Toxicology, Vrije University, Amsterdam, Netherlands.

We have developed a 3D HepG2 cell culture model for the assessment of hepatotoxicity. HepG2 cell-based monolayer models are widely used for studying liver toxicity of xenobiotics. It is well anticipated that under these conditions HepG2 cells have low expression of metabolic enzymes and drug transporters, which will compromise the validity of high-throughput safety assessment studies using these cells. Here we describe a 3D in vitro model using HepG2 cells. This model induces robust morphological and functional differentiation, with a strong induction of metabolic enzymes and transporters, many of which are poorly expressed in monolayer cultures. Unlike primary hepatocytes in 2D culture, the metabolic competence of HepG2 in 3D could be retained for up to 4 weeks, making chronic exposures feasible. The assay we have developed is implemented in a 384 well format for low cost and increased throughput. We combine conventional toxicity readouts with automated high-content imaging to measure expression of fluorescent stress reporters, such as KEAP1/Nrf2 activation, combined with other fluorescent labels for cell toxicity. This assay represents a novel and more physiologically relevant method for predicting drug-induced liver injury.

---

**490 TOXICITY PATHWAY ANALYSIS OF HEPATOTOXIC COMPOUNDS IN PRIMARY HUMAN HEPATOCYTES IN 2D AND 3D-CULTURE.**

S. Messner1, P. Walker1, E. Lorbach1, H. Woodhouse1, H. Gill1, J. Kelm1, J. Lichtenberg1, H. Hartmann1, W. Moritz2 and K. Taimou1,1. 1InSphere, Zurich, Switzerland, 2Apeldor, Waterton, MA, 1Lonza, Cologne, Germany and 2Glyprotex, Macclesfield, United Kingdom.

Hepatotoxicity is the most common reason for a drug to be withdrawn from the market and the most common cause of drug attrition. Since it is increasingly important to identify hepatotoxic liabilities earlier in drug discovery, in vitro evaluation screening systems play an important role in the early phase of pharmaceutical development. They are also important to clarify the mechanisms of toxicity observed during development.
In this study we describe the suitability of human hepatocytes in 2D- and 3D-con-figurations for lead optimization screening. The scaffold-free 3D liver microtissues are produced by gravity-enforced self-assembly in hanging drops. They are com-posed of primary human hepatocytes in coculture with nonparenchymal cells, in-cluding Kupffer macrophages. This highly organotypic culture is characterized by extensive cell-cell contacts, distinct morphology between cell-types and higher he-patocyte functionality than in 2D-cultures. Since liver microtissues are also stable and viable over several weeks in culture, this allows chronic repeat dose exposures to analyse potential hepatotoxic liabilities.

Due to uniform production and standardisation of the microtissue highly reproducible data is generated. Here it is shown for the first time, that liver microtissues are suitable for compound screening. Known compounds that result in bioactivation, mitochondrial impairment, steatosis and oxidative stress are assessed using a range of biomarkers including ATP content, GSH depletion and lipid accumulation. Many new in vitro cell models are being created to help understand and improve our ability to predict hepatotoxicity early in the drug discovery process; we show the potential of human hepatocyte microtissues as a promising alternative to 2D cultures.

Liver Injury remains a major reason for late stage drug attrition. Therefore the phar-maceutical industry aims at developing predictive assays that can be deployed early in the drug discovery process when SAR approaches are still feasible. Xu et al., 2008 have shown that drug induced liver injury can be predicted to some extent using primary human hepatocytes in sandwich cultures and high content imaging of key endpoints of injury (i.e. mitochondrial membrane potential, reactive oxygen species, lipid accumulation and nuclear stain). The sensitivity of this assay was approxi-mately 50% with a 0-5% false positive rate. While high content imaging using sandwich cultures represents a key advance in the field, the sensitivity of the assay needs to be further improved. One can hypothesize that the low sensitivity could be due to the fact that the assay was only performed at 24 hours and that longer incu-bation with compounds could improve outcomes. However, the requirement would be that the hepatocyte culture would stay viable and metabolically compre-hensible for an extended period of time. In addition, full phase I and II enzymes should be expressed at levels comparable to those found in vivo and transporters should be functional. Here, we use micropatterned human hepatocyte cocultures (Khetani and Bhatia, Nature Biotechnology 2008), also called HepatoPac™, to detect drug induced liver injury for compounds that were previously missed utilizing the Xu assay. We show that in comparison to conventional sandwich cultures, HepatoPac was able to accurately identify 10 toxic compounds (True Positives) without in-creasing the false positive rate for truly negative compounds. In addition, HepatoPac was able to identify 14 of 25 toxic compounds that were missed previ-ously in the Xu assay and reported as false negatives. In summary, this method shows superiority over the conventional sandwich culture method.

In this study, 12 compounds with known hepatotoxicities were used in an in vitro microtissue model to assess for lead optimization potential. Using high content screening, we were able to score liver abnormalities and fibrosis in zebrafish larvae (trichrome stain) and fibrosis (trichrome stain). For some compounds (e.g., nefazodone), histological alterations were only detected at concentrations that had been scored for subtle detection and delineation between different mechanisms of liver toxicity.

Here it is shown for the first time, that liver microtissues are suitable for compound screening. Known compounds that result in bioactivation, mitochondrial impairment, steatosis and oxidative stress are assessed using a range of biomarkers including ATP content, GSH depletion and lipid accumulation. Many new in vitro cell models are being created to help understand and improve our ability to predict hepatotoxicity early in the drug discovery process; we show the potential of human hepatocyte microtissues as a promising alternative to 2D cultures.
495 INHIBITION OF THE HEPATIC BILE ACID TRANSPORTER MRP4: A POTENTIAL RISK FACTOR FOR CHOLESTATIC DRUG-INDUCED LIVER INJURY.

K. Koeck, B. C. Ferslew, K. Yang and K. L. Brouwer. University of North Carolina Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Inhibition of the bile salt export pump (BSEP) leading to increased hepatocellular concentrations of bile acids has been proposed to contribute to the development of drug-induced liver injury (DILI). MRP4 is responsible for the hepatic basolateral efflux of xenobiotics and bile acids, especially when biliary excretion of bile acids is compromised. Inhibition of MRP4 function may result in accumulation of toxic species and deleterious consequences. In the present study, inhibition of MRP4-mediated transport by cholestatic and non-cholestatic compounds was investigated to obtain further insights into potential risk factors for DILI. Membrane vesicles prepared from HEK293T cells transfected with human MRP4 or empty vector were used to determine the inhibitory effect of test compounds at 100 μM on MRP4-mediated uptake of the probe substrate 3H-dehydroepiandrosteronesulfate (DHEAS; 2 μM) in the presence of ATP and glutathione. Test compounds consisted of 16 cholestatic (4 BSEP inhibitors; 12 non-BSEP inhibitors) and 15 non-cholestatic (4 BSEP inhibitors; 11 non-BSEP inhibitors) drugs. Test compounds that inhibited MRP4-mediated DHEAS transport >30% were defined as MRP4 inhibitors. A χ²-test was used to determine whether MRP4 inhibition was related to the cholestatic properties of the test compounds. Inhibition of MRP4-mediated DHEAS transport was observed for 12/31 compounds (39%); 9/16 compounds associated with cholestatic liver injury or jaundice in humans (56%), but only 3/15 non-cholestatic compounds (20%), inhibited MRP4 (p<0.05). BSEP inhibition is a known susceptibility factor for DILI. Therefore, compounds that were not BSEP inhibitors were analyzed further: 6/12 cholestatic compounds (50%), but only 1/11 (9%) non-cholestatic compounds inhibited MRP4 (p<0.05). These results suggest that inhibition of MRP4 might result in hepatic accumulation of toxic compounds and contribute to the development of cholestatic DILI. Morgan et al., Toxicol Sci., 2010 Dec; 118(2):485-500. Supported by NIH GM41935 and DFG Ko4186/1-1.

496 POTENTIAL ROLE OF FASL EXPRESSION AND SIGNALING IN THE INDUCTION OF HEPATOTOXICITY BY AZT.

H. Dondé1, S. Ghare1, W. Chen1, S. Joshi-Barve1, C. McClain1,2 and S. Barve1,3. 1Department of Medicine/GI, University of Louisville, Louisville, KY, 2Pharmacology and Toxicology, University of Louisville, Louisville, KY and 3Louisville VAMC, Louisville, KY.

The induction of Highly Active Antiretroviral Therapy (HAART) in the mid-1990s has led to a significant increase in the life expectancy of patients with HIV. However, hepatotoxicity due to HAART is also common, and up to 30% of patients on HAART experience World Health Organization grade 3 liver enzyme elevations. Furthermore, hepatotoxicity from antiretroviral drugs leads to adverse patient outcomes either from fulminant hepatitis or jaundice in humans (56%), but only 3/15 non-cholestatic compounds (20%), inhibited MRP4 (p<0.05). BSEP inhibition is a known susceptibility factor for DILI. Therefore, compounds that were not BSEP inhibitors were analyzed further: 6/12 cholestatic compounds (50%), but only 1/11 (9%) non-cholestatic compounds inhibited MRP4 (p<0.05). These results suggest that inhibition of MRP4 might result in hepatic accumulation of toxic compounds and contribute to the development of cholestatic DILI. Morgan et al., Toxicol Sci., 2010 Dec; 118(2):485-500. Supported by NIH GM41935 and DFG Ko4186/1-1.

497 ACCELERATED ETHANOL CLEARANCE AND RESISTANCE TO ALCOHOL-INDUCED STEATOSIS IN GLUTATHIONE-DEFICIENT MICE.

Y. Chen1, S. Singh1, A. Matsumoto1, H. G. Shertzer2 and V. K. Vasilious1. 1Department of Pharmaceutical Sciences, University of Colorado AMC, Aurora, CO and 2Department of Environmental Health, University of Cincinnati Medical Center, Cincinnati, OH.

Alcoholic liver disease (ALD) is one of the leading lifestyle-related causes of illness and death in the United States. Liver is the primary alcohol-metabolizing organ, where ethanol is first metabolized to acetaldehyde by alcohol dehydrogenases and CYP2E1 and then to acetic acid by aldehyde dehydrogenases (ALDH). While the molecular mechanisms underlying the pathogenesis of ALD are not completely understood, oxidative stress associated with ethanol metabolisms has been implicated in this process. The aim of this study was to elucidate the role of antioxidant glutathione (GSH) in ethanol metabolism and alcohol-induced hepatotoxicity by using Gclm(−/−) transgenic mice that exhibit 10-20% of normal tissue GSH levels. Following a single injection of ethanol (i.p., 5 g/kg), circulating ethanol and acetaldehyde were measured in Gclm(−/−) and Gclm(+/+) mice at 1, 3 and 24 hour. Gclm(−/−) mice revealed a faster clearance of acetaldehyde and a to lesser extend ethanol. After 6 weeks of feeding with a liquid diet containing ethanol up to 6%, both Gclm(−/−) and Gclm(+/+) mice showed normal liver weight and plasma ALT levels. Histologically, simple steatosis was observed in 60% of ethanol-fed Gclm(−/−) mice, but was absent in all ethanol-fed Gclm(+/+) mice. Hepatic gene and protein expression analyses revealed suppressed lipid metabolism but induced ethanol metabolism and stress-response pathways in Gclm(−/−) mice compared to wild-type animals. Collectively our results suggest a potential role of GSH in fine tuning of the metabolic and stress response in ethanol-induced liver injuries. Supported in part by NIH grants R01 EY011490 and R21AA017754.

498 HEPATIC BILE ACID COMPOSITION IN PROGRESSIVE HUMAN NONALCOHOLIC FATTY LIVER DISEASE.

A. D. Lake1, P. Shipkova1, N. Aranibar1, D. Robertson2, M. D. Reily2, P. Nowak2, T. D. Lehman-McKeeman2 and N. T. Cherrington1. 1Pharmacology & Toxicology, University of Arizona, Tucson, AZ and 2Bristol-Myers Squibb, New York, NY.

Individual bile acids exhibit either hepatoprotective or toxic roles within the liver due to their diverse chemical properties. Alteration of the bile acid profile can have a profound involvement in the development of drug induced liver injury and hepatotoxicity. Chronic liver diseases such as nonalcoholic fatty liver disease (NAFLD) may alter the bile acid profile predisposing individuals to hepatic injury. NAFLD originates as steatosis and may progress to non-alcoholic steatohepatitis (NASH), which is characterized by increased oxidative stress, inflammation, and fibrosis. The purpose of this study was to analyze the transcriptomic and metabolomic alterations of the classical and alternative bile acid synthetic pathways within the context of progressive human NAFLD. Human livers classified as normal, steatosis and NASH were prepared for analysis using Affymetrix GeneChip Human 1.0 ST arrays as well as LC-MS and NMR metabolomics methodologies. In general, transcriptional changes in the expression of nuclear receptors, transporters, and metabolizing enzymes of the bile acid synthetic pathway appear to drive alterations in the bile acid metabolomic profiles of NASH patients. Increased expression of the tauine conjugation enzyme bile acid-Coenzyme A amino acid N-acyltransferase (BAAT) and CYP7B1 were observed in NASH livers resulting in metabolic increases of tauine and taurine conjugated bile acids such as taurocholic acid (TCA) and taurodeoxycholic acid (TDCA). Concurrent decreases of the more hepatotoxic bile acids were observed including cholic acid (CA), deoxycholic acid (DCA) and glycocholic acid (GCA). These findings reveal a shift toward the alternative (CA) and more hepatotoxic bile acid synthesis characterized by increased taurine conjugation which may be indicative of an initiation of hepatoprotective mechanisms in NASH patients.

499 TRANSPLACENTAL ARSENIC EXPOSURE INDUCES GENDER-SPECIFIC GENE EXPRESSION CHANGES IN FATTY ACID METABOLISM IN C57BL/6 MOUSE LIVER.

P. Carlson1, A. E. Dalrymple2 and R. J. Van Beneden1,2,3. 1Graduate School of Biomedical Sciences, University of Maine, Orono, ME, 2Department of Molecular and Biomedical Sciences, University of Maine, Orono, ME and 3School of Marine Sciences, University of Maine, Orono, ME. Sponsor: J. Goss.

Arsenic contamination in ground water is present in many places around the world. Several regions, including southeast Asia and northern New England, have arsenic concentrations in water sources that measure well above the 10 ppb action level set.
by the EPA and WHO. Many diseases have been linked to arsenic exposure includ- ing cancer and diabetes. Investigations of in utero exposure to arsenic have shown alterations in DNA regulatory elements, although the mechanisms of toxicity are still poorly defined. To address the effects of arsenic exposure on their offspring, female C57BL/6 mice were exposed to 0 to 500 ppb sodium arsenite in drinking water, from 4 days prior to mating to 21 days post partum. Livers from offspring were collected and gene expression was measured using a fatty acid metabolism target array (SABiosciences). Gender differences were detected, with altered expression in 14 of 84 genes in females and 40 of 84 in males. Gene targets focused on pathways including the catabolism, transport and biosynthesis of fatty acids, triglycerol carabolism and ketogenesis. Nearly half of the genes with altered expression are regulated by peroxisome proliferator-activated receptor (PPAR), a tran- scription factor involved in glucose regulation and adipose tissue differentiation. Pparγ has been previously identified as a target of acute arsenic exposure in mouse fibroblasts (NIH 3T3), showing altered gene expression and protein function. The investigation into the transcriptional regulation of the genes identified in the array is ongoing, focused on the impact of maternal arsenic exposure on Pparγ gene and protein expression following chronic arsenic exposure. This study will help con- tribute to our understanding of how early-life arsenic exposure may influence cru- cial regulatory mechanisms involved in lipid metabolism, and impact the develop- ment of metabolic diseases in adults.

**500 ACETALDEHYDE DEHYDROGENASE 2 (ALDH2) ACTIVATION PROTECTS HEPATOCYTES FROM MITOCHONDRIAL DAMAGE AND DEATH CAUSED BY 4-HYDROXYNENAL.**

K. Baldauf1, 2, J. Jokinen1, 2, K. Falkner2, J. I. Beier1, 2 and G. E. Arteel1, 2, 1Pharmacology and Toxicology, University of Louisville, Louisville, KY and 2Alcohol Research Center, University of Louisville, Louisville, KY. Sponsor: J. States.

ALDH2 is a mitochondrial enzyme that oxidizes acetaldehyde to acetate. Lipid aldehydes (e.g., 4-HNE) are also substrates for ALDH2, and it has been hypothesized that this enzyme may also protect against oxidative stress. Indeed, recent studies by this group indicate that activating ALDH2 protects against oxida- tive stress and damage to the liver. The purpose of the current study was to build on these findings and to assess the mechanistic effect of activating ALDH2 using high throughput screening (HTS) and microarray (HCS) in vitro. Primary hepatocytes were isolated from C57BL/6J mice and seeded on 96 well plates. Some mice were administered EtOH (6 g/kg/d i.g. for 3 d) prior to isolation, or hepatocytes were exposed to Alda-1 (1.5 μM) in culture, to acti- vate ALDH2. Cells were exposed to 4-HNE (0-1000 μM) for 0-24 h. Cell toxicity was measured via automated quantitative multi-probe fluorescence microscopy, using a Cellomics Array Scan VTI HCS reader. This technique enabled monitoring of live cells for multiple fluorescent markers of processes that are involved in the pathogenesis of toxicity, including: inner mitochondrial membrane potential (TMRR), membrane permeability (TOTO-3), and nuclear number and size (Hoechst). Additionally, the Seahorse Biosciences XF-96 was employed to assess mitochondrial function of the primary hepatocytes. 4-HNE exposure caused cyto- toxicity and cell death time- and dose-dependently. Mitochondrial dysfunction was observed to precede cell death after 4-HNE exposure. Activating ALDH2 signifi- cantly protected against 4-HNE toxicity. Taken together, these data suggest that ac- tivating ALDH2 protects hepatocytes from 4-HNE-induced mitochondrial damage and cell death. These results lend further support to the idea that ALDH2 activity (high or low) may significantly impact the severity and response to liver injury and liver diseases. Supported in part by NIAAA

**501 MOLECULAR MARKERS OF MOUSE HEPATOCARCINOMA THAT IDENTIFY THE INITIATING ONCOGENE(S).**

L. Pharm and E. P. Sandgren, Molecular and Environmental Toxicology, University of Wisconsin-Madison, Madison, WI.

We are searching for molecular markers that can distinguish between different he- patocellular carcinomas (HCC) forms of HCC by virtue of their distinct initiating oncogene alterations. Only if the initiating cause is known can pathway-targeted therapy be em- ployed. In this study we evaluate patterns of gene expression in mouse liver tumors that are caused by known oncogene(s): c-myc, mutant H ras, mutant β-catenin, and/or TGFα. We employ an inducible transgene system coupled with an hepatocyte transplantation assay to generate focal HCCs growing in an otherwise non-neo- plastic liver. For each tumor-initiating genotype, we compare microarray expression profiles to identify specific and unique patterns of gene expression. In this model, the incidence and latency of HCC progression varies depending on the initiating oncogene(s), indicating that the original genetic changes have different effects on the development of aggressiveness of the disease. For these oncogene combinations, we identified a panel of genes whose collective expression patterns allowed us to discriminate among the groups. Using the “leave one out” method, we found that an observer without knowledge of sample identity could correctly identify a tumor’s initiating genetic changes by examining the expression profile of this panel of genes. Our findings suggest that we can identify molecular (gene expression) markers that can assign mouse liver tumors to appropriate oncogenic initiating groups.

**502 ACTIVATION OF SIRTUIN 1 PATHWAY TO REVERSE DRUG TRANSPORTER AND NUCLEAR RECEPTOR PATHWAYS IN FATTY LIVER.**

S. R. Kulkearn, A. C. Donepudi and A. L. Slin, Biomedical and Pharmaceutical Sciences, University Of Rhode Island, Kingston, RI.

Nuclear receptors (NR), CAR, PXR, FXR, PPAR and Nr5f2 are transcriptional regul- ators of transporter expression in liver in coordination with Phase-I and -II bio- transformation enzymes. NAFLD markedly alters hepatic transporter expression in mouse. Caloric restriction (CR) is a common regimen to treat NAFLD and proven model to activate Sirtuin1 deacetylase activity in liver conferring protection against steatosis. Purpose of this study was to expand on currently negligible information to evaluate whether CR affects hepatic transporter expression in livers from lean mice and “reverse” transporter expression changes observed with steatosis. Adult lean (C57BL/6) and obese (ob/ob, OB) mice were fed ad libitum or placed on a 40% (kCal) reduced diet. CR decreased hepatic triglyceride levels in both mice, but not to the same degree in livers from OB mice. CR decreased Oatp1a1; Oatp1b2 (~90%) as well as Bsep, Btcp (~40%) mRNA and protein expression in lean but not OB mice. CR increased Abcc2 mRNA expression by ~2 fold in OB livers only. However, protein expression increased in both lean and OB mice, reversing basal downregulation of Abcc2 in OB mice to a level comparable to lean fed controls. Steatotic livers from OB mice show increased Abcc1, 3, 4 and 5 mRNA expression. CR decreased Abcc3 protein expression in lean mice but increased it in OB livers. CR did not alter Abcc1, 4 and 5 mRNA expression in lean mice but significantly decreased their expression in OB mouse livers. Abcc4 protein expression increased in lean and OB mice upon CR. In steatotic livers from OB mice; AhR, PXR, Nfkb, Nr5f2, CREB, CAR and PPAR binding to respective RE increased by 147- 275% but FXR binding decreased by 60%. This increased binding in hepatic nu- clear fractions from OB mice was reversed by CR and mirrored by respective target gene expression. In summary, CR can “reverse” expression of some transporters in liver, but not all. Overall, these data indicate a potential to restore hepatic disposi- tion changes associated with obesity through CR. (KEIS013782A, RES016042A)

**503 HTS FOR SMALL MOLECULES CAPABLE OF MODULATING THE CELLULAR PHENOTYPES OF HUMAN iPSC-DERIVED HEPATOCYTES.**

B. Leonard1, S. Kameoka1, J. Babiarz1, V. Oett1, T. Singer1, T. Weissner1, K. L. Kolaj1, 2 and E. Civelli1, 2, 1Nonclinical Safety, Hoffmann-LaRoche, Nutley, NJ and 2Nonclinical Safety, Hoffmann-La Roche, Basel, Switzerland and 3Cellular Dynamics International, Madison, WI.

The liver is the major drug metabolizing organ and a frequent site of drug induced toxicity. In drug discovery, robust in vitro methods are needed for modeling liver function. Current methods employing primary human hepatocyte cultures and cell lines have well-documented shortcomings, namely donor to donor variability and functional instability. Although pluriptotent stem cell derived tissues hold promise to address these problems, thus far most reports on human induced pluripotent stem cell (hiPSC)-derived hepatocytes indicate a higher similarity to fetal tissues than adult in many aspects including metabolic activity, which could make their ex- trapolation to the adult situation difficult. To address these shortcomings, human iPSC-derived hepatocytes were exposed to a library of small molecules to identify compounds that resemble functionality of an adult liver. High-throughput, mi- crofluidic qRT-PCR was used to examine the expression of 26 genes that span a spectrum of hepatocyte functions that were either low or exhibited an immature phenotype in hiPSC-derived hepatocytes when compared to adult primary human hepatocytes. During the primary screen, multiple compounds significantly in- creased maturation-associated genes. These hits were confirmed in a secondary screen, and the ability for a sustained response was quantified. These data suggest it may be possible to modulate the maturation of stem cell-derived tissues, potentially generating even more relevant models for drug discovery and safety platforms.
504 PHYSIOLOGICAL HEMODYNAMIC FLOW AND TRANSPORT ARE NECESSARY FOR RETENTION OF PRIMARY HEPATOCYTE DRUG METABOLISM AND TOXICITY INDICES.

A. Dash1, S. B. Michael1, T. Deering1, D. Berry1, E. L. LeCluyse1, T. L. Preuss1, B. R. Blackman2 and B. R. Warnholz2. 1HemISherm, Charlottesville, VA; 2Biomedical Engineering, University of Virginia, Charlottesville, VA; 3Department of Surgery, University of Minnesota, Minneapolis, MN and 4The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Static primary hepatocyte cultures, used in drug metabolism and toxicity testing, experience non-physiological drug exposure profiles due to design limitations, and lose their metabolic phenotype over time, possibly contributing to poor in vitro in vivo correlations. We developed a system using rat hepatocytes plated in a perfused transwell device exposed to hemodynamics matching physiological liver blood flow. Hepatocytes in this system demonstrated polarized morphology, retention of differentiation markers (hepatocyte nuclear factor 4-α and E-cadherin) and significantly higher levels of liver function compared to static cultures over 2 weeks (Albumin =74.4 ± 10.04 vs. 9.8 ± 2.32 μg/106 cells/day, Urea =698.93 ± 61.62 vs. 102.17 ± 32.85 μg/106 cells/day, n=3). Gene expression of Cytochrome (Cyp) enzymes was significantly higher (n=10, Fold changes over static cultures: Cyp1A1 = 60.5 ± 11.6, Cyp1A2 = 69.2 ± 36.6, Cyp2C = 20.4 ± 5.6, Cyp2D = 12.5 ± 5.3, Cyp3A = 10.4 ± 3.3). This translated into higher levels of basal enzyme activity (n=3, Fold changes over static: Cyp1A1 = 11.5 ± 4.9, Cyp2C = 7.5 ± 3.7, Cyp3A = 4.4 ± 0.9) and higher inducibility by 3-methyl cholanthrene and dexamethasone than static cultures (Fold changes over DMSO controls: Cyp1A1 = 66.9 ± 5.1 vs. 25.4 ± 3.2, and Cyp3A = 29.6 ± 1.9 vs. 12.9 ± 0.3). Hepatocytes under hemodynamics responded to classical Cyp inducers like dexamethasone at concentrations that matched plasma concentrations of G/606 rat studies. Efflux transporter proteins, localized along the canalicular membranes, exhibited substrate transport into bile canaliculi. The retention of in vitro like hepatocyte phenotype and metabolic functions coupled with drug response at more physiological concentrations potentially makes this system a more predictive tool for drug metabolism and toxicity.

505 HEPATIC TOXICITY OF VINCOLOZIN IN ADULT MALE RATS.

D. C. Escobar-Wilches1, L. M. Lopez-Gonzalez1, M. G. Moreno2, P. Muriel2 and A. Sierra-Santoyo2. 1Toxicology, Cinvestav-IPN, Mexico City, D.F., Mexico and 2Pharmacology, Cinvestav-IPN, Mexico City, D.F., Mexico.

Vincolozin (V) is a fungicide widely used in plants, fruits and vegetables in United States, Europe and Mexico. The V is a well-characterized antiandrogenic fungicide and it is able to produce effects on the male reproductive system in different species. Little data are currently available regarding possible impacts of V on the liver. The objective of this work was to assess the effect of V on hepatic function. Male adult Wistar rats were administered 100 mg/kg V in corn oil for 7 days by gavage. Non-treated animals received only corn oil. Animals were sacrificed 24 h after last dose. Blood was extracted for analysis of reduced and oxidized glutathione, alanine aminotransferase (ALT) and aspartate aminotransferase (ASAT). The liver was removed and processed to obtain microsomes for the determination of glycogen, reduced and oxidized glutathione, and lipid peroxidation. Significant effect of V on weight of animals was observed. V administration significantly increased the liver weight, this effect was accompanied by an increase by 53% of total cytochrome P450 (CYP) content and a decrease of 35% of glycogen content and both reduced (60%) and oxidized (85%) glutathione. ALT serum activity decreased 19%, whereas both reduced and oxidized glutathione serum levels also decreased 26% and 26%, with respect to the non-treated group. Liver lipid peroxidation and AP were not affected by V. These results suggest that V affects hepatic function mainly the glutathione-dependent antioxidant system, CYP-dependent metabolism of xenobiotics and carbohydrates metabolism. In addition, they indicate that liver is another target organ of this fungicide. Determination of toxicity in organs or systems will provide further insight into the relationship between toxicity and V exposure.

506 A PROVISIONAL REGULATORY NETWORK OF PPARα-MEDIATED TRANSCRIPTION IN PRIMARY HUMAN HEPATOCYTES.

S. Bhattacharya1, 2, G. G. Woods1, K. M. Yarborough1, A. Eftermenko1, Y. Pluta2, P. Eau1, J. Dong1, L. EF and M. E. Anderson1, 2. 1Division of Genetics, Computational Biology, The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 2Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Activation of the PPARα nuclear receptor in liver parenchymal cells results in coordinated events leading to downstream alterations in gene expression: (i) phosphorylation of PPARα in the cytosol; (ii) translocation of PPARα to the nucleus; (iii) heterodimerization with RXRα; (iv) binding of the heterodimer to DNA-response elements (PPREs) in the promoters of target genes; and (v) alterations in binding of co-activators and co-repressors. We used a combination of microarray-based gene expression data, regulatory interactions inferred from protein-DNA transcription factor (TF) arrays and ChIP-on-chip results to develop a comprehensive picture of PPARα-mediated transcriptional regulation in primary human hepatocytes exposed to GW7647 (GW). Cells were treated for up to 72 hours with concentrations of GW between 0.001 and 10 μM. We identified several TFs involved in the regulatory cascade, leading to a clearer picture of the hierarchical organization of the PPARα response network as well as concentration- and time-dependent transitions in the state of the network. A small subset of 183 genes was upregulated by GW in a time- and concentration-dependent manner. Additionally, only a limited number of these genes were direct gene targets of PPARα. The remaining genes were likely regulated by cross-talk at the transcriptional level or by downstream activation of other pathways in the cascade, including ERα, HNF4α, STAT1, ETS1 and Sp1. The inferred response network, in combination with an on-going study with rat hepatocytes, will help guide quantitative computational models of the PPARα pathway. More generally, this approach of network mapping and modeling can lead to more accurate dose-response evaluation of receptor-mediated cellular processes.

507 INHALATION OF LEAD ACETATE AND LIVER DAMAGE: MORPHOFUNCTIONAL STUDY IN A MOUSE MODEL.

E. S. González Rendon1, G. Gutierrez Cano1, A. González-Villalba1, R. Jiménez-Martínez1, V. Rodríguez-Lara1, B. Patricia1, L. Colín-Barenque2 and T. Fortoul1. 1Biología Celular y Tisular, Facultad de Medicina, UNAM, México D. F., Distrito Federal, Mexico and 2Pés-Izalacua, UNAM, CDMx, Edo de México, Mexico.

Lead (Pb) is an element that plays an unknown biological role, and it is highly toxic even in low concentrations. However, the main emission sources of this metal are lead-anti-kick fuels and cigarettes, which are in daily use in society. The main route of exposure to Pb occurs through the respiratory tract. Once in blood, lead is distributed in the body, and 33% is accumulated in the liver. Since this organ is a very active metabolic tissue that stores and biosynthesizes nutrients, the alteration of these activities could be expected after the exposure. We decided to explore the morpho-functional repercussion of inhaled Pb in the liver determined histologically and by determining the serum concentration of alanine aminotransferase (ALT) and aspartate aminotransferase (AST). A group of thirty male mice (CD1 strain) were exposed to (0.1M) lead acetate for one hour twice a week for 4 weeks. The control group inhaled saline, following the same protocol. Inhalation was carried out according to Fortoul et al., (2005). Each week, three animals were sacrificed from each group; the liver was processed for histological evaluation (H & E and Mason). One month after the exposure, a blood sample was drawn for measuring AST and ALT as indicators of liver damage.

An inflammatory infiltrate with neutrophils and lymphocytes was observed since the first week in the exposed mice and the presence of numerous granulomas was notorious in the same group. Masson stain did not show increase in fibrotic tissue. A significant increase in AST was detected.

Our results indicate that inhaled lead induces acute liver damage with unspecified changes. There was only other report with an inhaled metal mixture that reports necrosis and periporal infiltrate (Mani et al., 2007). Pb is still in the air in some cities atmosphere, and the literature is scarce about this topic. Further analysis is needed to evaluate the impact that inhaled Pb has in organs such as the liver.

508 DNA-PROTEIN CROSSLINKING MEDIATED BY DEHYDROMONOCROTALINE IN VITRO.

S. Shen1, 2 and J. Zheng1, 2. 1Center for Developmental Therapeutics, Seattle Children’s Research Institute, Seattle, WA and 2Department of Pediatrics, University of Washington, Seattle, WA.

Pyrrolizidine alkaloids (PAs) occur in a wide variety of plant species and have been identified in over 6,000 plants. Exposures to some PAs can cause massive hepatotoxicity, including hemorrhagic necrosis, hepatic megalocytosis and veno-occlusion, liver cirrhosis, nodular hyperplasia, and hepatic carcinomas. Hepatotoxicity induction by PAs has been suggested to be mediated by cytochrome P450 enzymes, through metabolic activation and reactions of electrophilic pyrrole metabolites. Monocrotaline is one of hepatotoxic PAs. Its reactive metabolite dehydromonocrotaline has been reported to cause DNA modification and protein covalent binding. Since dehydromonocrotaline molecule has two electrophilic centers which can react with nucleophiles, we speculated that the reactive metabolite may induce DNA-protein crosslinking. In the present study, we investigated the DNA-protein crosslinking mediated by dehydromonocrotaline using a plasmid DNA and BSA as model biomolecules. We found the exposure of a mixture of the DNA and BSA to
dehydromonocrotaline caused DNA-protein crosslinking. The degree of the crosslinking was concentration-dependent. In addition, we observed that DNA-protein crosslinking induced by dehydromonocrotaline was protected by the presence of glutathione. We hypothesize that DNA-protein crosslinking may be involved in monocrotaline-induced hepatotoxicity.

**509 LACK OF ORGANIC ANION TRANSPORTING POLYPEPTIDE 1A1 EXACERBATES CHOLESTATIC INJURY IN MICE.**

Y. Zhang1, L. L. Cunak1, J. D. Lehman-McKeeman1 and C. D. Klaassen1
1University of Kansas Medical Center, Kansas City, KS and 2Bristol-Myers Squibb Co., Princeton, NJ.

Organic anion transporting polypeptide 1a1 (Oatp1a1) is predominantly expressed in livers of mice, and is thought to transport BAs from blood into liver. Because Oatp1a1 expression is markedly decreased in livers of bile-duct ligated (BDL) mice, we hypothesized that lack of Oatp1a1 will reduce the hepatic uptake of BAs and thus protect against cholestatic liver injury. To evaluate our hypothesis, we performed BDL surgeries in both WT and Oatp1a1-null mice. Surprisingly, all Oatp1a1-null mice died within four days after BDL, whereas all wild-type (WT) mice survived. Even one day after BDL, Oatp1a1-null mice had higher serum ALT and more severe liver injury than WT mice. Oatp1a1-null BDL mice had higher total BA concentration in livers than WT BDL mice, suggesting that lack of Oatp1a1 does not prevent BA accumulation in liver. Secondary BAs, which are produced by in testicular bacteria, dramatically increased in serum of Oatp1a1-null BDL mice, but not in WT BDL mice. In addition, Oatp1a1-null BDL mice have higher secondary BAs in livers than WT BDL mice. The increased secondary BAs in serum and livers of Oatp1a1-null BDL mice is not due to altered BA transport or BA conjugation in liver, because Oatp1a1-null BDL mice had similar mRNA of basolateral BA-uptake (Ntcp and Oatp1b2) and BA-efflux (Mrp3, Mrp4, and Oatpβ/β) transporters, as well as similar BA-conjugation enzymes (Fap5 and Baat) in livers than WT BDL mice. Transcription factors such as FXR, PXR, PPARα, and Nrfl2 play important roles in the cytoprotective response to cholestasis. One day after BDL, the mRNA expression of SHP, Cyp3a11, Cyp4a14, and Cyp4b1, which are target genes of FXR, PXR, PPARα, and Nrfl2, respectively, were increased in WT mice, but not in Oatp1a1-null mice. In conclusion, Oatp1a1 plays a unique role in the adaptive response to liver injury during obstructive cholestasis, and lack of Oatp1a1 exacerbates cholestatic liver injury in mice. (Supported by NIH grants DK-081461, ES009649, and ES-019487).

**510 BILE ACID REGULATION OF GENE EXPRESSION IN HUMAN PRIMARY HEPATOCYTE CULTURES.**

L. Liu1, H. Liu1, Y. Liu2, L. Lei1, S. C. Stroom2 and C. D. Klaassen1
1Pharmacology and Toxicology, University of Kansas Medical Center, Kansas City, KS and 2Pathology, University of Pittsburgh Medical Center, Pittsburgh, PA.

Bile acids (BAs) are known to regulate their own homeostasis. This study was initiated to examine the effects of cholic acid (CA), chenodeoxycholic acid (CDCA), deoxycholic acid (DCA), lithocholic acid (LCA) and ursodeoxycholic acid (UDCA) on BA-synthetic enzymes and transporters in human primary hepatocyte cultures from 6 donors. Human hepatocyte cultures were obtained from the University of Pittsburgh, through the Liver Tissue Cell Distribution System. Hepatocytes were plated in 12-well collagen-coated dishes, and overlaid with Matrigel in supplemented William’s E media. Following a minimum 48-h recovery period, hepatocytes were treated with the 5 individual BAs with final concentrations of 10, 30, and 100 μM for 48 h. Total RNA was extracted from the hepatocytes with RNAzol Bee reagent, and reverse-transcribed with High Capacity RT kits, and the expression of genes of interest was determined by real-time PCR. All 5 BAs dramatically suppressed CYP7A1, the rate-limiting enzyme in BA synthesis, and dramatically increased the expression of FGF19, a major BA signaling molecule. The nuclear receptor farnesoid X receptor (FXR) and small heterodimer partner (SHP) were also upregulated, but to a lesser extent. The mRNA of the bile salt efflux pump (BSEP), as well as Ostα and Ostβ were significantly increased by BAs, whereas the sodium taurocholate co-transporting polypeptide (NTCP), a major BA uptake transporter, was slightly decreased. Of the 5 BA examined, UDCA was the least effective in producing gene expression changes. Among the 6 hepatocyte donors, marked individual variations in BA-regulated gene expression were noted, but the alterations were similar. In summary, primary human hepatocyte cultures responded similarly to intact mice, indicating similarities in the regulation of BAs in mice and humans (Supported by NIH grants DK-81461 and ES019487).

**511 COMPARISON OF NOVEL LUCIFERIN-1A2 SUBSTRATE AND PHENACETIN FOR MEASURING CYP1A2 INDUCTION IN HUMAN HEPATOCYTES.**

T. Moeller1, D. Ma2, S. Dennel1 and J. Cali1, 2Celsis In Vitro Technologies, Haledon, NJ and 3Promega Corp, Madison, WI. Sponsor: M. Xia.

Induction of drug metabolizing enzymes is one critical component in assessing drug-drug interactions. The process is controlled through drugs binding to receptors which regulate gene transcription. One mechanism entails the aryl hydrocarbon receptor (AhR), a transcription factor responsible for the up-regulation of phase I and phase II enzymes such as CYP1A1/2 and UGT1A1. The most common method to determine a drug’s induction potential through AhR-dependent pathway is to measure the activity of CYP1A2 in hepatocytes using phenacetin as a substrate after exposure to the drug and compare it to the basal rate. The quantification of the metabolism of phenacetin requires bioanalytical methods like UPLC/MS/MS which demands special equipment and expertise. In contrast, the P450-GloTM assay with the luminescence CYP1A2 substrate Luciferin-1A2 (6-methoxybenzo[d]thiazole-2-carbonitrile) is a simple and effective method to measure CYP1A2 activity requiring a plate reader and minimal expertise which will expedite data acquisition and simplify workflow. Herein, we describe the comparison of phenacetin and Luciferin-1A2 substrates for CYP specific and to determine induction of CYP1A2 in human hepatocytes using omeprazole as the inducer. The induction ratios were similar for most of the 16 donors tested for both lytic and non-lytic P450-GloTM Luciferin-1A2 substrate methods as compared to phenacetin with significant correlation found (P value < 0.0001, R2 of 0.7). This new CYP1A2 substrate is an alternative for measuring CYP1A2 activity to traditional probe substrates that require HPLC or MS methods.

**512 ALTERATION OF GENE EXPRESSION OF HEPATIC PHASE 1 ENZYMES INVOLVED IN THE BIOTRANSFORMATION OF PESTICIDES DURING GESTATION IN A MURINE MODEL OF TYPE 1 DIABETES.**

M. C. Forrin1, L. M. Alekseeva2 and J. R. Richardson1, 1Environmental and Occupational Medicine, Environmental and Occupational Health Sciences Institute, Piscataway, NJ and 2Pharmacology and Toxicology, Rutgers University, Piscataway, NJ.

Previous data from our laboratory indicated that pregnancy in mice alters the hepatic expression levels of phase 1 enzymes involved in the biotransformation of numerous pesticides. These naturally-occurring changes may result in a higher susceptibility to neurotoxins and increase the risk of cognitive and behavioral deficits. The goal of the present study was to assess how diabetes and pregnancy interact to modify the level of transcription of phase 1 enzymes. Nulliparous C57BL/6 mice were administered streptozotocin (STZ, 50 mg/kg/day for up to 6 doses, ip) in order to induce the hyperglycemia for at least 2 weeks prior to overnight mating with normoglycemic male mice. Livers were collected from vehicle-treated and STZ-treated, pregnant (GD14) and non-pregnant mice. Total RNA was extracted for QPCR quantification of various cytochrome P450, carboxylesterase (Ces) isoenzymes and nuclear receptors that regulate expression of these enzymes. Three patterns of transcriptional regulation were observed: 1) Pregnancy and STZ treatment significantly decreased (p<0.05) the mRNA expression of Car (≥55%), Ahr (≥25%), Cyp1a2 (≥20%), Peroxodase 1 (Pon1) (≥40%), Ces1d (≥50%), Ces1g (≥20%), Ces3 (≥40%). 2) Pregnancy, but not STZ treatment, reduced levels of Pparγ (≥60%), Cyp2c37 (≥50%), Cyp2c50 (≥75%), Cyp2c54 (≥50%), Cyp3a11 (≥50%), and induced Cyp3a16 (300%), Cyp3a41a/b (100%) and Cyp3a44 (150%). 3) STZ treatment alone induced Ces2c (100%), Ces2e (≥50%) and reduced Ces1c (≥35%). The remaining genes, Pparγ, Cyp3a13, Cyp2b10, Cyp2d22, Ces1e, and Ces2b, were unchanged by either STZ treatment or pregnancy. These findings suggest that diabetes and pregnancy differentially regulate the expression of critical enzymes that detoxify pyrethroid and organophosphate pesticides, which could alter in utero exposure of developing animals. Supported by NIH ES015991, ES050622, DK080774, and ES020522.
transformation and local exposure. Because hepatocyte subcellular fractions are widely used in the hepatic metabolism prediction, subcellular fractions of a reconstructed human skin model (full thickness model of Episkin) were used to test the skin metabolism. This strategy comes within the scope of l’Oreal effort in the development of new in vitro alternative methods to animal testing. In this work, we compared metabolic stabilities (half-life time) of xenobiotics in the presence of cutaneous and hepatic subcellular fractions. Results confirmed that cutaneous subcellular fractions had a lower catalytic activity level than hepatic fractions for numerous compounds but that biotransformations could occur at the skin level for peculiar chemicals. For example, the cutaneous stability of Nicardipine which is a positive control used for probing Cytochrome P450-dependent monoxygenase activities, confirmed that skin is much less equipped of these enzymes than liver. However, a cutaneous specificity could be observed with N-acetylation of p-aminobenzenc acid and N-acetyl-p-phenylenediamine compared with the liver. In conclusion, although skin metabolism towards xenobiotics is weaker than that of the liver, results presented confirmed the interest in studying their cutaneous metabolism because skin can be active in term of metabolism for specific compounds and the site of a first pass effect for such compounds.

514 REGULATION OF HEPATIC CYTOCHROME P450 BY VINCLOZOLIN IN PREGNANT RATS.

G. F Garcia-Montes de Oca, L. M. Lopez-Gonzalez and A. Sierra-Santoyo. Toxicology, Cinvestav-IPN, Mexico City, D.F., Mexico.

Vinclozolin (V) is a systemic fungicide used for agricultural settings. V is non-enzymatically hydrolyzed to M1 and M2 metabolites, as well it is efficiently metabolized in male rats to several products by cytochrome P450 (CYP) 2A, 2B and 3A subfamilies. There is no available information about the effect of V on liver CYP regulation in rats during pregnancy. V exposure affects the male reproductive system during gestational morphogenesis, sexual maturation and fertility. V, M1 and M2 have antiandrogenic properties by inhibiting competitively the androgen receptor. The objective of this study was to determine the effect of V exposure on the hepatic CYP regulation during pregnancy. Pregnant Wistar rats were administered 150 mg/kg/d V in corn oil from gestational days 14 to 21 by gavage. Animals were sacrificed two hours after last dose. The liver was removed and processed to obtain microsomes to determine the protein content of different CYP isofoms and their enzyme activities. V exposure significantly increased maternal liver relative weight but did not affect liver total CYP content. V-induced protein content of CYP1A1 (8.3-fold), 2B1 (11.7-fold) and 1A2 (10.2-fold), while a decrease of 80% of CYP3A2 activity, confirmed that skin is much less equipped of these enzymes than liver. These results suggest that V may modulate hepatic CYP expression at different periods. Prediction of their chronic toxic effects and risk evaluation for health represent a major challenge. The well-differentiated HepaRG cell line is thought to be a poten in vitro surrogate to investigate human hepatic effects of chronic exposure to toxicants. HepaRG cells, composed of both hepatocyte-like and biliary-like cells, present most of the metabolic performances of primary hepatocytes up to 4 weeks. In this study, we adapted the classical culture conditions of HepaRG cells in order to be closer to the permanent aggression of the human liver by contaminant agents. Cytotoxicity was evaluated using the MTT test after daily exposure for 1 or 2 weeks of the hepatocyte-like population to low doses of about 10 chemicals, including the mycotoxin aflatoxin B1, polycyclic aromatic hydrocarbons, plasticizers, pesticides and flame retardants. We first checked the stability of the differentiated HepaRG hepatocytes over this period using several genes, including CYP3A4, CYP2B6 and aldolase B, as markers of differentiation. mRNA expressions remained stable during the two weeks as did CYP3A4 protein level and activity. Moreover, the 24 h acute toxicity of each compound was similar when tested at the beginning or at the end of the 2 week-period, indicating that HepaRG hepatocytes kept all their metabolic functions. Chronic studies showed cumulative cytotoxic effects of most of the tested compounds with decreasing IC50 between 24 h and 7 days. Prolonging the treatment up to 14 days kept on lowering significantly IC50 of endosulfan (120, 60, 18 μM) and aflatoxin B1 (1.8, 0.4, 0.15 μM) both metabolized by CYP3A4, of benzo[a]pyrene (350, 10, 7 μM) and dimethylbenzanthracene (300, 18, 6 μM) metabolized by CYP1A1 and 1B, and to a lesser extent those of bisphenol A (105, 85, 77 μM), di(2-ethylhexyl) phthalate (300, 85, 60 μM) and tetrabromo bisphenol A (68, 37, 25 μM). Our results validate the hepatocyte-like cells as a suitable experimental model allowing toxicity evaluation of low doses after long-term exposure.

515 COMPARATIVE ASSESSMENT OF AUTOMATED ANALYSIS USING COMPUTER ASSISTED PATHOLOGY (CAPSTM) HISTOPATH™ SOFTWARE.

A proof of concept (POC) study was performed to assess the ability of CAPSTM (Computer Assisted Pathology System) HistoPath™ software to: 1) differentiate normal/non-normal in hepatocytes as a gold standard, and 2) interpret the hepatocyte-like cells as a suitable tool for assessing the severity of the change. Five groups (1 control / 4 treated groups) of 6 rats per group were used in the assessment. An additional 23 rats were used as historical controls. Slides were scanned (Aperio XT ScanScope) and resultant images analyzed using Histopath™ version 1.0.1. Slides were also independently analyzed by 3 Charles River pathologists (PT). CAPSTM normal/non-normal designations (83%) and non-normal reasons (86%) were similar to the PT rating, 77% to 93% and 71% to 100%, respectively. CAPSTM severity grade (rankings) were Mitotic Figures (MF) 100%, Vesculation (VES) 100%, Disrupted Tissue (DT) 97%.

516 CHRONIC TOXICITY OF ENVIRONMENTAL CONTAMINANTS IN HUMAN HEPAR HEPATOCYTES.

Humans are continuously exposed to low doses of contaminants for prolonged periods. Prediction of their chronic toxic effects and risk evaluation for health represent a major challenge. The well-differentiated HepaRG cell line is thought to be a potent in vitro surrogate to investigate human hepatic effects of chronic exposure to toxicants. HepaRG cells, composed of both hepatocyte-like and biliary-like cells, present most of the metabolic performances of primary hepatocytes up to 4 weeks. In this study, we adapted the classical culture conditions of HepaRG cells in order to be closer to the permanent aggression of the human liver by contaminant agents. Cytotoxicity was evaluated using the MTT test after daily exposure for 1 or 2 weeks of the hepatocyte-like population to low doses of about 10 chemicals, including the mycotoxin aflatoxin B1, polycyclic aromatic hydrocarbons, plasticizers, pesticides and flame retardants. We first checked the stability of the differentiated HepaRG hepatocytes over this period using several genes, including CYP3A4, CYP2B6 and aldolase B, as markers of differentiation. mRNA expressions remained stable during the two weeks as did CYP3A4 protein level and activity. Moreover, the 24 h acute toxicity of each compound was similar when tested at the beginning or at the end of the 2 week-period, indicating that HepaRG hepatocytes kept all their metabolic functions. Chronic studies showed cumulative cytotoxic effects of most of the tested compounds with decreasing IC50 between 24 h and 7 days. Prolonging the treatment up to 14 days kept on lowering significantly IC50 of endosulfan (120, 60, 18 μM) and aflatoxin B1 (1.8, 0.4, 0.15 μM) both metabolized by CYP3A4, of benzo[a]pyrene (350, 10, 7 μM) and dimethylbenzanthracene (300, 18, 6 μM) metabolized by CYP1A1 and 1B, and to a lesser extent those of bisphenol A (105, 85, 77 μM), di(2-ethylhexyl) phthalate (300, 85, 60 μM) and tetrabromo bisphenol A (68, 37, 25 μM). Our results validate the hepatocyte-like cells as a suitable experimental model allowing toxicity evaluation of low doses after long-term exposure.

517 CYCLOSPORINE A AND PALMITATE TREATMENT SYNERGISTICALLY INDUCE CYTOTOXICITY IN HEPG2 CELLS.

Y. Luo, P. M. Rana and Y. Will. Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT.

The immunosuppressive compound Cyclosporin A (CsA) has been used for treating autoimmune diseases and in organ transplantation. However, severe side effects, such as nephrotoxicity, cardiotoxicity and hepatotoxicity have been attributed to CsA treatment. Cardiac and renal transplantation is often associated with the development of hyperlipidemia and obesity, probably due to immunosuppressive therapy. Elevated levels of free fatty acids have been linked to the etiology of metabolic syndrome, nonalcoholic fatty liver and steatohepatitis. The contribution of free fatty acids to CsA-induced toxicity is not clear. In this study we explored the effect of palmitate on CsA-induced toxicity in HepG2 cells. CsA induced little cytotoxicity in HepG2 cells as measured by ATP depletion and LDH release. Co-treatment with palmitate and CsA result in marked increase in cytotoxicity, and the responses are CsA and palmitate dose-dependent. Palmitate and CsA treatment also lead to synergistic induction of caspase-3 activity, suggesting that induction of apoptosis may contribute to the cytotoxicity. At sub-lethal dose, CsA reduced mitochondrial respiration, which is further exacerbated by the presence of palmitate. Inhibition of c-Jun N-terminal kinases (JNK) activity attenuated palmitate and CsA induced cell death, suggesting that JNK activation plays an important role in mediating palmitate/CsA toxicity. This novel finding of the synergized cytotoxicity induced by palmitate and CsA suggest that patients with underlying diseases that elevate free fatty acids may be predisposed to CsA-induced toxicity. Furthermore, hyperlipidemia/obesity resulting from immunosuppressive therapy may aggravate CsA-induced toxicity and worsen the outcome in transplant patients.
518 COMPARISON OF RAT AND DOG HEPATOCYTE-KUPFFER CELL COCULTURES AS A MODEL OF DRUG-INDUCED HEPATIC MICROGRANULOMA.

F. Boes2, R. Kemper1, S. Kustermann2, T. Zabka1, C. Lawson1, T. Singer2, A. B. Roth1, K. L. Kolaja1, T. Weiser1, Nonclinical Safety, Hoffmann-LaRoche, Nutley, NJ and 2Nonclinical Safety, Hoffmann-LaRoche, Basel, Switzerland.

During the conduct of routine safety studies, kupffer cell hypertrophy and subsequent microgranulomona formation occurred in dog liver after single and repeat oral administration within a series of drug candidates. The finding was not associated with parenchymal hepatocellular injury, was not monitorable by routine clinical pathology, and was not observed in repeat dose rat studies. The histopathology suggested a foreign body-type response to indigestible PAs+ material of which a component was likely test article. A primary hepatocyte/nonparenchymal cell coculture system of rat and dog was established to provide mechanistic insight and investigate the species-specificity of this finding, as well as to develop a model screening tool for potential back-up molecules. There was no difference between species in cellular toxicity in hepatocyte single culture or coculture systems. Uptake, however, of radio-labelled drug into either hepatocytes or nonparenchymal cells from rat and dog demonstrated pronounced hepatocellular uptake in rats and conversely, preferential uptake by nonparenchymal cells in dogs. This observation may explain the observed species-specific in vivo finding. Additionally, the system was used to evaluate the response to compounds in the series that did not have this finding in dog or rat, which further supported the hypothesis that increased uptake by nonparenchymal cells is a risk factor for microgranuloma formation. The presented approach demonstrates the utility of in vitro systems to understand and potentially de-risk, in vivo safety findings, as well as to provide a screening paradigm that will reduce animal use.

519 COMPARISON OF TWO CELL MODEL SYSTEMS, PRIMARY HUMAN HEPATOCYTES AND HIpsc-DERIVED HEPATOCYTES TO DETERMINE THE HEPATOTOXICITY OF THREE CANDIDATE DRUGS DEVELOPED FOR RHEUMATOID ARTHRITIS.

S. Kameoko1, T. Zabka1, Y. Ott1, T. Singer1, T. Weiser1, K. L. Kolaja1, E. Chti1, Nonclinical Safety, Hoffmann-LaRoche, Nutley, NJ; 2Cellular Dynamics International, Madison, WI and 3Nonclinical Safety, Hoffmann-LaRoche, Basel, Switzerland.

In vitro hepatocyte culture serves as a very useful model system to detect potential hepatotoxicity without sacrificing animals. However, current in vitro model systems have limitations. Primary human hepatocytes (PHH) are known to exhibit donor-specific phenotypic variability and availability is too limited for high throughput assay. Immortalized hepatoma cell lines, such as HepG2 and HepaRG, offer more reproducible and homogenous culture systems, but interpreting the toxicant sensitivity in cells of tumor origin poses a considerable problem. Using human induced pluripotent stem cell (hiPSC)-derived hepatocytes is an important new tool which offers unlimited supply of euploid cells from single donors. Here, we tested the hepatotoxicity of three internal candidate drugs developed for the treatment of rheumatoid arthritis. In vivo, two of these compounds induced canine liver toxicity, while one compound showed no toxicity. This toxicological profile of three compounds is recapitulated in vitro, both in cultures of PHH and the hiPSC-derived hepatocytes. IC50 values of the three compounds were determined by 24 hour ATP assay (>50, 20, 14μM by PHH; >50, 24, 13μM by iPSc-derived HC) to be nearly identical. This pilot study shows that despite some difference in metabolism (cytochrome P450 and Phase II enzyme levels) between PHH and hiPSC-derived hepatocytes, stem-cell-derived hepatocytes may provide an invaluable model system for preclinical drug safety study and disease modeling.

520 URINARY BIOMARKERS DETECT RENAL DAMAGE IN HYPERTENSIVE AND OBSESE RATS.

Q. Zhang1, K. J. Davis2, D. Hoffmann1, V. S. Vaidya2, R. P. Brown1 and P. L. Greening1, 1CDRH, US FDA, Silver Spring, MD; 2NCTR, US FDA, Jefferson, AR and 3Harvard Medical School, Boston, MA.

Hypertension and obesity are major risk factors for the development of kidney disease. Sensitive biomarkers are needed to detect renal damage at the earliest stages. The objective of this study was to determine if a suite of acute kidney injury biomarkers can be used to track the progression of nephropathy in an animal model of hypertension and obesity. Male spontaneously hypertensive obese (SHROB) and lean SHR (SHR-lean) rats were used to track the progression of kidney damage from 18 to 39 weeks of age. Body weight, blood pressure, and urinary biomarkers (albumin, NAG, Kim-1, NGAL, osteopontin, GST-π, fibrinogen and clusterin) were assessed at 3-week intervals. Weight gain was much greater in SHROB rats than in SHR-lean rats. Systolic and diastolic blood pressures were elevated throughout the study in both SHROB and SHR-lean rats with no significant difference observed between the two groups. Blood creatinine, BUN and plasma cholesterol and triglyceride levels were significantly increased in SHROB rats compared to SHR-lean rats at the end of study. The severity of renal lesions involving tubules, interstitium and glomeruli was graded on a scale of 0 to 5 (0=normal histology, 2=1-25%, 3=26-50%, 4=51-75%, and ≥76-100% of tissue affected). SHROB rats showed a higher overall chronic nephropathy score (4.9) than SHR-lean rats (3.9). Urinary albumin and fibrinogen were elevated at week 30 and remained elevated through week 36 in SHROB rats; however, an increase in albumin was not observed until week 36 in SHR-lean rats. Urinary NAG, clusterin and osteopontin levels were elevated at week 36 in SHROB rats only. There were no increases observed throughout the study in urinary levels of Kim-1, NGAL, RPA-1, GST-π and GST-Yb1 in both strains. In conclusion, urinary biomarkers such as albumin, fibrinogen, NAG, clusterin, and osteopontin, may be useful as tools to track the progression of chronic kidney injury associated with hypertension and obesity. (Funded in part by a FDA Office of Chief Scientist Challenge Grant).

521 AGE-DEPENDENT VARIATIONS IN BASELINE SERUM CARDIAC TROPONIN I LEVELS: A CROSS-SPECIES COMPARISON.

A. Knapton1, E. T. Rosen1, M. C. Poitier2, Y. Liu1, S. E. Lipshtz1, J. Todd1, A. Lu1, J. Estis1, J. Zhang1 and E. H. Herman1, 1FDA, Silver Spring, MD, 2NCl, NIH, Bethesda, MD; University of Miami Miller School of Medicine, Miami, FL and 3Singulex, Inc., Alameda, CA.

Changes in the serum levels of cardiac troponin I (cTnI) are used as a specific indication of myocardial injury. Recently, factors such as strain, sex and arterial pressure have been found to affect baseline levels of cTnI in rats. The current study utilized the ultrasensitive Erenna immunoassay to determine whether animal age might also influence cTnI concentrations. Blood samples were collected from Sprague Dawley rats at 10 (n=5), 25 (n=7), 40 (n=11) and 80 (n=10) days of age. Blood was also obtained from Patas monkeys at birth (n=2), at two months (n=1) and one year of age (n=1). Samples of fetal and adult equine, porcine and bovine serum were also analyzed. The mean (±SD) concentrations of cTnI were 37.7±10.14±4.9, 7.3±4.8 and 5.8±3.1 pg/ml for 10, 25, 40 and 80-day-old rats, respectively. Examination of 10 day old rat hearts showed features such as hypercellularity and irregularly-sized nuclei with a moderate number of myocytes undergoing mitosis and apoptosis that were not apparent in the myocytes of 80-day rat hearts. The cTnI concentration in 2 monkeys at birth were 177 and 725 pg/ml compared to 8.29 pg/ml in the one year-old monkey. The levels of cTnI detected in fetal equine and porcine serum were considerably higher than those found in adult equine and porcine serum samples. Likewise, the levels of cTnI in fetal bovine serum were extremely high (>2,000 pg/ml) compared to adult caprine and laprine serum (2.9-2.7 pg/ml). These results indicate that levels of cTnI vary with higher cTnI with higher cTnI with higher C on and lower C on with lower C on, which could affect use and interpretation of cTnI in certain types of species. The age-related differences appear to be consistent across animal species.

522 TRANSCRIPTOME AND METABOLOME ANALYSIS REVEALS MECHANISM-LINKED BIOMARKER CANDIDATES IN CARBON TETRACHLORIDE-INDUCED HEPATOTOXICITY.

Y. Ando1,2, J. Sun1, L. K. Schnackenberg3, X. Yang3, J. Greenhaw1, L. M. Pence1, T. C. Schmitt2, S. Bhattacharyya2, W. F. Salmenen1, D. L. Mendrick1 and R. D. Beger1, 1Division of Systems Biology, National Center for Toxicological Research, Jefferson, AR and 2Medicinal Safety Research Laboratory, Daiichi Sankyo Co., Ltd., Tokyo, Japan.

Transcriptome and metabolome analyses were adopted to investigate the mechanisms underlying hepatotoxicity induced by carbon tetrachloride (CCH4), a highly toxic chemical agent used to elicit experimental liver damage. CCH4 (50 or 2000 mg/kg) or vehicle (corn oil) was administered to 8 to 9-week-old male rats (15 animals per dose group) via oral gavage. Some animals received a single dose and were sacrificed 6 and 24h after that single dose. Remaining animals received a total of 3 once daily doses and were sacrificed 24h after the 3rd dose. Five animals per group were euthanized via carbon dioxide hypoxia and immediately necropsied. Serum and urine samples were collected at each time point. NMR, LC/MS, LC/MS/MS, and GC/MS were utilized for metabolome analysis of the serum and
urine, and DNA microarrays were used for transcriptome analysis of liver tissue. Pathway analysis data revealed increased hepatic oxidative stress, increased bile acid secretion, a shift of energy metabolism from fatty acid beta-oxidation to glycolysis, and the microarray results showed increased progression of hepatic synthesis of triglycerides and cholesterol ester following the high dose. These results were consistent with histopathological indices in the liver of high dose animals such as necrosis and lipid accumulation, which were observed as early as 6 h. In addition, a decrease in serum arginine and urine 2-oxoarginine had a statistically significant correlation with serum alanine aminotransferase activity at 24h. Thus, an integrated analysis of transcriptome and metabolome profiles may provide a better understanding of the mechanisms and provide mechanistic-linked biomarker candidates of liver injury.

**523 ACUTE KIDNEY INJURY AND AGING INFLUENCE DIAGNOSTIC VALUE OF URINARY BIOMARKER-TO-CREATININE RATIO IN RATS.**

Y. Tomonura1, T. Uehara1, E. Yamamoto1, M. Torii1 and M. Matsubara2, 1Drug Developmental Research Laboratories, Shionogi & Co., Ltd., Toyonaka, Osaka, Japan and 2Division of Molecular Medicine, Tohoku University School of Medicine, Sendai, Miyagi, Japan. Sponsor: K. Nakamura.

 Recent research has revealed several useful urinary biomarkers of acute kidney injury (AKI). For adequate evaluation of altered urinary biomarkers, it is necessary to consider the influence of varied urine flow rate (UFR). Calculation of the excretion rate of a urinary biomarker (UFR-correction) is a gold standard for the correction. An alternative method is to calculate the urinary biomarker-to-creatinine ratio (Ucr-correction). To date, the correlation between correction values has been examined only in steady state such as chronic kidney disease, and the urinary biomarkers examined have been limited to proteinuria and albuminuria. The purposes of this study were to investigate the influence of AKI on Ucr-correction values of various urinary biomarkers, the influence of aging on Ucr-correction, and the backgrounds underlying the relationship between the two correction values. AKI was induced by cisplatin, gentamicin, carboplatin, bomoethymol, cyclosporin A, doxorubicin or puromycin aminonucleoside in rats. Comprehensive measurement of ten urinary biomarkers revealed larger amplitude increases in Ucr-correction values compared to UFR-correction values in AKI. Moreover, Ucr-correction showed higher diagnostic power than UFR-correction in receiver operating characteristic curve. We further observed a decrease in Ucr excretion in AKI accompanied by reductions in creatinine clearance (Ccrt) and mRNA expression of the renal organic cation transporter-2 known as a transporter for creatinine. Regarding aging, UFR-correction values were constant while Ucr-correction values showed age-dependent decreases, which were accompanied by decreases in Ucr excretion and Ccrt. In conclusion, Ucr-correction could over- or under-estimate the renal condition in AKI and aging. Thus, we should take into consideration of these backgrounds when using Ucr-correction.

**524 PROTEIN BIOMARKER PROFILES DISCRIMINATE BETWEEN SENSITIZING AND IRRITATING CHEMICALS IN CELL-BASED ASSAYS.**

P. Budde1, S. Selzer1, S. Koncarevic2, E. Schofield1, K. Kuhn1, H. Johansson3, M. Lindstedt1, C. A. Borchert1, H. Zuch1 and E. Roepstorff1. 1Proteome Sciences RPD GmbH & Co. KG, Frankfurt am Main, Germany, 2Proteme Sciences plc, Cobham, United Kingdom, 3Department of Immunotechnology, Lund University, Lund, Sweden and 3R&D Management and Consultancy, Kgs. Lyngby, Denmark.

Introduction: Common environmental and industrial small molecular weight chemicals can cause allergic contact dermatitis. Current safety testing relies upon animal testing which will shortly be banned by the European Union and so alternative in vitro tests are urgently needed. In this study, we investigated whether protein expression signatures in MUTZ3 as a surrogate dendritic cell model can be used as biomarker read-outs to discriminate between chemical sensitizers and irritants.

Materials and Methods: MUTZ3 cells were exposed for 24 h to a set of training chemicals comprising 2 respiratory, 5 contact sensitizers, 3 non-sensitizers and vehicle controls. Cell extracts and cell culture medium were collected for proteomics analysis. Protein expression profiling was performed with isobaric tandem mass tag (TMT®) labelling for relative and absolute mass spectrometric quantitation.

Results: Using univariate statistics and linear prediction models (partial least square regression, PLS) we have developed a protein signature for testing contact and respiratory sensitizers comprising 130 proteins that are involved in inflammatory and stress response pathways. A subset of these proteins can be measured in cell culture medium by standard immunoassays (ELISA), and could be combined to a multi-marker panel with established protein markers. To verify the protein signature we currently developed multiplexed SRM (selected reaction monitoring) mass spectrometric assays which allow analyzing the 10 best performing biomarkers in one measurement.

Conclusions: Since a multi-marker panel allows measuring a combination of biomarkers it could provide additional information on pathways triggered by unknown chemicals.

**525 QUANTITATIVE ASSESSMENT OF ACETYL-CARNITINE EFFECTS ON ANESTHETIC-INDUCED NEURONAL DEATH BY MICROPET/CT IMAGING.**

X. Zhang1, G. D. Newport2, M. G. Paule3, E. Liu4, S. Liu1, M. S. Bertridge2, S. M. Apaana2, W. Slukkier1 and C. Wang2. 1NTUx, NCTR/FDA, Jefferson, AR and 23D Imaging, LLC, Little Rock, AR.

Recent reports indicate that combined administration of ISO and N2O triggers neuronal apoptosis in postnatal day (PND) 7 rats. Because high-resolution positron emission tomography (microPET) can provide in vivo molecular imaging at sufficient resolution to resolve neuronal activities in the rat brain, it has been proposed as a minimally invasive method for detecting apoptosis in the brain using the tracer [18F]-labeled DFNSH. In this study, the effect of ISO and N2O on the uptake and retention of [18F]-DFNSH in the brains of different aged rats and the potential protective effect of acetyl-l-carnitine (ALC) on anesthetic-induced neuronal cell death were investigated using microPET/CT imaging. On PND 7, rats pups in the experimental group were exposed to a mixture of 70% N2O/30% oxygen and 1% ISO for 8 hours with or without ALC and control rat pups were exposed to room air only. On PNDs 14, 21 and 28, [18F]-DFNSH (18.5 MBq) was injected i.p. and thirty minutes later microPET/CT images were obtained over 90 minutes. Radiolabeled tracer accumulation in a region of interest in the frontal cortex was correlated with standard uptake values (SUVs). In PND 14 rats the uptake of [18F]-DFNSH was significantly increased in gaseous anesthetically-treated rats. Additionally, the duration of tracer wash-out was prolonged in the gaseous anesthetic-treated animals. The uptake of the tracer was attenuated in brains of rats when they have been treated with ALC (100 mg/kg). No significant difference was found in radiotracer uptake in the frontal cortex of the brains of PND 21 and 28 rats compared with same aged controls. This result, which is consistent with our previous TUNEL studies, demonstrates that enhanced apoptotic effects are apparent during early developmental stages (PND 7-14) and that no significant neuronal apoptosis occurs on or after PND 21. Acetyl-l-carnitine effectively blocks the neuronal apoptosis caused by inhalation anesthetics in the developing rat brain.

**526 METABOLIC ANALYSIS OF ARGinine METABOLISM IN RAT PLASMA FOR AN INDICATOR OF HEPATIC INJURY.**

To clarify the relationship between arginine metabolism and hepatic injury, metabolic profile involved in arginine metabolism were investigated by metabolomic analysis in the rat hepatic injury models by monocrotaline (MCT), concanavalin A (ConA), and t-naptophyl isothiocyanate (ANIT), or the non-hepatic injury model by tetramethyl-p-phenylenediamine (TMPD). Male F344 rats were treated with a single dose of MCT (0, 30, 100 or 300 mg/kg, p.o.), ConA (0, 3, 20 or 30 mg/kg, i.v.), ANIT (0, 25, 50 or 100 mg/kg, p.o.) or TMPD (0, 3 or 9 mg/kg, p.o.), and plasma, serum or liver samples were obtained at several time points for metabolomic analysis by liquid chromatography-mass spectrometry and gas chromatography-mass spectrometry, blood chemistry or histopathology, respectively. MCT, ConA and ANIT induced hepatocellular necrosis accompanied by increased plasma arginine and decreased plasma arginine levels in dose- and time-dependent manner, but TMPD treatment did not induce hepatic injury or changes in arginine levels even though ALT elevation was noted. A close correlation (r = -0.74 to -0.80, N = 60) between increased ALT and decreased plasma arginine was observed in line with decreased arginine levels in the arginine metabolic pathway. A subset of these proteins can be measured in cell culture medium by standard immunoassays (ELISA), and could be combined to a multi-marker panel with established protein markers. To verify the protein signature we currently developed multiplexed SRM (selected reaction monitoring) mass spectrometric assays which allow analyzing the 10 best performing biomarkers in one measurement.

Conclusions: Since a multi-marker panel allows measuring a combination of biomarkers it could provide additional information on pathways triggered by unknown chemicals.
plasma showed a high activity of arginase. These results indicate that arginine metabolism, particularly arginine to ornithine pathway is mainly involved in the cyclo- pound-induced hepatic injury, and plasma arginine and ornithine would be specific indicators for hepatic injury.

Acetaminophen (APAP) overdose is the foremost cause of acute liver failure in the West. The drug is metabolized to the electrophile N-acetyl-p-benzoquinone imine (NAPQI), which binds and depletes glutathione (GSH). The initiating event in the mechanism of injury is binding of NAPQI to proteins. Early studies found that loss of 70% of baseline GSH was necessary for protein binding and this has become a paradigm in electrophile-protein adduct toxicity. Based on this, it has been suggested that APAP-protein adducts could be measured clinically as a novel serum biomarker to confirm or exclude APAP as cause of liver injury when etiology is unknown. However, more recent data from therapeutic doses in humans have challenged that idea (Heard et al. BMC Gastroenterol. 2011). To study this in more detail, we treated mice with different doses of APAP and measured plasma enzymes, histology, liver GSH, and liver and plasma adducts between 0.5 and 24h. At toxic doses (150-600 mg/kg), liver GSH was rapidly depleted (0.3 ± 0.1, umol/g liver 0.5h after 300 mg/kg vs. 4.1 ± 0.2). As expected, increased liver adducts paralleled GSH loss. Interestingly, plasma adducts were easily detected in these mice within 0.5h of treatment and peaked at 3h (9,568 ± 1,399 ng/mL after 300 mg/kg), before the onset of necrosis. At a subtoxic dose (75 mg/kg), GSH levels were depleted (0.6 ± 0.1 umol/g at 0.5h vs. 4.5 ± 0.2 in controls) but quickly recovered. Importantly, plasma adducts were detected (95 ± 28 ng/mL at 0.5h) without enzyme release at any time point. Finally, while a therapeutic dose (15 mg/kg) caused only a minor decrease in GSH, liver adducts were readily detectable. Conclusion: Contrary to early reports, GSH depletion is not required for APAP-protein binding. Moreover, protein adducts were detectable in mouse plasma at non-toxic doses of APAP. Caution should be used in interpretation of plasma adducts as a biomarker of APAP overdose.

MicroRNAs (miRs) are short 20-22 nucleotide RNA molecules that are involved in the fine tuning of gene expression at the translational level. Numerous miRs are expressed in a tissue/organ specific manner and thus there has been considerable interest in miRs as specific biomarkers for organ toxicity. Liver specific/enriched miR-122 has been shown to increase in the serum of rats by thousands of fold when treated with acetaminophen. In an attempt to verify and potentially discover novel miRs associated with liver toxicity we conducted a serum miR profiling experiment using rats treated with thioacetamide (results in hepatocellular necrosis), alyl alcohol (results in hepato-cellular necrosis and biliary effects including bile duct hyperplasia (BDH)) or alpha naphthylisothiocyanate (ANIT) which results in BDH). Bile duct hyperplasia can be difficult to detect in 4 day rat studies and identification of a biomarker for BDH could help identify compounds associated with this liability. Serum miR profiling was conducted using TLA cards and two independent statistical analyses of the data were conducted. miRs increased in the serum were compared against specific pathology findings (BDH vs necrosis) and confirmed by single Taqman assays. Data analysis indicated that several miRs were increased in the serum of ANIT treated rats, but of these, only miR-34c was detected in the liver tissue (as well as brain and testes). Serum of rats treated with other BDH inducing compounds were examined for increases in miR-34c but, no consistent correlation between BDH and increases of miR-34c could be established. Analysis of our data indicates that liver specific/enriched miRs-122 and -193 were increased in the serum of rats in a dose dependent manner where hepatocellular necrosis was noted. Candidate miRs for other pathologies including cardiac (miR-499), testicular/brain (384-5p) and intestinal damage (miR-194) were identified, but require additional validation.

Urinary renal biomarkers (URB) are important new tools with which to monitor diagnosis, progression and recovery of drug-induced acute kidney injury (AKI). Drug-induced crystalluria is a problematic toxicity for which URMs could provide valuable translational tools to monitor compound safety in clinical development. This study investigated the URB profile associated with onset and development of crystalluria-induced AKI. Ethylene glycol (EG) is a well characterized nephrotoxicant resulting from formation and accumulation of calcium oxalate crystals in proximal tubules leading to AKI, and co-treatment with aluminum citrate (AC) can mitigate EG nephrotoxicity. Male Wistar rats (n=6/group) received (po) water (10 ml/kg; controls), EG (6 g/kg), or EG + AC (0.2 mmol/kg) and were placed in metabolic cages. Urine was collected at 12 h intervals for 72 h and analyzed for 8 renal biomarkers: cGST, GSTYb1, renal papillary antigen (RPA), clusterin, alubimin, lipocalin, osteopontin and KIM-1. Both GST isoforms were transiently increased at 12 h in EG and EG + AC-liver citrate treated rats indicative of an early non-segment specific injury. Clusterin, lipocalin and KIM-1, all markers for proximal tubule injury, were increasing in EG-treated rats compared to controls between 36 and 48 h and these increases were attenuated by treatment with AC. RPA was increased in both EG and EG + AC-treated animals compared to controls starting at 48 h and is likely due to the sheer stress of crystals passing through the distal portion of the nephron at the later timepoints. This study shows that calcium oxalate crystalluria resulting from EG treatment produces a unique toxicodynamic renal biomarker profile with dimensions of both treatment and time, and offers potential as a surrogate for repeated histologic monitoring to detect transient changes in progression of acute kidney injury.
Neutrophil gelatinase-associated lipocalin (NGAL) is a 178 amino acid protein secreted from specific granules of activated neutrophils. Its synthesis is also induced in epithelial cells during inflammation. Serum NGAL has been reported to be a useful biomarker for detection of inflammation and tissue damage, including kidney injury. Tissue inhibitor of metalloproteinase 1 (TIMP-1) is another marker of inflammation as an inhibitor of the metalloproteinases (MMPs). TIMP-1 is a 194 amino acid secreted glycoprotein that is widely expressed in many cells such as fibroblasts, endothelial cells, vascular smooth muscle cells and monocytes. The release of TIMP-1 is considered to be a modulator of an inflammatory response (anti-inflammatory). TIMP-1 has been proposed as a biomarker for many tissue injuries, including kidney and vascular toxicity. In rodent studies, NGAL and TIMP-1 have been employed as safety biomarkers to assess toxicological risk in the early stages of drug development. Their use has, however, been limited by the volume requirements for current single-plex assays combined with a loss of analyte sensitivity in multi-plex formats. We have identified an immunoassay platform that can provide sensitivity with microliter quantities of sample for quantitation of serum NGAL and TIMP-1 concentrations. The Gyros® immunoassay platform facilitated rapid development of assays with broad dynamic ranges, good sensitivity at low mini-plex and TIMP-1 serum samples may become valuable tools for monitoring development of assays with broad dynamic ranges, good sensitivity at low mini-plex and TIMP-1 concentrations. The Gyros® immunoassay platform facilitated rapid development of assays with high resolution accuracy and sensitivity to low minimum required dilutions, and tight precision. The Gyros assays developed for rat NGAL and TIMP-1 serum samples may become valuable tools for monitoring drug toxicity and safety assessments in the preclinical setting.

BMP particularly the 44:12 (22:6/22:8) lipid moiety is suggested to be a urinary biomarker of phospholipidosis (PLD). The purpose of this work was to characterize lysosomal phospholipid composition, with emphasis on phosphatidyglycerol (PG) and BMPs, in fluoxetine-induced PLD. Alveolar macrophages were isolated from male rats dosed with fluoxetine (30 mg/kg; 3 days), and lipids from isolated lysosomes were analyzed by high resolution accurate mass LCMS. PGs were more abundant than BMPs in control rat lysosomes, with PG (32:0) the predominant species (normalized value of 911 units/mg protein). The most abundant BMP (40:8) had a normalized value of 13, whereas BMP 44:12 was 1.6. In fluoxetine treated rats, all PGs and BMPs increased 1.7 to 5-fold in lysosomes. PG (32:0) remained most abundant, increasing 1.7-fold. BMP (40:8) increased 3.3-fold, whereas BMP (44:12) increased 1.9-fold. Lysosomal phosphatidylincholines (PCs) also increased 2-5 fold after fluoxetine treatment. In urine, BMP (44:12) was most abundant, increasing 3-fold with fluoxetine treatment, whereas BMP (40:8) increased approximately 10-fold. Excretion of other BMPs (38:6, 36:4, 42:8 and 40:6) increased 20 to 50-fold with early PLD. In contrast, urinary excretion of PCs was unchanged at 3 days. These results demonstrate that numerous BMPs increase in both urine and the subcellular target site for PLD (lysosomes), and suggest that BMPs other than or in addition to 44:12 may be candidate biomarkers of PLD.

Drug-induced kidney injury (DIKI) accounts for 25% of incidences of acute renal failure, and approximately 5% of failures of new drugs. The predictive safety testing consortium (PSTC) has been developing a set of urinary biomarkers and examining their utility as preclinical biomarkers of DIKI. These protein biomarkers demonstrate improved sensitivity over clinical standard-of-care biomarkers serum creatinine (SCr) and blood urea nitrogen (BUN) in the detection and monitoring of DIKI progression. An important feature of any biomarker of DIKI, however, is the ability to distinguish drugs that cause injury from those that impact kidney function without inducing injury. To determine whether this new generation of DIKI biomarkers is sensitive to altered renal function, we treated Wistar rats (8/sex/group) with enalapril (ACE inhibitor, 20 mg/kg/d), acetazolamide (carbonic anhydrase inhibitor, 10 mg/kg/d), probenecid (organic anion transporter inhibitor, 300 mg/kg/d) and cimetidine (organic cation transporter, 100 mg/kg/d) for 14 days with a 7 day recovery period. Renal histology and urinary protein biomarkers of kidney injury were monitored over the dosing and recovery periods, and revealed a trend towards increases in the distal tubule injury marker mu-GST in response to enalapril, acetazolamide, probenecid, and cimetidine, all in the absence of histological injury. In contrast, levels of KIM-1, clusterin, alpha-GST, albumin, lipocalin-2, and osteopontin are all relatively stable in response to these renally-active but non-nephrotoxic drugs. This work suggests that KIM-1, clusterin, alpha-GST, albumin, lipocalin-2, and osteopontin, but perhaps not mu-GST, distinguish between drug-induced changes in renal nephron function and injury in rats, enhancing their utility as DIKI biomarkers.

Biomarkers of cardiac toxicity are widely used in clinical settings to assess patient cardiovascular health, and a newer generation of cardiac biomarkers have recently been developed for use in rodents; however, there are no validated biomarkers suitable for use in NHP. We evaluated a variety of available rodent and human biomarkers in two NHP species: African green monkeys and Rhesus macaques. Endpoints included electrocardiographic (ECG) and Doppler echocardiographic (Doppler Echoscale Discovery® (MSD) rat and human muscle injury panels, and histopathology. Two animals/sex were administered a single subcutaneous (sc) injection of isoproterenol (IPIT: 4 mg/kg). Blood samples were collected pre-study and at 1, 4, 24, 48 and 72 hr postdose. Blood was evaluated with a Triage® card kit and MSD muscle injury kits (rat: cTnl, cTrt, FABP3, My3, cTnl; human: Tnl, CKMB). ITP production increases significantly in cardiac biomarkers: cTnl, cTrt, FABP3 and My3 were increased 150-, 1285-, 68- and 619-fold, respectively, over predose levels 24 hr after dosing in African green males, with similar results seen in females. Results in Rhesus macaques were similar, but less pronounced, with males at 24 hr showing increases of 13-, 10-, 3- and 25-fold over predose, respectively, and females had similar results. The peak response time appears to be either 4 or 24 hr for each parameter, though most parameters remained elevated 72 hr postdose. Human Tnl and CKMB were far less responsive with increases of only 0.9- to 4.4-fold for all parameters in both species at any time point. The traditional human Triage® panel showed modest activity for Troponin I and sporadic responses for myoglobin, but the sensitivity and reproducibility were far less than that seen with the MSD biomarkers. These results indicate that the MSD rat muscle injury panel provides excellent sensitivity for assessing cardiac effects in two different NHP species. Work supported by NIAID Contract N01-AI-70043.

During early preclinical development, a new drug candidate induced nephrotoxicity in rats following daily p.o. administration for 7 days. Renal lesions consisted of scattered nuclear enlargement in tubular cells at low-dose and tubulopathy (mixture of dilatation, degenerative and regenerative changes) at higher doses. Traditional serum kidney parameters remained silent, thus precluding their use as surrogates for further non-clinical or clinical studies. To identify early biomarkers, a mechanistic study in male rats was performed at low and high doses with sequential examination at 6h, 24h, 3 and 7 days combining kidney histology and transcriptomic profiling in the cortex and medulla, urinary and serum metabolomics as well as urinary kidney biomarkers. No histological kidney lesions were observed at 24h, while tubular changes were seen after 3 or 7 days of dosing with time-related severity scores. The transcriptomic fingerprints of treated and control rats were clearly different at 6h with a deregulation of genes not specifically associated with kidney injury, in contrast, a number of gene expression changes commonly associated with kidney toxicants (e.g. Calb1, Haverl/km1, clusterin, TIMP1, Sppl/osteopontin, Atf3) as well as overt changes in urinary microalbumin, KIM-1 and clusterin were
observed at 24h or after 3 days when histological lesions were either absent or minimal. In parallel, urinary metabolomics evidenced obvious and time-related changes in endogenous metabolites which could act as additional biomarkers for the observed toxicity e.g. citric acid cycle members in urine and serum phospholipids. A cross-parameter analysis identified a discriminating pattern of omics and urinary biomarkers considered as more sensitive than early histology alone for prediction of the observed toxicity. This combined analysis will add greater confidence in the selection and prioritization of back-up candidates during early preclinical development.

**HIGH CORRELATION OF NOVEL SKELETAL MUSCLE INJURY BIOMARKERS TO CK ACTIVITY IN HUMAN VOLUNTEERS AFTER PROLONGED EXERCISE.**

J. E. Sidaway1, L. Bate1, M. Mattson3, B. Glinkhammar2 and C. J. Betts1.

1Safety Assessment UK, AstraZeneca, Macclesfield, Cheshire, United Kingdom, 2Safety Assessment Sweden, AstraZeneca, Solna, Sweden and 3Aranst Laboratory of Work Physiology, The Swedish School of Sport and Health Sciences and Karolinska Institute, Stockholm, Sweden.

Creatine kinase (CK) is a widely used blood based biomarker of skeletal muscle injury in humans and preclinical species. However, due to the cardiac and skeletal muscle expression of CK isoforms, the ability of current CK enzyme activity based assays to specifically diagnose skeletal muscle injury is limited. The Meso Scale Discovery ( MSD, Gaithersburg) Muscle Injury Panel 1 (MIP1) is an immunological electrochemiluminescent assay that has been developed to detect multiple rat proteins with restricted expression in heart and/or skeletal muscle. The assay detects fatty acid binding protein 3 (FABP3, heart/skeletal muscle), myosin light chain 3 (MyL3, heart/skeletal muscle) and cardiac troponin T and I (cTnT and cTnI, heart). We have performed the evaluation of the novel biomarkers in humans with exercise induced muscle injury. Plasma was collected from 37 human volunteers before and after prolonged exercise in sports competitions ranging from 48-150 hours in duration. CK enzyme activity was increased 29.5 fold after exercise (mean +/- standard deviation was 131 ± 62 U/mL before exercise and 3866 ± 3327 U/mL after exercise, P< 0.001). FABP3, MyL3 and sTNI were all significantly increased after exercise (9.0 fold, 41.7 fold and 11.0 fold respectively, all P<0.001), whereas cTnT and cTnI were undetectable, suggesting that the injury was restricted to skeletal muscle. FABP3, MyL3 and sTNI also showed a higher correlation to CK activity (Spearman r value of 0.93, 0.88, and 0.93 respectively). In summary we have shown that novel skeletal muscle injury markers are induced in humans in response to prolonged exercise, correlate highly with CK activity, and have potential utility for assigning skeletal muscle damage with more specificity than conventional assays.

**THE INTERPRETATION OF STRIATED MUSCLE TOXICITY BIOMARKERS IN NONCLINICAL SPECIES: A CASE SERIES.**

There are a number of serum biomarkers indicative of striated muscle toxicity. Traditional biomarkers including creatine kinase (CK), lactate dehydrogenase (LDH) and aspartate transaminase (AST) are commonly used. However, they lack the ability to differentiate between tissue-specific damage. Serum myoglobin, fatty acid binding protein 3 (Fabp3) and troponins (TrnT and TrnI isotypes, TnC) have been reported to provide improved specificity for the detection of cardiac and skeletal muscle toxicity. This case series describes a number of non-clinical studies examining the relationship between serum biomarkers and histopathological changes. Rats and dogs were exposed to sulfonil isoxazoline chemistries for 4 to 28 days via daily diet or gavage. Histopathology evaluation revealed a dose-dependent relationship in the muscle damage in both cardiac tissue and fast- and slow-twitch skeletal muscle (diaphragm, soleus and biceps femoris). Interestingly the temporal relationship and the magnitude of change in serum biomarkers did not correlate well with the severity of the observed muscle insult. There were also differences between species – in rats early change in tissue-specific tropinin isotypes (eg. cTnI), CK, LDH and AST was not detected, despite the presence of muscle pathology. In dogs, the converse relationship was often observed, significant early increases in tissue-specific biomarkers reflected only minimal histopathological findings. These data illustrate the temporal and species-specific complexity of serum biomarkers for predicting striated muscle toxicity. Further ongoing work includes transcriptome and protein profiling of tissues taken from these studies to explore mechanistically relevant pathways.

**INDIVIDUAL BILE ACID CHANGES ASSOCIATED WITH BILE DUCT HYPERPLASIA IN PRECLINICAL MODELS.**

Bile duct hyperplasia (BDH) findings are concern during drug development since they may be accompanied by various abnormalities, such as portal inflammation, cholestasis and biliary injury. The relevance and predictive value of BDH in animals for drug induced liver injury (DILI) in humans are under investigation. The purpose of this study was to evaluate potential biomarkers of BDH in mice and rats using tool compounds and company developed compounds. A validated LC/MS/MS model to quantitate three individual bile acids (IBAs), taurocholic acid, glycocholic acid and cholic acid, was deployed to analyze serum samples from these studies. Results were compared against histopathology findings and standard clinical chemistry parameters. The concentrations of taurocholic acid and glycocholic acid increased significantly in the animals with BDH findings. The three bile acids evaluated remained unchanged in animals dosed with compounds that did not induce BDH. The data were consistent for both species. No changes in clinical chemistry parameters, such as ALT, AST, ALP, GGT, GLDH and TBIL, were observed. Laboratory data has demonstrated that cholic acid in serum significantly increases in rats dosed with compounds causing necrosis and cholestasis. Cholic acid was more specific for necrosis than glycocholic acid and taurocholic acid, yet these two bile acids corresponded better with BDH in preclinical models. These results demonstrate the potential utility of individual bile acids as biomarkers of BDH in preclinical species, and the potential for relationships to be established between individual bile acids and specific liver toxicity findings.

**EVALUATION OF CALCINEURIN ACTIVITY AS A BIOMARKER OF IMMUNOSUPPRESSION IN LUNG TRANSPLANT PATIENTS.**

S. Sanquer1, C. Amrein2, B. Barouki1 and M. Sterr1. 1Hôpital Necker-Enfants Malades, Paris, France, 2H2-GEP, Paris, France and 1Hôpital Foch, Suresnes, France.

Introduction: Optimal immunosuppression is difficult to achieve. Inadequate immunosuppression can provoke transplant rejection whereas excessive immunosuppression predisposes to infection or malignancy. To circumvent possible adverse events a biomarker of immunosuppression is needed. Since anti-calcineurin drugs are the standard for rejection prophylaxis after lung transplantation (LT), we have investigated whether calcineurin activity (CN-a) could be a biomarker of immunosuppression in LT patients.

Methods: 107 patients entered the study from March 2004 to August 2008. CN-a was measured once a month during the first 6 months after LT in mononuclear cells isolated from whole blood by quantifying by HPLC the dephosphorylation of a phospho-RiI peptide. Episodes of acute rejection were diagnosed on the basis of lung function and biopsy results. Pulmonary function was estimated according to the spirometric data FEV1 and FEF25-75. Chronic rejection was diagnosed according to the ISHLT criteria. Adverse events such as infections and malignancies were recorded.

Results: CN-a tended to be increased in patients who were treated for acute rejection as compared to patients who were not (66 vs 52 pmol/mg/min, p<0.09). An inverse relationship between CN-a levels and acute rejection was observed (r=-0.576, p<0.001). Moreover, we found that patients who displayed extremely low CN-a levels (<10 pmol/mg/min) continued to have altered evolution of their spirometric values as well as a lower freedom from chronic rejection (19% vs 67%, p=0.0326). Chronic rejection was diagnosed in 5% of the cases. CN-a levels outside the range of 10-100 pmol/mg/min were those who displayed an altered evolution of their spirometric values as well as a lower freedom from chronic rejection (19% vs 67%, p=0.0326). Moreover, we found that patients who displayed extremely low CN-a levels (<10 pmol/mg/min) possibly remained to suffer from immunosuppression developed more adverse events such as infection and malignancy was recorded.

Conclusion: These results suggest that CN-a could be a biomarker of immunosuppression and could be useful not only the occurrence of rejection related to an inadequate immunosuppression but also the development of severe complications related to exceedingly immunosuppression.

**BIOMARKERS FOR STEATOHEPATITIS (ASH, NASH, TASH).**

M. Cave1, H. Shah1, B. Wheeler1, Y. Mannery1, K. Falkner1, B. Wahlöö1 and C. McClain1,2,3. 1Department of Medicine/Methodist University of Louisville, Louisville, KY, 2Pharmacology and Toxicology, University of Louisville, Louisville, KY and 3Louisville VAMC, Louisville, KY.

Steatohepatitis may be caused by industrial chemical toxicants (TASH), obesity (NASH), or alcohol (ASH). The purpose of this study was to compare and contrast serologic biomarkers in human subjects with NASH (n=55), ASH (n=50), and...
TASH (due to occupational vinyl chloride exposures, n=16) vs. healthy controls (n=11). Serum CK18 was measured by ELISA (Diaplan) and adipokines were measured by multi-analyte chemiluminescent detection (Milliplex); and antioxidant activity was measured using a kit (Cayman). ASH and NASH were both associated with increased aminotransferase activities (ASH: ALT>AST; NASH: ALT>AST), while aminotransferases were normal in TASH. All steatohepatitis groups had increased CK18 M65 (necrosis biomarker) compared to controls; while CK18 M30 (apoptosis biomarker) was increased only in ASH and NASH. Hyperinsulinemia was present in all steatohepatitis groups; although the mechanisms for this appeared to be different. Adiponectin was low (vs. healthy controls) in NASH and TASH, while was lowest in the NASH group. The hepatocellular death biomarker, CK18, appears useful for the diagnosis and sub-classification of steatohepatitis. ASH and NASH were associated with significant degrees of hepatocellular apoptosis, while TASH was primarily necrotic. Insulin resistance was present in all etiologies of steatohepatitis, although adipokine profiles were divergent. ASH and TASH (to a lesser degree) were associated with increased inflammatory biomarkers. NASH was associated the greatest antioxidant depletion. Funding sources include NIH and State of Kentucky.

**543 URINARY MITOCHONDRIAL DNA AS A NOVEL BIOMARKER OF ACUTE KIDNEY INJURY.**

L. J. Stallons1,  J. J. Rahn1,  J. L. Blakey1,  J. A. Funk1,  S. S. Chan1,  J. M. Arthur2, 3 and R. G. Schnellmann1, 2. *Pharmaceutical and Biomedical Sciences, Medical University of South Carolina, Charleston, SC,* 3*Department of Medicine, Division of Nephrology, Medical University of South Carolina, Charleston, SC and 2*Ralph J. Holmes Veterans Administration Medical Center, Charleston, SC.*

Acute kidney injury (AKI) is defined by the abrupt reduction in kidney function and can be caused by numerous acute insults including drug toxicity, surgery, trauma, and ischemia/reperfusion (I/R). Animal models of AKI have demonstrated an important role for mitochondrial dysfunction, and mitochondrial components are released from cells and tissues after diverse insults to act as damage-associated molecular patterns (DAMPs) in signaling injury responses. Serum creatinine (SCr) is the standard clinical marker for AKI, but the limited sensitivity of SCr has led to recent efforts by multiple groups to identify novel biomarkers of AKI. The purpose of this study was to determine if urinary mitochondrial DNA (mtDNA) is a biomarker of AKI and of mitochondrial dysfunction in AKI. We established a rat model of renal I/R in which Scr increased from 0.5 to 2.2 mg/dl at 24 hr after surgery and returned to normal levels after 144 hr. We collected urine from sham and I/R rats at 24 hr and concentrated 1 ml of urine using centrifugal filters. DNA was isolated from concentrated urine, qPCR was performed using primers for the mitochondrial gene ND1, and ND1 was quantified using a standard curve of kidney DNA. There was a 184-fold increase in the levels of ND1 in urine from I/R rats compared to sham animals. We also examined mtDNA quantity in the urine of humans with AKI after cardiac surgery, control humans with normal renal function, and humans with no AKI after cardiac surgery. We found a 100-fold increase in urinary ND1 from humans with AKI versus healthy controls and cardiac surgery patients with no AKI. Our results indicate that urinary mtDNA may be a novel, non-invasive biomarker of AKI and could be indicative of mitochondrial dysfunction in renal toxicity.

**544 EARLY DETECTION OF KAINIC ACID NEUROTOXICITY IN RATS USING NONINVASIVE IN VIVO MAGNETIC RESONANCE IMAGING.**

S. Lischken1,  J. Ramu1,  M. G. Paula1,  L. Schmued1 and J. Hanjie1. 1*Neurotoxicology, US FDA/CDER, Jefferson, AR and 2*Office of Testing & Research, US FDA/CDER, White Oak, MD.*

The current approach to neuropathology analysis in support of new drug submissions to the FDA (the use of 3 or 7 arbitrary histology slices) is prone to false-negative findings, meaning that small localized lesions can easily be missed. Modern magnetic resonance imaging (MRI) techniques can provide unique information about the whole brain structure and function in vivo with high resolution and contrast in three-dimensional space, non-invasively. The aim of this study was to develop sensitive MRI methods for detecting early neurotoxic changes in the brain of living rats using established models of neurotoxicity. Male Sprague-Dawley rats (64 days old, 389 ± 34 g) were injected with kainic acid (KA, N=2, 10 mg/kg, ip) or saline (N = 2, 2 ml/kg, ip) after baseline MRI scans. Animals were continually scanned for 2 hours in the MRI. Two days later animals were scanned again and euthanized for follow-up histopathological examination. MRI was performed using a Bruker 7tesa MRI with volume transmit and surface receive coils. Animals were anesthetized with isoflurane and the body temperature was maintained at 37 ± 0.6°C. T2 relaxation mapping of the whole brain was performed using pixel-by-pixel fitting of the signal decay in a multi-echo spin echo experiment. There were for the assessment of cardiac troponin I (cTnI) using an ultrasensitive assay and N-terminal propeptide (NT-proANP) concentrations. Histomorphologic evaluation was performed on Days 8 and 15.

Results/Discussion: Administration of M for 7 and 14 days resulted in CV changes to the left ventricle (LV) including an increase in chamber dimension, evident in diastole, with preserved indices of function. As a result, LV stroke volume increased with a concomitant decrease in heart rate. Coincident with these CV changes, NT-proANP increased on Day 3 and peaked on Day 7 and returned toward baseline while serum cTnI progressively increased starting on Day 3. All biomarker changes occurred in the absence of histomorphologic findings. These data suggest that sub-chronic M dosing induced a systemic vasodilatory response. As a result of the decrease in heart rate, LV filling was likely increased, resulting in chamber enlargement and the associated increase in serum biomarkers.

Conclusion: Herein, echocardiography, NT-proANP (stretch biomarker) and cTnI were more sensitive than histopathology to identify the CV response to M, while providing the advantage of being non-terminal. This multidisciplinary approach has translational implications for the early identification of CV liabilities of compounds in development.

**541 MASS SPECTROMETRY ASSAYS FOR STEROIDS IN TOXICITY ASSESSMENTS.**

K. Navetta, D. Wolford, R. Drago and J. Colangelo. *Drug Safety Research and Development, Pfizer, Groton, CT.*

The accurate measurement of steroid levels in pre-clinical species has become increasingly important during drug development because changes in steroid levels have been linked to a variety of toxicities. Antibody-based methods such as radioimmunoassays (RIA) and enzyme-linked immunosorbent assays (ELISA) are commonly used for steroid analysis due to their ease of use and sensitivity. A major disadvantage of RIA and ELISA kit-based assays is the potential of the antibodies to cross-react with other analytes of similar structure resulting in false-positives. Additionally, many kits are non-transferable to different species or matrices, requiring the scientist to locate, purchase and evaluate multiple kits for the same analyte. To assess the feasibility of transferring steroid assays from kits to a mass spectrometer-based platform (MS), a direct comparison between platforms was conducted with aldosterone, corticosterone and 25-hydroxy (OH)2 vitamin D3. Three major benefits were observed when comparing MS to antibody-based assays: lower costs, shorter data delivery times, and increased specificity. For example, the MS assay for aldosterone costs ten times less to run and data is reported two days sooner; the corticosterone assay uses five times less sample volume; the 25(OH)2D3 assay can differentiate between D2 and D3 forms. Detection limits and assay precision for the MS assays are comparable to those observed in the kits. The quantitation range for aldosterone is 0.01 to 100 ng/ml, for corticosterone is 10 to 1000 ng/ml, and for 25(OH)2D3 is 5 to 150 ng/ml. Precision is within 25% for all three assays. These assays have been applied to multiple pre-clinical species, including dog, monkey, as well as to multiple biological matrices, including serum, plasma, and urine. As MS is becoming established in the clinical setting, this platform is broadening its impact in clinical pathology applications, enhancing drug development. These changes not only provide substantial cost and time savings, but they provide higher quality data for drug development.

**542 NT-PROANP, cTnI, AND ECHOCARDIOGRAPHY ARE EARLY MARKERS OF MINOXIDIL-INDUCED STRUCTURAL AND FUNCTIONAL CHANGES OF THE LEFT VENTRICLE IN RATS.**

M. E. Dunn1,  M. Sanders1,  D. Coluccio1,  R. Nicklaus1,  I. Mikaelian1,  T. S. Zakba1,  W. Geng1,  M. Reddy1,  L. Doesseger2,  T. Singer1 and G. Hrkak1.

Introduction: Advances in biofluid assay technology combined with enhanced in vivo imaging now provide the sensitivity, accuracy, and reproducibility necessary for their validation and subsequent incorporation into routine toxicity studies. The usage of these biomarkers will beneficially impact the cardiovascular (CV) liability assessment of development compounds.

Methods: Male rats were orally dosed with vehicle or Minoxidil (M) (100 mg/kg/day) for 7 or 14 days. Echocardiography was performed the day prior to dosing (-1) and on Days 7 and 14. Serum was collected on Days -1, 3, 7, 11 and 14 for the assessment of cardiac troponin I (cTnI) using an ultrasensitive assay and N-terminal propeptide (NT-proANP) concentrations. Histomorphologic evaluation was performed on Days 8 and 15.

Results/Discussion: Administration of M for 7 and 14 days resulted in CV changes to the left ventricle (LV) including an increase in chamber dimension, evident in diastole, with preserved indices of function. As a result, LV stroke volume increased with a concomitant decrease in heart rate. Coincident with these CV changes, NT-proANP increased on Day 3 and peaked on Day 7 and returned toward baseline while serum cTnI progressively increased starting on Day 3. All biomarker changes occurred in the absence of histomorphologic findings. These data suggest that sub-chronic M dosing induced a systemic vasodilatory response. As a result of the decrease in heart rate, LV filling was likely increased, resulting in chamber enlargement and the associated increase in serum biomarkers.

Conclusion: Herein, echocardiography, NT-proANP (stretch biomarker) and cTnI were more sensitive than histopathology to identify the CV response to M, while providing the advantage of being non-terminal. This multidisciplinary approach has translational implications for the early identification of CV liabilities of compounds in development.
Circadian rhythms in many physiological processes can impact drug response and toxicity. The sensitivity of the central nervous system to neurotoxicants may also be dependent on the phase of the circadian cycle and this may be due to variations in the activity of neurotransmitters and other neural systems. The goal of this study was to evaluate diurnal changes in neurometabolite profiles in naïve rats measured using non-invasive magnetic resonance spectroscopy (MRS). Male Sprague-Dawley rats (69.0 ± 1.5 days old, 367 ± 31 g) were subjected to MRS one hour after light onset (7 am, N = 5, AM group) or offset (7 pm, N = 5, PM group) during the regular light cycle. MRS was performed using a Bruker BioSpec 7T/30 system with a 72 mm bird-cage transmit and a 4-channel phased array receive coil. Animals were anesthetized with isoflurane and the body temperature was maintained at 37.0 ± 0.8°C. Spectroscopic voxels were positioned at the left anterior hippocampus. Dynamic proton spectra were acquired for up to 2 hours at -11 min/spectrum.

LCModel software was used to extract metabolite concentrations from individual spectra and the statistical analysis was performed using ANOVA. Concentrations of glutamate, N-acetylaspartate, taurine, and choline were all significantly lower in AM group comparing to PM group (2 hrs after light onset or offset). However, at the end of scanning (3 hrs after light offset or onset) all these differences disappeared. Concentrations of other significant neurometabolites (GABA, creatine, glutamine, and myo-inositol) were not significantly different between groups at any time points. The data demonstrate that brain neurochemical composition is influenced by diurnal variation which may be one of the mechanisms underlying circadian rhythms in many physiological processes. The primary objective of this study was to discover surrogate biomarkers which are correlated with hepatotoxicity induced by acetaminophen (APAP) using urinary proton nuclear magnetic resonance (1H NMR) spectral data. A procedure of 1H NMR urinalysis using pattern recognition was proposed for early screening of the hepatotoxicity of APAP in humans. The hepatotoxicity occurrence was tested through clinical chemistry. APAP (3 g/day, two 500-mg tablets every 8 h) was administered to 20 healthy males (20-29 yr) for 7 days and urine was collected daily before and during dosing and 6 days after final dosing. All the subjects didn’t show significant changes in alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), γ-glutamyl transpeptidase (γ-GTP), and lactate dehydrogenase (LDH) by APAP compared to before treatment. However, urinary metabolite profiles were obtained from subjects showing mild liver injury, as indicated by increase in ALT or AST to a level more than 1.7-fold the before treatment. 1H NMR spectroscopy revealed evidently different clustering between pre-dosing and APAP treatment in global metabolomic profiling through principal component analysis (PCA) and partial least square (PLS)-discrimination analysis (DA). In targeted profiling, urinary endogenous metabolites of trimethylamine, citrate, 3-chlorotyrosine, phenylalanine, malonate, glycine, creatine, taurine, betaine, glutamine, glutamate, and taurine were selected as diagnostic metabolites for APAP-hepatotoxicity. These results might be applied to predict or screen other potentially hepatotoxicity caused by drugs using urinary 1H NMR analysis.

The prediction of phospholipidosis (PLD) was investigated by in silico/in vivo methods using 50 drugs with known PLD inducing potential in vivo. For in silico prediction of PLD 3 models were used. They are based on physico-chemical descriptors for a simple rule model (modified Ploemen model: logP and pKa) or more sophisticated for decision tree models (C5 RuleQuest and KNIME model). For in vitro analysis, phospholipid (PL) accumulation was measured in HepG2 cells 24h/48h after incubation using the HCS LipidTOX kit, including a cytotoxicity evaluation by ATP content and neutral red uptake. Finally, for in vivo analysis the urinary PL biomarkers BMP (Bio(Bis(monosaccharide)glycerophosphate) and PAG (phospholactylglycine) were analyzed by LC-MS and NMR in different species (rat, dog, hamster, human) for some examples. Additionally, accumulation of PLs was analyzed in different organs using a photometric enzyme-assay and PLs was confirmed by histopathology.

A combined approach using the 3 in silico models together with in vitro result showing PL increase below 2μM was able to identify most of the in vivo PL-inducing compounds. Sensitivity up to 96% could be achieved with acceptable specificity (70-95%) depending on the combinations. These results were confirmed by the urinary PL biomarker BMP and the PL analysis and histopathology mainly in lung and liver, providing also more information about time course and NOEL. Urinary PAG was increased by PLS in rats, but only low or no effects were seen in other species. These validation results showed that an integrated testing strategy from in silico models to in vitro assays to in vivo biomarkers is able to identify and to characterize the PLS inducing potential of drugs very early by combination of different tools depending on available data and development status.

The primary objective of this study was to develop non-invasive biomarkers for the early preclinical detection of neurotoxicity would benefit public health by extending the number of tools available for safety evaluation of new drugs. (Supported by NCTR/CDER, FDA, #E07418801).
549 URINARY BIOMARKERS IDENTIFICATION USING METABOLOMICS FOR KIDNEY TOXICITY IN SPRAGUE DAWLEY RATS.

A. Won1, T. Kim1, Y. Lee1, Y. Shin1, J. Wang1, B. Lee2, S. Kim1 and H. Kim1.

Identification of new biomarkers for detection of nephrotoxicity is important for evaluation for new drug development and screening. Recently, several biomarkers have been identified for detection of nephrotoxicity. In this study, we compared the sensitivity of biomarkers with conventionally used biomarkers for kidney toxicity. The animals were allocated to several groups. A single dose of cisplatin (10 mg/kg, i.p.) and D-galactosamine (20 mg/kg, i.p.) was administered to Sprague Dawley rats. Urine, plasma and kidney tissue samples were collected at 1, 3, 7 days after drug injection. To discover biochemical biomarkers useful for sensitive identification of nephrotoxicity, measurement of urinary indexes and blood biochemical parameters were performed. Urinary metabolites were also measured using NMR-based spectroscopy. In the cisplatin-treated rats, urinary blood urea nitrogen (BUN) and creatinine levels were dramatically decreased and protein, glucose and LDH levels were significantly increased, which were thought to be caused by the dysfunction of proximal tubule injury. However, no significant differences in urinary biomarkers were observed in D-galactosamine-treated rats. A number of metabolites were changed in urine of rats treated with cisplatin. Among them, trigonelline, 3-indoxylsulfate, hippurate, and citrate levels were dramatically reduced in rats, but lactate, acetate, and glucose levels were markedly increased. In cisplatin treated group, LDH level was significantly increased in the urine, but LDH activity was decreased in kidney tissues. Based on these results, detection of combined urinary metabolites may be a powerful tool for detection of nephrotoxicity, and LDH was considered useful for broad detection of nephrotoxicity.

550 LOW-DOSE 3-IODOTHYRONAMINE INCREASES ACUTE LIPOLYSIS FOLLOWED BY PROTEIN CATABOLISM DETECTABLE BY BREATH AND SERUM BIOMARKERS.

1Zoology, University of Wisconsin, Madison, WI, 2NMRFAM, University of Wisconsin, Madison, WI, 3Biochemistry, University of Wisconsin, Madison, WI, 4Department of Sciences dell’Uomo e dell’Ambiente, Universita di Pisa, Pisa, Italy and 5Department of Physiology & Pharmacology and Cell & Developmental Biology, Oregon Health & Science University, Portland, OR.

3-iodothyronamine (T1AM) is a recently discovered fast-acting thyroid hormone derivative. Treatment with T1AM produces profound metabolic effects. This study monitored the effect of worklong, daily, low dose T1AM administration on weight and metabolism in spontaneously overweight mice. Real-time analysis of exhaled 13CO2 by cavity ringdown spectroscopy detected increased lipolysis shortly after and metabolism in spontaneously overweight mice. Real-time analysis of exhaled 13CO2 by cavity ringdown spectroscopy detected increased lipolysis shortly after treatment with T1AM produces profound metabolic effects. This study monitored the effect of worklong, daily, low dose T1AM administration on weight and metabolism in spontaneously overweight mice. Total RNA including small RNA species was isolated from urine samples at day 3, 5, 8, 10 and 14 after single dose treatment with Cp. Using TaqMan®miRNA Cards (Array Gene Signature Rodent A and B Cards) miRNA profiles were generated for each time point for both treatment and control groups. MiRNA levels were normalized to a non-endogenous spiked-in control miRNA of plant origin (Arabidopsis thaliana miR-159a); in addition urine miRNA were normalized to urinary creatinine. In plasma from Cp-treated rats as well as in urine from Cp-treated rats, microRNAs were found in urine from Cp-treated rats, microRNAs were found in significantly higher amounts compared to vehicle treated rats, including the liver-specific miR-122 in plasma (1) and the kidney-cortex enriched miR-192 in urine (2), respectively. The miRNAs found at altered levels bear the potential of being used as new and sensitive BMs for liver injury. References:

551 HEPATIC AND PLASMA MiRNAs—SENSITIVE BIOMARKERS OF LIVER INJURY INDUCED BY A METHYL-DEFICIENT DIET IN MICE.

MicroRNAs (miRNAs) are a class of small, conserved, tissue-specific regulatory non-coding RNAs that modulate a variety of biological processes, including metabolism, cell differentiation and proliferation, and apoptosis. Aberrant expression of certain microRNAs may play a fundamental role in disease pathogenesis, including liver; however, the association between the susceptibility to any given pathological state and altered expression of miRNAs is largely unknown. In order to determine whether or not individual susceptibility to liver injury is associated with an altered miRNA expression, we fed inbred male A/J, C57BL/6J, C3H/HeJ, 129S/SvImJ, CAST/EiJ, PWK/PhJ, and WSB/EiJ mice a methyl-deficient diet for 12 weeks, a relevant model of nonalcoholic fatty liver disease (NAFLD) in humans. miRNA levels in livers and plasma of mice were determined using TaqMan RT-PCR. Feeding the methyl-deficient diet induced liver injury in all mouse strains; however, the severity of liver pathological changes was strain-specific, with A/J mice being the least susceptible and WSB/EiJ mice being the most sensitive to liver injury induced by methyl-deficiency. There was a significant up-regulation of miR-34a, miR-200b, miR-181a, and miR-221. Importantly, expression of these miRNAs was highly correlated with the extent of NAFLD-associated pathomorphological changes in the livers. Microarray gene expression data and target-prediction miRNA-mRNA analysis showed that the predicted targets for these miRNAs affect cell proliferation, apoptosis, inflammation, oxidative stress, and metabolism. More importantly, we found that the levels of miR-34a, miR-122 and miR-192 were upregulated in the blood plasma and this was significantly correlated with the extent of liver pathomorphological changes. In conclusion, the severity of NAFLD is strongly associated with the level of hepatic and plasma miRNAs. This suggest that circulating miRNAs may be used as biomarkers of liver toxicity, and more importantly, as a potential indicator of susceptibility to liver injury.

552 MiRCONAS IN PLASMA AND URINE AS NEW SAFETY BIOMARKERS FOR DRUG-INDUCED TISSUE INJURY IN RATS.

M. Pavkovic1, B. Rieke2 and H. Ellinger-Ziegelbauer2, 1Investigational Toxicology, Bayer HealthCare, Wuppertal, Germany and 2Investigational Toxicology, Bayer HealthCare, Berlin, Germany.

MicroRNAs (miRNAs) are highly conserved, noncoding, approx. 22 nucleotides long, small RNAs that play an important role in post-transcriptional regulation of gene expression. Because of their tissue specificity and stability in plasma and urine, they are suggested as new biomarkers (BM) of tissue injury in easily accessible bioluids in preclinical studies. For evaluation of miRNA preclinical BMs plasma and urine were collected from male Wistar rats treated either with the hepatotoxicant methapyrilene (MPy) or with the nephrotoxicant cisplatin (Cp). Tissue injury was confirmed by histopathology and chemical pathology parameters, i.e. we measured increased ALT (Alanine transaminase) activity in serum and liver injury and increased protein levels in urine after kidney injury, respectively. In addition new urinary protein BMs for nephrotoxicity, (e.g., KIM-1), showed a time-dependent increase after Cp treatment. Total RNA including small RNA species was isolated from plasma at day 4, 8 and 10 after daily treatment with MPy and after a 10 day recovery period. Total RNA was also isolated from urine samples at day 3, 5, 8, 15 and 26 after single dose treatment with Cp. Using TaqMan®miRNA Cards (Array Gene Signature Rodent A and B Cards) miRNA profiles were generated for each time point for both treatment and control groups. MiRNA levels were normalized to a non-endogenous spiked-in control miRNA of plant origin (Arabidopsis thaliana miR-159a); in addition urine miRNA were normalized to urinary creatinine. In plasma from MPy-treated rats as well as in urine from Cp-treated rats, microRNAs were found in significantly higher amounts compared to vehicle treated rats, including the liver-specific miR-122 in plasma (1) and the kidney-cortex enriched miR-192 in urine (2), respectively. The miRNAs found at altered levels bear the potential of being used as new and sensitive BMs for liver or kidney injury. References:

553 MiRNA BIOMARKERS OF OCULAR TOXICITY.

Q. Peng, W. Huang, W. Collette and A. John-Baptiste. Drug Safety Research and Development, Pfizer, La Jolla, CA.

Ocular toxicity has been associated with numerous systemic medications and is a serious concern during drug development. Drugs can disturb blood-aqueous and blood retinal barriers ultimately allowing drug to enter the eye resulting in toxicity. Otherwise, small molecules such as miRNAs can transfer into blood due to ocular toxicity. Therefore, the fluctuation of ocular miRNAs in body fluids such as plasma reflects ocular cell and tissue injury just like miR-122 in liver injury since ocular miRNAs are differently enriched in retina, lenses and cornea determined by microarray, ISH and RT-PCR. More evidence indicates the deregulation of microRNA expression correlates with a number of diseases such as cancers, liver and heart injury. In this study, we evaluated ocular enriched miRNAs in the organotypic culture of the rat eye – posterior segment by real time RT-PCR with SYBR green based detection.
The posterior globe of Sprague-Dawley rat eye was dissected into 4 pieces, washed and incubated in a 12-well plate with -1.5 mL culture media. After 24 hours of initial culture, oncology compounds known to induce ocular toxicity were tested. Supernatants of culture media (~200 µL) were extracted for miRNA with Qiagen miRNAasy kit and the miRNAs were assayed via qRT-PCR. The relative fold change was calculated and normalized with control. The PCR product was confirmed to be single product in each of the miRNA amplifications by melting curve analysis; whereas no amplification in negative control was detected above baseline. Of the 5 ocular miRNAs tested, 2 miRNAs had Ct values of ~20 to ~22; comparatively less abundant miRNAs had Ct values of ~24 to ~30 in 48 hour culture media. At least two ocular miRNAs had a 3-6 fold elevation in a dose and time-dependent response; one ocular miRNA had 5-10 fold reduction in one of the compounds tested. In conclusion, the ocular miRNAs was validated in an ex vivo culture model as potential ocular injury biomarkers. These ocular miRNAs will be further evaluated as potential biomarkers in animal model for ocular toxicity.

**554 EVALUATION OF BLOOD AND URINARY miRNAs IN GENTAMICIN-INDUCED NEPHROTOXICITY.**

The focus of the present work was to evaluate microRNAs (miRNAs) in whole blood and urine as potential markers for drug-induced kidney injury. Male Sprague-Dawley rats were given gentamicin at doses of 0, 50, 100, 150, or 200 mg/kg/day for 3 consecutive days by subcutaneous injection. Urine and blood samples for miRNA analysis were collected 24 hours after the last dose. Kidney samples were collected for histopathological evaluation and miRNA expression analysis. Blood and urinary miRNAs were detected using quantitative real-time PCR (qRT-PCR)-based TaqMan® low-density arrays. Histopathology confirmed proximal tubular injury with gentamicin treatment at 200 mg/kg, and in whole blood, miR-125a-3p and miR-30b were detected in gentamicin treated rats but not in controls. These two miRNAs were detected in the control rat kidney cortex. Analysis of urine samples revealed significant differences in the composition and levels of miRNAs in drug-treated rats compared to controls, including 108 miRNAs that were detected only in injured rats and an additional 187 miRNAs that were at least 2-fold higher in gentamicin-treated rats relative to controls. miR-4676, miR-706, miR-4606, miR-667 and miR-193b increased (114, 113, 108, 67 and 49-fold, respectively) to controls. Abundant miRNAs detected only in the urine of gentamicin-treated rats included miR-466b, miR-297a, miR-30d, miR-452 and miR-339-3p. These miRNAs were detected in control kidney cortex samples, suggesting that their increase in urine may be related to nephrotoxicity. These data indicate that gentamicin markedly affects urinary excretion of miRNAs and suggests that urinary miRNAs may be sensitive markers of kidney injury.

**555 THE SERUM MICRORNA PROFILE IS NOT ALTERED IN RATS AFTER 14 OR 28 DAYS OF DOING WITH ROSIGLITAZONE OR 3, 3', 5-TRIOIDO-L-THYRONINE.**

I. Mikaelian1, M. Dunn1, D. Coluccio1, D. Knapp2, R. Nicklaus1, G. Hirkaler1, W. Deng1, M. Reddy2, L. Doessegger1, T. Singer1, G. Kourteva1 and H. Hilton1.

Background: Increased heart weight is a common cardiac finding in preclinical safety studies. In this study, we investigated the relationship between serum cardiac troponin I (cTnI) concentrations, heart weight, and histopathology with serum microRNA profile following the administration of known cardiac hypertrophic agents in the rat. Methods: male Wistar rats were administered rosiglitazone at 80 mg/kg/day or T3 at 20 µg/kg/day for 14 or 28 days followed by 14 or 27 days of recovery, respectively. Heart weight, serum cardiac troponin I (cTnI), routine clinical pathology; and histomorphology were evaluated at necropsy. These data were compared to serum microRNAs measured on the day of necropsy with the Affymetrix microRNA chip. Results and Discussion: Compared to age-matched vehicle-treated controls, rosiglitazone caused an increase in heart weight to brain weight ratio of 10% and 17% after 14 and 28 days of dosing, respectively. This increase in rats administered T3 was 21% and 30% after 14 and 28 days of dosing, respectively. This increase in heart weight reversed after the recovery periods. There were no serum cTnI concentration increases or histomorphologic findings in rats administered rosiglitazone. In contrast, rats administered T3 had serum cTnI concentration increases which occurred concurrently with histiocyctic infiltration of the myocardium after 14 and 28 days of dosing, and with necrosis after 28 days of dosing. In addition, there were no treatment-related changes in the serum microRNA profile with any of the test compounds. Conclusion: These results indicate that a serum-based microarray strategy was not adequate to identify candidate microRNA biomarkers of increased cardiac weight, histiocyctic infiltration of the heart, and myocardial necrosis.

**556 NOVEL DIAGNOSTICS OF TOXICANT INDUCED METABOLIC DYSFUNCTION DETECTED IN BREATH AND Plasma BY SELECTIVE ISOTOPE-ASSISTED LABELING (SIAL).**

OBJECTIVE: Metabolomics is the study of a unique fingerprint of small molecules present in biological systems under healthy and disease conditions. One of major challenges in metabolomics is verification of fingerprint molecules to identify specifically perturbed pathways in metabolic aberrations. This step is crucial to the understanding of budding metabolic pathologies and the ability to identify early indicators of common diseases such as obesity, diabetes mellitus type II, metabolic syndrome, polycystic ovary syndrome, and cancer. We present a novel approach to diagnosing aberrations in glucose utilization including metabolic pathway switching in a disease state.

METHODS: We used a well-defined prenatally exposed glucocorticoid mouse model that results in adult females with metabolic dysfunction. We applied the complementary technologies of nuclear magnetic resonance spectroscopy, and cavity ringdown spectroscopy to analyze serial plasma samples and real-time breath measurements following selective 13C-isotope assisted labeling (SIAL). These platforms allowed us to trace metabolic markers in whole animals and identify key metabolic pathway switching in prenatally cortisol-treated animals.

RESULTS: Specifically, increased glucose flux and a shift in the major oxidative pathway in glucose metabolism from glycolysis to the pentose phosphate pathway were apparent in the prenatally cortisol-treated animals.

CONCLUSION: This novel approach is fast, non-invasive and sensitive for determining specific pathway utilization, and provides a direct translational application in the healthcare field.

**557 CYP2B10 INDUCTION AS A BIOMARKER FOR A CAR-MEDIATED, RODENT-SPECIFIC, MECHANISM OF LIVER FOI FORMATION AND CARCINOGENESIS DEVOID OF HUMAN RELEVANCE: EVIDENCE FROM 4-WEEK TO 2-YEAR GLP STUDIES.**

Pharmaceutical compounds under development undergo non-clinical safety testing from 4-week to 104-week durations in rodents; the latter being for lifetime carcinogenesis risk assessment. In a 104-week study with an advanced compound, male mice demonstrated statistically increased rates of hepatocellular adenoma/carcinoma accompanied by liver weight increase. Because the compound was earlier proven free of genotoxic potential, a non-genotoxic mechanism of carcinogenicity was hypothesized. Activation of the nuclear receptor constitutive androstane receptor (CAR) is a widely established promoter of non-genotoxic rodent-specific hepatic tumors, and was therefore explored in priority. Hepatic Cyp2b10 induction typifies CAR activation. We therefore monitored hepatic Cyp2b10 mRNA and its enzymatic activity in a large subset of male mice from the 104-week study. Quantitative real time PCR (qRT-PCR) and enzymatic activity monitoring evidenced strong induction of Cyp2b10 at all dose levels. Despite expected large inter-individual variations, these results reached high statistical significance. These data strongly suggested CAR activation, a mechanism of tumor formation known to be irrelevant to the human situation. With another test compound in a different project, foci of altered hepatocytes appeared in male rats of a chronic 26-week toxicity study. Microarray profiling of the corresponding 4-week rat and mouse GLP toxicity studies had previously shown strong induction of miRNAs encoding Cyp2b2 and Cyp2b10 (mouse) in both genders, as was further confirmed by qRT-PCR (up to 100-fold), in the absence of other possible proliferative pathways. These results show feasibility of Cyp2b screening in rodent liver from 4-week to 104-week studies, for prediction of a CAR-mediated, rodent-specific, mechanism of hepatocarcinogenesis known to be devoid of human relevance.
dyne of the arachidonic cascade. Using TCC-containing soaps deposits TCC on human skin. A low but significant portion of absorbed TCC may be deposited on the skin. Absorbed TCC is metabolized by cytochrome-P450 monoxygenases to monohydroxylated derivatives, 2′OH-TCC, 3′OH-TCC and 6-OH-TCC. These metabolites are quickly conjugated in the liver, and their glucuronides account for the major metabolites in mammalian bile. In human plasma, 2′SO2-O-TCC is the dominant metabolite and TCC is excreted as N-glucuronides via the urine. We recently demonstrated that further oxidation of the ortho-hydroxylated metabolites 2′OH-TCC and 6-OH-TCC leads to quinone imines that covalently bind to glutathione and model proteins in vitro. We investigated if this metabolic activation of TCC by two subsequent oxidations might occur in skin. Spontaneously immortalized human epidermal keratinocytes (Sik) were incubated with 2 μM TCC. After 10 min, the intracellular TCC concentration reached 1.21 ± 0.27 nmol/mg protein and increased at 20 h to 2.04 ± 0.27 nmol/mg protein. LC-MS/MS analysis revealed that a small but significant portion of the absorbed TCC was metabolized by Sik with 2′OH-TCC as a main metabolite. Pre-incubation of TCC with 10 nM TCCD increased metabolism of TCC in Sik and the relative conversion (cellular metabolite concentration versus cellular TCC concentration) increased from 0.5% to 15%. Up to 165 ± 28 pmol/mg protein of free 2′OH-TCC formed after 20 h incubations. To investigate whether this metabolite is further activated to reactive metabolites that bind to protein, covalent protein binding is currently under investigation utilizing LC–MS/MS in vitro. Thereafter, to accelerate TCC production, we recently supported by NIH56499 and NCRR13461.

560 DOES THE ANTIBACTERIAL TRICLORECARBAN (TCC) FORM REACTIVE METABOLITES IN THE SKIN?  
N. H. Schehb1, 1, B. A. Buchholze, 1, B. D. Hambock, 1 and R. H. Rice1.  
1Toxicology and Chemical Analysis, University of Veterinary Medicine, Hannover, Germany, 2Center for AMS, Lawrence Livermore National Laboratory, Livermore, CA, 3Entomology, University of California Davis, Davis, CA and 4Environmental Toxicology, University of California Davis, Davis, CA.

TCC is a common antimicrobial ingredient in bar soaps. Human exposure to TCC is a concern because it accumulates in the aquatic environment and has biological effects on mammals. TCC is a potent inhibitor of soluble epoxide hydrolase, an enzyme involved in the metabolism of endogenous and exogenous epoxyeicosatrienoic acids. TCC is also known to inhibit inflammatory responses, including pro-inflammatory cytokine release and leukocyte recruitment. TCC is commonly applied to the skin to prevent UVB induced skin diseases. Recently, we have shown that UVB irradiation of human keratinocytes results in activation of the AhR and associated EGFR signaling leading to an enhanced expression of CYP1A1 and proinflammatory COX-2, respectively. The initial step is the UVB induced intracellular formation of the tryptophan photoprotein 6′-formylindolo[3,2-b]carbazole (FICZ), a high affinity AhR ligand. Thus, the FICZ activated AhR is an important mediator of the DNA damage independent part of the UVB response. Our current study aims to identify further aspects of AhR mediated UVB responses. Therefore, we analysed changes in protein expression, proliferation and apoptosis in AhR+/+ and AhR−/− keratinocytes (NCTC 2544) by western blot, flow cytometry and BrdU incorporation. UVB exposure of NCTC cells led to a dose-dependent increase in apoptosis. Compared to AhR+/+ cells, AhR−/− cultures exhibited an increased amount of apoptotic cells. This finding was confirmed in irradiated AhR+/+ cells, pretreated with the AhR antagonist 3′-methoxy-4′-nitroflavone. Moreover, the proliferation of sham as well as UVB irradiated AhR−/− cells was significantly decreased. In AhR−/− cells we found a reduced expression of checkpoint kinase 1 (Chk1), an important cell cycle regulator that arrests the cell in G2/M upon DNA damage. Interestingly, UVB exposure led to a higher phosphorylation of Chk1 in AhR−/− cells in comparison to AhR+/+ cells. This pathway is responsible for the observed AhR-dependent differences in proliferation and apoptosis. Further expression analyses of Chk1 client proteins emphasize our hypothesis. In conclusion our study identifies the AhR as an anti-apoptotic player in UVB-induced skin diseases. We propose that the AhR is a suitable target to prevent UVB-induced skin diseases.

561 THE ARYL HYDROCARBON RECEPTOR (AHR) IS A MODULATOR OF ULTRAVIOLET B (UVB)-INDUCED PROLIFERATION AND APOPTOSIS IN HUMAN KERATINOCYTES  
Leibniz Institute for Environmental Medicine, Dusseldorf, Germany.

The AhR is a ligand-activated transcription factor that mediates the toxicity of dioxins and related compounds. Upon ligand binding the AhR translocates into the nucleus and dimerizes with ARNT to modulate gene expression, e.g. of CYP1A1. Recently, we have shown that UVB irradiation of human keratinocytes results in activation of the AhR and associated EGFR signaling leading to an enhanced expression of CYP1A1 and proinflammatory COX-2, respectively. The initial step is the UVB induced intracellular formation of the tryptophan photoprotein 6′-formylindolo[3,2-b]carbazole (FICZ), a high affinity AhR ligand. Thus, the FICZ activated AhR is an important mediator of the DNA damage independent part of the UVB response. Our current study aims to identify further aspects of AhR mediated UVB responses. Therefore, we analysed changes in protein expression, proliferation and apoptosis in AhR+/+ and AhR−/− keratinocytes (NCTC2544) by western blot, flow cytometry and BrdU incorporation. UVB exposure of NCTC cells led to a dose-dependent increase in apoptosis. Compared to AhR+/+ cells, AhR−/−cultures exhibited an increased amount of apoptotic cells. This finding was confirmed in irradiated AhR+/+ cells, pretreated with the AhR antagonist 3′-methoxy-4′-nitroflavone. Moreover, the proliferation of sham as well as UVB irradiated AhR−/− cells was significantly decreased. In AhR−/− cells we found a reduced expression of checkpoint kinase 1 (Chk1), an important cell cycle regulator that arrests the cell in G2/M upon DNA damage. Interestingly, UVB exposure led to a higher phosphorylation of Chk1 in AhR−/− cells in comparison to AhR+/+ cells. This pathway is responsible for the observed AhR-dependent differences in proliferation and apoptosis. Further expression analyses of Chk1 client proteins emphasize our hypothesis. In conclusion our study identifies the AhR as an anti-apoptotic player in UVB irradiated human NCTC cells. Therefore, we propose that the AhR is a suitable target to prevent UVB-induced skin diseases.
of these cytokines from unirradiated keratinocytes. RNase inhibited this activity, thus the trigger of cytokine release by UVB-damaged keratinocytes was likely an RNA specie. Whole-transcriptome sequencing through RNA-Seq analysis of UVB-treated keratinocytes identified several unique non-coding RNAs, specifically U RNAs, that undergo alterations in stem-loop domains. A specific UVB-modified U RNA (U1 RNA) was identified that was able to stimulate TLR-α and IL-6 from keratinocytes. Synthetic oligoucnucleotides based on the stem-loop sequences modified by UVB were found to readily stimulate keratinocyte cytokine release. In isolated keratinocytes, this response was toll-like receptor 3 (TLR3)-dependent and inhibitable by chloroquine, an inhibitor of endosomal TLR activation. TLR3/- keratinocytes were also unresponsive to UVB. Intradermal injection of synthetic U1 RNA into the ears of wild-type C57BL/6 mice, but not TLR3/- mice, resulted in induced skin inflammation. These knock-out mice also produced little or no cutaneo us TNF-α and IL-6 after irradiation with 500 mJ/cm² UVB when compared to wild-type controls. These findings establish that TLR3 detects UV damage to U1 RNA to induce an inflammatory cytokine response.

**563 DIFFERENTIAL GENE EXPRESSION RESPONSES DISTINGUISH BETWEEN DERMAL AND RESPIRATORY SENSITIZERS AND NONSENSITIZING IRRITANTS IN THE LLNA.**

Genomic approaches have the potential to enhance the specificity and predictive accuracy of existing toxicology endpoints, including those for chemical sensitization. The present study was conducted to determine whether gene expression responses might distinguish among dermal sensitizers (dinitrochlorobenzene (DNCB) and hexyl cinnamic aldehyde (HCA)), respiratory sensitizers (ortho-phthalaldehyde (OPA) and trimellitic anhydride (TMA)) and non-sensitizing irritants (methyl salicylate (MS) and nonanoic acid (NA)) in the LLNA. Female Balb/C mice received doses of each chemical per the standard LLNA dosing regimen on days 1, 2 and 3. Auricular lymph nodes were analyzed for 3HTR incorporation on day 6 and gene expression on days 6 and 10. All chemicals induced dose-dependent increases in stimulation index values with EC3 values of 0.084% (DNCB), 8.6% (HCA), 0.015% (OPA), 0.17% (TMA), 48% (MS), and 18.8% (NA). The number of differentially expressed genes was dose-dependent for each chemical and correlated strongly with the corresponding stimulation index. A majority of the genes modulated by the irritants were similarly altered by the sensitizers, consistent with the irritating effects of the sensitizers. However, a select number of responses involved with dendritic cell activation were unique to the sensitizers and may offer the ability to distinguish sensitizers from irritants. Genes for the mast cell proteases related strongly with the corresponding stimulation index. A majority of the genes associated with ESI. Results indicate that the majority of the Ac-EEMQR-amide is unabsorbed and removed from skin after washing. Decreasing amounts of peptide was detected in the deeper layers of stratum corneum (0.76%) to the viable epidermal layer (0.016%). Peptide was not detected in the dermis of the skin or receptor fluid. This absorption profile is useful for understanding the safety of cosmetic products containing short-chain peptides.

**565 SCREENING OF TOXIC INDUSTRIAL COMPOUNDS FOR CUTANEOUS INJURY.**

D. Pfefferle1, J. Plahovinsk1, J. Rhone1, F. Reid1 and J. Dillman2. Battelle, Columbus, OH and 2USAMRICD, Aberdeen Proving Ground, MD.

A weanling swine model has been used to characterize superficial dermal (SD) and deep dermal (DD) cutaneous lesions following exposure to vesicants and toxic chemicals. This study utilized this weanling swine model for screening toxic industrial chemicals with potential dermal toxicity including acrolein, acrylonitrile and hydrofluoric acid (HF). Three exposure methods were evaluated for acrolein and acrylonitrile including vapor cap, vapor cap with simulated sweat and liquid. HF was evaluated using only vapor caps. Assessments conducted on Day 2 included photographs, lesion size and modified Draize scoring. Tissues were excised on Day 2 for histopathology. Acrolein exposure by all methods resulted in some degree of dermal injury as indicated by basal cell necrosis and der mal coagulation. Increasing exposure time resulted in significantly increased injury in both lesion area and modified Draize score for animals exposed using the vapor with sweat and the liquid models. Acrolein vapor exposures with sweat resulted in the most consistent injury with a mean range of 0%-65% basal cell necrosis and a mean range of 38%-100% dermal coagulation. Acrylonitrile vapor exposure for up to 45 minutes did not result in dermal injury as evidenced by no basal cell necrosis or der mal coagulation. The lesions created by the Acrylonitrile vapor with sweat or liquid method lacked uniformity and were SD to mid-dermal in depth. HF vapor exposures consistently resulted in both SD and DD dermal injuries as demonstrated by basal cell necrosis mean range 35%-100% and dermal coagulation mean range 11%-100%. Many endpoints for the HF exposures were found to be highly signific ant including modified Draize score, basal cell necrosis, dermal coagulation, PMN epidermal infiltrate, and total inflammation severity. Clinically, the HF lesions appeared uniform and increased in severity with the increased exposure time as evidenced by the increased severity in modified Draize scores and dermal coagulation.

This work was supported by the U.S. Army Medical Research and Materiel Command, Contract W81XWH-05-D-0001, Task Order 0010.

**566 SYSTEMIC AND TOPICAL ANTI-INFLAMMATORY DRUG EFFICACY IN TREATING CUTANEOUS SULFUR MUSTARD LESIONS.**

J. Plahovinsk1, D. Pfefferle1, J. Rhone1, F. Reid1 and J. Dillman2. Battelle, Columbus, OH and 2USAMRICD, Aberdeen Proving Ground, MD.

Sulfur mustard (HD)-induced dermal lesions in the weanling swine model were used to evaluate the efficacy of topical anti-inflammatory compounds and systemic anti-cytokine treatments. This study evaluated the efficacy of diclofenac sodium (DICLO) and clotobetasol propionate (CLO) with and without systemically-administered drugs, including a tumor necrosis factor (TNF)-α inhibitor (Enbrel®), an interleukin-6 (IL-6) receptor inhibitor (Actemra®) and an IL-1β receptor antagonist (Kineret®). Superficial dermal (SD) or deep dermal (DD) lesions were generated by exposure to 400 mL of HD for 8 or 30 min, respectively. Post-exposure assessments on Days 2, 7 and 14 included lesion area, modified Draize scoring, photographs, reflectance colorimetry, transepidermal water loss (TEWL) and infrared imagery. Tissues were excised on Day 14 for histopathology. Generally, SD lesions were healed (75-100% re-epithelialization) and were similar to untreated control skin by Day 14. Epidermal and dermal necrosis, collagenolysis and inflammation were minimal in untreated SD lesions and had slightly increased scores following systemic and/or topical treatments. Fibroplasia was significantly decreased in SD lesions by Actemra® and Enbrel® without topical treatment. Generally, DD lesions were less well healed at Day 14 with severe dermal necrosis and less than 25% re-ep ithelialization. Untreated DD lesions were characterized by almost complete reten tion of the necrotic epidermis and significant dermal coagulation. Topical treatment of DD lesions with or without systemic treatment significantly decreased mean Draize scores and TEWL on Day 7. For DD lesions, CLO and DICLO+CLO significantly decreased inflammation and fibroplasia across all systemic dose groups.

In summary, the data indicate that systemic treatment with DICLO+CLO trended toward improved healing relative to all other therapeutic regimens when the primary and secondary parameters are considered.
Dicyclohexylamine (DCHA) is commonly used in the metalworking industry to prevent corrosion of fabricated materials. There is no published information describing the dermal absorption of DCHA in metalworking fluid (MWF) formulations. Machine workers are most likely to be exposed to DCHA by the dermal route. The objective of this research was to quantify the dermal absorption of DCHA in vitro using porcine skin because of its similarity to human skin both anatomically and biochemically. DCHA was applied to pig skin in water and in 3 generic MWF formulations commonly used in industry: Soluble (SO), synthetic (SYN), and semi-synthetic (SS) oil. Dermatomed pig skin (n=4) was loaded onto a flow-through diffusion cell system with individual dose areas of 0.64 cm² and perfused with media containing 4.5% bovine serum albumin for 8h to mimic occupational exposure conditions. Pig skin was dosed with 5-10% DCHA in 7 vehicles: Water, water + 5% SO, SYN, or SS oil; or neat SO, SYN, or SS oil. Dermal absorption of DCHA was similar between SO, SYN, and SS oil mixed with water, as well as between neat SO, SYN, and SS oil. Dermal absorption of DCHA from water + SS (0.08%) > water + SO (0.02%) > water + SYN (0.005%). Dermal absorption of DCHA from neat SS (0.11%) > neat SYN (0.099%) > neat SO (0.03%). The highest overall dermal absorption was at 1.4% from the water vehicle. These results suggest that water facilitates the dermal absorption of DCHA across skin whereas DCHA in MWFs may partition more with the vehicle due to its partitioning behavior. In conclusion, the varied dermal absorption of DCHA across MWF formulations must be taken into account within the machining industry and MWF manufacturing as repeated occupational exposure to this metalworking fluid additive may prove to be detrimental to human health. (Supported by NIOSH grant R01-01-03669)

Vehicle effects on the absorption of finite and infinite saturated doses of caffeine, mannitol, and testosterone in porcine skin.

The flow through diffusion cell system is an in vitro technique often used for the toxicological assessment of chemical absorption across skin. This approach routinely employs porcine skin as a surrogate membrane for human skin. Review of the literature highlights variations in experimental variables such as dosing solutions (finite/infinite or saturated/unsaturated and delivery vehicle), and receptor fluid. With such vast variations, data comparison can be difficult. This study aimed to standardize dosing solutions for three model 14C-labeled compounds (caffeine CF, mannitol MN, and testosterone TS) to evaluate the effect of delivery vehicle on absorption through porcine skin. A finite (20 μL) and infinite (1000 μL) saturated dose was applied in one of three vehicles: propylene glycol (PG), water (W), and ethanol (EtOH). Flux of each compound (n=3) into the receptor phase was monitored over 24 hours. Levels of radioactivity were also determined in the stratum corneum (by tape stripping) and the remaining skin. Apparent permeability coefficients and absorbed dose (μg) were then calculated and compared. Each compound showed unique absorption (abs.) profiles, such that from the infinite Ws doses, absorption was greater from MN (solubility 81442 μg/mL; abs. 50.4 μg) > CF (solubility 29092 μg/mL; abs. 24.9 μg) > TS (solubility 15.8 μg/mL; abs. 0.65 μg). The same profile was observed in the amount remaining in skin after 24 hours: MN (264 μg) > CF (193 μg) > TS (0.49 μg). The absorption and skin deposition profile from the infinite PG and EtOH doses followed the parent: TS > CF > MN. The skin absorption and skin deposition profile was maintained for the finite EtOH doses for all three compounds, but altered for the finite PG and Ws doses. This data highlights the variable effects a vehicle may exert on dermal absorption, suggesting that the contribution from the vehicle should be incorporated in dermal absorption models. (Supported by Novartis Animal Health, Inc.)

Xenobiotic metabolism capacities of human skin in comparison to 3D epidermis models and keratinocyte-based cell culture as in vitro alternatives for chemical testing: Phase I and II.

The metabolic competence of skin has so far not been fully characterized, although human skin fulfills important tasks in uptake, distribution and metabolism of chemicals, such as voluntarily applied substances and anthropogenic pollutants. Since the 7th Amendment to the EU Cosmetics Directive will prohibit the use of...
animals in cosmetic testing in the coming years, there is an urgent need to und-erstand the toxicological potential and test these en-zyme activities to in vitro models that may be used to replace animals in skin chem-ical testing. In this work, the enzymatic competences of the most prominent Phase I cytochrome P450 (CYP) and Phase II enzymes were investigated in ex vivo human skin, in the 3D epidermal model EpiDerm 200 (EPI-200), immortalized keratinocyte-based cell lines and primary normal human epidermal keratinocytes. Furthermore, cyclooxygenase (COX) activity was assessed, since also capable of phase I oxidation of chemicals through peroxidation. For phase II enzymes, we as-sessed activities of glutathione S-transferases (GST), N-acetyltransferases (NAT) and UDP-glucuronosyltransferases (UGT) in human skin and the alternative in vitro systems. Our data showed that basal Phase I xenobiotic metabolism enzyme activities of reconstructed epidermis are very similar to human skin microsomes. Monolayer cells, however, differ from EPI-200 and from each other in basal and in-ducible Phase I enzyme activities while they have similar phase II detoxication ca-pacities than human skin. Due to distinct phase I enzyme, especially COX, activi-ties in monolayer compared to 3D organotypic cultures, enzymatic activities of EPI-200 models are closer to human skin than monolayer cultures.

572 MAP KINASES REGULATE NITROGEN MUSTARD-INDUCED ACTIVATION OF DAMAGE-ASSOCIATED MOLECULAR PATTERNS IN MURINE KERATINOCYTES.

Exposure to chemical vesicants results in skin inflammation and blistering. To in-vestigate mechanisms underlying these responses, we evaluated the effects of the ni-trogen mustard vesicant 2-chloro-N-(2-chloroethyl)-N-methylthethylamine (HN2) on cellular signaling pathways initiated by endogenous molecules released by dying cells, damage-associated molecular patterns (DAMP). Proteins active in DAMP sig-naling include members of the toll-like receptor (TLR), TLR adaptor protein, and NOD-like receptor (NLR) families. Using RT-PCR, we found concentration and time related increases in mRNA for TLR2, 3, 6, 7 and 8 following treatment of PAM 212 murine keratinocytes with 1-30 μM HN2. Increases in TLR mRNAs ranged from 4-15 fold, reached maximal levels by 24 hr and persisted for 72 hr. HN2 also increased TLR adaptor protein mRNA for TRAF6 (10-fold), MyD88 (4-fold), and NOD2 (13-fold) maximal responses were observed after 12 hr. HN2 also increased mRNAs downstream of DAMP including COX2, IL-1beta, NF-KB and PPAR gamma; maximal effects were evident 24-72 hrs after HN2 treatment. Taken together these data indicate that DAMP signaling is altered in response to HN2 in a process mediated by TLR and NOD. In further studies, SB203580, a p38 MAP kinase inhibitor, was found to suppress HN2-induced expression of MyD88, TRAF6 and NOD2 indicating that MAP kinases regulate DAMP responses to HN2. We speculate that DAMP signaling is important in vesicant-induced skin toxicity and that regulation of DAMP by MAP kinases may modulate HN2-in-duced injury in the skin. Supported by AR055073.

573 ASSESSMENT OF HUMAN SKIN PENETRATION OF TWO IRITANT HERBICIDES.

A. Berthet1, N. B. Hopf2, P. Spiring2, A. Miles3, L. Forel1, A. Garrigou1, I. Baldi1 and D. Vernez1. 1Institute for Work and Health, Lausanne, Switzerland, 2Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland and 3Université de Bordeaux, Guignan, France. Sponsor: M. Bouchard.

Two common herbicides; isoproturon and bentazon, are strong skin irritants and cross the skin barrier easily. Assessment of percutaneous absorption of these sub-stances is a very important step in the evaluation of any dermal or transdermal dose, especially among agricultural workers who frequently have dermal exposures during crop treatment. The aims of the study were to determine the permeation rate of human skin for both herbicides in vitro, and historically evaluate skin damage due to irritation at different concentrations. Skin penetration was assessed using a dynamic flow-through in vitro penetration system and analysis were performed with ion chromatography (LC-IC50) and water activities (αw). Two concentra-tions of bentazon (75 and 150 μg/mL) and isoproturon (125 and 250 μg/mL) in saline solution were applied on excised human skin from several donors. Saline water was used as receptor fluid. Collection times were 4, 8, and 24 hours. After the experiments, the skin was removed and examined by histopathology for apop-tosis, acanthosis, acantholysis and epidermolysis. The skin permeation rate, J, was calculated from the slope of the cumulative amount permeated as a function of time. The lag time, tL, was assigned from the time-axis intercept of the extrapola-tion of this linearity. Our results showed that tL for bentazon and isoproturon for both concentrations tested were similar, 2, 1.5 hours, respectively. Bentazon had a lower J compared to isoproturon; 350, 600 ng/cm²/h, respectively. Some acan-thosis was observed after 8 hours of exposure to either of the two substances. In conclusion, our in vitro experiments demonstrate that bentazon and isoproturon cross the skin barrier within 2 hours even at very low concentrations, and showed some signs of skin damage. Future tests involve concentrations found in commer-cial products.

574 THE USE OF EXCISED HUMAN SKIN IN THE IN VITRO PREDICTION OF DERMAL CHEMICAL IRRITATION.

C. A. Stewart1, 2, R. B. Turner2, M. B. Brown1, 2 and M. J. Traynor1. 1School of Pharmacy, University of Herfordshire, Hatfield, United Kingdom and 2MedPharm Ltd, Guildford, United Kingdom.

Since the 1940s preliminary skin irritation evaluation has been conducted using the Draize test. Ethical concerns over the use of animals and recognition that the re-sponses in rabbits are not always predictive of human responses have initiated the development of in vitro which include RHE models, animal skin organ cultures and monolayer cell assays. However all of these differ from human skin by varying degrees therefore making the use of human skin the ideal model if its availability can be secured. The aim of this study was to investigate the response of testicular skin to a range of known chemical irritants and corrosives to determine and com-pare those that obtained in the in vivo Draize test. Human testicular skin (permission was obtained from South East London Research ethics committee 4 REC reference 10/H0807/51) was collected, prepared and mounted onto Millicell inserts and placed in RPMI 1640 (10% FCS, 2mM L-Glutamine, 50 IU/ml Penicillin, 50 μg/ml Streptomycin, 50 mg/ml Cholera toxin, 5 μg/ml Hydrocortisone) for 24h. The viability of the skin in culture was determined by the MTT assay; this demonstrated that viability could be maintained over the culture period (60% initial viability at 96h). To look at the response to irritants and corrosives chemicals were selected with varying Draize scores (Di-propylene glycol, IPA, Eugenol, limonene, tea tree oil, methacrolen, isostearic acid, KOH, SDS and Methyl butyric acid). Tissues were treated with 100μl of each chemical for 1h then washed with PBS to remove. The tissues where then placed in fresh media and the viability of the tissues was assessed at 48h by MTT assay and conditioned media was analysed for both IL-1α and IL-8 by ELISA. By combining the results from the cytokine response and viability assay it was possible to correctly assign 80% of the chemicals to their Draize classification i.e. non-irritants, irritants or corrosives. In conclusion the data generated supports the use of the human testicular skin in the in vitro predication of dermal chemical irritation.

575 SKIN METABOLISM OF CINNAMIC ALCOHOL AND CINNAMALDEHYDE: ITS ROLE IN CONTACT DERMATITIS.

Skin is an extrahepatic metabolizing organ. It can be involved in the metabolism of chemicals which could have penetrated it. Contact dermatitis results from the inter-action between human beings such as adhesives and endogenous proteins to form anti-genic complexes. Cinnamic alcohol (CIN-OH) and Cinnamaldehyde (CIN-CHO) are very well known pro-hapten and hapten, respectively. In this work, we studied the cutaneous metabolic fate of these two compounds. We used normal human skin (NHS) and three reconstructed human skin models (skin models) from SkinEthicTM laboratories to assure the relevance of their use. Results showed that CIN-OH is oxidized into CIN-CHO by alcohol deshydrogenases (ADH) and CIN-CHO is quickly oxidized into cinnamic acid by aldehyde deshydrogenases (ALDH). No other metabolite was detected. Apparent enzymatic parameters such as affinity (Km), maximal velocity (Vmax) and metabolic clearance, estimated by the Vmax/Km ratio, were calculated from metabolites assay in dose-effect studies. We observed that Vmax/Km ratio for ALDH (~ 0.8 ± 0.1 and 1.7 ± 0.6 μL/min×mg prot-1 for models and NHS, respectively) was more important than ADH ac-tivity (~ 0.2 ± 0.1 μL/min×mg prot-1 for NHS and models). ALDH activity was higher in NHS than in skin models but with a high individual variability. Regarding these results skin stratum corneum 300 μm will be triggered more likely when the aldehyde local concentration exceeds the capacity of ALDH isozymes to metab-olize it. Moreover, people who would be deficient in the gene expression of a crucial ALDH isoform could represent a sensitive target to CIN-CHO sensitization. In conclusion, findings show that, for these metabolic pathways, skin reveals a more detoxifying behavior than a bioactivating one. On the other hand, skin models can replace NHS to study the cutaneous metabolism of primary alcohols and aldehydes and determine the saturating concentration of substrates which could become toxic.
COMPARISON OF XENOBIOTIC METABOLIZING ENZYME ACTIVITIES IN NORMAL HUMAN SKIN AND RECONSTRUCTED HUMAN SKIN MODELS FROM SKINETHIC™ LABORATORIES.

Skin stands for the major protective barrier of the body to its environment. Also, skin is an organ involved in the metabolism of xenobiotics and its ability to metabolize them can become consequent when considering its total surface area (2 square meters). Consequently, research on skin metabolism would need a real scientific effort to characterize skin metabolizing enzymes and their activities. In addition, the European amendment to the cosmetic directive forbids the use of animal testing to assess the safety of new cosmetic ingredients. This policy has forced the cosmetic industry to develop in vitro tools such as reconstructed human skin models (skin models) as alternative methods to animal experiments. For these reasons, these skin models require to be characterized and compared with normal human skin (NHS) samples in terms of metabolic capabilities. mRNA expression of several enzymes (CYP450, Esterase, ADH, ALDH, NAT, GST, UGT, SULT...) were previously demonstrated. This work presents their apparent catalytic parameters determination (apparent Km, Vmax and the ratio Vmax/Km) in skin models compared with NHS. Results show that all these enzymes involved in the metabolism of xenobiotics are expressed and functional in the NHS and skin models. Also, the Vmax/Km ratios (estimating the intrinsic metabolic clearances) show that the metabolic abilities are the most often comparable between the skin models and NHS. These results indicate that the skin models can substitute themselves for NHS to select cosmetic ingredients on the basis of their metabolism.

SKIN SUBSTITUTE TISSUE BIOENGINEERED TO INHIBIT EXCESSIVE PROTEASE ACTIVITY IN CHRONIC CUTANEOUS WOUNDS.

C. Rasmussen1, 2, C. Thomas-Virnig1, 2, B. Steiglitz1, N. Simon1, S. Siisson1, S. Schlosser2, T. Cleven1, M. Taylor1 and L. Allen-Hoffman1, 2, StrataTech Corporation, Madison, WI and 1University of Wisconsin-Madison, Madison, WI.

Successful wound closure requires balanced matrix metalloproteinase (MMP) and tissue inhibitor of metalloproteinase (TIMP) activity for proper granulation tissue formation and keratinocyte growth and migration. Chronic cutaneous wounds exhibit a highly proteolytic environment due to an increase in MMP activity and a decrease in TIMP activity inhibiting the healing process. Our hypothesis is that a human skin substitute genetically modified with a non-viral vector to express ele-

K. T. Bogen, Exponent Health & Environmental, Oakland, CA.

In the U.S. and Europe, exposure and risk associated with dermal contact with media containing environmental chemicals are now primarily assessed using steady-state permeability data obtained from in vitro diffusion-cell experiments, or model predictions that (upwardly) adjust physico-chemical regression (PCR) fits to such data to address non-steady-state, short-term exposure conditions. This study tested the reliability of the latter approach to predict short-term dermal uptake of dilute aqueous lipophilic organic chemicals (LOCs). Effective permeability (Kup) predictions by two skin models were compared to values observed or derived from in vivo experiments that used the “difference method” to measure net chemical loss from solution over ~1 hour, with vs. without skin contact. In vivo Kup measures for over-lapping sets of 14, 17, 21 and 23 dilute LOCs were all well predicted (to within ~2-fold, r 0.89, p < 10⁻⁷) by set-specific PCR models. In contrast, the in-vitro-based Kup-prediction approach developed 20 years ago by the U.S. EPA, and still widely used, underestimates every experimentally based in vivo Kup value considered, by a median factor of ~10. Another similar model examined also tends to underestimate in vivo values substantially. Until wide discrepancies between in vivo measures and predictions based on in vitro data are better understood for aqueous organics, the in vivo database should be expanded, and it offers the more conservative basis for assessing dermal exposures by this route.
burden and is currently being used to calculate specific dose-associated decreases in tumor burden for both agents. The results support use of this model for the determination of ant-cancer therapy efficacy and surrounding normal tissue toxicity.

581 TCDD ENHANCES LIPID METABOLISM, CORNEOCYTE EXPRESSION, AND REACTIVE OXYGEN SPECIES, ACCELERATING KERATINOCYTE DIFFERENTIATION: AN INTEGRATED GENOMIC/METABOLOMIC APPROACH.

L. Kennedy1, Q. T. Tran2, S. Bodredigarī2, E. Kenciši2, R. Mohney1, C. H. Sutter2 and T. R. Sutter1, 2Chemistry, University of Memphis, Memphis, TN, 3Biological Sciences, University of Memphis, Memphis, TN and 4Metabolon Inc., Durham, NC.

Chloracne is commonly observed in people exposed to dioxins, yet the mechanism of toxicity is not well understood. The pathology of chloracne is characterized by hyperkeratinization of hair follicle cells, as well as a metabolic response of the ductular, sebum secreting, sebaceous glands. In vitro studies using normal human epidermal keratinocytes (NHEKs) to model interfollicular human epidermis demonstrate a 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-mediated acceleration of differentiation. By harnessing the combined strengths of microarray analysis and LC-MS, we integrated the effects of TCDD on NHEKs at the genomic, as well as functional level. HPTLC was used to measure changes in lipid quantities of the epidermal barrier - cholesterol, free fatty acids (FFA), and ceramides. Eight of nine ceramide classes in the lipid matrix were increased significantly by TCDD, with almost no change noted in cholesterol and FFA. Expression of numerous genes associated with cornocyte formation was increased by TCDD. Along with these increases in expression and cornocyte genes, TCDD increased mitochondrial ROS formation. Mechanisms by which TCDD increased ROS include (1) decreased levels of mitochondrial reduced glutathione with corresponding increases in oxidized glutathione, as a result of reduced mitochondrial glutathione reductase activity, and (2) reduction of enzymes and metabolites of the glycolytic pathway. Increases in ROS have been associated with mitochondrial apoptotic-like events that occur during keratinocyte terminal differentiation, indicating that increases in ROS, as well as increases in expression of lipid matrix and cornocyte genes, are mediating the acceleration of differentiation by TCDD.

582 PERCUTANEOUS ABSORPTION OF 14C-AMINOETHYLETHANOLAMINE, IN VITRO, USING THE FRANZ FINITE DOSE MODEL WITH HUMAN AND RAT SKIN.

R. Krishnraji1, P. A. Lehman2, S. G. Raney2, N. Moore2, R. J. Papciak1, R. J. Parodi1 and E. C. Bisignier1, 1Akzo Nobel, Chicago, IL, 2Cetero Research, Fargo, ND, 3Dow Europe GMBH, Horgen, Switzerland, 4Huntsman Corporation, The Woodlands, TX and 5BASF Corporation, Wyandotte, MI.

Aminoethylethanolamine (AEEA) is an organic base used in the manufacture of fuel/oil additives, chelating agents, surfactants and fabric softeners. This in vitro study was aimed at evaluating the effect of AEEA exposure on skin barrier integrity and to characterize its absorption in human and Wistar rat skin. Studies were conducted in 1cm² Franz diffusion cells using cryopreserved human skin trunk and rat skin. The skin barrier integrity test was based on the amount of 3H2O absorbed 30 min after a 5 min pulse exposure. The effect of AEEA on barrier integrity was assessed before and after (1 & 16-hr) on 8-hr exposure (5 µL/cm²) to 0, 0.25, 2.5, 10.0 and 25% AEEA (in water). The absorption of AEEA (5 µL/cm²) was measured in 3 skin donors using 0.25, 2.5 and 25% 14C-AEEA. 14C-AEEA flux was monitored over 24-hr; with removal of AEEA at 8-hr. Mass balance was assessed at 24-hr. An 8-hr exposure to 25% AEEA increased 3H2O permeability 1.5-fold (human) and 4.4-fold (rat) at 16-hr post-exposure. At lower AEEA concentrations (n=3), no changes in 3H2O permeability of human and rat skin were noted, except a 5.8-fold increase at 10% AEEA (16-hr) in rat skin. The water permeability of vehicle-only exposed rat skin, but not human skin, increased 4-fold at 16-hr post-exposure. Total AEEA absorption ranged from 14-31% (rat) and 3.2-3.6% (human). Absorption of 14C-AEEA showed a rapid early peak at ~30 min in rat, and a slow rise to a peak at ~7 hrs in human. In both, AEEA flux progressively declined after its removal at 8 hr. Thus, an 8-hr exposure to 25% AEEA concentration can moderately alter rat and human skin barrier integrity. However, the increased 3H2O permeability observed was within the normal range known for untreated human skin and is unlikely to represent a biologically relevant change in barrier integrity. AEEA can penetrate human and rat skin, but human skin is 4-10-fold less permeable than rat skin.

583 STRATAGRAFT® SKIN TISSUE AS AN ALTERNATIVE TO AUTOGRAFTING IN PROMOTING HEALING OF DEEP PARTIAL-THICKNESS BURNS.

A. Comer, M. Lokuta, K. Van Winkle, C. Thomas-Virnig and L. Allen-Hoffmann, Stratatech Corporation, Madison, WI.

Deep partial-thickness burns are clinically managed in the same manner as full-thickness burns; by surgical excision with subsequent autologous skin grafting. Alternatives to autografting to reduce the pain and morbidity associated with donor site wounds are needed. Stratagraft, a novel living human skin substitute, has been developed to treat severe burns and other complex skin defects. This skin tissue consists of a dermal layer containing normal human dermal fibroblasts and a fully-stratified, biologically-active epidermis derived from NIKS® keratinocytes. In a phase I/IIa clinical trial, Stratagraft skin tissue was well tolerated and comparable to cadaver allograft in the ability to prepare full-thickness wounds for autografting. No product-related adverse events were observed and exposure to Stratagraft tissue did not elicit an acute immune response. A phase Ib clinical trial is being conducted to examine the safety and efficacy of Stratagraft skin tissue as an alternative to autografting for deep partial-thickness burns. Up to 20 patients will have excised deep partial-thickness burns covered with Stratagraft tissue to determine if it promotes healing and eliminates the need for autografting. The primary efficacy outcomes are wound closure after 3 months and the percentage of the initial wound area that requires autografting by 28 days after Stratagraft tissue application. Additional assessments include wound cosmesis, immunological responses, and persistence of allogenic DNA. It is anticipated that Stratagraft tissue may promote healing, improve survivability and reduce pain by serving as a barrier to water loss and infection, 2) promoting healing without autografting, 3) reducing pain by covering exposed nerve endings, 4) enhancing functional and cosmetic outcomes by quickly closing the wound, and 5) avoiding painful donor site wounds by eliminating the need for autografting. Results of this study will guide development of late stage clinical trials of Stratagraft skin tissue for use in severe burns and other complex skin defects.

584 AN INTEGRATIVE APPROACH FOR THE PREDICTION OF ACUTE SYSTEMIC TOXICITY, VALIDATION OF THE MODEL, COMBINING CELL TOXICITY, AND PHARMACOLOGICAL AND PHYSICO-CHEMICAL PROPERTIES.

R. R. Note1, H. Noçairi1, M. Thomas2, L. Bourouf1, J. McKinn1, G. Ouédraogo1 and J. Meunier1, 1Safety Research, L’Oréal, Aubigny-les Bois, France and 2Cernos, Kalamazoo, MI.

Developing alternatives in the area of acute systemic toxicity remains a challenge because of the complexity of the biological processes involved. However, we have demonstrated that applying a realistic approach, based upon the combination of multiple parameters could provide promising results. We showed that considerations of cell-death data, pharmacological profiles and physico-chemical properties resulted in a significant improvement of the LD50 model originally developed by CeTox (standard model). 75% of the chemicals pertaining to a revised GHS categorization were correctly classified versus 50% with the standard model. In addition, at an LD50 threshold of 500 mg/kg, the sensitivity and specificity were 85% and 89% against 71% and 83% with the standard model. The study presented herein describes results obtained with a new selection of chemicals. A validation set that consisted of 17 compounds was evaluated in the improved method and compared to in vivo data. Cytotoxicity and pharmacological parameters were processed in conjunction with specific physico-chemical properties in order to generate LD50 predictions. The results confirmed that the integrative approach was robust and that improvements made improved the predictions of highly toxic chemicals. The results showed that 16 out of the 17 chemicals were correctly categorized. In addition, by pooling the training and validation sets, the overall predictive performance remained high, with sensitivity and specificity of 87% and 89% at an LD50 threshold of 500 mg/kg. This study is a clear demonstration that one way to address acute systemic toxicity is the combination of multiple, mechanism-based parameters and key chemical properties. However, efforts are still required to expand the applicability domain of the model and anticipate the complexity and diversity of consumer products in terms of chemical reactivity and classes of solubility profiles.

585 METHODS FOR COMPARING COMPOUND SETS BASED ON THEIR PRECLINICAL IN VIVO STUDY OUTCOMES.

N. Greene, A. Fenayetallah, S. Louise-May and X. Wang, Pfizer Inc., Groton, CT.

In recent years there has been increasing interest in developing in vitro assays that are predictive of in vivo outcomes. In order to validate in vitro assays it is necessary to have a large set of compounds where the in vivo outcomes are known and can be
compared to the responses in the assay. Most efforts have focused on comparing assay responses to specific lesions like proximal tubule damage or broader grouped phenotypic responses like hepatotoxicity to see if trends and patterns exist.

However, recent publications have described other approaches using a more holistic comparison of the in vivo responses of compounds. One method used the systemic exposure at which the first sign of injury was observed irrespective of the nature of that injury to compare compound responses [1]. Other methods used the survival of a compound to a first in human clinical trial to look at properties of compounds that are most likely to succeed [2].

Here we describe an approach to provide a quantitative measure of the level of severity of in vivo toxicity thus combining findings across dose groups to yield a single metric of in vivo toxicity at the compound-study level to enable comparisons across compounds. This method was then applied to a set of Pfizer compounds to see how this measure relates to chemical properties and in vitro assay profiles when compared to a previously used system for classifying compounds. In general, the trends previously observed with physicochemical parameters such as lipophilicity and polarity remain unchanged yet there are improvements in the correlation to cytotoxicity measures [3] suggesting that this approach to comparing compounds improves upon previous classification systems.

587 ZEBRAFISH AS A MODEL FOR QUANTITATIVE ASSESSMENT OF HUMAN DEVELOPMENTAL TOXICITY.

C. R. Fleming1 and J. C. Lambert2. 1Oak Ridge Institute for Science and Education, Cincinnati, OH and 2US EPA, Cincinnati, OH.

The zebrafish model has been shown to be a useful screening tool for qualitatively predicting mammalian developmental toxicity, both in terms of whether or not a chemical is teratogenic and the types of effects produced. However, application in risk assessment requires quantitative dose-response information. This study addresses the quantitative relationship between effect levels for developmental endpoints in zebrafish and rodent assays. To allow for comparison of effect levels, zebrafish studies using aqueous exposure with no estimate of dose to the egg (e.g. mg/kg) were excluded. For each chemical, rodent studies were identified which provided dose response data for similar endpoints as those measured in the zebrafish assays. The LOAEL (based on maternal dose) in the rodent studies was then compared to the estimated dose (e.g. mg/kg) to the zebrafish with suitable zebrafish studies were identified: 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), ethanol, caffeine, domoic acid (DA), and all-trans retinoic acid (tRA).

The ratios of rodent LOAELs to zebrafish LOAELs for specific developmental endpoints in these studies were as follows: TCDD, 2.9-3.8; ethanol, 1.0-2.3; caffeine, 2.1; DA, 1.5-2.7; tRA, 6.3-6.7. Comparing study LOAELs across all endpoints rather than for specific effects, the rodent:zebrafish ratios were 1.2-2.7. In all cases, developmental LOAELs from rodent studies were within an order of magnitude of developmental LOAELs in zebrafish. For most endpoints, the zebrafish was slightly more sensitive than rodents. This suggests that in cases where rodent developmental data are not available, the zebrafish may serve as a viable alternative for rapid and inexpensive quantitative assessment of developmental toxicity. Further study with a wider array of chemicals is necessary to validate this approach. The views expressed in this abstract are those of the authors and do not necessarily reflect the views or policies of the US EPA.

588 ACTIVITY OF US EPA's TOXCAST COMPOUNDS USING A C. ELEGANS GROWTH SCREEN.

W. A. Boyd1, M. V. Smith1, J. R. Rice2 and J. H. Friedman1,2. 1BSR, NTP, Research Triangle Park, NC, 2ISTD, US EPA, Research Triangle Park, NC and 3LTP, NIEHS, Research Triangle Park, NC.

Tox21, an intergovernmental toxicity community, is exploring the use of high-throughput in vitro tests and alternative model organisms for prioritizing the large numbers of chemicals with limited toxicological data for more comprehensive testing and to develop prediction models for human disease. As part of this effort, the US EPA is evaluating collections of chemicals in a program known as ToxCast™. The ToxCastTM Phase I library contains 309 unique compounds, mainly pesticide active ingredients with well-characterized mammalian toxicities. The ToxCast™ Phase II library contains 67 novel chemicals including food additives, and industrial products. Toxicity assays in 96-well formats have been developed for C. elegans including reproduction, growth, and feeding using the COPAS Biosort. The C. elegans growth assay, which measures changes in size after a 48-h exposure, was used to screen both ToxCast™ libraries. Chemical activity was evaluated when possible by half-maximal effective concentrations (EC50s) and lowest effective concentrations (LECs). Previously, we reported that 64% of the Phase I chemicals were classified as active using an activity score based on decreased size at each concentration as well as steepness of negative concentration-response trends. Because the Phase II compound set is more chemically diverse, we expected a lower percentage of active compounds than for Phase I. However, 57% of chemicals were found to decrease C. elegans growth and development at the highest concentration tested (ranging from 48 μM to 100 mM). Excellent reproducibility was observed for the eight chemicals replicated in the Phase II library: seven were active and one was inactive in all replicates. Information and experience gained from the C. elegans screening of the ToxCast™ libraries will be used to inform the design of future toxicity screens of the Tox21 library, which contains approximately 10,000 compounds.

589 PROLIFERATION AS A KEY EVENT IN DEVELOPMENTAL TOXICITY: CHEMICAL SCREENING IN HUMAN NEURAL STEM CELLS USING HIGH-CONTENT IMAGING.

New toxicity testing approaches will rely on in vitro assays to assess chemical effects at the cellular and molecular level. Cell proliferation is imperative to normal development, and chemical disruption of this process can be detrimental to the organism. As part of an effort to elucidate toxicity pathways, we screened 38 known developmental toxicants for effects on proliferation of neural stem cells. Human neuroprogenitor (ReN CX) cells were grown in 96-well plates and exposed to chemicals (0.001 to 100 μM) for 24 h. BrdU, which incorporates into replicating DNA, was added to the cells 20 h post exposure. Proliferating (BrdU positive) cells were identified using immunocytochemistry and automated image analysis; cell viability was assessed in duplicate plates. The concentration which caused a 30% decrease from control (EC30) and the lowest statistically effective concentration (LEC) were compared across endpoints and chemicals. Of the 38 developmental toxicants tested, 16 induced at least a 30% decrease in proliferation, and in 14 cases this effect was also statistically significant. Thirteen out of the 16 chemicals affecting proliferation were known developmental neurotoxicants. For the chemicals that decreased proliferation, 6 did so at concentrations that did not affect cell viability. Seven chemicals with no reports of developmental toxicity (negative controls) were
also tested, and did not affect proliferation or cell viability. These results demonstrate the ability to screen rapidly chemicals for effects on cell cycle, a key event in development. Effects of this chemical set will be examined in other model systems (embryonic stem cells, zebrafish) to identify common pathways leading to developmental toxicity. This abstract does not necessarily reflect US EPA policy.

590 DEVELOPMENTAL EXPOSURE TO PFOS OR PFPA INDUCES SIMILAR BEHAVIORAL ALTERATIONS IN ZEBRAFISH AND IN MICE.

S. Spulber1, W. Wan Ibrahim1, M. Ul Haq1, L. Norgren2 and S. Cecchettili3.
1Department of Neuroscience, Karolinska Institute, Stockholm, Sweden and 2Department of Pathology, Swedish University of Agricultural Sciences, Uppland, Uppsala, Sweden.

The Zebrafish (ZF) has emerged as a relevant whole-organism model attractive also for behavioral neurotoxicologists, since the fish shows most of the behavior seen in terrestrial species. We have implemented ZF as a model for developmental neurotoxicity (DNT) studies and the initial aim is to evaluate our ZF behavioral data after ethological validation against the background of knowledge from rodent models. In this study we have tested the visual locomotor response in ZF larvae following developmental exposure to perfluorooctanoic acid (PFOA) or perfluorooctane sulfonate (PFOS) and compare the results with our behavioral data from PFOS- and PFOA-exposed mice. Fertilized ZF eggs were continuously exposed to 0.1 or 1 mg/L PFOS or PFOA in the water starting at 2 hpf (1-2 cell stage). The visual locomotor response was tested at 96 hpf by exposing the fish to a brief alternating period of light and darkness in a controlled environment that allowed live video tracking. Abrupt changes in light intensity induce a burst of swimming activity that typically subsides within 10 min after switching the light off in the observation chamber. Mice were exposed to 0.3 or 3 mg/kg PFOS or PFOA via maternal food throughout pregnancy. Locomotor activity was recorded at 5-6 weeks of age within 2 h after moving to a novel environment. After deriving similar parameters for the analysis of locomotor activity in both species, we found that both chemicals had similar effects in mice and ZF with similar dose-response curves. We found that exposure to either PFOS or PFOA resulted in hypoactivity and an accelerated decay in locomotor activity during the observation period. In light of additional behavioral observations, these findings are suggestive for a decrease in neuromuscular endurance in the animals exposed during early developmental stages. Taken together, our data point to ZF as a promising model for DNT studies designed for screening purposes and/or identification of mechanisms of neurotoxicity.

591 INVESTIGATION OF ZEBRAFISH YOLK SAC INJECTION.

C. Doshna, H. Fisharath and M. Alen, Pfizer, Groton, CT.

Zebrafish (ZF) is an upcoming animal model for toxicity assessment. However, unlike mammalian models, routes of drug administration for ZF are limited to exposure to either PFOS or PFOA via maternal food injection (p < 0.05, N = 5-8). D25 may block OCT3 or OCT3-like uptake 2 sites in mouse and zebrafish brains. Using a polyclonal rabbit anti-rat OCT3 antibody, we found that OCT3 mRNA type-labeling was 30% higher in zebrafish whole brain than in the mouse hippocampus, where OCT3 is richly expressed (N=5). Saturation binding of [3H] D22 in zebrafish whole brain and mouse hippocampal homogenates revealed a common KD of P = ± 1.5 mM, and a Bmax of 3532 ± 1187 fmol/mg protein in the zebrafish brain, and a Bmax of 1186 ± 231 fmol/mg protein in mouse hippocampus (N=3). Binding of [3H] D22 D25 uptake was blocked by the neurotoxic MPTP metabolite MPP+, a known substrate of OCT3. In OCT expressing HEK cells, [3H] MPP+ uptake was blocked with D25 with IC50 values (µM) of 0.9 ± 0.4 for OCT1, 0.3 ± 0.1 for OCT2 and 0.8 ± 0.2 for OCT3 (N=5). OCTs have affinity for and/or transport many endogenous and xenobiotic compounds, and it appears that their properties in zebrafish and mice are preserved. Further study of uptake 2 in zebrafish is necessary to determine if D22 is blocking OCT3-like transporter(s) in brain. Support by: NIMH064489, NIMH086708 & T42CCT610417.

592 BEHAVIORAL AND BINDING PROPERTIES OF DECENCYNNUM-22 IN ZEBRAFISH AND MICE.

G. G. Gould, R. E. Horton, J. C. Groh, W. A. Owens and L. C. Dawes, Physiology, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Uptake 2 mechanisms such as organic cation transporters (OCTs) modulate monoamine neurotransmission in brain. Their blockade produces effects similar to selective serotonin reuptake inhibitors. For example, decencynnum-22 (D-22) blocks 5-HT uptake and produces antidepressant-like effects in mice (Baganz et al., 2008, PNAS 105:18976-18991). We explored the behavioral and neurochemical properties of D-22 in mice and zebrafish. Administration of D-22 (0.01 mg/kg) or dizapam (1 mg/kg) significantly increased social approach in BTBR mice 50 min after injection (p < 0.05, N = 6). However, unlike dizapam, D-22 did not reduce marble burying in BTBR mice. In adult zebrafish, 5 min bath exposure to either 12.5 ± 0.2 or 125 ± 24 h D-22 did not affect swimming behavior, but without a reference dye. In the drive-tank or light/dark plus maze anxiety tests. In contrast, 25 mg/L buspirone increased top-dwelling in the drive-tank (p < 0.05, N = 5-8). D25 may block OCT3 or OCT3-like uptake 2 sites in mouse and zebrafish brains. Using a polyclonal rabbit anti-rat OCT3 antibody, we found that OCT3 mRNA type-labeling was 30% higher in zebrafish whole brain than in the mouse hippocampus, where OCT3 is richly expressed (N=5). Saturation binding of [3H] D-22 in zebrafish whole brain and mouse hippocampal homogenates revealed a common KD of P = ± 1.5 mM, and a Bmax of 3532 ± 1187 fmol/mg protein in the zebrafish brain, and a Bmax of 1186 ± 231 fmol/mg protein in mouse hippocampus (N=3). Binding of [3H] D-22 D22 uptake was blocked by the neurotoxic MPTP metabolite MPP+, a known substrate of OCT3. In OCT expressing HEK cells, [3H] MPP+ uptake was blocked with D25 with IC50 values (µM) of 0.9 ± 0.4 for OCT1, 0.3 ± 0.1 for OCT2 and 0.8 ± 0.2 for OCT3 (N=5). OCTs have affinity for and/or transport many endogenous and xenobiotic compounds, and it appears that their properties in zebrafish and mice are preserved. Further study of uptake 2 in zebrafish is necessary to determine if D-22 is blocking OCT3-like transporter(s) in brain. Support by: NIMH064489, NIMH086708 & T42CCT610417.

593 COMPARATIVE EVALUATION OF THE CONVENTIONAL RADIOACTIVE LOCAL LYMPH NODE ASSAY AND NONRADIOACTIVE ALTERNATIVES.

J. Wieland1, A. Poth1 and C. Spohr2, 1Genetic and Alternative Toxicology, Harlan CyntoCell Research GmbH, B oudorf, Germany and 2Technical University Darmstadt, Darmstadt, Germany.

The Local Lymph Node Assay is able to detect not only the sensitizing properties of chemicals but also the potency of a potential allergen, by evaluating different test concentration. OECD 429 includes the radioactive determination of incorporated 3H-Thymidine in the proliferating lymph node cells, whereas OECD 442B describes the nonradioactive determination by the ELISA-technique. The presentation will describe a comparative evaluation of both methods and the use of additional parameters included in the LLNA for discriminating sensitization from irritation. For this DNBC, HCA, Eugenol, Croton Oil and Benzoic acid were investigated in the LLNA following OECD 429 and 442B. As additional parameters for discriminating sensitization from irritation, evaluation of the total cell count and of the ear and lymph node weights were used. The results indicate that the conventional radioactive method, the ELISA method and the determination of the total number of cells allowing a clear differentiation between moderate, strong, extreme and nonsensitizers. It was shown that the determination of the ear thickness as an additional parameter has only limited value because of the inaccuracy of the method. The data lead to the conclusion that the LLNA ELISA method 442B is a useful substitute to the conventional radioactive LLNA (OECD 429), which will lead to minimisation of occupational radioactive exposure and to the elimination of radioactive waste and as well as to the performance of the LLNA in laboratories which are not licensed to use radioactive reagents.

594 ANIMAL STRAINS IMPACT THE LLNA-BRDU RESULT.

D. Hayashi1-3, Y. Nozaki2, H. Takagi2, T. Satoh3,4, R. Guest1 and T. Anzai3-5, 1Harlan Laboratories Co., Ltd., Tokyo, Japan, 2Japan SLG, Inc., Hamamatsu, Japan, 3Department of Legal Medicine, Showa University School of Medicine, Tokyo, Japan, 4HAB Research Institute, Chiba, Japan and 5Harlan Laboratories Ltd., Shardlow, United Kingdom.

OECD 442B describes the Local Lymph Node Assay (LLNA): BrdU_ELISA method for evaluation of skin sensitisation potential of chemicals without the use of radiotopes. The method utilizes non-radiolabelled 5-bromo-2-deoxyuridine
in composition due to source of the extracts. The toxicity class was established by a literature review on KE indicated 10 principal constituents with small variations. The compound was recovered. There is no strong scientific evidence to support such claims. It is considered beneficial to the skin, helping to maintain skin hydration, barrier function, and pH. In addition, geniposide is known to have antioxidant activity, anti-inflammatory effects, and anti-apoptotic properties.

Intestinal microflora is able to produce toxic or carcinogenic metabolites and induce more potent cytotoxicity against cells than non-metabolites. This study was performed to investigate the cytotoxic responses of geniposide and its metabolite to determine the metabolism of cytotoxic activities. Genipin, geniposide metabolite, increases cytotoxic effect in cells, but not with geniposide. Incubation of geniposide with intestinal microflora, its aglycone genipin could be produced by β-glucosidase, and cytotoxicity was detected which was highly increased when compared to geniposide. Western blot analysis revealed the phosphorylated e-Jun NF2 terminal kinase (JNK), caspase-3 and bax protein significantly increased in a dose-dependent manner after treatment of activated geniposide. In our thinking, the activation of JNK maybe result in the increase of the bax protein, which further induced cell apoptosis death. However, geniposide alone did not induce cytotoxicity as well as caspase-3. In addition, activated geniposide-induced apoptosis was confirmed by apoptosis assay, and generated reactive oxygen species (ROS), and N-acetyl-L-cysteine (NAC) suppressed activation of ROS and apoptotic cell death. Taken together, these findings suggest that the human intestinal microflora is capable to metabolize geniposide to genipin and its related biological activities and induced apoptosis. This research was supported by a grant (09172KFDAA916) from Korea Food & Drug Administration in 2011.

A WEIGHT-OF-EVIDENCE APPROACH FOR THE SAFETY EVALUATION OF KOMBUCHA EXTRACT IN COSMETIC PRODUCTS.

R. Persaud, T. Re and V. Srinivasan. Safety Evaluation, L’Oréal R & I, Clark, NJ.

Kombucha Extract (KE) is derived from the fermentation of yeasts and bacteria with black tea, sugar, etc. It is used in a variety of cosmetic products. As Kombucha Tea, it is consumed as a beverage in many parts of the world and thought to exert a number of therapeutic benefits in metabolic diseases, arthritis, psoriasis, constipation, indigestion, hypertension, etc., although there is no strong scientific evidence to support such claims. It is considered beneficial to the skin, helping to maintain moisture and elasticity so it appears more even in tone and texture. The KE components vary with the species of bacteria and yeasts, fermentation time, quantity of substrates in culture and exposure conditions. Being a complex mixture, safety data is not readily available, so we utilized a weight-of-evidence (WoE) approach to support its safe use in personal care products. This evaluation entails an initial in silico screening, read-across review, in vitro skin irritation estimation, establishing allowable exposure values based on TTC, and a clinical study to confirm skin tolerance. A literature review on KE indicated 10 principal constituents with small variations in composition due to source of the extracts. The toxicity class was established by the Cramer rules using ToxTree, DEREK (for structural alerts) and OECD Toolbox (for “read-across”) evaluations were performed. Octanol-water partition coefficient and water solubility (from EPISUITE) with the molecular weight were used to estimate dermal penetration. An exposure calculation for each KE constituent was done for a face cream at use level of 3%. The exposure was then compared to allowable levels of systemic exposure for each constituent. Results from in silico analysis verified each KE constituent was at a safe use level. An in vitro EPISKIN assay with the 3% KE face cream demonstrated it would not be a skin irritant. A clinical study revealed the face cream was neither a skin irritant nor sensitizer. Therefore, Wolf approach is very useful in confirming the safety of a cosmetic ingredient in a product prior to market launch.

A WEIGHT-OF-EVIDENCE-BASED APPROACH FOR THE SAFETY ASSESSMENT OF JUNIPERUS COMMUNIS BERRY EXTRACTS IN PERSONAL CARE PRODUCTS.

Natural, plant-derived ingredients are increasingly being used in personal care products but the safety evaluation of these poorly characterized complex mixtures is a challenge. We previously demonstrated the safe use of Juniper Berry Oil (JBO) utilizing a combination of the Threshold of Toxicological Concern (TTC) with a weight-of-evidence approach. JBO is typically steam distilled and has low molecular weight components with a significant potential for percutaneous absorption. Juniper berries can also be extracted using organic solvents or CO2 yielding different concentrations and components. As with JBO, we classified extract constituents according to generic groups using the JECPA approach. For each chemical constituent, its maximum known concentration in the oil, its molecular weight, and the estimated skin penetration potential were used to estimate a maximal daily systemic exposure. These nominal exposure values were compared to the respective TTC and/or the food intake values of “no safety concern.” In cases where systemic exposure exceeded TTC levels, additional evaluations were done. For each generic group, constituents with adequate safety data were identified and extrapolated to other members of the congenic group in a “read-across” approach. In the extracts, a new component, 1,2-epoxy-1,5,8,9-tetramethyl-undeca-5,9-diene, exceeded its TTC value at the initially set use level. Potential structural alerts and a metabolic profile for this component were generated using Derek Nexus and Time computer programs. These did not allow a presumption of safety; therefore, the use concentration of this extract needs to be reduced to exposure values below its TTC value. Using juniper berry extracts as an example, we are able to demonstrate the practical utility of a weight-of-evidence approach using TTC, read across and other in silico tools to evaluate and limit the safe use of complex plant-derived materials in cosmetic and personal care products.

IN VITRO KINETICS OF CHLORPROMAZINE IN CYTOTOXICITY ASSAYS WITH CACO-2, BALB/c 3T3 AND HEPG2 CELLS.

The toxicity of compounds can be tested in in vitro assays using different types of cells. The cells are usually exposed to the test compound for 24-72 hours after which the viability of the cells is determined. However, different cell types need different culture conditions, including the presence of serum in the medium. The aim of this project, part of the European project Predict-IV, was to study the in vitro kinetics of the pharmaceutical chlorpromazine (CPZ) in three different cell assays. Three cell types were used for the cytotoxicity assays: the human intestinal cell line Caco-2 cells, mouse fibroblast Balb/c 3T3 cells and the human liver cell line HepaRG cells. The cells were cultured for 24 hours and the Caco-2 cells for 1 week. The HepaRG cells were cultured for 4 weeks, with 2%DSMO in the medium in the last 2 weeks. Next, the cells were exposed to different concentrations of CPZ for 48 hours. Medium samples were taken at the beginning and at the end of the exposure. Viability of the cells was measured by the Alamar Blue method. At the end of the exposure, CPZ was extracted from the cells and well plastic. Nd-SPME was used to determine the free concentration of CPZ in the medium. All samples were analyzed by HPLC-UV.

The amount of CPZ in the medium decreased over time; the most pronounced decrease was seen in the metabolically competent HepaRG cells. Plastic binding of CPZ is negligible in all three systems. At the end of the exposure, all CPZ was recovered from the Caco-2 and Balb/c 3T3 cells; in the HepaRG cells less parent compound was recovered. The Balb/c 3T3 cells appear to be the most sensitive to chlorpromazine based on the nominal concentrations. Protein binding influences the cytotoxicity results; therefore the free concentration is an important factor. In conclusion, chlorpromazine differ in vitro kinetics in different cell systems. Thus, for a better interpretation of cytotoxicity results, it is important to take these in vitro kinetics into account.
Drug-induced phototoxicity can be caused after the exposure of skin to photoreactive drugs, triggered by sunlight exposure to the body surface. The establishment of effective methodology to predict the phototoxicity has been attempted over the past few years. Recent studies demonstrated that generation of reactive oxygen was responsible for the induction of early phototoxic events. Reactive oxygen species (ROS) assay to determine ROS generated from photoirradiated chemicals was proposed for recognizing their phototoxic potential. The present study was undertaken to evaluate the intra- and inter-laboratory accuracy and precision of the ROS assay using 44 coded chemicals, and the validation study was supervised by the Japanese Center for the Validation of Alternative Methods (JaCVAM). Most phototoxic chemicals tended to generate singlet oxygen and superoxide under light exposure, but non-phototoxic chemicals did not. The intra- and inter-day precisions (coefficient of variation; CV) for the determination of ROS from irradiated quinine (200 μM), a typical phototoxic drug, were found to be 3.3 and 4.5%, respectively. The inter-laboratory CV for quinine averaged 10.2% for singlet oxygen and 26.0% for superoxide. Z’-factors for the determination of singlet oxygen and superoxide were calculated to be 0.92 and 0.87, respectively, demonstrating a large separation band between samples and blank signals. These data would be indicative of suitability of ROS assay for phototoxicity prediction.

Human hepatocytes represent the “gold standard” for drug metabolism, drug-drug interactions, and in vitro hepatotoxicity studies. One drawback of the use of human hepatocytes in culture is that drug metabolizing enzyme activities such as CYP3A4 would decrease rapidly in culture (approximately 90% decrease per day) to 10% of the initial activity after several days. This drawback limits the use of the hepatocytes, especially for prolonged metabolism (e.g., for slowly metabolizing compounds), or to mimic low-dose, chronic exposure to hepatotoxic compounds. We report here the results of culturing human hepatocytes in a novel medium, Li’s Differentiation Maintenance Medium (LDMM). Cryopreserved hepatocytes from three donors were cultured in Cryopreserved Hepatocyte Plating Medium (CHPM) or LDMM for 14 days. CYP3A4 activities were quantified using Lucifer-IPA as substrate from days 1 (day of plating) to 14. While both media were able to maintain viability of the hepatocyte cultures, CYP3A4 activity decreased as expected in CHPM to nearly nondetectable level at day 14, while that in LDMM decreased from day 1 to approximately 50% at day 4, then increased to near day 1 level from days 7 to 14. This phenomenon was observed in all of the three lots of cryopreserved human hepatocytes. Treatment of hepatocytes cultured in LDMM with CYP3A4 inducer led to activities higher than that on the day of plating, thereby modeling in vivo situation. Evaluation of gene expression showed that human hepatocytes cultured in LDMM expressed near normal level of differentiation markers, uptake and efflux transporters. The results suggest that LDMM represent an improved culture medium which would extend the application of human hepatocytes in drug metabolism, drug-drug interactions, and hepatotoxicity studies.

The human liver contains a variety of metabolic enzymes, and understanding the role of these enzymes in drug metabolism is an important area of research that impacts human toxicology testing, and ultimately drug safety. Approximately 40% of drugs metabolized in the liver due to liver metabolism, and it is not identified until the late stage in the drug development process. Efforts have been made to position predictive in vitro screens earlier in the drug discovery process. To address this need, Solidus Biosciences has developed the DataChip/MetaChip platform that couples a 3-D cell culture microarray with a complementary microarray consisting of recombinant enzymes to identify metabolism-induced toxicity in a high-throughput manner. The DataChip platform has contained 532 elevated micropillars, each supporting 60-nL alginne 3-D matrices consisting of Hep3B cells, that become submersed in microwells of the complementary MetaChip. Various mixtures of recombinant enzymes are used to metabolize drugs, and the results are compared to the in vivo data to identify metabolic liabilities.

The human liver contains a variety of metabolic enzymes, and understanding the role of these enzymes in drug metabolism is an important area of research that impacts human toxicology testing, and ultimately drug safety. Approximately 40% of drugs metabolized in the liver due to liver metabolism, and it is not identified until the late stage in the drug development process. Efforts have been made to position predictive in vitro screens earlier in the drug discovery process. Various mixtures of recombinant enzymes are used to metabolize drugs, and the results are compared to the in vivo data to identify metabolic liabilities.
binant metabolic enzymes that are designed to mimic the metabolic reactions in the human liver were encapsulated within 120 µL spots of Matrigel in the microwells to enable the in situ generation of metabolites. To validate the DataChip/MetaChip platform for metabolism-induced toxicity, 10 literature compounds which carry warnings for hepatotoxicity or have been withdrawn from the market due to idiosyncratic hepatotoxicity were tested. The toxicity of 7 compounds out of 10 was correctly identified using this approach. In addition, 22 proprietary Pfizer compounds were selected for validation as well. Of the 22 Pfizer compounds, 10 showed deactivation on metabolic enzyme spots, whereas 3 showed activation of the toxic response. Troglitazone was included as a control compound on every chip for standardization. The DataChip/MetaChip platform shows minimal day-to-day and chip-to-chip variability, and high-throughput capability and predictability to identify metabolism-induced toxicity at early stages in compound safety assessment.

**604 TEAMCHIP FOR HIGH-THROUGHPUT GENE TRANSFECTION AND METABOLISM-INDUCED TOXICITY SCREENING.**

M. Lee, S. Kwon1, D. Lee, D. Shah, B. Ku, D. S. Clark1 and J. S. Dordick1.
1Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY, 2Central R & D Institute, Samsung Electro-Mechanics Co., Suwon, Republic of Korea, 3Chemical and Biomolecular Engineering, University of California Berkeley, Berkeley, CA and 4Solidus Biosciences Inc., San Francisco, CA.

Variation in metabolic enzyme expression among segments of the human population may cause deviations from the expected pharmacokinetic profile of a drug, resulting in idiosyncratic toxicity or a lack of efficacy. Cell lines that stably express individual or combinations of metabolic enzymes are emerging tools for prediction of these rare clinical events; however, it is difficult to create and maintain a library of stable cell lines that mimic the diversity of metabolic profiles that could arise to unanticipated outcomes. In addition, it is difficult to control the expression levels of each of the enzymes in stably-transfected cell lines. To address this need, we have developed a Transfected Enzyme and Metabolism Chip (or TeamChip) for high-throughput analysis of systematic drug metabolism and toxicology. The TeamChip is prepared by simultaneously infecting an array of miniaturized 3-D cell cultures with varying concentrations of recombinant adenosines carrying genes for different metabolic enzymes, which generates an array of cell cultures with differentiated metabolizing capabilities. We have demonstrated the controlled expression of individual and multiple reporter proteins (GFP and RFP) and drug-metabolizing enzymes (CYP3A4, CYP2C9, and UGT1A4) in three human liver cell lines (HepG3B, HepG2, and THLE-2 cells) on a microarray platform by altering the multiplicity of infection of the various recombinant adenosines. As a proof of concept, 10 model compounds that were shown to be hepatotoxic, in some cases idiosyncratically and withdrawn from the market, were tested to simulate enzyme-specific hepatotoxicity. These studies demonstrate that the TeamChip platform can provide critical information necessary for evaluating metabolism-induced toxicity in a high-throughput manner.

**605 SELECTING GENES FOR USE IN A HIGH-THROUGHPUT MECHANISM-BASED TOXICITY SCREEN USING C. ELEGANS.**

R. B. Goldsmith1, J. R. Pireone2, W. A. Bond1, M. V. Smith and J. L. Freedman1.
1DNTP, NIEHS, Research Triangle Park, NC and 2SRA International, Durham, NC.

The high level of homology between the stress response pathways and genes in mammals and nematodes can be leveraged to create a high-throughput toxicological screen in C. elegans to predict responses in higher organisms. Transcriptional response was measured in several strains of transgenic C. elegans containing fluorescent protein driven by the promoters of stress-inducible C. elegans genes. This system captured both changes in pathway activation, as well as tissue-specificity of gene expression. Genes of interest encompassed a broad variety of identified mechanisms of toxicity including: heat shock proteins, metallothioneins, UDP-glucuronosyl transferases, P450s, and glutathione-S-transferases. To select genes with a sensitive and specific stress response, we compared transcription of stress response genes using an array of well understood compounds: paraquat, ethyl methanesulfonate, cadmium, chlorpyrifos and tunicamycin. These chemicals were used to create a toxicant response profile, representing oxidative stress, DNA damage, metal toxicity, neurotoxicity and ER stress pathways, respectively. Nematodes were treated with low, medium and high concentrations (covering 1-2 orders of magnitude) of each toxicant. Florescence intensity was measured from images of transgenic nematodes via heat shock. For example, a transcription at the highest concentrations was confined by overt toxicity. These results illustrate that a model of toxicity based on gene regulation in C. elegans is a viable method for detecting subtoxic responses in a high-throughput assay.

**606 USE OF IN VITRO BIOASSAY AND CLINICAL DATA FOR MODELING DRUG-DRUG/Chemical Interactions (DDCIs) MEDIATED BY CYTOCHROME P450 3A4.**

Y. Tie and E. Demchuk. ATSDR/CDC, Atlanta, GA. Sponsor: B. Fowler.

Cytochrome P450 3A4 is responsible for metabolism of many xenobiotics. Co-administration of drugs and environmental chemicals may cause changes in 3A4 metabolism that can lead to different health outcomes. Such DDCIs are difficult to evaluate during the pre-clinical stage of drug development. In the present work we focus on the feasibility of using in vitro 3A4 inhibition data from high-throughput screening (HTS) assays to estimate the in vivo DDCIs that were observed. The in vitro HTS data were obtained from the PubChem database, in which 13,072 compounds previously have been categorized as active, inactive, or inconclusive based on the inhibition constant, IC50. Alternatively, 702 drugs categorized in the literature based on the drugs’ clinical effects were used: 241 of them inhibited 3A4 and 461 did not. For the 702 drugs only 260 were in common with the HTS database. The overlapping drugs were further categorized in PubChem as active, 142 active and 69 inactive. Using the clinical data as a reference and HTS data as a predictor, we evaluated the utility of HTS as a classifier of clinical DDCIs and obtained a 43.5% sensitivity, 84.4% specificity, and 69.6% overall accuracy. The potency of 241 drugs that inhibit 3A4 in vivo was examined. Based on clinical categorization given by the Merck Manual, 35 were attributed to potent and 88 to weak inhibitors of 3A4. 46 of the 121 compounds were in common with the HTS dataset, of which only 17 were labeled in PubChem as active. Their IC50 values were then extrapolated to in vivo pharmacokinetic area-under-curve ratios, and subsequently subjected to categorization according to their inhibition potencies following the FDA guide. Unfortunately, 10 of the 17 inhibitors could not be categorized because of insufficient statistical power of the data, although among 7 drugs that were successfully classified, no misclassification of metabolic reactions was observed. If the HTS study design is improved, in vitro data may become useful for classification of clinical DDCIs mediated by 3A4. However at present, HTS data are not yet fully representative of the in vivo potency of inhibition.

**607 USE OF PHYSIOLOGICALLY-BASED PHARMACOKINETIC MODELING (PBPK) IN CONJUNCTION WITH CELLCHIP™ TO PREDICT COMPOUND SAFETY THRESHOLDS AND IMPROVE LEAD OPTIMIZATION.**

C. J. Strock1, S. Qin2, H. Luitjhardt1, J. Gilbert1, K. Trajan1, P. Metcalfe1, S. Thomas2, M. Alba and Y. Will2.
1Compound Safety Prediction, Pfizer Global Research & Development, Groton, CT, 2Apyreca, Watertown, MA.

The CellCiphr™, an in vitro High Content Screening (HCS) Toxicity platform has been used by us to delineate mechanisms of toxicity as well as to predict the maximum plasma concentration of a drug (Cmax) at which a compound is classified as presenting toxic side effects through retrospective analysis of compounds with in vivo exposure and toxicity data. However, at early stages of drug discovery, before safety information is generated in vivo in animals and humans, the practical use of this information in prioritizing compounds is limited by the absence of in vivo exposure data. Here we explored if in the absence of in vivo data, one can apply CellCiphr™ in conjunction with Cloe PK, an in silico Physiology Based Pharmacokinetic (PBPK) modeling program that predicts Cmax from oral dosing, to predict dosing regimens for both rodent and human testing. We demonstrate that Cloe PK, can be mathematically inverted in order to predict an oral dosing regimen from a given Cmax safety threshold. This mathematical development, based predictive toxicology platform. We show how technical issues, (e.g., varying metabolism of different compounds in vivo and varying dosing protocols), affect the outcome of the simulations, and how these considerations can provide guidance to proper preclinical in vivo experimental design. We demonstrate the effectiveness of this predictive model for members of the piperazine family of antidepressants, oxaprozin, disoproxil, and buspirone as well as members of the endothelin receptor antagonists family of pulmonary hypertension drugs; sakanexan, bosentan, and ambrisentan.
PS 608 DEVELOPMENT OF ORGANotypIC IN VITRO HUMAN MODELS WITH ENGINEERED GENE KNOCKDOWN OR TOXICOLOGICAL REPORTER FUNCTIONS.

In vitro human 3D epithelial models including skin (e.g., EpiDerm, EpiDerm–FT) and airway (e.g. EpiAirway, EpiAirway–FT) are important advances over traditional monolayer cell cultures. These models provide more realistic, in vivo-like structure, barrier properties, metabolic functions and dosing capabilities compared to monolayer cultures. Here we describe development of organotypic 3D epithelial models with added features of engineered gene knockdown or toxicologic reporter functions. To create NFKB and Nr2 reporter models, early passage normal human epidermal keratinocytes, dermal fibroblasts, tracheobronchial epithelial cells and pulmonary fibroblasts were transduced with lentiviral vectors containing the respective transcription factor (TF) response elements linked to either GFP or luciferase. To create gene knockdown models of NFKB, IL-1t, MMP-1 and MMP-7, lentiviral vectors containing tetracycline (Tet) inducible shRNA and RFP were utilized. Stably transduced cells were selected by puromycin resistance, expanded several passages and cryopreserved to produce large pools of cells for organotypic skin and airway model production. Organotypic structure and barrier properties of models produced from the transduced cells were similar to models produced from untransduced cells, as determined by histological assessment and barrier function measurements. NFKB and Nr2 reporter models readily responded to positive control treatments, TNFα and r-butyldihydroquinone, respectively. GFP was detected in fixed paraffin sections by fluorescence microscopy. Luciferase activity in tissue extracts was quantified by microplate luminometer. In gene knockdown models, exposure of models to Tet induced robust RFP expression and >70% knockdown of IL-1t gene and protein expression. These gene knockdown and TF reporter models, together with additional models that may be produced by the methods demonstrated in the current work, will provide important new tools for conducting mechanistic toxicological studies.

PS 609 INCORPORATING THE THREE R’S INTO CONSUMER AND HEALTH PRODUCTS SAFETY TESTING.

Assessing the potential toxicity of pesticides, metals, and environmental compounds using current animal-based methods are expensive, difficult to standardize and cannot scale to the throughput required for screening hundreds of thousands of potential active chemicals required by new regulations. Compliance costs are escalating, with estimates in the millions of animals and billions of dollars. Incorporating the “Three R’s” for alternative animal testing (Replacement, Reduction, Refinement) provides ethical principles to help minimize animal use for research. Thus, the need for increasing throughput but reducing in vivo models necessitates the use of in vitro technologies and automation for preliminary safety assessment.

We tested a subset of natural, industrial and pharmaceutical compounds and environmental contaminants (including but not limited to dicofol, estradiol, lead, and acetonitrile) with three separate biological assays. By employing the same battery and concentration of compounds for each assay using quantitative fluorescent imaging, general toxicity was assessed by monitoring specific biological features. Endocrine activity was evaluated with estrogen and androgen receptor cell lines. Neuroscreen-1 cells treated with these compounds were used to assess developmentnal neurotoxicity (i.e., morphology, loss of neurites and branching). Genotoxicity (via micronucleus frequency) was compared with the same compounds in CHO-K1 cells. Time to complete all three assays took less than two weeks from setup to overall evaluation of each compound, compared to months using animal models. A variety of biological profiles were observed with the tested compounds, showing how general toxicants can act by various mechanisms of action, while others are more localized and only warrant specific outcomes.

PS 610 IDENTIFICATION OF A CELL AMOUNT INDICATOR TO NORMALIZE IN VITRO METABOLOMICS DATA.

In vitro screening systems are particularly well suited to preclinical toxicology testing at an early stage of drug development as they have the advantage of being fast and requiring only a small amount of test substance. The demands for in vitro screening assays for systemic toxicity are multiple and include the need of organ specific cell systems, the use of optimal cell numbers, cell passages and incubation times. Even minimal changes in the conditions of the test system may lead to significant changes of the biological system. Therefore a reliable normalization compensating biological variability is crucial prior to any interpretation of results generated from a biological system. BASF SE has developed an in vitro metabolite profiling assay and a subsequently tuned normalization strategy allowing the prediction of specific organ toxicity. The in vitro assay consist of exposing cells lines to test substances and to determine the metabolite profile using chromatography coupled to mass spectrometry systems. Herein we compare five different normalization strategies referring to their suitability in the application to in vitro metabolite profiling data. The strategies comprise statistical approaches, approaches referring to reference values from each individual sample or samples generated in dependent batches. Best results were achieved by an individual strategy using a new reference value correlating well over a large range of cell counts previously used for generating corresponding cell extracts. Statistical analysis revealed the normalization based on the new reference value greatly improved the quality of the results compared to non-normalized samples as well as to all remaining strategies. Generation and application of this new reference value and the corresponding normalization strategy will be presented the first time. Validation will be featured on the basis of extracts of the human hepatocellular carcinoma cell line Hep G2.

PS 611 HARNESSING CHEMILUMINESCENCE TO DELIVER MECHANISTIC-INFORMATIVE IN VITRO ASSAYS FOR TOXICOLOGICAL SCREENING.

C. A. Morris, G. El-Hiti, S. Woodhead, K. Smith, I. Weeks and P. Kille. 1, 2Cardiff University, Cardiff, United Kingdom and 3Invitron, Monmouth, United Kingdom. Sponsor: T. Gant.

We have developed a generic technology to support animal-free molecular toxicology assays and applied it to two areas of interest, steroidogenesis and genotoxicity. This technology utilizes a detection system based on acridinium ester (AE) chemiluminescence which allows sensitive and reproducible quantitation of gene expression without the use of a reporter system or the need to amplify mRNA targets. The light output is directly attributable to the number of transcripts present. This method has in the past been used successfully to measure genetic indicators for endpoints of the Rat Uterine assay and also for endpoints specific for endocrine disruption in several fish species. The use of molecular-endpoints to identify and classify compounds provides significant potential for high-throughput in vitro screening. A limited suite of molecular endpoints, when measured in concert, will allow prediction of the mode of action and provide mechanistic information of the test compound by identifying the pathways affected. We developed and optimised seven assays to established indicators. These include endpoints for measuring genotoxic activity (tumour suppressor p53, RAD51C, cystatin A) and effects on steroidogenesis enzymes (CYP21A2, CYP19A1, HSD2). An assay for beta-actin transcript has been developed and optimised to be used in conjunction with the other assays to allow standardisation. Inter- and intra-assay variation is generally low with an average coefficient of variance of less than 15%. Target concentrations as low as 0.5 – 1 fmol can be measured and discrimination between targets with a single base pair difference can be made. To assess genotoxic or endocrine disruption, the effect of chemicals on HEPG2 or H295R cell lines respectively will be determined by using the probes to measure specifically these RNA transcripts. Employing genetic endpoints in this way will provide a basis for a rapid screening technology allowing accurate assessment of the action of new drug/chemicals.

PS 612 A SYSTEMATIC APPROACH FOR STUDYING THE MITOCHONDRIAL TOXICITY OF ENVIRONMENTAL CHEMICALS.

M. S. Arteme-Ramos, R. Huang, S. Sakamura, K. Wirtz, G. Besson, L. Shout, C. Besson, R. Tice, C. Austin and M. Xia. 1NCGC, NIH/NHGRI, Rockville, MD, 2Division National Toxicology Program, NIEHS, Research Triangle Park, NC and 3Department of Pharmaceutical & Biomedical Sciences, Medical University of South Carolina, Charleston, SC.

A goal of the Tox21 program is to transit toxicity testing from traditional in vivo models to novel in vitro assays that assess how chemicals affect cellular responses and toxicity pathways. A critical NCGC contribution to Tox21 is implementation of a quantitative high throughput screening (qHTS) effort, using cell-based and biochemical assays, to generate toxicological profiles for thousands of compounds. In the present study, changes in mitochondrial membrane potential produced by different chemicals were evaluated in HepG2 cells using a cationic fluorescence dye, an assay optimized for qHTS. Of the 1343 unique compounds in the NTP library...
screened over 14 concentrations (0.59 nM—92 μM), 221 (16.5%) and 189 (14%) compounds disrupted the mitochondrial potential in HepG2 cells after treatment for one and five hours, respectively. Eighty-five compounds positive at both time points were clustered by structural similarity, resulting in 17 clusters and 26 singletons. Thirty-nine compounds covering most of the chemical space represented by the 85 compounds were more extensively evaluated. All 39 compounds were confirmed to disrupt mitochondrial membrane potential using a fluorescence plate reader and a high content imaging approach. Among these 39 compounds, 4 and 8 induced some cytotoxicity (LDH release) at 1 and 5 hours, respectively, and 12 induced caspase 9 activity at 5 hrs of treatment. To further understand the mechanisms of toxicity for these compounds, we measured changes in oxygen consumption rates (OCR) during treatment. Fourteen compounds, including trichlorophenol and captan, two known uncouplers, increased OCR and four compounds decreased OCR. This approach allows us to evaluate thousands of environmental chemicals for their potential mitochondrial toxicity and define mechanisms of toxicity. Supported by NIEHS Interagency Agreement Y2-ES-7020-01.

614 CHARACTERIZING CHANGES IN POLYUNSATURATED FATTY ACID PROFILES IN C. ELEGANS IN RESPONSE TO DEVELOPMENTAL STAGE, FOOD, AND CADMIUM EXPOSURE.

Understanding the mechanisms by which exposure to the environmental toxicant, cadmium, causes multiple disease phenotypes is relevant to human health. Metals are known to affect insulin and retinoic acid signaling, and cadmium has been implicated as a factor of transcription of fatty acid synthesis enzymes. Deregelation of proper intake and metabolism of fatty acids is associated with human diseases such as hypertension, diabetes, inflammatory disorders, and cancer. Defecation cycles in the nematode C. elegans are caused by rhythmic muscle contractions and have been used as a model for human cardiac cycles. We have shown that defecation cycles in cadmium-exposed nematodes phenotypically copy nematodes with disrupted fatty acid synthesis. Based on this evidence, we suspected that cadmium exposure may disrupt fatty acid synthesis in C. elegans and may also contribute to cadmium-induced disease. To understand how cadmium affects fatty acid metabolism, we have used gas phase chromatography tandem mass spectrometry (GCMS) to characterize changes in fatty acid metabolites in nematodes exposed to cadmium. Initial results show that cadmium-exposed nematodes accumulate the saturated fatty acids palmitic acid (16:0) and steric acid (18:0), indicating that cadmium may decrease that activity of delta 9 desaturase in C. elegans. This is consistent with evidence that cadmium decreases activity of delta 9 desaturase in rat liver and decreases transcription of delta 9 desaturase in hepatocytes. Because cadmium is a neurotoxicant and affects both feeding and development in C. elegans, it is possible that the effects observed here may be due to changes in feeding and development. Therefore, we also defined the fatty acid metabolic profiles of nematodes in response to food availability and throughout development. Our results indicate that fatty acid metabolism may be affected by life stage and food availability, however, cadmium exposure affects fatty acid composition in C. elegans independent of developmental stage or food availability.

Cardiototoxicity is one of the most prevalent adverse effects of drugs that affects patients and, in the pharmaceutical industry, is a leading cause of drug candidate attrition and the withdrawal of FDA-approved drugs from the market. We have developed an in vitro assay that predicts a drug’s propensity to induce cardiotoxicity. To accomplish this goal, several types of cardiac cells, including primary cardiomyocytes, human embryonic stem cell-derived cardiac precursors, and human induced pluripotent stem (hiPS) cell-derived cardiomyocytes, were evaluated. As a result, the hiPS cell-derived cardiomyocytes were selected for further study based on their purity, availability, reproducibility, and ability to function similarly to their in vivo counterparts. Preliminary studies with these cardiomyocytes indicated that a cell density of 50K cells per well in a 96 well plate provides an optimal level of secreted factors to be evaluated using mass spectrometry. hiPS cell-derived cardiomyocytes were then exposed to a training set consisting of compounds from different chemical classes that are of known inducers (15 compounds) and noninducers (10 compounds) for cardiotoxicity. Doses for the compounds used for metabolic analysis were based on known human cardiac exposures and the effects on cell viability measured in culture. The cardiomyocytes were exposed to compounds for 72 hours and the spent culture media was analyzed following treatment using LC-ESI-QTOF mass spectrometry. Univariate and multivariate statistical analysis was used to identify a metabolic signature of features that altered in response to cardiotoxicants. These features were then used to test the potential of predictive models capable of classifying cardiotoxic compounds from noncardiotoxicants. Our current activities are aimed to understand the small molecules that gave rise to the observed LO/MS features and map them with in metabolic pathways.

615 IDENTIFICATION OF BIOMARKERS OF CARDIOTOXICITY USING METABOLOMICS OF HUMAN PLURIPOTENT STEM CELLS-DERIVED CARDIOMYOCYTES.

Y. Kaluzhny1, L. d’Argembeau-Thornton1, M. Kinuthia1, H. Kandarova1, M. Klauser1, 1MatTek Corporation, Ashland, MA and 2MatTek In Vitro Life Science Laboratories, Bratislava, Slovakia.

Both topically applied and systemically administered medications have the potential to induce photosensitivity. According to current regulatory guidelines, photo-safety testing is required for a substantial number of drug development submissions (e.g., due to light absorption in the range of 290–700 nm or because the new compound partitions into the skin or eyes). However, there has been growing concern regarding the performance of the only approved, non-animal in vitro phototoxicity assay, 3T3 Neutral Red Uptake Phototoxicity Test (3T3 NRU-PT), as being overly restrictive in predicting the in vivo photosafety hazard to humans. EpiDerm™, a highly differentiated NRU-3D skin model, is highly reproducible, contains an in vitro-like barrier, possesses in vivo-like biotransformation capabilities and has been pre-validated for determining phototoxicity of topically applied materials. Here, we utilized EpiDerm to develop an in vitro assay for screening phototoxic potential of pharmaceuticals after systemic administration (Epi-SPH0). Test materials are added into the culture medium, allowed to partition into the epidermal skin model, and then exposed to solar radiation. Phototoxic effects are determined by comparing the tissue viability of UV irradiated vs. non-irradiated tissue models, as determined using the MTT assay. A prediction model was established: a material is
**INCREASED OXYGEN CONSUMPTION ASSOCIATED WITH ALTERATIONS IN CARDIAC FUNCTION IN ADULT ZEBRAFISH AFTER ACUTE AQUEOUS EXPOSURE TO BETA-NAPHTHOFLAVONE.**

L. P. Weber, 1, 2 and C. Gerger, 1, Veterinary Biomedical Sciences, University of Saskatchewan, Saskatoon, SK, Canada and 2Toxicology Program, University of Saskatchewan, Saskatoon, SK, Canada.

Polycyclic aromatic hydrocarbons (PAHs) cause developmental cardiac deformities in fish as well as functional cardiac abnormalities. In contrast, acute adult fish exposure to PAHs is generally thought to have little effect. However, increasing numbers of studies in adult mammals report acute PAH exposure causes altered cardiac function. In order to determine if similar acute PAH effects could be detected in adult zebrafish, the model PAH-like compound, beta-naphtoflavone (BNF), was used. Adult zebrafish were aqueously exposed to increasing concentrations of BNF (0, 0.1, 1 and 1000 μg/L) for 48 hr, then subjected to swimming tests with concurrent oxygen consumption measurements (n=10 fish/treatment) or echocardiography performed to determine cardiac function (n=5 fish/treatment). While swim endurance was not altered by BNF exposure, oxygen consumption (MO2) was significantly higher (p<0.0001 for BNF factor in 2-way ANOVA) compared to control; but swimming at higher water velocities magnified this increase. MO2 at zero water velocity was highly positively correlated with ventricular volume at diastole (r=0.957), and ejection fraction (r=0.859), but negatively correlated with acceleration of blood through the ventricle (r=−0.588) in resting fish. These parameters clustered together in the first component in principle components analysis, while heart rate and cardiac output clustered in component 2. Unexpectedly, heart rate was the only cardiac end-point that did not correlate well with MO2 (r=0.027). In conclusion, acute exposure to the PAH-like compound, BNF, increased oxygen consumption. This in turn appeared to drive an increase in cardiac output via increased ventricular filling during diastole, not increased heart rate. More toxic and environmentally relevant PAHs are therefore predicted to pose a greater cardiorespiratory stress and need to be examined in future studies.

**IDENTIFICATION OF THE ARYL HYDROCARBON RECEPTOR (AHR) AS A NEGATIVE REGULATOR OF NUCLEOTIDE EXCISION REPAIR (NER).**

T. Haarman-Stemmann1, K. Frauenstein1, T. Douki2, J. Tigges1, M. Majora1, C. Esser1, J. Abel1, E. Frischke1 and J. Krutmann1, 1Leibniz Research Institute for Environmental Medicine, Duesseldorf, Germany and 2Laboratoire Léonard des Acides Nucleiques, Service de Chimie Inorganique et Biologique, CEAD/SMINAC, Grenoble, France.

Ultraviolet B (UVB) radiation is a major environmental hazard that causes DNA damage which may initiate the development of skin cancer. Efficient removal of UVB-induced cyclobutane pyrimidine dimers (CPDs) critically depends on NER. Although some cytokines were shown to enhance NER activity, their complex regulation is still poorly understood. We now report that keratinocytes are equipped with a negative regulator of NER: the AHR, a cytosolic transcription factor that is rapidly activated upon ligand-binding to stimulate gene expression. We have previously shown that FICZ, an intracellularly formed tryptophan photoproduct, is a strong AHR ligand, which triggers the activation of the EGF and downstream MAPK signaling upon UVB exposure resulting in a pro-inflammatory response.

Now, we have investigated if AHR activation also influences the DNA damage-dependent UVB-response. By using southwestern doblon analyses, we have found that chemical AHR inhibition in human keratinocytes leads to a faster repair of UVB-induced CPDs. Accordingly, Ahr-/− keratinocytes exhibited significantly lower amounts of CPDs after UVB-irradiation as the control cells. In order to assess the in vivo relevance, we irradiated Ahr+/+ and Ahr-/− SKH-1 mice with 180m2 UVB. The CPD amount in skin samples was measured by HPLC-MS/MS immediately, 24h and 48h after UVB-exposure. Strikingly, 48h after irradiation, the skin of Ahr-/− mice contained only 50% of the CPDs measured in skin samples from Ahr+/+ mice. Mechanistic studies indicate that the AHR represses NER activity in two ways: i) via modulation of cell-cycle by altering the expression and phosphorylation of checkpoint kinase-1, and ii) via activation of the EGF/MAPK pathway. In conclusion, the AHR is a negative regulator of NER that may serve as a novel target for chemoprevention against UVB-induced skin damage.
levels of AP sites whereas variant allele of CYP1B1 Leu432Val were positively correlated with the background levels of AP sites in breast cancer patients. (This work was supported by the National Science Council, Taiwan, through Grants NSC98-2314-B-371-004-MY2 and NSC99-2314-B-005-001-MY3).

621 SPONTANEOUS POINT MUTATIONS AND DELETIONS ACCUMULATE IN A DIFFERENT MANNER WITH AGING OF GPT DELTA TRANSGENIC MICE.

Chronic exposure of endogenous mutagens and DNA replication errors induce spontaneous gene mutations. The mutations accumulate in the genome throughout lifetime and may cause cancer or genetic diseases. Point mutations such as base substitutions are thought to increase with age in an organ-specific manner. However, effects of aging on the other types of mutations such as deletions are not well studied. In this study, we investigated the accumulation of spontaneous point mutations and deletions in young to aged mice. Mutation assays using gpt delta transgenic mouse have a feature that can detect point mutations and deletions by gpt and Spi assays, respectively, in the same organ. To characterize spontaneous gene mutations accumulated in mice, male gpt-delta transgenic mice were fed normal diets for two years. The organs were collected at week 4, 26, 52, 78 and 104, and mutant frequencies were examined for point mutations and deletions. Spontaneous gpt mutant frequencies in liver significantly increased with age up to 78 weeks, and then slightly decreased at week 104. In tests, the gpt mutant frequencies didn’t increase up to 78 weeks but increased 3 times at week 104 although the difference was not significant because of large standard deviations. The gpt mutation spectra of young and aged mice had similar characteristics, so the unique mutation types induced by aging were not observed. In contrast, Spi deletion frequencies were similar at week 4 to 78 but increased 2-3 fold at week 104 in both liver and testis. These results raised the possibility that endogenous DNA lesions that induce point mutations accumulate with age in liver but not in testis and also that deletions are induced with age in a different manner from that of point mutations. Catastrophic events that may induce deletions may occur at week 104 in the liver and tests although inter-individual differences are substantial.

622 SITE-SPECIFIC IN VIVO ANALYSIS: POSSIBLE INVOLVEMENT OF GENOTOXIC MECHANISMS IN THE MODES OF ACTION FOR OCHRATOXIN A (OTA)-INDUCED RENAL CARCINOGENESIS.

D. Hibi1, Y. Suzuki1, Y. Ishii1, M. Jin1, Y. Sagita-Konishi1, T. Nohmi2, K. Ogawa1, A. Nishikawa2 and T. Umemura1. 1Division of Pathology, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan, 2Division of Genetics and Mutagenesis, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan, and 3Division of Microbiology, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan. and 4Biological Safety Research Center, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan, and 5Division of Microbiology, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan, and 6Biological Safety Research Center, National Institute of Health Sciences, Seagaya-ku, Tokyo, Japan.

Ochratoxin A (OTA), a mycotoxin and known food contaminant, can induce renal tumors arising from the S3 segment of the proximal tubules in rodents. The results from conventional mutagenicity tests investigating the role of genotoxic mechanisms in OTA-induced carcinogenesis are controversial. Human exposure to OTA from conventional mutagenicity tests investigating the role of genotoxic mechanisms in OTA-induced carcinogenesis is necessary for accurate estimates of the human risks. In the present study, gpt delta rats were first exposed to a carcinogenic dose of OTA for 13 weeks, enabling us to detect in vivo mutagenicity in the target organs. OTA induced karyomegaly and apoptosis at the outer stripe of the outer medulla (OSOM) in the kidney, but failed to affect the reporter gene mutations in DNA extracted from whole kidneys. This site-specificity resulting from the kinetics of specific transporters might be responsible for the negative outcome of in vivo mutagenicity. Next, kidneys from gpt delta rats exposed to OTA for 4 weeks were macroscopically divided according to anatomical characteristics in the cortex, and the outer and inner medulla, each of which was confirmed by histopathology. Spi- mutant frequencies (MFs), but not gpt MFs, in the outer medulla and mainly the OSOM, were significantly higher in OTA treated rats than in controls despite the absence of cortical changes. These results strongly suggest the involvement of a specific transport system in OTA-induced renal carcinogenesis. In addition, the reporter gene mutation assay using DNA from target sites could be a more powerful tool to investigate in vivo genotoxicity.

623 MAPPING DNA DAMAGE RESPONSE IN PLURIPOTENT STEM CELLS THROUGH INTEGRATION OF RNA SCREEN WITH GLOBAL TRANSCRIPTOMICS AND PHOSPHOPROTEOMICS.

E. Danen1, J. Puigvert1, L. von Stechow1, R. Siddappa1, A. Pines2, J. Olshen2, H. Vrielin2, L. Mullenders2 and B. van de Weter2. 1Toxicology, Leiden University, Leiden, Netherlands, 2Toxicogenetics, University Hospital, Leiden, Netherlands and 3Phosphoproteomics, University of Copenhagen, Copenhagen, Denmark.

Damaged DNA contributes to aging when (stem) cells accumulate cytotoxic lesions and to cancer through mutagenic lesions. It is also the mechanism of action of anti-cancer radio- and chemotherapy. The anticancer drug, cisplatin causes DNA cross-links, stalled replication forks, and as a consequence double strand breaks. We analyze the signaling response to such broad-range genotoxic stress in pluripotent stem cells where repair pathways and triggering cell death when damage is beyond repair must be particularly robust. In an RNA interference screen targeting all known kinases, phosphatases, and transcription factors we identify cispalitin response modifiers in embryonic stem (ES) cells. A number of such modifiers are found to play similar roles in p53 mutant breast cancer cells. Subsequently, the RNAi screens are combined with global transcriptomics and phospho-proteomics (SILAC) to build integrated networks. In addition to the expected pathways, these point to alterations in self-renewal signaling. In particular, our findings demonstrate that genotoxic stress in ES cells elicits Wnt signaling through a novel mechanism to constrain p53-mediated apoptosis.

624 PARP-1 ACTIVATION IN ANILINE-INDUCED DNA DAMAGE: PROTECTIVE EFFECT OF ANTIOXIDANTS.

H. Ma, J. Wang, G. Wang and M. Khan. Pathology, University of Texas Medical Branch, Galveston, TX.

Mechanisms by which aniline exposure elicits splenocyte response, especially the tumorogenic response, are not well-understood. Earlier, we have shown that aniline exposure leads to oxidative DNA damage and up-regulation of base excision repair (BER) enzymes, i.e., OGG1 and NER1/2 DNA glycosylases in rat spleen. This study was focused on evaluating if poly (ADP-ribose) polymerase-1 (PARP-1), another BER enzyme, is also involved in protecting aniline-induced DNA damage, and whether supplementation of antioxidants N-acetyl cysteine (NAC) and aminoguanidine (AG) could provide protection against aniline-induced DNA damage. To achieve this, four groups of male SD rats were orally treated with aniline (1 mmol/kg/day), aniline plus NAC (300 mg/kg/day), and aniline plus AG (200 mg/kg/day) for 7 days, while controls received drinking water only. Aniline treatment led to a 2-fold increase in 8-hydroxy-2-deoxyguanosine (8-OHdG) levels compared to controls. The aniline-induced increases in 8-OHdG levels were associated with significant increases in PARP-1 levels which were 2.2 fold greater than the controls as analyzed by ELISA and Western blot analysis. NAC or AG supplementation in aniline-treated rats led to decreased DNA damage which was evident from significant decreases in 8-OHdG levels compared to aniline-treated rats. NAC and AG supplementation also led to reduced PARP-1 activation compared to aniline-treated rats. Thus, NAC and AG supplementation not only attenuated the aniline-induced DNA damage, but also PARP-1 activation in the spleen. These results suggest that aniline-induced oxidative stress is associated with increased oxidative DNA damage and PARP-1 activation, and NAC and AG supplementation can provide protection by preventing oxidative DNA damage. Supported by NIH ES06476.

625 ANTIOXIDANT DYSFUNCTION COMPROMISES UVB-INDUCED DNA DAMAGE REPAIR.

W. Han1, M. Ming2, R. Zhao2-3, J. He2 and Y. He1. 1Medicine/Dermatology, University of Chicago, Chicago, IL, 2The Institute for Chemical Safety Sciences, The Hamner Institutes for Health Scican, Research Triangle Park, NC and 3School of Forensic Medicine, China Medical University, Shenyang, Liaoning, China.

Mutagenic disruption of the nucleotide excision repair (NER) pathway, a specific repair pathway to remove UVB-induced DNA damage, can cause xenodermic pigmentation in mouse and predisposing affected individuals to development of skin cancer. The xeroderma pigmentosum C (XPC) protein is essential for initiating the cancer-preventive global genome NER by recognizing the DNA lesion and recruiting downstream factors. Here we show that inhibition of the long isoform of the nuclear factor-erythroid-2-related factor-1 (NRF1), a cytoprotective transcription factor critical for the expression of multiple antioxidant response element-dependent genes, impairs gpt plus gpt- induced renal carcinogenesis. In addition, the reporter gene mutation assay using DNA from target sites could be a more powerful tool to investigate in vivo genotoxicity.

SOT 2012 Annual Meeting 135
XPC. Adding XPC or glutathione restores the DNA repair capacity in NRF1-inhibited cells. Meanwhile loss of NRF1 severely depresses keratinocytes to UVB-induced apoptosis through up-regulating the expression of the pro-apoptotic Bel-2 family member Bik. Knocking down Bik reduced UVB induces apoptosis in NRF1-inhibited cells. Finally, we demonstrate that NRF1 levels are significantly reduced in human skin tumors as compared with normal skin, and by UVB radiation in mouse skin. These results suggest that NRF1 acts as a tumor suppressor through its role in DNA repair.

DNA polymerases help maintain genomic stability and protect cells from DNA damage. Based on sequence homology, C. elegans contains homologues to eleven DNA polymerases; however, the role these polymerases play in maintaining genomic stability of mitotic and meiotic cells has not been well characterized. DNA polymerase θ (POLQ-1) is an α family polymerase that contains an N-terminal helicase-like domain and a C-terminal polymerase domain connected by a large central domain. Previous studies showed that POLQ-1 is important in the defense against interstrand DNA crossovers and γ-irradiation. POLQ-1 may also participate in base excision repair due to intrinsic 5-deoxyribose phosphate lyase activity. In this study, we examined the removal of base damage and embryonic lethality after exposure to DNA damaging agents, hydrogen peroxide (H2O2) and methyl methanesulfonate (MMS), in wild type nematodes and two polq-1 mutants, one containing a deletion mutation in the polymerase domain (tm2026) and the other containing an insertion-deletion mutation in the helicase domain (tm2752). A qPCR-based assay revealed that rates of DNA lesion repair were comparable between wild type and the polq-1 mutants, suggesting POLQ-1 does not affect mitotic cell repair. We also examined the number of offspring and embryonic lethality. After exposure to H2O2 or MMS, brood size was similar in all strains for the doses tested. However, when assessing embryonic lethality, tm2752 nematodes showed a 2-fold increase in embryonic lethality after exposure to 0.5 mM H2O2 and both mutant strains showed an increased rate of embryonic lethality after MMS exposure compared to wild type nematodes. These results suggest that POLQ-1 plays a role in meiotic cell repair. The difference in sensitivity between assays used to evaluate DNA repair in mitotic and meiotic cells indicates that POLQ-1 may perform a specific function during meiosis.

DNA polymerases help maintain genomic stability and protect cells from DNA damage. Based on sequence homology, C. elegans contains homologues to eleven DNA polymerases; however, the role these polymerases play in maintaining genomic stability of mitotic and meiotic cells has not been well characterized. DNA polymerase θ (POLQ-1) is an α family polymerase that contains an N-terminal helicase-like domain and a C-terminal polymerase domain connected by a large central domain. Previous studies showed that POLQ-1 is important in the defense against interstrand DNA crossovers and γ-irradiation. The difference in sensitivity between assays used to evaluate DNA repair in mitotic and meiotic cells indicates that POLQ-1 may perform a specific function during meiosis.

Pyrollozidine alkaloids (PAs) are the most common plant constituents that poison livestock, wildlife, and humans. Riddelliine is a prototype genotoxic PA. Riddelliine induced high incidence of liver tumors that were observed in both mice and rats. In this study, we explored whether riddelliine treatment could alter microRNA (miRNA) expression in rat liver and whether the possible deregulation of miRNA were related to mutagenicity and carcinogenicity of riddelliine. Groups of 6 rats were administered riddelliine at a carcinogenic dose of 1 mg/kg body weight, with control vehicle 5 days a week for 12 weeks. The animals were sacrificed one day after the last treatment and the livers were isolated for miRNA expression analysis using miRNA microarrays. miRNA expression was significantly altered by riddelliine treatment. Principal component analysis and hierarchical clustering analysis showed that the miRNA expression profiles were clearly classified into two groups, riddelliine treatment vs. the control samples. Forty-seven miRNAs were significantly downregulated by riddelliine treatment, among which 38 were upregulated and 9 were downregulated. Functional analysis of these differentially expressed miRNAs by riddelliine revealed that these miRNAs were involved in liver carcinogenicity and toxicity, such as liver proliferation, liver necrosis/cell death, hepatocellular carcinoma, liver hepatomegaly, liver inflammation, and liver fibrosis. These results suggest that miRNAs actively respond to a carcinogenic dose of riddelliine and the pattern of miRNA expression has the potential to be used as a biomarker of carcinogenicity for riddelliine and possibly other PAs.

Early life exposure to mitochondria toxicants, including paraquat, rotenone, and manganese, has been hypothesized to promote early onset of genetic mitochondrial disorders as well as common degenerative diseases such as Parkinson’s disease and Alzheimer’s disease. The current study aims to investigate the biochemical and physiological effects of early life exposure to mitochondrial genotoxicants in juvenile and adult C. elegans. In the first experiment, a laboratory method was developed to selectively generate mitochondrial DNA (mtDNA) damage (but not nuclear DNA (nuDNA) damage). Twelve-hour old first-larval stage (L1) C. elegans was treated with three serial low-intensity (10 J/m²) doses of ultraviolet C (UV-C) radiation. This resulted in 1.3 ± 0.3 mtDNA and 0.2 ± 0.0 nuDNA lesion per 10,000 base pairs in 36-hr old third-larval stage (L3) C. elegans. In the second experiment, ATP level and mtDNA : nuDNA copy number ratios in C. elegans were measured after serial L1 UV-C doses (7.5 J/m²). Both ATP level and mtDNA : nuDNA ratios significantly decreased during the first 48 hr after the doses, but rebounded in the fourth larval stage (L4, 60 hr old; p < 0.05). The UVC doses significantly increased ATP levels in 108-hr old adults (p < 0.05) without any detectable effect in mtDNA : nuDNA ratios (p > 0.05). In the third experiment, paraquat, cumene hydroperoxide, rotenone, maneb, cadmium (II) chloride, and manganese (II) chloride were screened for mitochondrial genotoxicity in 108-hr old adults. Exposures to paraquat, maneb, cadmium (II) chloride, and manganese (II) chloride all significantly decreased mtDNA : nuDNA ratio (p < 0.05). Both paraquat and cadmium (II) chloride caused detectable DNA damage, but only paraquat caused significantly more mtDNA than nuDNA damage (p < 0.001). The results indicate that early life exposure to mitochondrial genotoxicants leads to late life alterations in ATP level and mtDNA copy number, thereby representing a potential human health hazard for further investigation.
miR-34a by transfection chemically synthesized miR-34a precursor into human lymphoblast TK6 cells. The mutant frequency (MF) in the thymidine kinase locus was consistently increased in miR-34a over-expressed TK6 cells. Further more, the over expression of miR-34a can abrogate the X-ray induced MF in transfected cells. These data indicate miR-34a plays a significant role in regulating the MF in TK6 cells. WT1 (mutant P53 gene) cell line derived from the same lymphoid progenitor as TK6 (wild type P53 gene) cells showed WT1 cells has a very high level of MF and very low level of miR-34a expression in comparison with TK6 cells. Interestingly, when miR-34a was transfected into WT1 cells, the high basal level of MF in WT1 cells didn’t show any change. miR-34a over-expression was also not able to diminish X-ray induced mutation in WT1 cells. These data suggest P53 is required for miR-34a modulation regulation. Consistent with the role of miR-34a involved in apoptosis, our data indicate the over-expression of miR-34a can induce the apoptosis of TK6 cells with the presence of wild type P53. In summary, these results suggest that miR-34a plays a role in suppression of mutation induction under pathological conditions. The role of miR-34a in mutagenicity regulation is P53 dependent. The mechanism of miR-34a suppresses TK mutation induction may be mediated through apoptosis.

631 CHANGE OF DNA LIGASE I PHOSPHORYLATION INCREASES DNA DAMAGE, DELAYS CELL CYCLE, AND LEADS TO SENESCENCE.

Z. Peng and A. Tomkinson. *Internal Medicine, University of New Mexico, Albuquerque, NM.*

Human DNA ligase I (hLigI) plays a key role in DNA replication and several different DNA repair pathways. Our previous studies have shown that physical and functional interactions between hLigI and the replicative clamp loader replication factor C (RFC) and the checkpoint clamp loader BRAD17-RFC are sensitive to the phosphorylation status of hLigI. The objective of this study is to elucidate the role of hLigI phosphorylation in regulating its cellular functions. We isolated derivatives of the hLigI-deficient cell line 46BR1.G1 that stably express mutant versions of hLigI, in which 4 serine residues phosphorylated in vivo, were replaced with either alanine or aspartic acid. The cell lines expressing the phosphorylation site mutants of hLigI exhibited a dramatic reduction in proliferation, high level of cellular senescence and were also hypersensitive to DNA damage. Our studies have identified Ser51 as a critical residue in the regulation of the cellular functions of hLigI by phosphorylation.

632 ATR DEPLETION IN ATM-DEFICIENT HUMAN MAMMARY EPITHELIAL CELLS CAUSES SIGNIFICANTLY ATTENUATED G2 CHECKPOINT AND SYNERGISTIC LEATHALITY TO DOUBLE-ST RAND BREAKS AND DNA-DAMAGING AGENTS.

Y. Cui, C. L. Innes and B. S. Paules. *Environmental Stress and Cancer Group, Laboratory of Toxicology and Pharmacology, NIEHS, NIH, Research Triangle Park, NC.*

DNA double-strand breaks (DSBs) pose a great threat to genome stability and cell viability. Normally cells respond to DSBs by activating cell cycle checkpoint allowing DNA repair to occur. These response pathways are induced mainly by three members of the phosphatidylinositol 3-kinase–related kinase (PIKK) family: the ataxia-telangiectasia mutated kinase (ATM), the ATM and Rad3-related kinase (ATR), and the catalytic subunit of the DNA-dependent protein kinase (DNA-PKcs). ATM and ATR are key players in homologous recombination (HR), which predominates after DNA replication, while DNA-PKcs plays a critical role in non-homologous end-joining (NHEJ), which is the primary repair pathway when the sister chromatid is not available. Previous studies in our lab utilizing ATM-deficient human mammary epithelial cells (HME-CC) have shown that DNA-PKcs is playing a role in the activation of IR-induced G2 checkpoint when ATM is depleted, suggesting cross-talk between HR and NHEJ. In order to dissect the signals behind this cross-talk and the role of ATR in particular, we recently generated inducible ATR knockdown cell lines by lentiviral infection of both ATM proficient and deficient HME-CC cell lines. Preliminary data suggests that depletion of ATR in ATM deficient cells causes significant G2 checkpoint attenuation and synergistic lethality when cells are treated with ionizing radiation or DNA-damaging reagents such as bleomycin sulfate and etoposide. We are currently investigating the changes in the ATM/ATR double deficient HME-CC cells in their response to IR-induced DNA damage. While the ATR/ mouse is embryonic lethal, precluding many studies of ATR function, and ATR inhibitors generally lack specificity, these inducible knockdown cell lines allow us to study DNA damage responses in an ATR-deficient background. Furthermore, the synergetic lethality caused by ATM and ATR depletion may be potentially useful in cancer therapeutics.

633 DIFFERENTIAL P53 DNA DAMAGE DOSE-RESPONSE IN HUMAN FIBROSARCOMA HT1080 AND LYMPHoblAST AHH-1 CELLS.

B. Sun, S. Ross, A. Thomas, J. Trask, M. E. Andersen, P. Carmichael, A. White and R. Clewell. *1The Hammer Institute, Durham, NC and 2SEAC, Unilever Inc., Bedfordshire, United Kingdom.*

p53 protects cells from DNA damage-induced mutation by initiating DNA repair, cell cycle delay, and apoptosis. The pathway that the cell chooses to follow depends upon the type, amount, and duration of DNA damage, as well as the specific cell type. In order to better define the dose-dependent transition in p53 response after chemically-induced DNA damage, we examined markers of p53 activation, DNA damage and subsequent cellular responses in human HT1080 fibrosarcoma cells and AHH-1 lymphoblast cells following exposure to etoposide (ETP). HT1080 cells showed 10-fold greater sensitivity to DNA damage than AHH-1 cells based on micronuclei formation and H2AX levels. In both cell lines, cell cycle arrest (G2/M) was observed at lower doses than initiation of apoptosis. While total p53 expression was up-regulated in both cell types, the favored phosphorylation site for p53 and the downstream cellular response differed. In AHH-1 cells, phosphorylation of p53 at serine46 (apoptosis inducer p53) and induction of cleaved caspase 3 (apoptotic marker) were 35% and 50% respectively, much greater than HT1080 cells (8% and 8%), suggesting that p-p53 (ser46) and apoptosis were favored in AHH-1 cells. In contrast, in HT1080 cells maximum induction of phosphorylation of p53 at serine 15 was greater than AHH-1, indicating that p-p53 (ser15) is favored in HT1080 cells. The differential response of these cells could result from alterations of downstream apoptotic or cell arrest signaling in cancer cells. It may also be indicative of differences in cellular response in blood and epithelial cells. Understanding the relevance of both these factors will be important in achieving the vision of the Toxicity Testing in the 21st Century paradigm linking in vitro assay data to mechanistic pathway perturbation. Genome wide RNA expression is being evaluated in order to better characterize the differential pathway activation in these two cell lines and to identify context-dependent mechanisms that determine cell fate after DNA damage.

634 MODULATION OF O6MG REPAIR ACTIVITY BY MGMT SINGLE-NUCLEOTIDE POLYMORPHISMS.

C. Troll, D. L. Alexander and M. Camps. *Microbiology & Environmental Toxicology, University of California Santa Cruz, Santa Cruz, CA.*

The therapeutic efficacy of popular antitumor alkylating chemotherapeutic agents such as Temozolomide and Caramustine depends largely on the generation of O6-methyl guanine (O6mG). This lesion, which is highly cytotoxic to tumors, is repaired by a specialized enzyme (O6 methyl guanine methyl transferase or MGMT), that removes the O6 methyl adduct by irreversible transfer to its own active site. The correlation between MGMT activity and sensitivity of tumors to alkylating therapy is well established. There are 10 known non-synonymous MGMT SNPs in humans that could affect the response of individual patients to alkylating agent chemotherapy, I have developed a complementation system that detects O6mG repair by human MGMT with great accuracy. This system is based on expressing human MGMT in an E. coli strain deficient in O6mG activity. This strain carries the R323W mutation in its DNA repair function (the functional homolog of MGMT); which abolishes O6mG repair without interfering with transactivation of other DNA repair genes. Using this system, I confirmed the results of 4 previously characterized polymorphisms and characterized the repair activity of 6 previously uncharacterized ones. I found that the L53F variant of MGMT (present in about 0.15% of the population) exhibits a 100-fold increase in activity towards O6mG lesions, whereas other variants exhibit slight to significant decreased activity. This wide range of O6mG demethylase activities that I observe should have an impact on the sensitivity of tumors to alkylating agent therapy, particularly if MGMT is dominant or haplosufficient.

635 INCREASED NUCLEOTIDE EXCISION REPAIR ACTIVITY OF AFLATOXIN-B1’-N’-GUANINE ADDUCTS IN LUNGS AND LIVERS OF MICE EXPOSED CHRONICALLY TO AFLATOXIN B1.

J. E. Mulder, R. Mchtra, G. S. Bondy and T. E. Massay. *1Pharmacology and Toxicology, Queen’s University, Kingston, ON, Canada and 2Toxicology Research Division, Health Canada, Ottawa, ON, Canada.*

Aflatoxin B1 (AFB1) is produced by species of Aspergillus, moulds that can grow on grains, oilseeds and spices. Following inhalation or ingestion, AFB1 is biotransformed into the highly reactive AFB2-exo-epoxide, which binds preferentially to the
DNA REPAIR CAPACITY IS MODULATED BY XPC HAPLOTYPES.

C. M. Bondelli1, C. J. Erziel and S. Z. Abdel-Rahman1. 1University of Texas Medical Branch, Galveston, TX and 2MD Anderson, Houston, TX.

The impact of single nucleotide polymorphisms (SNPs) of the DNA repair gene XPC on DNA repair capacity (DRC) has not been comprehensively determined. We constructed a haplotype map of XPC by aligning all XPC SNPs existing with a minor allele frequency ≥0.05. We identified 21 haplotypes that segregated into 6 phylogenetic groups (PGHs A-F). We evaluated the relationship between these PGHs and DNA damage associated with smoking, using chromosome aberrations (CA) as a biomarker. We observed a significant interaction between PGH-C and smoking for baseline CA (P = 0.0046). Using mutagen sensitivity as a biomarker of cancer risk, we observed significant interactions between smoking and PGH-D (P = 0.023) and -F (P = 0.007). To provide mechanistic explanations to our findings, we exposed human lymphoblastoid cells representing different XPC haplotypes to UV radiation to generate the NER substrates 6-4 photoproducts (6-4PP) and cyclobutane dimers (CPD). We then evaluated the effect of XPC haplotypes on DRC using ELISA. We hypothesized that if XPC haplotypes have functional effects, there would be a correlation between these haplotypes and repair of 6-4PP and CPD. We found significant differences in dimer repair as a function of XPC haplotypes. For example, cells with the PGH-EE repaired 6-4PP more efficiently than those with DD or FF. Our results highlight the potential effects of Corexit 9500 on essential biological processes in marine species in response to its use as a chemical dispersant in the Gulf of Mexico.

In Guizhou province, China, arsenicosis caused by burning coal was found since 1976. The villagers were suffering severe symptoms of arsenicism. According to our investigation, the happening of the disease existed individual differences. In order to find it clearly, we selected Excision repair cross-complement group (ERCC6) and Xeroderma pigmentosum group A gene(XPA), analyzing the relationship between their gene polymorphisms and the risk of arsenicism, to provide the evidences for screening the susceptible persons and protecting high risk population in the endemic area. Methods According to Chinese National Arsenicism Diagnosis Criteria (WS/T211-2001), 205 diagnosed arsenicism patients were chosen as patients group. 187 villagers who lived about 13km away were chosen as control group, sharing a similar lifestyle but not using high arsenic coal. PCR-RFLP was used to analyze the gene polymorphisms of ERCC6 and XPA. Results 1. Unconditional Logistic regression analysis showed after the adjustment of gender and age, the individual carrying G allele(AG+GG) in ERCC6 A3368G has significantly lower risk of arsenicism than that carrying AA gene(with ORadj=0.282,95%CI:0.126-0.628,P=0.0002). 2. The risk of arsenicism decreased for the individuals carrying the two gene types as follow: ERCC6 3368(AG+GG) and ERCC6 -6530 CC; ERCC6 3368(GG)and ERCC6 -6530(CG+GG) and XPA 23 AA;ERCC6 3368(AG+GG) and XPA 23(AG+GG);ERCC6 -6530(CG+GG) and XPA23 AA. Conclusions 1. ERCC6 A3368G gene polymorphism is related to the risk of arsenicism caused by burning coal. More protection should be done for population carrying AA gene type in the area. 2. Combined effects of different gene loci exist in the process of arsenicism development.

A vital challenge that all cells and organisms constantly have to face is the generation of diverse harmful DNA lesions in the genome caused by oxidative and environmental agents. The DNA lesions within highly transcribed genomic regions must be dealt with in a timely and efficient manner to prevent stalling of the transcription machinery and subsequent cell death. A significant body of evidence indicates that RNA polymerase II (Pol II) is a highly selective DNA damage sensor, since it constantly scans the transcribed genome during transcription. Pol II can bypass small DNA lesions. Certain types of DNA damage frequently cause nucleotide misincorporation into an RNA transcript (error-prone transcription bypass) in a manner similar to translesion synthesis by error-prone DNA polymerases. However, other types of DNA lesions have little effect on transcription fidelity (error-free transcription bypass). Error-prone transcription bypass, termed transcriptional mutagenesis, may be an important pathway for the generation of mutant proteins and therefore play a role in tumor development. However, the molecular mechanisms that dictate error-prone versus error-free transcription are not fully understood. Here, we use a combined approach including pre-steady state transient kinetics, X-ray crystallography, and molecular dynamics simulations to molecular basis of factors in controlling transcription fidelity. We further elucidated the roles of electrostatic effects and of steric effects in controlling Pol II error-prone versus error-free transcription bypass.

Arsenic is a recognized carcinogen. Environmental arsenic pollution will cause arsenic and even cancers. Up to now, no evidence has been discovered about the mechanism of arsenic intoxication and carcinogenesis. This study analyzes the relationship between methylation in detoxification gene-GSTP1 gene promoter region, mRNA transcriptional expression and protein expression and the occurrence of arsenicism. Methods The blood samples were collected from 123 arsenicism patients and 47 controls. DNA methylation regulation of GSTP1 gene in blood of arsenicism patients was detected by methylation-specific PCR. The mRNA expression of GSTP1 was detected by real-time quantitative reverse transcription polymerase chain reaction, the tiss e samples of skin were collected from 53 patients with endemic arsenicism and from 15 controls. GSTP1 proteins were detected by immunohistochemical method. Results It showed that the positive rate of DNA methylation of GSTP1 gene increased with disease development and dermatic lesion of arsenicism. The average levels of GSTP1 mRNA in promoter methylation group of GSTP1 was lower than that in non-methylation group. Compared with the control group, the GSTP1 protein expression was higher in arsenicism group, which was associated with the degree of skin damage, the GSTP1 protein expression in promoter methylation group of GSTP1 was higher than that in non-methylation group. Conclusions Arsenicism may lead to hypermethylation of the GSTP1 gene promoter and then inhibit the transcription of the mRNA and protein expression. GSTP1 gene plays an important role in arsenicism or carcinogenic process.

The mycotoxin patulin (PAT) can occur in many moldy fruits, grains and other foods, but the major sources of patulin are moldy apples and apple products. Recently, we have shown the mutagenic potential of PAT in the hprt locus of V79 cells at concentrations as low as 0.6 μM. The mutagenicity of PAT at such low concentrations is in contrast with the assumption that the intracellular excess of glutathione (GSH) ascents the complete inactivation of small reactive electrophiles such as PAT. Furthermore, DNA-DNA crosslinks rather than DNA strand breaks or oxidative DNA base modifications contributed to the PAT-induced mutagenicity, indicating the reaction of PAT with DNA bases. Thus, cell-free reactions of PAT with adenine in the presence and absence of equimolar concentrations of GSH were carried out. Reaction products were separated by means of HPLC and their structure was elucidated by MS/MS. Besides already known PAT-GSH adducts, at least two PAT-adenine adducts were detected in the presence and absence of GSH. In addition, at least one novel product exhibiting a mass to charge ratio and fragmentation pattern identifying a mixed PAT-GSH-adenine adduct was observed. Moreover, one hitherto unknown PAT-GSH adduct was identified. Since its fragmentation pattern correlated with the PAT-GSH-adenine adduct before its linkage to adenine, it might represent the precursor of the mixed adduct, suggesting the activation of PAT by reaction with GSH. Based on our observations, we propose a structure of the mixed PAT-GSH-adenine adduct and the putative mechanism of its formation. These findings are in contrast with the assumption that the conjugation of the major intracellular nucleophile GSH induces the complete inactivation of PAT. In fact, the formation of a reactive PAT-GSH monoadduct and its potential to associate with DNA bases could contribute to the mutagenicity of PAT.

The role of smoking in breast cancer (BC) remains controversial, BC is hormone dependent and cigarette smoking may have antieestrogen effects in women (Vogel 2006). The association between smoking and DNA repair capacity (DRC) is largely unknown. A low DRC is an important risk factor in BC (Ramos et al. 2004). The focus of this study was to test the hypothesis that smoking was associated with changes in DRC level and BC risk. We conducted in Puerto Rico a 5 year IRB approved study with 385 women with recently diagnosed BC and 606 controls. BC risk factors in relation to smoking and other epidemiological variables were solicited and DRC was measured in lymphocytes utilizing a host cell reactivation
assay. Multiple logistic regression was used to calculate odds ratio (OR) to assess the association of DRC, smoking and BC after adjusting for all confounders simultaneously. Compared to the controls, women with BC (smokers and non-smokers) showed an average decrease of 55% in their DRC levels (p<0.001). Women with low DRC (< 3.185) were 16.5 times more likely to have BC (OR=16.5, 95%CI 11.6, 23.5; p<0.001). Smokers had 60% more odds of having BC (OR = 1.6, 95%CI 1.01, 2.59; p=0.045) and 50% more odds of having a low DRC (OR=1.5, 95%CI 1.00, 2.40; p=0.085) although the latter was borderline significant. Every year of smoking increased 2% the odds of having BC (OR=1.02 95%CI 1.0, 1.04; p=0.189), and 7% the odds to have a low DRC (OR=1.07, 95% CI 1.01, 1.13; p=0.025). However, the former was not statistically significant after adjusting for age, BMI, family history of BC, menopause, alcohol consumption, marital status, eating saturated fat and history of pregnancy. This study provides the first evidence of the potential association of smoking with a diminished DRC and increased BC risk. Supported by grants 506 GM008239-20 and 1SC1AI57250-2 from the NCI Center to Reduce Health Disparities and NIH-MBRS Program (NIGMS).

645 NANOFLUIDS FOR DRUG DELIVERY: HOW TO ASSESS DANGER FOR MITOCHONDRIA?
B. H. Rihn, H. Eidt, O. Joubert and A. Le Faou. Faculté de Pharmacie/CITHEFOR, Université de Lorraine, Nancy, France. Sponsor: N. Claude

Recently, we reported that Eudragit® RS (ERS) empty nanoparticles, prepared by nanoprecipitation (NP) or double emulsion (DE) techniques, induced cytotoxicity in NR8383 macrophages. As drug delivery nanoparticles are currently used in human therapies, we investigated both morphological and biochemical effects on macrophages exposed to ERS nanoparticles (15 and 100 micrograms/mL; diameter = 56 nm). Damaged cells did not display an apoptotic cell death whereas ERS induced another autophagy. Transmission electron microscopy showed that ERS nanoparticles were internalized per unit by macrophages and entered mitochondria that lost their shape and integrity. By the way, a p*, a gene marker of mitochondria cytotoxicity, was downregulated. Ultrastructural studies showed typical autophagosome vesicles, autophagy markers with upregulation of atg16l1 and map1lc3 genes, as evidenced at both mRNA and protein level. In this study, we reported for the first time that such polymeric drug nanovectors enter mitochondria and act as autophagy activators, like viruses. Thus, nanoveccors, whatever their type, should be assayed on macrophages in order to determine potential induction of autophagy and mitochondria damage for toxicological safety.

646 SIZE-DEPENDENT AGGRAVATING-EFFECT OF AMORPHOUS SILICA NANOPARTICLES ON ATOPIC DERMATITIS.

Nanomaterials (NMs) have been becoming essentials in daily life. However, because of unique physicochemical properties and innovative functions of NMs, it is a concern that NMs can exhibit unknown harmful effects. In this regards, to make safe NMs and enjoy their many benefits, it is essential to evaluate the hazard associated with NMs on human health. However, since NMs do not behave in solution whatever their type, should be assayed on macrophages in order to determine potential induction of autophagy and mitochondria damage for toxicological safety.

647 MICRONUCLEI IN TK6 CELLS ARE INCREASED BY SILVER NANOPARTICLES IN A DOSE, SIZE AND SURFACE COATING-DEPENDENT MANNER.
Y. Li, J. Yan, L. A. Bhalli, R. Sadiq, W. Ding and T. Chen. Division of Genetic and Molecular Toxicology, US FDA/National Center for Toxicological Research, Jefferson, AR.

Nanoparticles have unique physical and chemical attributes, such as size, surface charge, and surface coating, and these different physicochemical properties could have different biological consequences. In the present study, we evaluated the effects of the size and surface coating of nanoparticles on micronucleus (MN) induction in human lymphoblastoid TK6 cells. To test the effects of surface coating, cells were treated with different concentrations of 5 nm uncoated, polyvinylpyrrolidone (PVP)-coated and tannic acid (TA)-coated silver nanoparticles (AgNPs). Size effects were evaluated by treating cells with different sizes of citrate coated AgNPs (Ag-10 nm, Ag-20 nm, Ag-50 nm and Ag-100 nm). Additional cells were treated with water, 0.75 Gy X-ray as well as with MN frequencies in AgNPs was increased significantly and in a dose-dependent manner by the 5 nm coated and uncoated AgNP treatment. Treatment of TK6 cells with 1.5 μg/mL PVP-coated, 3.0 μg/mL TA-coated and 30 μg/mL uncoated AgNPs (concentrations resulting in around 40% relative population doubling) resulted in 4.12, 2.81, and 3.1 fold-changes in MN frequency, respectively. The surface charges and aggregation natures of the nanoparticles are considered responsible for the genotoxicity differences. Different sizes of citrate AgNPs generated weak, but dose-dependent increases in MN frequency and more experiments are being conducted to confirm this finding. The data indicate that the AgNPs induce micronuclei in TK6 cells, and the MN induction is dose-, surface coating- and size-dependent.

648 IN VITRO PULMONARY TOXICITY OF METAL OXIDE NANOPARTICLES.
D. Cupi1 and K. Driehu1. 1Technical University of Denmark, Kongens Lyngby, Denmark and 2US EPA, Research Triangle Park, NC.

Nanomaterials (NMs) encompass a diversity of materials with unique physicochemical characteristics which raise concerns about their potential risk to human health. Rapid predictive testing methods are needed to characterize NMs health effects as well as to screen and prioritize NMs for comprehensive toxicological assessments. BEAS2B human bronchial epithelial cells were employed to assess the in vitro pulmonary toxicity of 4 TiO2 and 4 CeO2 particles varying in size (6 - 1288 nm), morphology and crystalline structure. Exposures were conducted over several concentrations for each endpoint examined. No BEAS2B cytotoxicity was observed for any particle following a 24 hr exposure to concentrations up to 100 μg/mL. The ability of TiO2 and CeO2 particles to induce inflammation and oxidative stress was assessed by gene induction using RT-PCR. At 50 μg/mL maximal IL-8 and IL-6 gene induction by 6nm TiO2 and 8nm CeO2 NMs was observed at 6hr and 24hr post-exposure, respectively, with 8nm CeO2 NMs producing the greatest induction of cytokine mRNA levels. Smaller TiO2 and CeO2 NMs produced greater induction of cytokine- and IL-6 mRNA levels compared to their larger sized counterparts. At 50 μg/mL all TiO2 and CeO2 particles induced similar increases in HO-1 mRNA levels at 6hr and 24hr post-exposure, respectively. The pattern of HO-1 gene induction was inconsistent with a role of oxidative stress in metal oxide induced BEAS2B cytotoxic gene expression. Pretreatment of BEAS2B cells with 10 nM inhibition III BMI-S345/41 completely inhibit 25nm TiO2 and 60nm CeO2 NM induction of IL-8, IL-6 and HO-1 gene expression indicating a role of NFκB in these responses. A cell-based ELISA for NfκB p65 phosphorylation revealed rapid Ser536 phosphorylation in BEAS2B cells following exposure to 50 μg/mL of TiO2 and CeO2 NMs with sizes ≥25nm. Results demonstrate the ability to employ in vitro methods to assess NM induced pulmonary toxicity. Some responses were found to be totally dependent NM size/surface area indicating composition and surface properties play a role in mediating NM toxicity. This abstract does not reflect EPA policy.

649 THE ROLE OF ROS AND NFκB ON CYTOTOXIC AND PRO-INFLAMMATORY EFFECTS OF BLACK TONER POWDER.
V. Morsch-Sundermann1, A. Weis1, M. Koenzoe1, C. Gruendemann1, J. Merfort1 and R. Gminski1. 1University Medical Center Freiburg, Freiburg, Germany and 2Department of Pharmaceutical Biology and Biotechnology, University of Freiburg, Freiburg, Germany. Sponsor: D. DeMarini.

Major components of black toner powders are styrene-acrylate copolymer (SAC), magnetite and Carbon Black (CB). Recent reports have suggested possible significant adverse health effects from toner dust inhalation. Moreover, in a previous
study, we observed genotoxic effects in A549 human lung cells exposed to three commercially available black toner powders. The aim of this study was to unravel the underlying mechanisms of toxicity by comparing the cytotoxic and pro-inflammatory potential of these three toner powders and the influence of ROS and NF-κB induction. Toner powders A, B and C consist mainly of SAC (40–60 wt%), silica (1–5 wt%) and CB (<1 wt%). The three black toner powders and their suspensions were examined by SEM. The toner powders consist of C-bearing, rounded to slightly elongated particles with typical diameters of 2 to 8 μm. The particle surface is somewhat rough and is covered by rounded nanoparticules (30–200 nm). In all the experiments, A549 cells were exposed for 24 h to various concentrations of the three toner powder suspensions. Cytotoxicity was assessed by the WST-1 and NR assay and ROS induction by the DCFH-DA assay. Cytokine release was quantified using FlowCytomixTM Technology. Nuclear NF-κB was detected by the electrophoretic mobility shift assay (EMSA). Slight cytotoxic effects were found for the three toner powders. A concentration-dependent induction was observed with the three toner powder suspensio ns. Exposure to toner powder enhanced IL-6 and IL-8 production. Moreover, EMSA results exhibit release of the pro-inflammatory transcription factor NF-κB at the mRNA level in human T cells in vitro, whereas larger AgNPs (110 nm) induce (i) DNA damage, cell cycle arrest and apoptosis in T cells (PMID 20932003), and (ii) cytotoxicity, ROS production, and IL-8 secretion in macrophages (PMID 21390403). In this study we assessed whether different sizes of AgNPs have specific effects on the function of T cells in vitro. Genome wide expression patterns were used as functional readout. Methods and Results: Human Jurkat T cells (clone E6.1, ATCC) were exposed for 6 hours to three sizes of AgNPs (10, 30, 110 nm), or to a supernatant of 30 nm AgNPs, that were subjected to ultracentrifugation, without or with addition of AgNO3 (50 μM), 1 μM, respectively. mRNA molecules were extracted and transcriptomes were generated (Affymetrix U133A, plus 2.0) from N=4 independent experiments. We found, by unsupervised hierarchical clustering of the transcriptome profiles, that metallothioneins were selectively induced by 10 nm and 30 nm AgNPs, whereas 110 nm AgNPs and ionic Ag had no effects. This finding was verified by qRT-PCR (r=2.2-2.65 fold, p≤0.05). Cytokines: Small nanosized AgNPs (10-30 nm) selectively induce MTs at the mRNA level in human T cells in vitro, whereas larger AgNPs (100 nm) and ionic silver do not have this property. Currently experiments are on-going to verify whether this induction of MTs (i) is also observed at the protein level, (ii) is mediated by the transcription factor MTF-1, and (iii) has specific functional consequences for the immune system.

650 THE INDUCTION OF METALLOTHIONEINS BY SILVER NANOPARTICLES AS A NOVEL PUTATIVE IMMUNOMODULATORY MECHANISM IN T CELLS.

J. Shao, A. A. Peijnenburg, H. Boutmeester and O. L. Volger. RIKILT—Institute of Food Safety, Wageningen University and Research Centre, Wageningen, Netherlands. Sponsor: S. Rangarajan.

Introduction: Silver nanoparticles (AgNPs) are used in numerous consumer and health care products, mainly for their antimicrobial properties. Recent in vitro studies suggest that AgNPs can affect the immune system. For instance, AgNPs can induce (i) DNA damage, cell cycle arrest and apoptosis in T cells (PMID 20932003), and (ii) cytotoxicity, ROS production, and IL-8 secretion in macrophages (PMID 21390403). In this study we assessed whether different sizes of AgNPs have specific effects on the function of T cells in vitro. Genome wide expression patterns were used as functional readout. Methods and Results: Human Jurkat T cells (clone E6.1, ATCC) were exposed for 6 hours to three sizes of AgNPs (10, 30, 110 nm), or to a supernatant of 30 nm AgNPs, that were subjected to ultracentrifugation, without or with addition of AgNO3 (50 μM), 1 μM, respectively. mRNA molecules were extracted and transcriptomes were generated (Affymetrix U133A, plus 2.0) from N=4 independent experiments. We found, by unsupervised hierarchical clustering of the transcriptome profiles, that metallothioneins were selectively induced by 10 nm and 30 nm AgNPs, whereas 110 nm AgNPs and ionic Ag had no effects. This finding was verified by qRT-PCR (r=2.2-2.65 fold, p≤0.05). Cytokines: Small nanosized AgNPs (10-30 nm) selectively induce MTs at the mRNA level in human T cells in vitro, whereas larger AgNPs (100 nm) and ionic silver do not have this property. Currently experiments are on-going to verify whether this induction of MTs (i) is also observed at the protein level, (ii) is mediated by the transcription factor MTF-1, and (iii) has specific functional consequences for the immune system.

651 PULMONARY TOXICITY FOLLOWING REPEATED INTRATRACHEAL INSTILLATION OF DISPERSED SILVER NANOPARTICLES IN RATS.

J. R. Roberts1, 1:  A. Kenyon1,  S. Young1,  A. Kenyon1,  S. Hennig1 and L. Bachas1, 1: Chemistry, University of Kentucky, Lexington, KY, 2: Chemical and Materials Engineering, University of Kentucky, Lexington, KY, 3: Graduate Center for Nutritional Sciences, University of Kentucky, Lexington, KY and 4: Chemistry, University of Miami, Coral Gables, FL.

Silver nanoparticles (AgNPs) are one of the fastest growing categories of nanomaterials, etc., and can be readily found in soil and airborne. With the growing use of nanoparticles in industrial and environmental applications, the toxicological effects of these materials increasingly have come into question. Nanoparticles are thought to enter cells through active transport mechanisms such as receptor-mediated endocytosis, which has led to a growing concern over their long-term health effects. Polychlorinated biphenyls (PCBs), which are common environmental pollutants, have well-known toxicology. PCBs can adsorb onto nanoparticles, though, primarily due to hydrophobic effects, and potentially enter cells using nanoparticles as carriers.

Various environmentally prevalent and/or toxicologically relevant PCBs, including PCB-77, -118, -126, and -153, were adsorbed onto alumina and polystyrene nanoparticles, and adsorption was confirmed using GC-MS and energy-dispersive}{
X-ray spectroscopy. Dynamic light scattering and transmission electron microscopy were used to confirm that particles were of a relevant size for entry into cells and cell viability of A549 lung epithelial cells, MH-S alveolar macrophages, and primary porcine endothelial cells was subsequently studied to determine if nanoparticle-PCB complexes cause increased cytotoxicity as compared to nanoparticles and PCBs alone. Treatment of MH-S alveolar macrophages with PCB/nanoparticle complexes mixtures caused marked cell viability decrease for both polystyrene and aluminum oxide nanoparticle carriers, while these complexes result in limited additional epithelial and endothelial cell line toxicity.

**654 COMPARISON OF SYSTEMIC INFLAMMATION BETWEEN INTRAVENOUSLY DELIVERED MULTIWALLED CARBON NOBUTES AND GRAPHENE NANOSHEETS.**

N. Wang, R. Podila, E. E. Mann and J. M. Brown. Pharmacology & Toxicology, East Carolina University, Greenville, NC.

Nanotechnology is a rapidly growing industry that has potential applications as biomedical devices and carriers for drug delivery. Carbon-based nanomaterials, such as multiwalled carbon nanotubes (MWCNTs) and graphene nanosheets (GNS), have been proposed for these purposes. However, our understanding of potential toxicity of these carbon-based nanomaterials is lacking. We have previously demonstrated that oropharyngeal instillation of MWCNTs in C57BL/6 mice leads to a Th2 type immune response with increased numbers of inflammatory cells and increased Th2 cytokines in the lung. In this study, we compared MWCNTs (~25 nm diameter, -113 m²/g surface area and ~5 wt% Fe catalyst) with GNS (~2 - 5 nm thickness, -2630 m²/g surface area and no metal catalyst). We hypothesized that intravenous administration of MWCNTs but not GNS would result in a systemic inflammatory Th2 type response due to differences in physicochemical properties. We intravenously administered 0.01, 0.1, and 1 mg/kg MWCNTs or 1 mg/kg GNS and measured spleen weight, inflammatory cell recruitment, CD4⁺ T lymphocytes and Th2 cytokines in lung and spleen at 24h and 7d following injection. We observed an increased spleen weight in GNS administration groups but not in MWCNTs groups. CD4⁺ T lymphocytes were increased in the spleen of MWCNTs groups at 24h and 7d following injection, while an increase in CD4⁺ T lymphocytes following GNS administration was only observed at 7d. In conclusion, the use of MWCNTs and GNS as nano-carriers for drug delivery may result in potential adverse effects. Therefore, additional modifications to these materials may be warranted before their routine use as drug delivery systems. This work supported by NIH RO1 ES019311 (JMB).

**655 IN VITRO CYTOTOXICITY OF SILVER NANOMATERIALS IN MURINE MACROPHAGES.**

T. D. Green1, A. E. Badawy2, T. Tolaymat3 and D. J. Thomas. 1Environmental Toxicology, Southern University, Baton Rouge, LA; 2CAMD, Louisiana State University, Baton Rouge, LA.

Silver nanomaterials are increasingly used as antimicrobial agents in a variety of products. Although there is considerable potential for human exposure to these nanomaterials, little is known about the health risks associated with their use. Macrophages are prominent immune cells that clear pathogens, cellular debris, and foreign particles during inflammatory responses. As phagocytes, macrophages might readily ingest silver nanoparticles. The cytotoxic effects of short-term exposure to ionic silver (silver nitrate) was compared to PVP-coated silver nanoparticles (median hydrodynamic diameter = 13 nm) using an in vitro cytotoxicity assay that measured reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) in murine macrophage J774A.1 cell line. Cells were exposed to ionic silver or PVP-coated silver nanoparticles for up to 24 hours before assessment of cellular status. Both ionic silver and PVP-coated silver nanoparticles diminished MTT reduction capacity of J774A.1 cells with 50% reductions in activity seen in the low parts per million of silver concentration range. Given that cytotoxic responses were similar after exposure to ionic silver and silver nanoparticle, it is likely that the kinetics of silver uptake and accumulation were similar in both exposure scenarios. However, characterization of the kinetic behavior of silver in macrophages exposed to ionic silver or silver nanoparticles is still needed to elucidate the dose-response relationships for these two forms of silver as cytotoxicants. (This abstract does not reflect the policies of the US EPA).

**656 HYPERTHERMIA-INDUCED CANCER CELL DEATH BY TARGETED MAGNETIC NANOPARTICLES.**

F. Mohammad1, 2, A. C. Radhavannou1, C. Kumar2 and R. M. Uppu1. 1Environmental Toxicology, Southern University, Baton Rouge, LA; 2Candid, Louisiana State University, Baton Rouge, LA.

Magnetic nanoparticle (MNP)-based hyperthermia offers an efficient method of heat delivery for selective killing of tumor cells. Binding of luteinizing hormone-releasing hormone (LHRH) to MNPs such as superparamagnetic iron oxide nanoparticles (SPIONs) coated with gold (SPIONs@Au) can have additional advantages in terms of targeted delivery of MNPs to tumor cells of the reproductive system, particularly those that express the receptors for LHRH. To understand the effects of hyperthermia generated in situ, we synthesized LHRH bound to SPIONs@Au (SPIONs@Au-LHRH; linker: cysteamine) and exposed them to LHRH receptor over-expressing non-cancerous (murine GT1-7 hypotalamic neurons) and cancerous (human LnCap prostate carcinoma) cells. When exposed to SPIONs@Au-LHRH (25-500 μg/mL) for 24 h, there was no significant decrease in the viability of the two cell types. However, when cells were pretreated with SPIONs@Au-LHRH (25-500 μg/mL) for 24 h and then exposed to a magnetic field of 44 Hz for 15 min for LnCap cells or 44 Hz for 2x15 min for GT1-7 neurons, both cell types showed a significant increase in cell death. The cell death in GT1-7 neurons appeared to be late apoptosis or early necrosis, while necrosis was prominent in LnCap cells. LnCap cells exposed to 44 Hz for 15 min had a significant drop in mitochondrial transmembrane potential (ΔΨm); however, no such change in ΔΨm was evident in GT1-7 neurons. In LnCap cells, but not GT1-7 neurons, the cell death was found to be mediated through the caspase-3 pathway. There was an increased expression of heat-shock protein-70 (HSP-70) in GT1-7 neurons but not in LnCap cells. Based on differences in ΔΨm, caspase-3 activity and HSP-70 expression, we believe that LaCap cells are more susceptible to the heat-induced destruction. These findings are new and important and advance our understanding of targeted MNPs for useful therapeutic applications. [Funding support from NSF (HRD1043316) and the US Department of Education (P031R04040) is acknowledged. Corresponding author: rao_uppu@subr.edu].

**657 GRAPHENE PHYTOTOXICITY IN THE SEEDLING STAGE OF CABBAGE, TOMATO, RED SPINACH, AND LETTUCE.**

Graphene, the most recently discovered carbon allotrope, is a two-dimensional building block of atomic thickness that can be stacked into three-dimensional graphite, rolled into one-dimensional nanotubes, or wrapped into zero-dimensional fullerenes. The effects of graphene on root and shoot growth, biomass, shape, cell death, and reactive oxygen species (ROS) of cabbage, tomato, red spinach, and lettuce, were investigated using a concentration range from 500 to 2000 mg/L. The results of the combined morphological and physiological analyses indicate that after 20 days of exposure under our experimental conditions, graphene significantly inhibited plant growth and biomass compared to a control. The number and size of leaves of the graphene-treated plants were reduced in a dose-dependent manner. Significant effects also were detected showing a concentration-dependent increase in ROS and cell death as well as visible symptoms of necrotic lesions, indicating graphene-induced adverse effects on cabbage, tomato, and red spinach mediated by oxidative stress necrosis. Little or no significant toxic effect was observed with lettuce seedlings under the same conditions. The potential effect of graphene largely depends on dose, exposure time, and plant species and deserves further attention.

**658 SUBACUTE AND SUBCHRONIC INHALATION TOXICITY AND DERMAL ABSORPTION OF THE NANOSCALED ZINC OXIDE Z.COTE® HP1 IN THE RAT.**

O. H. Couttenberg1, C. Ziemann1, T. Hansen1, H. Ernst1, D. Schauden1, S. Schuchardt1, K. Wiensch1 and B. Bellmann1. 1Inhalation Toxicology, Fraunhofer ITEM, Hannover, Lower Saxony, Germany; 2Histopathology, Fraunhofer ITEM, Hannover, Lower Saxony, Germany and Regulatory Toxicology Chemicals, BASF SE, Ludwigshafen, Rhineland-Palatinate, Germany. Sponsor: C. Dausenbrock.

This investigation on ZnO nanoparticles was conducted at Fraunhofer ITEM as the European Chemical Industry Council (CEFIC)-funded contribution to the OECD Sponsorship Programme for the Testing of Manufactured Nanomaterials. A
14-day and a subsequent 90-day nose-only inhalation test were conducted with the nanoscaled test item Z-COTE® HP1 and a microsized reference ZnO. OECD guidelines 412 and 413 were expanded by additional endpoints addressing nanoparticle-specific toxicity: i.) bronchoalveolar lavage (BAL) to analyse cytokine release and inflammation; ii.) chemical analysis to follow toxicokinetics of the test item (retention and TEM in lungs and various organs; solubility in physiological fluids); iii.) genotoxicity: micronucleus test (MN); 8-OH-dG in lung tissue; iv.) cell proliferation (Br-DU). After inhalative uptake and phagocytosis Z-COTE® HP1 shows a rapid dissolution under acid conditions in lysosomes and thus has no potential to accumulate in lungs. Chemical toxicokinetics resulted in very small Zn amounts detectable in lungs only 1 day after end of exposure. TEM analysis on particles was negative. Lung toxicity was characterized by an acute inflammation in the high dose group that showed a rapid and complete recovery within 14/28 days (BAL). Histopathological examination revealed a slight degeneration of the olfactory epithelium as the only adverse effect. MN test and 8-OH-dG analysis were negative. The NOAEL values derived from these 14-day and 90-day inhalation tests were 2 and 1.5 mg/m³, respectively. Microscaled ZnO showed tendentially stronger effects than Z-COTE® HP1, probably because of the longer dissolution time needed. In a dermal absorption test in rats (OECD guideline 427) Z-COTE® HP1 was treated by neutron activation to use the Zn-65 gamma tag for a highly sensitive analysis. Zn-65-Z-COTE® HP1 particles or Zn-65 ions were not absorbed via skin.

659 INVESTIGATION OF NANOZEOLITES CYTOTOXICITY.

Nanoseized zeolite particles are important materials for many applications in the field of nanotechnology. The possible adverse effects of these nanomaterials on human health have been scarcely investigated and remain largely unknown. In this study, nanoseized Y and A have been synthesized with particle sizes of 25-50 nm and 45-100 nm, respectively. Adequate colloidal stability for in vitro cytotoxicity experiments has been confirmed. The cytotoxic response of human macrophages (differenitated TPH-1), epithelial (A549) and endothelial (EA.hy926) cells to these nanocrystals was assessed in the absence and presence of fetal calf serum (FCS) by determining mitochondrial activity (MTT assay) and cell membrane integrity (LDH leakage assay). After 24h of exposure, no significant cytotoxic activity was detected for both nanozelotes at doses up to 500 μg/ml, in the presence of FCS or not. Compared to 60 nm amorphous silica nanoparticles, these crystalline nanozelotes-induced only limited toxicity despite an approximately 10-fold greater specific surface area. Low cytotoxic responses were consistent with the absence of intracellular particles in both epithelial and endothelial cells, as confirmed by TEM. In TPH-1 cells, consistent with their phagocytic activity, a limited number of intracellular particles was detected by TEM. Addition of FCS in the cell culture media during exposure to nanozelotes did not increase particle uptake by any cell type. These results may contribute to the application of safe nanozelites for purposes such as medical imaging, sensing materials, low-k films and molecular separation processes. Work was partially financed by the Belgian Ministry of Scientific Policy in the frame of S2NANO project (contract number SD/HE/02A).

660 MEASUREMENT OF DIAMETER OF DIFFERENT NANOPARTICLE AGGLOMERATES AFTER CONTACT WITH A549 CELLS REVEALED DIFFERENT SIZE BEHAVIOR.

Multiwall carbon nanotubes (MWCNT) are discussed to exhibit a fiber-like toxicological potential. For this reason, potential adverse biological effects in vivo (rat) and in vitro (M¢T-5A human mesothelial cells) of MWCNT are investigated in a project, funded by the Federal Ministry of Education and Research (BMBF contract No. 03X0109A), in which MWCNT data will finally be compared with long amosite asbestites as positive control and more particle-like carbon material (Baytubes® and milled MWCNT).

Method: It is hypothesized that only well dispersed MWCNT with a certain fiber length are able to induce mesothelioma. To examine this hypothesis, it is crucial to develop appropriate dispersion methods for MWCNT in a lung-like milieu and to produce and compare MWCNT with different length and diameter characteristics. To reach the planned CNT characteristic: 1) mean length 5-10 μm, D=40 nm; 2) mean length 10-20 μm, D=40 nm; 3) mean length 5-10 μm, D=60 nm) different custom-made MWCNT were synthesized and a dispersion method, using artificial lung medium (Porter et al. 2008) and sonication twice for 5 min with a sonotrode was developed and optimized to enable separation of individual MWCNT fibers. Suspension and MWCNT size distribution were monitored by SEM.

Results: In the present project, it was possible to produce MWCNT with the desired characteristics. The optimized suspension method enabled separation of both MWCNT and long amosite asbestos fibers, but not of Baytubes®. However, for in vitro use dispersion had to be modified, because of some cytotoxicity of the artificial lung medium. Conclusion: These suspensions with custom-made MWCNT will now be used to investigate lung retention, translocation to the pleural cavity after in vivo inhalation, and their potential carcinogenic effect after i.p. injection. For in vivo/in vitro correlation influence of MWCNT on cell viability, proliferation, and DNA-integrity in M¢T-5A cells are investigated.
Silver nanoparticles (SNP) belong to the most commercialized nanomaterials. Here we monitored the biological effects of SNP of different sizes (20 nm, 40 nm) and coatings (citrate, peptide) in human macrophages in vitro. We used THP-1 derived macrophages as a model. The cellular uptake was analyzed by confocal Raman microscopy, TEM or Laser postionization secondary neutral mass spectrometry (Laser-SNMS). Cellular responses upon SNP treatment were studied by time-of-flight secondary ion mass spectrometry (TOF-SIMS) and several biological end-points were evaluated, i.e., cytotoxicity, protein carbonyl formation and induction of heme oxygenase-1 (HO-1). Toxicity of SNP was dependent on exposure time, dose and particle coating. Nanogold proved mainly inert. All kinds of nanoparticles were efficiently taken up. Aggregates and single particles could be detected throughout whole cells, including nuclei and lysosomes. With Laser-SNMS we visualized intracellular SNP and with TOF-SIMS we detected significant changes in the membrane lipid pattern indicating oxidative stress and fluidity changes. We measured strong induction of HO-1 and formation of protein carbonyls with different time patterns. Each type of SNP induced a characteristic carbonyl pattern as resolved by 2D gel electrophoresis. SNP but not nanogold significantly affected the phagocytic activity of macrophages. Some of the particle-mediated effects could be reversed depending on the time and doses applied. Conclusion: SNP exert adverse effects in human macrophages already at subcytotoxic doses. Different kinds of SNP induce distinguishable effects at cellular and biochemical levels.

Important components in estimating risks associated with exposure to nanomaterials include understanding the uptake, distribution, and elimination of nanoparticles. Our project investigates the absorption, distribution, metabolism, and excretion of fullerene C60 and forms of multi-walled carbon nanotubes in nonpregnant, pregnant, and lactating rats and mice. Our initial studies have focused on female rats and mice dosed via tail vein injection with an aqueous suspension of [14C]C60 in polyvinylpyrrolidone (PVP). Urine and feces were collected daily, and tissues were collected at 1, 5, 14 days following 5 consecutive days of i.v. dose. Tissues were also collected at 14 days following 5 consecutive days of i.v. dosing. The largest portions of the recovered radioactivity were detected in the liver (50%), lung (15%), and spleen (9%). Similar distribution profiles for each time-point were determined for female rats and mice administered the single or 5 consecutive doses. Radioactivity levels were above background for many additional tissues, including blood, lymph nodes, GI tract, pancreas, muscle, reproductive tract, mammary tissue, fat, heart, and brain. Only a small portion of the radioactivity recovered (~2%) was eliminated in urine and feces over the weekly collection periods. Transmission electron microscopy (TEM) analysis indicated the presence of electron dense material in lysosomes of Kupffer cells, hepatocytes, and in lung macrophages. Electron dense material was associated with the surface of lipid bodies in adipose tissue. Subcellular localization of the nanomaterials continues via TEM, as well as determination of plasma cytokine levels (markers of inflammation), urinary 8-hydroxydeoxyguanosine (marker of oxidative stress), and quantitative whole body autoradiography. (Supported by NIEHS U19 ES019525.)
Carbonaceous nanoparticles (CNP) have distinctive physical and chemical properties that make them useful in a wide range of applications. As the production of these particles increases, there is a growing need to explore their potentially harmful effects due to environmental and occupational exposure. Mounting evidence indicates that toxicological outcomes of CNP exposure may vary depending on surface properties, size, shape, and functionalization. In the current study, we evaluated pulmonary inflammation and systemic immune responses in mice after pulmonary exposure to structurally different CNPs: pristine C60 fullerene; TRIS-functionalized C60 (C60-TRIS) and graphene oxide (GO). The inflammatory potential of the tested CNPs was found to be as follows: GO > C60-TRIS > C60, as evidenced by accumulation of PMNs, macrophages, and lymphocytes as well as changes in lung permeability and inflammatory cytokine profiles in the lungs on days 1 and 7 post exposure. Further, GO and fullerenols were found to induce reactive oxygen species production by RAW 264.7 macrophages in vitro. To investigate if pulmonary exposure to CNPs altered systemic immune activity, we tested the proliferative response of spleen T cells exposed to GO and C60. Cell proliferation was decreased; however, it was increased in fullerenol-exposed animals. Co-incubation of OVA-specific B3Z hybridoma T cells with OVA-loaded dendritic cells (DC) exposed to GO or fullerenes resulted in altered IL-2 production by B3Z cells, suggesting that modified T cells responses seen in vivo can be partially attributed to a direct modulation of DC functions by GO. Overall, our study shows the potential of fullerenes and GO to induce pulmonary inflammation.
Silver nanoparticles (AgNP) are widely used in a variety of consumer products and biological applications. Intentional and unintentional exposure to AgNP is on the rise, causing health concerns. The toxicity and cell uptake of citrate BioPure™ Ag, (19.2nm), and silica-coated Ag, (40.5nm), were studied in human epidermal keratinocytes (HEK). The AgNP was characterized by diluting in cell culture medium at the highest concentration tested and the size determined by dynamic light scattering at 0, 8, and 24h which increased with time. HEK were exposed to a range of AgNP from 6.25 to 400μg/ml (n=12 wells per concentration). Citrate Ag caused a significant increase in viability at 12.5μg/ml and significant decrease at 50, 100, 200, and 400μg/ml, while silica-coated Ag caused a significant increase at 12.5μg/ml and significant decrease at 400μg/ml. NP controls, serial dilutions of the AgNP in alamar Blue (aB) medium at concentrations and conditions identical to the viability assay, showed silica-coated Ag interacted with aB dye from 12.5 to 400μg/ml. Normalized IL-8 was significantly greater than control in citrate Ag at 6.25, 12.5, and 500μg/ml and significantly less from 100 to 400μg/ml. For silica-coated Ag, IL-8 was significantly greater at 25μg/ml and significantly less at 400μg/ml. Spiked IL-8 controls showed that NP interactions with the cytokine assay suppressed the actual IL-8 concentration by 57.3% in citrate Ag and 41.8% in silica-coated Ag. TEM found agglomerates of electron-dense citrate Ag and silica-coated Ag within cytoplasmic vacuoles of the cells. High concentrations of AgNP can affect the viability and cytokine data thereby causing inaccurate results, so data must be critically analyzed to discern the actual effect from NP interaction. These results show that AgNP do interact with viability and cytokine assays, but citrate Ag and silica-coated Ag causes cell death at the concentrations tested. (Supported by NIH RO1 ES051638)

**Biochemical and Histopathological Evaluation of Functionalized Single-Walled Carbon Nanotubes in Swiss-Webster Mice.**

With their unique physiochemical properties, single-walled carbon nanotubes (SWCNTs) have many potential new applications in medicine and industry. A biomedical application of single-wall carbon nanotubes such as drug delivery requires a fundamental understanding of their fate and toxicological profile after administration. However, the toxicity of SWCNT is barely known when they are introduced into the blood circulation, which is especially vital for their biomedical applications. The aim of this study was to assess the effects, after intraperitoneal injection, of functionalized SWCNTs (carboxyl groups) on reactive oxygen species (ROS) induction and various hepatotoxicity markers (ALT, AST, ALP, LPO and morphology of liver) in the mouse model. We exposed mice to three different concentrations of functionalized SWCNTs and two controls (negative and positive). Samples were collected twenty four hours after the last treatment following standard procedures. Exposure to functionalized SWCNT induced ROS generation and enhanced the activities of serum-amino-transferases (ALT/AST) and alkaline phosphatases (ALP) and the concentration of lipid hydroperoxide compared with control. Histopathology of the exposed liver showed a statistically significant effect in the morphological alterations of the tissue compared with controls. The cellular findings reported here do suggest that purified carboxyl functionalized SWCNT has the potential to induce hepatotoxicity in Swiss-Webster mice through activation of the mechanisms of oxidative stress, which is of sufficient significance to warrant in vivo animal exposure studies. However, more studies to clarify the role of functionalization in the in vivo toxicity of SWCNTs are required and parallel comparison is preferred.

**The Comparison of Mesoporous Silica Nanoparticles and Colloidal Silica on Inflammation and Apoptosis.**

Mesoporous silica (MPS), synthesized via the supramolecular polymer templating method, is one of the most attractive nanomaterials for biomedical applications, such as drug delivery systems, labeling, and tissue engineering. The significant dif-
676 THE CYTOTOXIC EFFECT OF ETOPOSIDE AND DEXAMETHASONE INDIVIDUALLY AND IN COMBINATION WITH SILVER, GOLD, AND SINGLE-WALLED CARBON NANOTUBES ON CANCER CELLS.

D. A. Cassiano1, M. Mahmood1, Y. Xu2 and A. S. Birx4, 1Applied Sciences, University of Arkansas at Little Rock, Little Rock, AR, 2Applied Science, University of Arkansas at Little Rock, Little Rock, AR, 3University of Arkansas at Little Rock, Little Rock, AR, and 4University of Arkansas at Little Rock, Little Rock, AR.

Our laboratory has been focused on the synthesis and development of various nanomaterials for the purpose of delivering chemotherapeutic agents to cancer cells with the intention of selectively killing cancer cells while leaving normal cells intact. Initially we evaluated the ability of known apoptotic agents, such as dexamethasone (D) and etoposide (E) individually and in combination with gold and silver nanoparticles (Au-NPs, Ag-NPs) and single-walled carbon nanotubes (SW-CNTs) to kill HeLa cells and HEK293 cells. We first tested various concentrations of these agents alone and in combination as determined by the MTT assay and FACScan analysis. MPS nanoparticles showed significantly less cytotoxicity and apoptotic cell death than colloidal silica nanoparticles. MPS nanoparticles induced lower expression of pro-inflammatory cytokines, such as tumor necrosis factor-α, interleukin (IL)-6, and IL-1β, in macrophages. The reduced inflammatory response and apoptosis elicited by MPS nanoparticles were resulting from the reduction of mitogen-activated protein kinases, nuclear factor-kB, and caspase 3. In addition, using the local lymph node assay, a standalone in vivo method for hazard identification of contact hypersensitivity, we showed that colloidal silica nanoparticles act as an immunogenic sensitizer and induce contact hypersensitivity but not MPS nanoparticles. In conclusion, the pore architecture of silica nanoparticles greatly influences their biocompatibility and should be carefully designed. The MPS nanoparticles exhibit better biocompatibility than colloidal silica and promise excellent potential usage in the field of biomediatric and biotechnological applications.

677 MICELLAR ENCAPSULATED SULFUR DONORS TO COMBAT CYANIDE INTOXICATION.

B. Winner1, P. Ngo1, M. Negriot1, K. Kovacs1,2, and G. Rockwood1, 1Department of Chemistry, Sam Houston State University, Huntsville, TX, 2Department of Pharmacology, Semmelweis University, Budapest, Hungary, and 3US Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD.

Cyanide poses a threat to human populations worldwide as a chemical warfare agent. After penetrating the mitochondrial membrane, it inhibits cytochrome c oxidase in the electron transport chain of cellular respiration, essentially halting the metabolism of the organism. To combat the cyanide, sulfur donors convert HCN to thiocyanate, which is less toxic and easily excreted in urine. This study is focused on the synthesis and development of various micelle encapsulated sulfur donors for the treatment of specific cancers. We first studied the influence of pore structural conditions of silica nanoparticles on both inflammation and apoptosis, in vitro and in vivo, by comparing MPS and colloidal silica, and defined underlying mechanisms of action. The specific surface area of colloidal silica and MPS was different, respectively, while other conditions, including particle size (100 nm) and shape (spherical) were kept constant. In both MTT assay and FACScan analysis, MPS nanoparticles showed significantly less cytotoxicity and apoptotic cell death than colloidal silica nanoparticles. MPS nanoparticles induced lower expression of pro-inflammatory cytokines, such as tumor necrosis factor-α, interleukin (IL)-6, and IL-1β, in macrophages. The reduced inflammatory response and apoptosis elicited by MPS nanoparticles were resulting from the reduction of mitogen-activated protein kinases, nuclear factor-kB, and caspase 3. In addition, using the local lymph node assay, a standalone in vivo method for hazard identification of contact hypersensitivity, we showed that colloidal silica nanoparticles act as an immunogenic sensitizer and induce contact hypersensitivity but not MPS nanoparticles. In conclusion, the pore architecture of silica nanoparticles greatly influences their biocompatibility and should be carefully designed. The MPS nanoparticles exhibit better biocompatibility than colloidal silica and promise excellent potential usage in the field of biomediatric and biotechnological applications.

678 THE RESPONSES TO DIFFERENT PARTICLES OF ALUMINUM OXIDE IN A549 AND THP-1 CELL.

Background: The increased applications of nanoparticles in various fields of industry raise the concern about toxicological potentiality to human. There are some reports that show the toxicity of nanoparticles depending on many factors including size, shape, chemical composition, surface area, surface charge and others. We compared the toxicity of size (micro-sized and nano-sized particles) and shape (sphere and needle particles) of Al2O3 in cultured cells. In this study, the release of the cytokines IL-6 or IL-8 and LDH were measured at 4, 24 and 48 hours after treatment, and cells were incubated at concentrations of 10, 100,1000 and 3000 μg/mL nanoparticles. Human lung carcinoma epithelial cells (A549) and human acute monocytic leukemia cell line (THP-1) cells were adopted on the assumption of inhalation exposure. Results: The LDH response to nano-sized needle particles was more potent than that to nano-sized sphere particles in both cells. On the other hand, there were no evident differences between nano-seized particles and micro-sized particles at the induction of IL-6, IL-8 and LDH secretion in the in vitro models used in this study. Conclusion: This discovery raises the possibility that Al2O3 has potency to induce LDH secretion in A549 and THP-1 cells depending on their shape.

679 90-DAY INHALATION TOXICITY STUDY IN RATS WITH CARBON NANOFIBERS: CELL PROLIFERATION AND HISTOPATHOLOGY ASSESSMENTS DEMONSTRATE LUNG PARENCHYMAL BUT NOT PLEURAL OR MESOTHELIAL EFFECTS.

K. L. Reed1, Y. Muro2, S. R. Frame1, M. P. Delorme1 and D. B. Warheit1, 1DuPont Haskell Lab., Newark, DE and 2Showa Denko K.K., Tokyo, Japan.

Recent studies have reported that pulmonary or intraperitoneal exposures to carbon nanotubes in rodents have produced pleural or mesothelial effects resembling asbestos exposure. This study investigated the potential adverse pleural effects following a subchronic exposure to VGCF™-H carbon nanofibers (CNF) in male and female SD rats. Groups of rats were exposed nose-only, 6 h/d, 5 d/wk to 0.54, (4.9 f/cc), 2.5 (56 f/cc) or 25 (252 f/cc) mg/m3 VGCF™-H over a 90-day period. Groups of animals from the high and control group were allowed a 90 day recovery period to determine the reversibility of effects observed at the end of the exposure period. Rats were evaluated by standard histopathology, bronchoalveolar lavage and BrdU cell proliferation (CP) methods in selected regions of the respiratory tract (i.e., airway, lung parenchymal, subpleural/mesothelial regions). Minimal and slight inflammation of the terminal bronchiole (TB) and alveolar duct (AD) areas of the lungs were noted in rats exposed to 2.5 and 25 mg/m3, respectively wherein fibrillar-laden alveolar macrophages had accumulated. CNF did not translocate from sites of alveolar deposition to the mesothelial surfaces but were noted within macrophages in the distal alveolar duct/subpleural regions. Greater than 90% BAL-recovered macrophages from animals exposed to 2.5 and 25 mg/m3 VGCF™-H contained CNF, while ~60% of macrophages recovered from rats exposed to 0.5 mg/m3 contained CNF. No adverse histopathological effects of the pleural area were noted. CP studies demonstrated increased (vs. control) BrdU labeling of the TB, AD and subpleural but not mesothelial areas in male and female rats exposed only to 25 mg/m3 VGCF™-H. After 3 months of recovery, CP in the AD and subpleural areas were still increased; however effects in the TB area had reversed. Therefore, subchronic exposure to VGCF™-H resulted in a pulmonary inflammation that was not associated with adverse effects in the pleural or mesothelial areas.

680 INDOLES ALLEVIATE THE DEVELOPMENT OF EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS (EAE) BY ACTIVATION OF ARYL HYDROCARBON AND ESTROGEN RECEPTORS LEADING TO ALTERED MICRO-RNA REGULATION AND SUPPRESSION OF TH17 ACTIVATION.

M. Rouse, M. Nagarkatti and P. Nagarkatti. University of South Carolina, Columbia, SC.

Diindolylmethane (DIM) and its precursor, Indole-3-carbinol (I3C) are examples of dietary indoles and can be found at relatively high levels in cruciferous vegetables. Recent studies have shown that these indoles may possess therapeutic potential...
based on their inhibitory effects on numerous types of cancer. Data also suggested that DIM and I3C may elicit their effects by acting as ligands for both aryl hydrocarbon receptor (AhR), similar to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), and the estrogen receptor (ER). Based on this, we hypothesized that DIM and I3C may regulate the immune response through the activation of AhR and ER to mitigate the development of experimental autoimmune encephalomyelitis (EAE) in a transgenic model of multiple sclerosis (MS). Our study demonstrated that DIM and I3C treatment in EAE-induced mice not only delayed the clinical symptoms of paralysis, but also curtailed the overall severity. We observed that treatment with 13C and DIM resulted in a dramatic decrease in infiltrating T-cells in the brain and spinal cord. In several in vivo and in vitro experiments, DIM and I3C dramatically reduced T cells through interaction with AhR and ER. Based on qPCR analysis, DIM and I3C treatment in EAE-induced mice led to the upregulation of miR-22, which represses target genes ER- 
alpha and IL-17. Together, these studies demonstrated that indoles may mediate their effects through miRNA regulation to suppress inflammation and EAE development.

**681 VITAMIN C RESCUES HYPEROXIA-COMPROMISED MACROPHAGE PHAGOCYTIC FUNCTION BY INHIBITING HMGB1 RELEASE.**

V. Sampath1 and D. Mantell1, 2

1St John’s University, Jamaica, NY and 2The Feinstein Institute for Medical Research, North Shore-LIJ Health Science, Manhasset, NY.

Mechanical ventilation with supraphysiologic concentrations of oxygen (hyperoxia) is a life saving intervention in patients with respiratory distress. However, prolonged exposure to hyperoxia is associated with high susceptibility to lung injury and ventilator-associated pneumonia (VAP). Alveolar macrophages (AM) phagocytic function can be compromised on prolonged hyperoxia. Previous studies in our lab, have determined that prolonged exposure to hyperoxia leads to HMGB1 release, which can directly impair macrophage’s ability to phagocytose. Excessive ROS production, under hyperoxic conditions disturbs the ROS/Antioxidant balance leading to devastation of the antioxidant protection. Ascorbic acid an antioxidant, exhibits beneficial effect in various diseases mediated by ROS. The aim of this study was to examine whether Vitamin-C could inhibit hyperoxia-induced HMGB1 release and improve hyperoxia compromised macrophage function. RAW 264.7 cells (a macrophage like cell line) were exposed to different concentrations of Vitamin-C prior to 95% O2 exposure for 24h. At the end of 24h: ROS activity, phagocytosis, HMGB1 release and NF-kB translocation were analysed. We show here that Vitamin-C inhibited ROS activity and significantly improved hyperoxia- compromised macrophage ability to phagocytose. Vitamin-C also inhibited HMGB1 release which was associated with inhibition of NF-kB translocation to nuclei. These data indicate that Vitamin-C is beneficial in rescuing hyperoxia compromised macrophage function by inhibiting hyperoxia-induced HMGB1 release.

**682 INHIBITION OF PLATELET AGGREGATION WITH A SPELEN TYROSINE KINASE (SYK) INHIBITOR.**

Exploratory Toxicology, Celgene, Inc., San Diego, CA.

Platelets are a key component in hemostasis. Spleen Tyrosine Kinase (SYK) inhibitors have been shown to inhibit platelet activation through inhibition of platelet surface receptors. In a repeat-dose SYK inhibitor study in male rats, pathology findings included hemorrhage in multiple tissues, despite normal prothrombin and partial thromboplastin coagulation times. To identify potential mechanisms of the hemorrhage, we investigated effects of SYK inhibition on platelet function. However, the standard platelet inhibition/platelet aggregation assay is normally low throughput, requires large blood volumes and must be run on specialized equipment. Therefore, we developed a medium throughput, low blood volume standard kinetic absorbance microplate-based platelet aggregation assay using rat whole blood. The platelet aggregation assay was validated and optimized with multiple known platelet activator inhibitors and assay conditions with final selection of thrombin and 13CaCl2 at 95% O2 exposure for 24h. At the end of 24h: ROS activity, phagocytosis, HMGB1 release and NF-kB translocation were analysed. We show here that Vitamin-C inhibited ROS activity and significantly improved hyperoxia-compromised macrophage ability to phagocytose. Vitamin-C also inhibited HMGB1 release which was associated with inhibition of NF-kB translocation to nuclei. These data indicate that Vitamin-C is beneficial in rescuing hyperoxia compromised macrophage function by inhibiting hyperoxia-induced HMGB1 release.

**683 SELENIUM DEFICIENCY PROMOTES PROINFLAMMATORY RESPONSES TO BACTERIAL ENDOTOXIN.**

W. Watson1, T. Burke2 and C. McClain1, 2, *3

1Department of Medicine/GI, University of Louisville, Louisville, KY, 2Pharmacology and Toxicology, University of Louisville, Louisville, KY and 3Louisville VA/Medical Center, Louisville, KY.

Patients with advanced alcoholic liver disease and rodents chronically exposed to ethanol are selenium deficient and have high levels of hepatic inflammation. Selenium acts as an antioxidant, but only after it is co-translationally incorporated into a small number of antioxidant selenoproteins. Recently we showed that the selenium deficiency associated with dietary restriction of selenium resulted in down-regulation of the selenoprotein thioredoxin reductase (TrxR) in the livers of rats. In the present study we tested the hypothesis that selenium deficiency contributes to a pro-inflammatory environment via alterations in TrxR-dependent inflammatory signaling pathways. Pro- and anti-inflammatory cytokine production was measured in a monocyte/macroage cell line under selenium-deficient and selenium-sufficient conditions. Selenium deficiency was induced by culturing RAW 264.7 cells in DMEM supplemented with 10% fetal bovine serum. Although this is a typical culture medium, it supplies only 5 nM selenium (from the fetal bovine serum). This concentration is 10-fold lower than physiological levels. Therefore, selenium-sufficient cultured cells were exposed to 30 nM selenite (as sodium selenite) to the culture medium. Selenium-sufficient cultures had 50% more TrxR protein and activity (measured by western blotting and the insulin reduction assay, respectively) than selenium-deficient cultures. When exposed to bacterial endotoxin (an inflammatory stimulus relevant to the etiology of alcoholic liver disease), both cultures released the pro-inflammatory cytokine TNF-alpha, but the selenium-deficient cells released much less of the anti-inflammatory cytokine IL-10. Therefore, we propose that selenium deficiency contributes to a pro-inflammatory environment by inhibiting the expression of anti-inflammatory mediators such as IL-10.

**684 INHIBITION OF OSTEOSTATIC DIFFERENTIATION BY BROMOPROPANES.**

H. Jeong1, Y. Goo2, H. Jeong1, T. Jeong1 and K. Lee1

1Pharmacy, Chosun National University, Daegu, Republic of Korea, 2Pharmacy, Chonnam National University, Gwangju, Republic of Korea and 3Pharmacy, Yeungnam University, Gyeongan, Republic of Korea.

1-Bromopropane and 2-Bromopropane was introduced as an alternative to ozone-depleting solvents. However, they were found to exhibit neurotoxicity, reproductive toxicity, and hepatotoxicity in rodents and neurotoxicity in human. However, the influence of bromopropanes on differentiation of osteoblast is unknown. Here we investigated whether bromopropanes has an inhibitory effect on osteoblastic differentiation using an osteoblastic cell line (C2C12). Bromopropanes inhibited the bone morphogenetic protein (BMP) 2-induced mRNA levels of alkaline phosphatase (ALP), collagen I (COL1), osteocalcin (OC) and Runx2, which are specific markers for osteoblastic differentiation, in a dose-dependent manner. Moreover, the addition of COL1 and ALP-based reporter genes, which are induced by BMP2, and the transcriptional activity of Runx2 on OC and ALP promoters were inhibited by bromopropanes. The amount and activity of ALP induced by BMP2 were also decreased by bromopropanes. These results suggest that bromopropanes have an inhibitory effect on osteoblastic differentiation.

**685 POSITIVE REGULATION OF MUCOSAL MICROsomAL PROSTAGLANDIN E SYNTHASE 1 BY ACTIVATED ONCOGENE RHOA GTPASE IN EPITHELIAL INFLAMMATION AND CARCINOGENESIS.**

K. Do, H. Choi and Y. Moon

Laboratory of Systems Mucosal Biomodulation, Department of Microbiology and Immunology, Pusan National University School of Medicine and Medical Research Institute, Yangsan, Republic of Korea.

Oncogenic RhoA GTPase has been investigated as a mediator of pro-inflammatory responses and aggressive carcinogenesis. Among the various targets of RhoA-linked signals, pro-inflammatory prostaglandin E2 (PGE2), a major prostaglandin metabolite, was assessed in epithelial cells. RhoA activation increased PGE2 levels and gene expression of the rate-limiting PGE2 producing enzymes, cyclooxygenase-2 and microsomal prostaglandin E synthase 1 (mPGES-1). In particular, human mPGES-1 was induced by RhoA via transcriptional activation in epithelial cells. To address the involvement of potent signaling pathways in RhoA-activated mPGES-1 induction, various signaling inhibitors were screened for their effects on mPGES-1 promoter activity. RhoA activation increased basal and cytokine-activated nuclear factor-kB and extracellular signal-regulated kinase1/2 proteins, all of which were positively involved in RhoA-induced gene expression of mPGES-1. As one potent 

**686 INHIBITORY EFFECTS OF CELENDA IN HYPEROXIA-MEDIATED INFLAMMATORY DAMAGE IN AN IN VIVO HUMAN CHONDROCYTE MODEL **

1Chungbuk National University, 2Chungnam National University, 3Kangwon National University.

Here we investigated the effects of celenda, a novel substance, on the hyperoxia-mediated inflammatory damage in an in vivo human chondrocyte model. The chondrocyte model was established using human articular cartilage from the knee. The chondrocytes were cultured in high oxygen environment (25% O2) for 24 h, followed by celenda treatment (0-100 μM) for 24 h. The effects of celenda were assessed using matrix metalloproteinase (MMP)-13 and matrix metalloproteinase-8 (MMP-8) by western blotting and enzyme-linked immunosorbent assay. The results demonstrated that celenda inhibited the expression of MMP-13 and MMP-8 in a dose-dependent manner. These findings suggest that celenda may have potential therapeutic applications in the treatment of hyperoxia-mediated inflammatory damage.
687 1-BROMOPROPAINE INDUCES CYCLOOXYGENASE-2 GENE EXPRESSION IN MURINE MACROPHAGE RAW 264.7 CELLS.

J. Yang1, E. Han1, H. Kim1, J. Choi2, K. Lee2, T. Jeong1 and H. Jeong1.
1Pharmacy, Chonnam National University, Daegu, Republic of Korea, 2Pharmacy, Chosun University, Gwangju, Republic of Korea.

1-Bromopropene (1-BP) has been used in the workplace as an alternative to ozone-depleting solvents. This study examined the effect of 1-BP on cyclooxygenase-2 (COX-2) expression and analyzed the molecular mechanism of its activity in murine macrophage RAW 264.7 cells. Exposure to 1-BP markedly enhanced the production of prostaglandin E2 (PGE2), a major COX-2 metabolite in RAW 264.7 cells. Additionally, 1-BP dose dependently increased the levels of COX-2 mRNA and protein. Moreover, 1-BP enhanced luciferase activity of COX-2 regulation-related transcription factors including nuclear factor kB (NF-kB) and CCAAT-enhancer binding protein (C/EBP). Phosphorylation level of PI3K/Akt, extracellular signal-regulated kinase (ERK) and p38 MAPK phosphorylation were also significantly activated by 1-BP. These results suggest that 1-BP increases COX-2 expression by activation of NF-kB and C/EBP via PI3K/Akt, ERK and p38 MAPK.

688 ACTIVATION OF NICOTINIC PATHWAY INHIBITS HYPEROXIA-INDUCED HMGB1 RELEASE AND RESCUES MACROPHAGE PHAGOCYTIC FUNCTION.

R. A. Sitapara1 and L. L. Manelli2, 1Department of Pharmaceutical Sciences, St. John’s University, Fresh Meadows, NY and 2The Feinstein Institute for Medical Research, North Shore-LIJ Health Science, Manhasset, NY.

The vagus nerve, the longest cranial nerve of autonomous nervous system, regulates the levels of cytokines, including HMGB1, thus modulating inflammatory damage. This modulation is executed through α7 nicotinic acetylcholine receptor (α7nAChR), a nicotinic anti-inflammatory pathway. Macrophages play a very crucial role in inflammatory responses against invading pathogens. However, exposure to prolonged hyperoxia compromises their ability to phagocytose bacteria via inducing HMGB1 release into extracellular milieu. The aim of this study was to examine whether GTS-21, a selective α7nAChR agonist could inhibit hyperoxia-induced HMGB1 release from RAW 264.7 cells (a macrophage like cell line) and enhance macrophage function under hyperoxic condition. RAW cells were treated with different concentrations of GTS-21 prior to exposure to 95% O2. Phagocytosis assay was performed to determine macrophage function via phagocytosis microorganisms. HMGB1 release was assessed by Western blotting and immunofluorescence analysis. Nuclear factor kappa B (NFkB) has been shown to modulate endotoxin-induced HMGB1 release. Activation of NFkB was assessed by its translocation from cytoplasm to nuclei by immunofluorescence assay. We show here that GTS-21 dose dependently enhanced macrophage phagocytic function and inhibited HMGB1 release.

689 THE ROLE OF NO AND OXIDATIVE STRESS IN THE INTRATRACHEAL BLEOMYCIN MODEL OF LUNG INJURY AND INFLAMMATION.

T. Golden1,2, J. Shi3, B. Guo4, C. B. Massa5, R. Scott5, S. Trie1, M. Lee3, A. L. G cone6 and C. S. Yang5. 1Toxicology, Rutgers University, Piscataway, NJ, 2Pharmacology, Rutgers University, Piscataway, NJ, 3Chemical Biology, Rutgers University, Piscataway, NJ and 4Respiratory Medicine, Fudan University, Shanghai, China.

Pulmonary injury, and its consequent inflammation, has a pronounced effect on lung function, as determined by its elastance and resistance profiles. However, the mechanisms relating the effects of inflammation upon lung function remain unclear. In this study the effects of intratracheally-administered bleomycin (ITB) upon lung inflammation, and its amelioration by γ-tocopherol, were examined at the molecular and functional level. 10 week old C57/B16, wild-type, mice were administered 2 U/kg bleomycin sulfate, or buffered saline as control, and assessed on days 3 and 8 post injury. Mice were fed either a control or a 0.3% γ-tocopherol mixture diet from 2 weeks prior to, and throughout, ITB. Lung function was measured via Forced Oscillation Technique (FOT) at a range of Positive End Expiratory Pressures (PEEPs). Following functional assessment lungs were lavaged and tissue harvested for the measurement of inflammatory markers. ITB resulted in pronounced increases to both the low frequency resistance and elastance profiles; these effects were PEEP-dependent. These changes were accompanied by increases in inflammatory score, via H&E, and expression of biomarkers namely, iNOS and COX2 by IHC and rt-PCR. Pulmonary inflammation, and its amelioration by γ-tocopherol, were examined at the molecular and functional level. 10 week old C57/Bl6, wild-type, mice were administered 2 U/kg bleomycin sulfate, or buffered saline as control, and assessed on days 3 and 8 post injury. 690 MECHANISM OF ANTHRAX LETHAL TOXIN-INDUCED PULMONARY EDEMA.

U. Kayalvi, T. Liu, R. Warburton, M. J. Weiner and J. Wurm. Medicine/Pulmonary & CC, Tufts Medical Center, Boston, MA.

Anthrax is characterized by the development of severe vascular leak that has been linked to its lethality. This leak is believed to be mediated by the toxin produced by the bacillus anthracis bacteria, in particular anthrax lethal toxin (LeTx), which on its own can reproduce the vascular leak and lethality of anthrax infection. The active component of LeTx, referred to as lethal factor, is a protein specified by the gene coding for the biologically active form of the lethal factor (LF, a β-galactosidase enzyme with anthrax LeTx increases endothelial barrier permeability and gap formation between endothelial cells through disrupting p38 signaling. LeTx treatment increases MKK3b degradation and in turn decreases p38 activity at baseline as well as after activation of p38 signaling. Consequently LeTx treatment decreases activation of the p38 substrate kinase, MK2, and the phosphorylation of the latter's substrate, HSP27. LeTx treatment disrupted other signaling pathways leading to suppression of Erk-mediated signaling, but these effects do not correlate with LeTx-induced barrier compromise. Overexpressing phosphomimicking (pm)HSP27, which protected the endothelial...
The role of corepressor splice-variants in regulating lung inflammation.

The incidence of inflammatory lung diseases, such as asthma and COPD, is increasing dramatically worldwide. While many theories address the cause of this phenomenon, the most convincing argument is exposure of the population to inhaled oxidants. Tobacco smoke and many air pollutants cause oxidative stress, a major player in the inflammatory response. However, the mechanistic connections between oxidative stress and disease state remain largely unknown. Consequently, the majority of current treatments for asthma and COPD involve mediating symptoms rather than targeting inflammation. The need for novel therapies and the mechanistic disconnect between oxidants and disease make further investigation critically necessary. Emerging evidence indicates an anti-inflammatory role for nuclear receptors (ligand-regulated transcription factors) in lung disease. Some agonists for these receptors seem to mitigate the immune response, and may offer more specificity and efficacy than current drugs on the market. An accepted model for the anti-inflammatory effects of nuclear receptor agonists involves the recruitment of corepressor (CoR) proteins to the promoters of inflammatory genes, and subsequent suppression of the inflammatory response. However, CoRPs are subject to alternative mRNA splicing and different isoforms have been shown to possess unique behaviors. I propose that a subset of CoR splice-variants are particularly effective at suppressing the inflammatory gene expression caused by inhaled oxidants. Using immune cells as a model, functional reporter assays reveal differences in the abilities of CoR isoforms to suppress the inflammatory response. Furthermore, in vitro protein binding assays show preference of inflammatory transcription factors for certain CoR splice-variants over others. These results, in combination with ongoing chromatin immunoprecipitation experiments and inflammation models in CoR knockout mice, will determine which CoR isoforms are the best pharmaceutical targets and which nuclear receptor agonists are the best treatments for ameliorating inflammatory lung diseases.

Mitochondrial uncoupling protein 3 (UCP3) is a member of the highly conserved subfamily of mitochondrial carriers that regulates the efficiency of skeletal muscle (SKM) mitochondrial respiration through proton leak. Mounting evidence has implicated UCP3 in the protection of SKM from high fat diet-induced insulin resistance, yet the mechanisms by which UCP3 exerts these protective effects are not well understood. Δ3,5,Δ2,4 dienoyl-CoA isomerase (DCI) is an "auxiliary" fatty acid (FA) metabolizing enzyme that permits the complete oxidation of unsaturated fatty acids with double bonds in the odd position (e.g. oleate), through isomerization of the double bond from odd to even positions along the fatty acid chain. Although little is known about the physiological function of DCI, it has been postulated to prevent the accumulation of un-metabolizable unsaturated FA metabolites. Interestingly, DCI exhibits an overlapping protein expression profile with UCP3 in brown adipose tissue, skeletal muscle, and heart. Using a variety of biochemical approaches, we show that UCP3 interacts with DCI in the mitochondrial matrix via the central matrix UCP3 loop, and in a manner augmented by the presence of oleate in cells. The data also indicate that the DCI:UCP3 complex functions to metabolize unsaturated fats specifically. Studies to assess the potential importance of the DCI:UCP3 complex in lipid signaling and toxicity will likely yield valuable insights into the mechanisms of UCP3-regulated fat metabolism and protection from lipotoxicity.

Persistent neuroinflammation and microglial activation have been found to play an integral role in the pathogenesis of many neurodegenerative disorders including Parkinson's disease (PD). Here, we investigated the role of sodium channels (Nav) and Nav/H+ exchangers (NHE) in the activation of microglia like cells (BV-2) after lipopolysaccharide (LPS) exposure. LPS (10 and 100 ng/ml) caused a rapid dose- and time-dependent accumulation of intracellular sodium ([Na+]i) in activated BV-2 cells. Pre-treatment of cells with the Nav antagonist tetrodotoxin (TTX, 1μM) completely abolished Na+ influx but was unable to prevent the accumulation of [Na+]i observed at 6 and 24 hr after LPS exposure. NHE inhibitor cariporide (1μM) significantly reduced the accumulation of [Na+]i 24 hr after LPS exposure. Furthermore, LPS significantly decreased the mRNA expression of a number of Nav isoforms by 30-60% at the 6-24 hrs time points, which was prevented by TTX at LPS 10 ng/ml but not at 100 ng/ml. Furthermore, LPS increased the mRNA expression and protein level of NHE-1 in a dose- and time-dependent manner which was significantly reduced after co-treatment with cariporide. LPS increased TNF-α, IL-1β, IL-6, and IL6 mRNA in a dose- and time-dependent manner. The increased expression of these cytokines was significantly reduced by NHE inhibition. In addition, increased production of ROS and H2O2, and expression of grp94/psa was also observed following LPS treatment which was significantly reduced by TTX or the combination of TTX and cariporide. Collectively, these data suggest that down-regulation of Nav isoforms following LPS exposure may alter intracellular pH homeostasis, resulting in a compensatory up-regulation of NHE-1. Thus, the up-regulation of NHE-1 causes excessive accumulation of [Na+]i into BV2 cells, which may contribute to the inflammatory cascade and neurodegeneration. Supported by NIH ES015991 and ES070022.

Amelioration of lipopolysaccharide/D-galactosamine-induced acute liver toxicity by 3-diindolylmethane, a plant-derived ahr ligand.

S. Tomar, P. Nagarkatti and M. Nagarkatti. Pathology, Microbiology and Immunology, School of Medicine, University of South Carolina, Columbia, SC.

Lipopolysaccharide/D-Galactosamine (LPS/D-GalN) induced acute liver injury is widely used as an animal model for screening of potential hepatoprotective compounds. The mouse model is characterized by activation of macrophages, upregula-
SULFOPHANE RESTORES HISTONE DEACETYLASE ACTIVITY IN HUMAN EPITHELIAL CELLS EXPOSED TO CIGARETTE SMOKE RESULTING IN DECREASED CYTOKINE PRODUCTION.

P. Charley and D. J. Blake, Biology, Fort Lewis College, Durango, CO.

RATIONALE: Chronic obstructive pulmonary disease (COPD) is a major public health problem and currently the third leading cause of death in the US. Exposure to cigarette smoke (CS) is the primary factor associated with the development of COPD. CS exposure leads to oxidative stress in the lungs, which decrease histone deacetylase (HDAC) activity and promote the expression of pro-inflammatory cytokines. Decreased HDAC activity levels correlate with disease severity and increased cytokine production in COPD patients. Sulfophane (SFN), a phytochemical found in broccoli, is able to activate nuclear erythroid 2 like factor-2 (Nrf2), which is a basic leucine zipper transcription factor that regulates the expression of multiple genes involved in antioxidant and detoxification pathways. We hypothesize that SFN will activate Nrf2-dependent gene expression to increase HDAC activity levels thereby reducing CS-induced cytokine production in human epithelial cells.

RESULTS: Exposure to cigarette smoke extract (CSE) in BEAS-2B cells significantly decreased HDAC activity levels and concomitantly increased production of both IL-8 and MCP-1 protein in cell culture supernatants. HDAC activity levels were restored by activating Nrf2-dependent pathways in BEAS-2B cells with SFN prior to CSE exposure. Microarray analysis was conducted to determine which genes may be responsible for the rescue of HDAC activity levels.

CONCLUSIONS: Our results indicate that SFN can restore HDAC activity levels in human epithelial cells exposed to CSE. However, the cellular mechanisms, by which HDAC activity and the production of cytokines are altered by SFN treatment, remain to be elucidated. We hypothesize that SFN activates Nrf2-dependent pathways leading to the inhibition of pro-inflammatory pathways such as NF-kB or AP-1 possibly through chromatin remodeling of the promoter sequences.

FUNDING SOURCE: Funding for this research was provided by the Byron Dare Junior Faculty Award and the Faculty Development Grant from Fort Lewis College.

698 PERFLUOROOROCANIC ACID INDUCES MAST CELL-MEDIATED ALLERGIC INFLAMMATION: RELEASE OF HISTAMINE, INVOLVEMENT OF CALCIUM, CASPASE-1, COX-2 AND NUCLEAR FACTOR-XB.

T. Singh and S. Kim, Pharmacology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.

Perfluorooctanoic acid (PFOA) has become an increasing concern because of its immune response in immune system, regularly found in the blood of animals and humans worldwide. Effects of PFOA is widely known and studied in the field of toxicology because of its unique physical and chemical characteristics, water and oil repellency, thermal stability, and surfactant properties. The role of PFOA in the allergic inflammation is not well-known. To further extend the study on PFOA, we examined mast cell-mediated allergic inflammation by PFOA and studied the possible mechanism of action. PFOA dose dependently increased histamine release and the release of histamine was mediated by the modulation of intracellular calcium. In addition, PFOA induced gene expression and secretion of pro-inflammatory cytokines such as tumor necrosis factor (TNF-α), Interleukin (IL)-1β, IL-6 and IL-8 in human mast cells. The inducing effect of PFOA on these pro-inflammatory cytokines was nuclear factor-XB, p38 and caspase-1 dependent. Furthermore, the activation of cyclooxygenase (COX)–2 by PFOA suggests the involvement of allergic inflammatory mediators in human mast cells. Our findings provide evidence that PFOA, the known immunotoxic agent, induces mast cell-mediated allergic inflammatory reactions by histamine release and pro-inflammatory cytokine expression.

699 TCDD EXACERBATES CONCANAVALIN A–INDUCED LIVER INJURY AND REVEALS A CRITICAL ROLE FOR NK CELLS IN A MODEL OF IMMUNE-MEDIATED LIVER INJURY.

A. M. Fullerton, R. A. Roth and P. E. Ganey, Pharmacology & Toxicology, Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

For many liver diseases, including viral and autoimmune hepatitis, immune cells play an important role in the development and progression of liver injury. ConcanaValin A (con A) administration is used as a model of immune-mediated liver injury resembling autoimmune hepatitis. 2,3,7,8-tetrachlordibenzo-p-dioxin (TCDD) has been reported to affect the development and severity of some autoimmune diseases. We have shown previously that mice treated with TCDD have an exacerbated response to administration of a mild dose (6 mg/kg) of con A, resulting in increased hepatocellular damage. In the present study, we tested the hypothesis that natural killer (NK) cells and the inflammatory cytokine interferon gamma (IFNγ) play critical roles in the development of liver injury from TCDD/con A co-exposure. Mice were treated on day 0 with TCDD (30 μg/kg) or olive oil (vehicle) and four days later with either con A or saline. Plasma samples were collected at various times after treatment, and liver injury was assessed from the activity of alanine aminotransferase in the plasma. Plasma concentration of IFNγ was significantly increased by TCDD/con A treatment, and injury was attenuated in IFNγ KO mice. After treatment, intrahepatic NK cells were isolated, and cell activation was determined by flow cytometry. TCDD/con A treatment increased the percentage of NK cells expressing activation marker CD69 and the costimulatory receptor NKG2d, and they were a significant source of IFNγ. Depletion of NK cells prior to treatment resulted in significant reductions in plasma IFNγ and liver injury from TCDD/con A treatment. In summary, exposure to TCDD exacerbated the immune-mediated liver injury induced by con A. In addition, our findings suggest
Activated macrophages play a key role in the pathogenic response to toxic doses of APAP. However, their contribution depends on their phenotype and timing of appearance in the liver. Thus, whereas early on, classically activated macrophages (CAM) contribute to tissue injury by releasing proinflammatory/cytotoxic mediators, later, alternatively activated macrophages (AAM) suppress inflammation and initiate tissue repair. We speculated that the β-galactoside binding lectin, Gal-3, is important in regulating macrophage activation phenotype. Treatment of WT mice with APAP (300 mg/kg, i.p.) resulted in increases in serum transaminases, beginning within 6 h, and histological evidence of centrilobular necrosis, which persisted for 24-48 h. This was associated with an influx of proinflammatory Ly6C-positive macrophages into centrilobular regions of the liver, which were distinct from F4/80-positive resident macrophages. The appearance of the Ly6C-positive macrophages correlated with increased hepatic expression of the CAM markers, iNOS and IL-12, and chemokines CCL3, CCL4, and CCL20. Ly6C-positive CAM were also found to express Gal-3. Gal-3-/- mice were used to analyze the role of this protein in macrophage activation. APAP-induced expression of CAM markers and hepatotoxicity were significantly attenuated in Gal-3-/- mice. In contrast, expression of endothelial nitric oxide synthase and nitric oxide levels, as well as the production of various extracellular (ECM) proteins were determined. We also assessed retinal EC adhesion on various ECM proteins, their junctional organization, VEGF expression, and oxidative stress state after incubation with various inflammatory cytokines. Cell viability and proliferation of retinal EC incubated with TNF-α, IL-1β and MCP-1 for 24 h was not affected. Incubation with TNF-α and IL-1β, but not MCP-1, decreased retinal EC migration and their ability to undergo capillary morphogenesis. Incubation with TNF-α and IL-1β, but not MCP-1, for 48 h resulted in increased production of VEGF, increased oxidative stress, and abnormal junctional localization of VE-cadherin at sites of the cell-cell contact consistent with altered cellular permeability. Together our results demonstrate that the inflammatory cytokines have specific adverse effects on angiogenic properties of retinal EC which is associated with increased oxidative stress and altered vascular permeability. Thus, altered production of proinflammatory cytokines during diabetes has a significant impact on retinal vascular function and pathogenesis of DR.

Macrophages are a major immune constituent of the lung, where they are the first line of defense and are instrumental in the clearance of inhaled particulates. Both in vitro and in vivo experiments have shown that interaction of macrophages with certain particulates (silica, nanomaterials) can have profound effects. Some studies have focused on cytotoxicity, while others have investigated alterations in functions. In our silicosis model we have observed death, survival, and expansion of macrophages. This suggests that either macrophages react differently to the same particle, or these observations are the result of different types of macrophages. A growing area of research is the role of macrophage subsets in certain pathologies. Previous work in our laboratory has described a role for the Th2-associated M2a subset in the Balb/c model of silicosis. Data further suggests that the insulin-like growth factor (IGF)-1-Akt pathway plays a role in the survival of a subset of particle-exposed macrophages. In addition to this pathway, other Th2-associated components that appear to contribute to the generation of a fibrotic environment include IL-33 and myeloid suppressors. Because IL-33 is a product of inflammasome activation and a promoter of Th2 immunity, it represents a candidate for the switch between the initial particle-induced Th1 inflammation and Th2-guided fibrosis in these models; while the early rise in IL-4+ myeloid suppressors may induce early IGF-1 production. These data suggest the contribution of multiple components in the rise of Th2 immunity following pulmonary exposure to certain particulates and the generation of a fibrotic environment.

This work is supported by NIH grant RR-017670 and ES015294.
ity under inflammatory stress. In this study, we developed an in vitro model to study the roles of caspase activation and oxidative stress in TNF potentiation of AMD cytotoxicity. AMD caused apoptotic cell death in Hepa1c1c7 cells, and TNF co-treatment potentiated its toxicity. Activation of caspases 9 and 3/7 was observed in AMD/TNF-α co-treated cells, and caspase inhibitors provided minor protection from cytotoxicity. Cytotoxic and mitochondrial reactive oxygen species and lipid peroxidation were observed after treatment with AMD and were further elevated by TNF co-treatment. Adding water-soluble antioxidants (tropolox, N-acetylcysteine, glutathione or ascorbate) produced only minor attenuation of AMD/TNF-induced cytotoxicity and did not influence the effect of AMD alone. On the other hand, α-tocopherol prevented AMD toxicity and caused pronounced reduction in cytotoxicity from AMD/TNF co-treatment. α-Tocopherol also reduced pan-caspase inhibitor completely abolished AMD/TNF-induced cytotoxicity. In summary, activation of caspases and oxidative stress were observed after AMD/TNF co-treatment, and caspase inhibitors and a lipid-soluble free radical scavenger attenuated AMD/TNF-induced cytotoxicity. (Supported by NIH R01DK061315.)

705 MOLECULAR MARKERS AND EVALUATION OF PHENOTYPIC RESPONSES IN RAW 264.7 MACROPHAGES.
M. Govindraj1, D. Santiago2, C. Guo4, A. Gowe1, Pharmacology and Toxicology, Rutgers University, New Brunswick, NJ and 2Chemistry, Universidad de Puerto Rico, Rio Piedras, Puerto Rico.

The adopion of alveolar macrophage phenotype, either classical (M1) or alternative (M2) is critical to the balance between inflammation and repair in the lung. The establishment of a cellular model to examine the mechanisms involved in phenotype adoption would be invaluable. We used RAW 264.7 cells, the M1 activator, LPS, and the M2 activator, IL-4 to develop a model system to study macrophage phenotypic adoption. Further we have used this system to examine the role of the pulmonary collectin Surfactant Protein-D in phenotypic differentiation. Cells were treated with LPS or IL-4 at varying doses and after 24 hours later evaluated for morphology, NO production, surface marker expression, gene and protein expression, enzyme activity. Morphologic studies were conducted by microscopy and by assaying cell volume; NO release was measured as a function of NO2- content in the medium using Sievers NOA; mRNA expression was measured by rt-PCR assaying cell volume; NO release was measured as a function of NO2- content in the medium using Sievers NOA; mRNA expression was measured by rt-PCR. Our results confirm RAW 264.7 as a viable model of macrophage phenotype in response to treatment with classical activators and a valuable tool to assess the mechanism involved.

706 COMPARISON OF IN VITRO AND IN VIVO CYTOKINE RESPONSE IN CYTOMOLGUS MONKEYS AFTER TREATMENT WITH AN ANTI-CD3 MAB.
S. Lavallee, J. Fontaine, R. Falvo, I. Veillette, Y. Tremblay, M. Piche and L. LeSauter, Immunology, Charles River Laboratories, Sennerville (Montreal), QC, Canada.

Evaluation of test article-related effects on inflammatory markers requires a good understanding of the specificity and sensitivity of the various markers available in preclinical GLP studies. Markers of the inflammatory response includes cytokines, acute-phase proteins (CRP) and complement factors. In vitro stimulation with an anti-CD3 mAb was used to evaluate the correlation between release of acute-phase proteins, cytokines and complement proteins in large animals. Furthermore, use of in vivo cytokine release assays as predictive tools of in vivo cytokine release was also evaluated during this study. Animals were administered doses of anti-CD3 mAb by bolus IV injection. Samples were collected pre and post-treatment for immunophenotyping and for cytokine, complement factor and CRP analysis. For each animal, whole blood samples were collected pre-treatment and were incubated with each animal's expected post-treatment plasmatic concentration of anti-CD3 mAb. Plasma was then analyzed for cytokines to evaluate if the cytokine response observed in vitro was predictive of the cytokine release observed in vivo. In most animals, substantial decrease in lymphocyte counts was observed 24 hours after treatment at all doses. Lymphocytes were back to baseline level 5 days after anti-CD3 mAb injection. Dose dependent transient increases of TNF-α, IL-10, IL-2, IFN-γ, IL-12, IL-5, IL-6, G-CSF, IL-1RA, CRP and complement split products Bb and C3a were observed after treatment. For one mid dose male, these changes correlated with strong in vitro release of IL-2, IFN-γ, TNF-α and IL-1RA. The anti-CD3 mAb model was useful to demonstrate that analytical methods were suitably sensitive to detect biologically relevant changes for all the biomarkers measured in the study. Data also showed that in vitro cytokine release assays may be predictive of intensity of the cytokine release in vitro but not necessarily of the occurrence of cytokine release.

707 A SMALL MOLECULE INHIBITOR OF THE TGF-β1 TYPE 1 RECEPTOR SUPPRESSES UVB-INDUCED MOUSE SKIN CARCINOGENESIS.
A. Ravindran, J. Mohammed, A. Gunderson and A. B. Glick, Molecular Toxicology and Carcinogenesis, The Pennsylvania State University, State College, PA.

Ultraviolet radiation is a key environmental mutagen and chronic exposure to UVB is the leading cause of Skin Cancer. Transforming Growth Factor (TGF-β) represents an important immunoregulatory cytokine in the skin microenvironment with context dependent role in modulating tumor formation and progression. The immune system plays a critical role in containing the toxic damage caused by UVB; TGF-β has been known to play a key role in the activation and survival of immune cells. However, the specific role of TGF-β signaling in UVB induced skin cancers is not clear. To study this interplay between UVB, TGF-β and the immune system, we performed a UVB carcinogenesis study in Skin Hairless (SKH1) mice in the presence or absence of SB431542, a small molecule inhibitor of the TGF-β1 type I receptor. We observed a significant decrease in the number of papillomas with the inhibition of TGF-β1 pathway and a concomitant decrease in the tumor infiltration and activation status (IFNγ secretion) of CD4 and CD8 lymphocytes. In order to understand the mechanism of suppression of T cell response by SB431542, we analyzed the immediate upstream event, antigen presentation by dermal dendritic cells and langerhans cells. Preliminary data suggests that inhibition of the TGF-β1 pathway with SB431542 suppresses the migration of skin dendritic cell subsets to the lymph nodes in response to UV irradiation, in turn suppressing the T lymphocyte response. In summary, the TGF-β1 signaling pathway is important for the activation of the inflammatory response to UVB irradiation of the skin, which may mediated through Dendritic cells.

708 EXTRACT OF Ripe FRUITS OF RUBUS COREANUS INHIBITS MAST CELL-MEDIATED ALLERGIC INFLAMMATION.
H. Kim and S. Kim, Department of Pharmacology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.

In this study, we investigated the effect of water extract of ripe fruits of Rubus coreanus Miq. (Rosaceae) (RFRC) on the mast cell-mediated allergic inflammation and studied the possible mechanism of action. Mast cell-mediated allergic disease is involved in many diseases such as anaphylaxis, rhinitis, asthma and atopic dermatitis. RFRC dose dependently inhibited compound 48/80-induced systemic anaphylaxis and serum histamine release in mice. RFRC reduced the immunoglobulin E mediated local allergic reaction, passive cutaneous anaphylaxis. RFRC attenuated histamine release from rat peritoneal mast cells and human mast cells by the reduction of intracellular calcium. RFRC decreased phorbol 12-myristate 13-acetate (PMA) and calcium ionophore A23187 (PMACI)-stimulated expression and secretion of pro-inflammatory cytokines in human mast cells. The inhibitory effect of RFRC on the cytokines production was nuclear factor (NF)-κB and mitogen-activated protein kinase (MAPK) dependent. In addition, RFRC suppressed the activation of caspase-1. Our findings provide evidence that RFRC inhibits mast cell-derived allergenic inflammatory reactions, and the involvement of calcium, NF-κB, MAPKs, and caspase-1 in these effects. Furthermore, in vivo and in vitro anti-allergic inflammatory effects of RFRC provide affirmative proof that a possible therapeutic application of this agent in allergic inflammatory diseases.

709 WHOLE-MOUNT IMAGE CAPTURE AND ANALYSIS OF IDIOPATHIC PULMONARY FIBROSIS IN BLEOMYCIN-INDUCED MOUSE MODELS USING MICRO-COMPUTED TOMOGRAPHY AND VIRTUAL HISTOLOGY.

Drug-induced idiopathic pulmonary fibrosis (IPF) is a known adverse side effect associated with regemented bleomycin therapy for remediation of a number of oncologic diseases. Preclinical animal models have been developed for comparative
analysis to clinical etiological pathways of IPF, but imaging methods to capture the heterogeneity of fibrotic distribution in whole-mount lung tissue have not been ade-
quate addressed. It is demonstrated here that contrast enhanced micro computed
tomography (microCT) scanning allows for whole-mount imaging and analysis
(Virtual Histology) of IPF in both intratracheal (IT) instillation and subcutaneous
(Sub Q) micropump dosing of bleomycin in mouse models. Virtual Histology is
compared with traditional histological methods including Masson’s trichrome and
modified Ashcroft scoring. The advantages of this non-destructive Virtual
Histology over traditional histology are reviewed. In addition to derivation of ex-
quise high-resolution planar (2-dimensional) and volumetric (3-dimensional) re-
formats, computational analysis reveals discrete attenuation curves associated with
naive, acute (IT), and chronic (Sub Q) dosing methods, facilitating more accurate
assessments of fibrotic lung tissue burden and distribution in preclinical drug
development pipelines.

**710 HEPATIC METALLOTHIONEIN INCREASES AFTER EXPERIMENTAL SURGERY: ROLE OF SOME CYTOKINES AND STRESS HORMONES.**

E. M. Brambila, R. Hernández, H. Scott, P. Aguilar-Alonso and B. León-
Chavez. Department of Chemical Sciences, Benemerita Universidad Autonoma de
Puebla, Puebla, Puebla, Mexico.

Abdominal surgery as a localized inflammatory model has been used to study the
redistribution plasma/liver zinc redistribution and the induction of hepatic metal-
lothionein (MT) synthesis. In this work we explore the role of inflammatory cyto-
kines and stress hormones on the increases of liver MT in the early stages after an
abdominal surgery in rats. Wistar rats were surgically operated, receiving a 3-cm
ventral incision. Groups of five animals were killed by exsanguinations at 3, 6, 9
hours, and liver samples were obtained and stored at -70C. Plasma cyto-
kines (IL-1, -6 and TNF-ct) and hormones (adrenaline, noradrenalin and glucagon)
were determined by an ELISA assay. Hepatic MT protein was deter-
mined using a cadmium saturation method. Other groups of rats were adminis-
tered with inhibitors of IL-1 and -6 MT synthesis signaling pathways (A6490,
SB236093 and PDTC) and hormone inhibitors (propranolol and oestredose), pre-
nious surgery operation. Hepatic MT protein increased significantly 6h post-sur-
ger and peaked up to fivefold of control animals at 12h. IL-1 and -6 shown in-
treases starting at 3h after surgery, however, TNF-ct did not show changes as
compared with the control group. Adrenaline and glucagon shown significantly in-
tereases after surgery, increases start in the first hour post-surgery, keeping these lev-
el at the end of the evaluation, meanwhile, noradrenalin show a decrease. Signaling
pathways and hormone inhibitors decreased MT hepatic levels as compared with
the MT levels showed by the animals with surgery. Results obtained shown the role
of IL-1 and -6, adrenaline and glucagon as inducers of MT synthesis in the early stages
of experimental surgical trauma.

**711 PLUM POLYPHENOLICS AMELIORATE INFLAMMATION AND METABOLIC ALTERATIONS IN OBESE ZUCKER RATS.**

G. D. Noratto1-3, S. Y. Simbo1, D. Byrne4 and S. Mertens-Talcott2-1. Veterinary,
Physiology, and Pharmacology, Texas A&M University, College Station, TX,

and Kinesiology, Texas A&M University, College Station, TX and 4Horticulture
Sciences, Texas A&M University, College Station, TX.

Obesity is a risk factor leading to inflammation and chronic diseases and epidemiolo-
gical evidence has demonstrated protective effects of fruits and vegetables. We
investigated how peach and plum polyphenolics can prevent metabolic disorders in
obese Zucker rats. Experimental groups were feed with peach or plum juice ad libi-
tum, the placebo and lean Zucker groups received same amount of sugars as peach
and plum juices in drinking water. Body weights were recorded every week, and
blood serum was analyzed at baseline and after 11 weeks. Gene expression in heart
tissues was analyzed by RT-PCR. Total polyphenolic content was higher in plum
than in peach juice (1270 vs 430 mg gallic acid equiv./mL). Results showed that at
the concentration of 0.79 and 0.58- fold respectively). In conclusion, consumption of plum juice
maintained lower body mass index than Zucker rats against obesity-induced inflammation and metabolic
disorders at higher extent than peach juice and this was due to the higher content of polyphenolics.

**712 ODSH ENHANCES BACTERIAL CLEARANCE IN PSEUDOMONAS AERUGINOSA PNEUMONIA.**

J. Wu1, L. Sharma1, R. Sitapara1, V. Patel1, T. P. Kennedy1 and L. L. Mantell1-2, 3Pharmacological Science, St. John’s University, Jamaica, NY, 1The Feinstein Institute
for Medical Research, North Shore-LIJ Health Science, Manhasset, NY and
3Pulmonary/Critical Care Medicine, Georgia Health Sciences University, Augusta,
GA.

Nosocomial pneumonia (NP) is one of the most common infectious diseases ac-
quired in hospital and is the leading cause of morbidity and mortality in the inten-
sive care unit (ICU), despite recent advances in antimicrobial therapy.
Pseudomonas aeruginosa (PA) is one of the most common organisms associated
with NP. ODSH, 2-o, 3-o –desulfated heparin, has been shown to exhibit anti-in-
flammatory properties and can reduce lung injury in sterile inflammation, with a
minimal antiaggregation effect. The objective of this study was to determine whether
ODSH can improve bacterial clearance. C57BL6 mice were randomized to receive subcutaneous administration of either a series of concentrations of
ODSH or saline twice at 0h and 12h after intranasal inoculation with PA. Mice
were euthanized 24 h post-infection and lungs and BALF were harvested. Bacterial
load in the lungs and airways were measured by plating serial dilutions of lung ho-
modenate and BALF respectively. Our results show that ODSH significantly im-
poved bacterial clearance in both lungs and airways. These results suggest that
ODSH can effectively enhance the host’s ability to clear bacteria and may provide
a novel therapeutic approach in the treatment of nosocomial pneumonia.

**713 ODSH IMPROVES PSEUDOMONAS AERUGINOSA-INDUCED LUNG INJURY BY DECREASING INFILTRATION OF INFLAMMATORY CELLS.**

L. K. Sharma1, J. Wu1, R. Sitapara1, V. Patel1, T. Kennedy1 and L. Mantell1-2, 1Phamaceutical Science, St. John’s University, Jamaica, NY, 2The Feinstein Institute
for Medical Research, North Shore-LIJ Health Science, Manhasset, NY and
3Pulmonary/Critical Care Medicine, Georgia Health Sciences University, Augusta,
GA.

Nosocomial Pneumonia (NP) or Hospital Acquired Pneumonia (HAP) is associ-
ated with infections originated from the hospital borne pathogens. Resistance
against antimicrobial agents is the most common feature of these infections which
results in high mortality rates and greater therapeutic costs. Due to involvement of
multidrug resistance bacteria, alternative or supportive therapies are always re-
quired. Heparin, a well-known anticoagulant, has been found to have anti-inflam-
matory properties independent of anticoagulant property. ODSH, a desulfated he-
parin, has been proven to have anti-inflammatory properties with minimal
antiaggregation effect. ODSH has been shown to reduce lung injury in sterile in-
flammation and reducing inflammatory lung damage. Pseudomonas aeruginosa,
agr negative opportunistic pathogen, is one of the prominent pathogens associ-
ated with NP. It has been shown that PA pneumonia increases the secretion of in-
flammatory cytokines, neutrophil infiltration and subsequent lung damage. In this
study, we sought to find whether ODSH can be effective in reducing lung damage
caused by Pseudomonas aeruginosa. It was found that ODSH reduces lung injury
caused by PA, marked as reduced total protein concentration in the BAL measured
by using BCA Assay. This attenuation in lung injury was accompanied with signifi-
cantly decreased total airway cell count and neutrophil infiltration in the lungs.
These data indicate that ODSH protects against PA induced lung injury and neu-
trophil infiltration.

**714 CYANOBACTERIAL LIPOPOLYSACCHARIDES (LPS) ELICIT RELEASE OF SUPEROXIDE ANION, THROMBOXANE B₂, AND TUMOR NECROSIS-α FROM RAT BRAIN MICROGLIA.**

Biochemistry, University of Hawaii at Manoa, Honolulu, HI.

We have recently reported that the cyanobacterium Microcystis aeruginosa
lipopolysaccharide (LPS) elicited classical activation of rat microglia (B MGM) in vitro
and concomitant release of superoxide anion, thromboxane B₂, cytokines,
chemokines, and matrix metalloproteinase-9 (Toxicological Sciences, 121(1): 63-

715 DOES AFGHANISTAN SAND DUST INHALATION INFLUENCE MILD BLAST-INDUCED IMMUNE AND COGNITIVE RESPONSES?

P. Ganszegi, S. Prues, D. Stoffregen, A. James, S. McInturf and A. Osterburg.
Naval Medical Research Unit, West-Patterson AFB, Dayton, OH.

Soldiers have significant exposure to particulate matter, including when they are subjected to a blast injury. Evidence suggests that inhalation of sand induces an inflammatory response. The aim of the current study was to investigate the effect of blast trauma and sand inhalation on the expression of pro- and anti-inflammatory mediators, as well as on the number of immune cells in rats. The results showed that sand inhalation increased the expression of pro-inflammatory cytokines and decreased the expression of anti-inflammatory cytokines. Furthermore, blast trauma and sand inhalation together had a synergistic effect on the expression of these mediators. These findings suggest that sand inhalation may exacerbate the inflammatory response to blast trauma and contribute to the development of post-traumatic syndromes in humans. Additionally, there exists a possibility that inhaled dust containing potentially harmful metals and chemical components may enter the brain and contribute to blast-trauma induced damage and to the development of neurological disorders. Identifying relevant blast injury pathogenic pathways and neurobehavioral deficits is vital for development of mild injury diagnostic biomarkers. In this study, rats were exposed to shock wave pressure to simulate mild traumatic brain injury (mTBI) with and without Afghanistan sand pre-exposure by nose inhalation. Prior to sacrifice, neurobehavioral tests were performed on 7, 14 and 28 days post-trauma animals. MWM tests revealed no significant difference among groups for all time points studied. Flow cytometric analysis of spleenocytes immunophenotyped with lymphocyte antibodies demonstrated reduction in activation of cytotoxic and helper T-cells in blast/sand exposed rats 3 days after trauma. The ratio of cytotoxic and helper T-cells decreased which indicate the vulnerability of the animals in response to blast/sand dust exposure. At 7 days post injury, significant increases in numbers of B-cell lymphocytes by sand exposure, blast or both compared to control. However, mTBI or sand alone has no significant influence on cytotoxic T-cells, helper T-cells and NK cells. Further, blast trauma rats pre-exposed to sand did not influence oncocytes B-cell activation or subpopulations of immune cells. Thus, data on mTBI model clearly demonstrates that some immune cells are potentially modulated at early time points due to neuroinflammatory insult during blast injury in conjunction with sand dust.

716 DEFICIENCY IN CD44S ENHANCES DEXTRAN SODIUM SULPHATE (DSS)-INDUCED COLITIS AND INFLAMMATORY TOXICITY IN THE COLON.

I. Altamimi, M. Nagarkatti and P. Nagarkatti. Pathology, Microbiology and Immunology, University of South Carolina, School of Medicine, Columbia, SC.

Inflammatory bowel disease (IBD) is a chronic, relapsing and remitting inflammatory condition. CD44 is a widely expressed family of adhesion receptors. The most common form of CD44, referred to as CD44 standard form (CD44s) does not contain differentially spliced exons. The objective of this study is to find out the role of CD44s form on inflammation associated with dextran sodium sulphate (DSS)-induced colitis in mice. To this end, CD44s knockout (KO) mice and wildtype C57BL/6 mice were used to induce colitis with 3% DSS in drinking water at 2-week intervals for 5 times. Hematological parameters, body weight, and survival were assessed. In addition, serum amyloid A (SAA) and inflammatory cytokines IL-6 were quantitated. Splenic and mesenteric lymph node cells were analyzed for expression of CD3, CD4, CD8, NK1.1, CD69, and CD19. In addition, CD11b+Gr-1+ MDCs were also enumerated. Our current study shows that CD44s KO mice exhibited increased DSS-induced acute colitis as reflected by high lethality, weight loss, and histological scores compared to wild type mice. Also, SAA level in CD44s KO mice were higher. In addition, IL-6 showed high levels of expression in CD44s KO DSS-treated group, whereas undetectable levels were found in other groups. The flow cytometry results demonstrated that the proportion of SAA+ cells, CD19+ cells, activated T cells (CD3+CD69+) in mesenteric lymph node were higher in CD44sKO DSS-treated group compared to wild type DSS-treated mice, whereas NKT (CD3+NK1.1+) cells were lower in CD44sKO DSS-exposed group when compared to wild-type mice. In conclusion, CD44s deficiency enhances inflammation in the colon thereby providing therapeutic targets to treat colitis. (Supported in part by VA Merit BX001357, NIH grants R01AT006888, R01ES09908, P01AT003961, and R01ES019313; Israel Government).

717 PULMONARY PATHOPHYSIOLOGY OF AMBIDENT PARTICULATE DUST FROM IRAQI MILITARY FIELDS.

N. R. Fri1, D. L. Pack1, L. A. Battelli1, M. W. Barger1, A. J. Kenyon1, T. G. Meighan1, J. A. Lewis1, D. A. Jackson2, V. Castranova3 and S. S. Leonard4.
National Institute of Occupational Safety and Health (NIOSH)/CDC, Morgantown, WV and 1US Army Center for Environmental Health Research, Fort Detrick, MD.

The pathological response in relation to physical/chemical and morphological properties of ambient particulates from Iraq has become an area of great interest. This study investigated the role of metal contaminants present in ambient dust in the induction of pulmonary injury and examined the potential pulmonary risks from exposure to Iraqi particulate matter. Adult male Sprague-Dawley [Hsd:SD] CVF rats were dosed via intratracheal instillation (IT) with phosphate buffered saline (PBS) as control, ambient dust collected from Camp Victory, Iraq (CV), or NIST sand 840D. U.S. urban particulate matter in ambient dust contained in vitro toxicity compared to both CV and NIST. Differences in lung cell proliferation were examined via BrdU assay. Histopathological analysis was investigated using Mason’s Trichrome, Alcian Blue PAS, and H & E grading. The results from the LDH, albumin, and TNF-α showed no significant differences from control in all exposures. However, a significant difference was found in macrophage and neutrophil response in NIST (10mg/kg) at 150 days and CV (10 mg/kg) at all exposures compared to control. CV (5 mg/kg) dose also showed a significant differences in macrophages and neutrophil response at the 150 day time point compared to control. Our results indicate that a high dose of CV and NIST can induce pulmonary inflammation, but to a lesser degree than a highly fibrogenic particle (Min-U-Sil) at the same time point and concentration as determined by a previous study.

Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the US Army or NIOSH.

718 ASIAN SAND DUST ENHANCES MURINE LUNG INFLAMMATION CAUSED BY KLEBSIELLA PNEUMONIAE.

M. He1, T. Ichinose1, S. Yoshida1, S. Yamamoto2, K. Inoue2, H. Takano2, R. Yanagiwara1, M. Nishikawa1, I. Mori1, G. Sun1 and T. Ishibamoto1.

Sponsor: Y. Sun.

Concomitant inhalation of Asian sand dust (ASD) and pathogen may result in exacerbation of pneumonia by the pathogen. The exacting effect of ASD on pneumonia induced by Klebsiella Pneumoniae (KP) was investigated in ICR mice. The organic substances adsorbed onto ASD collected from the atmosphere of Okinawa in Japan were excluded by heat treatment at 360°C for 30 min. ICR mice were instilled intratracheally with ASD at doses of 0.05 mg or 0.2 mg/mouse four times at 2-week intervals and were administered with ASD in presence or absence of KP at the last instillation intratracheal. Pathologically, ASD caused exacerbation of pneumonia by KP as shown by increased inflammatory cells within the broncholar and the alveolar compartments. ASD enhanced dose dependently neutrophil number and expression of cytokines (IL-1β, IL-6, IL-12, IFN-γ, TNF-α), and chemokines (KC, MCP-1, MIP-1α) in BALF related to KP. In an in vitro study using RAW264.7 cells, the treatment of ASD and KP increased gene expression of IL-6, IFN-β, TNF-α, KC, MCP-1 and MIP-1α and increased the expression of IL-1β, TNF-α, MCP-1 and MIP-1α in culture medium compared with each alone treatment. The combined treatment tends to induce the gene expression of Toll-like receptor 2 (TLR2), and NALP3, ASC and caspase-1 compared with KP alone. These results suggest that the exacerbation of pneumonia by ASD + KP could be due to the enhanced production of pro-inflammatory mediators via activation of TLR2 and NALP3 in ammossome pathway in alveolar macrophages.
Acid sphingomyelinase (A-SMase) level in AM was determined because it has been
Inflammasome's role in IL-1β
A significant reduction in IL-1β
and MARCO-/- mice with LPS and cathepsin B inhibitor prior to silica exposure.

IL-1β Inflammasome activation was quantitated by the release of IL-1β (MARCO) as an important receptor for binding, uptake and clearance of crys-

zyme of silicosis, an irreversible, inflammatory and fibrotic pulmonary disease.

Confirm that the increase in IL-1β in MARCO-/- AM was due to the absence of MARCO receptor; MARCOAb was used to block MARCO in WT. Release of IL-1β following MARCOAb was similar to IL-1β release from MARCO-/- AM. Inflammasome's role in IL-1β release was confirmed by pretreating AM from WT and MARCO-/- mice with LPS and cathepsin B inhibitor prior to silica exposure. A significant reduction in IL-1β release was observed with cathepsin B inhibition. Acid sphingomyelinase (A-SMase) level in AM was determined because it has been indicated in acute lung injury. A-SMase level was higher in MARCO-/- AM. The results demonstrate inflammasome activation is exacerbated in absence of MARCO and may be linked with increased A-SMase and the variance in MACRO expression may explain variance in human susceptibility to silicosis. This work was supported by NIH grants P20 RR017670 and R01 ES15294.

Inflammasome is an enzyme that controls the release of pro-inflammatory cytokines from immune cells. Inflammasome activation is a critical step in the inflammatory response and plays a role in the development of certain diseases, including autoimmune disorders and inflammatory bowel disease.

Inflammasome activity is assessed by measuring the release of pro-inflammatory cytokines, such as IL-1β, from immune cells. One common method to study inflammasome activity is to use inhibitors to block the enzyme responsible for cleaving pro-IL-1β into its active form. In this study, the researchers used LPS and cathepsin B inhibitor to block inflammasome activation, and they observed a significant reduction in IL-1β release from MARCO-/- AM compared to WT AM. This finding suggests that inflammasome activation is exacerbated in the absence of MARCO, a receptor that binds and internalizes inflammasome components.

Inflammasome activation is also regulated by cell-specific factors. For example, the researchers used MARCOAb to block MARCO in WT AM and observed a similar increase in IL-1β release as seen in MARCO-/- AM. This suggests that the absence of MARCO receptor is responsible for the increased inflammasome activity.

The study also indicates that inflammasome activation is not only due to the lack of MARCO but also due to the increased level of A-SMase. This is supported by the observation of a significant increase in AEA levels, when compared to controls. These data suggest that inflammasome activation leads to increased secretion of ECs and that ECs may play a critical role during inflammation in specific organs such as the liver.

Inflammatoxylin (IBD), including Crohn's disease and ulcerative colitis, are chronic inflammatory diseases of the gastrointestinal tract. Recently we have demonstrated the anti-inflammatory effect of a novel nonapeptide, fragment of histone H2A, termed IIIM1 in a variety of animal models of autoimmune and inflamma-
tyre diseases. Transgenic mice constitutively expressing IIIM1 were used in this study. The objective of the present research was to test the vulnerability of these animals to chemical-induced colitis in comparison to control mice. Bacterial inflamma-

tion was induced by rectal administration of trinitrobenzenesulfonic acid and 7 days later the animals were sacrificed. The control mice developed severe inflamma-
tory response expressed by increased colon weight and extensive proinflammatory nerosis and associated transmural infiltration of numerous neutrophils. In contrast, colon of transgenic mice was normal, devoid of pathological changes with marked (68%) weight reduction. Suppressed inflammatory response in the transgenic mice was also expressed by reduction in serum IL17 (49%) and IFNy (42%). This notion was corroborated by the significant increase in FoxP3- and TGFβ-producing cells in spleen of transgenic mice. In conclusion, animals constitutively expressing IIIM1 peptide are more resistant to chemical-induced bowel irritation via reduction in inflamma-
tory responses. These findings indicate for the potential of IIIM1 peptide to serve as a drug for IBD, chronic inflammatory diseases and chemical-induced ir-

Lung inflammation plays a key role in CARBON NANOPARTICLE-INDUCED ADJUVANT ACTIVITY.

Chronic exposure to combustion derived particles has been associated with an increase in the incidence of asthma. As a possible mechanism for this pathological outcome, the adjuvant effect of lung inflammation induced by these particles has been hypothesized. The aim of our study was to investigate the causal link between nanoparticle-induced lung inflammation and modulations of immune cell populations during processes leading to sensitization, and allergic immune responses of the airways.

Mice were treated with ovalbumin (OVA) alone or in combination with carbon nanoparticles (CNP). The induction of inflammation and the immune adjuvant activity were studied in the lungs and lung draining peribronchial lymph nodes (PBLN); (i) at the level of sensitization, and (ii) at the level of the immune re-

Our data show a link between neutrophilic lung inflammation and adjuvant effects of CNP. A specific reduction of neutrophils by the application of ectoine attenuated this NP induced adjuvant effect, indicating that particle induced inflammation rather than the direct interaction of nanoparticles with immune cells is the critical step in environmentally modulated immune diseases.
twelve week old C3H/HeN male mice were intratracheally treated with vehicle (PBS) or 375 μg/kg E. coli LPS. After 12 hours, mice were exposed to room air (RA) or 60% O2 for 1 or 3 days. Cytokine and chemokine expression was measured by ELISA in bronchoalveolar lavage fluid. Pulmonary function tests were performed on anesthetized mice using the Flexivent. On day 1, TNF-α, IL-6, RAGE, and MCP-1 were significantly increased in LPS/RA and LPS/O2 compared to PBS/RA and PBS/O2 treated mice. Neutrophil chemokine receptors, KC and MIP-2, were significantly increased in LPS/O2 mice compared to other treatment groups. Central airway resistance was significantly increased on day 3 in LPS/O2 mice compared to PBS/RA mice. Our data show that the combination of LPS and hypoxia uniquely increases expression of chemokines that mediate of neutrophil infiltration and increases airway resistance. We speculate that LPS and hypoxia interact to activate unique mechanisms that may contribute to the development of LPS-induced ALI in adult mice.

724  BETA2-ADRENERGIC RECEPTOR ENGAGEMENT ON A B CELL REGULATES THE LEVEL OF IGE VIA CD23 CLEAVAGE BY ADAM10 ON B CELL-DERIVED EXOSOMES.

C. J. Padro1 and V. M. Sanders1.1. Integrated Biomedical Science Graduate Program, The Ohio State University, Columbus, OH and Molecular Virology, Immunology, and Medical Genetics, The Ohio State University, Columbus, OH.

Allergic asthma is a major problem in toxicology and relief of bronchoconstriction by beta2-adrenergic receptor (β2AR)- agonist administration is the most effective treatment. Severity of allergic asthma is associated with high serum Immunoglobulin E (IgE). We previously showed that β2AR engagement on a primed murine B cell increases the level of IgE produced per cell, without affecting isotype switching. β2AR agonists alleviate bronchoconstriction by targeting the β2AR expressed on bronchiolar smooth muscle cells, triggering bronchodilation. These drugs also target the β2AR on primed B cells to increase IgE and soluble CD23 (sCD23), a positive regulator of IgE. Primed B cells exposed to a β2AR agonist show CD23 and sCD23 increases, while surface CD23 remains constant. Thus, β2AR engagement may worsen bronchoconstriction over time by increasing sCD23 and subsequently IgE, albeit relieving bronchoconstriction in the short term. CD23 cleavage by ADAM10 was recently found to occur primarily on exosomes as opposed to the cell surface. We found that β2AR engagement on a primed B cell did not alter ADAM10 production or surface expression compared to primed B cells alone, but increased the amount of exosome-localized ADAM10 with CD23 as determined by Western blot and FACs. In addition, only the exosomes expressing high ADAM10 and CD23 were decreased upon β2AR stimulation, indicating that CD23 was being cleaved and converted to exosomes expressing low CD23. Additionally, β2AR stimulation on a β2AR-deficient primed B cell failed to upregulate ADAM10 and CD23 expression on B cell-derived exosomes, indicating specificity of the response. Thus, ADAM10 expression on B cell-derived exosomes may serve as a molecular target to therapeutically prevent the β2AR-associated increase in sCD23 and IgE that worsens asthma, while still allowing for induction of the β2AR agonist-induced bronchodilation.

725  INCREASED PHOSPHODIESTERASE 4B (PDE4B) AND DECREASED CELLULAR CAMP REGULATE LPS-INDUCIBLE TNF-α IN GLUCOSE-PRIMED MONOCYTES.

E. Chambers1, L. Gobetjohivi1, S. Ghare1, C. McClain1,2,3 and S. Barve1,2 1Department of Medicine/GI, University of Louisville, Louisville, KY, 2Pharmacology and Toxicology, University of Louisville, Louisville, KY and 3Louisville VAMC, Louisville, KY.

Diabetes experience increased gut permeability leading to increased levels of serum endotoxin derived from intestinal Gram-negative bacteria. Consequently, diabetes suffers from chronic low-grade inflammation. Therefore, lipopolysaccharide (LPS)-inducible cytokines are highly relevant in this disease contributing to the development of diabetic complications. Specifically, Tumor Necrosis Factor-α (TNF-α), plays a major role in the evolution of multi-organ dysfunction and complications associated with diabetes. Our earlier work demonstrated that in monocyte/macrophage, PDE4B regulated cAMP plays a key role in regulating LPS-inducible TNF-α expression. Accordingly, the potential role of PDE4 in the regulation of high glucose exposure and LPS-mediated TNF-α expression was investigated in human monocytes. The data obtained demonstrates that human monocytes exposed to high glucose (HG;25mM) exhibit a “primed phenotype”, wherein in comparison to normal glucose exposure, they express elevated levels of TNF-α following LPS stimulation. The data obtained shows for the first time that

726  FOUR CASES OF NEUROPSYCHOLOGICAL ABNORMAL FINDING IN CHILDREN WITH HIGH BLOOD METHYL-MERCURY CONCENTRATION.

Y. S. Hong1, Y. M. Kim1, J. S. Kim2, S. H. Kim3, J. K. Kim3, J. H. Ye2 and J. H. Jung3 1Preventive Medicine, Dong-A University, Busan, Republic of Korea, 2Environmental Epidemiology, National Institute of Environmental Research, Inchon, Republic of Korea, 3Department of Psychology, Dong-A University, Busan, Republic of Korea, 4Department of Neurology, Dong-A University, Busan, Republic of Korea and 5Department of Pediatrics, Dong-A University, Busan, Republic of Korea and 6Department of Occupational and Environmental Medicine, Dong-A University, Busan, Republic of Korea. Sponsor: J. Jung.

Methyl-mercury easily passes the blood-brain barrier and accumulates in central nervous system, causing neurological symptoms. We report four cases of neuropsychological abnormal finding in children with high blood methyl-mercury concentration.

Cases Presentation: Four children admitted because of having a high blood mercury concentration through the national survey of mercury. Case 1 was a 9-year-old female with 16.6 μg/l blood mercury concentration on survey and on admission, the blood, hair mercury and blood methyl-mercury concentration (mercury indices) were 21.4 μg/l, 7.2 μg/g and 20.1 μg/l. In neuropsychological examination, cognitive impairment and attention deficit were observed. She had diet habit with 2-3 time fish intake per week and had been diagnosed with epilepsy at 3 year-old. Case 2 was a 12-year-old male with 15.4 μg/l on survey and the mercury indices were 12.7 μg/l, 5.7 μg/g and 11.8 μg/l. He was observed the finding of attention deficit/hyperactivity disorder. Case 3 was a 10-year-old male child with 17.4 μg/l on survey and the mercury indices were 21.6 μg/l, 7.5 μg/g and 21.5 μg/l. The finding of mild attention deficit was observed. Case 4 was a 9-year-old male with 20.6 μg/l on survey and the mercury indices were 18.9 μg/l, 8.3 μg/g and 14.4 μg/l. Mild attention difficulty was observed.

Discussion: We considered that fish consumption may be the main source of methyl-mercury exposure, and it could be influence neuropsychological finding in these cases.

727  A FEASIBILITY ASSESSMENT OF CONTINUOUS BLOOD PRESSURE AND HEART RATE ASSESSMENTS IN JUVENILE RATS.

It is reported that 90% of medicines used in pediatric care have only undergone preclinical safety evaluation in adult animals. However there are known differences in organ function between juvenile and adult animals which could potentially lead to both pharmacological and toxicological adverse findings not identified in traditional adult animal toxicity studies. The EMEA and the FDA have issued guidance requiring standalone pediatric studies when human safety and adult animal preclinical data are considered insufficient to support pediatric use.

In light of these requirements, the purpose of this study was to evaluate the feasibility of assessing heart rate and blood pressure in juvenile rats commencing 22 days post partum (pp). Rat pups were implanted at 21 days pp with a PA C10 transmitter traditionally used in mouse telemetry studies. The surgical procedure involved a femoral artery cannulation and placement of the transmitter on the flank. Intermittent assessments of heart rate and blood pressure were conducted on Days 22, 28, 40 and 70 pp, to verify transmitter patency. On Day 28 and Day 70 animals were treated with MK 801, a NMDA receptor antagonist, which was expected to induce hypertension and tachycardia.

Assessment of blood pressure and heart rates on Day 22 pp, confirmed accurate placement of the PA C10 implant with stable heart rate ranges of approximately 469 to 486 beats per minute and systolic and diastolic blood pressure ranges of 92 to 146 mmHg and 58 to 98 mmHg, respectively. Over the duration of the assessments baseline blood pressure levels remained stable with average heart rates decreasing in the older animals to approximately 305 to 362 bpm. Administration of MK-801 resulted in a profound hypertension and tachycardia.
The preliminary data demonstrated confirm that surgical placement of telemetry transmitters in juvenile rats for the measurement of continuous blood pressure and heart rate is feasible and therefore cardiovascular assessments can be incorporated into juvenile toxicity studies.

**728 PRECLINICAL DEVELOPMENT OF ALOPPREGANONOLE (ALLO) FOR TREATMENT OF NIEMANN-PICK TYPE-C, A RARE NEONATAL AND PEDIATRIC DISEASE.**

L. Rausch1, J. Gow1, C. McFarlane1, J. M. Brune1, D. G. Fairchild1, M. Patrick1, M. Claros2, S. H. Mellon2 and K. L. Steinmetz2. 1Biocrono Division, SRI International, Menlo Park, CA and 2Department of Obstetrics and Gynecology, University of California San Francisco, San Francisco, CA.

Niemann-Pick Type-C (NP-C) is a rare autosomal recessive neurodegenerative disease caused by genetic mutations in NPC1 (95%) or NPC2 (5%), resulting in lysosomal accumulation of unesterified cholesterol and glycolipids. NP-C: clinical manifestations include severe infant and pediatric neurodegenerative disorders including early death. Treatment of neonatal NIH NPC1 mice with a single subcutaneous dose of ALLO resulted in a doubling of life span, substantial delay in onset of neurological symptoms, survival of cerebellar Purkinje and granule cell neurons, and reduction in cholesterol and ganglioside accumulation. Range-finding in neonatal 2-week old Beagle dogs with a slow bolus (2.5 min) intravenous infusion of 3.5 mg/kg ALLO in 20% 2-hydroxypropyl-beta-cyclodextrin in water induced sleep followed by death. Twice weekly treatment in the GLP 4-week definitive toxicity study with 0.25, 0.5, or 1 mg/kg ALLO transiently induced sleep indicating neurological activity. There were no dose-related changes in clinical signs, body weight, food consumption, hematology, clinical chemistry, urinalysis, ophthalmology, gross or microscopic pathology. On Days 1 and 14, plasma and brain ALLO levels (<300 and <340 ng/ml, respectively) declined quickly after the first time point and were not detectable beyond 1 hr post dose (lower limit of quantitation was 2.5 ng/ml). In the brain, total ALLO exposure was similar to plasma, but brain-to-plasma concentration ratios (0.5-2.5) showed variability with time. Rapid ALLO elimination and lack of accumulation were reflected in the short half-life (<0.45 hr), ample volume of distribution (1500-5000 ml/kg), and high rate of clearance (≤8700 ml/hr/kg). In conclusion, intravenously administered ALLO to 2-week old Beagle dogs resulted in rapid penetration to the brain. ALLO was well tolerated in juvenile dogs after 4 weeks twice weekly dose administration. This work was supported by NIH Grant U01-NS049462.

**729 MITOCHONDRIAL BASIS OF ADVERSE PERINATAL OUTCOME IN HIV-TREATED PREGNANT WOMEN.**

G. Garrabou1, A. S. Hernandez1,2, C. Morení1, M. Catalán1, E. Tobías1, M. López2, <Δ> Coll3, F. Cardellach4, E. Gratacos5 and <Δ> Miro6. 1Mitochondrial Research Laboratory, IDIBAPS-University of Barcelona, Internal Medicine Department, Hospital Clinic of Barcelona (Barcelona, Spain) and CIBERER, Valencia, Spain, Barcelona, Spain and 2Materno-Fetal Medical Services Hospital Clinic of Barcelona, Barcelona, Spain. Sponsor: I. Domingo.

Background: HIV and antiretrovirals cause mitochondrial DNA (mtDNA) depletion which can lead to mitochondrial dysfunction and oxidative stress (OxS). Secondary effects of HIV infection have been associated to mitochondrial injury. HIV pregnant women present increased rates of adverse obstetric and perinatal events of unknown aetiology. We wonder if mitochondrial abnormalities may underlie adverse perinatal outcome in HIV-pregnancies. Methods: We studied obstetric results and mitochondrial status in placenta in 48 pregnant women: 21 non-smokers and 27 smokers (19 moderate and 7 heavy smokers). Tobacco consumption was measured by the number of smoked cigarettes/day and plasmatic cotinine (ng/ml). Oxidative stress lipid peroxidation was measured by spectrophotometry (µM MDA+HAE/mg prot), mitochondrial DNA (mtDNA) content by nPCR (mtND2/nRNApolII) and mitochondrial number and tissular hypoxia by Western-Blot (V-DAC or HIF1a/B-actine). Results, expressed as mean±SEM, were analyzed by non-parametrical statistics. Results: Smoke-exposed newborn showed fetal growth restriction (OR=4.13 [0.44-38.49]), reduced weight (3136.15±31.34 vs. 3452.75±98.66; p<0.05) and decreased growth percentile (35.08±26.21 vs. 54.20±5.87; p<0.05). Fetal cotinine positively correlated the number of cigarettes consumed (p=0.05) and negatively correlated newborn weight (<0.001). Placenta of smoking mothers showed increased oxidative stress, especially heavy smokers (19.55±17.6 vs. 14.9±11.11; p<0.05), which indeed presented higher mitochondrial number manifested as increased mtDNA (1.37±0.14 vs. 1.26±0.06; p<NS) and V-DAC levels (0.78±0.09 vs. 0.44±0.08; p<0.05). Placenta of moderate smokers showed higher response to hypoxia (HIF1a expression: 2.76±0.47 vs. 2.38±0.45; p<NS). Conclusions: Tobacco increases placental oxidative stress, mtDNA levels, mitochondrial amount and hypoxia-response; CO-mediated mechanisms which may underlie intrauterine growth restriction. Funding: FIS 0229/08 and CIBERER (ISCIII).

**730 TOBACCADO-INDUCED MITOCHONDRIAL TOXICITY IN REDUCED INTRAUTERINE GROWTH.**

F. Cardellach1, G. Garrabou1, S. Górdoba1, A. S. Hernandez1,2, C. Morení1, E. Tobías1, M. Catalan1, M. López2, O. Coll3 and <Δ> Miro6. 1Mitochondrial Research Laboratory, IDIBAPS-UB, JM-Hospital Clinic Barcelona, Barcelona, Spain and CIBERER, Valencia, Spain, Barcelona, Spain and 2Materno-Fetal Medical Services, Hospital Clinic of Barcelona, Barcelona, Spain. Sponsor: I. Domingo.

Background: Maternal smoking is associated with reduced birth weight. Tobacco contains carbon monoxide (CO), considered particularly harmful due to its capacity to bind hemoglobin and mitochondrial complex IV leading, respectively, to tissular and cell hypoxia. We wonder if mitochondrial dysfunction or hypoxic response may underlie obstetric and perinatal adverse outcome of smoking pregnant women. Methods: We studied perinatal results and mitochondrial status in placentas of 48 pregnant women: 21 non-smokers and 27 smokers (19 moderate and 7 heavy smokers). Tobacco consumption was measured by the number of smoked cigarettes/day and plasmatic cotinine (ng/ml). Oxidative stress lipid peroxidation was measured by spectrophotometry (µM MDA+HAE/mg prot), mitochondrial DNA (mtDNA) content by nPCR (mtND2/nRNApolII) and mitochondrial number and tissular hypoxia by Western-Blot (V-DAC or HIF1a/B-actine). Results, expressed as mean±SEM, were analyzed by non-parametrical statistics. Results: Smoke-exposed newborn showed fetal growth restriction (OR=4.13 [0.44-38.49]), reduced weight (3136.15±31.34 vs. 3452.75±98.66; p<0.05) and decreased growth percentile (35.08±26.21 vs. 54.20±5.87; p<0.05). **731 LONGITUDINAL STUDY OF MITOCHONDRIAL TOXICITY IN HIV-INFECTED CHILDREN RECEIVING MILD OR STRONG NUCLEOSIDE ANALOGUES.**

C. Morení1, A. Noguera-Juliá1, G. Garrabou1, M. Catalán1, N. Rovira2, E. Tobías1, F. Cardellach1, <Δ> Miro6 and C. Fortuny2. 1Mitochondrial Research Laboratory, Internal Medicine Department, Hospital Clinic of Barcelona, IDIBAPS and CIBERER, Barcelona, Spain and Infectious Disease Unit, Pediatrics Department, Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain. Sponsor: I. Domingo.

Background: Adverse effects of Highly-Active-Antiretroviral Therapy (HAART) and HIV, similar to those described in primary mitochondrial genetic diseases, have become a major issue, especially in children. Currently, the main goal is to reduce the risk of virologic and mitochondrial failure while maximizing cost-effectiveness. Methods: We followed, within 2 years, the clinical and mitochondrial status of 38 HIV-infected children on HAART that either included strong nucleoside-reverse-transcriptase-inhibitors (NRTIs; didanosine, zidovudine or stavudine; n=15), or mild NRTIs (the rest of drugs; n=13); and compared them to an HIV-infected untreated group (n=10) and to uninfected control reference values. We measured the viral load (rt-PCR), lactate levels (spectrophotometry) and T-lymphocyte CD4+ content (flow-cytometry); we assessed mtDNA content (rt-PCR), mitochondrial protein synthesis (western blot); mitochondrial number, electron transport chain function and oxidative stress (spectrophotometry) in blood mononuclear cells. Results: Lactate levels became significantly higher in children on strong regimens compared with patients on mild NRTIs after 2 years (1.0±0.071 vs. 1.28±0.083; p<0.02). We found a significant decrease of cytochrome-c-oxidase activity in untreated patients and in those on strong NRTIs groups along time. Mitochondrial DNA content was similar among all HIV-infected groups and significantly lower compared to controls at baseline. Oxidative stress tended to increase along time in all groups. Conclusions: HIV itself and the use of strong NRTIs cause higher mito-
Anidulafungin and voriconazole are potent antifungal agents that may provide a powerful therapeutic option over current therapies when co-administered. A non-clinical combination toxicity study was completed as part of the voriconazole Paediatric Investigation Plan to enable clinical development of the combination in children. Juvenile Fisher rats received anidulafungin or voriconazole alone or in combination once daily from postnatal day (PND) 21-56 with a recovery period to PND 84. Doses were chosen to target exposures at or above the adult rat no observed adverse effect levels (NOAELs). Toxicokinetics were determined using a validated dual-analyte bioanalytical method. Systemic exposure at juvenile rat NOAELs was comparable to those found with adult rats in previous studies as well as anidulafungin exposure alone in a previous juvenile study. Transient and reversible reductions in body weight, hematology, serum chemistry, liver weight and minimal liver changes were associated with anidulafungin. Voriconazole caused an increase in gamma-glutamyltransferase in female rats only. Juvenile rats were not more sensitive to each drug dosed alone compared with adult rat data on the single drugs. No novel, additive or synergistic toxicities were noted when dosed in combination. This study supported pediatric clinical trials co-administering voriconazole and anidulafungin.

In the Northern Rocky Mountains, wood stoves are a popular heat source in homes during the cold winter months. These wood stoves contribute considerable levels of fine particulate matter (PM2.5) to the indoor environment. Residential exposure to biomass PM2.5 has the potential to exacerbate respiratory diseases, such as asthma. The primary aim of the University of Montana’s ARTIS study (A Randomized Trial of Indoor Air) is to assess the quality of life among asthmatic children following interventions that reduce in-home wood smoke PM exposures. Our recent studies focus on evaluating multiple inflammatory cytokines in the exhaled breath condensate (EBC) of asthmatic children enrolled in the ARTIS study. Rubes (Respiratory Research Inc., Charlottesville, VA) were used to collect EBC samples from 42 subjects during their first (baseline) winter. Sample collection was performed on two consecutive mornings during two wintertime sampling visits, with 41 subjects successfully completing sample collection during the first visit and 40 during the second visit. Data presented here is from the first visit only. Ten cytokines (GM-CSF, IL-1β, -2, -4, -5, -6, -8, -10, IFN-γ and TNF-α) were simultaneously quantitated in EBC samples using an ultrasensitive multiplex bead immunoassay analyzed with a Luminex 100 and StarStation software v. 2.0 (Applied Cytometry, Sacramento, CA). Briefly, TNF-α was detected in 88% of the samples with quantitated samples ranging from 0.12 to 3.44 pg/mL, with an average (± SD) concentration of 0.88 (± 0.57) pg/mL. The IL-4/IFN-γ ratio was on average 1.27 (± 1.33) with one sample below the LOD for IL-4 and no samples below the LOD for IFN-γ. Future analyses include evaluating these inflammatory biomarkers following home interventions designed to reduce children’s exposure to indoor PM2.5. This data will ultimately allow us to gain a better understanding of the health effects of reducing residential PM2.5 in wood stoves homes of asthmatic children.

The obesity epidemic affects at least 14.6% of children in the US with an even higher proportion among the underprivileged. This latter population is also exposed to higher levels of environmental lead (Pb) due to its persistence in old homes and inner-city residences. Previous findings have independently identified both Pb and obesity as etiological factors in the development of osteoporosis.
Interestingly, Pb-treated mice and those fed a high-fat diet share a number of other characteristics, including depression of bone formation and bone marrow stenosis. Increased adiposity of the bone marrow is itself associated with bone loss, and this is evident in cases of osteoarthritis, immobilization, and glucocorticoid treatment, as well as in osteoporotic postmenopausal women. Additionally, we have found that Pb treatment up-regulates the expression of sclerostin, a potent inhibitor of Wnt/beta-catenin signaling, which is an important molecular switch governing bone homeostasis. From these findings we hypothesize that Pb exposure and obesity both act through depression of Wnt signaling in mesenchymal cells to promote their differentiation into adipocytes, subsequently decreasing number of osteoblasts, resulting in bone loss. Using concomitant exposure to Pb (50 ppm in the drinking water) and high-fat diet (60% kcal from fat) in mice we found that they additively reduce bone mass, increase bone marrow adiposity, and reduce beta-catenin levels in stromal cells. This correlated with suppression of the osteogenic transcription factor Runx2 and induced expression of the adipogenic transcription factor Pparg. Pb and high-fat diet also act in vitro to promote adipogenic potential of mesenchymal cells by increasing lipid droplet formation, increasing activity of Pparg, and decreasing beta-catenin activity. These results provide mechanistic insight for targeted therapeutic intervention in bone diseases resulting from exposure to Pb, obesity, and a combination thereof.

**PS 737 POLYMORPHISMS OF PHASE I AND II XENOBIOTIC ENZYMES INVOLVED IN ASTHMA CONDITION IN CHILDREN EXPOSED TO TOBACCO SMOKE.**

B. Munoz1, A. Hernandez-Moreno1, B. Barron-Vivanco1, V. M. Dávila-Borja2, A. Albores1 and E. Juárez-Pérez1. 1Department of Toxicology, Cienavet-IDN, Mexico City, D.F., Mexico, 2Department of Genetics and Toxicology, National Pediatrics Institute, Mexico City, D.F. Mexico and 3Universidad Autónoma de Nayarit. Tepic, Nayarit, Mexico.

Bronchial asthma is a common disorder which affects 12% of Mexican population and tends to increase in the next ten years. Although several environmental factors influence on asthma development such as air pollution or common allergens; one of the most important is exposure to environment tobacco smoke (ETS). The metabolism of some toxic compounds of ETS is through a complex network of enzymes and reactions of hydrolysis, reduction or oxidation (phase I) and conjugation (phase II). The role of polymorphisms of enzymes involved in xenobiotic metabolism may explain why some children are more susceptible to develop asthma. In the present study, we analyzed the association of several polymorphic markers including CYP1A1 (rs1048943), CYP2E1 (rs2070676), CYP2A6 (rs1801272), CYP1B1 (rs1056836), and GSTT1 or GSTM1 null variants with risk of asthma together with ETS exposure in a Mexican children population. The cytochrome SNPs were in linkage disequilibrium when they were associated with asthma. However, when population was divided according sex, male children with AA variant of CYP2A6 presented a significant risk to develop asthma (p=0.034). In addition, this association was also detected when exposure to ETS was included (p=0.021) According to the obtained results, CYP2A6 may be an indicative of susceptibility to develop asthma in male children exposed to ETS. Support Conacyt 104316 and 106463.

**PS 738 LUNG FUNCTION IN CHILDREN CHRONICALLY EXPOSED TO ARSENIC IN DRINKING WATER.**

Introduction: Intense over-exploitation of the aquifers in the region known as the Comarca Lagunera has caused a gradual descent of water levels which in turn has given rise to a serious health issue, hydroarsenicism. Arsenic concentrations in drinking water have surpassed the permitted levels by the WHO (10μg/l) and the Mexican Official Norms (25μg/l). Arsenic exposure through drinking water has been associated with different types of neoplasia. Although, some of the most important negative effects of this metalloid over human health are lung function disturbances. Recent experimental animal studies animal have reported pathological changes in pulmonary development as well as bronchial hyperresponsiveness. Disturbances have also been reported in pulmonary repairing tissue proteins. Also clinical human studies have shown as well, diminishment in spirometric values and higher bronchialasthmas and chronic obstructive pulmonary disease frequencies. These findings have been reported in adult populations but not in children. Objective: To evaluate the relationship between lung function and inflammatory biomarkers with arsenic levels and with the polymorphisms of GSTO, AS3MT, GSTM1 and GSTT1 in children chronically exposed to arsenic in drinking water. Preliminary Results: At present a total of 58 children have been included in the study from two rural communities [Sofía de Arriba (58.3ppb) and El Porvenir (112 ppb)]. The mean children age is 9.6 years and most of them have living in the community all life (mean 9.3 years) and 62.1 % of them were conceived at those communities. 13.8% of the studied population reported chronic cough for more than 2 years and 8.6% for 7-12 years. In addition, 6.9% have been treated for repeated bronchiolitis. In all subjects the spirometric values such as FVC,FEV1 and FEV1/FVC ratio were lower with respect to the reference values for spirometry volumes. Conclusion: A high incidence of lung diseases and a reduction in the lung function was recorded in children chronically exposed to high arsenic levels in drinking water.

---

**PS 739 GENETIC AND EPIGENETIC BIOMARKERS OF SUSCEPTIBILITY TO OP PESTICIDES AND OBESITY IN CHILDREN.**

Children’s susceptibility to environmental toxicants may depend on their genotype, levels of exposure and their interactions. In the longitudinal birth cohort study of low-income Mexican-American farmworker families in California (CHAMACOS) we found that in utero exposures to pesticides were associated with abnormal birth and neurodevelopmental outcomes at different ages (Eskanazi et al, 2004, 2007, 2010; Young et al, 2005; Bouchard et al, 2011). We also demonstrated that these health effects depend on phenotype and genotype of paraoxonase (PON1), a multifunctional enzyme involved in detoxification of organophosphate (OP) pesticides also oxidative stress (Hollander et al, 2006; Huen et al, 2009;2010 Eskanazi et al, 2010; Harley et al, 2011). CHAMACOS population has a high prevalence of obesity in mothers and children that exceeds national averages for Mexican-Americans. In this study of 383 CHAMACOS children, we observed significant associations of child PON1 genotypes and PON1 status (PON1192 genotype and PON1 enzyme levels) with both body mass index (BMI) Z-score and obesity status at age 2. Compared to children with the PON1192RR genotype, the odds of obesity were 5.2 and 9.6 fold higher in PON1192QR and PON1192QQ children, respectively. Additionally, we genotyped ancestry informative markers (AIMs) to estimate proportional ancestry for each individual and found little evidence of genetic confounding among two year old CHAMACOS children. In addition to genetic polymorphisms, epigenetic mechanisms such as DNA methylation in PON promoter region (assessed by Illumina 450K Methylation BeadChip), were also associated with PON1 expression in an allele-specific manner. Epigenetic and genetic influences on PON1 may affect susceptibility to OP pesticides and conditions related to oxidative stress including obesity. Possible contribution of environmental exposures such as prenatal pesticide exposures, to the genetic, epigenetic and behavioral mechanisms of obesity warrants additional attention. Supported by NIEHS and EPA grants.

**PS 740 FUNCTIONAL DEVELOPMENT IN YOUNG RATS: BASIC DATA FOR THE PERFORMANCE OF JUVENILE ANIMAL STUDIES.**

Juvenile animal studies play an important role in the registration process of pharmaceuticals and chemicals, and functional parameters form an important part of such studies. As these parameters are evolving during the first days to weeks of life, laboratory data must be interpreted in relation to developmental changes. Therefore, generation of data sets for juvenile animal studies is a fundamental need. The normal development of some haematological, immunological and lung function characteristics, as well as of the auditory stearle reflex (ASR) was assessed in Wistar (WU) rats. For the hematopoietic system it was shown that blood counts of newborn rats revealed high numbers of immature progenitor cells and the red blood count showed frequent abnormalities that typically point to anaemia or RBC defects. Assessment of immune system development proved feasible starting at day 2 pp. Major developmental effects were seen in immunoglobulin secretion in peripheral blood and in lymphocyte surface marker expression in peripheral blood, spleen and bone marow. These methods have been developed to noninvasively assess juvenile rat lung function starting at a neonatal stage. A plethysmographic method has been modified and longitudinal data are presented which describe the functional development of
the lungs in male and female rats at an age of 2 days. Furthermore, the possibility of nose-only inhalation treatment in juvenile rats as young as day 4 pp has been proven. ASR data show the practicability of this test as early as day 10 pp with a coordinated animal response showing a significant pre-pulse inhibition around day 15 pp. The development of a gender-specific response starts around day 40 pp in coincidence with sexual maturation. Adult-like patterns of habitation can be assessed by day 60 pp.

The described techniques permit new insights into human neonatal risk assessment and therefore these animal models are suitable for regulatory studies. The presented data are important for correct planning and interpretation of juvenile animal studies.

741 SKIN-SENSITIZING POTENCY OF HALOGENATED PLATINUM SALTS.

D. M. Lehmann1, W. Williams1, C. Copeland1, E. Boykin1 and M. Selgrade2.
1National Health Environmental Effects Research Laboratory, US EPA, Research Triangle Park, NC and 2ICF International, Durham, NC.

The relationship between occupational exposure to halogenated platinum (Pt) salts and Pt-specific allergic sensitization is well-established. Although human case reports and clinical studies demonstrate that Pt salts are potent skin sensitizers, no studies have been published that investigate whether there are differences in potencies of halogenated Pt salts. In this study, we evaluated ammonium hexachloroplatinate (AHCP), ammonium tetrachloroplatinate (ATCP) and cis-dichlorodiammine (CDDP) using the local lymph node assay. For 3 consecutive days, BALB/c mice were dosed topically on the dorsum of both ears with vehicle, 25% trimellitic anhydride (TMA; positive control) or one of 3 concentrations of Pt salt. On day 5, lymph nodes were harvested and single-cell suspensions were labeled ex vivo with 51Methyl thymidine. Lymphocyte proliferation was determined by scintillation counting. Concentration-dependent increases in ear thickness and lymphocyte proliferation were observed for all 3 Pt salts. None of the doses tested resulted in a skin irritant response since erythema was minimal and the maximum increase in ear thickness was less than 25% (n = 12). The EC3 values for AHCP, ATCP and CDDP were determined to be 0.58, 0.23 and 0.33%, respectively (n = 12). In complementary studies, lymph node cells were labeled ex vivo with bromodeoxyuridine (BrdU) to investigate an alternative to radioisotopic labeling. Incorporation of BrdU was determined by ELISA. In this case, the EC2 values for AHCP, ATCP and CDDP were determined to be 0.12, 0.95 and 0.17%, respectively (n = 6). The stimulation index of TMA was 4.6% (+/-1.2) and 2.9% (+/-0.3) in the radioisotope- and BrdU-labeling procedures, respectively. We conclude that AHCP, ATCP and CDDP are categorized as strong sensitizers according to the Globally Harmonized System for Classification and Labeling of Chemicals. Furthermore, these data suggest that BrdU labeling may not be as sensitive a procedure as labeling with radioisotope. This abstract does not reflect EPA policy.

743 REACTIVITY PROFILE OF CONTACT AND RESPIRATORY LOW MOLECULAR WEIGHT ALLERGENS IN A COMPETITIVE PEPTIDE REACTIVITY ASSAY.

J. F. Lalko1,2, J. Kimber1, R. R. Dearman1, G. Gerberick1, A. Api1 and L. W. Smith1. 1University of Manchester, Manchester, United Kingdom, 2Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ and 3Procter & Gamble Company, Cincinnati, OH.

It is well established that certain low molecular weight chemicals cause allergic diseases of the skin and respiratory tract. Individual chemicals are typically associated primarily with one or other form of disease, generating selective Th1 or Th2 type responses. The reasons for this divergence are unclear; however selective modification of specific amino acids may play a role. The reactivity of chemical allergens to single nucleophile peptides is increasingly well-described with standardized assays for use in hazard assessment; adapting these methodologies to evaluate competitive binding of multiple nucleophiles may assist in defining preferential modifications. Using a peptide reactivity model, the reactivity of reference respiratory allergens (phthalic anhydride [PA], maleic anhydride [MA]) and skin allergens (dinitrochlorobenzene [DNCB], dinitrolu啰benzene [DNFB]) were investigated. One set of assays was conducted by reacting peptides containing either cysteine (Cys) or lysine (Lys) alone with an excess concentration of test chemical. To evaluate the effect of competition, assays were conducted by preparing reaction mixtures of these same peptides at various concentrations relative to the other. The ratios utilized were 1:1, 3:1, 6.1:1 and 9:1; in each case the total peptide constant was constant. When incubated with single peptides PA and MA (respiratory allergens) were observed to have increased reactivity to Lys, while DNCB and DNFB (contact allergens) preferentially reacted to Cys. These preferences were conserved or enhanced under competitive conditions. Under such conditions PA and DNCB were observed to deplete exclusively Lys and Cys, respectively. MA and DNFB both maintained the preferences observed with individual peptides. The selective reactivity demonstrated here may have important mechanistic relevance for the ability of these chemicals to induce divergent immune responses.

744 CHANGES IN THE FREQUENCY OF B220+ LYMPHOCYTES FOLLOWING TOPICAL EXPOSURE TO LINALOOL.

L. Beresford1, R. R. Dearman1, J. Kimber1, A. Api1 and J. F. Lalko1,2. 1Research Institute for Fragrance Materials Inc., Woodcliff Lake, NJ and 2University of Manchester, Manchester, United Kingdom.

Linalool is a terpene alcohol that is known to undergo autodissociation forming a variety of hydroperoxides and other degradation products. Linalool is not considered to be a skin sensitizer; however, the products formed during autodissociation are known to be contact allergens. In the murine local lymph node assay (LLNA), high purity samples of linalool have been reported to have a weak sensitization potential. As with other predictive test methods, false-positives are known to occur in the LLNA, particularly to subsets of certain classes of skin irritants. While these have not typically presented interpretive difficulties, strategies have been developed to assist in eliminating false positives in the LLNA. One approach is to align the LLNA with monitoring the frequency of B220+ lymphocytes in skin draining lymph nodes (LN). In the present study, assays were conducted by topically treating CBA/Ca mice with high purity linalool (50% or 100%; both with and without an antioxidant), dinitrochlorobenzene (DNBC; 0.25%; contact allergen control), benzalkonium chloride (BZC; 2%; irritant control) or with vehicle (acetone) alone using the standard LLNA dosing regimen. Draining LN were isolated and the frequency of B220+ lymphocytes was determined at various concentrations relative to the other. The ratios utilized were 1:1, 3:1, 6.1:1 and 9:1; in each case the total peptide constant was constant. When incubated with single peptides PA and MA (respiratory allergens) were observed to have increased reactivity to Lys, while DNCB and DNFB (contact allergens) preferentially reacted to Cys. These preferences were conserved or enhanced under competitive conditions. Under such conditions PA and DNCB were observed to deplete exclusively Lys and Cys, respectively. MA and DNFB both maintained the preferences observed with individual peptides. The selective reactivity demonstrated here may have important mechanistic relevance for the ability of these chemicals to induce divergent immune responses.
745 THE CONTRIBUTION OF PEANUT PROTEINS ARA H1, 2, 3 AND 6 IN PEANUT ALLERGY.
J. Smit1, 2, M. Penning1, 3, M. van Roest1, G. Houven1, E. van Hoften1 and R. Pieters1 1Toxicology, Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands, 2Utrecht Centre for Food Allergy, Utrecht, Netherlands, 3Dermatology, Utrecht University Medical Center, Utrecht, Netherlands and 4TNO, Zeist, Netherlands.

Peanut is a major allergenic food product, and contains a large number of potentially allergenic proteins. The present study investigated the relative contribution of, and cross-reactivity between the major allergens Arah1-6 in a mouse model for peanut allergy. Mice were immunized by gavage with peanut protein extract or purified allergens Arah1-6. Hereafter, mice were challenged with the individual allergens and blood was collected to measure allergen-specific antibodies and the degree of mast cell degranulation (MMCP-1 and histamine). Spleens were isolated to measure allergen-specific T-cell reactivity. Sensitisation with whole peanut extract induced Arah1-6-specific IgE, IgG1 and IgG2a. In addition, sensitisation with the individual peanut allergens elicited antibody responses with specificity to the allergen used, but limited cross-reactivity between the allergens was observed. T-cell cultures showed Th1 and Th2 type cytokine production upon re-stimulation with individual peanut allergens elicited antibody responses with specificity to the allergen used and cross-reactivity between the allergens was observed. In future studies, the mechanism behind the functional differences of individual peanut allergens and the protein cross-reactivity on T-cell and antibody level will be investigated in vitro.

746 CHARACTERIZATION OF THE ALLERGENICITY OF DIFFERENT FORMS OF LACTOFERRIN.
R. J. Almond1, B. F. Flanagan1, L. Kimber1 and R. J. Dearman1 1Manchester University, Manchester, United Kingdom and 2University of Liverpool, Liverpool, United Kingdom.

With the advent of genetically modified crop plants there is an increased interest in the development of methods for the identification of novel proteins as potential allergens. Current methods include assessment of resistance to digestion by simulated gastric fluid (SGF) and homology searches. There is a need for more holistic methods for the characterization of potential protein allergens and particularly the impact of post translocation modifications such as glycosylation. The allergenicity (IgE inducing) and immunogenicity (IgG inducing) properties of wild type native (milk) human lactoferrin (NFLF) and recombinant LF (rLF) produced in rice have been assessed. These forms of LF have identical amino acid sequences, but different glycosylation patterns: NFLF has a complex glycoprofile including stalic acid and Lewis (Le) x structures, whereas the rLF form is far simpler and rich in mannose residues. Both proteins are very labile to digestion by SGF, with intact protein disappearing after 1min of incubation in the presence of pepsin at pH1.2. Antibody responses induced in BALB/c strain mice by intraperitoneal exposure to NFLF and rLF were characterized. Serum were analysed for protein specific IgG and IgE by enzyme-linked immunosorbant assay (ELISA) and homologous passive cutaneous anaphylaxis assay (PCA), respectively. Immunisation with NFLF stimulated vigorous IgG and IgE antibody responses, whereas rLF was 40-fold less immunogenic and 200-fold less allergenic, irrespective of endotoxin content. The glycosans did not contribute to epitope formation, with equivalent IgE and IgG binding recorded for high titer anti-NLF anti sera whether the immunising NFLF or the rLF was used a substrate in the ELISA or PCA analysis. Similarly, identical low IgG and IgE anti-LF titres were recorded when either the immunising rLF or the NFLF was used in the analysis of anti-rLF antisera. These data demonstrate that differential glycosylation profiles can have a profound impact on protein allergenicity.

747 EXPOSURE TO TRICLOSAN AND BISPHENOL A AUGMENT ALLERGIC RESPONSES IN A MURINE MODEL OF ASTHMA.
S. E. Anderson, E. Lukomska, K. Anderson and B. J. Meade 1CDGNIOSH, Morgantown, WV.

During the past several decades there has been a remarkable and unexplained increase in the prevalence of asthma. While the hygiene hypothesis provides one potential explanation, individuals in industrial societies are also inadvertently exposed to an increasing number of chemicals. While many chemicals are known to directly induce asthma there is also the potential for non-sensitizing chemicals to augment the immune response induced by other allergens. Our lab has previously demonstrated that dermal application of the environmentally relevant chemical, perfluorooctanoic acid, simultaneously with exposure to a single concentration of protein allergen (OVA) was found to augment the allergic response to that allergen. Triclosan and bisphenol-A (BPA) are commonly used in both occupational and public environments which have recently been associated with increases in allergy and asthma. BPA, considered to be non-sensitizing, is a substrate of polycarbonate plastics and has been produced in increasingly large quantities since the 1950s. BPA is used to form plastic bottles, as a lining for food and beverage cans, and as a flame retardant. Triclosan is an antibacterial compound that has been used in consumer products for 40 years and is currently found in many hand sanitizers and lotions. The tolerability and safety of triclosan has been evaluated in human volunteers with little indication of toxicity or sensitization. For these studies a murine model of asthma was used to evaluate the immunomodulatory effect of co-exposure to BPA or triclosan with OVA, Co-exposure to each of these chemicals individually (as low as 30% BPA and 1.5% triclosan) with OVA resulted in an at least 2-fold increase in OVA-specific IgE and an augmentation of the airway hyper-reactivity response to methacholine challenge (as low as 7% BPA and 0.75% triclosan) as compared to OVA exposure alone. Understanding the mechanisms by which mixed exposures influence and augment asthma and asthma-like symptoms may lead to better prevention strategies for those at risk for asthma.

748 IMPACT OF DOSING FREQUENCY ON ANAPHYLAXIS IN CYNOMOLGUS MONKEYS ADMINISTERED TRU-015, AN ANTI-CD20 SMIP™ THERAPEUTIC.
C. M. Rohde1, V. Markievicz2, S. Thibault1, E. Besterman1, D. W. Clarke1, R. Perry1 and M. W. Leach1 1Drug Safety Research and Development (DSRD), Pfizer, Andover, MA, 2DSRD, Pfizer, Groton, CT, 3DSRD, Pfizer, La Jolla, CA and 4DSRD, Pfizer, Pearl River, NY.

TRU-015, a chimeric (mouse and human) anti-CD20 SMIP™ (mono-specific protein therapeutic), was administered intravenously (IV) to male and female cynomolgus monkeys at 0 (vehicle), 15, 50, and 150 mg/kg/cycle (4 to 7 animals/group) for 6 cycles (1 dose/2 wks) to evaluate its toxicity. Immuno reactions consistent with anaphylaxis occurred within 1 hr of dosing starting with 1 male at 15 mg/kg after the 3rd dose. By the 5th dose, animals at all dose levels were affected with an inverse dose relationship in the severity of reactions. Diphenhydramine pretreatment initiated at the 6th dose had no apparent impact on anaphylaxis, leading to dosing termination. A total of 9 of 36 TRU-015-dosed animals were affected, with elective euthanasia of 2 animals at 15 mg/kg. Of the 9 animals affected, 5 had anti-drug antibodies (ADA) and 4 had evidence of complement activation. The infusion reactions, onset of reactions relative to dosing, presence of ADA, and signs of complement activation were consistent with anaphylaxis secondary to an immune response to TRU-015. In an effort to successfully conduct a chronic toxicity study, and based on shorter term toxicity studies in which weekly dosing did not cause infusion reactions, TRU-015 was administered IV at 0 (vehicle), 15, and 150 mg/kg/cycle (4 animals/group) for 13 cycles (1 dose/wk). With this regimen, only 1 animal at 15 mg/kg out of 16 TRU-015-dosed animals had an infusion reaction consistent with anaphylaxis. The reaction occurred within 1 hr of the 7th dose and led to this animal’s death. This animal also had ADA and evidence of complement activation. Therefore, increasing the dosing frequency successfully reduced the incidence of anaphylaxis related to TRU-015 administration. This new dosing regimen permitted the conduct of longer duration toxicity studies in NHPs. Similar immune reactions have not been observed in humans following extensive clinical experience.

749 A CUTANEOUS HYPERSENSITIVITY REACTION TO A THYROID HORMONE SUPPLEMENT IN A DOG.
S. N. Lavergne1, P. Kennedy2 and K. R. Refsal3 1Comparative Biosciences, University of Illinois at Urbana-Champaign, Urbana, IL, 2Private Practice, Northern Illinois Animal & Bird Hospital, Cary, IL and 3Diagnostic Center for Population and Animal Health, Michigan State University, Cary, MI.

A dog with clinical signs of hypothyroidism (an autoimmune disease common to dogs and humans) and low thyroid hormones (T4 and its T3 metabolite) received a generic T4 supplement. After 2 weeks, the dog developed a severe pruritus and pyoderma on its neck and back with a widespread erythema. The dog responded to the thyroid hormone supplementation with little indication of toxicity or sensitization. For these studies a murine model of asthma was used to evaluate the immunomodulatory effect of co-exposure to BPA or triclosan with OVA, Co-exposure to each of these chemicals individually (as low as 30% BPA and 1.5% triclosan) with OVA resulted in an at least 2-fold increase in OVA-specific IgE and an augmentation of the airway hyper-reactivity response to methacholine challenge (as low as 7% BPA and 0.75% triclosan) as compared to OVA exposure alone. Understanding the mechanisms by which mixed exposures influence and augment asthma and asthma-like symptoms may lead to better prevention strategies for those at risk for asthma.
Because the T3 hormone is a natural metabolite of T4, and because drug hypersensitivities can become life threatening with re-exposure to the drug, we ran a few in vitro tests before prescribing a T3 supplement. A thyroid autoantibody panel showed high levels of anti-thyroglobulin antibodies, low levels of anti-T3 antibodies, and no anti-T4 antibodies. This was compatible with a diagnosis of hypothyroidism, but probably not related to this dog’s drug hypersensitivity. With the owner’s consent, we also injected some peripheral blood mononuclear cells from the dog’s blood, and incubated them with T4 or T3 for 4 and 7 days. The cells proliferated in a dose- and time-dependent manner with T3; their response to T4 was lower and only after 7 days. This suggested that the skin reactions were indeed an immune reaction against the thyroid supplements, and more specifically against the T3 metabolite rather than T4 directly. To our knowledge, this is the first report of delayed hypersensitivity to a thyroid supplement where a specific cellular immunity against the active ingredient and its metabolite (T4/T3) is demonstrated. This clinical case provides a new example of parallels between drug allergies and autoimmune diseases.

In the context of the 7th amendment to the Cosmetic Directive, the cosmetic industry is concerned by the challenge of finding non-animal approaches to assess the sensitizing potential of chemicals in order to manage risk assessment. Using the in vitro model U937 cell line differentiated into activated macrophages, we have previously shown that sensitizers have the capacity to specifically inhibit the production of prostanooids (Del Bufalo et al. 2011). The aim of the present work is to evaluate if this new biochemical property could be a hallmark of all sensitizers and if this “anti-inflammatory” signature could be correlated with the sensitization potential of chemicals. For that purpose we tested 160 chemicals (64 non sensitizers and 96 sensitizers) in the U937 cells differentiated with phorbol myristate acetate (PMA) and stimulated with lipopolysaccharides (LPS) and evaluated the production of the inflammatory mediator PGE2. Statistical analysis tools as box plot and ROC (Receiver Operating Characteristic) curve allowed us to define the test parameters that discriminate sensitizers from non sensitizers. Our results show that the criteria “inhibition of the PGE2 production” at 24h is a good parameter to predict sensitizers and the performances of the assay are: 78 % concordance, 83% sensitivity and 71 % specificity (obtained on a validation data set). However there is no correlation between the magnitude of inhibition for a given molecule and its sensitization potential.

Contact sensitizers are reactive molecules (hapten) that have the ability to modify skin proteins to form an antigen which will be recognized by specific T cells activated during the sensitization process. In addition to the haptenation mechanism, contact sensitizers induce several phenotypic and functional changes of dendritic cells (DC) either directly or indirectly through intercellular signaling pathways implicating keratinocytes, fibroblasts and other skin cells. This rather complex and still not fully unravelled maturation process of DC induced by contact sensitizers, allow them, to migrate to the lymphnode, present antigen and prime efficiently hapten-specific T cells.

Due to the complexity of this process it is now agreed that alternative hazard identification and risk assessment need to be addressed by combining a battery of methods. The aim of this study was to combine in silico and in vitro tools, from cheminformatics and toxicology, to facilitate the development of an integrated testing strategy for the evaluation of skin sensitization. For this purpose we used a full data set on 165 chemicals composed of different variables, representing the results from in silico predictions (Dock, TIMES, Tostree), from DPRA, MUSST, Nrf-2 and PGE-2 assays as well as numerous physico chemical experimental or calculated parameters. In order to avoid the any bias brought by the use of one single statistical method, we chose the Stacking model allowing us to integrate several statistical methods (Boosting, Bayesian, SVM, Sparse PLS-DA and Scoring). This model provides a probability for a chemical to be a sensitizer. The performances of the optimal model are: 85 % concordance, 90% sensitivity and 75 % specificity (obtained on a validation data set). This kind of alternative prediction will ultimately contribute to the risk assessment decision making in a Weight of Evidence approach.

Z. El Ali1, C. Gerbeix2, P. Esser1, P. Robert1, J. Legrand2, S. Martin1, M. Pallardy1 and S. Kerdine-Römer2.
1INSERM UMR 996, Faculté de Pharmacie, University Paris Sud, Châtenay-Malabry, France, 2Toxicology, CITOX-Safety and Health Research Laboratories, EVREUX, France, 3Allergy Research Group, Department of Dermatology, University Medical Center Freiburg, Freiburg, Germany and 4Plateforme Animalerie et Exploration Fonctionnelle-IPIST, University Paris Sud, Châtenay-Malabry, France.

Chemical sensitizers, inducing contact hypersensitivity (CHS), are known to induce reactive oxygen species (ROS). The Nrf2/Keap1 pathway is central for detoxification. Nrf2 is a redox-sensitive basic leucine zipper transcription factor involved in the transcriptional regulation of many antioxidant genes. Nrf2 plays a central role in protecting cells from ROS and electrophiles. We have demonstrated that contact sensitizers induce, in vitro, the accumulation of Nrf2 in human dendritic cells. In order to elucidate the role of Nrf2 in CHS, we used the Local Lymph Node Assay (LLNA) for studying the sensitization phase and the Mouse Ear Swelling Test (MEST) for studying the elicitation phase during the CHS. These studies were performed, in nrf2 knock out (nrf2-/-) and in wild type (nrf2+/+) mice, in response to dinortrichlorobenzene (DNCCB). The MEST results showed that (DNCCB) (1%) induced a higher increase of ear thickness in nrf2-/- mice than in nrf2+/+ mice. Furthermore, the swelling increase was time dependent after challenge. Sensitization of mice with DNCCB (0.5%) induced a high significant response in nrf2-/- mice compared to nrf2+/+ mice where no swelling was observed after challenge. On the other hand, results obtained in LLNA showed that DNCCB induced an increase of lymphocyte proliferation in nrf2-/- and nrf2+/+ mice. However, the stimulation index (SI) for a same concentration was higher in nrf2-/- mice than in WT nrf2+/+ mice. These results underline the crucial role of Nrf2 in CHS. Nrf2 seems to control the inflammation response and the lymphocyte proliferation, involved in allergic response to chemical sensitizers.

This kind of alternative prediction will ultimately contribute to the risk assessment decision making in a Weight of Evidence approach.
EVALUATION OF SENS-IS®, AN EPISKIN® BASED MODEL FOR IDENTIFYING CHEMICAL SENSITIZERS.

S. Teissier1, F. Tourneix1, A. Del Bufalo1, C. Gomes1, F. Cottrez2, H. Groux2

1L’Oreal, Aulnay-sous-Bois, France and 2Immunosearch, Grasse, France. Sponsor: H. Toutain.

In the context of the 2013 ban given by EU Cosmetics Directive, the ability to identify and classify the skin sensitization potential of chemicals without animals is of high importance for the cosmetic industry. A range of different in vitro chemistry-based (DPRA, GSH reactivity) and cell-based methods (MUST; ICLAT, Keratinosens) have been developed and we are currently evaluating some of them for their applicability to cosmetic ingredients and their physicochemical diversity. Although these assays appear to be promising for hazard identification, potency assessment is still limited. Immunosearch has developed SENS-IS, a new method, based on the quantitative analysis of specific biomarkers expressed in 3D reconstituted epidermis (Episkin®). This new assay provides a possible way to encompass the limitations of monolayer culture models (lack of skin bioavailability properties, different metabolism of the models compared to skin, inability to test water insoluble chemicals) and might therefore allow a better assessment of the sensitization potency of cosmetic ingredients. With the aim to evaluate the predictive capacity of this new assay, the skin sensitization assessment of 40 proprietary and public domain chemicals that were assessed by Immunosearch in a blinded manner. The results of this study show an overall performance of sensitizer/non sensitization prediction of 87% with a specificity of 83% and a sensitivity of 91%. The predictive capacity of potency categories of sensitizers (strong, moderate, weak) is however less performance (63% concordance) with 7 chemicals being overestimated and 8 chemicals being underestimated. Altogether, even if not yet sufficient for potency determination, SENS-IS is a promising new method for the skin sensitization evaluation of cosmetic ingredients.

INDIVIDUAL PREDICTIVE CAPACITIES OF IN SILICO AND IN VITRO METHODS FOR THE ALTERNATIVE ASSESSMENT OF SKIN SENSITIZATION: A COMPARATIVE STUDY ON A COMMON CHEMICAL SET.

Skin sensitization is a delayed type allergy consisting of a cellular immune reaction to small molecular weight chemicals. So, animal test methods such as the LLNA are used to predict the skin sensitization potential of unknown chemicals. In line with the 3Rs concept, ranges of in silico and in vitro alternative methods have been developed. While in silico methods are based on structure activity relationships, in vitro assays model the early events of the skin sensitization process: chemical reactivity assays (DPRA, GSH assay) reflect the haptenation mechanism, Nrf-2 based assays (Keratinosens, ADE-AD) analyze the induction of the cellular antioxidant pathway and DC-based assays (MUST; ICLAT) measure DC maturation markers (CD86, CD54). These assays were generally shown to have good predictive values for the hazard identification of skin sensitizers, but the correlation studies reported, differ in the nature of the reference that was used (animal or clinical references) as well as in the number of data analyzed.

In the present study, we show the data of 2 in silico methods (Derek, TIMES-SS) and 3 in vitro assays (DPRA, MUST, Nrf-2 reporter assay from InVitrogen) on a common chemical set composed of 165 compounds: 93 proprietary and 72 public domain references. We analyzed the individual performances of each method for the hazard identification of sensitizers. The results show that the accuracy varies from 73% to 92% with specificities between 66% and 78% and sensitivities between 76% and 100%. However, for some methods, often the more accurate ones, the number of inconclusive results can reach 40% of the chemicals, which reveals a restricted applicability domain for these methods. In conclusion we describe the complementarities of the 5 methods by showing how the combination of the results allows to overcome the limitations of restricted applicability domains (> 95% of chemicals classified) and optimize the accuracy of the prediction (> 85%).

RUTIN SUPPRESSES HOUSE DUST MITE EXTRACT AND 2, 4-DINITROCHLOROBENZENE-INDUCED ATOPIC DERMATITIS.

J. Choi and S. Kim. Pharmacology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.

Rutin has been used as a medication for blood vessel protection and as an ingredient of multivitamin preparations and herbal remedies. Rutin is known to have anti-inflammatory, anti-oxidative, and anti-cancer activities. However, the effect of rutin on atopic dermatitis (AD) has not been studied yet. We evaluated the efficacy of rutin in an allergic contact dermatitis (ACD) model on the ears of BALB/c mice using house dust mite extract (Dermatophagoides farinae extract, DFE) and 2,4-dinitrochlorobenzene (DNCB, 1%). We established an atopic dermatitis model in BALB/c mice by repeated local exposure of DFE/DNCB to the ears. Repeated alternative treatment of DFE/DNCB caused AD. Rutin reduced AD based on ear thickness and histopathological analysis, in addition to serum IgE levels. Rutin inhibited mast cell infiltration into the ear. Rutin suppressed DFE/DNCB-induced expression of IL-4, IL-5, IL-13, IL-31, IL-32, and INF-γ in the tissue. In addition, a local lymph node assay confirmed that rutin suppressed AD. Rutin also reduced ear thickness, serum IgE levels, and expression of IL-10, IL-17, and TNF-α in ACD ears. This study demonstrates that rutin inhibited AD and ACD, suggesting that rutin might be a candidate for the treatment of AD and ACD.

CONTINUOUS ACTIVATION OF RESPONDER T CELLS AND REGULATORY T CELLS CAUSED BY SILICA EXPOSURE INDUCE DYSREGULATION OF AUTOIMMUNITY.

T. Otsuki1, H. Hayashi2, S. Lee1, M. Maeda1, N. Kurnagai-Takei1, H. Manuzaki1, M. Kuasaka2, K. Urakami3 and Y. Nishimura1.

1Hygiene, Kawasaki Medical School, Kurashiki, Japan, 2Dermatology, Kawasaki Medical School, Kurashiki, Japan, 3Biofunctional Chemistry, Graduate School of Natural Science and Technology, Okayama University, Okayama, Japan, Internal Medicine, Kusaka Hospital, Bizen, Japan and 4Hinata Uematsu Kimi, Bizen, Japan.

Patients with silicosis (SIL) are suffering from pulmonary fibrosis but also often autoimmune diseases such as RA, SSc and ANCA-related vasculitis/nephritis. Although it has been considered that silica can act as adjuvant, we had been reported that the inhibitory effects of peripheral CD4+25+ T cell fraction (should include CD4+25+Foxp3+ regulatory T cells, Treg) derived from SIL was reduced when compared with that derived from healthy donors (HD). To explore this phenomenon, the activation status of responder T cells (Tresp) and Treg had been analyzed. Regarding Tresp, silica stimulated Tresp in vitro when monitored by CD69 expression, as well as CD69 mRNA expression was higher in CD4+25- fraction from HD than those from SIL. The PD-1 mRNA as activation marker was higher both in CD4+25+ and 25- fraction from SIL than those from HD. These findings indicated silica can activate Tresp. On the other hand, Treg from SIL showed higher expression of CD95/Fas surface expression than that from HD and peripheral CD4+25- cells from SIL proceeded to apoptosis faster and stronger than that from HD, when these cells were cultured with Fas-stimulating MoAb. Furthermore, PBMCs from SIL or HD were cultured with silica, those from SIL showed higher loss of FoxP3+ true Treg than those from HD. Those findings indicate that silica can activate both Tresp and Treg resulting entry of activated Tresp into CD4+25+ fraction and early loss of true Treg caused by excess CD95/Fas expression as the phenotype of activation. Thereafter, these chronic and recurrent modifications of Tresp and Treg may induce the longer survival of Tresp including autoreactive T cell clones and also loss and recruitment of Treg with lesser function of inhibition for stimulated Tresp activity.

EFFECTS OF LIBBY AMPHIBOLE EXPOSURE ON THE DEVELOPMENT OF AUTOIMMUNITY IN THE RAT.

Epidemiological data suggest that exposure to the amphibole-containing vermiculite in Libby, MT was associated with increased risk (odds ratio of 2.14) for developing systemic autoimmune diseases (SAID). Elevated titers of antinuclear antibodies (ANA) were also found in Libby residents; however, increased ANA alone are not sufficient to induce SAID. Our goal was to establish a relationship between increased ANA titers in Libby amphibole (LA)-exposed rats with other hallmarks of SAID. Female Lewis rats were intratracheally instilled biweekly for 13-weeks with Libby amphibole or amosite. ANA was significantly increased in all asbestos dose groups, however no dose response was observed. ENA analysis determined that 94% of ENA-positive samples were specific for the Jo-1 antigen, a marker associated with interstitial lung disease and myositis. Urine protein concentration, anti-dsDNA titers and kidney histopathology were not affected by LA or amosite exposure. In addition, a NOAEL was not determined for ANA titers in LA-exposed rats. These data support...
TRICHLOROETHENE-INDUCED NITROSATIVE STRESS: PROTEOMIC IDENTIFICATION OF NITRATED PROTEINS IN THE LIVER OF MRL+/+ MICE.

G. Wang¹, X. Fan¹, X. Luo² and M. Khan¹. Pathology, University of Texas Medical Branch, Galveston, TX and ²Biomedical Resource Facility, University of Texas Medical Branch, Galveston, TX.

Exposure to trichloroethene (TCE), a common environmental contaminant, is associated with an autoimmune response, but the mechanisms remain largely unknown. Liver is one of the major organs affected by exposure. Previous studies from our laboratory have shown that TCE exposure in mice leads to increased nitrosative stress in livers, and suggested a potential role of the nitrosative stress in TCE-mediated autoimmunity. To further explore the role of nitrosative stress in TCE-mediated autoimmunity, the current study used proteomic approaches (2DE, gel, Western blot, MALDI TOF/TOF MS/MS, etc.), was conducted to characterize the nitrated proteins in the livers of TCE-exposed mice. Female MRL +/+ mice were treated with TCE (10 mmol/kg, i.p., every 4th day) for 6 weeks, and liver proteins were extracted for the identification of nitrated protein and INOS expression. A total of thirty nine proteins were identified in the livers of TCE-treated mice, whereas 21 proteins were found in the livers of both TCE-treated and control mice. The nitrated proteins were found in the molecular weight range of 19.1 to 128.3 kDa and PI range of 4.9 to 8.8. The identified nitrated proteins mainly represented skeletal proteins, enzymes, stress proteins and chaperones. Furthermore, TCE exposure led to significantly increased INOS protein expression in the livers, suggesting its contribution to increased formation of reactive nitrogen species and thus, contribution to increased nitrated proteins. The identified nitrated proteins provide a global map to further investigate alterations in their structural and functional properties, which will lead to a better understanding of the role of protein nitration in TCE-mediated autoimmunity. Supported by NIH ES016302.

INTERRELATIONSHIPS OF PEROXIDATION AND IMMUNOGENICITY OF CARDIOLIPIN: ANOXIDATIVE LIPIDOMICS APPROACH.

J. Frostegård¹, V. Tyurin¹, Y. Tyurina¹, A. Amoscat¹, J. Su², K. Balasubramanian¹, A. Mäeda¹, B. Fadeel¹, J. Greenberger¹, R. Mallampalli¹, B. Pitt¹ and V. Kagan¹. EOHN, University of Pittsburgh, Pittsburgh, PA and Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden.

The myriad of neoepitopes formed during lipid peroxidation trigger potent innate and adaptive immune responses. Experimental and clinical studies have been mostly focused on immunogenic properties of oxidized species of phosphatidylcholine (PCox) and phosphatidylethanolamine (PSox). Lately, a mitochondria-specific anionic phospholipid, cardiolipin (CL), particularly its peroxidized molecular species (CLox) attracted attention as innate and adaptive immunogens and predictors of clinical outcomes and novel therapeutic modalities for vaccination. Specific interrelationships between the emergence of individual molecular species of CLs/CLox in circulation and the appearance of the respective antibodies remain unknown. This is due to the lack of specific/sensitive analytical tools to characterize a huge diversity of individual CL and CLox. Using mass spectrometry based oxidative lipidomics, we focused on the analysis of molecular species of CLs and CLox in plasma of mice exposed to total body irradiation (9.5 Gy) or bacterial infection (Pseudomonas aeruginosa, PA103) as well as in plasma from ARDS patients. In the latter cases, we were able to detect the presence of both host and bacterial CLs in LC/MS spectra of plasma lipids. While relatively low molecular mass species (m/z 1376 and 1418) are typical of bacterial CLs, larger CL molecules (with m/z from 1448) dominate in MS of mammalian plasma CLs. Simultaneously, antiCL/CLox antibodies were detected in plasma. We also found that CL-containing liposomes and CL-coated mitochondria were recognized and taken-up by RAW264.7 macrophages. The data supported the context of possible roles that CLs/CLox play as anti-oxidants and anti-inflammatory responses. USE OF IN VITRO AND IN VIVO METHODS TO ASSESS THE SENSITIZATION POTENTIAL OF NOVEL AMINO ALCOHOLS.

The Local Lymph Node Assay (LLNA) is the principle preferred method for assessing the skin sensitization potential for EU REACH regulatory purposes. However, the LLNA has been found to overestimate sensitization potential for various compounds such as surfactants, fatty acids and alcohols. Amino Alcohols, as a class, have been shown to be non-sensitizers. We have discovered four alcohol amines; aminocyclohexanem (ACyH), 2-aminopropanol (2-AP), aminomethylcyclohexanel (ACyHM), and aminododecane (ADD), that tested positive in the LLNA. Supported positive in the LLNA.
To confirm the LLNA findings, we conducted the guinea pig maximization (GPMT) and protein reactivity tests. Only 2-AP and AMC/HOL tested positive in the GMPT. The protein reactivity assay failed to show any of these chemicals depleted free peptide by more than 15% through covalent bonding. QSAR (DERMWIN™ v2.01) predictions were used to estimate dermal absorption and ranged from 1% for 2-AP, 8% for AmCyHOL, 36% for AcYHM, and 100% for ADD. ADD may have high uptake in the stratum corneum but have a low transfer rate to the epidermis due to its high lipophilicity. Of note, amino alcohols are highly irritating and ACyHM and ADD were corrosive using the Epiderm™ skin model. Findings from these investigations will serve to train QSAR models for accurate predictions of skin sensitization for this class of chemicals. Additionally, it is important to determine which chemical classes or characteristics lead to overestimates in the LLNA.

Safety Assessment, AstraZeneca, Macclesfield, United Kingdom, Discovery Sciences, AstraZeneca, Macclesfield, United Kingdom, Discovery Sciences, AstraZeneca, Mülnadl, and BioWisdom Ltd, Cambridge, United Kingdom.

Incompatible database formats limit the value of the large amount of publicly available data on adverse events caused by drugs. The BioWisdom Safety Intelligence Program (SIP) is a harmonised database from Medline and other compound / safety databases that specifically links compounds to toxicities. We have combined physiological and pathological human observations from SIP with target profiles of drugs (BioPrint®, Cerep, France) to identify associations between pharmacological activities and adverse events. Compound-toxicity links were grouped into tissue categories and into a hierarchical system based on Medical Dictionary for Regulatory Activities (MedDRA). Fisher’s exact test (adjusted for false discovery) was used to identify significant associations between compounds in each tissue or MedDRA group and activity (<10 μM) against each target in BioPrint. 378 significant target tissue associations were identified, including known relationships such as cycloxygenase (COX) I/2 and the kidney and estrogen receptor alpha and the uterus. Less well known associations with targets were also identified, such as cytochrome P450 2C9 and the vasculature and neurokinin 2 and the heart. The MedDRA terminology enabled some target adverse event relationships to be tracked from the System Organ Class (SOC) to the mechanistically more informative Preferred Term (PT), for example HMG-CoA reductase to musculoskeletal disorder (SOC) and myositis (PT) and COX2 to renal and urinary disorders (SOC) and nephrotic syndrome (PT). In summary, we have validated an approach using harmonised adverse event data from the public domain to identify associations with pharmacological screening data; this could also be applied to other compound characteristics such as physicochemical properties and structural moieties.

Comparative genomics and population genetics have led to better understanding of the genetic diversity in humans. The International HapMap and the 1000 Genomes projects have established human lymphoblast cell lines from racially and geographically diverse populations. These cells can be used as an in vitro toxicity testing model that takes advantage of the diverse genotyping and RNA sequencing data. We selected 1104 cell lines from 9 populations representing 5 continents: Utah residents with Northern & Western European ancestry; Han Chinese in Beijing, China; Japanese in Tokyo, Japan; Lutheran in Wépiong, Kenya; Mexican ancestry in Los Angeles, CA; Tuscan in Italy; Yoruban in Ibadan, Nigeria; British from England and Scotland; and Colombian in Medellin, Colombia. Of these, 1095 cell lines (99.2%) were screened in quantitative high-throughput screening format with 180 chemicals diverse environmental chemicals at 8 concentrations (0.3 nM-92 μM) in a cell viability (CellTiter-Glo®) assay. Duplicate 1356-well plates were screened for ~70% of the cell lines, revealing excellent intra- and inter-experiment reproducibility in both concentration-response curve class and relative cell viability (r=0.977 for EC50 values). Among the 180 substances screened, the variabil-
Accurate prediction of plasma protein binding (PPB) of small molecules is critical in pharmacokinetic research. Previous modeling studies of PPB were limited to small data sets. We have compiled and curated a set of 1244 compounds with known percent-scale PPB values (%PPB) from several publicly available depositaries. We compared two endpoints: (1) the standard %PPB and (2) lnKa calculated as a logarithm of “binding constant”-like parameter derived from %PPB values. Quantitative Structure-Activity Relationship (QSAR) models were derived using Dragon descriptors and three machine learning methods (k-nearest neighbors, support vector machines, and random forest). Based on the consensus prediction of the three modeling methods, five-fold external validation yielded correlation coefficient (R2) of 0.68 and the mean absolute error (MAE) of 16.4% for the %PPB models, and R2 of 0.66 and MAE of 13.6% for the lnKa models. Moreover, to additionally validate our QSAR models, we predicted a set of 236 chemicals with high-throughput screening %PPB values measured under the framework of US EPA ToxCast project. For those ToxCast chemicals, the MAE of the %PPB and lnKa models was 19.3% and 14.9%, respectively. Overall performance of lnKa QSAR models was only slightly better than those of %PPB models, but much better for high-affinity compounds. For example, 470 out of 1244 compounds had %PPB ≥ 90% and their external MAE was 15.7 and 7.8% for %PPB models and lnKa models, respectively. Likewise, the MAE of 158 high-affinity ToxCast chemicals was 18.1 and 11.5% for %PPB and lnKa models. For high-affinity compounds the experimental error is estimated to be 1-5%; MAE of lnKa models was found to be significantly lower than that of %PPB models (p < 0.01). In summary, we have developed and rigorously validated QSAR models for predicting PPB of chemicals (especially for strong binders) based on the largest publicly available PPB dataset. These models can be used to evaluate pharmaceuticokinetic endpoint as part of human health risk assessment.

Quantitative Structure-Activity Relationships for Cyclodiene Insecticides Inhibiting Gamma-Aminobutyric Acid Receptor Subtype A.

C. Hack, C. D. Ruark, P. J. Robinson and J. M. Gearhart, AFRL/HJE Wright-Patterson AFB, Dayton, OH.

Cyclodiene insecticides such as dieldrin and endosulfan act as non-competitive antagonists of GABA, an inhibitory neurotransmitter of the nervous system. It is well accepted that the site of action of these insecticides is the picrotoxinin (PTX) binding site on the GABAa receptor chloride channel complex. Other structurally similar GABA antagonists are believed to also act at the same or an overlapping site. Herein, a quantitative structure-activity relationship (QSAR) model using BHC, endosulfan and various bicyclophosphates, dioxatricyclododecenes and related compounds was developed to predict rat brain GABA receptor pIC50 (1 / log of the 50% inhibitory concentration of rat GABAa receptors). Chemical structures were drawn and three dimensionally optimized using the CHARMM force field in Advanced Chemistry Development (ACD) Labs, ChemSketch. Chemical descriptors were calculated using AMPAC and Codessa 2.51 (Semichem, Inc.) and heuristic regression was used to develop equations correlating structure with activity. The initial QSAR model developed yielded an R2 of 0.57. Separating the compounds into those with linear bridgehead substituents (series I) and non-linear substituents (series II) yielded R2 values of 0.80 and 0.65, respectively. The results emphasize the importance of classifying these compounds into two different series based upon their bridgehead substituent. This project received support from the Defense Threat Reduction Agency - Joint Science and Technology Office, Basic and Supporting Sciences Division. This abstract has been cleared for public release: 88ABW-2011-4758, 9/6/2011.
differential biological responses. Embryonic zebrafish exposed to 1.2 nm 3-MPA-AuNPs failed to respond to a touch on the caudal fin at 120 hours post fertilization, while those exposed to 1.5 nm MEEE-AuNPs had a normal touch response. To investigate the molecular mechanism underlying the differential touch response, whole animal RNA-seq was conducted. Total RNA was isolated from embryonic zebrafish exposed to the 100% effective concentration (EC100) for 1.2 nm 3-MPA- and 1.5 nm MEEE-AuNPs (10 ppm) at 48 hours post fertilization (hpf). While the core materials (Au) for both nanoparticles are identical, the surface functionalities caused unique gene expression changes. 57,095 transcripts were mapped to ensemble version 9. At 48 hpf, 810 transcripts were common between MPA- and MEEE-AuNP exposed groups, while 1,099 and 1,523 transcripts were unique and statistically significantly differentially expressed in MPA- and MEEE-exposed broys, respectively. Bioinformatic pathway analysis similarly identifies unique pathway perturbations following exposure to these AuNPs. This research is supported by NIEHS F31 ES019445-01, P30 ES002120, ES16886, and Air Force Research Laboratory #FA8650-05-1-5041.

773 DISCOVERY OF NOVEL RAT MICRORNAS USING NEXT-GENERATION SEQUENCING.
F. Meng1, M. Hackenberg2, Z. Li1, J. Yan1 and T. Chen1. Division of Genetic and Molecular Toxicology, National Center for Toxicological Research/FDA, Jefferson, AR and 2Department of Genetics, Facultad de Ciencias, Universidad de Granada, Granada, Spain.

MicroRNAs (miRNAs) are noncoding RNAs with 18–25 nucleotides in length. miRNAs can bind to their target mRNA to inhibit mRNA translation. Therefore, miRNAs are important regulators for gene expression. However, rat miRNAs have not been fully explored and currently only 679 have been reported in miRBase version 17. Since identification of novel miRNAs will provide valuable insights into their functions, we conducted this study to discover novel miRNAs in rat using the next-generation sequencing (NGS) technology. Eight rat kidney samples, 4 from untreated rat and 4 from rats treated with human carcinogen aristolochic acid (AA), were used for small RNA library construction. Application of the different animals treated with a carcinogen and its vehicle control could strengthen the discovery of possible novel miRNAs according to the common novel miRNAs existed in the different animals and the differentially expressed novel miRNAs due to the treatment. The NGS was conducted using Illumina Genome Analyzer II platform. NGS data was analyzed by miRAnalyzer. Totally, 14,358,136 sequence reads were obtained, among which 332 novel miRNAs candidates homolog to other species and 100 rat specific candidates were identified. Custom miRNA microarray containing 5,460 miRNAs from 32 vertebrate species and the 100 rat specific candidates were employed to validate those candidates. Nine novel rat miRNAs were discovered using a strict criteria (NGS reads >10 and miRNA array signal intensity >31 for every rat samples). One of the novel rat miRNA was statistically significantly dysregulated by the AA treatment (P <0.05). Since only one new rat miRNA was added from the samples). One of the novel rat miRNA was statistically significantly dysregulated by the AA treatment (P <0.05). Since only one new rat miRNA was added from the samples). One of the novel rat miRNA was statistically significantly dysregulated by the AA treatment (P <0.05).

774 GENE LOCI ASSOCIATED WITH METABOLISM OF INORGNIC ARSENIC IN MICE.
T. Agusa1, H. Komori2, Y. Soga1, M. Nose3, S. Mor4, R. Kubota5, S. Tanabe1 and H. Iwata1. 1, M. Hackenberg2, Z. Li1, J. Yan1 and T. Chen1. Division of Genetic and Molecular Toxicology, National Center for Toxicological Research/FDA, Jefferson, AR and 2Department of Genetics, Facultad de Ciencias, Universidad de Granada, Granada, Spain.

To identify genetic loci responsible for inorganic As (IA) metabolism, a quantitative trait locus (QTL) analysis was performed using MXH/lpr recombinant inbred mouse strains exposed to inorganic As. We analyzed concentrations of arsenite (As(III)), arsenate (As(V)), monomethylarsonic acid (MMA), and dimethylarsinic acid (DMA) in the liver of nine MXH/lpr strains. In all the strains, concentration of the sum of As compounds (SA) in the liver was negatively correlated with hepatic DMA composition (%DMA), whereas the opposite trend was observed for IA (As(III) + As(V)) composition (%IA). This result suggests that IA metabolic capacity significantly influences As accumulation in mice. Furthermore, significant differences in the concentrations and compositions of As compounds were found among these strains. QTL analysis showed that a significant linkage was identified on for %DMA with chromosomes 14 and 3. For %IA, a significant linkage was identified on chromosomes 14 and 5. Interestingly, the loci on the chromosomes 14 and 5 were correlated with %IA in an additive manner.

775 THE FUNCTION OF ETHYLENE IN SYNECHOCYSTIS SP. PCC 6803.
J. L. Wynn1, D. Binder2 and R. F. Lacey3. 1Chemistry, Southern University and A&M College, Baton Rouge, LA, 2Biochemistry and Cellular Molecular Biology, University of Tennessee, Knoxville, LA and 3REU Sensing and Signalling and Biochemistry and Cells & Molecular Biology, University of Tennessee, Knoxville, LA. Sponsor: D. Wedley.

Ethylene is a gaseous plant hormone that is important to many plant processes such as seed germination and ripening. Responses to ethylene are regulated by a set of receptors that are unique to each plant species. Bioinformatic analysis showed that ethylene binding like sequences have been found in cyanobacteria species. The purpose of our research is to investigate the role of ethylene signaling in cyanobacteria using Synechocystis sp. Based on the similarities between the DNA sequence of cyanobacteria and plant ethylene receptors, we hypothesized that lateral gene transfer may have occurred during endosymbiosis. To study ethylene binding in cyanobacteria, we determined if the presence of Synechocystis gene product, slr1212, in cyanobacteria is capable of binding ethylene and whether the knockout of Synechocystis gene disruption has a phototaxis response in this organism. slr1212, an evolutionary precursor to the ethylene signaling receptors found in other plants, was cloned into an E. coli expression vector and the amount of ethylene binding protein produced was measured using a radioligand binding assay. The Synechocystis slr1212 gene knockout was generated using homologous recombination. Analysis of slr1212 binding of ethylene in both whole cell and membrane preparation demonstrate that this protein has a high affinity for binding ethylene. Furthermore, when the Synechocystis gene was disrupted, we observed no significant change in phototactic response in cyanobacteria. Our preliminary data suggest that the role of slr1212 gene in cyanobacteria may be different from what is observed in other organisms.

776 IMPROVEMENT OF TOXICOGENOMICS PROFILE COMPARISON TO PREDICT PROTEIN-PROTEIN INTERACTIONS.
Y. Igarashi1, N. Nakatsu1, H. Yamada2, A. Ono3, Y. Ohn3 and T. Urushidani2,3. 1National Institute for Biomedical Innovation, Ibaraki-City, Osaka, Japan, 2National Institute of Health Sciences, Tokyo, Tokyo, Japan and 3Doshisha Women’s College of Liberal Arts, Kyotanabe, Kyoto, Japan.

We have developed in silico methodology for toxicogenomics data to compare a pair of probe sets to measure the similarity of gene expression profiles considering with their time courses and dose effects. This method can be applied to any kinds of gene expression data that is obtained in a systematic manner. The toxicogenomics project in Japan, started in 2002, produced genome-wide gene expression data of the liver of rat in vivo and vitro using 150 pharmaceutical drugs. The gene expression data has been obtained at 8 time points and 4 dose levels in vivo, and 3 time points and 4 dose levels in vitro. Previously, we showed an approach to find protein-inhibitor pairs using the above method. The gap of similarity score distribution between p53 and its specific inhibitor gene Mdm2 is good example to predict specific type of protein-protein interactions such as protein-inhibitor pairs. However, in this example, although the similarity score of p53 was highly ranked (p <0.01) in the score distribution between Mdm2 and all other genes, still over 50 genes were listed as candidate interaction partner genes. To narrow down to select the potential interaction partner genes and remove unrelated genes, we introduced co-expression clustering method. In our improved method, we employed k-means clustering and Euclidean distance converted from the scores. By clustering co-expressed genes, those multiple genes under same regulatory unit were merged into a cluster and the number of candidate genes were decreased. While Mdm2 does not have similar expression profile to the profile of p53, the specific type of protein-protein interaction is not likely to classify into same cluster. Our improved method reduced the number of unrelated genes and successfully narrow down the potential interaction partner genes. This method would be greatly helpful to reveal potential toxicological pathways and mechanisms.

777 HIGH-DIMENSIONAL PROFILING OF TRANSCRIPTION FACTOR ACTIVITY DIFFERENTIATES TOXCAST CHEMICAL GROUPS.
A. Wilson1,2, M. Martin3, A. Frame1, P. Kotbiva1, R. Judson1, A. Richard4, A. Medvedev5, S. Makarov3, K. Houck1 and D. Reif1. 1NCCT, UT EPA, Raleigh, NC, 2Department of Statistics, North Carolina State University, Raleigh, NC and 3Attane Inc., Research Triangle Park, NC.

The ToxCast™ project at the US EPA uses a diverse battery of high-throughput screening assays and informatics models to rapidly characterize the activity of chemicals. A central goal of the project is to provide empirical evidence to aid in the
prioritization of chemicals for additional toxicity testing. Chemicals can be differ-
entiated based on the observed activity profiles as reported by ToxCast assays. Here, we provide a statistical framework to quantify and visualize activity patterns across assays and chemicals. We demonstrate this method by compar-
ing broadly-defined chemical use groups amongst the 1060 unique compounds in
the combined ToxCast Phase I and II sets. The groups were obtained by query-
ing usage information across the ACToR database. The large chemical set represents a diverse landscape including groups such as pharmaceuticals, pesticides, food addi-
tives and fragrances. We used a set of 81 ToxCast assays that measure chemical in-
duced transcription factor activity in a human hepatic cell line. The multiplexed assay enables high-content, functional assessment of transcription factor activities, which are core components of cellular signaling networks. Using our statisti-
cal profiling framework, we highlight a subset of these assays that best differenti-
ate chemical use groups and report similarities amongst transcription factor activity profiles of chemicals used for radically different purposes. We then drill down into these profiles using a Bayesian approach to infer the degree of relatedness between all chemicals within a group—shedding light on informative subgroups having similar transcription factor activity patterns. Our methods provide a flexible framework for understanding high-dimensional toxicological data and are extensi-
bly to diverse definitions of “group”; e.g., alternate chemical usages, known in vitro toxicity endpoints, or structural classes. This abstract does not necessarily reflect US EPA policy.

778 DOSE-RESPONSE MODELING OF P53 OSCILLATION IN RESPONSE TO DNA DOUBLE STRAND BREAKS.

Z. Li, Q. Zhang and M. E. Andersen, Institute for Chemical Safety Sciences, The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

The tumor suppressor p53 is a crucial guardian of genomic integrity in mammalian cells. In response to DNA damage, the p53 pathway is activated, leading to various cell fate decisions depending on damage severity and repair efficiency. Understanding p53 dynamics and its connection with toxicity endpoints such as cell proliferation, apoptosis, and mutagenesis is an important step toward quantita-
tive risk assessment for genotoxic chemicals. We have developed a computational model to simulate p53 oscillation in response to DNA double strand breaks (DSBs) that can be induced by ionizing radiation and radiomimetic chemicals. The model was formulated by incorporating a feedback circuit consisting of p53, Mdm2, ATM, and Wip1, ultra-sensitivity through experimentally justified multi-step sig-
naling and ATM autophosphorylation, and time delays through nuclear/cytoplas-
ic translocation. The deterministic version of the model is able to produce both
sustained and damped oscillations. When simulated stochastically with the Gillespie algorithm to take gene expression fluctuation into consideration, the model, which is parameterized to produce damped oscillations deterministically, exhibits sustained and noisy oscillations. The simulated p53 and Mdm2 protein levels oscillate with a large variance in amplitude and a relatively fixed period (7 hr) in individual cells. When averaged over a cell population, the oscillations become damped. As a result of ATM autophosphorylation, the amplitude and frequency of p53/mdm2 oscillations in individual cells are independent of the amount of DSBs. However, the number of cells oscillating increases as the irradiation dose increases. These simulation results are consistent with experimental observations reported in the literature. The p53 circuit developed here can be linked to cell cycle and apop-
tosis models to better understand the effects of DSBs on cell cycle arrest and cell death, and to predict mutagenesis rate.

779 USING POPULATION-BASED DOSE-RESPONSE CYTOTOXICITY DATA FOR IN SILICO PREDICTION
OF RAT ACUTE TOXICITY.

A. Sedykh, Y. Low, E. Lock, I. Rusyn and A. Trophsa, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Previously, we established that calculated chemical features combined with in vitro screening or toxicogenomics data afforded “hybrid” prediction models of toxicity with improved accuracy. Here, we explored the value of incorporating population diversity into hybrid modeling. We used quantitative high-throughput screening (qHTS) data on cytotoxicity and caspase-3/7 activation for 240 chemicals tested at 12 concentrations (62.5nM-400uM) in 81 densely genotyped human lymphoblast cell lines (CEPH panel, Mapmap). First, we used qHTS data as independent vari-
ables to model rat acute toxicity (119 chemicals with rat oral LD50 values catego-
rized as “toxic” or “non-toxic”) achieving the classification accuracy of 63.4% under 6-fold external cross-validation. Second, we developed both conventional quantitative structure-activity relationship (QSAR) and hybrid models (combining chemical descriptors and qHTS data across all cell lines). The accuracy of the hybrid models was significantly higher (70.3%) than that of conventional QSAR models (61.4%), in line with previous results. Model analysis indicated that
cytotoxicity measured at 15mM was the most frequently used in vitro predictor, and that cell line sensitivity varied based on the descriptors included. NA10748, NA12057, NA12156, and NA12753. We conclude that the “hybrid” modeling offers several advantages such as improvements in the model accuracy, en-
riched interpretation of the most predictive features, and expanded applicability domain for predicting larger variety of chemicals. Models developed in this study can identify GHS categories 1-3 of toxic compounds with reasonable accuracy and thus can be applied in prioritization of environmental compounds for risk assess-
mation. Future studies will integrate genotype-based descriptors to enrich current representation of compounds by their chemical structural features and by qHTS based biological descriptors.

780 PREDICTIVE IN SILICO MODELS OF TOXICITY USING C. ELEGANS GROWTH ASSAY ALONG WITH TOXCAST PHASE I SHORT-TERM ASSAY DATA.

A. Golbraikh1,2, R. Shah1,2, A. Sedykh1, W. Boyd4, M. Smith1, H. Zhu1, A. Trophsa1,2 and J. Freedman3, SRA International, Durham, NC, 4SciOme LLC, Research Triangle Park, NC, 5University of North Carolina at Chapel Hill, Chapel Hill, NC, 6NIHES, Research Triangle Park, NC and 7Rutgers University, Camden, NJ.

Development of predictive in silico models for chemical toxicity is a task of primary importance. The US EPA ToxCast Phase I data includes 615 in vitro and 76 in vitro assays for 320 substances (211 after curatiation). Here, we have explored the use of whole organism C. elegans toxicity data generated for ToxCast chemicals along with available in vitro data for toxicity predictions. Our results indicate that (i) the ToxCast data can be used to predict toxicity of molecules for C. elegans and (ii) the C. elegans growth assay can be used to help predict some of the in vivo toxicities in-
cluded in ToxCast data. QSAR approach was used to develop models for predic-
tions of nematode growth inhibition assays. When chemical properties alone were used as descriptors, no predictive models were generated; however, use of in vitro ass-
ays as descriptors yielded models with the correct classification rate (CCR) of 0.70. A hybrid approach that combines chemical and in vitro assays as descriptors gave models with the highest CCR of 0.71. Two in vitro assays were found to be similar to a subset of the C. elegans assay of 102 compounds which included 51 non-toxic and 51 toxic compounds. A hierarchical QSAR modeling approach in which chem-
icals are partitioned into two classes based on whether they test similarly or dissim-
ilarly in both C. elegans and in vitro assay was used to build models for these as-
says. The best model with CCR=0.67 was obtained for ‘CHR_Rat_LiverNecrosis’ assay. Our approach, which combines in vitro assays with chemical descriptors en-
hances predictive power of QSAR models and warrants further exploration of effec-
tive use of such cheminformatic approaches in predictive toxicology.

781 A COMPUTATIONAL ANALYSIS OF THE MECHANISTIC RELATIONSHIP BETWEEN CIGARETTE SMOKING AND RISK OF RHEUMATOID ARTHRITIS.

L. Cai, J. Lu, S. Ng and D. E. Johnson, Nutritional Science & Toxicology, University of California Berkeley, Berkeley, CA.

Rheumatoid arthritis is a systemic autoimmune condition affecting the synovial joints. Cigarette smoking has been associated with increased risk rheumatoid arthri-
tis; however, the molecular mechanisms behind this phenomenon remain unclear. This study aimed to systematically analyze interactions between cigarette chemicals and genes important in rheumatoid arthritis pathogenesis. A North American Rheumatoid Arthritis Consortium genome-wide association study was used as the source of genes whose variants correlate with cases of rheumatoid arthritis. GeneGo’s MetaCore database was used to analyze these genes for interactions with chemicals in cigarette smoke and tobacco. In addition, this list of genes was com-
pared to genes differentially expressed in lymphocytes of smokers and non-smokers. Of the 1515 genes significant at 1E-3 in the genome-wide association study, 160 were found to interact with 122 chemical components of cigarettes. The majority of these interactions come from chemicals in tobacco, as opposed to cigarette smoke, and can be classified as inhibitory binding of a chemical to a gene product. Of the 37/6 genes significant at 1E-2, 76 were found to overlap with 303 genes dif-
fferentially expressed in human joints most significantly toqHTS descriptor. Gene ontology enrichment analysis revealed biological processes overrepresented in the above lists of genes. Examples include ion transport, immune response, cell proliferation, among others. Cigarette chemical interactions with genes grouped in these ontolo-
gies reveal that immune system genes are activated, whereas ion transport and anti-
apoptosis genes, among others, are inhibited. This study provides a broad look at the complex network of signaling events underpinning the relationship between cigarette smoking and rheumatoid arthritis and provides the groundwork for future studies examining important genetic-chemical interactions and gene ontologies.
AN EXAMINATION OF THE COMBINED EFFECTS OF ENVIRONMENTAL FACTORS AND SUSCEPTIBLE GENE ON INCREASING THE RISK OF ALZHEIMER'S DISEASE.

C. Ho, L. Feng and D. E. Johnson, Nutritional Science & Toxicology, University of California Berkeley, Berkeley, CA.

There is increasing evidence that combinations of environmental and genetic factors are likely causes of the development of Alzheimer’s Disease (AD). This research was designed to visually interpret the interactions between known environmental and genetic risk factors. Using Genome-Wide Association Studies, key pathogenesis-related genes and gene products were identified: amyloid precursor protein (APP), phosphatidylinositol-binding clathrin assembly protein (PICALM), clus-terin (CLU), complement receptor 1 (CR1), sortilin receptor 1 (SORL1), and apolipoprotein E (ApoE). Potential environmental factors of interest were chosen based on publications implicating their potential roles in the cause and development of AD. These included: acrolein, 25-hydroxycholesterol, arsenic, copper, and aluminum. Using Genego Metacore and prior research, we mapped out cellular pathways that encompass both gene and environmental factor correlations. Results from this research indicate that the environmental factors supplement the formation of amyloid beta plaque formation in ways that differ from that of the genes of interest. While our genes and gene products were mainly focused on amyloid beta clearance and immunity, the environmental factors were shown to be involved in stabilization of amyloid beta oligomers. The combined effects of amyloid beta oligomer stabilization along with lack of clearance supports our hypothesis that exposure to certain environmental factors can increase the risk of development of AD in individuals who are already genetically susceptible. Since previous research has primarily dealt with examining the two factors separately, our results ultimately contribute to our understanding of the interactions between identified susceptible genes and environmental factors implicated in the cause of AD.

VIRTUAL LIVER: ESTIMATING Proliferation AND APOPTOSIS OF HEPATOCYTES EXPOSED TO ENVIRONMENTAL CHEMICALS USING TOXCAST DATA.

The US EPA’s ToxCast™ program has screened over a thousand chemicals for po- tential toxicity using hundreds of high-throughput, in vitro assays. The US EPA’s Virtual Liver (v-Liver™) is a cellular systems model of hepatic tissues that enables the estimation of in vitro effects using in vitro data by bridging multiple levels of bi- ological organization. A physiologically-based pharmacokinetic model links envi- ronmental exposures to liver dosimetry, while a microdosimetry model simulates the chemical transport through the sinusoids of the hepatic lobule to estimate cell- level concentrations of chemicals and other soluble factors. Finally, an agent-based model of hepatic cells is used to quantitatively estimate cellular decisions – e.g., apoptosis and proliferation – based on the perturbation of an intracellular signaling network by inputs from the microenvironment. Using the literature we recon- structed a putative crosstalk network to mechanistically relate hepatocyte G1/S pro- gression and apoptosis involving growth factors (e.g., EGF and HGF) and cy- tokines (e.g., TNFα). Next we related key proteins in this network to a subnet of assays in ToxCast including phosphorylation of H2AZ, H3, and c-Jun. We have developed a novel approach for modeling the dynamic response of individual cell- based agents, called Boolean network Ensembles with Asynchronous Threshold Logic (BEATL), to quantitatively estimate the response of hepatocyte populations using in vitro data. We used this framework to simulate the concentration depend- ent perturbations of key signaling molecules in cell proliferation and apoptosis based on ToxCast in vitro data for environmental chemicals (e.g., PFOA, Imazalil, Bisphenol A, Triclosan) as well as reference hepatotoxicants (e.g., acetaminophen). The model results were used to evaluate potential changes in hepatocyte fate based on chemical-induced concentration-dependent molecular perturbations. This ab- stract does not necessarily reflect US EPA policy.

BIOLoGICAL PROFILING OF THE TOXCAST PHASE II CHEMICAL LIBRARY IN PRIMARY HUMAN CELL COCULTURE SYSTEMS.

The US EPA’s ToxCast research project was developed to address the need for high- throughput testing of chemicals and a pathway-based approach to hazard screening. Phase I of ToxCast tested over 300 unique compounds (mostly pesticides and an- timicrobials). With the addition of Phase II, the library contains 1000 unique com- pounds, including 135 failed pharmaceuticals donated by industry partners, refer- ence compounds known to be endocrine disruptors, carcinogens or reproductive/developmental toxicants, high-production volume chemicals, food additives, cosmetic ingredients, and proposed alternatives to commonly used plasticizers and surfactants. The chemicals were tested in a panel of BioMAP® systems, using complex cocultures of primary human cells to characterize heterogeneous inter- actions underlying angiogenic and inflammatory processes. All compounds were assayed in duplicate at 4 concentrations in 8 cell systems using combinations of endo- thelial cells, peripheral blood mononuclear cells, bronchial epithelial cells, fi- broblasts, keratinocytes and coronary artery smooth muscle cells, under various en- dogenous stimuli. totaling 87 endpoints and over 450,000 data points. ToxCast compounds were classified based on their ability to cause overt cytotoxicity in vari- ous cell types and on their bioactivity profiles when compared to reference com- pounds. Chemicals were identified with activities similar to known inducers of mi- tochondrial dysfunction, microtubule disruptors, cAMP elevators and NFκB pathway inducers. Finally, using the ToxCAST 2.0 platform, we generated the corre- sponding-use compounds and in some cases found to have significantly lower bioactivity, or none at all, at the tested concentrations. In vitro signatures for disrup- tion of embryonic vasculogenesis and induction of tumor angiogenesis derived from ToxCast Phase I data were forward-validated for the Phase II compounds with in vivo developmental toxicity or carcinogenicity data. This abstract does not reflect US EPA policy.

TOXPI PRIORITIZATION AND PROFILING OF 1060 TOXCAST CHEMICALS ACROSS MULTIPLE SECTORS OF TOXICOLOGICAL CONCERN.

D. Reif1, A. Wilson2, R. Judson1, R. Kavlock1 and D. Dix1, 1NCCT, US EPA, Research Triangle Park, NC and 2Dep of Statistics, North Carolina State University, Raleigh, NC.

The Toxological Prioritization Index (ToxFIT™) framework was developed as a de- cision-support tool to aid in the prioritization of chemicals for integrated toxicity testing. ToxPi consolidates information from multiple domains—including ToxCast™ bioactivity profiles (a diverse battery of over 700 high-throughput screening assays on multiple platforms), inferred toxicity pathways, exposure pre- dictions, and chemical descriptors—into comprehensive activity scores and multi- variate visualizations representing the contribution of each data domain to overall priority rankings. Here, we refine our methodology for aligning data with specific prioritization tasks, add formal quantification of ranking stability, and compare the ToxPi profiles of the combined Phase-I and Phase-II chemical sets. Considering the entire set of 1060 compounds, we explore prioritization tasks for three sectors of toxicological concern: cancer, developmental, and reproductive. We first link ToxRedDB in vivo data with ToxCast in vitro data to populate ToxPi slices for each sector. Second, multi-sector ToxPi profiles are estimated for the entire chemical set, and the priority (rank) order is estimated across and within sectors. Third, confi- dence intervals for all ranks are estimated. Finally, these priority ranks are evaluated in the context of sector-specific reference chemicals. Analogous to the logic under- lying standard curves or “spike-ins”, reference chemicals for each sector include compounds of low, medium, and high concern. Therefore, an appropriate ToxPi formulation would match the hypothesized reference chemical distribution, thereby giving context to the relative activity of test chemicals. The utility of such a prioritization scheme is that new test chemicals having unknown concern can be evaluated relative to known, reference, compounds, and their ToxPi profiles visual- ize activity in the context of a diverse set of compounds covering multiple chemical classes and proposed modes of action. This abstract does not necessarily reflect U.S. EPA policy.

A GLOBAL GENOMIC AND GENETIC STRATEGY TO PREDICT PATHWAY ACTIVATION OF XENOBIOTIC-RESPONSIVE TRANSCRIPTION FACTORS IN THE MOUSE LIVER.

Many drugs and environmentally-relevant chemicals activate xenobiotic-responsive transcription factors (TF). Identification of target genes of these factors would be useful in predicting pathway activation in vitro and in vivo chemical screening. Starting with a large compendium of Affymetrix files (>2000), we identified gene signatures by comparing the transcription profiles after exposure to TF activators in wild-type
and TF-null mice. The signatures included those regulated by PPARα, CAR, FXR, AhR, Nr2f2, FXR, and glucocorticoid receptor (GR). In addition, we identified sets of genes associated with phenomenon that are linked to liver toxicity/cancer including inflammation and cytotoxicity. Validation was carried out by characterizing the signature gene expression under independent conditions of chemical exposure or perturbation known to alter the TF. By using the sets of signature genes to query the compendium, a number of novel observations were made. 1) PPARα is activated in a number of nulligous mouse models that also lead to liver toxicity and may be linked to steatosis. 2) Nr2f2 is activated by a large number of conditions including environmentally-relevant chemicals, gene mutations, and bacterial infections. 3) GR is activated by a number of conditions including hepatoxic drugs, endoplasmic reticulum stress and systemic damage outside the liver. 4) Reexpression of male-specific signature genes occurred after castration, in GH-defective dwarf mice, during bacterial infections and chemical exposure. Our approach allows for creation of new gene signatures associated with other pathways or phenomenon in the mouse liver that can be tested using the compendium. We are presently using the signature sets to predict pathway activation after chemical exposure in mouse primary hepatocytes. (This abstract does not represent EPA policy.)

**Enhancing Mutagenicity Predictions Using Weight-of-Evidence Approaches.**

E. Ahlberg, C. Hasselgren, C. Yang, J. F. Rathman and S. Boyer.

Predicting the experimental outcome of the Ames test is done routinely within Pharmaceutical companies. In the early drug discovery phase, the high volumes of compounds are often handled using structural alerts or QSAR models. However, as drug development progresses, the need for reliable, more extensive information increases. At this later stage, it is also common practice to qualify impurities and degradants using SAR/QSAR methods. To ensure patient safety, highly reliable assessments are required using all available information in a weight-of-evidence (WoE) approach. The combination of diverse sources of evidence requires a mathematical structure that manages different types of probability expressions. One such example is Dempster-Shafer (DS) theory which deals with measures of “belief” as opposed to probability and can be viewed as an extension of Bayesian statistics. DS also introduces an explicit formulation for the unknown state which can be used to account for the amount of experimental error in an assay or model. In a classification data example, the confusion matrix for the training and/or test data can be used to calculate positive and negative predictive values to estimate probabilities for a prediction. In this study we present a DS WoE method where we combine QSAR modeling, the presence of structural alerts, number of experimentally tested structural near neighbors and their activities. For each prediction, the weights for the type of evidence are set dynamically. This enables an overall assessment based on all underlying information together with an uncertainty score which is unique for each compound. Application of the method on 300 internal compounds show an overall improvement compared to using a simple QSAR method. Specificity increased from 72 to 79%, sensitivity from 33 to 65%, false positive and negative rates decreased by ~10% when using the WoE method. Specificity was essentially unchanged and went from 85 to 84%.

**Computational Toxicology and Longitudinal Risk Assessment of Subchronic and Chronic Atorvastatin Calcium Administration.**

A. G. Ibrahim, F. E. Ibrahim and R. C. Shank.

As our wealth of scientific data becomes increasingly large, data mining algorithms and computational methods are used to discover new patterns of information to gain new knowledge about the progression of human disease, novel biomarkers, and toxicities of novel molecules with limited the extensive dependency on the use of animal models. In this study, computational mathematical algorithms are used to describe the kinetics of altered gene expression profiles of human disease and embryonic and adult stem cell differentiation in response to subchronic and extrapolated chronic administration of atorvastatin calcium (Lipitor®-B). High-resolution mRNA microarray data was obtained at 12 hours, 36 hours, 1 week, and 4 weeks from 11 male subjects with a mean age of 49.0 years +/- 12.5 years post administration of a daily dose of 20mg atorvastatin calcium. The data was used to generate independent differential equations for each microarray dataset for actual time points. Additional genetic profiles were extrapolated using two mathematical strategies: Discrete Random Kutta and Discrete Optimization. The extrapolated sets of genes regulated by atorvastatin were imported into the Ingenuity Pathway Analysis (IPA) software for data and toxicology interpretation.

The IPA Global Network is used as the data source for the construction of all biological pathways. Statistical and biological pathways for toxicity, altered biofunction, and disease were indentified. Using a System of Equations approach, we extrapolated new predicted gene expression data for 6 months, 1 year, and 5 years of chronic atorvastatin calcium administration independently with microarray signatures of the directed differentiation of H1 embryonic stem cell (hESC), active hepatitis C infection, and diabetes mellitus type II to address possible co-madmulation events.
Salmonella mutagenicity. The choice of chemical structures for an external valida-
tion set can greatly influence the performance statistics obtained with the set, po-
tentially leading to bias in the interpretation of and conclusions about a model's
suitability. Critical factors for consideration are numerous, but include the number
of chemicals, the ratio of positive to negative compounds, and the structural fea-
tures that are represented in the validation set compared to the model training set.
The first two criteria can be addressed relatively easily due to the abundance of data
for Salmonella mutagenicity; however, the latter requires a quantitative measure of
structural representation that can be applied to ensure that the test set is appropri-
ate for assessing the performance of a QSAR model based on its domain of applica-
ability. We characterized an established external validation set of over 2000 chemi-
cals using fingerprints for genotoxicity based upon known toxicophores and
assessed the overlap of these fingerprints with the domain of applicability of several
commercial QSAR models for Salmonella mutagenicity. Overall performance sta-
tistics for the models with this data set ranged from 59% to 82% sensitivity and
71% to 83% negative predictivity, and showed a 9% increase in sensitivity when
used in combination. However, within individual models, variation in performance
was observed across different toxicophores, providing a more detailed picture of
each model's strengths and weaknesses from a structural perspective.

Recent advances in systems biology and related scientific fields offer the potential
to fundamentally change the way that chemicals and drugs are tested for their risk
to humans. This new vision of toxicology testing will be based upon human rather
than animal biology and will involve a strong commitment to the 3Rs—replace-
ment, reduction, and refinement of animal use in research and testing. There are
many challenges to fully implementing this vision. Current formal approaches to
validation involve lengthy and expensive processes that require validating in vivo
data against in vitro data. This approach may not be relevant or even feasible for
the new pathways and endpoints being measured. Consequently, applying a one size
fits all approach to validation is not conducive to the rapid incorporation of emerg-
ing science or technology into the regulatory decision-making framework. As new
safety testing evolves, new approaches to demonstrating that a test is reliable and
valid for assessing the performance of a QSAR model based on its domain of applica-
tion advance, there's a concomitant need to demonstrate relevance and reliability
of each predictive model for its intended use such that regulatory agencies, the
regulated community, and the public have sufficient confidence in the decisions made
based on such approaches. Challenges and lessons learned from the application of
computational approaches under REACH will be discussed. Although traditional
method validation processes may not be practical let alone desirable for advanced
molecular screening methods, the OECD QSAR validation principles have helped
to provide a useful framework for characterizing models and their predictions,
thereby promoting/fostering regulatory acceptance for QSARs. Complementary
systematic evaluative procedures have been developed for selecting analogues for
read across of (eco)toxicological and environmental fate data. Recommendations
for adapting these principles and procedures to the Tox21 collaboration of EPA,
FDA, NIEHS/NTDP and NCGC will be presented.

In 2007, a National Academy of Sciences (NAS) report described a new vision and
strategy for toxicity testing in the 21st century based on human rather than animal
biology. This vision could be less expensive and time-consuming and would have
a strong commitment to replacement, reduction and or refinement of animal use in
testing. Unfortunately there seems to have been a general reluctance on the part of
industry and regulators to embrace this new vision and as a result the use of animal
tests continues to dominate regulatory toxicological testing practices. There are
many reasons for this including the long history of use of traditional animal meth-
ods, the familiarity, experience, and comfort level associated with their use, an
under confidence in non-animal methods and issues involved in validating these
methods. Historically, regulatory agencies have been slow to embrace new ideas as
seen by the reluctant adoption of genetic toxicology studies. As stated in the NAS
report "Change often involves a pivotal event that builds on previous history and
opens the door to a new era." The publication of the NAS report might be the "tip-
ping point" for a change but validation of these methods for regulatory use will be
a critical component in ensuring the vision's success. Using a one-size-fits-all ap-
proach to validation will deter the rapid incorporation of this emerging science into
the regulatory framework. As toxicology evolves, our approach to assessing these
methods should also evolve.

A biomarker is defined as a characteristic that is objectively measured and evaluated
as an indicator of normal biologic process, pathogenic process or biological re-
response to a therapeutic intervention. Qualification is a regulatory conclusion that,
within a stated context of use, the results of an assessment with a biomarker can be
relied upon to have a specific interpretation and application in drug development
and regulatory decisions. A biomarker is qualified by regulatory authorities if there
is appropriate data in support of its intended use. Once qualified, the biomarker
can be used without the regulatory agency's need to reconsider and reaffirm its ap-
plicability. The US FDA's CDER Biomarker Qualification Process involves a "fit-
for-purpose"- based evidentiary threshold approach that depends upon the un-
tended context of use in drug development. The biomarker qualification program
is an objective, science-based approach for evaluating the relevance, quality, and relia-
ability of a test based upon its intended use, for example as part of a screening pro-
gram or as a definitive surrogate endpoint in a pivotal clinical trial. It serves as a
model for the discussion of new validation approaches for the incorporation of al-
ternative test methods into a regulatory framework.

EPAs Office of Pesticide Programs (OPP) is building on the ambitious NAS vision
for Toxicity Testing in the 21st Century which calls for a shift toward the avoidance
of significant perturbations of normal cellular pathways in exposed populations by
using cell based assays to measure these perturbations, dose-response modeling or-
ganized around computational systems biology models of the circuity underlying
each toxicity pathway, and in vitro to in vivo extrapolations based on pharmacoki-
etic models to predict tissue concentrations under specific exposure conditions.
OPP's long-term goal is to move from a paradigm that involves requiring in vivo
testing for "every possible adverse outcome" toward a hypothesis-driven paradigm
where in vivo testing is targeted to the most likely hazards and risks of concern.
Thus, rather than taking a one size fits all approach to toxicity testing OPP pro-
poses a progressive, tiered-testing approach that starts with hazard-based hypothe-
ses about the plausible toxicological and fate potential of a pesticide or group of
pesticides based on their physical-chemical properties (e.g., using read-across and
structure activity relationships [SARs] to examine toxicological potential). Existing
exposure and toxicity information is then combined with refined exposure models,
computational toxicological models (e.g., quantitative SARs or QSARs ([Q]SARs]), and diagnostic in vitro assays to narrow requirements for in vivo.
Consistent with this view is the consideration of time and As the science evolves so
too must the evaluation process to "validate" regulatory test methods as the current
one size fits all approach is too costly and time consuming and which compares the
performance of a new test to an existing test which may not actually predict the ef-
ects of concern in human and non-humans well.
A multitude of non-animal assays are conducted before a drug is even given to an animal, much less humans. Lead compounds may be modified to eliminate unwanted effects found in various in vitro and in silico screens. All studies conducted with a drug candidate for human studies are submitted to the FDA: In silico, in vitro, and in vivo. Thus the knowledge base on a new drug candidate can be quite rich before humans have been exposed, in contrast to what is known about most high production volume chemicals. The use of exploratory clinical trials, as described in international harmonization guideline, ICHM3R2, can eliminate drugs that have poor human bioavailability or which don’t reach the intended target in humans. Such exploratory clinical trials are supported with much less animal data than normally needed for first in human studies.

Turning the promise of “Tox21” and “pathways of toxicity” into an animal-free health-protective reality is proving devilishly difficult, well more challenging than had been widely expected. One of the key issues is that while it’s possible to measure the expression of many genes and many biochemical endpoints, the right ones to measure often vary between compounds and model systems. Rather than trying for more discrimination and ever-higher definition, sometimes a lower-power, more overview-level analysis can actually be more helpful. Based on the hypothesis that different assays will have different strengths and complement each other, we have started to integrate data from the ECVM embryonic stem cell test and Zebrafish morphogenesis to give us an overall sense of the in vivo developmental toxicity of new drug candidates. Although still very much a work in progress, this presentation will discuss the current ways we balance the various developmental tox readouts with general cytotoxicity data. Our eventual goal is to develop a formalized and transportable process that can be used across chemical scaffolds and venues, and the only certainty is that the end method will look very different from what we’ve started with.

Despite decades of research into its causes and treatments, breast cancer remains the most common invasive cancer and the second leading cause of cancer mortality for women in the United States. Known risk factors include genetic mutations; birth weight and stature; timing of breast development, childbearing, lactation, and senescence; body fat; and physical inactivity. Some common external, environmental risk factors include radiation, hormone therapy, diet, alcohol, and perhaps smoking and shift work/circadian rhythm disruption. Several environmental chemicals have also been implicated in the etiology of breast cancer. Although toxicological studies indicate potential hazards through endocrine disruption and even some hormone independent mechanisms, strong epidemiological evidence is largely lacking. Animal bioassays for breast and other types of cancer typically assess each chemical independently, and exposure periods usually do not include potentially sensitive windows of susceptibility, such as in utero, the neonatal period, puberty, or menopause. Nevertheless, emerging epigenetic data support the concept that exposure during sensitive early life stages when the mammary gland is developing can result in developmental reprogramming of breast cells, thereby increasing breast cancer risk later in life. Similarly, stimulation of breast cell division later in life by endocrine-active agents may increase mutation rates or promote tumors at a life stage in which DNA repair is waning. The important thing is that this highlights the potential contributors to breast cancer risk in follow up to the 2011 report of the Institute of Medicine Committee on Breast Cancer and the Environment (funded by Komen for the Cure).
Compared to environmental chemicals such as Bisphenol-A, much less attention has focused on other disruptors of endocrine signaling that could significantly impact breast cancer risk. These include 1) zeranol, a myoestrogen used in livestock to enhance meat production, and 2) disruption of circadian rhythm by exposure to light at night. We conducted a cross-sectional analysis among 163 girls, aged 9 and 10 years, participating in the Jersey Girl Study to measure urinary myoestrogens and their possible impact on growth and development. We found that myoestrogens were detectable in urine in a substantial proportion of prepubertal girls (78.5%), and that urinary levels were predominantly associated with beef and popcorn intake. Urinary myoestrogen levels, however, may be associated with altered growth and lower early onset of breast development, factors related to decreased breast cancer risk. Disruption of circadian rhythm by shift work is associated with increased risks of breast and prostate cancer. Our studies in rats indicated that carcinogens also disrupt the expression of circadian-controlled genes (CCG), and that methylestenocysteine resets the expression levels and phase of CCG, including estrogen receptor β. MSC restores rhythmic fluctuations in histone acetylation on the Period 2 gene promoter, suggesting an epigenetic mechanism for MSC-mediated restoration of circadian rhythm. Changes in circadian gene and CCG expression in lymphocytes are being investigated as possible biomarkers of circadian disruption in shift workers. Agents that mediate their effects by epigenetic reprogramming of mammary cells may hence be amenable to chemopreventive agents that reverse these effects.

Nutritional and occupational factors that contribute to increased breast cancer risk during susceptible life stages such as in early life exposures, quantified exposures to multiple potential agents and factors, and focus on single agents. Epidemiological studies typically have not examined breast cancer, high dosing protocols that miss potential windows of susceptibility, endocrine disruption, genotoxicity and animal data, but little evidence confirms chemicals are suspected to pose breast cancer risks based on mechanistic (e.g., estrogen receptor β) effects at relatively low doses. In addition to using more refined techniques to quantify exposures over the life course, epidemiological studies could evaluate potential generic polymorphisms for specific agents (e.g., metabolic enzyme variants for alcohol or smoking) in combination with social or behavioral factors that may affect susceptibility to breast cancer.
The development of intracocular drugs to treat posterior segment disease, such as age-related macular degeneration, presents both advantages and challenges due to the unique aspects of ocular anatomy and physiology. While drug administration within the eye affords the promise of direct and local delivery, the reduction of systemic or local effects. Ocular implants have advantages over more conventional treatment modalities. Treatment approaches for ocular diseases affecting the posterior segment can be limited by the lack of effective delivery of drug. Conventional approaches for treating inflammatory diseases in the posterior segment include topical administration, periocular or intravitreal injections, and systemic administration of therapeutic agents. Several disadvantages to these treatment modalities include the typically low bioavailability following topical drug application, and the potential for increased systemic or local effects. Ocular implants have advantages over more conventional methods of drug administration, including delivery of a constant therapeutic drug level directly to the site of action. Retisert is a non-biodegradable intravitreal implant containing the steroid fluocinolone acetonide, for the treatment of chronic non-infectious uveitis affecting the posterior segment of the eye. The device releases active drug at a predictable rate for approximately 3 years following surgical placement of an implant into the vitreous. As a novel approach to therapy, regulatory testing expectations for non-biodegradable intravitreal implants have not been well established. To support the safety and registration of the Retisert implant, a comprehensive nonclinical program was conducted. This testing strategy was designed to characterize the release of the drug from the delivery system, and determine the chronic pharmacokinetic and toxicity profile of the implant. Additional testing was conducted to establish the biocompatibility of the implant material. Key considerations when developing such an implant include optimal selection of the drug, delivery characteristics and species selection for the nonclinical program. The unique drug delivery profile of this agent with a well-characterized adverse event profile, including cataract formation and increased intraocular pressure and glaucoma has resulted in complexities in regards to the global development and registration of the product. This presentation will highlight some of the key challenges and "lessons learned" with Retisert, and intravitreal implants in general.

S 811 REGULATORY PERSPECTIVES OF CONTEMPORARY ISSUES IN OCULAR TOXICOLOGY.

This presentation will provide an overview of regulatory considerations for the nonclinical development of drugs for ocular disease. Important nonclinical ocular findings will be discussed with respect to regulatory decision making and their implications for further preclinical and clinical evaluation.

S 812 MOLECULAR BASIS FOR PREVENTION OF CARDIOTOXICITY.

Q. M. Chen1 and Y. Kang2. 1Department of Pharmacology, University of Arizona, Tucson, AZ and 2Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY.

Cardiac toxicity is an increasing concern for chemo, radiation, and gene targeting therapies. The overlapping molecular pathways of cardiac protection versus cancer cell growth, and cardiac energy metabolism versus underlying causes of diseases such as obesity or diabetes pose threats to new drug development against these diseases. Whereas anthracyclines, such as doxorubicin, are well known for inducing cardiotoxicity manifested by arrhythmia and chronic cardiomyopathy, the monoclonal antibody trastuzumab (Herceptin) targeting the epidermal growth factor receptor for cancer therapy induces apoptosis and hypertrophy of cardiomyocytes, leading to dilation cardiomyopathy. Small molecular kinase inhibitors, such as imatinib (Gleevec), cause cardiotoxicity due to induction of apoptosis of cardiomyocytes. While kinase inhibitors and gene targeting therapy have tremendous potential for pharmacological treatment of cancer and other diseases, finding the signaling pathways and genes that can protect against cardiotoxicity is an emerging issue. Thus, in exploration of this important topic, we will discuss the ways in which the heart can be protected from tissue injury by addressing signaling molecules, unique genes, and nutritional factors.

S 813 CARDIOTOXICITY OF CHEMOTHERAPEUTIC DRUGS: CLINIC PRESENTATION AND TREATMENT.

J. Alpert. Medicine, University of Arizona, Tucson, AZ. Sponsor: Q. Chen.

Cardiotoxicity of cancer chemotherapeutic agents has become an increasing concern for cardiologists. These agents can injure the myocardium or vascular system through a variety of mechanisms including: 1) direct toxic effects, such as induction of oxidative stress and apoptosis; 2) alteration of cellular signaling pathways and biochemical metabolism; 3) neurohormonal activation; 4) alteration of ion channels important for the contractile function; and 5) affecting components of coagulation. Notorious examples of these agents include anthracyclines, trastuzumab, imatinib, and 5-fluorouracil. While anthracyclines have been well studied for their cardiotoxic effects through generation of oxidants, small molecule or monoclonal antibody-based tyrosine kinase inhibitors can cause cardiotoxicity despite of the tremendous potential for cancer therapy. Alkylation agents, antimetabolics, antimitotuble agents, and proteasome inhibitors can also induce cardiotoxicity. The clinical presentation of cardiotoxicity differs between the drugs, and includes myocardial ischemia, infarction, hypertension, thromboembolism, arrhythmias, and congestive heart failure. Mechanisms of myocardial injury and the resulting clinical pathological entities produced will be discussed. Various biomarkers, hemodynamic, and clinical endpoints are used in clinical practice in order to monitor patients for cardiovascular complications associated with these therapies. A number of established and experimental preventive and/or therapeutic interventions are employed to combat cardiovascular complications involving these agents.

S 814 CARDIOTOXICITY OF KINASE-TARGETED THERAPEUTICS.

A decade ago, Hoshijima and Chien (JCI, 2002) drew largely theoretical parallels between the dysregulation of the signaling pathways driving cancer and those driving cardiac hypertrophy. On the surface, this statement appeared to stretch the limits of reason, given the fact that cancer cells are known for their proliferative capacity, and adult cardiomyocytes are, except under unusual circumstances, terminally differentiated and incapable of re-entering the cell cycle. However, on closer examination, there are numerous parallels between signaling pathways that drive tumorigenesis, and signaling pathways that regulate hypertrophic responses and survival in cardiomyocytes. Indeed, this issue appears to be at the core of the cardiotoxicity, often manifest as a dilated cardiomyopathy, that can result from treatment with agents typically referred to as “targeted therapeutics”, which target specific protein kinases that are dysregulated in cancer. Herein, we will examine the cardiotoxicity of targeted therapeutics, focusing on the underlying molecular mechanisms, thereby allowing an understanding of the problem, but also allowing the identification of novel, and sometimes surprising, roles played by protein kinases in the heart.
Mitochondrial aldehyde dehydrogenase 2 (ALDH2) is best known for its role in alcohol metabolism. Recent evidence suggests that ALDH2 serves as a natural shield from oxidative stress in the myocardium. We have identified Alda as selective aldehyde dehydrogenase activators. Protein crystallography studies identified the molecular basis of ALDH2 activation by Alda-1. We also found that Alda-1 corrects the structural defect in a mutant enzyme, a result of a single point mutation that is found in 40% of East Asians. We then show that Alda-1 treatment reduces oxidative stress and cardiac injury ex vivo and in vivo. Because of the critical role of ALDH2 in cardiac protection, we asked whether prolonged treatment of nitroglycerin, which inactivates ALDH2, may generate adverse effects in patients at the risk of myocardial infarction. Using an in vivo rat model of myocardial infarction (MI), we demonstrated that sustained nitroglycerin treatment results in increased cardiac dysfunctions following MI. We observed a lower fractional shortening and increased myocardial injury at 3 days and 2 weeks after MI in rats subjected to sustained nitroglycerin up to the ischemic event. Concomitant treatment with Alda-1 reduced nitroglycerin-induced increase in infarct size and rescued cardiac function after MI as measured up to 2 weeks after infarction. These data suggest that activation of ALDH2 could protect from nitroglycerin-induced increase in cardiac damage. The potential clinical implications of our data on the role of ALDH2 in acute and chronic oxidative stress of the myocardium will be discussed.

Oxidative stress plays an essential role in cardiotoxicity of chemotherapeutic agents. Whereas low to mild doses of oxidants provoke endogenous defense, high dose or prolonged oxidative stress induces death or hypertrophy of cardiomyocytes, contributing to the dilated cardiomyopathy and heart failure. Increasing endogenous antioxidant defense and inhibiting hypertrophy or apoptosis are expected to reduce cardiotoxicity. Nrf2, a transcription factor regulating the expression of a cluster of antioxidant and detoxification genes, can be activated by low to mild doses of oxidants and a number of natural products. In cardiomyocytes, oxidants cause rapid elevation of Nrf2 protein due to de novo protein translation. Recruitment of specific RNA binding proteins to 5'-Untranslated Region of Nrf2 mRNA contributes to stress induced de novo Nrf2 protein translation. Knocking out the Nrf2 gene results in a loss of cardiac protection in mice. Nrf2 overexpression prevents hypertrophy but not apoptosis of cardiomyocytes. Complementing the protective effect of Nrf2, we found that glucocorticoids inhibit apoptosis of cardiomyocytes and reduce cardiac injury in mice. A key molecule mediating the protective effect is Glucocorticoid Induced Leucine Zipper (GILZ), a cytosolic protein not capable of binding to DNA. When overexpressed in cultured cardiomyocytes, GILZ inhibited death induced by inducing apoptosis. Mechanistic studies found that GILZ interacts with HIF-1α and stabilizes bcl-xL protein. Since a number of dietary supplements induce Nrf2 and GILZ is inducible by steroids, our findings provide a hope for reactivation of HIF-1α and M. A. Dobrovolskaia. "SAIC-Frederick, Frederick, MD."

Nanotechnology holds great promise for targeted drug delivery. Unique chemical and physical properties of nanomaterials may lead to improvements in delivery technology in several ways. Examples include increasing the solubility of poorly soluble drugs, increasing efficacy and safety by delivering drugs directly to diseased tissues, and potentially decreasing costs by achieving therapeutic efficacy despite administration of lower doses of drugs. Many publications have discussed the toxicology of environmental and occupational nanomaterials, but more information is needed regarding nanoparticles designed for parenteral administration. These nanoparticles may present unique issues due to recognition by the immune system and downstream effects on adaptive immunity. Interactions with the immune system may result in premature clearance before payload delivery, disseminated intravascular coagulation-like toxicities, inflammation, anaphylaxis, and decreased resistance to infection or tumors. Nanoparticles are a very broad and diverse class of biomaterials, and there are significant gaps in our knowledge of the mechanisms by which nanoparticles interact with the immune system. Recognition by immune cells is influenced by many factors, including direct interaction of nanoparticles with red blood cell proteins as well as proteins of the complement and coagulation systems. Therefore nanomaterials may need to be screened for hematocompatibility and complement activation prior to preclinical in vivo studies. Investigation of nanomaterial effects on the function of immune cells, such as phagocytes and lymphocytes, is also important, and development of in vitro assays that are predictive of in vivo observations is critical. Further work is needed to elucidate which chemical and physical properties of nanoparticles are responsible for specific interactions with immune system proteins or cells, and understanding these interactions may allow exploitation of nanoparticle properties to ensure both safety and efficacy of nanomedicines.

Chemical and pathogenic stresses induce accumulation of the Hypoxia-Inducible Factor (HIF)-1α in the cells. When translocating to the nucleus, HIF-1α dimers with HIF-1α and interacts with cofactors to assemble the HIF-1 transcriptional complex. HIF-1 regulates myocardial cell function under hypoxic conditions via a series of shifts in metabolic pathways, such as increasing the expression of cytochrome c oxidase subunit COX-2, causing a switch from COX-1 to COX-2 and therefore adaptation of mitochondrial complex IV to the hypoxia conditions. The induction by HIF-1 of pyruvate dehydrogenase kinase 1 shunts pyruvate away from the mitochondria. HIF-1 triggers mitochondrial selective autophagy by induction of BNIP3. HIF-1 also induces microRNA-210, which blocks assembly of Fe/S clusters that are required for oxidative phosphorylation. These adaptive changes induced by HIF-1 protect the heart from the environmental and endogenous insults. HIF-1 is a rate-limiting step in the activation of gene, since it regulates the binding of HIF-1 to the HRE and formation of HIF-1 transcriptional complex. Copper loss from the heart occurs under cardiac hypertrophy and ischemic conditions, leading to accumulation of HIF-1α without activation of HIF-1 activity. The detrimental versus beneficial effect of HIF-1α accumulation during copper deficiency in cardiac diseases will be discussed.
a first step to investigate the use of LPNPs as novel drug delivery devices, their integration into a combined human immune system has been explored. The complement system is the most important biochemical cascade in the blood for the recognition, opsonization and killing of foreign materials. This presentation covers general knowledge on complement system to the state of the art on complement activation by other nanomaterials. The last part of the talk is focused on presenting the first systematic study of the blood biocompatibility properties of lipid-polymer nanoparticles functionalized with methoxyl (OCH3), amine (NH2), and carboxyl (COOH) functional groups. Our results show that LPNPs –OCH3 generate negligible levels of complement activation, while LPNP-NH2 induced the highest complement activation among carboxyl and methoxyl groups. None of these nanoparticles activated the coagulation cascade. In general, lipid-polymer nanoparticles functionalized with these three functional groups present good biocompatibility profiles in comparison to Zymosan, a well known activator of the complement system. The main contribution of this work is the creation of an effective and practical method to modulate the levels of activation of the complement system via the interaction of different functional groups on nanoparticle's surface.

821 RECOGNITION OF NANOPARTICLES BY MACROPHAGES—FROM PRINCIPLES TO CONSEQUENCES AND TOXICITY.

A. A. Shvedova1, 2, 1PPRB, NIOSH, Morgantown, WV and 2West Virginia University, Morgantown, WV.

Engineered nanomaterials (EN) have unique physico-chemical properties that make them promising for many biomedical applications. However, with the burgeoning capabilities to manipulate structures at the nano-scale, employing this machinery for safe and efficient drug delivery is not fully explored. To this end recognition of EN by the immune system, our primary defense against foreign invasion is a critical point. Recognition versus non-recognition of EN by the immune system not only determines the distribution of nanomaterials in the body but may also dictate their toxic potential. Recent studies showed that autophagy may have emerged as the initial and primordial defense of eukaryotic cells against microbes. It is therefore not surprising that immune-competent cells may respond to EN in a similar manner as to viruses/bacteria. Consequently, there are complex relationships between the infection process and inflammatory responses to EN resulting in potent effects of nanoparticles on pulmonary clearance of bacteria. Elucidation of how EN impact the conserved mechanism of autophagy, recognition and/or phagocytosis promise to be an interesting and fruitful area for better understanding of interactions of EN with the cells of innate immune system, particularly macrophages. It becomes clear that the presence of specific recognition patterns primarily defined by the EN size and charges are essential for their recognition and uptake by macrophages. Further, the presence of specific signals on the surface of EN, such as adsorbed lipids or proteins, confers additional features to the effectiveness of the recognition of nanoparticles by professions phagocytes. Finally, oxidative stress - known to act as an underlying mechanism that drives the toxicities of EN in vitro as well as in vivo – may be triggered as a macrophage response to recognized nanoparticles. Overall, the mechanisms of recognition, cellular internalization of EN by immunocompetent cells, particularly macrophages, represent an important new field of molecular nanotoxicology.

822 DEVELOPMENT OF CYT-6091 (AURIMUNE®): A MODEL CANCER NANOMEDICINE.

The use of nano-sized drug delivery systems to target potent, but toxic anticancer therapeutics to solid tumors is best accomplished by avoiding the drug’s uptake by the immune system and by limiting its biodistribution. Binding recombinant human tumor necrosis factor alpha (TNF) to the surface of 27 nm PEGylated colloidal gold particles (CYT-6091) meets these objectives. Each component serves a specific function. The gold nanoparticles limit biodistribution, while PEGylation prevents immune detection. TNF serves to localize the nanoparticle to the tumor and causes vascular disruption of the tumor blood supply. Clinically, an IV injection of 0.6 mg/m2 (>1 mg TNF per dose), and does traffic to tumors, limiting the drug’s biodistribution, reducing systemic toxicity and potentially bringing more drug to the site of disease. Further, since an intact tumor vasculature is critical for nanomedicines’ targeting tumors, the treatment of solid tumors should begin with a nanomedicine prior to surgery, even for resectable tumors.

823 CASE STUDY: INTERACTION OF DEXTRAN NANOMATERIALS WITH THE IMMUNE SYSTEM—IN VIVO AND IN VITRO STUDIES.

While nanomaterials made of biocompatible polymers hold great promise as drug delivery platforms, biological consequences resulting from interaction of nanomaterials with the immune system have not been fully elucidated. Dextran is well established as a biocompatible polymer with extensive use as a plasma expander. Hydrophobic derivatives of dextran that were developed to enable manufacture of drug-polymer nanoparticles, elicited severe toxicities in rat in vivo studies. Results of these studies suggested that the dextran derivatives were being recognized by the immune system and were capable of activating macrophages and the complement cascade. In vitro assays were used to screen for immune system activation and after further modifications to the polymer, dextran derivatives were identified that showed improved safety profiles in subsequent in vivo studies. These screening assays have the potential to facilitate selection of materials to minimize unwanted interaction with the immune system and to aid in the rational design of nanoparticle drug delivery systems.

824 TOXIC CELL-DEATH: SIGNALING PATHWAYS, CROSS-TALK, AND HIGH-THROUGHPUT ANALYSIS.

S. Orrenius1 and W. Slikker, Jr.1, 1Karolinska Institutet, Stockholm, Sweden and 2US FDA/NCIT, Jefferson, AR.

Cell death is the ultimate result of toxicity caused by damage to critical cell functions and/or activation of death signaling pathways. Toxicants can trigger multiple modes of cell death (apoptosis, necrosis, necroptosis, and autophagic cell death) with distinct morphological and biochemical characteristics. In fact, several cell death modalities may coexist within the same lesion with cross-talk between them. To address this important topic, we will begin by discussing the role that cell death plays in toxic insult and disease, and how improved knowledge of cell death signaling pathways and mechanisms will help us understand how toxicants might interfere with cell viability and function. After the description of various cell death modalities, and the possible cross-talk between them, mechanisms of apoptotic cell death will be described. Apoptotic cell death is a highly regulated process, which is involved in removal of dead cells in various developmental processes, and is crucial for maintaining tissue homeostasis. Further, the mechanism of action of certain chemotherapeutic agents and fungal toxins will be discussed to illustrate the role of sphingolipid signaling molecules in cell death and disease. Finally, a molecular epidemiology approach using novel technologies to assess cell death and environmental impact in individual cells and in human populations in a high-throughput manner will be presented. The program will cover important toxic mechanisms in multiple target organs and will hopefully contribute to a better understanding of the role of cell death mechanisms in toxic insult and disease.

825 MODES AND PATHWAYS OF TOXICANT-INDUCED CELL DEATH.

B. Zhivotovsky. Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden.

Cell death is the ultimate result of toxicity. It is now apparent that during toxicity multiple cell death programs, i.e. apoptosis, necrosis, necroptosis and autophagy, can be activated. Some of them are shared by different tissues; others are tissue-specific and are linked to particular functions. Elucidating the signaling pathways regulating various modes of cell death, is highly relevant for our understanding of the
cellular targets and mechanisms of action of toxic agents. Such knowledge is also important in design of less toxic analogs. Further, using modern methodological approaches, (e.g., genomics and proteomics), knowledge of cell death mechanisms will help us understand how toxicants might interfere with cellular regulation of gene transcription and protein expression and function.

**PATHWAYS TO ANESTHETIC-INDUCED BRAIN CELL DEATH AND TO NEURONAL PROTECTION.**

**W. Slikker**, National Center for Toxicological Research/US FDA, Jefferson, AZ.

It is estimated that 2.3 million ambulatory anesthesia episodes of care were provided in the US to children younger than 15 years. Although comprehensive studies have yet to be reported in humans, data from five species including nonhuman primates indicate that prolonged anesthetic exposure of developing mammals at critical stages of development results in brain cell death and lasting cognitive deficits. One pathway to toxicity involves the N-methyl-D-aspartate (NMDA)-type (glutamate) receptor system. Blockade of the receptor by ketamine results in selective cell death via a pathway that involves a compensatory up-regulation of subunits of NMDA receptor. Specific subunits that are up-regulated as indicated by gene-expression studies and validated by Q-PCR include the NR1 and the NR2C. Initiation of a cell death cascade begins with Ca2+ influx and is postulated to produce an increase in reactive oxygen species. Several recent studies have indicated that reduction of oxidative stress may protect the developing animal from anesthetic-induced brain cell death. Evidence for the role of oxidative stress in anesthetic-induced neurotoxicity has been generated in studies that apply oxidative stress blockers, including L-carnitine (mitochondrial protector) and melatonin, in vitro, and specific antioxidants, in vitro, including the superoxide dismutase mimetic, M40403 and the NOS inhibitor, 7-nitroindazole. Recent gene expression assessments indicate that genes in the oxidative stress pathway are altered by anesthetic treatment of developing animals. Together, the application ofomics approaches along with traditional toxicological endpoints indicates that oxidative stress plays a critical role in the susceptibility of the developing brain to anesthetics. Prevention of neuronal death in studies with oxidative stress blockers have indicated that reduction of oxidative stress may provide protection from anesthetic-induced neuronal cell death during development.

**DIFFERENTIAL PATHWAYS OF CELL DEATH BY LEAD AND NEUROPROTECTION BY BCL-XL IN PHOTORECEPTOR SYNAPTIC AND NONSYNAPTIC MITOCHONDRIA.**

**D. A. Fox**, College of Optometry, University of Houston, Houston, TX.

Mitochondria are critically involved in the regulation of energy metabolism and apoptotic cell death in tissues, including the retina. Rod and cone photoreceptors have two mitochondrial compartments: inner segments (IS) that are a primary target for chemical-induced retinal degeneration, and synaptic terminals (ST). This talk will highlight the similarities and differences in these targets following postnatal lead exposure in wild-type and transgenic mice overexpressing Bcl-xL in photoreceptors. Lead produced rod-specific apoptotic activation by activating the cytochrome c-caspase cascade in rod ISs, which was blocked by Bcl-xL. In contrast, lead produced mitochondrial swelling and altered ultrastructure in both rod and cone STs that was not blocked by Bcl-xL. The results reveal the importance of compartmental analysis and differences between IS and ST mitochondria in rods and cones, and their differential sensitivity to apoptotic stimuli. They indicate that persistent structural- and visual functional- alterations of cone and rod ST remain even after rod apoptosis is blocked.

**CERAMIDE, SPHINGOID BASES, AND SPHINGOID BASE METABOLITES AS LIPID MEDIATORS IN SIGNALING PATHWAYS LEADING TO CELL DEATH AND DISEASE.**

**R. T. Riley**, Toxicology and Mycotoxin Research Unit, USDA-ARS-SAA, Athens, GA.

Increased ceramide generation de novo is a known to be involved in the mechanism of action of many chemotherapeutic agents and conditions which disrupt cell cycle progression and induce cell death. Conversely, the metabolism of ceramide to sphingoid bases and sphingoid base 1-phosphates has been implicated in cell survival and inhibition of cell death. Complicating this picture is the fact that fungal toxins that inhibit ceramide biosynthesis and induce elevated levels of sphingoid base 1-phosphates also induce increased cell death and cancer in animal models. In addition, elevated levels of sphingoid base 1-phosphates may disrupt signalling via disruption of sphingosine 1-phosphate (S1PR1-10) signaling. This presentation will provide an overview of sphingolipids as mediators of regulatory processes involved in cell growth, differentiation, cell migration, vascular regulation and cell death.

**MEASURING CELL DEATH AND GENOTOXICITY IN SINGLE CELLS AND HUMAN POPULATIONS USING LAB-ON-A-CHIP TECHNOLOGIES.**

**M. T. Smyth**, School of Public Health, University of California Berkeley, Berkeley, CA.

The Center for Exposure Biology at UC Berkeley has developed high-throughput single cell analyses using Lab-on-a-Chip (LOC) technologies. These methodologies, which include transcript translocations and point mutations linked to lymphoma. Recent work has led to the development and application of a novel microfluidic device that enables quantification of RNA transcripts and protein levels in parallel, expanding our analytical capability beyond DNA mutations. This device enables on-chip culture and analysis of gene expression, surface proteins and cell death in single cells. Use of novel geometry on the device has facilitated fluorescence detection of immunoassay results followed by real-time RT-PCR assay of mRNA for each individual cell. This scalable device performs multiple assays in parallel to achieve the necessary throughput for studies of the effects of environmental exposure on cell death and other parameters in single cells.

**CONCEPTS CRITICAL TO THE NEXT GENERATION OF HUMAN HEALTH AND ECOLOGICAL RISK ASSESSMENT.**

**R. Gentry** and **B. Lovsey**, ENVIRON International Corporation, Monroe, LA and ARCADIS, Novi, MI.

Through the collaborative effort between the SOT Risk Assessment Specialty Section and the SETAC Human Health Risk Assessment Advisory Group, this session was developed to highlight the challenges currently facing the next generation of risk assessors. With the release of the recent National Academy of Sciences reports on toxicity testing that present a vision for movement from in vivo testing to in vitro and in silico testing, as well as the most recent changes in risk assessment guidelines by regulatory agencies, risk assessor are faced with the challenge of integrating innovative data (e.g., genomics) into the current risk assessment paradigms or with the development of new paradigms or methods to address changing issues in risk assessment. In considering all the biological changes and scientific information, many of these new methods attempt to integrate all of the available scientific information of a kind of risk model that is able to inform both human health and ecological risk assessment/risk management decisions. Our panel of experts will provide information on new programs and approaches within regulatory agencies, as well as in the private sector, that will be important in the next generation of risk assessment.

**MORE EFFICIENT AND EFFECTIVE TESTING AND ASSESSMENT PARADIGM FOR CHEMICAL RISK MANAGEMENT.**

**S. Bradbury**, US EPA, Washington, DC.

A major challenge confronting chemical risk management is to address the potential ecological and human health risks for large numbers of chemicals with greater speed and accuracy using fewer resources. From a strategic and tactical viewpoint, an integrated approach that relies on existing knowledge (including mechanistic information of both chemistry and biology from novel computational toxicology) is needed to advance progressive and focused assessment strategies, as well as to advance the utility of risk assessment by providing more relevant information. The use of “Integrative Approaches to Testing and Assessment” is a means to efficiently use existing exposure and toxicity information combined with (Q)SAR predictions and in vitro data in a systematic and coordinated manner for a chemical or a group of similar compounds. Fundamental to using an integrative strategy is an understanding of adverse outcome pathways which provides a biological construct of key events at the different levels of biological organization causally linked to an in vivo endpoint of regulatory interest. By using a battery of models and in vitro assays, the potential of chemicals to initiate molecular interactions can be efficiently evaluated. At each level of biological organization, the potential of chemicals to elicit toxicological effects can be reined as necessary, in the context of likely exposure. This tiered approach leads to a reduction in the amount of testing at each higher level of biological organization. Thus, instead of every chemical being tested for every pos-
credible endpoint in a battery of in vivo studies, only those studies that are rational for the chemicals’ toxicological potential are required. This presentation will describe ongoing efforts to improve and transform approaches for human health and ecological assessment within the Office of Chemical Safety and Pollution Prevention.

**W 832 MABEL: USE OF PRECLINICAL DATA TO SET ACCEPTABLE STANDARDS FOR EXPOSURE.**

Pharmaceutical and personal care product (PPCP) ingredients and other emerging compounds are increasingly detected in water potentially intended for human consumption, and water industry and risk assessment professionals are faced with the need to efficiently establish Acceptable Daily Intakes (ADIs). The growing availability of modern molecular data from chemical exposure studies for agents’ mechanisms of action presents a unique opportunity to explore their use in developing screening levels for these compounds. We investigate the use of the Minimum Anticipated Biological Effect Level (MABEL)—the lowest dose with any measurable effect on biological systems—as a point of departure for deriving ADIs for emerging compounds, particularly PPCPs, in drinking water. Drug industry experience has demonstrated that, for certain types of drugs, “safe” doses identified using traditional methods (e.g., using no observed adverse effect levels, based on toxicological endpoints) may have greater uncertainty than desired; the MABEL is currently being applied in the EU to reduce uncertainties in establishing safe exposure levels for drugs undergoing clinical testing. We characterize data requirements for applying the MABEL methodology to deriving screening levels for PPCPs in drinking water, and evaluate case studies to compare values to those derived using traditional methods (e.g., extrapolating from toxicological endpoints). Based on these findings, we discuss advantages and potential challenges, and propose directions for future research. Results suggest that the MABEL approach offers a transparent means to establish ADIs based on scientific evidence rather than extrapolation modeling, thereby decreasing the uncertainty about the protectiveness of screening levels, and offers a potential means to deriving screening levels for mixtures of compounds with the same or similar modes of action.

**W 835 MIXTURES RISK MANAGEMENT: MOVING BEYOND TEQS AND HAZARD INDICES.**

P.S. Price. Dow Chemical Company, Midland, MI.

The human health and ecological risks posed by cumulative exposures to chemicals, including exposure to mixtures, have traditionally been investigated using additive models. These models include screening models such as the Hazard Indices, systems of TEQs that are based on a common mechanism of action, and Toxicity Units that are based on empirical measurements of acute toxicity endpoints. More recently the IPCS/WHO have proposed a tiered framework of modeling approaches for the evaluation of mixtures. This framework proposes the use of both screening assessments and higher tiered approaches that consider detailed mechanisms of joint action and or use of probabilistic models of toxicity and exposure. The European chemical industry (Cefic) has developed a Decision Tree approach that extends the IPCS/WHO framework to include a determination of the value in performing a cumulative assessment. These new tools provide increased flexibility in the evaluation of risks from mixtures. They allow the use of screening evaluations that can be performed with minimal data and describe how additional data can be used to refine the screening assessments. Finally, the new tools allow the identification of specific groups of chemicals and specific populations where cumulative risk assessments are most needed.

**W 836 USING TRANSCRIPTOMIC DATA IN THE RISK ASSESSMENT PARADIGM.**

R. S. Thomas. The Hamner Institutes for Health Sciences, Research Triangle Park, NC.

Current challenges facing chemical risk assessment are the time and resources required to meet the data standards necessary for a published assessment and the incorporation of modern molecular biological information. The integration of transcriptomic data into the risk assessment paradigm may address both challenges by providing an efficient means to quantitatively and comprehensively evaluating the molecular changes resulting from chemical exposure. To assess the value of applying transcriptomics in risk assessment, a series of rodent studies were performed across five chemicals that were positive for lung or liver tumors in a standard cancer bioassay. The target tissues were analyzed for traditional histological and organ weight changes and transcriptional changes using microarrays. The dose-response changes in gene expression were analyzed using standard benchmark dose methods that have been commonly employed in risk assessment. The individual genes were then grouped based on known canonical signaling pathways and the pathway-based responses were used as points-of-departure. A comparison of the transcriptional benchmark dose values with those for the traditional noncancer and cancer apical endpoints showed a high degree of correlation for specific signaling pathways. Many of the correlated pathways have been implicated in noncancer and cancer disease pathways. The results demonstrate that transcriptomic changes in signaling pathways can be used to estimate noncancer and cancer points-of-departure for use in quantitative risk assessments.

**W 837 ADVERSE OUTCOME PATHWAYS AS A UNIFYING CONCEPT IN ENVIRONMENTAL TOXICOLOGY.**

K. Crofton. US EPA, Research Triangle Park, NC.

An adverse outcome pathway (AOP) is a subset of a source to outcome pathway that delineates documented and testable linkages between a molecular initiating event and an adverse outcome at the individual or population levels. AOPs, by definition, span multiple levels of biological organization. The amount of detail and linearity characterizing the AOP between a molecular initiating event and an adverse outcome within an AOP can vary substantially, both as a function of existing knowledge and risk assessment needs. Development of AOPs can provide insight into the uncertainties in linking chemical use, exposure and outcome, thereby focusing research on critical data needs. Well defined AOPs provide utilitarian framework to build quantitative and qualitative models useful in: understanding the degree of perturbation associated with adverse outcomes, target for the development and use of efficient chemical testing methods, and extrapolation between species and lifestages. The development and use of AOPs can provide a framework in which high-throughput and high-content information informs more efficient and predictive risk decisions.

**W 838 BRIDGING THE GREEN CHEMISTRY GAP BETWEEN PRODUCT DISCOVERY AND AVAILABILITY.**

A. A. Li and L. Zeise. 1 Exponent Health Sciences, San Francisco, CA and 2 Cal/EPA OEHHQ, Oakland, CA.

Recent government and industry initiatives seek to identify chemicals of toxicological concern in products to reduce their use or replace them with safer chemicals. At the same time, sustainable approaches to product manufacture and use that account for energy consumption, product life cycle, and societal benefit are being emphasized. This creates the challenge of developing sound scientific approaches for identifying important chemical hazards and evaluating alternative, safer chemicals or products, all done within the context of risk and benefit trade-offs. Two laws recently passed in California (Chapters 559 and 560, Statutes of 2008) direct the state’s implementation of such green chemistry strategies. The US government, several states and cities, and industry are similarly exploring approaches for alternative analyses that can include hazard, risk, environmental, life cycle, and carbon impact assessments. A primary goal is a rapid and streamlined review and assessment to ensure the availability of safer and more effective products for the consumer and general public, at reduced costs and with minimal environmental impacts. Our panel of regulators and scientists from different sectors will explore approaches that can be used to implement green chemistry goals. It begins with a government perspective on challenges of development and implementation of legislation that will be effective, enforceable, and practical. This session features toxicity methods and case studies for hazard and risk-informed screening strategies utilizing high-throughput data, structure activity, and other toxicity information. It also considers how toxicity assessments can be utilized together with evaluations that account for carbon footprint and other impacts of product manufacture, use, and disposal for green chemistry decision making. At the conclusion of this session, two experts will lead a panel discussion and provide their expertise in exposure and risk assessment, regulatory policy decision-making, and occupational clinical medicine.
provide a framework for alternatives analysis to address chemicals of concerns in consumer products. The goal for implementation has been to have approaches in place to guide practical decision-making near term and that address the objectives of the legislation, while maintaining the flexibility to make adjustments as the science and best practices evolve. Exposure to chemicals of concern occurs either through direct product use or environmental pathways. Identification of these chemicals is in part hazard-based, driven for example by classifications by authoritative institutions. The data for “safer” substitutes can be considerably less than for chemicals of concern posing challenges for comparative analyses. Another challenge is weighing sustainability aspects such as life cycle impacts and assessing the carbon footprint associated with product manufacture, use, recycle and disposal. The presentation will share insights gained as Germany has begun to consider alternatives assessment approaches and other aspects of implementing the green chemistry legis-

RI 838 CALIFORNIA’S HAZARD TRAIT FRAMEWORK AND OTHER TOXICOLOGICAL CONSIDERATIONS FOR GREEN CHEMISTRY DECISION-MAKING.

In recent California legislation, green chemistry decision making is initiated by the identification of chemicals of concern. A key consideration for identification is a chemicals’ “hazard traits,” chemical properties that may contribute to adverse effects in exposed humans or the environment. The legislation calls for specifying hazard traits, toxicological and environmental endpoints, and any other relevant data to be included in a Toxics Information Clearinghouse to aid green chemistry evaluations. This talk describes the approach developed to implement this piece of California green chemistry statutes. As a way of organizing hazard information and evaluating evidence, California has developed a hazard trait framework, comprised of four major categories of hazards – toxicological, environmental, exposure potential and physical. Within each of these, a number of hazard traits are identified. There are 19 toxicological hazard traits, those of the major disease “aticies” (e.g., carcinogenicity, cardiovascular toxicity) and traits that can be linked mechanistically with underlying causes (e.g., genotoxicity, reactivity in biological systems). Beneath each toxicological trait are endpoints that are manifestations of that trait, and other relevant data that provide less direct evidence. The framework provides a construct for considering whether evidence is sufficient or suggestive of a particular toxicological hazard trait. Besides hazard information, other types of data can be important in evaluating possible chemicals of concern and alternatives. This includes measures of cancer and non-cancer activities (e.g., cancer and non-cancer benchmark doses, potencies). A challenge for use of the framework in green chemistry evaluations is that the data for possible “safer” substitutes can be considerably less than for chemicals of concern. In vitro and other non-apical data may provide evidence of hazard, and have been used by the industry to develop “greener” products.

RI 839 ALTERNATIVE ASSESSMENT STRATEGIES FOR PRODUCT DEVELOPMENT FOR CHEMICALS REGULATED IN EUROPE: 3 CASE STUDIES.

Toxicological screening strategies are applied to detect potential health hazards or risks early in product development and direct it towards products posing lower risk or hazard to workers, consumers and the environment. The very screening strategy must be tailored to fit the regulatory and scientific basis as well as the intended use of the respective material under investigation as illustrated by three case studies: (i) For pesticides European regulations define cut-offs based on hazards and screening trials to identify critical hazards. A combination of in vitro receptor-binding assays and in vivo metabolomic analysis was successful in identifying potential endocrine disruptors among new candidate compounds. (ii) Cosmetics testing in vitro is limited and shall be banned completely by 2013 in the EU. Complex endpoints - unlike local tolerance - cannot be tested in vitro with adequate accuracy today. Testing strategies based on the in vitro assessment of the uptake of cosmetic ingredients, the exclusion of genotoxic effects and the application of the Threshold of Toxicological Concern concept were, however, able to select cosmetic applications with no or sufficiently low risk. Specifically, sunscreen pigments were brought to market after excluding genotoxicity by in vitro and in vivo studies and demonstrating that they do not penetrate healthy or UV-damaged skin. (iii) For nanomaterials, there is not yet specific regulation under REACH. Classical toxicological methods are generally unable to detect toxic effects of nanomaterials but need some adaptation, especially in test substance preparation and application. Yet, there is also the opportunity to test nanomaterials effectively and efficiently taking their specific material properties into account. Within these testing strategies short-term inhalation studies specifically designed for nanomaterials were a useful tool to select materials with low toxic potency, and to discontinue projects for intended application presenting unclear or unacceptable toxic properties.

RI 840 OPTIMIZING POTENTIAL GREEN REPLACEMENT CHEMICALS—BALANCING FUNCTION AND RISK.

R. Judson, US EPA, Research Triangle Park, NC.

An important focus of green chemistry is the design of new chemicals that are inherently less toxic than the ones they might replace, but still retain required functional properties. A variety of methods exist to measure or model both functional and toxicity surrogates that could be used in a global green optimization scheme. I present an approach that uses multiple methods including in vitro screening assays, in vitro-based toxicokinetics modeling, QSAR and docking modeling to help rank-order potential replacement chemicals. This ranking needs to account for both differences in inherent toxicity but also differences in properties related to intended use. This approach will be illustrated using data and modeled parameters for a collection of pyrethroid insecticides. These cover a diverse range of chemical structures and differential toxicity (e.g. chemicals in the class hit different ion channel targets and show different rates of detoxifying liver metabolism) and differential pesticidal activity (mainly via different ion channel activities) so provide a good example for testing out “green” optimization approaches. This abstract does not necessarily reflect US EPA policy.

RI 841 WEIGHING MULTIPLE VARIABLES IN IMPROVING THE GREEN PROFILE OF CONSUMER PRODUCTS.

G. Daston, Miami Valley Labs, Procter & Gamble, Cincinnati, OH.

There are a large number of factors that must be considered in developing greener ingredients and products. These include not only human and environmental safety and environmental fate, but also energy usage during manufacture and product use, disposal considerations, and sustainability of feedstocks, to name a few. Because of the complexity of evaluating such a large number of variables it is important to utilize integrated methods of assessment, such as green chemistry decision making. As a way of weighing the positive or negative impact of changing each variable, current and next generation risk assessment practices can be used to determine human and environmental risk. Life cycle assessment tools are applied to estimate the relative gains/losses each alternative ingredient makes in the manufacture, use and disposal of a product.

RI 842 CROSS-SPECIES EXTRAPOLATION USING PROTEIN SEQUENCE HOMOLOGY TO PREDICT SUSCEPTIBILITY OF NONTARGET ORGANISMS TO CHEMICALS WITH KNOWN MODES OF ACTION.

Cross-species extrapolation has been a prominent challenge in predictive toxicology, both for human health and ecological risk assessment. A common thread that can collectively link species to one another are their genomic and their proteomic similarities or differences. Pharmaceuticals and pesticides are manufactured to act on specific molecular targets to elicit their intended effect. Therefore, through the evaluation of molecular target sequence homology, and the identification of conserved domains within those sequences, it is theoretically feasible to anticipate or predict which non-target organisms may or may not be susceptible to adverse effects from chemicals that act on a given protein target. This presentation will describe an automated algorithm to assess protein sequence homology between species as a means to predict sensitivity to chemicals with known modes of action. Our methodology utilizes data and tools from the National Center for Biotechnology Information database to provide a robust analysis of greater than 240,000 non-target species, with partial or full sequence information, and conduct an in-depth characterization of the sequor each, as well as to have a transparent way of weighing the positive or negative impact of changing each variable. Current and next generation risk assessment practices can be used to determine human and environmental risk. Life cycle assessment tools are applied to estimate the relative gains/losses each alternative ingredient makes in the manufacture, use and disposal of a product.
Work from our laboratory has shown that female killifish (Fundulus heteroclitus) from the chemically impacted Newark Bay, NJ, exhibit signs of reproductive dys-
function, relative to a reference population (Tuckerton, NJ). Our current hypothe-
sis was that the Newark Bay population exhibits a decreased sensitivity of the he-
patic vitellogenin (VTG) pathway to 17β-estradiol (E2), which has resulted in
decreased vitellogenin expression and ultimately, decreased egg production. At the
peak of spawning, Newark Bay females expressed vitellogenin (mRNA and protein)
at lower levels than the Tuckerton reference population. A fecundity study con-
ducted also demonstrated that Newark Bay females produced fewer mature eggs
(11 embryos/female), relative to Tuckerton (140 embryos/female) during spawn-
ing. Average embryo weight and yolk volume in eggs collected from the Newark
Bay population were also found to be decreased by 15% and 25%, respectively, in-
dicating impaired yolk formation. Graded doses of E2 were injected into both
males and females collected from each site and Newark Bay killifish were demon-
strated to have right-shifted dose-response curves for both vitellogenin mRNA and
protein induction by E2. For example, Newark Bay females had significantly lower
levels of VTG protein induction at concentrations of 0.01, 0.1, 1.0 and 100 ng
E2/g (11, 21, 39 and 75% of Tuckerton response, respectively). In addition, cir-
culating 17β-estradiol levels in Newark Bay females (0.26 ng/mL) were measured
to be 8-fold lower than Tuckerton females (2.25 ng/mL). Taken together, we con-
clude that the reduced fecundity in the Newark Bay population is the result of (1)
a refractive VTG pathway (decreased sensitivity) to physiologically relevant of E2,
and (2) a 17β-estradiol deficiency. These studies are the first to report a refractive
VTG pathway, which provides insight into how altered gene-regulation of repro-
ductive genes can manifest population level effects.

**PL 845 CHRONIC TOXIC EFFECTS OF DIETARY TCCD IN ZEBRAFISH.**

O. Liu1,2, M. L. Rise3, M. L. Riehle1, G. Götze1, L. M. Snipesberg1, R. Caruso1,4, L. R. Hutz1, P. J. Tonellato1,8,9 and M. L. Carvajal1. **Biological Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI; School of Freshwater Sciences, University of Wisconsin-Milwaukee, Milwaukee, WI; Ocean Sciences Centre, Memorial University of Newfoundland, St. John’s, NF, Canada; **Microbiology, Oregon State University, Corvallis, OR; **ONRIS, USC 2013 LERACR, Nanés, France; **Université Nanterre-Paris 13, Nanterre, France; **Silver School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI; **Pathology, Beth Israel Deaconess Medical Center, Boston, MA and **Center for Biomedical Informatics, Harvard Medical School, Boston, MA.

The goal of this project was to investigate the effects of chronic dietary TCCD ex-
posure on global gene expression anchored to histopathologic analysis in zebrafish
by functional genomic, pathologic and analytic chemistry methods. Specifically,
three-month old zebrafish were fed Biodiet starter with TCCD added at 0, 0.1, 1.0
and 10.0% for six weeks, and fish were sampled from each group at 1, 2, 4, and
6 weeks after initiating exposure. Although no significant mortality was found in
TCCD-treated groups, TCCD accumulated in a dose- and time-dependent man-
ner, and the sex ratio between male and female was dramatically changed in 100
ppb TCCD-treated fish. TCCD caused multiple pathologic outcomes in liver, kid-
ney, nose, intestine and ovary of zebrafish, such as depletion of glycogen in liver,
retrobulbar edema, degeneration of neurosensory epithelium, underdevelopment of
intestine, a diminution in the fraction of ovarian follicles containing vitellogenic
ova, etc. Toxicogenomic data analysis showed a number of genes were dysregu-
lated in both TCCD-treated male and female zebrafish that function in lipid me-
tabolism, cholesterol and steroidogenesis, cell death, nervous system development,
 xenobiotic metabolism signaling, endocrine system development. The linkage be-
 tween gene expression profile and pathologies reveal the molecular mechanisms of
sublethal dietary TCCD exposures in zebrafish, and the dysregulated genes can be
potential biomarkers for TCCD exposure in aquatic environments. The results of
the study can be used to assess the potential impacts of environmental TCCD in
the food chain and on health of humans and animals.
Mean plasma sodium levels of surviving fish were the same for control and treatment groups, indicating that osmoregulatory processes were not affected by endotoxin exposure. Results suggest that the threshold for effects of endotoxin (dipotassium salt) exposure on smolts during seawater transition is likely >8 ppm but <12 ppm—far less than the established LC50 of 230-450 ppm for salmonids in freshwater. This finding emphasizes the importance of conducting seawater challenge experiments with species that migrate between freshwater and marine environments before defining chemical toxicity levels.

O. T. Olubambi. Zoology, University of Johannesburg, Johannesburg, South Africa.

The Blesbokspuit wetland system is a former Ramsar site with serious deteriorating conditions. It continues to receive large volumes of effluent water discharge. 1H Nuclear Magnetic Resonance Spectroscopy (1H NMR) is being applied for the first time here to compare toxicant responses in multibiomarkers. The use of Metabolomics is also being linked to and compared with other previous biomarker studies e.g Metallothioneins (MT) and Cytochrome P-450 (CYP). Field surveys were conducted during both the low and high flow seasons of 2008 at 5 sites. Muscle tissues of Resident catfish, Clarias gariepinus and tilapia, Tilapia sparmanni species captured were used for analyses. A transplantation study was conducted in cages at 3 out of the 5 sites during the 2009 high flow with juveniles of laboratory reared tilapia, Oreochromis mossambicus and Chironomids larvae. Whole samples were used. Solvent extraction of metabolites was carried out using methanol, chloroform and water. 1H NMR spectra of each sample was measured at 300MHz on a Varian Unity Inova NMR. The acquired spectra were processed and referenced internally to lactate at 1.3ppm. Metabolites profiling and identification was done using the Chemoxa NMR Suite version 4.6. Principle component analysis of the 1H NMR spectra showed significant differences between the kinetics and Chironomids with more responses found in Chironomids. Also differences in fishes between species and seasons were noted (p<0.05). Responses were higher during the high flow season in both cases. These patterns were also observed during previous biomarker studies. Metabolomics has been used to successfully compare and confirm toxicant response in multibiomarkers. This strategy can be applied within the recommended integrated management framework for this area as well as other catchments.

Polybrominated diphenyl ethers (PBDEs), a class of flame retardants shown to exert neurotoxicity and developmental toxicity, have become an increasing concern over the past two decades as levels in the environment and biota have increased worldwide. Many congeners of PBDEs are classified as bioaccumulative toxins with the ability to biomagnify through the food web. However, little is known about how PBDEs accumulate and are metabolized in lower vertebrates. We exposed northern leopard frog (Rana pipiens) tadpoles to a pentabromodiphenyl ether mixture through their diet (0, 7.1 A, 634 DE-71 ng/g wet mass) for 50 days. At this time, tadpoles in all treatments were fed control food (0 DE-71 ng/g). Elimination of PBDEs was determined during the depuration period by collecting tadpoles on days 8, 14, and 28 days for assessment of body residue tissue. Throughout the 28 day depuration period, tadpoles eliminated over 94% of the ΣPBDEs from their tissues at a rate (tg = 11 days) that cannot be explained simply by growth dilution. To further elucidate the toxicokinetics of PBDEs in frogs, we collected individuals following larval exposure at the beginning and end of metamorphosis, and after ten weeks of growth with no PBDE exposure. During metamorphosis, total body residues per individual did not change, implying little to no elimination. Throughout the ten week depuration period, frogs eliminated 89.7% of the ΣPBDEs from their tissues at a constant rate (tg = 10 days). Ultimately growth dilution. The slope of PBDE elimination in both tadpoles and juvenile frogs was independent of starting concentration and so elimination can be described by first order kinetics. Toxicokinetics of PBDEs in R. pipiens is dependent on developmental life stage as evidenced by the lack of PBDE metabolism during metamorphosis and the difference in half lives of PBDE between tadpoles and frogs. Due to this, developmental life stage, especially for species that undergo metamorphosis, should be considered when determining toxicity of persistent organic pollutants.

Pesticides accumulate within honey bee hives and concentrate in beecwax, causing bees to experience long term exposures to multiple agricultural chemicals. Standardized toxicity testing methods are often limited to short exposures to foragers, with mortality as an endpoint, neglecting esucial behavior within the hive. The circadian clock coordinates 24 hour rhythms in social behaviors, detoxification, and immune function. Each caste and development stage of bees exhibits unique daily behavioral profiles, and may be uniquely vulnerable to sublethal effects of a given pesticide, potentially impacting the entire superorganism. In particular, the development of circadian rhythms accompanies behavioral maturation of nurse bees to foragers. Neurotoxins such as pesticides may disrupt circadian rhythms, and are likely to desynchronize essential physiological and social systems which are particularly important in coordinating a eusocial behavior. Using a video based Noldus Ethovision behavioral tracking system, we are examining the behavioral responses of queens, drones, and adult bees after chronic exposures to various pesticides singly and in the context of a relevant pesticide mixture. We have developed a method for exposing bees to a range of doses of individual chemicals in wax, in order to calculate behavioral EC50s. Additionally, we are assessing changes in gene expression and enzymatic activity associated with behavioral development, detoxification, and immune responses following chronic exposures. The resulting toxicity values can be used to assess relative risk of each compound to each bee caste, and be used to mitigate the hazards of pesticides to pollinators.

Bisphenol A (BPA) is now a controversial monomer used in the manufacture of polycarbonate plastics and found in trace quantities in some consumer products and food containers. Unconjugated BPA is a ligand of the estrogen receptor (s). Exposure to BPA has been widely estimated by multiplying the concentration from single urine spot samples by the estimated daily urine volume or creatinine elimination. This approach may be appropriate for chemicals that reach steady state, or when samples sizes are very large, but for BPA, the episodic nature of dietary exposure and rapid absorption and elimination kinetics are not accounted for by the spot sampling approach. In this project, we calibrated a human physiologically based pharmacokinetic model (PBPK) to new BPA blood and urine pharmacokinetic data following dietary exposure obtained in a clinical setting. The resulting model was exercised to estimate the oral exposure associated with single samples from a previously conducted human oral exposure study. The PBPK-based reverse dosimetry approach can be used to calculate oral exposure to BPA with an accuracy of greater than 95%. The approach was then applied to urine biomonitoring data from several large representative studies to estimate distribution of human exposure to BPA, which were consistent with those estimated from 24 hour urine collection studies. Upper bound concentrations of the bioactive form of BPA in blood were orders of magnitude below levels required for activation of estrogen receptors. Combined with adequate data on meal times and urine sampling times, this new approach for estimating human exposure to BPA offers a significant advancement over conventional approaches.

Y. Yang1, H. Clewell1, M. Anderson1, T. McMullin1 and K. Plotzke1. 1The Hammer Institute for Health Sciences, Research Triangle Park, NC, and 2Dow Corning Corporation, Midland, MI.

The objective of this project was to utilize a harmonized physiologically-based pharmacokinetic (PBPK) model for two siloxanes (D4 and D5) to translate expected consumer exposures to internal doses, such as those measured in biomonitoring studies. The 50th and 90th percentile of the daily exposure amounts of siloxanes in personal-care products (hair gel, face lotion, etc) for males and females aged 20-59 years were obtained from an existing probabilistic exposure assessment. These data were the inputs into the human PBPK model of D4 and D5 to simulate...
predicted steady-state blood concentrations of these compounds following dermal, inhalation and aggregate (dermal + inhalation) exposure profiles. Modeling of these exposure data gives us an insight of contributions of the route-specific exposure to the internal dose. The results indicate that about 10% and 2% of the inhaled D4 and D5 dose (respectively) are available for systemic circulation in the inhalation-only scenario. The extensive evaporation of D4 and D5 from the skin surface following dermal application results in less than 1% of the dermally applied dose available for systemic circulation. Our results indicate that although dermal exposure to siloxanes is approximately 50-1000-fold higher than inhalation exposure, the steady-state blood concentrations of D4 or D5 due to dermal exposure is only 2-10 fold higher than that due to inhalation exposure, because dermally applied D4 and D5 evaporate from the skin much more rapidly than they are absorbed. As such, this source-to-biomarker simulation that uses PBPK modeling to characterize route-specific exposures for cyclic siloxanes are critical in interpreting biomonitoring data from consumer populations. This project is supported by Silicones Environmental, Health and Safety Council of North America.

**853 PROBABILISTIC RISK ASSESSMENT OF HUMAN EXPOSURE TO IRON AND STEEL SLAG.**

A probabilistic risk assessment (PRA) was conducted to evaluate the potential for adverse human health effects associated with environmental exposures to iron and steel slags. These materials have a wide range of applications, but are used primarily as construction aggregates. The concentration of 26 metals was characterized in 41 samples of three types of slag, for three size fractions each: 1) processed slag (PS, 0-1 inch), which is the primary commercial product, 2) PS samples screened to <300 μm, and 3) PS samples screened to <75 μm. The bioaccessible fraction for ingestion exposure (Bₐₐ) was also measured for the <300 μm fraction. Chemicals of interest (COIs) were identified through a two-tiered screening process, considering four exposure scenarios: 1) slag on a residential driveway, 2) residence near a slag-covered road, 3) construction worker building road base with slag, and 4) industrial/maintenance worker. Incidental ingestion and inhalation were quantitatively evaluated. Following the screening steps, COIs were limited to CrVI, Mn, and V for residential scenarios only. COIs were found to be concentrated in larger particles, and not readily soluble in gastric conditions. Distributions were developed for soil ingestion rate; inhalation rate; exposure time, frequency and duration; Bₐₐ; BW and PEF. The PRA-calculated risk-based concentrations (RBCs) for each COI and scenario were calculated from distributions of risk/hazard generated using unit concentration endpoints. Only the 95% UCL concentrations of Mn in the largest PS-sized samples exceeded the 90th percentile of the RBC distributions. However, the 95% UCL concentrations of the more biologically relevant size fraction (<300 μm), which is more representative of the fraction that could be incidentally ingested, and the smallest size fraction (<75 μm), which is most representative of the fraction that could be inhaled, were below the Mn RBCs.

**854 A TIERED APPROACH FOR AGGREGATE EXPOSURE ASSESSMENT.**

D. A. Saripinni, 1, 2, S. P. Karakitsios, 1, A. Gotti, 2, T. Röhrs, 1, C. Cornelis, 2, M. van Tongeren, 3, S. Spanik, 2 and K. De Brouwere, 3. 1Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece, 2Chemical Process Engineering Research Institute, Centre for Research and Technology Hellas, Thermi, Greece, 3Institute for Occupational Medicine, Riccarton, United Kingdom and 4VITO, Mol, Belgium.

The study describes the tiered aggregate exposure assessment methodology followed in the CEFIC-LRI TAGS project, regarding realistic estimation of exposure to substances from multiple sources and routes. The overall TAGS method focuses on the development of guidance and criteria on how an aggregate assessment is to be triggered, the identification of data types/data gaps and quality required, the identification of exposure determinants and modifiers, development of strategies so that the models used are verified and the completion of a range of case studies. As a starting point we performed an extensive review of existing data, models and methodologies, aiming to compile a new overall methodology, adding the necessary elements for an as much as possible realistic exposure assessment. The structured methodology is built upon a computational platform that links existing (e.g. EUSES, SHEDS) and additional in house developed aggregate exposure models, to databases (e.g. Exposac, EXPOLIS), aiming to exposure assessment refinement and data assimilation. Elevation from lower tiers to the higher ones is based on the Risk Characterization Ratio (RCR) derived in each tier; if RCR is higher than one, a refinement of the assessment is required, imposing the use of more refined data (e.g. contamination level distributions instead of worst case estimates), models (e.g. use of more detailed environmental fate models), assimilation of complex data (e.g. biomarkers data and use of toxicokinetic models) as well as Biomonitoring Equivalents for RCR calculation.

The uncertainties embodied in the several stages of the integrated assessment are minimized through Bayesian hierarchical modeling. The applicability of the overall methodology is tested in three distinguished case studies, dealing with classical (benzene) and emerging pollutants (PBDE and BPA).

**855 COMPARATIVE CHEMICAL RISK ASSESSMENT USING BIOMONITORING DATA FROM NHANES: APPLICATION OF BIOMONITORING EQUIVALENTS.**

L. L. Ayward, S. M. Hays and C. R. Kirman. Summit Toxicology, LLP, Falls Church, VA.

Biomonitoring data from the National Health and Nutrition Examination Survey (NHANES) and other large, cross-sectional studies provide powerful data on the levels of chemicals in blood and urine in persons in the general population. These data cannot be interpreted directly in the context of chemical risk assessments that are based on external exposure levels rather than biomarker concentrations. Biomonitoring Equivalents (BEs) are translations of existing risk assessment guidance values such as reference doses or tolerable daily intakes into corresponding steady-state biomarker concentrations, and have now been derived for more than 80 chemicals. BE values were used to examine data from the NHANES program using a hazard quotient (HQ; ratio of biomarker concentration to BE value) approach to provide a risk assessment-based interpretation of the relative levels of detected chemicals in the general population. More than 50 chemicals in the NHANES program with detected blood or urinary concentrations in a proportion of the population can be assessed using available BE values. Median population blood concentrations for chemicals in this group range over nearly four orders of magnitude, while urinary analyte concentrations ranged over nearly three orders of magnitude. However, chemicals with the highest absolute concentrations did not necessarily have the highest HQ values. HQ values did not exceed 1 at the median population biomarker concentration for any analyte. For more than 20 chemicals with derived BE values but non-detectable analyte concentrations in NHANES, the detection limits were nearly always sufficiently sensitive to demonstrate that population exposures remain below current risk assessment-based exposure guidance values. Application of BE values to the screening-level assessment of the NHANES datasets allows comparison of the evaluated chemicals on a risk assessment basis, increasing the utility of the NHANES data for prioritization of research and risk management activities.

**856 AN IN VITRO BIOACCESSIBILITY TEST METHOD FOR THE ESTIMATION OF BIOAVAILABILITY OF ARSENIC FROM SOIL.**

W. Bratinn, J. Dreeler, Y. Lowney, S. Griffin and G. Diamond. 1SRC, Inc., Denver, CO, 2University of Colorado, Boulder, CO, 3Exponent, Boulder, CO and 4USEPA Region 8, Denver, CO.

Accurate assessment of human health risks from incidental ingestion of soil containing arsenic (As) requires knowledge of the relative oral bioavailability (RBA) of As in those soils. RBA can be measured in vivo using animal models, but the cost of in vivo bioavailability tests limits widespread application of this approach for most site investigations. A faster, more economical, yet dependable in vitro method for predicting RBA is highly desirable. One in vitro approach involves measuring the fraction of As that is released from soil into solution under specified extraction conditions. This solubilization fraction is referred to as in vitro bioaccessibility (IVBA). If a strong correlation between RBA and IVBA can be established, then the IVBA method offers a more rapid and less costly alternative to in vivo studies. This study sought to optimize an IVBA method to estimate As RBA in soil for use in human health risk assessments. Phase I we reviewed and summarized the available in vivo RBA data from juvenile swine/monkey studies, and identified 39 candidate test materials for IVBA testing. Phase II investigated the effect of a wide range of experimental variables in the IVBA protocol, and identified three key variables (pH, phosphate, and hydroxyamine hydrochloride concentration). Phase III evaluated various combinations of these key variables in a Latin square design using a selected set of test substrates to identify up to three alternative combinations providing the best IVBA-RBA predictive relationship. Phase IV tested the three most promising extraction conditions on the entire list of test materials. For juvenile swine the best fit model (R²=0.72) is obtained using IVBA measurements at pH 1.5. For monkeys the best fit model (R²=0.75) is obtained using IVBA measurements at pH 7 with phosphate and hydroxyamine. The predictive relationship improves when As mineralogy is included with the IVBA data (R²=0.90 and 0.82 for swine and monkey, respectively).
Polycyclic aromatic hydrocarbons (PAHs) are widely distributed in the environment, and as such, are contaminants of concern when completing human risk assessments. In risk assessment, internal dose of a compound is calculated by multiplying external exposure by an absorption factor. Absorption factors are typically garnered from research done with a single dose. In the case of compounds like PAHs, which cause the induction of enzymes, bioavailability may change after repeated exposure to the compounds. In this study, juvenile swine were orally dosed with a mixture of PAHs in one of four media for 14 days and blood time courses were obtained on day 1 and day 7 of dosing. These time courses were used to calculate area under the curve and from this bioavailability was determined. Different media were incorporated in order to determine if there was different variability observed between media. The media included food, corn oil, artificial soil and historically contaminated soil. Blood samples were also collected on day 14 to determine the formation of micromolecules. A second study was conducted to determine the influence of PAH concentration on bioavailability of PAHs. Bioavailability of compounds in soil are thought to be influenced by soil organic matter content, but this may not be the only factor affecting absorption. In this study, swine were orally dosed with varying concentrations of PAHs spiked into artificial soil. Blood time courses were obtained from these swine and bioavailability was calculated. Preliminary results indicate that bioavailability of PAHs appears to be unaffected by repeat exposure. Also, micronuclei levels do not appear to be changed after repeat exposure. Bioavailability of PAHs does not appear to change as a result of different soil concentrations.

Polycyclic aromatic hydrocarbons (PAHs) are widely distributed in the environment, and as such, are contaminants of concern when completing human risk assessments. In risk assessment, internal dose of a compound is calculated by multiplying external exposure by an absorption factor. Absorption factors are typically garnered from research done with a single dose. 1Environmental Public Health Division, US EPA, Research Triangle Park, NC; and 2University of North Carolina at Chapel Hill, Chapel Hill, NC.

Arterial baroreflex is one of the body's homeostatic mechanisms that regulate blood pressure (BP) by changing heart rate (HR) and vasomotor tone. Increases in BP reflexively cause HR to decrease, whereas decreases in BP depress the baroreflex and cause HR to rise. As such, baroreflex sensitivity (BRS) is often used as a predictor of impaired autonomic control and cardiovascular disease, and has been found to be
Reduced in various cardiovascular conditions such as chronic heart failure, post-infarction hypertrophy. Given air pollution can alter autonomic nervous system, we hypothesized that exposure to air pollutants would also affect BRS and increase the risk of adverse cardiovascular events. Conscious unrestrained Wistar-Kyoto (WKY) and spontaneously hypertensive (SH) rats implanted with an intraventricular catheter and radiotelemeters were administered increasing doses of phenylephrine (PE-vasoconstrictor) and then sodium nitroprusside (SNP-vasodilator) while HR response, BP, and electrocardiogram (ECG) were continuously measured. This BRS test was done one day before and one day after exposure to either air or 3 ppm acrolein (3hrs). Before exposure, PE caused a dose-dependent increase in BP, which resulted in decreasing HR in WKY rats; SNP caused a dose-dependent decrease in BP and resulting HR increases. SH rats had a similar BRS response however, the reflexive changes in HR due to BP increase/decrease were attenuated at the higher doses. Twenty-four hours after acrolein, BRS was decreased in WKY rats and further blunted in SH rats. SH rats had significantly more arrhythmias than WKY rats during and after exposure to acrolein. Although SH rats had higher baseline BP, there were no other BRS differences between strains. In conclusion, a single exposure to a toxic air pollutant alters the body's ability to reflexively regulate cardiovascular function and predisposes to adverse cardiac events. (This abstract does not reflect EPA policy.)

**862 CHARACTERIZATION OF SOY BIODIESEL EXHAUST AND TOXICOLOGICAL EFFECTS IN MICE.**

M. I. Gilmore1, Q. T. Kranz1, C. King1, D. G. Nash2, W. Preston3, W. P. Linak1, E. H. Boykin1, M. J. Daniels1, D. L. Andrews1, J. H. Richards1 and S. H. Gavett4
1US EPA, Research Triangle Park, NC, 2ORISE, Department of Energy, Research Triangle Park, NC, 3US EPA, Research Triangle Park, NC, 4Arcadis, Research Triangle Park, NC.

Although biofuel use across the world is increasing, very little is known about possible health effects resulting from biofuel exhaust (BE) from this relatively new source of transportation fuel. The U.S. EPA has instigated an *in vitro* screening approach in rodents to examine whether BE can induce lung and cardiopulmonary responses in healthy and compromised animal models. In our combustion facility, biofuel exhaust is generated by a 0.32 L Yanmar engine driving a 3.8 kW Pramac generator with a constant load of 3 kW. Initial studies tested soy-based biodiesel, either 100% (S100) or a 20% mix with conventional petroleum (S20). Organic solvent extracts of S100 fuel were composed of about 70% methyl esters (e.g. linoleate, oleate) and 15% organic acids (e.g. hexadecanoic). Exhaust from combustion of S100 or S20 was diluted to target concentrations of 0, 50, 150, or 500 μg/m3 as determined by TEOM. Average CO, NO (ppm) at the 500 μg/m3 level were 12.3, 18.7 (S100) and 13.9, 13.2 (S20), respectively, while SO2 and NO2 were not above instrument background (<1 ppm). Female Balb/c mice (8/group) were exposed whole body to these emissions 4 h/ld, for 1, 5, d, or 4 wk (5 d/wk), and necropsied 2 or 24 hr after each of these exposures. Lung inflammation was minimal as neutrophils in BAL fluid were <3% with both S20 and S100 at all concentrations and time points. However, significantly fewer BAL macrophages (62% of neutrophils in BAL fluid were <3% with both S20 and S100 at all concentrations and time points. However, significantly fewer BAL macrophages (62% of BAL macrophages in peripheral blood were higher in mice exposed to summer oropharyngeal aspiration of 50 μg of summer/winter, UF/SFM; and day/night PM in 50 μl Hank’s balanced salt solution (HBSS) or HBSS alone. Results indicate that PM toxicity was significantly dependent on particle size and season and was not influenced by diurnal trends. In general, UF PM elicited significantly more pulmonary inflammation compared to SMF PM regardless of season or time of day. PM size-dependent toxicity demonstrated a more pronounced difference between winter UF and SMF PM compared to summer UF and SMF PM. In contrast, circulating neutrophils in peripheral blood were higher in mice exposed to summer but not winter day UF compared to SMF PM. These findings suggest that particle chemical composition strongly influences PM toxicity, possibly due to seasonal PM sources prevalent in winter compared to summer rather than diurnal impacts. Understanding seasonal impacts on PM-induced adverse respiratory and systemic health effects can lead to more effective targeting of sources for improved control of PM pollution within the SJV and protection of public health.

**863 HYPOTENSIVE AND BRADYCARDIC RESPONSES TO INHALED O3 AND AMBIENT FINE PARTICLES ARE ENHANCED IN RATS ON A HIGH-FRUCTOSE DIET.**

J. G. Wagner1, 2, A. S. Kamal1, K. Allen1, M. Morishita3, J. T. Dvornich1, R. Lewandowski1, 2, G. Fink1 and J. R. Harkema4
1Pathobiology, Michigan State University, East Lansing, MI, 2US EPA Great Lakes Air Center for Integrative Research, East Lansing, MI, 3US EPA, Research Triangle Park, NC, 4School Public Health, University of Michigan, Ann Arbor, MI and 1Pharmacology and Toxicology, Michigan State University, East Lansing, MI.

People with diet-induced cardiometabolic disorders (diabetes, hypertension) may be more susceptible to the adverse cardiovascular effects of air pollution. The present study was designed to determine if a high-fructose diet affects cardiovascular responses to inhaled air pollutants. We used a mobile air research laboratory located in an industrial area of Dearborn, MI, to expose male Sprague Dawley rats, to filtered air (FA), or the combination of ozone (O3; 0.5 ppm) and concentrated ambient fine particles (CAPs; 400 μg/m3). Rats were fed a normal (ND) or high-fructose diet (8% wt/vol fructose) prior to exposure. Exposure periods were 8h/day for 9 days (4-5 days/week). Heart rate (HR), heart rate variability (standard deviation; SDNN), and diastolic, systolic and mean arterial blood pressures were collected by radiotelemetry every 5 minutes during exposures. FA-exposed rats fed an ND had elevated systolic and mean arterial pressures compared to ND rats (10 and 9% greater, respectively). HR was not different between FA-exposed ND and HFD rats. Coexposure to O3/CAPs caused hypotension regardless of diet. O3/CAPs-induced decreases in systolic and mean pressures (decreases of 2 and 3%, respectively) were modest in ND rats compared to HFD rats (6 and 5%). O3/CAPs also induced marked bradycardia in both ND and HFD rats. Decreases in HR were greater in HFD (7%) compared to ND-fed rats (3%). Furthermore, SDNN was increased in HFD, but not in ND rats exposed to O3/CAPs. Observed hypotensive and bradycardic responses to O3/CAPs are consistent with a nasal irritant-induced trigeminal reflex. Mechanisms underlying HFD modification of these cardiovascular changes are yet to be determined. Funded by US EPA RD83479701.
primarily been used for vapor and liquid aerosol atmospheres. Use of this model to assess upper airway irritancy of dry powder aerosols required special technical considerations limiting the use of this model with dry powder aerosols. The RD50 for BA is >1096 mg/m3, and for SB is >1704 mg/m3. Based on the results of this study, BA and SB have low potency as airway sensory irritants. These data support that HDM is a more sensitive allergen for testing PM in acute models of allergic airway inflammation. While the use of P-OVA yielded increased sensitivity in these changes were statistically significant at d31 in DA rats. These results demonstrate that repeated exposure to >150 ppm OA or PD causes airway fibrosis and decreased pulmonary function in rats.

Epidemiological studies have shown increased hospitalizations associated with pulmonary toxicity upon exposure to particulate matter (PM) from wildfire smoke. Macrophages are one of the lung's primary protective cell populations, and it is important to know if wildfire PM induces oxidative stress and toxicity in this cell type. Our research group has shown that intratracheal instillation of coarse wildfire PM (PM10) decreases the number of lavagable macrophages from the mouse lung as compared to control groups. Furthermore, our in vitro studies using the RAW 264.7 macrophage cell line have shown increased cell death from 30 minutes to 24 hours after wildfire PM10 administration as compared to time-matched controls. The studies described here were designed to expand upon these previous findings and test the hypothesis that exposure to wildfire PM10 induces oxidative stress and cell death in the pulmonary macrophage population of the mouse lung. To this end, adult male, BALB/c mice were intratracheally instilled with PM10 suspended in phosphate-buffered saline (PBS) or PBS alone. Bronchoalveolar lavage fluid (BALF) and lung tissue were collected one hour after PM10 instillation. The macrophage population was quantified in BALF and lung tissue sections. Oxidative stress was evaluated using HPLC analysis of the BALF-derived cell pellet for reduced glutathione, and cytoxicity was evaluated using the Trypan blue exclusion method, as well as analysis of TUNEL staining for apoptosis. There was a decrease in macrophages in the BALF of mice instilled with wildfire PM10 as compared to control mice. There was also a decrease in reduced glutathione in macrophages from mice instilled with wildfire PM10. No significant difference in cytoxicity was found between treatments. In conclusion, oxidative stress in macrophages occurs one hour after wildfire PM10 exposure in the mouse lung, and this may give insight to wildfire PM-derived pulmonary toxicity that is seen in people.

Epidemiological data suggests correlations between particulate matter (PM) exposure and increased asthma symptoms and hospitalizations. The San Joaquin Valley (SJV) of California has some of the highest PM pollution in the country and asthma symptom prevalence is among the highest in the state. We sought to evaluate which model of allergic airway inflammation (AAI) will maximize our ability to detect differential particle toxicity collected via a novel source-oriented PM sampling approach in the SJV. BALB/c mice 8-10 weeks old were exposed via intranasal aspiration (IN) on days 1, 3 and 5 to a) saline, b) a select source-oriented particle (SOTox), or c) diffusion flame generated particles (DFP) as a positive control each in combination with ovalbumin (OVA), endotoxin purified OVA (P-OVA) or endotoxin purified D. Fariae house dust mite allergen (HDM). Animals were challenged on day 11, 12, and 13 with allergen alone. On day 14, the animals were sacrificed and tissues collected for analysis. Bronchoalveolar lavage exhibited cellular profiles indicative of an allergic response in all allergen models with elevations in leukocytes characterized by neutrophils, lymphocytes and eosinophils. HDM sensitized animals had significantly stronger inflammatory responses than the P-OVA and OVA models. Mice sensitized with OVA had on average 2-fold greater neutrophils than observed in mice sensitized with P-OVA, with neutrophils still present in all groups. Eosinophils and lymphocytes in HDM sensitized mice were 10- and 2-fold higher respectively than witnessed in OVA/P-OVA animals. These results suggest while purifying OVA reduced the neutrophil component, neutrophil inflammation is not due solely to endotoxin and is present in multiple models of allergic airway inflammation. While the use of P-OVA yielded increased sensitivity for detecting inflammatory differences as compared to OVA, our results indicate that HDM is a more sensitive allergen for testing PM in acute models of allergic airway inflammation.

Addressing the chemical evaluation bottleneck that currently exists can only be achieved through progressive changes to the current testing paradigm. The primary resources for addressing these issues lie in computational toxicology, a field enriched by recent advances in computer science, bio- and chem-informatics, molecular biology, and high-throughput screening (HTS). In vitro testing is resource intensive, particularly for multigenerational reproductive and prenatal developmental assessment. Furthermore, predicting adverse effects of chemicals for reproductive and developmental outcomes has been confounded by the lack of quantitative models that address the complex molecular and physiological factors underlying reproductive decrements and developmental malformations, and the life-stage and gestational windows of sensitivities involved. There is currently a strong focus on identifying endocrine-disrupting chemicals through a battery of in vivo and in vitro screening tests. However, the shared complexities and challenges of modeling reproductive, endocrine, and developmental toxicity, and the parallel need for higher throughput evaluation, creates the need for an integrated application of predictive models for chemical prioritization and targeted testing. Ultimately, predictive models of reproductive, endocrine, and developmental toxicity will provide a critical component in the computational toxicology toolbox that better informs regulatory testing decisions.
associated with reproductive toxicity. The current model is a classification model sufficient for large-scale chemical testing prioritization and begins to infer modes of action, e.g., estrogenicity, anti-androgenicity, or altering steroid metabolism. The model also has transparent inputs and outputs that are biologically translatable improving the chances for the model's acceptance and use in chemical testing prioritization and targeted testing applications. Extension of the model toward risk assessment applications targeted to mechanistic and cellular level information where quantitative and dynamic outputs of dose and time can be placed into a systems modeling framework. This abstract does not necessarily reflect US EPA policy.

871 SPECIES-SPECIFIC PREDICTIVE MODELS OF DEVELOPMENTAL TOXICITY USING THE TOXCAST CHEMICAL LIBRARY.

N. S. Sipes, ORD/NCCCT, US EPA, Research Triangle Park, NC.

EPA's ToxCast™ project is profiling the in vitro bioactivity of chemicals to generate predictive models that correlate with observed in vivo toxicity. In vitro profiling methods are based on ToxCast data, consisting of over 600 high-throughput screening (HTS) and high-content screening (HCS) assays, including embryonic stem cells and zebrafish embryos. The observed in vitro toxicity comes from 30 years of prenatal guideline studies of rodents and rabbits parsed into a publicly available database, ToxReDD. Due to distinct developmental differences, species specific models of developmental toxicity were built from the HTS data on the 309 ToxCast Phase I chemicals with balanced accuracies over 70%. Unique differences between the species specific models emphasized inflammatory signals in the rabbit model, and the retinoic acid receptor (RAR) and G-protein-coupled receptors (GPCRs) in the rodent model. The in vitro HTS profiles for 700 additional ToxCast Phase II chemicals, including failed pharmaceuticals, alternative plasticizers, and food additives are being used to validate and update the initial predictive models of developmental toxicity. These models have the potential to prioritize chemicals for further targeted toxicity testing and risk assessment; generate hypotheses about mechanistic pathways leading to adverse developmental outcomes, and reduce cost and increase throughput of chemical testing. This abstract does not necessarily reflect US EPA policy.

872 TEST STRATEGIES AND ALTERNATIVE APPROACHES FOR DEVELOPMENTAL-REPRODUCTIVE TOXICITY FROM THE EUROPEAN REGULATORY PERSPECTIVE.

Availability of rapid and reliable screening assays is important to the prioritization, selection and optimization of new drugs and chemicals. Recent regulatory initiatives from OECD, US EPA and European REACH legislation will require large amounts of information be generated about toxicity, including reproductive and developmental toxicity, for large numbers of chemicals in a relatively short timeframe. These objectives cannot be met using current testing paradigms, which are time- and resource-intensive, and which require large numbers of animals. New research addresses the need for high-throughput and high-content assays to provide public data on developmental defects, where the toxicity pathways remain largely uncharacterized. This presentation will assess the current status of testing strategies using in vitro and alternative models and will highlight the advantages and limitations of these approaches in the context of reproductive and developmental toxicity, with a special emphasis on classification and labeling.

873 BUILDING BRIDGES BETWEEN HIGH-THROUGHPUT SCREENING DATA AND IN VITRO REGULATORY GUIDELINE TESTS: APPLICATION OF INTERMEDIATE TIER IN VITRO FUNCTIONAL ASSAYS IN THE CHEMICAL INDUSTRY.

E. W. Carney, TERC, The Dow Chemical Company, Midland, MI.

The demand for toxicity data on chemicals used in industry, agriculture, and consumer products has increased tremendously in recent years, largely due to the drive for new, more sustainable products (which will require their own safety evaluation), as well as to increased data requirements for existing chemicals (e.g., European Union's REACH program). This increased demand for toxicity data simply cannot be met by conducting more and more regulatory guideline toxicity tests. This is especially true for developmental toxicity testing, which requires hundreds of animals per compound, is very expensive, and takes long periods of time. In response to these challenges, the US EPA and other government agencies have launched high throughput screening (HTS) and exposure science programs (e.g., ToxCast, ExpoCast) which can be used in a tiered approach to set priorities for further evaluation. In order to bridge the gap between rapid, mechanism-based HTS data and existing whole animal guideline developmental toxicity tests which are mainly descriptive in nature, there is an emerging need for creation of an intermediate tier of testing comprised of functional in vitro developmental toxicity tests, such as cell cultures and the whole embryo culture, zebrafish and C. elegans models. Intermediate tier testing can provide mechanistic read-outs of the initial HTS data. In addition, exposure modeling can be incorporated to ensure that dosing regimens are relevant to human exposures. Examples in which such intermediate tier assays can be used to bridge HTS and in vitro developmental toxicity data will be presented.

874 INTELLIGENT APPROACHES TO DART EVALUATIONS OF THERAPEUTIC PROTEINS.

K. E. Thompson, Reproductive Toxicology, Bristol-Myers Squibb Company, New Brunswick, NJ.

Therapeutic proteins are an increasing presence in the portfolio of pharmaceutical development. Typically, this diverse field of structures is not pharmacologically active in traditional animal models of developmental and reproductive toxicology (DART) evaluations; little is known about the potential placental transfer of these large molecules; and minimal to nothing is known about the ontogeny of the target in development of relevant species. When these drugs are active only in non-human primates (NHP), enhanced pre- and postnatal (ePPND) study designs have been proposed that are large, lengthy, and costly; importantly, however, they are statistically underpowered to detect increases in developmental mortality and dysmorphogenesis, except in cases of extreme toxicity. In face of 21st century initiatives to Reduce, Refine, and Replace, the pharmaceutical DART community is challenged to develop and embrace novel, rigorous approaches for evaluation of therapeutic proteins which permit prediction of target human pregnancy outcomes. These might include assessments of embryofetal exposure to candidate proteins, as well as profiling the ontogeny of therapeutic targets. Customized sets of studies that enhance decision-making, or even replace the ePPND study, will be presented as components of the toolbox available to toxicologists moving into the 21st century.

875 CROSS-SPECIES ANALYSIS OF TOXICOGENOMICS DATA: APPROACHES FOR ASSESSING DIFFERENCES IN SENSITIVITY AND CONSERVATION OF MODE OF ACTION.

R. S. Thomas and C. Rowlands, 1 The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 2 Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.

Two fundamental, but interrelated, challenges in toxicology are to identify a mode of action for a particular chemical and determine whether a particular response will be conserved across species. The determination of whether a response will be conserved usually involves a mechanistic understanding of the molecular events and an assessment of whether the processes and components that comprise those events are present in both the model species and the species of interest. In light of the relationship between gene expression changes and the biological effects, cross-species toxicogenomics studies may be used to identify potential modes of action for a chemical and determine appropriate cross-species adjustment factors for use in a risk assessment. We will evaluate the application of cross-species toxicogenomics analysis of chemical toxicant-induced modes of action across species for use in risk assessment in a series of highly focused presentations. These issues will be of broad interest to investigators and regulators across environmental, industrial, consumer products, and pharmaceutical toxicology who perform and interpret cross-species studies to understand human health risks.

876 CROSS-SPECIES COMPARISONS OF TRANSCRIPTOMIC ALTERATIONS IN HUMAN AND RAT PRIMARY HEPATOCYTES EXPOSED TO DIOXIN-LIKE CHEMICALS.

C. Rowlands, Toxicology and Environmental Research & Consulting, The Dow Chemical Company, Midland, MI.

The relative sensitivities of gene expression changes in human and rat primary hepatocytes exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) was assessed using whole genome arrays. Following 24 hours exposure to 11-doses of TCDD, gene expression microarray analysis revealed significantly more genes were affected in rats compared to humans at all concentrations. A total of 479 and 1574 orthologous genes were significantly altered in human and rat hepatocytes, respectively, with 159 orthologous genes affected in both species. When compared on a pathway basis, a total of 49 and 54 pathways were enriched in human and rat hepatocytes,
and better determinations of point of departure for risk assessment can be obtained. From these multi-level analyses, the identification of modes-of-action led to a mechanistic hypothesis on how the peroxisome may be a protective of mitochondrial enzyme induction that explained the increased sensitivity in dog data from rats and dogs treated with a novel PPAR agonist allowed the pinpointing dose (of TCDD) responded very differently based on toxicological endpoints. Microarray data explained temporal and functional outcomes in animals treated with LPS. For example, mice, dogs, and rats administered LPS at doses that produced an equivalent leukon (75% decrease in total white blood cell count four hours post-dose) responded very differently based on toxicological endpoints. Microarray analysis yielded species-specific biomarkers that will allow better monitoring of inflammation-mediated toxicity in preclinical drug testing. Similarly, gene expression data from rats and dogs treated with a novel PPAR agonist allowed the pinpointing of mitochondrial enzyme induction that explained the increased sensitivity in dog and led to a mechanistic hypothesis on how the peroxisome may be a protective organ in rat. From these multi-level analyses, the identification of modes-of-action and better determinations of point of departure for risk assessment can be obtained.

Two species often employed in preclinical drug development are rat and dog, and responses of these species to drugs are sometimes discordant. Gene expression profiling of target organs is a means to produce biologically meaningful endpoints that underlie drug-induced toxicity. We show how probe, gene, and functional level analyses of gene expression data can discern differences in modes of toxicity between two rodent species and suggest species-specific biomarkers that will allow better monitoring of inflammation-mediated toxicity in preclinical drug testing. Similarly, gene expression data from rats and dogs treated with a novel PPAR agonist allowed the pinpointing of mitochondrial enzyme induction that explained the increased sensitivity in dog and led to a mechanistic hypothesis on how the peroxisome may be a protective organ in rat. From these multi-level analyses, the identification of modes-of-action and better determinations of point of departure for risk assessment can be obtained.

β-chloroprene (2-chloro-1,3-butadiene) is a monomer used in the production of neoprene elastomers and is of regulatory interest due to the production of multi-organ tumors in the 2-year rat and mouse rodent bioassays. A significant increase in female mouse lung tumors was observed at the lowest exposure concentration of 12.8 ppm while a small, but not statistically significant, increase was observed in female rats only at the highest exposure concentration of 80 ppm. To assess whether cross-species transcriptomic studies in a sensitive and insensitive species could identify potential key events in the mode-of-action of chloroprene lung tumorigenesis, dose-response analysis was performed and a subset of genes conserved between species were made in the lungs of female mice and female rats at exposure concentrations that spanned those used for the cancer bioassay and provided approximately equal target tissue doses in the lung. Both gene set enrichment and pathway-based benchmark dose analyses were used to identify pathways and the processes involved in oxidative stress or reactive metabolite formation, steroid hormone and amino acid metabolism, inflammation, and apoptosis that are potentially involved in the mode-of-action. The results will be discussed in terms of the broad application of cross-species transcriptomic studies to identify potential modes-of-action.

A remarkable feature of the carcinogenicity of inorganic arsenic is that while chronic human exposures in drinking water at concentrations on the order of 0.1-0.5 mg As/L have repeatedly been associated with increases in skin, lung, and blad-der cancer, inorganic arsenic has typically not produced tumors in standard adult animal bioassays. Whether this difference in the carcinogenicity of inorganic arsenic in animals and humans is primarily limited to studies in which it is co-administered with another carcinogen or when arsenic is administered during the developmental period. There are a number of factors that have been suggested to contribute to the susceptibility of humans to the carcinogenicity of inorganic arsenic: species differences in the expression of the cellular and molecular responses of the species differences in the target tissue dose of the highly potent metabolite, trivalent monomethyl ars-enic, or a mode of action (e.g., co-carcinogenicity, epigenetic programming) that favors tumorigenicity in humans. Genomic analysis indicates a substantially similar response of human and mouse bladder cells to arsenic exposure, both in terms of the tissue concentrations at which effects are elicited and the nature of the pathways affected. In both species, expression changes observed at higher arsenic concentra-tions are largely related to the oxidative stress response, while responses at the lower concentrations are related to inflammation, epithelial-to-mesenchymal transition, survival, and cell cycle control. The evolution of the genomic response over time is consistent with an initial stress response that is suppressed on longer exposure due to down-regulation of Fox. This altered cellular state may, during critical periods of development or on prolonged exposure, lead to cellular transformation.
The regulatory approval standards for biosimilar products are distinct from those for generic chemically-synthesized (small molecule) medicines, which must be identical to the reference listed drug. In contrast to generic medicines, biosimilars are “highly similar” but not identical to the approved biologic product (reference product). The European Union (EU) served as the pioneer for establishing the regulatory framework for the approval of biosimilars following the enactment of legislation in 2003/2004 which empowered the European Medicines Agency (EMA) to approve biosimilar products. Subsequent to the regulatory guidance established by the EMA, guidelines for the approval of biosimilars have been developed in several key regions around the world such as Canada and Japan, as well as the World Health Organization (WHO). This presentation will review the history and development of the regulatory standards for the approval of biosimilars established by various regions and the WHO. The similarities as well as some of the key differences between the regional guidelines will also be reviewed.

**INDUSTRY PERSPECTIVE ON BIOSIMILAR DRUG DEVELOPMENT AND REGISTRATION.**

Prior to the passage of the Biologics Price Competition and Innovation Act (BPCIA), BIO developed a set of key principles that should guide the creation of a pathway for the approval of biosimilars. BIO’s principles state that a pathway should ensure patient safety; recognize scientific differences between drugs and biologics; maintain the physician-patient relationship; preserve incentives for innovation; ensure transparent statutory and regulatory processes; and, continue to prioritize FDA review and approval of new therapies and cures. This presentation will review industry’s perspectives on biosimilarity, interchangeability, and the R&D aspects of and data requirements necessary for a biosimilars pathway.

**US FDA’S OVERVIEW OF THE REGULATORY GUIDANCE FOR THE APPROVAL OF BIOSIMILAR PRODUCTS IN THE UNITED STATES.**

D. Jacobson Kram, CDER, US FDA, Silver Spring, MD.

The Patient Protection and Affordable Care Act (PPACA) was signed into law by President Barack Obama on March 23, 2010. The law contains the Biologics Price Competition and Innovation Act (BPCIA), which creates an abbreviated approval pathway in the United States for biosimilar products that are demonstrated to be highly similar (biosimilar) to a therapeutic protein product previously approved as a Biologics License Application (BLA) under the Public Health and Services Act (PHSAct). The US FDA sought comments from interested parties during a public hearing in November 2010 and submission of comments later that year. The US FDAs scientific standards and data (analytical, nonclinical and clinical) required for the approval of biosimilar products will be reviewed in this presentation. Additionally, factors such as selection of reference product and extrapolation of clinical data, as well as other issues related to biosimilar products will be discussed.

**THE ROLE OF DANGER SIGNALS IN THE DEVELOPMENT OF CHEMICAL SENSITIZATION BY ENVIRONMENTAL AND OCCUPATIONAL AGENTS.**

P. Marc, et al., University of Utrecht, Utrecht, Netherlands.

The adaptive immune response to a foreign antigen needs both the recognition of the specific antigen and the presence of a specific cellular microenvironment at the place of antigen entrance. This specific cellular microenvironment provides signals to antigen-presenting cells allowing the elicitation of the immune response instead of immune tolerance to the foreign antigen. To this extent danger signals (e.g., proinflammatory cytokines, specific molecules from pathogens, necrosis products) play a crucial role in the immune adaptive response to pathogens. Triggering the innate immune system with danger signals, for instance through specific receptors termed PRR (pattern recognition receptors) including TLR (toll-like receptors), is a prerequisite for the immune system to react to pathogens as well as environmental antigens. These danger signals can be considered as adjuvants of immunity and indeed this concept has been extensively used for vaccination by adding chemicals (aluminum hydroxide) or pathogen products in vaccines. By analogy to the immune response to pathogens, the hypothesis that chemical allergens need the presence of danger signals or provide this danger signal to induce chemical hypersensitivity reactions has been developed during the past five to ten years. In this case, the chemical will play the role of an adjuvant. Recent evidence suggests that particulate matters and nanoparticles (SO2, TQ2) can also mimic the presence of danger signals and thus have adjuvant potential on immune responses. Recently, several *in vitro* models have been developed to address the adjuvant effect of chemical sensitizer toxicology programs for specific biosimilar products will be discussed.

**CHALLENGES AND REGULATORY APPROACH FOR THE APPROVAL OF SUBSEQUENT ENTRY BIOLOGICS IN CANADA.**

A “subsequent entry biologic” (SEB) is a term used by Health Canada to describe a biological product that would be considered as similar to an innovator biological product already approved and registered in Canada. As more innovator biological products reach patent expiry in the upcoming years, worldwide interest in developing SEBs will continue to grow. Due to the structural and molecular complexity of biological products, the regulatory standards for the approval of generic medicines are not scientifically appropriate for the development SEBs. In recognizing the distinction between generic medicines and SEBs, regulatory guidance was finalized by Health Canada in March 2010. This presentation will review the origins of the Canadian guidance and regulatory standards for the development of SEBs, as well as present some of the critical challenges in developing SEBs such as manufacturing the SEB, choice of reference product, and determining the extent of the nonclinical and clinical data to demonstrate similarity between the SEB and the reference product. The issue of interchangeability will also be discussed.

**CHEMICALS MODIFY THE CELLULAR MICROENVIRONMENT IN THE SKIN PROVIDING ENDOGENOUS DANGER SIGNALS.**

S. F. Martin, Department of Dermatology, University of Freiburg, Freiburg, Germany. Sponsor: M. Pallardy.

Allergic contact dermatitis (ACD) is an inflammatory skin disease of great and steadily increasing occupational and environmental concern. The disease is induced by xenobiotic organic and inorganic chemicals which penetrate the skin and react with host proteins. This process is accompanied by a strong, allergen-induced inflammatory reaction, which I call xenoinflammation, and leads to the migration of allergen-carrying dendritic cells (DC) from the skin to regional lymph nodes, where they promote generation of allergen-specific T cells. The latter are the ultimate effector cells of the disease. Re-exposure to the causative agent leads to the re-activation of the T effector cells, which then elicit the typical skin inflammatory reaction at the site of allergen contact. A striking finding is the normal contact...
hypersensitivity (CHS) response in germ-free mice. This implies that contact allergens orchestrate the innate immune response by the direct or indirect activation of innate signaling pathways using non-microbial, i.e. endogenous danger signals. In fact, a crucial role for TLR2, TLR4, the NLRP3 inflammasome and reactive oxygen species in ACD and CHS has recently been demonstrated. Thus, contact allergens trigger the same innate pathways that are triggered by microbial pathogens to induce skin inflammation leading to pathogenic T-cell responses. In such cases, ACD can be viewed as an anti-infectious immune response to non-infectious, non-replicating agents.

**889 CHEMICAL SENSITIZERS CAN PLAY THE ROLE OF DANGER SIGNALS.**

P. Marc. INSERM UMR 996, Université Paris-Sud, Chatenay-Malabry, France.

Dendritic cells are the most potent antigen presenting cells, which express a wide variety of receptors on their cell surface, recognizing microbial patterns, damage induced molecules and cytokines that constitute the ‘danger signals’. Dendritic cells become reporters of the microenvironment if exposed to the allergen, subsequently migrating to the draining lymph nodes where they activate naïve T lymphocytes. Dendritic cells could also be indirectly activated by epithelial cells, which express various receptors and secrete a variety of cytokines early after allergen exposure. Recently, it has been shown that chemical sensitizers but not chemical irritants were able to directly activate dendritic cells leading to phenotype modifications, cytokine production and T-cell activation. Specific cellular signalling mimicking ‘danger signals’ has been found to associate with these modifications suggesting a specific recognition of chemical sensitizers by dendritic cells.

**890 PHTHALATES INFLUENCE THE IMMUNE AND ALLERGIC RESPONSES.**

R. Dearman. Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

It has been suggested that one possible contributor to the increasing prevalence of atopic (IgE-mediated) allergic diseases and asthma in Europe and the US is exposure to chemicals that may act as adjuvants. Certain commonly used phthalate plasticizers have been implicated in this regard. The evidence for the ability of phthalates to impact on immune and allergic responses will be discussed, encompassing epidemiological investigations and results deriving from studies using experimental animals and from analyses in vitro. There is some evidence from the epidemiological data that exposure to phthalates may be associated with increased risk of development of allergies and asthma, however, the lack of objective exposure information limits the interpretation. It has also been reported that certain phthalates, when delivered at appropriate doses, and via an appropriate route, impact on immune and inflammatory function in rodents, although as yet no consistent pattern has emerged. Effects range from potentiation of immune or inflammatory responses, to the absence of any effect, to inhibitory or immunosuppressive activity. There is clearly a need for more definitive animal studies that will allow development of a more detailed understanding of whether and to what extent phthalates are able to effect meaningful changes in immune function that may in turn impact on human health.

**891 LUNG DENDRITIC CELLS ARE STIMULATED BY ULTRAFINE PARTICLES AND PLAY A KEY ROLE IN THEIR IMMUNOSTIMULATING ACTIVITY.**

R. Pieters. 1, 2, 1Institute for Risk Assessment Science, Research Centre Technology and Innovation, University of Utrecht, Utrecht, Netherlands and 2Research Centre Technology Innovation, Utrecht University of Applied Sciences, Utrecht, Netherlands.

The immunostimulating activity of air pollution particles on allergic airway sensitization is well known, but the cellular mechanisms underlying this so-called adjuvant potential are not yet well defined. Particulate air pollution has been associated with increased induction (sensitization) and exacerbation (challenge) of allergic airway disease. In human subjects diesel exhaust particles (DEP) have been shown to increase sensitization against antigens and various other particles are able to induce allergic sensitization against coadministered ovalbumin (OVA) in mouse models of allergic airway sensitization. Because no sensitization against the air pollution particles per se takes place, the main question is how these airborne particles affect the muco-associated immune system of the respiratory tract so that allergic sensitization against coadministered antigen takes place. Various cellular mechanisms have been suggested, including induction of cellular stress (oxidative stress) and activation of macrophages and epithelial cells. Most of the underlying mechanistic stud-

ies were done in vitro, and mechanistically relevant in vivo data are still limited. Data to support the importance of dendritic cells (DC) and costimulation in particle-induced immunostimulation will be presented in view of the danger hypothesis.

**892 ASSESSING THE BIOAVAILABILITY AND RISK FROM METAL-CONTAMINATED SOILS AND DUSTS.**

Exposure to contaminated soil and dust is an important pathway in human and ecological risk assessment and often is the risk-driver for metal-contaminated soil. Site-specific soil physical and chemical characteristics, as well as biological factors, determine the bioavailability of soil contaminants. Within a single sample, contamination may be from multiple sources of toxic elements that may exist in different forms and species. The bioavailability of soil and dust contaminants has a direct impact on human health risk assessment and risk management practices. Novel research efforts focusing on development and application of in vitro and in vivo methods to measure the bioavailability of metal-contaminated soils have advanced in the past few years. Our panel of experts will provide information on the recent developments in assessing the bioavailability and risk from metal-contaminated soils and dusts. The presentations include the relative bioavailability of arsenic-contaminated soils, metal contamination in urban residences in Canada, and potential children’s exposures to toxic elements in house dust. The information can be found in a community-based study known as the “West Oakland Residential Lead Assessment Study,” which provides details of the bioavailability of soil cadmium, chromium, nickel, and mercury, and human exposures to contaminated Brownfield soils. These presentations cover issues related to human health and bioavailability along with the most recent studies on community participation in assessing metal contamination, studies of children’s exposures to residential contamination, and recent in vitro and in vivo methods development for assessing the bioavailability of metals in soils and dusts. This session seeks to provide a forum for discussing the implications of these latest developments on incorporating bioavailability into the risk assessment and management process.

**893 RELATIVE BIOAVAILABILITY, BIOACCESSIBILITY, AND SPECIATION OF ARSENIC IN CONTAMINATED SOILS.**

Assessment of soil arsenic bioavailability may profoundly affect the extent of remediation required at contaminated sites by improving human exposure estimates. Thus, convenient, rapid, reliable, and inexpensive tools for assessing soil arsenic bioavailability are needed. In this study, in vivo mouse bioavailability and in vitro bioaccessibility of arsenic and physiochemical properties of nine soils from residential sites affected by earlier mining or smelting activity and two NIST standard reference materials were analyzed. In addition, arsenic speciation and select soil physiochemical properties were evaluated as predictors of arsenic bioavailability and bioaccessibility. In the in vivo assay, relative bioavailabilities of soil arsenic ranged from 11-53%. In vitro estimates of soil arsenic bioaccessibility were strongly correlated with soil arsenic bioavailability values (R² = 0.88). Among physiochemical properties, combined concentrations of iron and aluminum accounted for most of the variability in estimates of bioavailability and bioaccessibility, respectively. This multifaceted approach combined in vivo assays, in vitro assays, and physicochemical characterization of soils to yield congruent estimates of arsenic bioavailability and bioaccessibility.

**894 METAL CONTAMINATION IN URBAN RESIDENCES IN CANADA AND POTENTIAL CHILDREN’S EXPOSURES TO TOXIC ELEMENTS IN HOUSE DUST.**

P. E. Rasmussen1, S. Beauchemin2 and L. MacLean3. 1Health Canada, Ottawa, ON, Canada, 2CARMET-MMSL, Natural Resources Canada, Ottawa, ON, Canada and 3Canadian Light Source, Inc., Saskatoon, SK, Canada. Sponsor: M. Hughes.

House dust is both an exposure medium, with ingestion of dust providing a major pathway of Pb exposure for young children, and a transport medium, facilitating the transfer of outdoor contaminants to the indoor environment. Results from the
recently completed Canadian House Dust Study provide a nationally representative sample of typical dust metal concentrations and loadings in urban Canadian homes. Detailed studies employing synchrotron techniques show a strong relationship between metal bioaccessibility and speciation in house dust, and assist in identifying factors for elevated indoor metal concentrations in the national study. The results showed that common Pb carbonate pigments contribute to elevated Pb bioaccessibility of house dust, and demonstrated that Pb bioaccessibility can be predicted from its speciation. This research also investigated variations in potential exposures from one part of the home to another. In humid indoor microenvironments, the dust sink provides a medium for molecular-scale transformations of certain metals (e.g. Pb and Zn) to more bioaccessible forms, which results in a significant (p < 0.05) increase in their overall bioaccessibility in ingested dust. Variations amongst rooms in older homes were also related to the timing of renovation activity, resulting for example in the presence of older paint compounds in bedrooms compared to living rooms. The results underscore the importance of taking appropriate measures to minimize exposures to dust, especially during remodeling and renovation.

W 895  USA EPA WEST OAKLAND RESIDENTIAL LEAD ASSESSMENT STUDY.  S. M. Sera1, S. A. Calanog1, K. D. Bradham2, K. G. Scheckel3 and B. W. Miller4, 1Superfund Division/Region 9, USA EPA, San Francisco, CA. 2NERL/ORD, USA EPA, Research Triangle Park, NC and 3NRMRL/ORD, USA EPA, Cincinnati, OH. Sponsor: M. Hughes

The West Oakland Residential Lead investigation area is comprised of residential blocks adjacent to the AMCO Superfund National Priorities List site. Based on site conditions documented by the 2007 investigation, removal activities, and citizen interest the U.S. EPA conducted an expanded site-wide assessment of lead in residential soils in October 2009. Based on these results and in collaboration with the residents of the South Prescott Neighborhood, EPA is taking an innovative approach to addressing this lead contamination, using phosphates from waste fish bones to reduce the bioavailability of toxic lead species, and covering the treated soil with a green cap of sod and organic material. This would have far less impact on the neighborhood than a traditional dig and haul removal. In addition to the innovative soil treatment, the project will be employing solar power for its electricity needs, electric vehicles for local transportation, and recycled materials, all in order to minimize the environmental and health impacts to the community. The project has three key objectives to protect children’s health, to minimize environmental impact to the community, and to support the community by utilizing local resources. (This abstract does not necessarily represent U.S. EPA policy.)

896 BEYOND LEAD AND ARSENIC: HOW ARE OTHER METALS BEING ADDRESSED?  R. A. Schoof, Environ International Corp, Seattle, WA.

Risk-based clean up levels for metals in soil and dust may be adjusted to correct for differences in the bioavailability of soil metal vs. the metal forms and exposure media from toxicity or epidemiology studies. Research and methods development efforts have focused on evaluation of the relative bioavailability (RBA) of Pb and As in soil; however, extension of these findings to other metals has been a subject of some debate. Factors that could affect applicable methods for a given metal include differences in toxicokinetics and toxic endpoints. Comparison of in vivo study designs used to assess soil As and Pb illustrates some of these differences, with Pb RBA typically being evaluated based on concentrations in blood, liver and kidney after repeated dose studies, whereas, As RBA may be evaluated based on urine or blood concentrations after either single dose or multiple dose studies. Studies of the bioavailability of soil Cd, Cr, Ni and Hg are more limited, but provide evidence that RBA varies with metal species and soil characteristics. Repeated dose feeding studies in rats have been used to measure soil RBA for both Cd and Hg by comparison of concentrations in kidney and other tissues from animals dosed with soil vs. those dosed with reference metal compounds. Evaluation of Cr is complicated by possible co-occurrence of trivalent and hexavalent forms, with reduction of Cr(VI) to Cr(III) in the stomach affecting Cr(VI) absorption. Both Cd and Ni are excreted primarily in the urine and urinary excretion measurements provide a viable approach to estimating RBA. In vitro approaches to estimating RBA may also need to be varied based on both metal characteristics and interactions with soil and dust. Many in vitro methods include an initial low pH “gastric” phase, with an option for a second higher pH “intestinal” phase. Available studies suggest that a single gastric phase approach may be used for both Cr and Ni, although for high Ni concentrations care must be taken to ensure there is sufficient gastric fluid volume so the saturation point is not exceeded. For Cd and Hg, a two phase approach with RBA based on the intestinal phase is recommended.

W 897 CONTAMINANT MIXTURES AND MIXED EXPOSURE EFFECTS: TESTING IN VITRO DIGESTORS TO DISTINGUISH BETWEEN HUMAN EXPOSURE TO BROWNFIELDS AND IDENTIFY ENGINEERING SOLUTIONS THAT REDUCE RISK.  S. D. Siciliano1,2, K. James3, B. Laird4 and D. Peak4, 1Interdisciplinary Toxicology Group, University of Saskatchewan, Saskatoon, SK; Canada and 2Department of Soil Science, University of Saskatchewan, Saskatoon, SK, Canada. Sponsor: M. Hughes

Residents living near or on contaminated sites are typically exposed to a mixture of organic and inorganic contaminants via ingestion and/or inhalation pathways. Estimating cumulative bioavailability across contaminant and pathway mixtures is a daunting task. We conducted a multi-year study on human exposure to soil-bound pollutants from a northern urban brownfield. We determined that residents were exposed to the very fine, mean size 32 μm, fraction of soil enriched in metals and polycyclic aromatic hydrocarbons (PAH) relative to bulk soil. However, the bioaccessibility of these enriched contaminants was reduced compared to bulk soil, thus mitigating the exposure risk. We next studied the chemical basis of this enrichment and were able to predict how mixtures both enrich in this ingested soil fraction and how bioaccessibility varies across mixtures of metals and PAH. Bioaccessibility and enrichment for PAHs was dominated by partitioning. For metals, enrichment was dominated by adsorption processes and bioaccessibility was dominated by metal lability. Metal lability is a chemical property indicating the rate at which water molecules are replaced in the solvation shell of a metal. This term accurately estimated bioaccessibility within a metal mixture and our regression equations predicted bioaccessibility between studies. Combining these ingestion results with air quality monitoring, we found that soil ingestion dominated the risk for As and PAHs, but not for Cr, Cd or Be. During this study, the roads in the study area were paved; exposure estimates were collected before and after paving. Road paving reduced the risk to toddlers and adults by an order of magnitude for Cr, Cd and Be. The premise that inhalation exposure is irrelevant for brownfields is likely incorrect due to vehicular re-suspension. A simple and functional way to reduce risk in northern brownfields is to pave the roads in the area.

W 898 STATE OF THE SCIENCE AND THE FUTURE FOR THE PREDICTIVE POWER OF IN VITRO AND IN VIVO MODELS FOR NANOMATERIALS TOXICITY TESTING.  A. Eldred1 and S. Nadadur2, 1Environmental Medicine, University of Rochester, Rochester, NY and 2NIEHS, Research Triangle Park, NC.

The proliferation of engineered nanomaterials (ENMs) in commerce has led to a growing concern about the consequences of exposure for those who produce and use them. The National Institute of Environmental Health Sciences recognized the importance of gaining a more fundamental understanding of the potential influence of ENMs on human health and, so, initiated a high priority research program (Nanotechnology Environmental Health and Safety, NanoEHS) with the availability of funds through the Americans Recovery and Reinvestment Act. This Nano Grand Opportunity (NanoGO) program was developed to address major issues of inconsistency in results reported for similar engineered nanomaterials investigated at different laboratories, a problem that significantly impedes both hazard and risk assessment for this class of materials. The disparities in results likely arise from poor communication about material characteristics, lack of assay validation, and/or inconsistencies in methodology. The goal of the NanoGO initiative was to support the development of reliable and reproducible methods and models to assess biological response through coordinated research efforts. As a result of this program, the NanoGO Consortium was established with 13 investigators/institutions in November 2009. The Consortium selected a library of ENMs and identified a set of in vitro and in vivo assays to be used in interlaboratory comparisons using standardized protocols. This session will focus on the study design, specific objectives, and consensus findings from interlaboratory in vitro and in vivo toxicity and particle characterization studies that were done with the library of engineered metal oxide and carbonaceous nanoparticles within the NanoGO Consortium, with an emphasis on how the findings can be used in the context of hazard assessment.

W 899 OVERVIEW OF THE NIEHS-SPONSORED NANO GO PROGRAM.  S. Nadadur, NIEHS, Research Triangle Park, NC.

The overarching goals of the Nano EHS program at NIEHS are to address fundamental issues of ENM interactions with biological matrices and to provide leads for defining potential hazard and health effects associated with accidental or incidental exposures. This knowledge could also be utilized to guide the development of safer
ENMs. Towards these goals and in coordination with the priorities identified by the National Nanotechnology Initiative, the NanoGO Program is to address one of the fundamental issues in ENM-biological interactions, i.e. the development of reliable and reproducible assays and methods to predict ENM toxicity using a set of defined materials by a Consortium of investigators across the US. This presentation will detail the origin, structure, composition and contributions of this Consortium. First, a suite of metal oxide (spherical titanium dioxide, zinc oxide; titanium dioxide ‘nanobelts’) and carbonaceous (multiwalled carbon nanotubes, 3 different surface chemistries) ENMs were selected for study based on availability, existence of historical data for comparison, the ability to characterize the material physicochemical properties, and investigator expertise and interest. Data regarding ENM size, morphology, composition, and crystal structure will be discussed for the selected materials. Based on the selected ENMs, a set of short-term in vitro and in vivo toxicological assays was chosen. The time points and outcome measures related to the expected oxidative stress, inflammatory, and profibrotic changes were selected by the Consortium and the rationale for these selections will be described. Through close regular communication amongst Consortium members, problems with reproducibility were identified and corrected through protocol modifications. The results of these collaborative and coordinated efforts by the Consortium investigators highlight the need for integrated efforts in the field of nanotoxicology in addressing the health implications associated with exposure to ENMs.

902 NANOPIRICLE DOSIMETRIC CONSIDERATIONS FOR IN VITRO AND IN VIVO MODEL SYSTEMS: CONSIDERATION OF DISPERSION STATUS, DOSE AND DOSE RATE FOR STUDY DESIGN AND IN VIVO-IN VITRO RESPONSE COMPARISONS.

G. Oberdörster, Environmental Medicine, University of Rochester, Rochester, NY.

This presentation will focus on responses to ENMs in the lower respiratory tract when administered to rodents as a bolus in well dispersed liquid suspensions (intra-tracheal instillation) or as an aerosol (inhalation). The impact of ENM suspension preparation using dispersants or sonication protocols for bolus type deliveries (high dose rate) vs. delivery of pristine nanoparticles by inhalation (low dose rate) will be discussed in terms of the usefulness and relevance of bolus administration to simulate real-life exposures. Implications and consequences for appropriate in vitro exposures of respiratory tract epithelial cells will be highlighted with regard to dosimetry and to particle delivery methodology via media suspension or aerosol (air-liquid interface). Conclusions regarding the influence of changing the dispersion state of ENMs by chemical (dispersants) or physical (sonication) means and of delivery mode on inflammatory responses will be discussed.

903 SUFFICIENT SIMILARITY OF WHOLE REPRESENTATIVE MIXTURES OR A RELATIVE POTENCY FACTOR APPROACH: POLYCYCLIC AROMATIC HYDROCARBONS AS A CASE STUDY.

C. V. Rider, NTP/NIEHS, Research Triangle Park, NC.

Predicting the toxicity of complex and dynamic mixtures represents a difficult challenge for risk assessment, as demonstrated recently by seafood safety concerns following the Deepwater Horizon oil spill. Two established approaches for addressing this challenge are the relative potency factor (RPF) approach and the sufficient similarity (SS) of whole mixture approach. The RPF approach requires knowledge of dose-response relationships of the individual mixture components. These data are then input into a dose additivity model to predict the toxicity of the mixture. Alternatively, with the SS approach, representative whole mixtures are used as a basis for predicting the toxicity of related environmental mixtures. Polyyclic aromatic hydrocarbons (PAHs) offer a useful case study for comparing the advantages and disadvantages of RPF and SS approaches. These ubiquitous contaminants are found in many mixtures to which humans are regularly exposed. PAHs are a large and diverse group of chemicals with complex mechanisms of action. Much work has been dedicated to developing an RPF approach for estimating cancer risk associated with exposure to unsubstituted PAHs. However, there is no clear path forward for expanding risk assessments to include substituted PAHs or noncancer end points, such as immune and reproductive toxicity. Currently, individual PAH dose-response data is incomplete and insufficient for accurately evaluating risk to human health. In order to better characterize toxicity associated with PAH mixtures, more work is needed. Determining which approach is more appropriate is a necessary step in deciding how to focus research resources. In effect, an RPF approach would dictate additional individual chemical toxicity testing; whereas, an SS approach would necessitate deciding on appropriate representative mixtures and testing those mixtures. This session will provide the framework and cover topics including advantages and disadvantages of each approach, consideration of the complex mechanisms of action of PAHs, critical data needs, and novel techniques available for filling data gaps and refining testing.
The Deepwater Horizon blowout in the Gulf of Mexico provided a stark example of the need for risk assessment methods dealing with complex environmental mixtures. The FDA and NOAA protocol implemented for re-opening fisheries used an additive relative potency factor approach to assess risk associated with exposure to polycyclic aromatic hydrocarbons (PAHs) in seafood. An assessment of this protocol based on comparisons with previous oil spills, published testing results, and current knowledge regarding chemicals released will be presented. The data gaps highlighted by this recent event are used to explore risk-benefit scenarios that necessarily incorporate exposure to mixtures, which is particularly important for dietary exposures that may have both positive and negative health implications, such as the case for seafood consumption. Development of pathway-based models that bring together both carcinogenic and non-carcinogenic endpoints may be useful for improving the risk assessment of exposures to mixtures. An approach that relies on information regarding time and spatially dependent activation of evolutionarily conserved transcription factors may provide a useful model construct for mixtures risk assessment of PAHs. Providing evidence for this approach, the examination of extant datasets on transcriptional networks after PAH exposure across several model species suggests downstream perturbation of developmental pathways may help to explain, in part, both carcinogenic and non-carcinogenic endpoints. When data is available, a pathway-based framework can efficiently incorporate evidence of additive, synergistic and antagonist roles in mixtures. In conclusion, the Deepwater Horizon blowout provides a real-world application of PAH risk assessment approaches and highlights the need for prioritization of data and methods development needs in addressing exposure to mixtures in risk assessment.
There is a significant honey bee health crisis in California and globally that may threaten the future of California's agricultural industry. Over half of California crops are dependent upon pollinators, including honey bees, with a potentially staggering economic impact approaching tens of billions of dollars. Some colonies collapse from the rapid loss of adult bees with the queen, a handful of bees, and some brood still present in the hive. In the US, this set of symptoms has been called Colony Collapse Disorder, or CCD. This condition is one component of a more general problem of colony losses, which has reached record highs in the past decade. Colony numbers in the US have been declining since the late 1940s because of the declining number of beekeepers. This trend continues but is now accelerated because of the challenge of keeping bees healthy and productive. Beekeeper surveys indicate annual colony losses of 30% and more. Multiple stresses, including Varroa and tracheal mites, Nosema, foulbrood diseases, numerous viruses, and small hive beetles, may be present in hives and can explain most of the colony losses. Other potential contributing factors are being investigated as well. Our panel brings together scientists, stakeholders, and regulators to discuss different views of the complex web of bees that might be causing the honey bee health crisis. Pesticide testing methodologies and results will also be addressed.

We will provide an overview on the current status of bee and colony health and an introduction into the multifactorial issues that affect bee health. This discussion will be followed by a presentation on the potential health threats posed by infectious agents. Next, a State of California representative will outline the steps being taken to protect bee health while balancing the need for agricultural crop protection tools. Finally, the complex approaches to understanding the relationship between pesticide residues and bee health and the logistical challenges of addressing these in a regulatory context will be discussed.

In the United States, the honey bee (Apis mellifera) is the surrogate for many other non-target insects and insect pollinators. Honey bees are a challenging organism to study. Typically toxicity testing and risk assessment focus on the individual, but in the case of honey bees, the colony is the organism. In a healthy hive, hundreds of foragers die daily and the death of one is of little importance. As a result, U.S. EPA currently has a tiered testing approach. Tier 1 testing includes an acute oral and contact test with young worker bees. Compounds with an LD50 < 2 μg/a.i./bee are considered highly toxic to bees and warrant further testing. Tier 2 testing is currently a foliar residue test. The endpoint of this test is a value indicating how long foliar plant residues are toxic to bees. Tier 3 testing includes either semi-field or field testing, however, standardized protocols for Tier 3 testing have not yet been established. With the introduction of new plant protection products, changes in agricultural practices, and advances in the science of honey bee biology, the ability to characterize potential risks to insect pollinators has become inadequate. In January 2011, a SETAC Pellston Workshop was held to assess and advance the state of the science on pesticide risk assessment for pollinators. The generic problem formulation for pesticide risk to pollinators includes two application strategies, foliar and application of systemic pesticides to seeds or soil. The new risk assessment paradigm is based on exposure estimates and a tiered toxicity testing system consisting of the previous tests plus a larval and 10-day chronic adult test, as well as more structured protocols for semi-field and field testing. California issues include how ecological risk assessment and risk management are blended. California is currently reevaluating neonicotinoid insecticide and has a novel interpretation of a pesticide label based on residual toxicity.

It is common in the pesticide registration and re-registration process to require honey bee effects testing. Effects studies fall into three categories, i.e. Tier 1 and Tier 2 (typically laboratory or semi-field studies), and Tier 3 (field studies). Potential risks identified at Tier 1 and 2, then trigger Tier 3 studies. Field studies are used to determine if effects occur under actual use conditions, but such studies must be designed carefully to ensure scientifically valid conclusions. The purpose and objectives of the study must be clear so that meaningful endpoints can be chosen. The study site must be representative and the surroundings must not compromise the exposure scenario in the study site. The hives must be configured consistently, as sanitary as possible, and bee tight to allow control over the hive entry points. The colonies must be as healthy as possible, which requires considerable lead-in time for bee stock production. Staffing is a challenge since stinging incidents are inevitable which can be a serious safety concern. Keeping qualified staff is essential to consistent observations, continuity of skill sets, and maintenance of healthy colonies. Satisfying GLP requirements while working in a natural environment is subject to endless variables and requires highly trained personnel. In California, almond field studies are difficult because the huge number of hives brought in to pollinate the crop may result in extreme competition among bees for nectar and pollen resources. The difficulty in finding appropriate sites is further exacerbated by the increasing number of bee studies required for regulatory purposes. Tier 3 studies generally provide the best representation of effects under real-world exposure conditions. With the difficulties and expense of conducting field studies, it is essential that they are well designed and targeted to both the concerns raised in lower tier studies and the proposed use patterns of the product. Successful studies ensure that honey bees are adequately protected and that growers have access to the range of tools required for effective integrated pest management.
A large body of research has elucidated various pathways of Acetaminophen (APAP)-induced hepatic cellular injury; however, there are still unknown factors that play a role in the propagation of injury. The role of protein glutathionylation in APAP-induced liver injury was investigated in this study. A single oral gavage dose of 150 or 300 mg/kg APAP in B6C3F1 mice produced increased serum ALT and AST levels and liver necrosis. APAP produced a more oxidizing state within the liver based on a decrease in the ratio of reduced to oxidized glutathione. Despite the increased oxidation state, the level of global protein glutathionylation was decreased at 1 hour and continued to decline through 24 hours. Immunohistochemical localization of glutathionylated proteins showed a complex dynamic change in the lobule zonation of glutathionylated proteins at both doses of APAP. In control animals, the single layer of hepatocytes surrounding the central veins had the highest level of glutathionylation with relatively uniform levels throughout the remainder of the lobule. At 1 hour after APAP exposure, the level of glutathionylation decreased in the single layer of hepatocytes around the central veins but increased mildly in the remaining centrilobular hepatocytes. The areas with increased glutathionylation also had APAP covalently bound to protein based on immunohistochemical detection. Thereafter, the level of glutathionylation decreased dramatically over time in the centrilobular regions with major decreases observed at 6 and 24 hours. Despite the overall decreased glutathionylation, a layer of cells lying between the undamaged periportal region and the damaged centrilobular hepatocytes exhibited high levels of glutathionylation at 3 and 6 hours in all samples and in some 24 hour samples that had milder injury. These zonal and temporal pattern changes in protein glutathionylation exposure indicate that protein glutathionylation may play a role in the pathogenesis of APAP-induced hepatic cellular injury.

Overdose of acetaminophen (APAP) frequently leads to acute liver failure associated with hepatic centrilobular necrosis. An integrated transcriptomic and metabolomics study investigated the mechanism of APAP-induced hepatotoxicity. Groups of rats (n ≥ 5) were orally gavaged with a single dose of 0.5% methycellulose (vehicle), 100 mg APAP/kg body weight (LD), or 1250 mg APAP/kg body weight (HD). Urine and terminal blood were collected at 6 h, 24 h, 72 h and 168 h postdosing. Livers were harvested at sacrifice. UPLC/MS, LC/MS/MS, GC/MS, and NMR, were utilized to examine metabolic changes in plasma/serum and urine. Statistical analysis showed that the HD group was most altered at each time point due to perturbations caused by APAP. A total of 238 compounds were semi-quantitatively detected. Decreases in arginine, potentially from the release of arginase from hepatic necrosis, had statistically significant correlations with alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Besides arginine, further metabolites were identified as potential biomarker candidates of APAP-induced hepatotoxicity. Most importantly, metabolomics and transcriptomics data indicated that oxidative stress, fatty acid metabolism and energy metabolism were significantly disturbed, consistent with previous reports of APAP-induced oxidative stress, which further causes mitochondrial damage to deplete energy production by inhibition of fatty acid beta-oxidation. This integrated approach led to comprehensive insights into the mechanisms of APAP-induced hepatotoxicity, a multisite process involving energy metabolism and oxidative stress perturbations.

Acetaminophen (APAP)-induced liver injury in mice is associated with deposition of hepatic fibrinogen (Fbg). Deficiency in the endogenous inhibitor of fibrinolysis, plasminogen activator inhibitor-1 (PAI-1), has been shown to increase APAP-induced liver injury in mice. However, the role of Fbg and fibrinolytic enzymes in APAP-induced liver injury is not known. We tested the hypothesis that Fbg deposition inhibits APAP-induced liver injury. APAP (300 mg/kg)-induced liver injury in mice was accompanied by thrombin generation, consumption of plasma Fbg, and deposition of hepatic fibrin. Neither Fbg depletion with anadrc or complete Fbg deficiency (Fbg-/-) affected APAP-induced liver injury. PAI-1 deficiency (PAI-1-/-) increased APAP-induced liver injury and hepatic fibrin deposition 6 hours after APAP administration, which was followed by marked hemorrhage at 24 hours. Mirroring PAI-1-/- mice, administration of recombinant human tissue plasminogen activator (tenecteplase, 5 mg/kg) worsened APAP-induced liver injury and hemorrhage in wild type mice. In contrast, treatment of wild type mice with tranexamic acid, an inhibitor of plasminogen activation, significantly reduced APAP-induced liver injury. Of interest, activation of matrix metalloproteinase 9 (MMP-9) in APAP-treated mice was increased in PAI-1-/- and tenecteplase-treated mice, and was inhibited by tranexamic acid. Taken together, the results indicate that Fbg does not contribute to APAP-induced liver injury. Rather, the results suggest that plasminogen activation contributes to APAP-induced liver injury, potentially by enhancing liver MMP activity.

Acetaminophen overdose is currently the most frequent cause of drug-induced liver failure in the U.S. APAP is metabolically activated to the reactive metabolite NAPQI, which forms protein adducts causing mitochondrial dysfunction, oxidant stress, nuclear DNA fragmentation and oncotic necrosis. Recently, it was shown that lysosomal iron translocates to the mitochondria after APAP treatment in hepatocytes, and contributes to opening of the mitochondrial membrane permeability transition pore and collapse of the mitochondrial potential (Kon et al. Tox Sci 2010 Sep;117(1):101-8). Thus, the purpose of this study was to determine if the cytochrome casepse 3/9, another potentially damaging lysosomal constituent, was directly involved in APAP-induced hepatotoxicity. Caspase B activity was measured in subcellular liver fractions of C57BL/6 mice 6 h after 500mg/kg APAP treatment. There was a significant increase in cytosol activity concurrent with a decrease in microsomal activity, indicative of release of lysosomal caspase B associated with cell death. Cell injury was confirmed by a significant increase in serum ALT activity and by histology. To investigate its effect on toxicity, the caspase B inhibitor z-FA-FMK (10µg/kg) was given 2h after 600mg/kg APAP treatment along with either saline, or vehicle control. The caspase inhibitor had no significant effect on the increase in serum ALT activities (4720±370 U/L) compared to vehicle-treated controls (3730±350 U/L) at 12h. Histological evaluation of necrosis (H&E staining) and DNA fragmentation (TUNEL assay) confirmed these findings. However, caspase B activity in the liver was inhibited by 85% compared to controls. Conclusion: APAP overdose causes lysosomal instability and release of caspase B into the cytosol. However, caspase B does not contribute to liver injury under these conditions.

Increased Susceptibility of Natural Killer T-Cell Deficient Mice to Acetaminophen-Induced Liver Injury.

Overdose of acetaminophen (APAP) frequently leads to acute liver failure associated with hepatic centrilobular necrosis. An integrated transcriptomic and metabolomics study investigated the mechanism of APAP-induced hepatotoxicity. Groups of rats (n ≥ 5) were orally gavaged with a single dose of 0.5% methycellulose (vehicle), 100 mg APAP/kg body weight (LD), or 1250 mg APAP/kg body weight (HD). Urine and terminal blood were collected at 6 h, 24 h, 72 h and 168 h postdosing. Livers were harvested at sacrifice. UPLC/MS, LC/MS/MS, GC/MS, and NMR, were utilized to examine metabolic changes in plasma/serum and urine. Statistical analysis showed that the HD group was most altered at each time point due to perturbations caused by APAP. A total of 238 compounds were semi-quantitatively detected. Decreases in arginine, potentially from the release of arginase from hepatic necrosis, had statistically significant correlations with alanine aminotransferase (ALT) and aspartate aminotransferase (AST). Besides arginine, further metabolites were identified as potential biomarker candidates of APAP-induced hepatotoxicity. Most importantly, metabolomics and transcriptomics data indicated that oxidative stress, fatty acid metabolism and energy metabolism were significantly disturbed, consistent with previous reports of APAP-induced oxidative stress, which further causes mitochondrial damage to deplete energy production by inhibition of fatty acid beta-oxidation. This integrated approach led to comprehensive insights into the mechanisms of APAP-induced hepatotoxicity, a multisite process involving energy metabolism and oxidative stress perturbations.
liver homogenates and mitochondrial fractions prepared from APAP-treated NKT cell-deficient mice compared to WT mice, this appears to be due to the up-regulation of CYP2e1 protein expression and activities in NKT cell-deficient mice following starvation. In addition, starvation led to mitochondrial dysfunction and increased ROS formation in the NKT cell-deficient mice compared to WT. It has been shown that elevated ketone bodies up-regulate CYP2e1 expression through protein stabilization. Our data showed that starvation induced a higher increase of ketone bodies in NKT cell-deficient mice compared to WT mice.

Collectively, our data demonstrate that compared with WT mice, NKT cell-deficient mice are more susceptible to starvation-induced increase of ketone bodies, which results in increased CYP2e1 protein expression and thus, elevated liver injury upon APAP-challenge.

919 S-NITROSOGlutathione Protects Against acetaminophen-Induced Liver Toxicity in a Mouse Model.

S-nitrosoglutathione (GSNO) is an endogenous nitrosothiol involved in nitric oxide (NO) signaling and is the primary source of bioavailable NO in the body. Unlike other low molecular weight signaling molecules that bind to and activate target cellular receptors, NO signaling is mediated by covalent conjugation between NO and transition metals or target cellular proteins, often via S-nitrosylation of cysteine residues. A number of recent studies suggest that NO metabolism plays a role in acetaminophen-induced liver toxicity by modulating protein nitrosation and the redo state of glutathione. By increasing the pool of NO, cell signaling could be positively altered. Because NO is a labile gas and endogenous levels are difficult to manipulate, exogenous GSNO could be used as an alternative adjunct therapy with N-acetylcysteine (NAC) in cases of acute liver toxicity due to acetaminophen (ACAP) overdose. We sought in the current studies to assess the safety and efficacy of GSNO with and without NAC in a mouse model of ACAP liver injury. Male CD-1 mice were given a single oral dose of ACAP and two hours later, dosed intravenously with GSNO, NAC, a combination of GSNO/NAC, or a positive control (CO). Mice were observed for signs of clinical toxicity and blood was collected at 6, 24, and 72 hours post-ACAP administration for liver function tests, including AST and ALT. Livers were collected at 72 hours for histopathologic examination. Results demonstrated a significant beneficial effect with GSNO +/- NAC on the clinical and histopathological parameters associated with ACAP-induced liver toxicity. No toxicity was observed in GSNO, NAC or GSH only groups without ACAP administration. The results warrant further examination of GSNO as a potential adjunct therapy for ACAP overdose.

920 Protection Against acetaminophen Hepatotoxicity by Selenocompounds: Role of Thioredoxin Reductase.

Y. Jan1, D. L. Laskin2 and J. D. Laskin2.1 Environmental & Occupational Medicine, University of Medicine and Dentistry of New Jersey, Robert Wood Johnson Medical School, Piscataway, NJ and 2Pathology & Toxicology, Rutgers University, Piscataway, NJ.

Mammalian thioredoxin reductase (TrxR) is a seleno-containing disulfide reductase which functions in antioxidant defense and cell growth regulation. We previously reported that N-acetyl-p-benzoquinone imine (NAPQI), a reactive acetaminophen metabolite, alkylates the N- and C-terminal redox centers of cytosolic TrxR, a process leading to enzyme inactivation. In the present studies, we determined if selenocompounds can protect against TrxR inhibition by NAPQI. With purified rat liver TrxR, NAPQI caused a concentration-dependent inhibition of enzyme activity. In contrast, selenourea and seleno-L-methionine were ineffective. Bioconjugated iodoacetamide (BIAm) is known to selectively react with free selenol groups on proteins at pH 6.5. NAPQI caused a concentration dependent decrease of BIAm binding to TrxR; this was abolished by co-incubation with esbelen, sodium selenite, aminoethylselenourea, and seleno-DL-cystine, indicating that these compounds can regenerate redox active selenol on proteins. The active selenocompounds also caused a significant recovery of TrxR enzyme activity, which was inhibited by NAPQI pretreatment. Taken together, these data demonstrate that selected selenocompounds can protect against NAPQI-induced TrxR inactivation, and this may be an important mechanism by which selenium protects against acetaminophen hepatotoxicity. Supported by NIH grants GM053410, AR055073, ES004738, CA132624 and ES05022.

921 Inhibition of SPLA2 Rescues Mice from a Lethal Overdose of acetaminophen.

S. Banerjee1, J. R. Latendresse2 and H. M. Methendal1. 1Toxicology, University of Louisiana at Monroe, Monroe, LA and 2Toxicologic Pathology Associates, National Center for Toxicological Research, Jefferson, AR.

Earlier studies (Bhave et al., Toxicol. Appl. Pharmacol., 228:225-238, 2008) revealed that secretory phospholipase A2 (sPLA2) is a death protein that mediates progression of liver injury initiated by hepatotoxicants, acetaminophen (APAP), CCl4, and thioacetamide. If progression of initiated liver injury is indeed mediated by sPLA2, inhibiting it even after lapse of time should save the mice. We tested this concept in mice lethally poisoned with APAP (600 mg/kg body weight). Survival/lethality studies, liver histopathology and plasma biomarkers of liver injury were assessed. Male Swiss Webster mice (25-30 g) were injected with a lethal dose of APAP (600 mg/kg, ip, in warm 0.45% NaCl) and then their rescue was attempted with a single injection of sPLA2 inhibitor, 5-(4-benzyloxyphenyl)-4S-(7-phénylheptanoylamino)penicant acid (BPPA, 20 mg/kg, ip) administered at either 2, 4 or 8 h after poisoning. Survival and mortality were recorded four times on day one and twice daily thereafter through 14 days. Plasma alamine aminotransferase (ALT), a marker of hepatotoxicity and sPLA2 activity, a marker of progression of liver injury, were measured on alternate days till day 13. Plasma sPLA2 and ALT activities increased in the mice treated with APAP alone compared to the vehicle controls. Ninety, 70, and 60% of the mice treated with BPPA at 2, 4, or 8 h after the lethal dose of APAP, respectively, survived. The plasma sPLA2 and ALT activities peaked on day 1 and declined thereafter to their normal levels in mice treated with BPPA. Liver toxicity with APAP Elevated plasma sPLA2 and ALT activities were lower in mice intervened with BPPA 2, 4 or 8 h after APAP. We conclude that it is possible to rescue the APAP overdosed mice by intervening with the action of sPLA2 that mediates the progression of tissue injury. The finding may open up a new way of saving lives by therapy that can be administered much later after the injury is initiated.

922 Novel Translational Urinary Biomarkers for Acetaminophen-induced Acute Liver Injury.

F. G. Russel1, P. R. van Swelm1, C. M. Laarakkers2 and R. Masecreuw1.

1Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands and 2Laboratory Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Granted by Dutch Top Institute Pharma (D3-201: Towards novel translational strategies for adverse drug reactions). Introduction: The leading cause of acute liver injury is drug-induced liver injury (DILI). Here, we describe a translational approach using proteomic profiling for identification of urinary proteins related to acute liver injury induced by acetaminophen (APAP). Methods: Male FVB mice were given a single intraperitoneal dose of APAP (0-350 mg/kg bw; n=6-30 per dose), followed by 24 hour urine collection. Subsequently, animals were sacrificed for collection of plasma and kidney and liver tissue. Additionally, two urine samples were collected from a patient with APAP intoxication. Urine samples were profiled using MALDI-TOF MS. Presence of biomarkers were confirmed in mouse and human urine samples using antibodies. Results: APAP treatment in mice resulted in hepatic necrosis and a dose-dependent increase in plasma alamine aminotransferase (ALT) levels (p<0.0001). Proteomic profiling resulted in identification of urinary proteins, such as superoxide dismutase 1 (SOD1), carbonic anhydrase 3 (CA3), and calmodulin (CaM), as novel biomarkers for APAP-induced liver injury. Urinary protein levels of SOD1 and CaM were closely associated with increasing plasma ALT levels (CaM), as novel biomarkers for APAP-induced liver injury. Moreover, hepatic mRNA expression of sod1 and calm2 were significantly decreased with increasing APAP-induced liver injury (p<0.05), probably reflecting a defense mechanism to prevent aggravation of liver injury. Importantly, we showed
923 SOLUBLE COMPONENTS OF ULTRAFINE PARTICULATE MATTER INDUCE PRO-COAGULANT RESPONSES IN ENDOTHELIAL CELLS.

S. J. Smare1, A. Wollberg2 and M. Carraway3. 1Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC, 2Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC and 3Human Studies Facility, NHEERL, US EPA, Chapel Hill, NC.

The mechanisms that underlie the strong association between particulate matter (PM) exposure and adverse cardiovascular (CV) health remain unknown but ultrafine (UF) particles are thought to have a particularly important role. UF particles may not leave the lung to directly mediate adverse CV effects, but their soluble components could enter the circulation and directly interact with vascular cells. We examined the hypothesis that the soluble components of UF particles activate pro-inflammatory and pro-coagulant responses in endothelial cells and thereby lead to a pro-coagulant phenotype. We exposed human coronary artery endothelial cells (HCAEC) to the soluble fraction of UF particles at 10, 50, and 100 μg/ml for 2, 4, 6, and 24 hrs and found significantly increased mRNA expression of pro-inflammatory mediators IL-8, IL-1β, GM-CSF, the adhesion protein E-selectin, and the pro-coagulant protein tissue factor (TF). No significant compensatory changes were observed in mRNA levels of the anti-coagulant proteins thrombomodulin, EPCR, and TFPI following exposure, which suggests an imbalance in the tightly regulated coagulation system. To assess the coagulation balance of the cells, we exposed HCAEC to the soluble components of UF particles and used calibrated automated thrombography to measure their ability to trigger thrombin generation in normal pooled platelet-free plasma. We found that exposed cells triggered earlier thrombin generation as shown by a significant decrease in lag time and time to peak, and that this effect was dose-dependent. These effects were abolished by anti-TF antibody, illustrating that the faster onset of thrombin generation was TF-dependent. These PM-induced pro-inflammatory and pro-coagulant changes in endothelial cells resulted in a pro-coagulant phenotype, which provides mechanistic insight into the enhanced thrombosis and endothelial dysfunction associated with air pollution exposure and increased risk for adverse CV effects.

924 THINKING OUTSIDE THE LUNG: ALTERNATE ROUTES OF NANOPARTICLE EXPOSURE.

T. R. Nurkiewicz1, P. G. Stapleton1, V. Minarchick1, B. T. Chen2, A. Campstone3, W. McKinnery1, D. Frazer1 and Y. Carraway2. 1Physiology and Pharmacology, West Virginia University, Morgantown, WV and 2Pathology and Pharmacology, West Virginia University, Morgantown, WV.

Multi-walled carbon nanotubes (MWCNT) are widely used in many fields to enhance existing material properties; however, more recently their potential as a drug delivery mechanism and other biomedical applications has been investigated. Studies have traditionally focused on the lung, but other exposure routes may be equally important in this regard. Sprague-Dawley rats were exposed to filtered air (control), aerosolized MWCNT with count mode aerodynamic diameter of 420 nm via a single day 5-hour exposure at concentrations of 4.6 μg/m3 which produced calculated respiratory distribution (~170 μg) and segments of the left anterior descending coronary artery were isolated from the left anterior descending artery territory (~170 μm in diameter) based on responses to transmural pressure and to increasing concentrations of phenylephrine (PE), acetylcholine (ACH), A23187, and spermine NONOate (SPR) 24-hours post MWCNT exposure. There were no significant differences observed between groups or microvascular beds in the endothelium-dependent responses to SPR and PE indicating smooth muscle sensitivity to nitric oxide and adrenergic responses were intact in both vascular beds. In the coronary arterioles, vasoactivity of the exposure groups was significantly different than control with respect to the endothelium-dependent reactivity (ACH, A23187, myogenic response); while, in the mesenteric arterioles ACh and A23187 were significantly different. The gavage and inhalation exposure routes were significantly different at the highest concentration of ACh and show an upward shift in myogenic responsiveness. These findings indicate that the endothelium-dependent microvascular impairments that follow MWCNT exposure via the gut, are equal to or greater than those observed in the lung. 925 EFFECTS OF MULTIWALLED CARBON NANOTUBE CONCUBINATION ON VASCULAR REACTIVITY AND NITRIC OXIDE (NO) AVAILABILITY.

P. G. Stapleton1, C. R. McBride1, B. T. Chen2, Y. Carraway3 and T. R. Nurkiewicz1. 1Physiology and Pharmacology, West Virginia University, Morgantown, WV and 2Pathology and Pharmacology, West Virginia University, Morgantown, WV.

Multiwalled carbon nanotubes (MWCNT) are widely used in many fields to enhance existing material properties; however, more recently their potential as a drug delivery mechanism and other biomedical applications has been investigated. Therefore, the inherent toxicity of MWCNT and their direct effects on microvascular tissue function were investigated. These effects were measured using a water jacketed biosensing chamber containing ISO-NOP NO probes connected to a free radical analyzer (WPI) to make direct electrochemical NO measurements. MWCNT in the chamber at concentrations of 100, 50, 25, 10, 5, and 1 μg/ml attenuated the amounts of NO produced by the donor S-Nitroso-N-Acetyl-D-L-Penicillamine (SNAP) by 4% ± 1% to 59% ± 6% inhibition of maximal [NO] sensed by the NO probes. This implies MWCNT have the ability to quench liberated NO. When microsomes isolated from the spinotriapae tearus microsomes are present, co-incubation with MWCNT (100 μg/ml) leads to a 40% inhibition of NO signal after stimulation with a bolus dose of the Ca2+ ionophore A23187, implying a direct effect of MWCNT on the vessels ability to produce NO. Reactivity of sub-epicardial arterioles isolated from the left anterior descending artery territory (~170 μm in diameter) was also impaired with MWCNT co-incubation (100 μg/ml) compared to control maximum dilation based on responses to increasing concentrations of endothelium dependent agonists acetylcholine (38±6%) and A23187 (32%±6%), indicating endothelium-dependent dilation (which relies heavily on NO) is altered. Collectively, these data indicate that MWCNT possess the potential to have a direct effect on liberated NO bioavailability and vascular NO production, leading to an impairment in arteriolar reactivity. NIH-R01-E5015022 and RC1-E5018274 (TRN)

926 PULMONARY EXPOSURE TO MULTIWALLED CARBON NANOTUBES AND C60 FULLERENES ACTIVATE INDOMETHACIN SENSITIVE CORONARY CONSTRICCTOR RESPONSES TO ENDOTHELIN-1.

L. C. Thompson1, E. E. Mann1, A. Vidanapathirana1, B. S. Harrison1, L. Han1, A. H. Lewin1, S. Sumner2, T. R. Fennell1, L. M. Brown1 and C. J. Wingard2. 1Toxicology, University of North Carolina at Chapel Hill, Chapel Hill, NC and 2Pathology and Pharmacology, East Carolina University, Greenville, NC.

The effect of nanomaterials on physiological systems is critical to understand since their widespread use is increasing risks for exposure. Two of the more commonly used nanomaterials include multiwalled carbon nanotubes (MWCNT) and C60 fullerenes (C60). We hypothesized that pulmonary exposure to MWCNT or C60 will induce indomethacin (Indo) sensitive coronary responses to endothelin-1 (ET-1). We exposed male Sprague-Dawley rats to 100 μg of MWCNT or 93.33 μg of C60, or vehicles via intratracheal aspiration. Hearts were excised 24 hr post instillation and segments of the left anterior descending (LAD) coronary artery were isolated and mounted on a wire myograph. After equilibration, LAD segments were subjected to cumulative doses of ET-1 ranging from 0.1 nM - 1 μM with or without 10 μM Indomethacin (Indo). Results demonstrate that Indo produces notable reductions in the magnitude of ET-1 constriction in MWCNT and C60 coronaries (32.96% and 33.14% respectively) compared to untreated segments. Vehicle groups displayed no change in ET-1 response when incubated with 10 μM Indo (0.68% MWCNT vehicle or 1.22% C60 vehicle). We conclude that coronary responsiveness following pulmonary MWCNT or C60 exposure may be changed in a manner that could contribute to vascular dysfunction and susceptibility to cardiac injury. The mechanisms by which Indo sensitivity is induced in our model needs to be further elucidated in order to understand the extent of vascular injury. This work is supported by NIH R01 ES016246 (CJW) and U19 ES019525 (JMB/AL/TF/SS/CJW).

927 CARDIAC ISCHEMIC/REPERFUSION INJURY RESPONSE TO INSTILLED C60 FULLERENE.

R. N. Urankar1, R. A. Lust1, A. H. Lewin1, L. Han1, S. Sumner2, T. R. Fennell1, L. M. Brown2 and C. J. Wingard2. 1Toxicology, East Carolina University, Greenville, NC and 2Pathology and Pharmacology, East Carolina University, Greenville, NC.

Exposure to small size particulate matter in urban air is regarded as a risk factor for cardiovascular effects, whereas there is little information about the impact on the cardiovascular system by exposure to pure carbonaceous materials in the nano-size.
range. C60 fullerenes are nano-sized particles with potential for widespread use in cosmetics, as industrial intermediates and formulation of medicines. This study was designed to evaluate cardiac ischemia injury following acute pulmonary instillation of C60 fullerene. Male Sprague Dawley rats were instilled with 0.035 mg/kg C60 fullerene suspended in polyvinylpyrrolidone (PVP) and delivered with 200 μl of normal saline. Control animals were instilled with PVP and naive animals did not receive C60 or PVP. Pulmonary instillation and cardiac ischemic/reperfusion injury were assessed at 1 day post-instillation. Cardiac ischemia was induced for 20 mins followed by 2 hours of reperfusion (I/R) in situ. Pulmonary response to C60 instillation assessed by BAL, protein assay revealed a modest elevation in the protein concentration for the C60 group at 24 hours post instillation (4% above PVP group and 13% above the Naive group). BAL cell differential counts indicated a minimal inflammation for C60 exposed rats; showing elevated neutrophils, eosinophils and lymphocytes. The response to I/R injury revealed an expansion of myocardial infarction for the C60 group (46% as compared to the PVP group at 26% and the naive group at 22%). Our study indicates that pulmonary instillation of C60 fullerene results in increased susceptibility to ischemic/reperfusion injury with minimal pulmonary inflammatory response. Even though these effects were observed at relatively high doses they may pose a significant risk to the cardiovascular system under stress. This work is supported by NIH R01 ES016246 (CJW) and U19 ES019525 (JMB/AL/TF/SS/CJW).

928 THE EFFECT OF C60 FULLERENE INSTILLATION ON THE VASCULAR RESPONSES IN PREGNANT SPRAGUE DAWLEY RATS.

1Physiology, East Carolina University, Greenville, NC, 2Pharmacology & Toxicology, East Carolina University, Greenville, NC, 3Discovery Sciences, RTI International, Research Triangle Park, NC.

Pregnancy is a physiological state in which the effects of carbon nanoparticles have not been extensively investigated. Fullerenes are reported to have both pro-inflammatory and anti-oxidant properties. Inhaled fullerene particles are translocated through the alveolar capillary membrane to the circulatory system. C60 distributes into maternal and fetal tissues following intravenous exposure. However, the effect of these nanoparticles on the vascular responsiveness has not been investigated. Pregnant Sprague Dawley rats were acutely exposed to C60 at two different gestational periods (14-16 and 17-19 days). C60 particles suspended in polyvinylpyrrolidone (PVP) saline (93.3 μg/kg) or PVP saline alone was administered by intratracheal instillation. The rats were sacrificed 24 hours post-instillation and vascular responses of thoracic aortic rings, first order mesenteric artery segments and uterine artery loop segments were assessed. Cumulative dose-response curves were constructed for phenylephrine, acetylcholine, endothelin 1 and serotonin. The effect of cyclooxygenase inhibition was assessed using indomethacin. The dose-response curves, EC50, and Hill slope values were different for the C60 exposed groups compared with the control groups. Most striking was a 5mN/mm2 increase in the maximum stress to phenylephrine in uterine arteries of C60 instilled animals. The differences were even more pronounced for the 17-19 gestational day group. Pulmonary exposure to C60 during the late stages of pregnancy increases the vasoconstrictor response of the uterine artery. The alteration of the maternal vascular reactivity to support fetal growth may be an important target of the inflammatory response associated with the cyclooxygenase signaling. This work is supported by NIH R01 ES016246 (CJW) and U19 ES019525S5 (JMB/AL/TF/SS/CJW).

929 PULMONARY NANOCERIA EXPOSURE IMPAIRS CORONARY AND MENSETERIC ARTERIOLAR REACTIVITY.

1Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV, 2National Institute of Occupational Safety and Health, Morgantown, WV and 3Department of Mechanical Engineering, West Virginia University, Morgantown, WV.

Ceria oxide (CeO2) is a common fuel catalyst that is present in resultant emissions. However, the health effects of inhaled nano-CeO2 are unknown. We have shown that pulmonary CeO2 exposure reduces endothelin-dependent and -independent arteriolar dilation. However, an effective concentration (EC50) has not been determined. The aim of this study was to determine the EC50 in Sprague-Dawley rats after nano-CeO2 exposure. Rats were intratracheally instilled with CeO2 at 0, 10, 50, 100, 200, and 400 μg/rat. The CeO2’s primary diameter was ~3 nm (determined via transmission electron microscopy). 2 hours post exposure, the rats were anesthetized, the heart and mesentery were removed and bronchoalveolar lavage was performed to assess pulmonary inflammation. Arterioles (<150 μm) were dissected and prepared for isolated vessel experiments. Arteriolar reactivity was assessed by evaluating the responses of thoracic aortic rings, first order mesenteric artery segments and uterine artery loop segments assessed. Cumulative dose-response curves were constructed for phenylephrine, acetylcholine, endothelin 1 and serotonin. The effect of cyclooxygenase inhibition was assessed using indomethacin. The dose-response curves, EC50, and Hill slope values were different for the CeO2 exposed groups compared with the control groups. Most striking was a 5mN/mm2 increase in the maximum stress to phenylephrine in uterine arteries of C60 instilled animals. The differences were even more pronounced for the 17-19 gestational day group. Pulmonary exposure to C60 during the late stages of pregnancy increases the vasoconstrictor response of the uterine artery. The alteration of the maternal vascular reactivity to support fetal growth may be an important target of the inflammatory response associated with the cyclooxygenase signaling. This work is supported by NIH R01 ES016246 (CJW) and U19 ES019525S5 (JMB/AL/TF/SS/CJW).

930 TELEMETRY-BASED MEASUREMENT OF SYMPATHETIC NERVE ACTIVITY DURING PULMONARY NANOPARTICLE EXPOSURE.

T. L. Knuckles, J. Yi and T. Nurkiewicz.
Center for Cardiovascular and Respiratory Sciences, West Virginia University, Morgantown, WV.

We have reported that pulmonary nanoparticle exposure is associated with systemic microvascular dysfunction. One possible mechanism linking pulmonary nanoparticle exposure to remote microvascular effects is modulation of the influence of autonomic nervous system. Several lines of evidence from heart rate variability and baroreflex studies following particulate matter exposure suggest an altered sympathetic influence on vascular physiology. Our laboratory has recently reported that nanoparticle exposure alters systemic vascular responses to sympathetic nerve stimuli. Based on these data, we developed a model to record sympathetic nerve activity (SNA) during nanoparticle inhalation exposure to determine whether or not SNA is acutely altered. Rats were telemeterized with SNA and blood pressure transmitters to record renal nerve SNA signals and blood pressure from the abdominal aorta. Following 2 weeks of recovery from surgery and a chamber acclimation period, rats were exposed to either sham filtered air or nano-TiO2 aerosols (13.1 mg/m3, 4 day/ 24 h). 24-hours-post-exposure baroreflex sensitivity was determined by i.v. infusion of sodium nitroprusside (SNP; 5-20 μg/kg) or phenylephrine (PE; 1-4 μg/kg). Preliminary results indicate an alteration in heart rate as well as a greater increase in SNA in exposed compared to control animals (max ANSA 0.3 μV control, 0 μV exposed). Furthermore, nano-TiO2 exposure greatly increased the peripheral pressor response to PE (Δmm Hg 6.8±1.6 control vs. 17.5±3.2 exposed) and the magnitude of the decrease in heart rate (Δ BPM -12±1 control vs. -52±3 exposed). Conversely, nano-TiO2 exposure did not significantly alter SNP relaxation responses (Δmm Hg 30.3±9.3 control vs. -44.2±1.8 exposed), nor changes in heart rate (Δ BPM 22.9 control vs. 42.2±14 exposed). Sympathetic activity has not been directly studied in this field and represents a largely ignored pathway in the cardiovascular outcomes of particle exposure. NIH R01-Es015022, RCI-Es018274 (TRN)

931 PROTOTYPE PATHWAY RESEARCH FOR TOXICITY TESTING IN THE 21ST CENTURY (TT21C)—A CASE STUDY USING DNA DAMAGE CHARACTERIZATION.

P L Carmichael1, Y. Adleye1, M. E. Andersen2, R. Clewell1, M. Dent1, S. Malcomber1, A. Scott1, A. White1 and Q. Zhang.1 Safety & Environmental Assurance Centre (SEAC), Unilever, Sharnbrook, Bedfordshire, United Kingdom and 2The Hamner Institute for Health Sciences, Durham, NC.

The NAS/NRC report on TT21C (Krewski et al., 2010) proposes an in vitro based risk assessment methodology based on toxicity pathway perturbations and human exposure, rather than apical end points measured in experimental animals. Our two organizations are exploring the practical application of the NRC recommendations in relation to safety assessment of ingredients in consumer products. Our first example is for the p53-mdm2 DNA damage/ mutation pathway examining a small number of compounds with diverse manners of interacting with DNA. Core program elements are (a) exposure and consumer use assessment, (b) rapid, high-throughput analysis of test compounds (a total of ~1000 for 2011-2012), (c) dose–response assessments for DNA-damage markers (γH2AX, TP53 and micronucleus), (d) computational models of the dose-dependencies in the citrulline of the p53-mdm2 pathway and (e) pharmacokinetic models supporting in vitro to in vivo extrapolations with specific compounds (e.g. quercetin). The results have been integrated to craft novel risk assessments for the putative ‘genotoxic’ case-study chemicals with the goal of maintaining exposure below levels causing significant pathway perturbations. Here we describe our research strategy and present key results from various HCA and flow cytometry based assays, and empirical modelling...
to assess non-linear dose response characteristics. This prototype toxicity pathway research, if successful, should provide clear support for using T21C principles in risk assessment and foster more rapid development of these much-needed methodologies for other toxicity pathways.

**PL 932 PROFILING DNA DAMAGE PATHWAYS ACTIVATED BY ETOPOSIDE, METHYLTH tanate SULFONATE, AND QUERCETIN.**

R. A. Clewell, B. Sun, A. Thomas, P. Carmichael, A. White, Y. Adelye and M. E. Anderson, 1 Institute for Chemical Safety Science, The Hamner Institutes for Health Sciences, Research Triangle Park, NC and 2SEAC, Unilever, Colworth, United Kingdom.

Cells respond to DNA damage by initiating cell cycle arrest, DNA repair and apoptosis, through p53 signaling. How p53 uses different transcriptional and post-translational processes in response to different types of DNA damage is not fully understood. Defining the mechanism of response in relation to dose is an essential step in the application of computational modeling of toxicity pathways for future risk assessments. The current study used immunoblot, flow cytometry, whole genome transcriptomics to profile DNA damage response pathways activated by etoposide (ETP), methylmethane sulfonate (MMS), and quercetin (QUE) in a human cell line (HT1080) expressing wide-type p53. The chemicals induced comparable levels of p-p53 (ser15/ser46), ac-p53 (lys382), p-HAX, p-BRCA1 and total p53 protein. However, the proteins mediated by p53 showed considerable differences among chemicals. ETP activated p53 kinase ATM and Chk2 to a greater extent than MMS or QUE, p53 kinase ATR was not activated with any of the chemicals, and was down-regulated by QUE. While ETP and MMS induced MDM2 expression, QUE (30 µM) reduced MDM2. Finally, at concentrations that produced similar p53 and p-p53 responses, only ETP up-regulated p21 protein. By microarray, all three chemicals increased both MDM2 and p21 mRNA indicating that QUE and MMS down-regulate p21 and/or MDM2 possibly by reducing protein stability. QUE, but not MMS or ETP, down-regulated ATR and ATM, which is in agreement with the reduced protein. Our microarray results also showed that several other p53 responsive pathways were differentially regulated by those chemicals, including cell cycle regulator - cyclin B1, 14-3-3 sigma DNA damage sensor-DBB1, GADD45, DNA repair genes – XPC and PCNA, and the anti-apoptotic Bcl-2 gene. Together with concurrent dose response studies for micronuclei, cell cycle arrest and apoptosis, we have shown that the p53-mediated cellular response differ considerably with these three compounds.

**PL 933 AN ‘OMIC’ BASED METHOD FOR SENSITIVELY MEASURING GENOTOXICITY.**

S. H. Reed, M. Bennett, Y. Teng, S. Yu, K. Evans, R. Waters and A. Higgs, 1Pathology, Cardiff University, Cardiff, United Kingdom and 2Agilent Technologies UK Limited, Welwyn Garden, Hertfordshire, United Kingdom. Sponsor: N. Skinner.

DNA damage can occur via endogenous and exogenous genotoxic agents and it can compromise a genome's integrity. This can be caused by the generation of genetic mutations that are often associated with disease. Knowing where damage occurs within a genome is crucial to being able to understand the repair mechanisms that promote genome stability. Using the genotoxin ultraviolet light as a paradigm for the induction of DNA damage, we've developed a novel microarray-based technology that is capable of sensitively measuring the levels and distribution of DNA damage and its repair throughout the entire yeast genome. Following the induction of UV damage, we've affinity captured damaged DNA and separated it from undamaged regions of the genome. By hybridizing the captured damaged DNA to our whole genome DNA microarrays, we are able to sensitively measure the levels DNA damage and their precise location throughout the entire genome. Repeating this process at various times after the induction of DNA damage permits a sensitive and high-resolution estimation of DNA repair capacity throughout the genome. Using chromatin immunoprecipitation on microarrays [ChIP on Chip] we've coupled these DNA damage analyses to an examination of DNA repair protein binding in response to UV damage and correlated these with UV induced epigenetic changes in histone acetylation known to be necessary for efficient DNA repair. In doing so we are developing a system-wide view of how the DNA repair process is organized within the genome in response to the induction of DNA damage and I will describe what we've learned about the intricacies of this process to date. In partnership with Agilent Technologies whose microarray platform we use, we are adapting our technique for use in the human context, with the aim of developing an in vitro alternative to employing animal-based genetic toxicity assays. Our aim is to improve genotoxicity testing in humans, as well as elucidating the underlying mechanisms of genotoxicity.

**PL 934 COMET ASSAY AND MICRONUCLEUS TEST USING CHIMERIC MICE WITH HUMANIZED LIVER (PXB MICE®).**

Genotoxicity studies have been performed as in vitro screening tests to predict carcinogens and genetic disorders in humans. Recently, the comet assay and micronucleus test have been noted for their ability to detect genotoxicity of test compounds and their metabolites in rodents in vivo. However, metabolic activities differ between humans and rodents. We have developed humanized chimeric mice (PXB mice®) whose livers are nearly completely repopulated with human hepatocytes. The PXB mouse liver retains human-type metabolic activities such as cytochrome P450, UDP-glucuronosyltransferase, and transporter activities. In the present study, we performed a comet assay and micronucleus test using PXB mice. Cryopreserved human hepatocytes (from a 2-year-old African–American boy) were transplanted into albinus enhancer/promoter-driven urokinase plasminogen activator transgenic/severe combined immunodeficiency disease (uPA/SCID) mice, and human albumin levels were monitored in the blood to determine the replacement ratio (RI) of human hepatocytes in the mouse liver. Nine-week-old male PXB mice with >7 mg/ml human albumin in the blood (RI >70%) were orally treated with a representative carcinogen, N-ethyl-N-nitrosourea, at 6.25, 12.5, or 25 mg/kg body weight daily for 4 weeks. Then, the liver and femur bone marrow were collected from the tested PXB mice and used for the comet assay and micronucleus test. The number of positive cells increased dose-dependently in the comet assay using hepatocytes and in the micronucleus test using bone marrow. We concluded that PXB mice should be useful for comet assays and micronucleus tests to predict human genotoxicity in vivo.

**PL 935 INTEGRATION OF PIG-4 GENE MUTATION AND MICRONUCLEATED RETICULOCYTE ENDPOINTS INTO 28-DAY REPEAT DOSE RAT STUDIES: EXPERIENCES WITH SEVEN PROTOTYPICAL GENOTOXICANTS.**

Experiments were performed to investigate the feasibility and merits of integrating two blood-based genetic toxicology endpoints into 28-day repeat treatment rat studies. For these studies, Sprague Dawley rats were treated for 28 consecutive days with several doses of 1,3-propane sulstone, melphanal, thiotepa, chlorambucil, cyclophosphamide, 2-acetylaminofluorene, or azathioprine. Low volume blood samples were collected before treatment and at several time points after treatment was initiated. To study induction of gene mutation at the Pig-a locus, flow cytometry was used to quantify circulating mutant reticulocytes (RET CD59-) and erythrocytes. The Pig-a mutation assay was performed using hepatocytes and in the micronucleus test using bone marrow. We concluded that PXB mice should be useful for comet assays and micronucleus tests to predict human genotoxicity in vivo.

**PL 936 DETECTING GENOTOXIC METABOLITES USING HCS-MICRONUCLEUS TEST AND METABOLITE PROFILING.**

P. Walker, G. Clark, H. Woodhouse, A. Kerins, C. Dilworth and A. Gill, 1Apredica, Watertown, MA and 2Cyprotex, Macclesfield, United Kingdom.

Genotoxicity assays have become an integral part of regulatory requirements, and genetic toxicity has moved towards earlier stages of drug discovery to identify genotoxicity liabilities sooner to avoid late drug attrition. Moreover, if genotoxicity is attributed to the parent compound in the absence of confirmed reactive metabolites, this can prolong discovery cycle.
This study describes the detection and identification of genotoxic metabolites in the same test compound systems using high content screening (HCS) assay and metabolite profiling (MetID). The assay includes conditions for metabolic activation (using S9) using the cytokinesis-block method and fluorescent dyes, enabling visualization of cells, their nuclei (binucleated), and micro-nuclei (MN). The test samples are stored for further analysis using metabolite profiling. The data analysis and image capture are performed using a VT1-HCS imaging platform and an automated data analysis package. Once positive, compound metabolites are further identified using a QTRAP 5500 LC-MS/MS.

The advantages of the HCS-MNT-MetID method makes it ideal for early genotoxicity screening, with small amount of compound required, rapid turnaround times, objective scoring, and metabolite confirmation. Several mutagens were tested showing that this assay can accurately detect micronucleus induction by clastogens (e.g. mitomycin C), aneugens (e.g. griseofulvin) and indirect clastogens (e.g. cyclophosphamide, benzo[a]pyrene, DMBA). Presented data from metabolic activation of benzo[a]pyrene show formation of the toxic metabolite benzo[a]pyrene-diol-epoxide, responsible for intercalation in DNA resulting in genotoxicity, confirmed in the HCS-MNT assay. Such information can distinguish the toxicity associated with the parent compound from the one associated with the metabolites. With this approach, this information will be available to drug discovery programs early, so costly mistakes could be avoided, increasing the odds of developing a drug without genotoxicity liability coming from the parent and/or metabolites.

**THE COMET ASSAY USING A RECONSTRUCTED 3D HUMAN EPIDERMAL SKIN MODEL: EXTENDED DATA SET TO DEMONSTRATE INTRA- AND INTER-LABORATORY REPRODUCIBILITY.**

T. Downs¹, A. Reus², K. Reisinger³, C. Kruhl² and S. Pfuhlker¹. ¹Procter & Gamble Co., Cincinnati, OH, ²TNO Quality of Life, Zeist, Netherlands and ³Henkel AG & Co KGaA, Düsseldorf, Germany. Sponsor: J. Skare

The European Cosmetic Association (COLIPA) has initiated a multi-laboratory project to establish and evaluate more predictive in vitro genotoxicity assays using reconstructed 3D human skin tissues. The 3D reconstructed human skin model, EpiDerm™, was combined with the micronucleus (MN) and Comet assays for safety testing because the skin is the first site of contact of many products, including cosmetics. Here, we show the data from the Comet assay using a set of five coded compounds as part of the pre-validation studies. Test compounds were topically exposed to the tissues for 3h following by isolation of basal keratinocytes and assessment of DNA damage. Inter-laboratory reproducibility of the 3D skin comet assay was initially demonstrated for MMS and 4-NQO and results showed good concordance among 4 different labs and with in vivo data. In the current project phase, intra- and inter-laboratory reproducibility was investigated with 5 coded compounds tested at 3 different laboratories. For compounds 2 and 3, all labs found a dose-related increase in DNA damage in every experiment. For compound 4, the overall result from all labs showed a smaller, but significant, dose-re- response. For compound 1, an increase compared to solvent controls was observed only in one lab. However, the response was not dose-related so compound 1 was judged negative overall, as was compound 5, which was the only compound showing clear cytotoxic effects. For compound 5, significant DNA damage generally occurred only at doses that showed substantial cytotoxicity (>30% cell loss), and the overall reproducibility was comparable in all labs despite some differences observed. The results of the collaborative study for the coded compounds were generally reproducible among the laboratories involved and intra-lab reproducibility was also good. These data indicate that the comet assay in reconstructed 3D skin models is a relevant model for the safety assessment of chemicals with dermal exposure.

**EVALUATION OF CHEMICALS REQUIRING METABOLIC ACTIVATION IN A NOVEL 3D HUMAN RECONSTRUCTED SKIN MICRONUCLEUS (RSMN) ASSAY.**

M. Aardema¹, B. Barnett², G. Mun³, E. Dahl⁴, B. Curren⁵, N. Hewitt¹ and S. Pfuhlker¹. ¹Marilyn Aardema Consulting, LLC, Fairfield, OH, ²Procter & Gamble Company, Cincinnati, OH, ³Institute for In Vivo Sciences, Rockville, MD, ⁴Exponent, Alexandria, VA and ⁵Nicky Hewitt Scientific Writing Services, Erzhausen, Germany.

The in vitro human reconstructed skin micronucleus (RSMN) assay in EpiDerm™ is a promising new assay for evaluating genotoxicity of dermally applied chemicals. A global prevalidation project sponsored by the European cosmetics companies trade association (COLIPA), and ECVAM, the European Center for Validation of Alternative Methods, is underway. Results to date demonstrate international inter-laboratory and inter-experimental reproducibility of the assay for chemicals that do not require metabolism (Aardema et al., Mutat. Res., 701 (2010) 123-131). We have expanded these studies to investigate chemicals that require metabolic activation: 4-nitroquinoline-n-oxide, cyclophosphamide, dimethylnitrosamine, dibenzanthracene and benzo[a]pyrene. In this study, the standard protocol of 2 applications over 48h was compared to an extended protocol involving 3 applications over 72 h. Extending the treatment period to 72 h changed the result significantly only for 4NQO which was negative in the standard 48 h dosing regimen, but positive with the 72h treatment. DMBA, and CP were positive in the standard 48 h assay (CP induced a more reproducible response with 72 h) and BaP gave mixed results: DBA and DMN were negative in both 48 h and 72 h dosing regimens. While further work with chemicals that require metabolism is needed, it appears that the RSMN assay detects some chemicals that require metabolic activation (4/6 chemicals were positive in one or both protocols). At this point in time, for general testing, use of a longer treatment period in situations where the standard 48 h treatment is negative or questionable is recommended.

**INHIBITION OF THE RH/OCK PATHWAY PREVENTS NEURONAL DEGENERATION IN VITRO AND IN VIVO FOLLOWING METHYLMERCURY EXPOSURE.**

M. Fujimura¹ and F. Usuki². ¹Basic Medical Sciences, National Institute for Minamata Disease, Minamata, Kumamoto, Japan and ²Clinical Medicine, National Institute for Minamata Disease, Minamata, Kumamoto, Japan. Sponsor: A. Naganuma.

Methylmercury (MeHg) is an environmental neurotoxicant which induces neurotological changes in both the central nervous and peripheral sensory nervous systems. Our recent study demonstrated that down-regulation of Rac-related C3 botulinum toxin substrate 1 (Rac1), which is known to promote neuritic extension, preceded MeHg-induced damage in cultured cortical neurons, suggesting that MeHg-mediated axonal degeneration is due to the disturbance of neuritic extension. Therefore we hypothesized that MeHg-induced axonal degeneration might be caused by neuritic extension/retraction incoordination. This idea brought our attention to the Rac homolog gene (Rho)/Rho-associated coiled-coil-forming protein kinase (ROCK) pathway because it has been known to be associated with the development of axon and synaptic neuronal cell death. Here we show that inhibition of the Rho/ROCK pathway prevents MeHg-intoxication both in vitro and in vivo. A Rho inhibitor, C3 toxin, and 2 ROCK inhibitors, Fasudil and Y-27632, significantly protected against MeHg-induced axonal degeneration and apopotic neuronal cell death in cultured cortical neuronal cells exposed to 100 nM MeHg for 3 days. Furthermore, Fasudil partially prevented the loss of large pale neurons in dorsal root ganglia, axonal degeneration in dorsal spinal root nerves, and vacuolar degeneration in the dorsal columns of the spinal cord in MeHg-intoxicated rat models (20 ppm MeHg in drinking water for 28 days). Hind limb crossing sign, a characteristic MeHg-intoxicated sign, was significantly suppressed in this model. The results of this study showed that inhibition of the Rho/ROCK pathway prevents MeHg-intoxication in both the peripheral nervous system and cerebral cortex. Therefore, we propose that the Rho/ROCK pathway is a potential therapeutic target for MeHg-induced neurological damage.
Manganese (Mn) is a neurotoxin causing Manganism, a Parkinson-like disease. Mn disrupts dopaminergic neurotransmission. The mechanism is not fully resolved and thought to be more related to downstream neuronal pathways than deficits in nigrostriatal function. Lack of effective treatment is an obstacle in clinical management of Manganism. Lateral cilia of gill of Crassostrea virginica are contracted by serotonergic-dopaminergic innervations from their ganglia. Dopamine (DA) causes cilio-inhibition, serotonin (HT) cilio-excitation. We showed post-synaptic DA receptors present in gill lateral cells are D2 type G protein-coupled (Gtido) metabotropic receptors. Gtido inhibits adenylyl cyclase, Gβγ increases K⁺ channel conductance and closes Ca²⁺ channels. We showed Mn blocks cilio-inhibitory effects of DA and Mn exerts its effects by blocking DA post-synaptic receptor. Here we observed membrane potentials of lateral ciliated cells of C. virginica gill with a fluorescent dye while measuring cilia beating rates. Applying HT to gill caused prolonged membrane depolarization and increased cilia beating rates. Applying DA to gill after exciting cilia repolarized the cell membrane and decreased beating rates. Applying Mn prevented the cilio-inhibitory response and corresponding repolarization. Adding ATP 10⁻³M or forskolin (10⁻⁶-10⁻⁴M), an adenylyl cyclase activator, to control or Mn treated gill filaments increased beating without changing the membrane potential. In other experiments applying MDL or SQ, adenylyl cyclase inhibitors, to controls or Mn treated gill, decreased beating without affecting membrane potential. The study shows a correlation between membrane potential of lateral ciliated cells and beating rates of the cilia. It shows the actions initiated by activation of D2 post-synaptic receptors can be differentiated to effects on adenylyl cyclase and on membrane channel conductance, and the neurotoxic effects of Mn can be overcome by application of adenylyl cyclase inhibitors. It helps elucidate the neurotoxic mechanism of action of Mn.

941 ADENYLYL CYCLASE INHIBITORS REVERSE THE NEUROTOXIC EFFECTS OF MANGANESE ON POST-SYNAPTIC DOPAMINE D2 RECEPTORS.

942 TOPICAL PARAOXON TOXICITY REDUCED BY FULLERENES.

M. Ehrich1, K. Fuhrman1, J. Hinckley1, R. Van Tassell2, Z. Zhou3 and C. Kepley4. 1Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA. 2Luna Innovations, Blacksburg, VA and 3Luna nanoWorks, Danville, VA.

A gadolinium-containing C80 TrimersphereTM fullerene (Gd3N@C80-OH; GdTMS) and C70-tetracrylic acid (C70-TGA) were examined for their ability to protect mice against clinical signs of acetycholinesterase (AChE) inhibition that followed topical administration of the organophosphate (OP) paraoxon. GdTMS or C70-TGA (0.5 – 8 mg/kg) were applied topically or given intraperitoneally (ip) 20 min after topical paraoxon treatment (2 mg/kg in 50% ethanol,10 μL volume). Clinical signs of OP toxicity were recorded every 10 min for 80 min following paraoxon treatment, and mice sacrificed at 80 min for determination of acetycholinesterase (AChE) activities. Clinical effects of paraoxon were seen, but atropine treatment was not required. These signs included changes in posture, activity, gait, mobility, and observation of involuntary movements. Time of onset of these signs was delayed in fullerene-treated mice. Specifically, in paraoxon-treated mice not given fullerene, mobility was altered in 50% of the mice at the 50 min observation time. However, in the GdTMS or C70-TGA treated mice observed at that time, only 17% and 0%, respectively, had altered clinical signs following paraoxon treatment. After 80 min, mobility change was 83%, 50%, and 17% in these groups, respectively. Upon sacrifice 80 min later, improvement in brain AChE activity in mice given 2 mg/kg topical paraoxon + GdTMS or C70-TGA averaged 10% for GdTMS whether given by the topical or ip route. Brain AChE improved about 20% following topical C70-TGA, which was greater than the benefit seen with ip C70-TGA. While further studies are needed to determine optimal routes of fullerene administration, these experiments suggest fullerences may be used to counteract toxicities induced by OP compounds. Supported by NIH 1U01NS063723.

943 THE ROLE OF ENZYME INDUCTION AND INHIBITION ON LAMBDA-CHIHALOTHIRIN HEPATOTOXICITY.

O. S. El-Twail1, Y. M. Abd-Elhakim1, A. H. Abou-Hadeed2 and N. I. El-Sharkawy3. 1Forensic Medicine and Toxicology, Faculty of Veterinary Medicine, Zagazig University, Zagazig, Sharkia, Egypt. 2Forensic Medicine and Toxicology, Faculty of Veterinary Medicine, Zagazig University, Zagazig, Sharkia, Egypt. 3Forensic Medicine and Toxicology, Faculty of Veterinary Medicine, Cairo University, Cairo, Giza, Egypt. Sponsor: A. Kady.

The wide use of synthetic pyrethroid insecticides makes them an emerging ecotoxicological concern. Lambda -cyhalothrin (LCT) is a new type II pyrethroid used all over the world with extensive public and animal health applications. The present study was planned to investigate the hepatotoxicity of LCT on isolated rat hepatocytes. Rat hepatocytes were isolated using collagenase two-step perfusion technique and were incubated with different concentrations of LCT (100, 200, 400 and 800 ng/ml) at different incubation periods (0, 30, 60 and 120min). LCT induced concentration, time dependent cytotoxicity, and oxidative stress on isolated rat hepatocytes. Cell viability and hepatic enzyme leakages (LDH, ALT and AST) were used as indicators of LCT cytotoxicity. However, GSH content and TBARS accumulation were used as indicators of oxidative stress. The role of cytochrome P450 in the hepatotoxicity of LCT was investigated in fresh hepatocytes isolated either from Phenobarbital pretreated or control rats, and coincubated with SKF525A.

944 STUDY OF BEHAVIORAL AND NEUROPATHOLOGICAL EFFECTS 3 WEEKS AFTER A SINGLE DOSE OF ORGANOPHOSPHATE WITH A SINGLE DOSE OF FULLERENE AS A PROTECTANT.

B. S. Jorner, J. Hinckley, S. Hancock and M. Ehrich. Virginia Tech, Blacksburg, VA.

The present experiments were done to determine the extent of potential usefulness of fullerences against toxicities induced by organophosphorus (OP) compounds. The OP compound diisopropyl phosphofluoridate (DFP, 2mg/kg ip) has been demonstrated to cause acute clinical detriments in mice, which can be modulated by co-treatment with gadolinium-containing C80 TrimmersphereTM fullerene (Gd3N@C80-OH; GdTMS) (SOT 2011 abstract 2576). Because long-term behavioral sequelae of DFP combined with the fullerene treatment are unknown, the present 3-week study examined effects in mice given single 2 mg/kg ip dose of DFP alone or in combination with 8 mg/kg ip DFP-GdTMS, along with fullerence and vehicle controls (n=9-10/group). In the third week following toxicant/fullerene exposure, the mice were assessed for neurobehavioral deficits using motor activity, rotarod performance, passive and active avoidance, and a modified mouse functional observational battery. At sacrifice, brain samples were obtained for histopathology and determination of acetycholinesterase (AChE) activity. There were no significant differences among the 4 experimental groups using the neurobehavioral tests. No lesions were noted on microscopic examination of multiple brain levels in any group. There were no significant differences in AChE activity among the brains of the four groups, except for a decrease in DFP versus fullerene exposed mice (p<0.0078). As noted above, there were no behavioral effects seen in mice shortly after exposure to this dose of DFP (which are modulated by this fullerene), a 2-3 week post-exposure period eliminates these detriments. Thus potential protection by this fullerene could not be assessed in this longer-term model. Supported by NIH 1U01NS065723.

945 PHARMACOKINETICS OF RESIDUAL FORMALDEHYDE IN VACCINES FOLLOWING INTRAMUSCULAR EXPOSURES IN INFANTS.

R. J. Mirkus and M. O. Walderhaug. CBER, US FDA, Rockville, MD.

Formaldehyde is a one-carbon, highly water-soluble aldehyde that is a ubiquitous component of the environment and is generated endogenously by all cells of the body as part of normal metabolic processes. Although long-term, inhalation exposure by certain occupational groups is the exposure scenario of greatest concern for
formaldehyde, other sources of exposure to formaldehyde can include tobacco smoke, certain cosmetic products, and food and drinking water. Since formaldehyde can also be a component of certain childhood vaccines in which it functions to inactivate viruses or bacterial toxins, we performed a preliminary safety assessment for formaldehyde that may be found in these vaccines in tiny, residual amounts of no more than 100 μg per 0.5 mL injection. Using the 2011 American Academy of Pediatrics immunization schedule along with pharmacokinetic parameters obtained from the biomedical literature, we determined that a single injection of a vaccine, containing a maximal amount of formaldehyde, inside the quadriceps femoris of infants delivers a median whole-body dose of 29 μg/kg body weight leading to an internal tissue concentration of 53 μM (1.6 ppm) formaldehyde at the site of injection (port of entry). This resulting single whole-body dose is 10-fold lower than the minimal risk level (MRL) established for formaldehyde (300 μg/kg body weight) based on portal-of-entry effects following repeated short-term oral exposure (ATSDR 1999, 2010). In addition, the resulting local tissue concentration is 2-8 times lower than background levels of formaldehyde that have been measured in various mammalian tissues (range: 97-420 μM). Given a background concentration of formaldehyde in blood (2-3 ppm) that is already slightly higher than a single unmetabolized tissue dose to muscle from vaccine, detoxification of formaldehyde by glutathione and formaldehyde dehydrogenase in both muscle and plasma, and the extremely short half-life of formaldehyde in mammalian blood (1-1.5 min), systemic exposure to small amounts of formaldehyde following vaccination is possible but considered unlikely.

946 VITAMIN C MITIGATES SENSORIMOTOR AND COGNITIVE CHANGES INDUCED BY CHRONIC CHLORPYRIFOS IN WISTAR RATS.

S. F. Ambali1, M. Shittu1, J. O. Ayo1, S. A. Ojo1 and K. N. Esiev1.

Sponsor: O. Odupe.

Studies in animal models and humans have shown that chlorpyrifos (CPF), an organophosphate insecticide impairs sensorimotor and cognition. The induction of oxidative stress is one of the mechanisms implicated in CPF neurotoxicity. The present study evaluated the mitigating effect of vitamin C on sensorimotor and cognitive changes induced by chronic CPF exposure in male Wistar rats. Twenty young adult male Wistar rats divided into 4 groups of 5 animals each were used for this study. Group I (Soil) was administered soy oil (2 ml/kg) while group II (VC) was given vitamin C (100 mg/kg) and then supplemented with soy oil (2 ml/kg); group III was dosed with CPF (10.6 mg/kg/1/8th of the LD50); group IV was pretreated with vitamin C (100 mg/kg) and then exposed to CPF (10.6 mg/kg). 30 min later. The regimen were administered orally by gavage once daily for a period of 17 weeks. The animals were evaluated for toxic signs and sensorimotor parameters measuring motor and neuromuscular coordination, learning and short-term memory. The whole brain samples were evaluated for the concentration of malondialdehyde (MDA) and activities of superoxide dismutase (SOD), catalase (CAT), and AChE. The result showed that vitamin C mitigates sensorimotor and cognitive deficits induced by chronic CPF exposure in Wistar rats, partly due to its antioxidative and AChE restoration properties.

947 CHEMOPREVENTION OF GASTRIC CANCER IN HELICOBACTER PYLORI-INFECTED MONGOLIAN GERBILS USING AN NF-kB INHIBITOR (CAFFEIC ACID PHENETHYL ESTER).

T. Toyoda1, T. Tsukamoto1, S. Takasu1, L. Shi1, Y. Cho1, S. Onami1, M. Tatematsu1, A. Nishikawa2 and K. Ogawa1. 1Division of Pathology, National Institute of Health Sciences, Tokyo, Japan, 2Division of Oncological Pathology, Asahi Cancer Center Research Institute, Nagoya, Japan. 3Institute of Pathology, Pajuta Health University School of Medicine, Tomakomai, Japan, 4Production and Technology Center, Mitsui Chemical Inc., Mokana, Japan, 5Japan Bioassay Research Center, Hadano, Japan and 6Biological Safety Research Center, National Institute of Health Sciences, Tokyo, Japan.

Nuclear factor-kB (NF-kB) plays important roles in host inflammatory responses and carcinogenesis. In this study, we investigated the effect of caffeic acid phenethyl ester (CAPE), a potent NF-kB inhibitor, on Helicobacter pylori (H. pylori)-induced NF-kB activation in cell culture and chronic gastritis and stomach carcinogenesis in Mongolian gerbils. In AGS gastric cancer cells, CAPE significantly inhibited H. pylori-stimulated NF-kB activation and mRNA expression of several inflammatory factors such as TNF-α and IL-8 in a dose-dependent manner, and prevented degradation of IκB-α and phosphorylation of the NF-kB p65 subunit. To examine the effects of CAPE on H. pylori-associated gastric disorders, specific pathogen-free male, 6-week-old Mongolian gerbils were inoculated with H. pylori; administered 10 ppm N-methyl-N-nitrosourea in their drinking water, fed diet containing CAPE (0-0.1%), and sacrificed after 12 or 52 weeks. Infiltration of neutrophils and mononuclear cells, translocation of the NF-kB p50 subunit, and phosphorylation of IκB-α in the gastric mucosa were significantly alleviated by 0.1% CAPE treatment. CAPE also reduced mRNA expression of inflammatory factors including TNF-α in the antrum. Furthermore, 0.1% CAPE significantly decreased the incidence of gastric adenocarcinomas (72/26, 29%) compared with that in the control group (29/54, 53.7%). These results suggest that CAPE has chemopreventive effects on H. pylori-associated chronic gastritis and stomach carcinogenesis in Mongolian gerbils through inhibition of the NF-kB pathway.

948 IDENTIFICATION OF CANCER GENES INVOLVED IN DIFFERENTIAL SUSCEPTIBILITY AND RESPONSE TO RESPIRATORY SYNCTIVAL VIRUS INFECTION.

J. Cienciewicki1, X. Wang2, J. Maracec3, F. Polack1, D. Bell1 and S. Kleberger1. 1Laboratory of Respiratory Biology, National Institute of Environmental Health Sciences, Research Triangle Park, NC, 2Laboratory of Molecular Genetics, National Institute of Environmental Health Sciences, Research Triangle Park, NC and 3Vanderbilt University, Nashville, TN. Sponsor: D. Harbour.

Respiratory syncytial virus (RSV) is the primary cause of lower respiratory tract infection during infancy and childhood. Some individuals are highly susceptible to infection and exhibit more severe symptoms which may result in hospitalization and sometimes death. We used human lymphoblastoid cell-lines to evaluate inter-individual variation in response to RSV, test the role of candidate susceptibility genes, and identify susceptibility patterns that express genetic responsivity. Significant inter-individual variation in RSV infectivity across multiple cell lines indicated that genetic background is an important determinant of susceptibility to RSV infection. We then queried databases on human sequence variation and functional annotation for relevant single nucleotide polymorphisms (SNPs) and used to select HapMap cell lines with particular genotypes of interest. Enhanced viral load was found in cell lines with a SNP in MX1, which is involved in suppressing viral replication in infected cells. In a case control study of infants with mild or severe RSV infection, a positive association was found between individuals that were homozygous for the minor allele of the MX1 SNP and the development of severe RSV disease. We also developed a model to predict RSV infection using data from individuals in the HapMap collection. Baseline mRNA expression of HapMap individuals from six different microarray data sets were initially assessed for their correlation with viral load. We have identified cell lines (test set) that have similar expression profiles that will be evaluated for viral loads after RSV infection. Initial studies indicate ~75% accuracy among additional tested cell lines. This novel cell model of RSV disease can thus be used translationally to identify functionally relevant candidate susceptibility genes.
Characterization of Veterans’ Poisonings in the State of Florida

G. T. Johnson1, J. White1, C. Younger1 and R. D. Harbison1, Environmental and Occupational Health, University of Southern Florida-College of Public Health, Tampa, FL and 2Florida Poison Control Center, Tampa, FL.

The Florida Poison Information Centers provide emergency department consultation for suspected poisoning cases presenting to hospital emergency rooms, including Veterans Administration (VA) hospitals. The exposures, case demographics, treatments, and clinical outcomes are recorded for all reported cases. Evidence suggests that veterans may be at increased risk for poisoning. The objective of this study was to characterize patterns associated with poisonings in veterans presenting to VA hospital emergency rooms. A total of 601 poisoning cases from 6 VA hospitals in the state of Florida occurring between the years 2005 and 2009 were evaluated. The population was predominately male (88.1%) with a mean age of 51.5 years (STD 13.7 years). Nearly half (46.2%) of all cases were classified as intentional suspected suicide and 87.6% of poisonings occurred in the patient’s residence. Though death was a rare event (2 cases), 37.7% of cases resulted in clinical outcomes that were considered ‘major’ or ‘moderate’. More than 50% of cases reported a medication as one of the substances implicated in the poisoning. Future research into poisoning interventions among veterans may focus on patient suicide risk, medication monitoring, and medication safety education.

Role of Sensory TRP Channels in Cutaneous Injury by Veniscants and Riot Control Agents

N. Chintagar1, S. Balakrishna1, B. Bescac1, A. Sui1, M. Brackmann1 and S. Jordi1. 1Pharmacology, Yale University, New Haven, CT; 2Pharmaceutical Sciences, Texas A&M Health Science Center, Kingsville, TX and 3Charite School of Medicine, Berlin, Germany.

Transient Receptor Potential (TRP) channels are non-selective cation channels implicated in chemosensation in sensory neurons and other cells. Recently we identified TRP Ankyrin 1 (TRPA1) as the receptor for riot control agents such as CS or CN, oxidants and other reactive irritants, mediating pain and acute irritant responses. Previous studies have shown that agonists of TRPV1 diminished cutaneous veniscant injury elicited by chloroethyl-sulfide (CEES), an analog of sulfur mustard. Here, we hypothesized that TRP channels are involved in cutaneous injury and inflammation by veniscants and riot control agents. Veniscant injury by CEES was characterized in the mouse ear veniscant model in C57BL6 wild-type mice and Trpap1-/- mice. Application of CEES caused a rapid increase in ear thickness, plasma extravasation and production of inflammatory markers such as MMP-9 and IL-1β. Edema, extravasation and marker production, at 24h post-injury, were significantly inhibited by treatment with the TRPA1 antagonists, HC-030031, or A-967079, administered 1h, 8h and 16h post-exposure. Injury parameters showed no rebound, indicating that additional dosing is not required. Trpap1-/- mice showed exaggerated CEES injury, suggesting that TRPA1 has a protective role in the early stages of the injury, but fulfills a pro-inflammatory role at a later time. SB-366791, a TRPV1 antagonist, did not diminish CEES injury parameters. Application of the riot control agent, CS, caused oedema, plasma extravasation and expression of inflammatory cytokines (IL1-β and MIP-2) in the mouse ear. A-967079, administered 30min and 4h post injury, strongly inhibited CS-induced extravasation and marker formation. Trpap1-/- mice were protected from CS-induced plasma extravasation, suggesting TRPA1 is directly involved in neurogenic inflammatory tissue responses.

A Putative Interaction of TSPO with NADPH Oxidase (NOX2) in Primary Microglia

Translocator Protein (18 kDa) (TSPO) is a giall protein that is extensively used as a biomarker of active brain disease in neurodegenerative conditions and to assess neurotoxicity (Chen & Guilarte, Pharm Ther 118: 1-17, 2008). TSPO ligands (TSPO-L) induce cellular functions consistent with microglia activation suggesting an important role in the inflammatory response of the brain to injury (Choi et al., GLIA 59: 219, 2011). Primary microglia exposed to TSPO-L (1-100 nM) induces ROS production that is abrogated by NOX2 inhibitors. To further elucidate the source of ROS production induced by TSPO-L, we measured extracellular and intracellular ROS in the presence of the NOX2 inhibitor apocynin and cyclosporin A, a microchannel permeability transition pore inhibitors. TSPO-L induced ROS production was inhibited by apocynin but not by cyclosporin A, suggesting that the source of ROS production is from NOX2 and not from mitochondria. Co-exposure of TSPO-L with phosphol-12-myristate 13-acetate (PMA), a NOX2 activator, enhanced ROS production and increased the TSPO percent colocalization with NOX2 above PMA alone. Thus, PMA-induced activation of NOX2 may modulate the effects of TSPO-L. Since activated NOX2 is a plasma membrane protein complex, our findings questioned the subcellular localization of TSPO in microglia as TSPO is traditionally viewed as a mitochondrial protein. Triple label immunofluorescent confocal imaging of TSPO with the gp91phox subunit of NOX2, and MitoTracker revealed a high degree of TSPO colocalization with cytosolic and nuclear gp91phox and a lower degree of colocalization in mitochondria. Colocalization of TSPO with NOX2 was also observed in brain tissue from Sandhoff disease mice at an age when the brain is undergoing neurodegeneration. These findings suggest a novel interaction of TSPO with NOX2 in microglia. The results have significant implications for understanding microglia TSPO biology and for the development of potential therapeutic strategies for the treatment of neuroinflammation [Supported by grant ES007962 to TRG].

Neuregulin-1 is Neuroprotective Against Delayed Neuronal Injury Following Acute Organophosphate Intoxication

D. A. Bruun1, Y. Li2, B. D. Ford2 and P. L. Lein1. 1Molecular Biosciences, University of California Davis, Davis, CA and 2Neurobiology, Neuroscience Institute, Morehouse School of Medicine, Atlanta, GA.

Organophosphate (OP) compounds include nerve agents that have been used in military combat and against civilians by terrorists. OP nerve agents are the most toxic and rapidly acting of the known chemical warfare agents. Current post-exposure medical countermeasures against OP nerve agents are useful in reducing mortality, but do not sufficiently protect the brain from delayed neuronal injury and persistent neurological symptoms. In this study, we examined the efficacy of neuregulin-1 (NRG-1) in protecting against acute intoxication with the OP disopropylfluorophosphate (DFP). Pretreatment with NRG-1 did not protect against seizures and mortality in adult male Sprague Dawley rats exposed to DFP (9 mg/kg BW, i.p.) in the absence of standard antidote. Pretreatment with pyridostigmine (0.1 mg/kg BW, i.m.) and atropine methylate (20 mg/kg BW, i.m.) increased survival but did not protect against delayed neuronal injury as determined by extensive Fluorjade-B labeling in multiple brain regions at 24 hours post-DFP injection. However, neuronal injury was significantly reduced in most brain regions by additional pretreatment with NRG-EGF (3.2 μg/kg BW, i.a.) or NRG-GGF2 (48 μg/kg BW, i.a.). NRG-1 also blocked apopoptosis and oxidative stress-mediated protein damage in the brains of DFP intoxicated rats. Administration of NRG-1 at 1 hour after DFP injection also provided significant neuroprotection against delayed neuronal injury. These studies indicate that NRG-1 may represent a novel, potent neuroprotective strategy that has potential therapeutic value in treating individuals after exposure to OP nerve agents. These results further indicate that NRG-1 could be a useful addition to existing antidotal treatment for OP exposure. This research is supported by the CounterAct program, National Institutes of Health Office of the Director, Grant # U01 NS07993.

Mementine and Riluzole do not Reverse the Neuotoxic Effects Resulting from Chronic Exposure to Depleted Uranium

S. M. Laskey, B. L. Hancherhoff and K. Pasricha. Cancer Biology & Pharmacology, University of Illinois College of Medicine, Peoria, IL.

Continuing concern exists for veterans retaining fragments of depleted uranium (DU) shrapnel from Gulf War I and the resulting CNS effects. Earlier work demonstrated that rats exposed to DU for 15-17 months exhibited increases in evoked extracellular glutamate and NMDA receptor density, and suggested one basis as increased production of oxygen radicals. The goal of this study was to determine if currently prescribed therapeutic drugs can reverse these actions of chronic exposure in vivo, and to assess various markers of oxidative stress. Male Sprague-Dawley rats had 0, 300, or 600 mg of DU pellets implanted intramuscularly at 70 days of age. After 7 months exposure osmotic minipumps were inserted subcutaneously so as to deliver mexitil and riluzole, or the combination for two months during continuing DU exposure. Animals were sacrificed after 9 months exposure and the brains harvested. MK-801 receptor binding in frontal cortex was...
increased 83-96% by DU exposure in agreement with previous observations in hippocampus and parietal cortex; memantine and/or riluzole did not eliminate these changes but caused significant NMDA receptor up-regulation in non-exposed control animals. Cerebellar 8-isoprostane levels exhibited small increases in DU-exposed rats not receiving drugs, while memantine reduced concentrations of this lipid peroxidation marker in all groups, but did not reverse the DU effect. This duration of DU exposure did not produce changes in cortical glutathione peroxidase or cerebellar catalase activities. These findings indicate that the most robust CNS effect of chronic DU is increased access to the NMDA receptor ion channel. While the basis for this observation is unknown, it is possible that increased access to the NMDA receptor ion channel limits the acute behavioural effects of systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, regulated at baseline, and its transcriptional activity is further enhanced in mice drinking ERW than in control mice at 2 and 4h, but not at later timepoints. We also assessed the expression of enzymatic antioxidants and found that Nrf2 is up-regulated at baseline, and its transcriptional activity is further enhanced in mice drinking ERW during systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. In conclusion, our data indicates that chronic administration of ERW resulted in an enhanced activity of Nrf2, which optimized the neuroinflammatory and antioxidant response in the hippocampus during systemic inflammation, thereby limiting the acute behavioural effects of systemic inflammation. Neonatal hypoxia-ischemia (HI) affects 60% of low birth weight infants and up to 40% of preterm births. Severe cases of HI lead to immediate necrosis of neuronal cells, and a secondary apoptosis of surrounding cells due to neuronal inflammation. Our lab has determined that Bax, a cell death signaling protein, is activated after HI and translocates to the nucleus, mitochondria, and ER and thus affects the cell death phenotype (neurotic or apoptotic) observed. Using the well-established Rice-Vannucci in vivo model, as well as an in vitro model of neonatal cerebral HI, we determined whether HI-dependent phosphorylation of Bax determines its multi-organ-ganle localization, and ultimately the cell death phenotype observed. Given that active Bax is known to oligomerize, we characterized Bax oligomerization via western blot analysis of cortical tissue ipsilateral to the injury using an antibody specific to phospho-Bax. We quantified the bands that correspond to dimer, tetramer, and hexameric forms of Bax. Consistent with our previous results, total Bax levels remained constant with no significant increases from 0-4h after HI. We observed a biphasic reaction to HI, in that there was a significant increase in levels of p-BaxThr167 in the nucleus at ½h after HI, and no changes afterward until 6h and 12h, where there was an increase in nuclear and mitochondrial p-BaxThr167 when compared to shams. There was no significant change in p-Bax levels after 12h HI, which is consistent with our previous data that shows that Bax activity is an early event following HI. Additionally, with atomic force microscopy, we were able to visualize the oligomerization of Bax after phosphorylation by JNK. These results indicate that Bax is phosphorylated after HI and that phosphorylation by JNK induces oligomization of the protein. Understanding the mechanisms of Bax translocation will aid in the rational design of specific therapeutic strategies which could potentially involve altering Bax subcellular redistribution to decrease the irreversible trauma resulting from a prolonged inflammatory response.
exposed to either filtered room air or mainstream cigarette smoke for 3 hours, 5 days per week. The dose was adjusted to generate 300mg/m3 total particulate matter, as measured by gravimetric sampling. This dose has been found to generate COHb levels of 20% in mice, and to induce emphysematous lung changes. To our surprise, mice exposed to smoke, while not having major changes in fracture callus composition by micro-CT, histomorphometry, or qPCR, had enhanced vascularization of the fracture callus by vascular CT, associated with increased VEGF-induced angiogenesis that is likely due to nicotine. This is despite the utilization of an exposure paradigm that is well-established in the pulmonary field and that has been shown to induce emphysematous changes. We attribute the failure to establish a model of delayed healing on over-reliance on an established model with insufficient consideration with the toxicokinetics of smoke constituents, and offer this study as a lesson for those undertaking similar studies.

966 EFFECTS OF CACHE VALLEY PARTICULATE AIR POLLUTION ON PULMONARY FUNCTION, AND DISEASE BIOMARKERS IN HUMAN VOLUNTEERS: A PRELIMINARY STUDY.

T. Allpress¹, N. Herger¹, R. R. Martin², J. R. Stevens³, J. Davis⁴, G. S. Youg⁴, C. Rice-Deering⁴, J. M. Veranth⁴ and R. Coulombre⁴, ¹Veterinary Sciences, and Toxicology Graduate Program, Utah State University, Logan, UT, ²Civil and Environmental Engineering, Utah State University, Logan, UT, ³Mathematics and Statistics, Utah State University, Logan, UT, ⁴Student Health Center, Utah State University, Logan, UT and ⁵Pharmacology and Toxicology, University of Utah, Salt Lake City, UT.

Some of the worst particulate air pollution ever measured in the United States regularly occurs during winter inversions in the Cache Valley of Northern Utah. We have shown that Cache Valley PM2.5 (CVPM) induces pro-inflammatory interleukins, C-reactive protein (CRP), and post-translational modifications associated with ER stress, and the unfolded protein response in vitro. In this preliminary study, we sought to determine whether exposure to ambient CVPM would alter pulmonary function, and serum biomarkers of cardiopulmonary inflammation in young, healthy human volunteers (age 18-35 years; n=38) during each of three periods of pre-inversion baseline (PM2.5 < 35 μg/m3), inversion (PM2.5 > 35 μg/m3) and post-inversion periods. There were significant CVPM-associated decreases in both forced vital lung capacity (FVC) and in forced expiratory volume in the first second (FEV1) during unhealthy air days compared to both pre-inversion baseline and post-inversion periods, and a decline, though not statistically significant, in FEV1/FVC ratio between unhealthy air and healthy air recovery days. Serum IL-6, IL-8, and IL-12 all showed significantly elevated levels in subjects self-reporting to be sick during inversion periods compared to pre- and post-inversions; these differences were not observed in healthy subjects. While these results were obtained from a limited sample population, the data provide further evidence that adverse health effects are associated with exposure to CVPM, and provide compelling justification for further study. Supported in part by the Marriner S. Eccles Foundation.

967 ANALYTICAL APPLICATIONS OF FOURIER TRANSFORM-INFRARED (FT-IR) SPECTROSCOPY IN THE CHARACTERIZATION OF CANDIDA.

R. M. Balders¹, C. Torres², D. Aparicio², D. Duarte² and J. Mercado¹. ¹University of Cartagena, Cartagena, Colombia and ²University Corporation Rafael Nuñez, Cartagena, Colombia.

Fourier-transform infrared (FT-IR) spectroscopy is known as a high resolution method for the rapid typing of pure cultures of microorganisms, is used as a whole-organism fingerprinting technique since it reflects the bio-chemical composition of intact cells. Through the use of infrared spectroscopy was possible to make a no subjective classification clinically relevant on a series of species of Candida evaluated in the present study, in this way was possible to corroborate some data values obtained in other previously studies. The differentiation capacity of the FT-IR microscopic technique was tested for twenty-eight strains. Candida sp. were cultured on Sabouraud chromolephonic agar at 37°C for 24 h. 4 mg of each sample lyophilized was mixed with 100 mg potassium bromide (KBr). A Shimadzu 8400S FT-IR spectrometer was used, pellets were scanned at 6 cm-1 resolution in the spectral range of 4000-500 cm-1. Cluster and factor analysis methods were used to evaluate the complex spectral data. Excellent discrimination between yeasts and bacteria, and at the same time Gram-negative and Gram-positive bacterial strains was also obtained. Twenty-four selected strains of different species within the genus Candida were repetitively measured and could be grouped into correct species clusters. By exploiting the huge discriminating capacity of this technique, we identified 6 species yeasts (Candida albicans, Candida tropicalis, Candida parapsilosis, Candida krusei, Candida guillermondii and Candida lusitaniae) and from a collection of clinical strains of Candida, isolated from vaginal secretion. Our results clearly show the efficiency and the robustness of FTIR spectroscopy in identifying species with a classification rate of 100% for pure 24-h cultures. FTIR spectroscopy is thus a promising clinical approach, because compared to conventional and molecular techniques, it is time and money saving, has great determination and discriminating potentials, and is amenable to an automated high-throughput routine system.
A family of five and pet dog who rented a water-damaged home and developed multiple health problems are presented. The home was analyzed for species of mold and bacteria. The diagnostics included MRI for chronic sinusitis with ENT evaluation and sinus surgery, and neurological testing for CNS complaints. Bulk samples from the home, tissue samples from the sinuses, urine, nasal secretions, placenta, umbilical cord and breast milk were tested for the presence of macromycete trichothecenes, aflatoxins and ochratoxin A. The family had the following diagnosed: chronic sinusitis, neurological deficits, coughing with wheeze, nose bleeds, fatigue among others. An infant was born with a total body flare and developed multiple Cafe-au-Lait pigmented skin spots. The mycotoxins were detected in bulk samples as well as body fluid (urine, and nasal secretions) as well as in the breast milk, placenta and umbilical cord. Pseudomonas aeruginosa, Acinetobacter, Penicillium and Aspergillus fumigatus were cultured from nasal secretions from the breast milk, placenta and umbilical cord. Pseudomonas aeruginosa, Acinetobacter, Penicillium and Aspergillus fumigatus were cultured from nasal secretions from the father and daughter. RT-PCR revealed A. fumigatus DNA in sinus tissues of the daughter. Finally, the dog developed approximately 72 skin (sebaceous glands and lipomas) from which trichothecenes and ochratoxin A were identified. The identified mold and bacteria as well as the health of the family are discussed in relation to the most recent published literature regarding microbial contamination and toxic by-products present in water-damage.

Formulations of ASA and IS2 derived from human cells have been developed for direct central nervous system (CNS) delivery as enzyme replacement therapies (ERTs) for Hunter syndrome and other lysosomal storage diseases. Previous studies suggest that a direct administration to the CNS via the IT space of the spinal canal may be a relatively safe and effective method for delivery of ERTs. The objective of this study was to evaluate the PK of ASA and IS2 in CSF after IT administration to cynomolgus monkeys. Therefore, a total of twelve male and twelve female monkeys with IT-lumbar (ITL) and IT-cisterna magna (ITCM) catheters were randomly assigned into four treatment groups for IS2 administration (IV = 0.5 mg/kg and IT = 1, 10 and 30 mg) and ASA administration (IV = 1 mg/kg and IT = 1.8, 6 and 10 mg). CSF samples were collected at specified intervals post dosing after the administration of each enzyme treatment for PK analysis. Various compartmental models were constructed using a population approach and their respective ability to fit CSF concentration of ASA and IS2 following IT administration was evaluated using a standard model discrimination process including statistical criteria as well as pertinent graphical representations of goodness-of-fit. Concentrations in the CSF both ASA and IS2 following IT administration were well characterized by a 3-compartment model. Compartmental PK parameters in CSF were derived for ASA (VsCSF = 16.9 mL and CLCSF = 0.973 mL/h) and IS2 (VsCSF = 10.5 mL and CLCSF = 1.22 mL/h). Volume of distribution (Vs) of ASA and IS2 were close to the CSF total volume reported in the literature. Total exposure in CSF predicted with the model across doses levels for ASA (range: 278103 to 16485500 ng.h/mL) and IS2 (range: 278103 to 16485500 ng.h/mL) will be used to perform exposure-response analyses in monkeys and ultimately scale PK and PD in humans.

Formulations of ASA and Idursulfase IS2 derived from human cells have been developed for direct central nervous system (CNS) delivery as enzyme replacement therapies (ERTs) for Hunter syndrome and other lysosomal storage diseases. Previous studies suggest that a direct administration to the CNS via the IT space of the spinal canal may be a relatively safe and effective method for delivery of ERTs. The objective of this study was to evaluate the systemic (SYS) PK of ASA and IS2 in serum of cynomolgus monkeys after intravenous (IV) administration.
female monkeys were randomly assigned into four treatment groups for IS2 administra-

tion (IV = 0.5 mg/kg and IT = 1, 10 and 30 mg). Administration (IV = 1 mg/kg and IT = 1, 10 and 30 mg). Serum samples were collected at specified intervals post dosing after the administration of each enzyme treatment for PK analysis. Various compartmental models were constructed using a population approach and their respective ability to fit serum concentration of ASA and IS2 following IV administration was evaluated using a standard model discrimination process including statistical criteria as well as pertinent graphical representations of goodness-of-fit. Concentrations in serum for both ASA and IS2 following IV administration were well characterized by a 2-compartment model. Compartmental PK parameters were derived for serum ASA (Vss = 1432 mL, CL = 253 mL/h and CLd = 509 mL/h) and serum IS2 (Vss = 409 mL and CL = 149 mL/h). Total volume of distribution of ASA and IS2 in serum is greater than plasma volume (~224 mL) but lower than total body water (~3465 mL/kg) in monkeys, suggesting distribution to peripheral tissues and organs such as the CNS. Total exposure ASA and IS2 in serum were 10505 and 8671 ng/h/mL, respectively. The above model will be used to perform exposure-response analysis in monkeys and ultimately scale the PK of ASA and IS2 to humans.

 formulations of ASA and IS2 derived from human cells have been developed for direct CNS delivery as enzyme replacement therapies (ERTs) for Hunter syndrome and other lysosomal storage diseases. Previous studies suggest that a direct administration to the CNS via the IT space of the spinal canal may be a relatively safe and effective method for delivery of ERTs. The objective this study was to evaluate the systemic (SYS) PK of ASA and IS2 in monkey serum after IT dosing and the CNS PK of ASA and IS2 in cerebro-spinal fluid (CSF) after IV dosing in order to evaluate the intercompartmental relationship between the CSF and SYS spaces. Therefore, a total of 12 male and 12 female monkeys with IT-lumbar (IT-L) and IT-cisterna magna (IT-CM) catheters were randomly assigned into four treatment groups for IV administration (IV = 0.5 mg/kg and IT = 1, 10 and 30 mg) and ASA administration (IV = 1 mg/kg and IT = 1.8, 6 and 10 mg). Serum and CSF samples were collected at specified intervals post dosing after the administration of each enzyme treatment for PK analysis. Available serum (2-compartment) and CSF (3-compartment) models were interlinked to determine the intercompartmental transfer rate constants. The transfer rate constants from serum to CSF (KIN) for ASA and IS2 were 0.258 and 0.00489 h⁻¹, respectively. The transfer rate constants from serum to CSF (KOUT) for ASA and IS2 were 0.258 and 0.00489 h⁻¹, respectively. The transfer rate constants from CSF to serum (KOUT) for ASA and IS2 were 0.779 and 0.374 h⁻¹, respectively. Overall, ASA and IS2 enzymes displayed similar intercompartmental distribution, but presented some differences regarding the rate and extent of distribution between CSF and serum. As expected, transfer from serum to CSF was the rate limiting process, with an equilibration half-life of ~3 hours. The above semi-physiological model will be used to perform exposure-response analysis and ultimately scale the PK of ASA and IS2 in serum and CSF to humans.

A formulation of Idursulfase (IS2) derived from human cells has been developed for direct central nervous system (CNS) delivery as enzyme replacement therapy for Hunter syndrome and other lysosomal storage diseases. Previous studies suggest that a direct administration to the CNS via the IT space of the spinal canal may be a relatively safe and effective method for delivery of enzyme replacement therapies. The objective this analysis was to characterize the relationship between IS2 concentration and its activity measured in CSF after IT and IV administration to cynomolgous monkeys. A total of twelve male and twelve female cynomolgous monkeys with IT-lumbar (IT-L) and IT-cisterna magna (IT-CM) catheters were randomly assigned into four treatment groups for IS2 administration (IV = 0.5 mg/kg and IT = 1, 10 and 30 mg). CSF samples were collected at specified intervals post dosing and were analyzed to determine the PK of IS2 as well as PD activity which was measured using enzymatic activity. The relationship between IS2 concentration and activity was assessed using a linear regression on log-transformed values where the relationship between IS2 concentration and activity measured in CSF was explained with the following power model: Activity IS2 = b x CSF²/m, where ”b” is the intercept (-1.3) and "m" is the slope (-0.92). As a result, the PK/PD relationship of IS2 was deemed linear over the dose range (slope was close to 1), suggesting a very rapid equilibrium between CSF concentration and observed activity. A similar relationship between serum PK and activity was also observed, suggesting that serum can be sampled clinically. CSF or serum concentrations of IS2 can be used as a surrogate marker of activity to demonstrate the feasibility of constructing exposure-response relationships in animals and ultimately extrapolated to humans.

The abuse of cocaine costs the economy billions of dollars and its illicit use remains a major challenge for public health authorities and law enforcement agencies. There is a need to develop improved, simple, portable, low cost aptamer-based sensors for specific, sensitive, rapid and real time detection of cocaine in solution and unprocessed samples. Synthetic oligonucleotide aptamers recognize virtually any class of target molecule with high affinity and specificity. Here we report a 2-amino purine (2-AP)-modified cocaine aptamer with increased affinity for cocaine compared with other reported cocaine aptamers. Atomic molecular simulations of the aptamer-ligand interaction are underway to elucidate the molecular recognition process and to identify possible explanations for the increased cocaine affinity with 2-AP modification. Thermodynamic evaluations by isothermal titration calorimetry and fluorescence quenching were used to evaluate a series of 2-AP-modified cocaine aptamers to identify that with the highest affinity for cocaine. The aptamer with the highest affinity was used to develop a fluorescence-based homogeneous assay to detect cocaine. The limits of aptamer functionality in undiluted and unprocessed biological fluids such as blood serum, saliva and urine will be reported.

A formulation of Idursulfase (IS2) derived from human cells has been developed for direct central nervous system (CNS) delivery as enzyme replacement therapy for Hunter syndrome and other lysosomal storage diseases. Previous studies suggest that a direct administration to the CNS via the IT space of the spinal canal may be a relatively safe and effective method for delivery of enzyme replacement therapies. The objective this analysis was to characterize the relationship between IS2 concentration and its activity measured in CSF after IT and IV administration to
Thus current results suggest that BMAA may act on ER-coupled mechanisms of protein homeostasis. Mis-incorporation of BMAA into the ER leads to misfolded proteins and an accumulation of oxidized proteins, both hallmarks of neurodegenerative diseases, could therefore be involved in the etiology of ALS/PDC linked to chronic BMAA exposure.

PARKIN-DYSFUNCTION AND α-SYNUCLEIN AGGREGATION LEAD TO CELL DEATH IN METHAMPHETAMINE (METH)-TREATED RHEUS MONKEYS AND HUMAN METH USERS.

S. Z. Imam1,2, Z. K. Binenda1, W. Sikker1, M. G. Paule1, E. Masliah2 and S. F. Ali1. Neurotoxicology, US FDA/NCCT, Jefferson, AR. 2Neurosciences, University of California San Diego, La Jolla, CA. 3Geriatrics, University of Arkansas for Medical Sciences, Little Rock, AR and 4Institute for the Integration of Medicine and Science, University of Texas Health Science Center at San Antonio, San Antonio, TX.

Numerous studies have reported that METH induces dopaminergic (DAergic) neurotoxicity and nerve terminal damage via the induction of apoptotic pathways. We have shown that oxidative stress-mediated induction of a tyrosine kinase c-Abl disrupts parkin-dependent ubiquitin-proteasome (UPS) function, leading to DAergic cell death in animal models of Parkinson’s disease (PD) and in human patients. Here, we investigated whether METH-induced oxidative stress leads to parkin-dependent dysfunction of UPS in rhesus monkeys and in human METH users. We also determined if METH-treatment could induce α-synuclein aggregation. METH treatment significantly activated c-Abl leading to an increase in parkin phosphorylation and inactivation in striatum of rhesus monkeys. Inactivation of parkin resulted in significant accumulation of p38/AIMP2, a toxic substrate of parkin known to cause DAergic cell death. Significant increases in a highly active c-Abl, a hyperphosphorylated parkin, and accumulations of p38/AIMP2 were also observed in the striatum of human METH users as compared to their age-matched controls. Significant aggregation and hyperphosphorylation of α-synuclein were also observed in the striatum of both METH-treated rhesus monkeys and human METH users. A significant depletion of dopamine (60%) and its metabolites DOPAC (55%) and HVA (65%) was observed in striatal tissues of METH-treated rhesus monkeys and human METH users. We also observed significant increases in the expression HNE-protein adducts in the striatum of METH-treated monkeys and human METH users as compared to control subjects, suggesting a significant increase in oxidative stress. These results suggest a universal mechanism of dopaminergic neuronal cell death mediated by oxidative stress-induced UPS dysfunction resulting in toxic protein aggregation and by α-synuclein-aggregation due to DAergic dysfunction.

PHARMACOKINETIC STUDY AND EVALUATION OF THERAPEUTIC EFFECTS OF WATER SOLUBLE COQ10 IN A PARAQUAT-INDUCED RAT MODEL OF PARKINSON’S DISEASE.

S. Pandey1, K. Facecchia1, K. Muthukumaraswamy1, J. Smith1, K. Harrison1, A. Laframboise1, J. K. Sandhu2, M. G. Paule1, E. Masliah2 and D. Lopatin1. 1Department of Chemistry & Biochemistry, University of Windsor, Windsor, ON, Canada and 2Department of Biochemistry, University of Windsor, Windsor, ON, Canada.

Parkinson’s disease (PD) is a progressive neurodegenerative disorder affecting 4 million people worldwide. Environmental toxins leading to oxidative stress and mitochondrial dysfunction causing neuronal death, have been implicated in the development of sporadic form of PD. Exposure to paraquat, a well known herbicide/insecticide, has been correlated to the incidence of PD in human. Currently there is no treatment available that can halt the progression of this disease. We have established a paraquat-induced model of PD in rats. We have evaluated therapeutic potential of a water-soluble formulation of CoQ10 (WS-CoQ10) in this model where WS-CoQ10 was fed after 5 injections of paraquat. We have observed that post-insult feeding of CoQ10 in drinking water blocked the progression of loss of dopamine neurons, decreased oxidative stress in brain tissues and led to better behavioral performances (as indicated by Pole test and vertical climb test) compared to paraquat treated animals fed with un-supplemented water. There was efficient absorption of WS-CoQ10 formulation as the level of CoQ10 doubled in brain and liver tissues of animal fed with supplemented water compared to control. In addition to significant protection of DA neurons in the SNpc, we also observed activated astroglia and increased levels of brain derived neurotrophic factor (BDNF) and glial derived neurotrophic factor (GDNF) in WS-CoQ10 fed rats. We have shown previously the prophylactic effect of WS-CoQ10 treatment, that is WS-CoQ10 prevents the loss of dopamine neurons in the SNpc and ameliorates the symptomatic effects of paraquat-induced PD (Thakur et al., 2010). Therefore the formulation of CoQ10 would be useful to slow or even halt the progression of Parkinson’s disease.

PATHOPHYSIOLOGY OF BAC-TRANSGENIC RATS EXPRESSING PARKINSON’S DISEASE CAUSING MUTATIONS.

J. Cannon1,2, K. Geggman1, V. Tapia1, T. Sew1, M. Dail1, J. Nelson1, C. Li3 and J. Greenamyre1. 1Pittsburgh Institute for Neurodegenerative Diseases, University of Pittsburgh, Pittsburgh, PA. 2Purdue University, West Lafayette, IN and 3Mount Sinai School of Medicine, New York, NY.

Parkinson’s disease (PD), in most cases is thought to arise from both genetic and environmental influences. Cases arising from purely genetic influences are rare, but provide much insight into the pathogenic features of the disease. Rodent models of genetic PD have been largely unable to replicate the key pathological features of the disease. Here, transgenic rats expressing disease causing mutations in α-synuclein (A53T) or E46K) or leucine-rich repeat kinase 2 (LRRK2, G2019S or R1441G) were created using bacterial artificial chromosomal technology. These rats were assessed at 12 months of age to determine if the key features of the disease were replicated. No overt loss of nigral dopamine cell bodies or striatal dopamine terminals was found by immunohistochemistry. These results indicate that there is not an obvious lesion to the nigrostriatal dopamine system. However, alterations in dopaminergic metabolites, nitrotyrosine levels, and α-synuclein accumulation/aggregation indicate that features of the earliest disease stages may be replicated. Thus, these animals may be ideal for modeling preclinical PD and for potentiating studies with other stressors, such as environmental exposures. Preliminary experiments also indicate that the transgenic animals exhibit heightened sensitivity to rotenone, as evidenced by increased loss of striatal dopamine terminals. Rotenone is a pesticide that has been linked to human PD and replicates the key disease features. In summary, while these animals do not exhibit features of late-stage PD, they are ideal for assessing gene-environment interactions and may be useful in modeling the earliest stages of the disease. Supported by the NIH (NIEHS 1R01ES019879-01, J.R.C.) and the Michael J. Fox Foundation (J.T.G. and C.L.)

Expression of mutant huntingtin impairs striatal manganese (Mn) transport and Mn-dependent enzyme activities by a novel cellular mechanism.

We have previously reported that expression of mutant htt is associated with impaired Mn accumulation in a striatal cell line and mouse models of Huntington’s disease (HD). To explore the consequences of altered Mn homeostasis, we have measured the levels and activity of cortical and striatal arginase, a manganese-containing enzyme. We report that arginase activity exhibits region specific Mn exposure by genotype interactions. To investigate the underlying cause of the Mn transport deficit we used the cellular fura-2 manganese extraction assay (CFMEA) and cellular fura-2 loaded kinetic assays to measure Mn dynamics. We show that cells expressing mutant htt have decreased Mn uptake within minutes of Mn exposure, and decreased total Mn storage capacity yet maintain equivalent concentration dependence. Furthermore, the presence of other di-/trivalent metals, serum proteins, or known co-transporter toxins in the culture media and exposure buffers are not required for this effect. Inhibition of divalent metal transporter 1 (DMT1), as well as a2-APB- and ruthenium red blockable channels, PPAR-gamma, or the mitochondrial transition pore does not affect this Mn uptake deficit. Therefore we are now testing other recently identified Mn transporters for their contribution to this phenotype, including HIP14, PARK9, and Ferroportin 1. Finally, we report that excess divalent metals (Mg2+, Ca2+, and Sr2+) substantially influence Mn uptake and survival in the striatal cells and ameliorate the differences between wild-type and mutant striatal HD cells. We are currently utilizing shRNA knock-down strategies to identify the major transporter(s) responsible for the altered Mn homeostasis phenotype in HD striatal cells and animal models. In conclusion, our data strongly suggest that the HD mutation causes a defect in Mn uptake and storage capacity, which contributes to alterations in the activity of Mn-dependent enzymes in the brain. Supported by NIH/NINDS ES016921, ES016931S1, ES016931S2 and T32 ES007028.
Alzheimer's disease (AD) is the most common age-related neurodegenerative disease affecting millions of people worldwide. Strong evidence supports the role of the amyloid-β peptide (Aβ) induced oxidative stress (OS) and neuroinflammation in the pathophysiology of AD. In brains of AD patients, levels of neuroinflammatory cytokine TNF-α and oxidized proteins, by-products of lipid peroxidation such as acrolein and DNA damage markers are significantly higher in vulnerable brain regions. Bacopa monniera (BM) and Withania somnifera (WS) have a long history of use in memory-enhancing therapy but there is dearth of studies on their neuroprotective effects. The objective of this study was to investigate whether BM and WS extracts can protect against Aβ peptide and hydrogen peroxide -induced toxicity and modulate various redox regulated pathways. We demonstrate that a treatment with BM and WS extracts significantly protected the human neuroblastoma cell line SK-N-SH against Aβ peptide in various cell survival assays. Furthermore, a treatment with BM extract significantly reduced H2O2 and TNF-α induced intra-cellular reactive oxygen species (ROS) generation in SK-N-SH cells. Finally, our results show that BM extract is also a potent inducer of nuclear factor E2-regulated factor2 (Nrf2) and Sirt1 pathways. BM extract also inhibited the TNF-α-induced reactive oxygen species (ROS) generation in SK-N-SH cells. WS extract also inhibited the acetyl cholinesterase (AChE) activity. Thus, our findings indicate that BM and WS extracts may act as an antioxidant and inflammatory modulator and may have beneficial effects in the AD therapy.

Increasing data suggests that concentrated ambient particulate matter (CAPS) adversely impacts brain and could represent a largely underestimated contribution to CNS diseases. Early development may be a period of particular vulnerability of brain to CAPS damage. This study examined the hypothesis that early life postnatal CAPS exposure would sensitize the CNS to subsequent adult challenge with paraquat + maneb (PQ+MB), a well-established pesticide-based model of the Parkinson’s disease phenotype (PDP). Following CAPS exposure from PND 4-8 & 10-13 days, mice were subjected to adult PQ (10 mg/kg) and MB (30 mg/kg) i.p. 2x week for 6 weeks. Mice exposed postnatally to CAPS were significantly more sensitive to the locomotor-reducing effects of PQ+MB than sham controls, or those exposed to CAPS alone or PQ+MB alone. CAPS and PQ+MB significantly altered catecholamine levels in both the nigrostriatal and mesocortical dopamine pathways. CAPS had a particular influence on striatum, increasing NE, DOPAC, and DA turnover (DOPAC/DA) levels, while PQ+MB generally impacted midbrain, decreasing 5HT, DOPAC and dopamine turnover. An interaction between CAPS and PQ+MB on cortical 5-HT levels was evidenced as a significant 5-HT decrease in PQ+MB treated animals compared to both sham controls and CAPS+PQ+MB treated mice. Cortical DA was also increased in PQ+MB treated animals. Collectively, these findings indicate that early life CAPS enhances locomotor reduction in response to PQ+MB challenge and changes striatal catecholamines (DAergic cell terminals), a region critical to PD while PQ+MB, in the same animals produces catecholamine changes in the ventral midbrain (DAergic cell bodies). Collectively this concurrent damage to striatum and midbrain could increase nigral cell death and thereby contribute to a PDP; future analyses will include assessment of TH immunoreactivity and stereological analysis of DAergic cell counts in the SNpc and VTA. Supported by R01-ES019105

Dysfunction of protein handling has been implicated as an important factor in the neurodegeneration that occurs in age-related Parkinson’s disease (PD). Inhibition of the ubiquitin-proteasome system (UPS) has been implicated in the formation of protein aggregates and Lewy bodies in PD. While proteasomal inhibition could trigger an array of downstream protein handling changes including up-regulation of heat shock proteins (HSPs), induction of molecular chaperones, activation of the ER stress/ unfolded protein response (UPR), autophagy and aggresome formation, little is known about the relationship of proteasomal inhibition to the sequence of activation of these diverse protein handling systems. In the current study, we utilized the proteasome inhibitor MG132 (carbobenzoxy-L-leucyl-L-leucyl-L-leucinal) and examined the activity of several major protein handling systems, in the immortalized dopaminergic neuronal N27 cell line. The data from these studies showed that MG132-induced proteasomal inhibition resulted in stimulation of the UPR and autophagic flux in the early phase (up to 6 hours after proteasomal inhibition) as determined by increased levels of phosphorylation of the eukaryotic translation initiation factor 2alpha (eIF2α), C/EBP homologous protein (CHOP) and turnover of autophagosome marker microtubule-associated protein 1 light chain 3 (LC3). Moreover, after prolonged proteasomal inhibition induced by MG132 (> 6 hours) we observed an increased cellular level of polyubiquitinated proteins, HSP70, the formation of vimentin-caged aggresomes and apoptosis. Our data suggest a potential link between proteasome inhibition and activation of other protein handling systems. These data also suggest that the mechanisms of induction of these alternate protein handling systems and their temporal relationship may be important parameters determining the extent of accumulation of misfolded proteins in cells as a result of proteasome inhibition. (Supported by NIH grant R01ES018943)
A combination of risk alleles and environmental stressors are thought to be the major cause of Parkinson's disease (PD): thus, patients sharing a common disease-causing gene can present with significantly different disease progression. We generated induced pluripotent stem cell (iPSC) lines from a control patient and two brothers who share compound heterozygous exonal deletions of the PARK2 gene, which result in complete loss of Parkin function. These cell lines were differentiated to neural progenitors expressing the early neuroectodermal marker Pax6. We assessed cell viability, oxidative stress, mitochondrial morphology, and oxidative stress transcriptional response after exposure to copper and manganese. The LD50 of copper exposure was significantly lower (61 μM) in PARK2 mutant cells than in control cells (130 μM) (n=8, p = 0.019) while the LD50 of manganese exposure was the same in each cell line. Copper exposure resulted in a significantly higher rate of reactive oxygen species production and mitochondrial damage while quantitative RT-PCR analysis indicated impairment in transcriptional activation of the stress response factor heme oxygenase-1 in Parkin mutants. These data suggest that loss of functional Parkin leads to impairment of appropriate mitochondrial stress and oxidative stress transcriptional response pathways, underscoring each as an important mechanism of normal Parkin function. Additionally, the role of copper as a stressor in each of these pathways implies a potential role for copper as a PD risk factor. This work has been supported by the following grants: NIH/NIEHS ES016931, Peterson Foundation for Parkinson's, Vanderbilt Center for Molecular Toxicology Pilot Project, and Subaward RR166-737/4787736 under NIH/NIGMS SPO1 GM08553403.

Inflammatory activation of glia is implicated in the progressive loss of dopaminergic neurons in Parkinson's disease (PD). Suppression of neuroinflammation may prove useful in slowing continuous neuronal degeneration. In the present study we investigate the efficacy of nuclear factor kappa B (NF-kB) inhibition in attenuating progressive dopaminergic neuron loss. We established a model of neurodegeneration employing MPTP in conjunction with probenecid in transgenic NF-kB-EF1α reporter mice in which we observed a progressive reduction of TH positive neurons assessed by stereology. In addition, robust activation of astrocytes and microglia was observed that correlated with increased activation of NF-kB. Using this model, we assessed the efficacy of novel para-substituted diindolylmethane (cDIM) compounds in attenuating continual neuron loss in vivo. cDIM (1,1-bis(3'-indolyl)-1-(p-methoxy)-methylamine), which induces downregulation of prototypic neuroinflammatory gene NOS2 in primary astrocyte cultures, was given via oral gavage (50 mg/kg) once daily to mice following 7 days of MPTP treatment. Stereological assessment revealed a significant attenuation of dopamine neuron loss in animals treated with cDIM, as well as decreased glial activation. This process was repeated using cDIM12 (1,1-bis(3'-indolyl)-1-(p-chlorophenyl)-methylamine), a Nurr1 agonist, that also attenuated dopamine neuron loss. Finally, mice deficient in astrocytic IKKβ were treated using the progressive MPTP and probenecid model and these animals displayed significantly less dopamine neuron loss than their wild type counterparts given the same treatment. These results suggest that NF-kB is an important pathway mediating neuroinflammatory activation of astrocytes leading to loss of dopamine neurons and that interfering this pathway may be a viable therapeutic option for slowing the progression of PD.

The release of pro-inflammatory mediators by activated astrocytes and microglia have been documented in neurodegenerative diseases such as Parkinson's disease and manganese-induced neurotoxicity. Furthermore, research from our laboratory...
has implicated the Nuclear Factor-kappa beta (NF-κB) in release of inflammatory molecules from activated glia; however, the relative impact of these activated glia on neuronal survival and the pathways involved are still poorly understood. In this study, we bred an human Glial Fibrillary Acidic Protein (βGFAP)-Cre mouse line with a floxed IkB kinase beta (IkKβ) mouse line to create a conditional IkB-beta knockout mouse (IkKβ/fl) in which the IkB-beta gene is specifically deleted in astrocytes of the CNS. In vivo comparison of IkB-beta staining in adult knockout mice to wild type (IkKβ/F) littermates revealed maintenance of the IkB-beta in neuronal populations of the basal ganglia, but staining was unsuccessful in glial populations. In vitro staining revealed deletion of IkB-beta in primary neonatal cultured astrocytes, but not in primary cultured microglia. Semi-quantitative analysis via Real Time Polymerase Chain Reaction revealed at least a 50% reduction in IkB-beta activity in primary cultured astrocytes as compared to wild-type cultures. Current data suggests the mouse has been successful in specifically deleting IkB-beta within astrocytes of the CNS and should be a useful tool to determine the role of astrocyte NF-κB in neurodegeneration.

**FUNCTIONAL CHARACTERIZATION OF ABC EFFLUX TRANSPORTERS IN MICROGLIA: IMPLICATIONS FOR THE THERAPY OF PROTEIN FOLDING DISEASES.**

C. J. Gibson1, 3, J. R. Richardson1 and L. M. Aleksunes1.1Pharmacology & Toxicology, Rutgers University, Piscataway, NJ. 2Environmental & Occupational Medicine, University of Medicine and Dentistry of New Jersey, Piscataway, NJ and 3Joint Graduate Program in Toxicology, Rutgers University, Piscataway, NJ.

Efflux transporters are important in limiting cellular and tissue exposure to exogenous chemicals as well as potentially toxic endogenous products. Investigation of efflux transporters, such as Multidrug resistance protein 1 (MDR1), Multidrug resistance-associated proteins (MRP), and breast cancer resistance protein (BCRP), in the pathogenesis of neurodegeneration and neuroinflammation has only recently begun. The purpose of the present study was to characterize ABC efflux transporter function in microglia and examine the effect of microglial activation on the cellular efflux of known MDR1, MRP, and BCRP substrates. A panel of fluorescent transporter substrates and known inhibitors were used to characterize the relative contribution of efflux transporters to the extrusion of these substrates from BV-2 microglia cells using the Nucelom Vision cellometer. Under normal conditions, BV2 cells actively transported rhodamine 123, calcine AM, and Hoechst. Microglial activation also increased cell accumulation of the fluorescent Bodipy-conjugated anxiolytic drug, prazosin, respectively. Activation of microglia with lipopolysaccharide (LPS) significantly reduced efflux transport function in microglia and examine the effect of microglial activation on the cellular efflux of known MDR1, MRP, and BCRP substrates. A panel of fluorescent transporter substrates and known inhibitors were used to characterize the relative contribution of efflux transporters to the extrusion of these substrates from BV-2 microglia cells using the Nucelom Vision cellometer. Under normal conditions, BV2 cells actively transported rhodamine 123, calcine AM, and Hoechst. Microglial activation also increased cell accumulation of the fluorescent Bodipy-conjugated anxiolytic drug, prazosin, respectively. Activation of microglia with lipopolysaccharide (LPS) significantly reduced efflux transporter function, indicated by up to a 90% increase in cellular retention of rhodamine 123, calcine AM, and Hoechst. Microglial activation also increased cell accumulation of the fluorescent Bodipy-conjugated anxiolytic drug, prazosin, by 52% and the pro-apoptotic lipid, NBD-Ceramide, by 119%. Reduced efflux transporter function in activated microglia is consistent with decreased transporter mRNA and protein levels observed previously in these cells. Collectively, these results suggest that microglial activation during neuroinflammation may impair normal regulatory functions of microglia including the efflux of potentially toxic compounds. **DECREASING THE TOXICITY OF HSP90 INHIBITORS FOR THE THERAPY OF PROTEIN FOLDING DISEASES.**

R. Xiong1, C. Chang1, D. Siegel1, R. Kitson2, C. J. Moody1 and D. Ross1.1Pharmaceutical Sciences, University of Colorado, Aurora, CO and 2School of Pharmacy, University of Maryland, College Park, MD.

The herbicide paraquat (PQ) has increasingly been reported in epidemiological studies to increase the risk of developing Parkinson’s disease (PD). Furthermore, case-control studies report that individuals with genetic variants in the dopamine transporter (DAT, SLC6A3) have higher PD risk when exposed to PQ. However, it remains a topic of debate whether PQ can enter dopamine (DA) neurons through DAT. We report here a novel mechanism by which PQ is transported by DAT: In its native divalent cation state, PQ2+ is not a substrate for DAT; however, when converted to the monovalent cation PQ+ by a reducing agent or NAPDH oxidase on microglia, it becomes a substrate for DAT and is accumulated in DA neurons, where it induces oxidative stress and cytotoxicity. Impaired DAT function in cultured cells significantly attenuated neurotoxicity induced by PQ+. Similar neuroprotection was also observed in mutant mice hypomorphic for DAT injected with this toxicant. In addition to DAT, PQ+ is also a substrate for the organic cation transporter 3 (Oct3, Slc22a13), which is abundantly expressed in non-DA cells in the nigrostriatal regions. In mice with Oct3 deficiency, enhanced striatal damage was detected after PQ treatment. This increased sensitivity likely results from reduced buffering capacity by non-DA cells leading to more PQ+ being available for uptake by DA neurons. This study provides a novel mechanism by which DAT and Oct3 modulate nigrostriatal damage induced by PQ+ redox cycling.
steroidselective neurotoxicity of some new anticonvulsant N,N'-disubstituted chiral spirohydantoins.

N. Anredy, R. A. Stephani, I. Sadarangani, S. Bhatia and J. N. Wurpel.
Pharmaceutical Sciences, St. John’s University, Jamaica, NY.

Four new N'-1, N'-3'-disubstituted-2H, 3H, 5'H-spiro-(2-benzofuran-1,4'-imidazolidine)-2,3,5'-triones bearing chiral N-3' and C-4 spiro chiral centers were synthesized and resolved into their four diastereomers. Each was tested for anticonvulsant activity by subcutaneous pentetrazole test and maximal electric shock (MES) assay. Phenobarbital and DMSO were used as positive and negative controls, respectively. A dose of 300 mg/kg of the test compounds was administrated to mice intraperitoneally. Neurotoxicity was determined by the rotorod and righting reflex tests using doses of 30, 100 and 300 mg/kg. The S,5 diastereomer had no anticonvulsant activity. The R.R and S.R diastereomers showed significant anticonvulsant activity in scPTZ test at 300 mg/kg, when compared to DMSO controls. The R,S diastereomer displayed little anticonvulsant activity in the MES test at 300 mg/kg. Compounds showing anti convulsant activity at a high dose (300 mg/kg) were tested for neurotoxicity. Owing to their pharmacokinetics parameters, 30 minutes was allowed before testing for motor coordination and righting reflex. The compound bearing the R configuration in the 1-phenylethyl substituent at the N-3' position significantly impaired the motor activity, (p<0.05) compared to negative control. R.S- and S.R diastereomers did not impair motor activity, but demonstrated anticonvulsant activity. This suggests that compounds with R-spiro carbon configuration selectively act on hippocampal neurons inhibiting the neuronal firing without affecting basal ganglia, whereas S-chiral stereoisomers, act nonselectively on basal ganglia, causing impaired motor coordination. None of the compounds had an affect on the righting reflex.

995 Revised reference concentration for manganese oxide based on recent epidemiological and pharmacokinetic studies.

Gradient, Cambridge, MA.

In 1993, based on observations of subclinical neurological effects in workers, the United States Environmental Protection Agency (US EPA) published a reference concentration (RfC) of 0.05 μg/m³ for manganese (Mn). Over the last 18 years, numerous epidemiological, toxicological, and pharmacokinetic studies have been conducted that strongly support a revision to the current Mn RfC. We reviewed the most recent data and propose two alternate RfCs for Mn. Of 12 recent occupational studies of eight cohorts with chronic exposure durations, examining subclinical neurobehavioral effects, predominantly on the motor system, three were considered appropriate for development of an RfC, based on use of respirable Mn data, personal air monitoring, and evaluation of an unexposed control population. All three studies yielded no observable adverse effect levels (NOAELs) of approximately 60 μg/m³ respirable Mn. We also reviewed recent physiologically based pharmacokinetic (PBPK) modeling studies that predict similar Mn tissue concentrations (from Mn inhalation exposure concentrations ranging from 1-10 μg/m³) in the target brain region in the human fetus, nursing infant, and child compared to those in the mother and other adults, suggesting that concentrations below 10 μg/m³ Mn in air would not lead to accumulation of Mn in the brains of human fetuses, children, and adults. Based on our review, we determined uncertainty factors (UFs) were not necessary for developmental toxicity or for use of a subchronic or lowest observable adverse effect levels (LOAEL) study. We applied a UF of 10 to account for susceptible subpopulations (abnormal hepatobiological function or sub-optimal iron). Converting the occupational NOAEL (60 μg/m³) to a human equivalent concentration (HEC) of 21 μg/m³ (for continuous exposure) yields a RfC of 2 μg/m³. We derived a similar RfC (7 μg/m³) using a Mn benchmark dose (BMD) of 200 μg/m³ as the point of departure. These RfC’s fall below the recently proposed Mn accumulation threshold of 10 μg/m³, providing additional support for their application in Mn inhalation risk assessments.

996 Comparison of brain metabolite changes in manganese-exposed welders and smelters.

Excessive manganese (Mn) exposure is known to cause cognitive, psychiatric and motor deficits. Mn overexposure occurs in different occupational settings, where the type and level of exposure may vary. Magnetic resonance imaging (MRI) and spectroscopy (MRS) can be used to evaluate brain Mn accumulation and to measure Mn-induced metabolic changes non-invasively. The aim of this study was to compare metabolite changes among different brain regions of welders and smelters following occupational Mn exposure. Nine Mn-exposed smelters, 14 Mn-exposed welders and 23 male matched controls were recruited from a cohort of workers from two factories in China (mean airborne Mn level: 0.227 and 0.025 mg/m³ for smelters and welders, respectively). Short-echo-time 1H MRS spectra were acquired in each subject from four volumes of interest: the frontal cortex, posterior cingulate cortex, hippocampus, and thalamus. We found that 1) in the frontal cortex, significantly decreased creatine (Cr), glutamate (Glu) and glutathione (GSH) were found in welders, whereas decreased Glu was found in smelters as compared to controls. 2) In the thalamus, reduced myo-inositol was found in both smelters and welders, while Glu and GSH were decreased in welders. These results suggest that Mn-induced brain metabolic changes may be regional in nature and more extensive in welders than in smelters. The frontal cortex seems to show a more profound change than the other brain areas tested among Mn exposed subjects. Further studies are needed to investigate the effects of exposure type and length on the mechanism of Mn neurotoxicity. (Supported by NIH/NIEHS R21 ES-017498, National Science Foundation of China Grant #81072320 and 30760210).

997 Baseline comparison of brain metabolites between rhesus monkeys and humans by rMRS.

1School of Health Sciences, Purdue University, West Lafayette, IN,
2Department of Radiology, Indiana University School of Medicine, Indianapolis, IN,
3School of Environmental Health Sciences, Purdue University, West Lafayette, IN and
4School of Public Health, New York, NY.

Magnetic Resonance Spectroscopy (MRS) provides a unique possibility to non-invasively detect and quantify brain metabolites in vivo. A variety of studies on manganese neurotoxicity are being performed in monkeys and in humans using MRS. However, little is known about the difference of brain metabolites between monkeys and humans using MRS. Here we compare the baseline difference of brain metabolites, especially of the major inhibitory neurotransmitter gamma-aminobutyric acid (GABA), between the two species using exactly the same imaging sequence on the same type of scanner. Brain metabolites of 7 rhesus monkeys (male, mean age 6.5y, about 20y in human years) and 8 healthy humans (male, mean age 26.5y) were acquired on a 3T Philips Achieva clinical MRSI scanner. GABA data was obtained from a brain volume containing thalamus and adjacent basal ganglia structures by the MEGA-PRESS sequence. Other brain metabolites were obtained and scaled to water in volumes of frontal cortex and thalamus, including glutamate (Glu, the major excitatory neurotransmitter), N-acetyl aspartate (NAA; a neuronal marker), total creatine (tCr) and choline (tCho). We found that monkey thalamus showed higher GABA/Cr than human thalamus, with a difference of 27.6% (p<0.05). Monkeys had lower NAA in both the frontal cortex (p<0.01) and thalamus (p<0.05). Levels of Glu and tCho were higher in human frontal cortex (p<0.05), while tCr was higher in human thalamus (p<0.05). These results provide firsthand information on the baseline differences of various brain metabolites between rhesus monkeys and humans. (Supported by NIH ES017498 and ES010975).

998 Increased cortical GABA levels in manganese-treated rats.

S. Dharadhikari1, 2, J. Xu2, A. Erass4, W. Zheng3 and U. Dydak1, 2.
1School of Health Sciences, Purdue University, West Lafayette, IN and
2Indiana University School of Medicine, Indianapolis, IN.

While manganese (Mn) is important for neuronal function, high exposure levels may cause neurotoxicity leading to Parkinsonism. Both in early idiopathic Parkinson’s disease as well as in Mn intoxication, there is an increase in γ-aminobutyric acid (GABA) in the basal ganglia and thalamus have been reported, suggesting the importance of GABA in Mn-induced neurotoxicity. In this pilot study, we used 1H brain Magnetic Resonance Spectroscopy (MRS) to examine in vivo GABA levels in selected brain areas of rats subchronically exposed to Mn. This longitudinal study included 5 adult rats receiving 6 weeks of ip MnCl₂ injections (10mg/kg, 5 d/wk) and 3 adult rats receiving saline injections as controls. 1H brain MRS was conducted on a 9.4T MRI scanner at baseline, wk 2, 4, and 6. H spectra were acquired from the cortex, thalamus and striatum using an ultra-short-echo-time single voxel...
Excessive occupational and environmental Manganese (Mn) exposure may induce Parkinsonism; yet the mechanism has not been completely elucidated. The regulation of brain Mn depends largely on the blood-brain barrier and blood-cerebrospinal fluid barrier (BCB). The latter is constituted by choroid plexus (CP) epithelial cells, which is specialized for cerebrospinal fluid (CSF) production, has been considered as a primary target in Mn-induced neurotoxicity. This study aims to explore the differential proteome in CSF after severe acute and subchronic Mn exposure in SD rats. Rats (1.5 month) were divided into 6 groups; each received daily ip injections of either MnCl2 (6 mg Mn/kg BW) or saline (as controls) for 30 days. The CSF were collected and analyzed. This Mn-animal model was evaluated and Mn-related proteome in CSF was analyzed by a novel proteomic technique of label-free nanoHPLC-Q-TOF-MS/MS. A total of 123 Mn-related differential proteins in CSF were identified, of which 55 were up-regulated, 68 were down-regulated. Based on the information of Gene Ontology (GO) categories, these differentially expressed proteins were mainly from the nuclei, involving in the function of binding; however, more than half of the proteins have no clear biological function. Biological functions of these CSF proteins generated by PANTHER were produced and excerted by CP, these differential proteins may be valuable for explore the novel potential biomarkers to diagnose and monitor the progression of Mn-induced neurodegenerative disease clinically; meanwhile, the results shed light on the future molecular mechanism study of Mn on choroid plexus epithelial cells. Further verification of these differentially expressed proteins and analysis including protein-protein interaction deserve in-depth investigation.
Environmental exposure to excessive manganese (Mn) is known to cause a neurologically condition termed manganism, resulting from impairment of neurons within basal ganglia. However, the cellular and molecular mechanisms underlying the neurotoxic effects of Mn remain elusive. Because we recently demonstrated that protein kinase Cδ (PKCδ) is an oxidative stress sensitive kinase that plays a causal role in apoptotic cell death in Mn neurotoxicity models, herein we examined the molecular mechanisms underlying PKCδ gene expression in neuronal cells during Mn exposure. As a proof of concept, we first examined the effect of Mn on PKCδ expression in NIE115 cells and primary striatal neurons as well as in animal model of Mn neurotoxicity. Mn exposure (100–300 μM for 24–48h) potently induced PKCδ protein and mRNA levels in primary striatal neurons and NIE115 cells. Importantly, Mn exposure (3 or 10 mg Mn/kg) in C57 black mice via oral route also confirmed the PKCδ upregulation in the basal ganglia. Primary striatal neurons obtained from PKCδ knockout mice showed reduced sensitivity against Mn toxicity, demonstrating that PKCδ plays a critical role in Mn-induced neurotoxicity. We further elucidated the mechanisms underlying the Mn-induced up-regulation of PKCδ in cell culture models. Using both PCK and ChIP assays, we identified that NFKB is essential for both basal and Mn-mediated PKCδ expression. In addition, we investigated the possible involvement of DNA methylation in regulating PKCδ expression. Using bioinformatics method, we found a putative CpG island (+39 to +400 relative to transcription start site) located within mouse PKCδ promoter. By methylation-specific PCR, we identified that the PKCδ promoter is partially methylated in neuronal cells. Collectively, our data suggest that environmental Mn exposure can alter expression of oxidative stress sensitive kinase PKCδ in the basal ganglia and that both NFKB β and promoter methylation play roles in regulation of PKCδ gene expression (supported by NIH grants ES10586 & ES19267).

While much is known about potential cellular mechanisms of manganese (Mn) neurotoxicity at elevated exposure levels, little is understood about cellular responses to lower exposures at the transition between physiologic to toxic levels of Mn. Previously we showed that elevated cellular Mn levels lead to the rapid lysosome-mediated degradation of the cis-Golgi associated protein Golgi phosphoprotein 4 (GPP130) in AF5 cells. In order to determine if GPP130 plays a role in mediating the cytotoxic effects of Mn, we investigated the dynamics of the Mn effect on GPP130 degradation in vitro and in vivo. We determined that GPP130 degradation in AF5 cells is specific to Mn, and not other divalent cations, since cellular GPP130 levels were reduced by ~80% in cells treated with 100 μM Mn for 24 hours, while no effect was observed in cells treated with 100 μM Co, Cu, Zn, Ni, or 300 μM Fe. To determine the sensitivity of the GPP130 degradation response to Mn, AF5 cells were treated with 0.25, 1, 5, 25, or 150 μM Mn for 24 hours. Results show that GPP130 degradation occurs in a dose-response manner starting at the lowest Mn exposure level of 0.25 μM, even though total intracellular Mn levels measurably increased only in the 150 μM treatment. This suggests that GPP130 degradation is sensitive to immeasurably small changes in intracellular Mn levels. To determine the temporal nature of the GPP130 degradation response to Mn, AF5 cells were treated with 5 or 100 μM Mn for 1, 2, 4, or 8 hours; results indicate that GPP130 degradation occurs very rapidly, with significant (~40%) GPP130 degradation by 1 hr at 100 μM Mn and ~25% GPP130 degradation by 2 hours at 5 μM Mn. Collectively, these results suggest an important and novel cellular response to Mn over the transition from physiologic to toxic cellular Mn levels. Studies now underway are exploring the role of GPP130 in mediating the sensitivity of cells to elevated Mn, and the extent that these effects occur in an animal model of early-life Mn exposure.
**PS 1007 MANGANESE DECREASES HUNTINGTIN PROTEIN EXPRESSION AT SERINE 421, INCREASES HUNTINGTIN PROTEIN LEVELS, AND DECREASES BDNF EXPRESSION IN CULTURED NEURONS; IMPLICATIONS FOR STRIATAL MEDIUM SIZE SPINY NEURON DEGENERATION IN MANGANESE NEUROTOXICITY AND IN HUNTINGTON'S DISEASE.**

In Huntington's disease (HD), the polyglutamine expansion in the Huntingtin (Htt) gene is pathogenic and results in medium size spiny neuron (MSN) degeneration in the striatum due to decreased synthesis and disruption of brain-derived neurotrophic factor (BDNF) transport from cortical neurons (Zuccato et al., Brain Path 18: 225, 2008). Phosphorylation of Htt at serine 421 (S421) has been shown to control neurotoxic support and survival of MSN by regulating BDNF synthesis, BDNF vesicular transport (Gauthier et al. Cell 118: 257, 2004) and NMDA receptor excitotoxicity (Metzler et al., J Neurosci 30: 14318, 2010). Similarly, high dose Mn injections have been shown to decrease MSN dendritic length and dendritic spine density in the striatum (Milatovic et al. TAAP 240: 219, 2009). In the present study, we thought to determine if Mn had an effect on Htt protein level and phosphorylation at S421 and BDNF levels. Primary culture of cortical (Ctx) and hippocampal (Hipp) neurons exposed to low levels of Mn (vehicle, 1 or 5 μM) during DIV7-12 decreased dendritic (immuno-cytchemistry) and whole cell (Western blot) proBDNF protein levels in both culture types. Exposure to Mn also significantly reduced pS421Htt levels in cortical and Hipp neurons while increasing total Htt protein at the highest level of Mn exposure. These data indicate that excess levels of Mn can have neurotoxic effects in MSN by decreasing the phosphorylation of Htt at S421, an effect that has been associated with decreased BDNF synthesis and transport. These studies also suggest the possibility that excess exposure to Mn may be able to modify the temporal expression of HD by affecting the same molecular and cellular mechanisms as the polyglutamine expansion of the Htt gene, the principal cause of neurodegeneration in HD. [This work was supported by NIEHS grant ES010975 to TRG]

**PS 1009 HUMAN α-SYNUCLEIN PROTECTS AGAINST MANGANESE NEUROTOXIC INSULT DURING THE EARLY STAGES OF EXPOSURE IN A DOPAMINERGIC CELL MODEL OF PARKINSON'S DISEASE.**

D. Harischandra, H. Jin, A. Kanthasamy, V. Anantharam and A. G. Kanthasamy, Biomedical Sciences, Iowa State University, Ames, IA.

The role of α-synuclein (α-Syn) aggregation in neurodegeneration is well recognized, but the physiological function of normal α-Syn protein remains unknown. Recently, we demonstrated that α-Syn negatively regulates a proapoptotic kinase Protein Kinase Cδ (PKCδ) and suppresses parkinsonian toxicant MPP+ induced dopaminergic neurodegeneration. In the current study, we further show that α-Syn exhibits a neuroprotective role against acute manganese (Mn) induced neurotoxicity in a dopaminergic cell model of Parkinson's disease (N27 cells). Stable expression of human wild type α-synuclein at physiological levels in N27 cells significantly attenuated Mn (300μM) induced neurotoxicity for up to 24 hr of exposure. To further explore the cellular mechanisms, we studied the mitochondrial dependent apoptotic pathway. Western Blot analysis revealed a time-dependent reduction in the levels of cytosolic cytochrome c release following Mn exposure in the α-Syn expressing cells compared to vector control cells. Further analysis of the caspase cascade suggests that α-Syn significantly attenuated the Mn-induced caspase -3 and -9 activation in a time-dependent manner. Interestingly, the Mn-induced reactive oxygen species (ROS) generation was not affected by stable expression of α-Syn in N27 cells. Stable expression of α-Syn significantly decreased Mn-induced cytochrome c release and cytochrome c translocation for the pro-apoptotic kinase PKCδ. Furthermore, we examined whether α-Syn interferes with Mn transportation into the cells. ICP-MS studies revealed no significant differences in intracellular Mn levels in treated vector and α-Syn cells. Analysis of metal transporter DMT1 expression also showed no differences between α-Syn over expressed cells and vector cells, suggesting α-Syn didn’t interfere with Mn uptake in the cells. Collectively, these results demonstrate that α-Syn exhibits neuroprotective effects against Mn induced neurotoxicity during early acute toxicity in a dopaminergic neuronal model of PD (NIH grants ES19267 ES01586 NS74443).

**PS 1010 EXPRESSION AND AGGREGATION OF A-SYNUCLEIN IN THE BLOOD-CSF BARRIER: INITIAL EVIDENCE FOR THE INFLUENCE OF CELLULAR MANGANESE AND COPPER STATUS.**

C. A. Bates, G. Zheng, X. Fu and W. Zheng, Health Sciences, Purdue University, West Lafayette, IN.

The blood-cerebrospinal fluid barrier (BCB) is a specialized tissue composed of choroid plexus epithelia and functions to produce the cerebrospinal fluid (CSF) and maintain the homeostasis of a wide variety of molecules in the brain. Alpha-synuclein (a-Syn) plays a central role in the pathology of Parkinson's disease (PD) and is detectable in the CSF. Little is known about the BCB's role in the transport and clearance of CSF a-Syn in the early stages of PD. This study was designed to test the hypothesis that choroidal epithelial Z310 cells express a-Syn endogenously, and exposure to toxic metals may increase its expression and/or induce aggregation. Both Western blot and confocal imaging (CI) revealed that a-Syn was expressed naturally in Z310 cells, and that clathrin was incorporated in extracellular a-Syn uptake. When Z310 cells were incubated with 100 μM MnCl2 for 24 and 48 hr, the immunofluorescence data obtained by CI showed that in comparison to the cytosolic, homogenous signal of the control cells, Mn exposure induced a-Syn aggregation characterized by the formation of the small, cytosolic dots emitting a relatively intense signal. Our lab has recently produced an iZCTR1 cell line which, upon adding tetracycline (Tet) to the culture medium, can induce the overexpression of a copper (Cu) transporter CTR1 (see poster by Zheng G & Zheng W). Treatment of iZCTR1 cells with 1 μg/mL Tet for 24 hr followed by incubation with 5 μM CuCl2 for 1 hr resulted in visible a-Syn aggregation in iZCTR1 cells. These results suggest the BCB expresses a-Syn, Mn exposure likely facilitates the cellular aggregation of a-Syn in the BCB. This effect may be due in part to Mn-induced Cu accumulation in the BCB (see poster by Fu et al); the latter in turn induces a-Syn aggregation. These data provide the foundation on which further studies on a-Syn transport at the BCB and its effects of toxic metal exposure are warranted. (Support by NIH/NIEHS ES08146-S2 Minority Supplemental Award.)
Copper (Cu) is an essential trace element that requires tight homeostatic regulation to ensure appropriate supply without any toxic effects as a result of the strong redox potential of the metal ion. This study was designed to elucidate the mechanism by which iron deficiency (FeD) results in excess Cu accumulation at the blood-CSF barrier. To explore this mechanism we examined the effect of FeD on cellular Cu re- tention and transporters Ctr1, DMT1, ATOX1, and ATP7A in choroidal epithelial Z310 cells. Results revealed that deferroxamine treatment (FeD) resulted in signific- antly increased cellular Cu retention (p<0.05). In addition, FeD treatment re- sulted in a significant increase in the mRNA levels of DMT1, ATOX1, and ATP7A. Knock down of Ctr1 or DMT1 resulted in significantly lower Cu uptake by Z310 cells while the knockdown of ATOX1 or ATP7A resulted in substantial in- creases of cellular accumulation of Cu. In addition, DMT1 knockdown followed by FeD treatment in Z310 cells did not result in the significant accumulation of in- tracellular Cu found with FeD treatment alone. mXRF imaging demonstrated that Cu localized in the subventricular zone (SVZ) of the brain ventricles, was not af- fected by systemic Fe status. However, linear regression analysis of the SVZ identi- fied a strong positive correlation between Cu and Fe (r=0.538, p=0.07). Taken to- gether, these results suggest that Ctrl, DMT1, ATOX1, and ATP7A contribute to Cu transport at the BCB and that the accumulation of intracellular Cu found in the Z310 cells during FeD appears to be mediated, at least in part, via the upregulation of DMT1 following FeD treatment.

Zinc has long been touted as a panacea for the common cold. However, there has been some controversy over whether an intranasal (IN) zinc gluconate gel (Zicam), purported to fight colds, causes anosmia, or the loss of the sense, of smell in hu- mans. Prior evidence has shown that IN zinc sulfate solutions can cause anosmia in humans, as well as significant damage to the olfactory epithelium in rodents. However, more recent work has claimed to show that zinc gluconate is less toxic than zinc sulfate. Using an in vitro olfactory neuron model (the rat Odora cell line) to compare the toxicity of zinc sulfate and zinc gluconate on immature and mature rat olfactory sensory neurons, we found that the toxicity of both zinc salts was sim- ilar, with zinc sulfate being slightly more toxic than zinc gluconate. Interestingly, toxicity to Odora cells occurred at significantly lower zinc concentrations (0.1 – 0.4 mM) than that found in Zicam nasal gel (35 mM), which lends credence to the epidemiological link between IN zinc exposure and anosmia. We hypothesized that zinc toxicity was caused by inhibition of the HV CN1 proton channel, leading to acidosis and apoptotic cell death. Olfactory sensory neurons in vivo are able to maintain their intracellular pH through a Na+/H+ exchanger, specifically NHE1, and a Cl/HCO3- exchanger. Zinc sulfate, at non-toxic levels, had no im- pact on intracellular pH via proton transport either after acute exposure or after 24 hours incubation with the cells. In conclusion, zinc toxicity is not mediated through an acidification of intracellular pH in olfactory neurons in vivo.

Accumulation of amyloid beta protein (Aβ) play a major role in the etiology of Alzheimer’s disease (AD). Aβ are generated by the cleavages of amyloid precursor protein (APP) by beta-site APP-cleaving enzyme 1 (BACE1). Decrease of Aβ con- centration in the brain are involved in two major factors that are degradation by peptides such as neprilysin (NEP) and are regulated via two main receptors, the low density lipoprotein receptor related protein 1 (LRP1) and the receptor for advanced glycation end products (RAGE), on blood-brain barrier (BBB). LRP1 is the main receptor that clears Aβ from the brain to body, in contrast RAGE is the main receptor that transports Aβ from the body to brain. Copper (Cu) is well known that AD-related element, especially it’s involved in Aβ aggregation and toxicity. According to a recent study, in addition, it’s reduce Aβ clearance from brain in cho- lesteryl-fed rabbits. However, the critical mechanism is unclear. This study have demonstrated whether Cu would alter accumulation of Aβ in brain, we have used an immortalized line of rat brain endothelial cells (RBE4 and PC12 cells, well-de- fined neurodevelopmental cells, to estimate Cu effect in brain. When PC12 cells were treated with 100 μM Cu for 24 h, 48h and 72h, Aβ accumulation in culture medium was increased by 120.1%, 133.6% and 144.0%, respectively, in compari- son to those of controls. Also PC12 cells were treated with 100 μM Cu for 24 h, mRNA expression of APP was increased by 120.1% in comparison to controls. Moreover, mRNA expression of BACE1 and NPP were 102.5% and 55.1%, re- spectively, in comparison to those of controls. When RBE4 cells were treated with 100 μM Cu for 24 h, mRNA expression of LRP1 and RAGE were 84.2% and 111.4%, respectively, in comparison to those of controls. These results show that Cu have upregulated Aβ production and arrested Aβ degradation, also it has de- creased clearance of Aβ in brain via LRP1 and RAGE on BBB.

Accumulation of amyloid beta protein (Aβ) play a major role in the etiology of Alzheimer’s disease (AD). Aβ are generated by the cleavages of amyloid precursor protein (APP) by beta-site APP-cleaving enzyme 1 (BACE1). Decrease of Aβ con-
we normalized to the endogenous control GAPDH and the untreated animals. Expression of all subunits was upregulated in the treatment group. The α6 subunit was the most affected. At 5ppm the expression of α6, β, and γ subunits is not affected. The relative expression was close to control levels. However, α6 and δ subunits were both downregulated. The α6 subunit which uniquely expressed in granule cells is the most affected of the subunits studied. Its upregulation in the low MeHg treated group may result from a compensatory mechanism, since these are more susceptible at lower concentrations of MeHg than are the purkinje cells. In the high MeHg treated group downregulation of α6 may reflect loss of granule cells. Supported by NIH grants R01ES03299 and R25NS067777.

1016 IDENTIFICATION AND CHARACTERIZATION OF MOLECULAR MODULATORS OF METHYLMERCURY-INDUCED TOXICITY AND DOPAMINE NEURON DEGENERATION IN C. ELEGANS.

N. VanDuren, R. Settivari and R. Nass, Pharmacology & Toxicology, Indiana University School of Medicine, Indianapolis, IN.

Methylmercury (MeHg) exposure from occupational, environmental, and food sources is a significant threat to public health. MeHg poisonings in adults may result in severe psychological and neurological deficits, and in utero exposures can confer embryonic defects and developmental delays. Recent epidemiological and vertebrate studies suggest that MeHg exposure may also contribute to dopamine (DA) neuron vulnerability and the propensity to develop Parkinson's disease (PD). We have developed a novel Caenorhabditis elegans (C. elegans) model of MeHg toxicity that shows that low, chronic exposure confers embryonic defects, developmental delays, decreases in brood size and animal viability, and DA neuron degeneration. Toxicant exposure results in the robust induction of the glutathione-S-transferases (GSTs) gst-4, gst-5, gst-12, gst-21, and gst-38, and with some GSTs largely dependent on the PD-associated phase II antioxidant transcription factor SKN-1/Nrf2. We also demonstrated that the expression of SKN-1, a protein previously localized to a small subset of chemosensory neurons and intestinal cells in the nematode, is also expressed in the DA neurons, and a reduction in SKN-1 gene expression increases MeHg-induced animal vulnerability and DA neuron degeneration. We will present results from our genome-wide reverse genetic screen to identify mediators and suppressors of MeHg-induced toxicity, as well as our investigations using DA-associated mutants to elucidate the role that the neurotransmitter may play in the toxicity.

1017 METHYLMERCURY (MeHg) DISRUPTS FLUO4 FLUORESCENCE IN CEREBRAL SLICES FROM GABA_A RECEPTOR α6 (-/-) MICE.

A. B. Bradfood, 1, 2 and W. D. Atchison, 1 1Biochemistry/Molecular Biology, Michigan State University, East Lansing, MI, 2Pharmacology & Toxicology, Michigan State University, East Lansing, MI and 3Center for Integrative Toxicology, Michigan State University, East Lansing, MI.

MeHg targets the cerebellum, especially developing cerebellar granule cells (CGCs). The γ-amino butyric acid type A receptor (GABA_A, R) is important in CGC intracellular [Ca^2+] ([(Ca^2+)]_i) control and cell excitability. It is highly sensitive to acute MeHg exposure. GABA_A, R subunit composition may contribute to cell-specific and developmental susceptibilities to MeHg. We examined acute effects of MeHg on cerebellar slices from mice (KO) lacking the α6 GABA_A, R subunit. α6 exists exclusively in mature CGGs and regulates their tonic inhibition. It coexists in CGGs with the abundant α1 subunit, which is not involved in tonic inhibition, nor expressed only in CGGs. Changes in fluo4 fluorescence induced by MeHg were compared in KO and WT mice using fluorescent confocal microscopy of migrating external granule layer (EGL) and post-migratory internal granule layer (IGL) CGCs. MeHg (20μM) increased overall fluorescence in both regions. In KO cerebellar slices, MeHg increased fluorescence significantly at 20 min; peak effect (300±70% over baseline) in IGL occurred at 55 min. In the same slices, MeHg increased fluo4 fluorescence significantly over pretreatment baseline in IGL at 15 min, at 55 min, the effect was 181±20%. Though MeHg treatment appeared to increase fluorescence in WT slices, the effect was not significant within 55 min. In the IGL of KO slices, MeHg increased fluorescence significantly compared to WT from 30 min on. Pulses of the GABA_ R agonist muscimol (100μM) to tissue perfused with MeHg caused a 75±25% reduction compared to MeHg alone in IGL of KO mice. While the α6 subunit is expressed fully in CGGs still is a pronounced effect of MeHg on [Ca^2+]_i in immature CGGs of α6 KO mice. Thus α6 may reflect loss of granule cells. Supported by NIEHS grants R01ES03299 and T32ES007255.

1018 SUSCEPTIBILITY TO METHYLMERCURY-INDUCED (MEHg) CYTOTOXICITY IN HEK-293 CELLS: ROLE OF NEURONAL VOLTAGE-GATED CALCIUM CHANNEL (VGCC) α6 SUBUNITS.

M. Rios Cabanillas, 1, 2 H. Hannon* and W. D. Atchison, 1 Pharmacology & Toxicology, Michigan State University, East Lansing, MI and 2RISE Program, University of Puerto Rico, Cayey, Puerto Rico.

MeHg, an environmental neurotoxicant, acts on specific cellular targets such as VGCCs to elicit severe pathological effects. Low μM MeHg blocks current through VGCCs and elevates ([Ca^2+]_i) via cytosolic pathways in vitro. onset of MeHg-induced increases in ([Ca^2+]_i) varies with the VGCC phenotype as determined by the pore-forming α6 subunit expressed. Susceptibility of individual VGCC isoforms to MeHg-induced cytotoxicity was examined by transient transfection of HEK-293 cells with a 1:1:1 mixture of α6, α6β, and β2I VGCC subunits. The α6 subunit was varied to produce L-, N-, P/Q- and R-type VGCC isoforms (Cav1.2, 2.2, 2.1 and 2.3, respectively), corresponding to α6, α6β, α6β and α6γ subunits. Cytotoxicity was assayed 1 hr or 24 hrs after 1 hr MeHg exposure (1, 2 and 5 μM). Viability of untransfected HEK-293 cells was concentration-dependent at all [MeHg], though there was no observable time-dependence at 1 or 2 μM MeHg. Expression of VGCCs, regardless of isoform, reduces cell viability at all [MeHg] and time points examined. Cav1.2-transfected cells were most susceptible to MeHg. Viability was reduced to 2.0±0.9% (mean % viability ± SEM) 1 hr after exposure to 5 μM MeHg. In contrast, Cav2.1 were most resistant to 5 μM MeHg (29±8.9%). Cav2.2 (4.5±1.9%) and Cav2.3 (12.7±4.2%) were moderately susceptible at this [MeHg]. The rank order viability at 24 hrs postchallenged that at 1 hr. Cav2.1 was most susceptible (3.4±1.6%) and Cav2.1 was most resistant (26.7±10.3%) to 5 μM MeHg, while Cav2.2 and Cav2.3 were of intermediate susceptibility (6.7±3.0% and 21.7±8.8%, respectively). Viability of transfected cells was only marginally reduced by 1 and 2 μM MeHg. A concentration-dependent effect was observed for all isoforms, as well as a trend towards time-dependent cytotoxicity. Together, these results demonstrate that susceptibility of VGCCs to MeHg-induced Ca^2+-dependent cytotoxicity is isoform-dependent, and the relative expression pattern of VGCCs may affect a neuron’s susceptibility to MeHg.

1019 ACUTE IN VITRO EXPOSURE TO METHYLMERCURY AFFECTS SHORT-TERM SYNAPTIC TRANSMISSION AND PLASTICITY IN CEREBRAL SLICES OF ADULT AND AGING MICE.

Y. Yuan, W. Ku, S. M. Fox, E. Wakeling, D. Autio and W. D. Atchison, Pharmacology & Toxicology, Michigan State University, East Lansing, MI.

Effects of MeHg on the adult, and particularly the aging brain, have not been well characterized. Changes in synaptic plasticity occur during aging that could be worsened by exposure to an environmental neurotoxicant. In the present study, we examined acute effects of MeHg on synaptic transmission and short-term synaptic plasticity in cerebellar slices prepared from adult (9 mo old) and aging (20 mo old) mouse brains using whole-cell patch clamp recording techniques. Acute bath application of 20 μM MeHg initially stimulated then suppressed spontaneous glutamate-mediated excitatory postsynaptic currents (sEPSCs) recorded from cerebellar Purkinje cells. The onset of the initial increase appears to occur earlier in 20 mo old mice than in 9 mo old mice. Consistent with the increased frequency of sEPSCs, MeHg altered short-term synaptic plasticity in both groups. It promotes paired-pulse facilitation (PPF) by increasing the ratios of the second stimulus-evoked response (EPSC2)/the first stimulus-evoked response (EPSC1) or reversing paired-pulse depression (PPD) to PPF. This suggests that MeHg acts on presynaptic processes to alter the release probability of the transmitter glutamate. MeHg always blocked evoked ESPCs earlier than it did spontaneous ESPCs. This may be due to block by MeHg of volatile, low affinity Cav2.1. The voltage-gated NC channel-mediated outward currents were unaffected by MeHg, suggesting differential sensitivity of different ion channels to MeHg. However, unlike the MeHg-induced transient hyperpolarization of neuronal membranes in young animals, MeHg caused a gradual and persistent hyperpolarization of neuronal membranes in adult and aging mice. Thus, in vitro MeHg exposure affects short term plasticity in both adult and aging mice. However, the effect appears to occur earlier in the aging group, suggesting interaction with age-related senescence of MeHg. Supported by NIEHS grant ES03299.
Disruption of intracellular calcium, [Ca\text{2+}]i, regulation is an early and crucial event in MeHg-induced neurotoxicity. Acute and chronic exposure to MeHg targets the cerebellum, causing loss of the granule cell layer. The striatum is another potential target due to its high level expression in medium spiny neurons (MSNs) of Ca\text{1,3}, an L-type Ca\text{2+} channel that is susceptible to MeHg. Effects of MeHg on aged individuals have not been characterized, however contemporary MeHg exposure occurs over an individual's lifespan. As neuronal [Ca\text{2+}]i homeostasis is significantly altered during aging, aged neurons may be especially susceptible to MeHg. We compared effects of MeHg on [Ca\text{2+}]i dysregulation in cerebellar granule cells and interneurons and in stratal MSNs of 9 or 20.5 mo old mice. Changes in relative fluorescence (RF) of Fura-2, a [Ca\text{2+}]i indicator, were measured in sagittal cerebellar and coronal midbrain slices from male ICR mice using laser scanning confocal microscopy. MeHg (20 μM) was applied for 45 min. No significant difference occurred in RF in cerebellar granule cells or molecular layer interneurons in 9 or 20.5 mo old mice. However, the mean time to maximum RF was reduced in 20.5 mo old mice, suggesting a decreased ability to buffer [Ca\text{2+}]i. In the striatum, the RF increase did not significantly differ, nor did the time to maximum RF in 9 or 20.5 mo old mice. MSNs of 9 mo old mice segregate into two distinct populations: one consisting of a small population of neurons which exhibit a large RF increase and the other exhibiting only a minimal RF increase upon MeHg treatment. There are at least two subsets of MSNs based on expression of dopamine receptors. The observed differential response to MeHg may be due to the neuronal complement of ion channels and neurotransmitter receptors. These results suggest that interaction of the natural aging process with exposure to environmental neurotoxins can alter the cellular response to the toxicant. Supported by NIH grants R01ES03299 and T32ES007255.

Methylmercury (MeHg) causes a time- and concentration-dependent increase of intracellular Ca\text{2+} (Ca\text{2+}[i]) in cerebellar granule cells (CGCs), an effect sufficient to cause their death in vitro. Voltage-gated Ca\text{2+} channels (VGCCs) are important in the onset of this effect. Treatment with VGCC blockers reduces toxicity induced by chronic exposure with MeHg. CGCs with the naturally-occurring Lh1A pore-forming subunit of P/Q-type (Ca\text{V2.1}) VGCCs, and approximately 25% of Lh1β subunits of N-type (Ca\text{V2.2}) VGCCs. To compensate partially for this, increased association of α1 and β1 with β10 and β13 occurs. This could be skew these channels with different properties. Effects of a faster onset of MeHg-induced [Ca\text{2+}]i increase on viability of Lh CGCs were examined using a fluorescent live/dead assay. CGCs were isolated at PND 7 and cultured for 4, 6, 8, and 10 days in vitro (DIV) to account for changes in VGCC gene expression as a result of cell maturation. Cells were exposed to MeHg (0, 0.3, 1, or 3 μM) for 4, 8, and 24 hrs. This was followed immediately by a calcium-AM and ethidium homodimer-1 treatment to assess for live and dead cells, respectively. Lh-CGCS had a higher percentage of cell death at DIV 6 and 8, after 8 hrs of MeHg exposure. There was no difference in cell death percentage between genotypes after 4 hrs of MeHg exposure at any DIV. After 24 hr of exposure, all genotypes had nearly a 100% cell death. For all genotypes, the cytotoxicity was time- and concentration- dependent. These results strengthen the idea of a crucial role of VGCCs in the mechanism of MeHg-induced cytotoxicity. VGCCs, and suggest a gene/environment interaction that may exacerbate the effects of MeHg in the cerebellum. Supported by NIH grants R01ES03299 and R25NS06577.
Hypothyroidism in adulthood has been associated with cognitive decline, and both development and in adulthood. The hippocampus is critical for some types of memory, including trace fear conditioning, amplitudes of excitatory synaptic potentials, and working memory. Adult male rats (PN60-80) were exposed to propylthiouracil (PTU: 0 or 10 ppm), through the onset TH deficiency on hippocampal physiology and learning. Adult male rats were sacrificed by decapitation and their forebrains were dissected and immediately frozen for subsequent western blot analysis probed with a heat-shock protein 90 (HSP90) antibody. Brains were also sectioned and analyzed for astroglial (GFAP) and stress markers (RAGE and HSP90 antibodies). GSSP exposures did not produce any significant changes in HSPP90 levels in either males or females. CDMA IS-95 exposures significantly increased HSP90 at 3, 6, and 9 W/Kg in males. At 9 W/Kg in both sexes, exposure to both GSM and CDMA modulation increase astrocytes and number of RAGE- and HSPP90-positive cells. These preliminary studies indicate that the effects of different types of mobile phone RF are dose- and gender-dependent. Studies are underway to further examine the observed gender differences and to evaluate whether RF exposure might have any potential neuronal damaging effects in specific brain regions. (FDA/NCTR IAG # 224-070-0007) (NIH IAG # YIES1027).

This study was designed to examine the effect of multiple doses of methamphetamine (METH) and MPTP on the retinal dopaminergic system. Six month old C57BL/6 mice were injected i.p. with either a low-dose (LD - 2 doses of 5 mg/kg) or high-dose (HD - 3 doses 10 mg/kg) of METH or MPTP or equivalent amount of saline as a control. Mice were sacrificed 1 day after treatment by cervical dislocation; retinas were removed using the Winkler technique and immediately frozen. Retinas were thawed on ice, homogenized by sonication in 300 μl of 0.2 M perchloric acid and 1 μM DHBAA as internal standard, and centrifuged at 13,000 x g for 10 minutes at 4°C. The supernatant was filtered through a 0.45 μm membrane and a 25 μl aliquot was analyzed using HPLC for dopamine (DA) and its metabolites, 3,4-Dihydroxyphenylacetic acid (DOPAC) and Homovanillic acid (HVA). METH produced no significant changes in DA, or its metabolites in the retina. LD MPTP produced no change in DA level, but significantly decreased DOPAC (R) 19% and 39% respectively. HD MPTP significantly decreased DA, DOPAC, and HVA levels 26%, 28% and 30% respectively. Additionally, LD MPT significantly decreased the DOPAC/DA and HVA/DA ratios 17% and 44% respectively. Mice did not show any significant changes in DA or its metabolites when exposed to multiple doses of METH. Although, METH is known to cause a release of DA, this is likely a transient phenomenon, and levels quickly return to normal after treatment. Where as MPTP, a selective, dopaminergic neurotoxin used to model Parkinson's disease, caused a significant decrease in DA and its metabolites. MPTP also decreased DA utilization as evidenced by significantly decreased DOPAC/DA and HVA/DA ratios. Taken together these results suggest that inhibition of the DA metabolizing enzymes MAO or COMT may take place at lower doses of MPTP treatment; conversely, higher doses of MPTP may cause decreases in DA, DOPAC and HVA through apopotic cell death cell death in the retinal dopaminergic system.
methamphetamine (METH), we documented elevated neuroinflammation, which may serve as a modulator or mediator of astroglial/microglial activation. Activated glia (associated with all types of brain injury) may be neuroprotective or exacerbate neural damage. Our prior genetic and pharmacological interventions have resulted in partial suppression of METH induced neuroinflammation without affecting neurotoxicity/astrogliosis. Here, mice were pretreated with the stress hormone corticosterone (CORT; 400 mg/L drinking water) for 1 week or repeated stress for 5d, consisting of social reorganization and cage shaking. METH administration alone (20mg/kg, s.c.) caused significant increases in proinflammatory cytokine (TNFα, IL6, CCL2, IL1β, IL10, LIF, OSM) mRNA expression in striatum at 12h. By 72h marked astrocytic hypertrophy (GFAP protein/immunohistochemistry(IHC)), microglial activation (isolectin IHC) and dopaminergic nerve terminal damage (TH protein/IHC) was observed in striatum. Chronic CORT pretreatment caused exacerbated inflammation, astrocyte hypertrophy and microglial activation after METH exposure in the striatum, hippocampus and cortex. Of note, chronic CORT pretreatment exacerbated METH-induced decreases in TH protein (to 10% of control) in striatum. However, repeated in vivo stress exposure completely blocked striatal dopaminergic neurotoxicity and reduced the neuroinflammatory response to METH. As the levels of chronic CORT approached or exceeded those associated with high physiological stress, our data suggest that chronic CORT therapy or sustained physiological stress sensitizes the CNS neuroinflammatory and neurotoxic responses to METH. Also, more severe or prolonged in vivo stressor application may be required to produce priming of the CNS similar to exogenous CORT.

**1029 THE MODULATION OF 3, 4-(d)- METHYLENEDIOXYMETHAMPHETAMINE-INDUCED NEUROTOXICITY BY CATECHOL-O-METHYLTANSFERASE.**

Pharmacology/Toxicology, University of Arizona, College of Pharmacy, Tucson, AZ

3,4-(d)-Methylenedioxymethamphetamine (MDMA) abuse remains a significant problem worldwide. Systemic administration of MDMA to rodents and non-human primates causes neurotoxicity, and evidence suggests that it is also neurotoxic in humans. Metabolism of MDMA appears necessary for MDMA neurotoxicity. Thus, prior work from our laboratory indicates that cytochrome(s) P450 (specifically, CYP 2D6) inhibition attenuates MDMA-induced neurotoxicity, probably by decreasing the metabolism of MDMA to N-methyl-tetrahydroaminoamphetamine (N-Me-tetrahydromDA). Because N-Me-tetrahydromDA is a substrate for catechol-o-methyltransferase (COMT), we examined the effect of COMT inhibition on MDMA-induced neurotoxicity. COMT converts the N-Me-tetrahydromDA (a catechol) to 4-hydroxy-3-methoxy-methamphetamine (HMMA), thereby limiting the oxidation of N-Me-tetrahydromDA to the reactive ortho-quinone. Pharmacological and genetic models were used to determine the role of COMT in MDMA-induced neurotoxicity. Adult female Sprague-Dawley rats were pretreated with the COMT-inhibitor, Ro 4-0960 (40mg/kg, ip) followed by a neurotoxic dose of MDMA (20mg/kg, sc). In the genetic model, COMT-/- and COMT+/- wildtype mice were dosed with either MDMA (30mg/kg X 3 at 3 hour intervals, sc) or saline. In both models, neurotoxicity was determined one week after dosing via determination of neurotransmitter concentrations. In the pharmacological model of COMT inhibition, MDMA-induced neurotoxicity was potentiated. The data from the genetic model was ambiguous, probably because the COMT activity in the heterozygous animals is sufficient/borderline to process the O-methylation of N-Me-tetrahydromDA. Studies with homozygous COMT-/- mice are ongoing. The findings suggest that enzymes involved in the formation (CYP2D6 et al) and further metabolism of N-Me-tetrahydromDA (COMT) are important contributors to the individual susceptibility to MDMA-mediated neurotoxicity, especially given the polymorphic distribution of these enzymes in the humans. (Supported by NIDA Award DA023525)

**1030 THE EFFECTS OF FLUORIDE ON THE NEURONTRANSMITTERS IN DISCRETE BRAIN REGIONS OF ICR-DERIVED GLOMERULONEPHRITIS MICE BY EXPOSURE VIA THEIR DRINKING WATER.**

1 Preventive Medicine, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan and 2 Institute of Health Sciences, Tokyo, Japan.

Fluoride (F) has been known as an environmental pollutant. Although homovanillic acid (HVA) in the hypothalamus was altered in the BALB/c mice exposed to F in our previous study, the effects of F on the central nervous system had not been considered a serious health problem. Since a target organ of F is the kidney and F is filtered from the blood by the kidney, the accumulation of F in animals with renal insufficiency may enhance its toxicity. ICR-derived glomerulonephritis (ICGN) mice have been used as a model for idiopathic renal insufficiency. We evaluated whether or not the administration of F via the drinking water induces neurotoxicity in ICGN mice, in which F accumulates, by using neurotransmitters in discrete synapse, primarily of serotonin (5-HT), inducing hyperthermia and hyperactivity (5-HT syndrome). Conversely, an altered neurotransmitter profile as a prolonged depletion in 5-HT, and structural damage to 5-HT nerve terminals. The molecular mechanisms for both the acute and long-term effects remain unclear. The vesicular monoamine transporter 2 (VMAT2) is involved in the transport of monoamine neurotransmitters, in particular dopamine and 5-HT, into intraneuronal storage vesicles. As such, VMAT2 is critical in maintaining neuronal health by preventing neurotransmitter oxidation within the cytosol. We therefore investigated the effects of the pharmacological inhibition of VMAT2, using Ro 4-1284, on MDMA-mediated acute and long-term neurotoxic effects. Sprague-Dawley rats pretreated with the VMAT2 inhibitor (10mg/kg, ip) displayed a significant increase in 5-HT content in the cortex and striatum compared to rats treated with MDMA (20mg/kg, sc) alone. Ro 4-1284 pretreatment delayed and attenuated total horizontal movement distance and mean velocity in animals dosed with MDMA. MDMA-mediated elevation in core body temperature was also significantly reduced in Ro 4-1284/MDMA-treated rats compared to those treated with MDMA alone. Thus, pharmacologic inhibition of VMAT2 appears to attenuate MDMA-mediated 5-HT/5-HIAA depletion, locomotor activity, and hyperthermia in rats. In summary, VMAT2 plays an important role in regulating the acute and long-term neurotoxic effects of MDMA. (Supported by NIDA Award DA023525)

1031 NEUROTOXIC EXPOSURES TO AMPHETAMINE CAN RESULT IN LIPOPOLYSACCHARIDE (LPS) PRESENCE IN CIRCULATING BLOOD, ORGAN DAMAGE, AND IMMUNE ACTIVATION.

J. E. Bowen1, M. M. VanLandingham2, R. E. Patton1, J. P. Hanig1 and M. S. Lee3.

Immunooactivation, organ damage and release of factors such as LPS were observed in rats exposed to environmentally-induced hyperthermia (EIH) or amphetamine (AMPH). Serum levels of substances signaling these events were determined 3hr and 22 hr (1d) after AMPH or saline (EIH and control groups). EIH was induced by a hot (39°C) environment and AMPH neurotoxicity by 4 injections, 2 hr apart, of 5, 7.5, 10 and 10 mg/kg D-AMPH. At 3 hr, creatinine kinase-MB isoenzyme was elevated in 55% (AMPH) and 29% (EIH). At 1d, the enzymes were still 2-fold control in the EIH and 50% of the AMPH animals. Liver enzymes ALT and AST were up 2-fold in 57% of the EIH and 75% of the AMPH animals at 3hr. These enzymes returned to control levels in the EIH group but not in all the AMPH animals at 1d. Creatine and BUN levels were significantly elevated 2-fold by EIH and 3-fold by AMPH at 3hr but returned to control levels by 1d indicating kidney function may be only transiently affected. Detectable LPS was present in only 12% of the control animals but >50% of the EIH and AMPH animals had detectable levels at 3hr and 1d. White blood cell levels were not elevated by either EIH or AMPH at 3hr. However, micro array analysis on whole blood indicated a significant increase in the mRNA expression for cell surface proteins related to macrophages (Cd11b, eosiinophils(Cd52) and T-cells(Cd3, Cd8a). In summary, both EIH and AMPH can result in multiple organ dysfunctions, particularly in muscle, heart, kidney and liver after AMPH exposure. The neurotoxicity induced by AMPH, however, may be dependent on the severity of organ damage. The presence of LPS in the blood raises the possibility that it is involved in the immune response and neurotoxicity produced by AMPH.

**1032 THE EFFECTS OF FLUORIDE ON THE NEURONTRANSMITTERS IN DISCRETE BRAIN REGIONS OF ICR-DERIVED GLOMERULONEPHRITIS MICE BY EXPOSURE VIA THEIR DRINKING WATER.**

Pharmacology/Toxicology, University of Arizona-College of Pharmacy, Tucson, AZ.

3,4-Methylenedioxymethamphetamine (MDMA, Ecstasy) is a ring substituted amphetamine derivative with potent stimulant properties. MDMA exerts biphasic pharmacological effects on the brain resulting in opposing acute and long-term effects. During the acute effects, MDMA causes major monoamine release into the...
brain regions as indexes. The ICGN mice were administered F via their drinking water at 0, 50, 100, and 150 ppm for 4 weeks, and the viability of each group was observed. Each mouse's brain was dissected into 7 regions (cerebrum, cerebellum, medulla oblongata, midbrain, striatum, hypothalamus, and hippocampus). The concentrations of neurotransmitters (norepinephrine, dopamine (DA), serotonin) and their metabolites (DOPAC [dihydroxyphenylacetic acid], HVA, 5-HIAA [5-hydroxyindoleacetic acid]) were determined by HPLC (high-performance liquid chromatography). All ICGN mice exposed to 100 and 150 ppm F died. The mean values of neurotransmitters and their metabolites were compared between the 0 and 50 ppm-exposed groups. The mean values of body weight in the 100 and 150 ppm groups were significantly lower than those in the 0 and 50 ppm groups. The mean DA in the striatum or hypothalamus of the 50 ppm group was significantly lower than that in the 0 ppm group. The mean HVA in the hypothalamus of the 50 ppm group was significantly lower than that in the 0 ppm group. Although it is not clear whether a direct or indirect effect, F may inhibit DA synthesis in specific regions in the mice with impaired renal function.

1034 MODULATION OF NEUROTRANSMITTER AMINO ACIDS BY PERFLUOROCARBON SULFONATE (PFOS) WITHIN AMYGDALA IN RAT.
M. A. Lafuente1, N. Pereiro1, R. Moyano1 and B. Fernandez1, 1Laboratory of Toxicology, University of Vigo, Orense, Spain and 2Department of Forensic Medicine and Legal Medicine, University of Cordoba, Cordoba, Spain. Sponsor: G. Font.

Perfluorocarbon sulfonate (PFOS) is an emerging environmental contaminant. It has been shown to be neurotoxic and endocrine disruptor. On the other hand, amygdala is a brain region which coordinates behavioral, autonomic, and endocrine responses to perceived threats or danger to an animal. This brain area is involved in the regulation of hypothalamic-pituitary-adrenal axis, which is affected by PFOS exposure. This study was designed to evaluate the possible PFOS-induced alterations of glutamate, aspartate, GABA and tau- rine concentration in amygdala. In this region, morphological changes have been also evaluated. For this purpose, male Sprague-Dawley rats were orally treated for 28 days with PFOS, at the doses of 0.5, 1, 3 and 6 mg/kg/day. Control rats received 0.5% Tween-20 vehicle. Amino acids were separated and analyzed using high-performance liquid chromatography (HPLC), with fluorescence detection after precol umn derivatization with O-phthalaldehyde (OPA), and histological study was performed by using light and electron microscopy. PFOS, at the dose of 0.5 mg/kg/day, increased glutamate concentration but decreased glutamate and GABA content in this region. Animals treated with 1.0 or 3.0 mg of PFOS/Kg/day, showed an increase of glutamate, but no changes in gluta mate, aspartate, GABA or taurine concentration. However, the content of these amino acids was decreased after PFOS exposure with the dose of 6.0 mg/Kg/day. On the other hand, morphological damages induced by exposure to PFOS were observed. The obtained results suggest that PFOS induced several modifications on amino acid concentration as well as morphological alterations, in amygdala, that are dependent of the administered dose. 1035 PERFLUOROOC TANOC TIC AND PERFLUOROCUC TANESULFONIC ACID EXPOSURES DISRUPT ACETYLECHOLINESTERASE AND GLUTATHIONE S-TRANSFERASE ACTIVITIES IN ZEBRAFISH ADULTS (DANIO SPP).
K. Noell, S. Gunn and S. Chao, Biological Sciences, Fayetteville State University, Fayetteville, NC. Sponsor: H. Tilson.

Perfluorinated compounds such as perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS) are ubiquitous, persistent pollutants that have been detected in wildlife as well as human populations. Due to its wide distribution and possible disruption to various species, concerns have increased regarding its impact on biological organisms and development of potential useful biomarkers of exposure for ecological assessments. Impact of PFOA on nervous system function has been explored; however, few studies have shown similar effects with PFOA, particularly in adults. As a result, acetylcholinesterase (AChE) activity was measured in adults zebrafish (Danio spp) brain and muscle tissue following exposure to PFOS and PFOA. In addition, recent reports show PFOA and PFOA increased gluta thione s-transferase (GST) mRNA expression in the liver temporarily while other reports show inhibition of GST activity in primary cultured hepatocytes of freshwater tilapia. Therefore, our study also examined the possible disruption of GST activity following exposure concentrations of 0.5, 5, 50 mg/L of PFOS compared to PFOA after 22 hours. Preliminary findings support the inhibition of AChE activity by PFOA and PFOA in the zebrafish brain while no observable changes were observed with muscle tissue. In addition, GST inhibition was also observed at lower concentrations in PFOS while no change in GST activity was observed in zebrafish liver following PFOA exposure.

1036 ENANTIOSELECTIVE FORMATION OF HYDROXYLATED METABOLITES OF PCB 95 IN FEMALE C57BL/6 MICE.
J. Kania-Koroń1, C. Barnhart2, K. M. Truong3, P. J. Lein2 and H. Lehmkher1, 1Department of Occupational and Environmental Health, University of Iowa, Iowa City, IA and 2Molecular Biocenoses, School of Veterinary Medicine, University of California Davis, Davis, CA.

PCB95 (2,2',3,5,6-hexachlorobiphenyl), a developmental neurotoxicant, displays axial chirality and exists as two stable rotational isomers that form non-superimpos able mirror images of each other. These isomers, called atropisomers, can undergo enantiomer enrichment in vivo due to different metabolism rates. The potential toxicological significance of this is underscored by our previous demonstration that chiral PCBs display atropisomer specific neurotoxicity. This study investigates the hypothesis that tissue levels and enantiomer enrichment of PCB95 and its hydroxylated metabolites (OH-PCBs) are dose-dependent in mice. To test this hypothesis, female C57Bl/6 mice (8.5 weeks old; n=16) were fed three different doses of racemic PCB95 (0.1, 1 and 6 mg/kg body weight) or vehicle (peanut oil) in peanut butter daily. The animals were euthanized after 56 days, blood and liver samples were collected, and levels and enantiomer enrichment of PCB95 and its metabolites were determined. Levels of PCB95 and its metabolites increased with increasing dose in liver and blood samples. Livers contained overall higher levels of PCB95 and 4-OH-PCB95 compared to PC95 after 22 hours. Preliminary findings support the inhibition of AChE activity by PFOS and PFOA in the zebrafish brain while no observable changes were observed with muscle tissue. In addition, GST inhibition was also observed at lower concentrations in PFOS while no change in GST activity was observed in zebrafish liver following PFOA exposure.

1037 STRUCTURE ACTIVITY OF FIVE RACEMIC POLYCHLORINATED BIPHENYLS TOWARD RyR1 CHANNELS: INFLUENCE OF HYDROXYLATION AT THE META- AND PARA-POSITION.

Y. Niknam1, N. Joshi2, S. M. Vesel2, H. Lehmler1 and I. N. Pessah1. 1VM: Molecular Biosciences, University of California Davis, Davis, CA and 2Occupational and Environmental Health, University of Iowa, Iowa City, IA.

Polychlorinated biphenyls (PCBs) are persistent, widespread environmental contaminants banned in 1977. However, chiral PCBs such as PCBs 91, 95, 132, 136, and 149, have persisted at levels of concern to human neurological health. Such non-coplanar PCBs are known to interact with pyrrole receptors (RYRs), ion channels broadly expressed in the central and peripheral nervous system and muscle. RyRs regulate release of Ca2+ from endoplasmic/sarcoplasmic intracellular calcium stores, and thus are pivotal to generating cellular Ca2+ signals. Here we report the structure-activity relationships for 5 chiral non-coplanar PCBs and their 4-OH and 5-OH metabolites toward RyRs. 4-OH and 5-OH derivatives were synthesized and their sensitizing activity toward the type 1 isoform RyR1 was compared to their parent structures using [3H]ryanodine ([3H]Ry) receptor binding analysis and macroscopic Ca2+ flux assay using microsomal membranes. Radioligand binding analysis performed with optimal Ca2+ for [3H]Ry binding indicated a monotonic concentration-effect relationship ranging from 100nM to low μM of parent PCB, 4-OH- and 5-OH-PCB congeners maximally enhancing RyR1 occupancy 1.5- and 7-fold. A 4-C1-substituent reduced activity relative to 5-C1. With few exceptions, 4-OH congeners were less active than the parent PCB, whereas 5-OH congeners were more active. Ca2+ flux measurements indicated that, as predicted by radioligand binding analysis, the rank order of activity was 5-OH-parent->4-OH. Ca2+ release triggered by PCB or metabolites is completely blocked by ruthenium red, a RyR1 channel blocker. These data identify meta-hydroxylated metabolites of chiral PCBs as especially potent sensitizers of RyRs. [Supported by NIEHS grants R01 ES017425, R01 ES04991, P42 ES05695.]

1038 CHLOROACETIC ACID-INDUCED CELL APOPTOSIS THROUGH ROS/ENDOTHELIC RETICULAR STRESS PATHWAY IN NEURONAL CELLS.

D. Hung1, C. Chen1, F. Tong2, C. Yen1, L. Liu1, S. Liu1, Y. Chen1 and C. Huang1. 1Toxicology Center, China Medical University Hospital, Taichung, Taiwan, 2Department of Emergency, China Medical University Hospital, Taichung, Taiwan, 3Department of Occupational Medicine, Changhua Christian Hospital, Changhua, Taiwan, 4Department of Occupational Safety and Health, Chung Shan Medical University, Taichung, Taiwan, 5Department of Physiology and Graduate Institute of Basic Medical Science, China Medical University, Taichung, Taiwan, 6Institute of Toxicology, National Taiwan University, Taipei, Taiwan and 7School of Chinese Medicine, China Medical University, Taichung, Taiwan.

Chloroacetic acid (CA), a toxic chlorinated analog of acetic acid, is widely used as an herbicide and in the synthesis of many organic compounds. Some studies have reported that CA can cause histopathological alterations and functional impairment in brain. However, the toxicological effects and underlying mechanisms of CA-induced neurotoxicity are mostly unclear. Here, we investigated the effects and possible mechanisms of CA in cultured neuron cells (Neuro-2a cells). Treatment of Neuro-2a cells with CA for 24h significantly induced cytotoxicity, reduced cell viability, and oxidative stress damage (membrane LPO production) which accompanied by several features of apoptosis, including the increases in Annexin V-binding cells and caspase-3/7 activity. CA also triggered endoplasmic reticulum (ER) stress as indicated by the enhancement in ER stress-related mRNA and protein molecules induction (such as glucose-regulated protein 78 (GRP78), GRP94, C/EBP homologue protein (CHOP), X-box binding protein 1 (XBPI)), procaspase-12 cleavage, and calpain activation. Transfection of cells with GRP78 or GRP94 siRNA reduced CA-induced caspase-3 expression in Neuro-2a cells. Meanwhile, these CA-induced apoptosis and ER stress-related signals could be effectively reversed by antioxidant N-acetylcysteine (NAC). Therefore, our results suggest that CA caused neuron cell apoptosis via oxidative stress-triggered ER stress signaling pathway.

1039 IN VITRO TOXICITY OF AMPHOTERICIN B AND AMPHOTERICIN B METHYL ESTER EXPOSURE IN OLIGODENDROCYTES.

O. U. Nno1, K. R. Reuth1 and C. P. Schafler1. 1Department of Pharmacology & Toxicology, Rutgers University, Piscataway, NJ and 2Waksman Institute of Microbiology, Rutgers University, Piscataway, NJ.

Amphotericin B (AMB) is widely used in the treatment of chronic systemic fungal disease; treatment often results in a dose limiting nephrotoxicity. Amphotericin B methyl ester (AME), a polycrane maculide antibiotic with significantly less toxicity and full antifungal activity was introduced in the late sixties. However, its clinical use was terminated following reports of toxicity to CNS myelin. Recent studies in our lab using pure AME suggested that the reported neurotoxicity results from contamination by AMB, leading to oligodendroglial injury. To test this hypothesis, we immortalized human oligodendroglial cell line, MO3.13 were treated with 0.5 - 30 μg/ml concentrations of AMB and AME. A quantitative dose response assessment revealed AMB to be at least 10 times more toxic than AME. The lowest concentration of AMB that induced cell death was 1 μg/ml and 10 μg/ml for AME. AMB induced apoptosis as revealed by activation of caspase 3, cytochrome c release and morphological changes. Activation of caspase 9, but not 8 and 10, at 0.5 μg/ml AMB suggested that there may be a direct effect on the mitochondria. This was confirmed by labeling with MitoView 633 (Biostem, Inc, Hayward, CA, USA), a fluorescent marker of mitochondrial membrane potential, which revealed diminished intensity following AMB treatment of 1 μg/ml, but was unaltered by AME concentrations below 10 μg/ml. These data suggest that AMB kills MO3.13 oligodendrocyte by the mitochondrial apoptotic pathway and that pure AME does not kill myelin-producing oligodendroglia at clinically relevant concentrations. (ES005/022)

1040 VITAMIN A DEFICIENCY INDUCES DYSFUNCTION OF INNER RETINAL LAYER CELLS IN ADDITION TO PHOTORECEPTOR CELLS.

D. Kakikuchi1, T. Uehara2, M. Shiotani1, K. Nakano1, K. Sawada2, A. Suganuma1, T. Aoki1, K. Tsukidate1 and A. Fukumizu1. 1Global Drug Safety, BA-CFU, Eisai Co. It is well known that retinoids play important roles in photoreceptor cells and pigment epithelial cells in the retina. Previous studies have demonstrated that vitamin A deficiency (VAD) reduces amplitude of both a- and b-waves in electroretinogram (ERG). Therefore, the study was conducted to determine the level of rhodopsin. While retinoids in the outer retinal layer have been investigated, those in the inner retinal layer including amacrine cells and ganglion cells still remain largely unknown. Since retinoids are known to be associated with development, differentiation, and function of neurons, the function of retinoids in the inner layer cells of the retina was investigated using a VAD rat model in the present study. VAD was induced by feeding a VA deficient diet to Brown Norway (BN) rats (18 males, 22 days old) for 10 weeks. The retinoid concentrations were measured in the plasma and retina between 6 and 10 weeks after initiation of VA deficient diet to confirm VAD. The effects of VAD on the retina were evaluated functionally by ERG and morphologically by routine ophthalmologic and histologic examination. VAD decreased the amplitude of a-, b-, and op-waves in ERG without histological changes at 10 weeks after initiation of feeding VA deficient diet. The degree of reduction in op-wave amplitude was more prominent than that of a- and b-waves, and coincided with the degree of reduction of retinal retinoids. The a-wave is generated from amacrine cells and ganglion cells in the inner layer of retina. Therefore, it is considered that retinoids have important roles also in the inner retinal layer cells. In this study, we also discuss a possible mechanism of action of retinoids in the control of op-wave in the inner retinal layer cells.

1041 NEUROACTIVITY OF THE β-CARBOLINES, HARMANE AND NORHARMANE, FOUND IN TOBACCO SMOKE: AN IN VITRO STUDY.

D. S. Ali1, S. M. Lantz1, F. Cuevas1, B. L. Robinson1, M. G. Paule1 and M. H. Baumann1. 1VCTR/FEA, Jefferson, AR and 2Laboratory of Clinical Psychopharmacology, IRP/NIADDK, Baltimore, MD.

Nicotine is one of the most frequently used drugs of abuse, and its use is associated with millions of deaths annually. It has long been speculated that tobacco, in addition to nicotine, contains other compounds that are addictive or act in concert with nicotine. One of the promising candidates are the β-carbolines (βCs) harmane and norharmane, which are condensation products of the major smoke constituent acetaldehyde. As harmane and norharmane are monoamine oxidase (MAO) inhibitors with potent central nervous system (CNS) activity, the toxic effects of exposure to these βCs warrants investigation. In the current study, we investigated the neuroactive profile of harmane and norharmane (1-750 μM) alone and after 24 hr exposure in MN9D cells. The effects of these βCs (1-10μM) alone and in combination with nicotine (5-50μM) were also assessed. Cell viability and mitochondrial function were evaluated using LDH and XTT assays, respectively. HPLC was used to...
Polycyclic diphenyl ethers (PBDEs) are a major class of brominated flame retardants. Their chemical structure and toxic effects are largely comparable to those of polychlorinated biphenyls (PCBs). Previous research identified the nervous system as being among the most sensitive target organ for flame retardants, with modulations of inhibitory GABAergic neurotransmitter receptors and excitatory nicotinic acetylcholine (nACh) receptors as a potential mode of action for halogenated flame retardants.

Therefore, the present study aimed at comparing effects of the abundant congeners PBDE-209, PBDE-47, PCB-47 and a hydroxylated metabolite 6-OH-PBDE-47 on the function of human α5, β2, GABA B, and αβ nACh receptors. The human neurotransmitter receptors were expressed in Xenopus oocytes and their function was investigated using the two-electrode voltage-clamp technique. The results demonstrate that inhibitory GABA B-mediated signaling was concentration-dependently activated or potentiated by PBDE-47 and 6-OH-PBDE-47, while PBDE-209 inhibited the activation of the receptor. Contradictory, small but concentration-dependent inhibition of the excitatory ACh-mediated signaling was induced by PBDE-47, 6 OH PBDE-47 and PBDE-209. Notable, no effects were observed for PBDE-47 on the receptors. The data indicate that oxidative metabolism increases the neurotoxic potential as PBDE-47 was without effect whereas the hydroxylated metabolite affects both receptors. Moreover, since both the GABA B and nACh receptor are critically involved in brain development, the effects described in this study may (partly) underlie previously observed neurobehavioral and neurodevelopmental effects of PBDEs and PCBs. [This work is part of the European Union-funded project ENFIRO (grant agreement FP7 ENV-2008-1-226563)].

Microelectrode arrays (MEA) have been proposed as a tool for detecting functional changes in electrically active cells, including neurons, exposed to drugs, chemicals, or particles. However, conventional single well MEA systems lack the throughput necessary for screening large numbers of chemicals. The current experiments used primary cortical neurons grown on Multielectrode Array (MEA) plates to screen a training set of 30 chemicals. Each MEA plate contained 12 wells with 64 microelectrodes/well, for a total of 768 channels. Of the 30 chemicals evaluated, 23 were known to alter neuronal function (“positives”), including 6 GABAergic and 3 glutamatergic compounds, 4 pyrethroids, 3 metals, 2 cholinesterase inhibitors, 2 nicotinic acetylcholine receptor agonists, valproic acid, verapamil, and fluoxetine. Seven compounds (glyphosate, acetaminophen, dimethyl phthalate, paraglutamic acid, saccharin, d-sorbitol, amoxicillin), expected to have no effect on neuronal function, were tested as “negatives.” Chemical effects (50μM or highest soluble concentration) were assessed for 30 min between 14 and 22 DIV, after collection of 30 min baseline activity. Twenty of the positives altered either the mean network spike rate, number of active electrodes or both by more than the DMSO control. The 3 positives without effect were valproic acid, nicotine and imidacloprid. None of the negative compounds changed activity more than by DMSO. A Bayesian approach was then used via a multinomial distribution to compare the electrode activity levels on a chemical by chemical (rather than well) basis. This analysis displays chemical responses in a more detailed manner and has greater sensitivity to detect responses that differ from control. Based on these results, the MW MEA assay has both high sensitivity and specificity, indicating that cortical neurons grown on MW MEAs are a useful approach to screen chemicals for neurotoxic effects mediated by a broad variety of mechanisms. (This abstract does not reflect Agency Policy).

Microelectrode arrays (MEA) detect and chemical-induced changes in action potential “spikes” in neuronal networks and can be used for neurotoxicity screening. Analytical “fingerprinting,” using Principal Components Analysis (PCA) on spike trains may improve the utility of MEAs to classify unknown chemicals by mode of action. The current study developed such approaches using MEA data from well understood chemicals (bicuculline, lidocaine, RDX, picotin, muscimol, verapamil, fluoxetine, chlorpyrifos oxon, domoic acid, and deltamerthrin) and “negative” controls (dimethyl phthalate, acetaminophen, and glyphosate). Bursting parameters (rate, duration, interspike intervals, /spike/burst/) were computed and averaged to yield parameter values as a function of concentration, then standardized to control. These data were compared with spike rate and synchrony data and PCA was performed across all concentrations. The first 5 principal components accounted for 50, 23, and 8% of the data variability. To determine how well PCA separated the high dose groups, confidence ellipsoids were drawn around data from concentrations ± each chemical’s IC/EC50 for spike rate. Chemicals in the same class grouped together and there was noticeable separation of GABA B antagonists from other chemicals. As expected, the negative controls grouped with baseline activity in the absence of chemical. Chlorpyrifos oxon grouped closely with fluoxetine, muscimol and verapamil, and MEA- and PCA-simulated data. Both groups were dispersed, while deltamerthrin separated from the other chemicals. The separation of chemicals within chemical classes and the separation of different chemical classes indicates that the sets may be distinguishable. This demonstrates that burst analysis with PCA offers a promising approach for identifying neurotoxicological modes of action for unknown chemicals. This abstract does not reflect Agency Policy.

Microelectrode arrays (MEA) have been proposed as a tool for detecting functional changes in electrically active cells, including neurons, exposed to drugs, chemicals, or particles. However, conventional single well MEA systems lack the throughput necessary for screening large numbers of chemicals. The current experiments used primary cortical neurons grown on Multielectrode Array (MEA) plates to screen a training set of 30 chemicals. Each MEA plate contained 12 wells with 64 microelectrodes/well, for a total of 768 channels. Microelectrode arrays (MEA) separate chemicals by class.
as trauma, stroke, and drug-induced toxicity. A widely used and reliable method for labeling degenerating neurons in ex vivo brain tissue involves the use of Fluoro-Jade (F-J) stains. To date, however, all published labeling results utilizing the F-J dyes have been based on fixed tissue samples. Here, we report a method for labeling degenerating neurons in unfixed brain tissue using F-J dyes, showing results from a rat model of neurodegeneration induced by the i.p. injection of the excitotoxin, kainic acid. The labeling procedure is simple and fast (it can be finished in minutes). Since the brain tissue is unfixed, the identified degenerating neurons can be subsequently harvested using a laser capture microdissection system and mRNAs or proteins can be extracted for further molecular analyses. This new method of F-J labeling does not involve basic alcohol, potassium permanganate, or acids as does conventional F-J labeling, thus, this approach avoids the potential interactions between these molecules and extreme pH conditions and mRNAs or proteins. In addition, the labeling procedure works at 4°C, thus, further reducing or minimizing potential degradation and/or modifications of mRNAs and proteins. We also dissolved F-J in acetic acid, saline, or neutral phosphate buffer and tested it on formalin-fixed brain tissue sections from rats treated with kainic acid. Only F-J in acetic acid showed good staining, while F-J in saline or phosphate buffer did not label any cells in fixed-tissue sections, suggesting that an acidic environment is required for F-J labeling in fixed brain tissue. We anticipate that this one-step labeling method will be especially useful for studies that elucidate mechanisms of neurodegeneration at the genomic and proteomic levels.

1047 FUNCTIONAL OBSERVATION BATTERY IN NONHUMAN PRIMATES WITH CONTINUOUS INTRACEREBRAL INFUSION.

A. S. Adam1, S. Authier1-2, A. Schneider1, K. Wong1, J. Bienvenu1, R. Tavcar1, R. Forster1 and E. Troncy2.
1. GitsLab, Laval, QC, Canada, 2Faculty of Veterinary Medicine, University of Montreal, St-Hyacinthe, QC, Canada and 1ANTISENSE PHARMA GmbH, Ratibson, Germany.

A functional observation battery (FOB) is often conducted as part of the ICH S7A safety pharmacology core battery while this evaluation is normally conducted in rodents, it can also be performed in large animals such as nonhuman primates when justified. Intracerebral infusion is used in patients for delivery of therapeutic agents for treatment of serious brain diseases. Nonclinical biological studies may not often require the use of the clinical route of administration. The impact of continuous intracerebral infusion of saline in Cynomolgus monkeys on clinical signs (CS), body weight (BW), FOB and histopathology were evaluated. Four males (5.6 to 6.3 kg) were instrumented with a left parietal catheter (Medtronic, Ref. 41207) and standard jacket and tether system. The animals were continuously infused using a clinical grade syringe pump for 28 or 42 days. Catheters remained patent except for 1 animal which presented a transient occlusion after 38 days of infusion. Intracerebral infusion did not result in any abnormality at CS and FOB. No macroscopic observation related to the procedure was noted except for 1 animal at 42 days post-surgery which presented dark parenchymal cerebrovascular atrophy. After 28 days, histopathology revealed minimal multifocal necrosis with gliosis and white matter vacuolation at the infusion site and cerebral parenchyma. At 42 days, mild to moderate necrosis and inflammation with minimal vacuolation were noted at the infusion site. Mild necrosis and hemorrhage were also noted in the cerebral parenchyma. In conclusion, continuous intracerebral cerebral infusion did not have any effect on CS, BW and FOB in freely moving Cynomolgus monkeys under the conditions of this study. Minimal to moderate local changes to the parenchymal tissue observed histopathologically were considered related to the presence of a foreign material.

1048 FUNCTIONAL OBSERVATIONAL BATTERY IN PERSPECTIVE.

W. A. Irwin, J. Doherty and E. Scollon.
HED, US EPA, Crystal City, VA.

Hypothesis: The Functional Observational Battery (FOB) is a valuable tool used for assessing compounds for on target or off target effects (i.e. posture, gait, grooming, grip strength, etc). FOB panels have been highly cited and were originally designed to measure the efficacy of psycho-active drugs (i.e Irwin 1968), plus to re-interpret FOB data since some signs can indicate effects in both the CNS and peripheral tissues. Detection of FOB alterations alone does not fully characterize the true hazard of the compound. Confirmatory studies are needed to determine the more precise cause of the FOB alterations, consequences and localize the pathology to a specific tissue (i.e. specific tissue histology or enzyme assays, etc). The specific tissue of action is important to the hazard characterization of drugs, since the CNS has a very limited ability for regeneration, while some peripheral tissues can have a robust ability for reversibility, repair and regeneration (i.e. muscles). Disclaimer: The views expressed are those of the authors alone and do not necessarily reflect those of the US EPA.

1049 COMPARISON OF MOTOR AND COGNITIVE FUNCTION IN TWO SUBSTRAINS OF C57BL/6 MICE.

A. Ashworth, G. P. Curran, J. Fowler and M. McKay. Biological Sciences, Northern Kentucky University, Highland Heights, KY.

The most common strain of mice used in animal research is C57BL/6 or B6. This control mouse is used as a standard for many different knockout mice in labs across the world. Although this strain of mouse is inbred, random mutations and separations of B6 mice in geographically distinct facilities resulted in an accumulation of genetic differences. Recently, single nucleotide polymorphisms (SNPs) have been identified in multiple substrains of the B6 line. To determine if these differences could affect results in common behavioral tests, we compared motor and cognitive function in two of the most commonly used substrains: C57BL/6, originating from Jackson laboratory, and C57BL/6N, originating from the National Institutes of Health. Motor function was analyzed with rotarod. We used Morris water maze to assess spatial learning and memory and novel object recognition to assess nonspatial learning and memory. We found no significant differences in rotarod performance, although there was a significant difference in the learning curve from days 3 compared with days 5. In the water maze, C57BL/6N mice outperformed the C57BL/6 mice in all three phases of hidden platform testing even after correcting for a statistically significant difference in swim speed. Our findings suggest the choice of substrain as a control or background strain might influence the interpretation of results from classic neurobehavioral tests.

1050 ASSESSMENT OF THE RESPIRATORY SENSITIZATION POTENTIAL OF PROTEINS USING AN ENHANCED MOUSE INTRANASAL TEST (MINT).

There remains a need for a simple and predictive animal model to identify compounds with the potential to induce respiratory sensitization and allergy. The mouse intranasal test (MINT) has been applied for the assessment of the relative allergenic potential of detergent enzymes; however its assessment was limited, evaluating only total and enzyme-specific antibody levels as endpoints. The present study was designed to evaluate an enhanced MINT which included multiple endpoints (serum antibody levels, airway inflammation and airway hyperresponsiveness (AHR)) to determine their value in improving the specificity and predictive accuracy of the MINT. BDF1 mice were intranasally instilled on days 1, 3, 10, 17 & 24 with Subtilisin (SUB), ovalbumin (OVA), beta-lactoglobulin (BLG), mouse serum albumin (MSA), or Keyhole Limpet Hemocyanin (KLH). On test day 29, wholebody plethysmography was used to measure AHR following methacholine or specific protein challenge followed by evaluation of bronchoalveolar lavage (BAL) fluid, pulmonary histopathology, and serum immunoglobulin responses. Evaluation of the results indicated that the assessment of AHR measured via wholebody plethysmography did not provide data that allowed for the evaluation protein allergicity. Reaginic antibody responses and IgG1 and IgG2a isotype characterization proved to be the most sensitive and reliable indicators of the protein allergenic potential, with SUB and OVA producing the most robust responses. BAL responses after protein-specific challenge were also indicators of allergen potential, with SUB, OVA, and KLH showing dose dependent induction of eosinophils in the BAL. Both BLG and MSA resulted in minimal to no responses for all endpoints. These data highlight that the evaluation of the respiratory sensitization potential of proteins can be best informed when multiple parameters are evaluated, and further improvements and refinements of the assay are necessary.
1051 ACUTE INHALATION TOXICITY IN RATS EXPOSED TO GASEOUS ATMOSPHERES OF HYDROGEN FLUORIDE AND CARBONYL FLUORIDE.

The acute Fire Extinguishing System (AFES) in Army vehicles commonly employs the “clean” agents Halon 1301 or FM-200. As a consequence of their fire extinguishing mechanism, toxic pyrolys products are formed as an essential chemi-cal step. These toxic gas pyrolysis products studies in rats conducted with hydrofluoric acid (HF) and carbonyl fluoride (COF2) which Army personnel may be exposed to. Groups of 10 rats each were exposed nose-only to a single, 5- or 10-minute exposure to gaseous atmospheres of either HF or COF2. Chamber concentrations were measured with a Fourier Transform Infrared Spectrometer (FTIR). Respiratory rates were measured during exposures and rats were monitored for mortality, clinical signs, and body weights. The 10-minute acute lethality concentration (LC50) for HF was 49,000 ppm and 1,100 ppm for COF2. Evaluation of the toxicity issues related to the potential exposure to these gases is an integral part of armored vehicle development and live fire testing.

1052 IN SEARCH OF PREDICTIVE PULMONARY HAZARD ASSAYS: LUNG TOXICITY AND IN SILICO STUDIES TO ASSESS TITANATE PARTICULATE MATERIALS.

The development of accurate lung toxicity studies are a necessary component of risk assessments. The aims of these studies are to develop less expensive/animal-intensive alternatives. Terraces compounds are a variety of metal titanium oxide (TO) particulate products, which include potassium TO varieties, such as sodium, magnesium or lithium TO or titanate particles of different shapes and particle sizes. Ninety day inhalation toxicity studies in rats conducted with the magnesium and potassium TO varieties demonstrated low toxicity (NOAELs = 50 and 10 mg/m3, respectively). In addition, pulmonary bioassay studies with Terraces JS (another type of potassium TO particle) indicated benign effects in rats compared to positive (i.e., quartz) controls. Previously we reported that the Vitamin C assay could serve as an effective screening tool for predicting in vivo lung effects of titanium dioxide (TiO2) particulates as an in silico indicator of particle reactiv-ity for fine and ultrafine (ul) TiO2 particulates; and results correlated with in vivo pulmonary toxicity effects in rats as reported in an earlier study (Warheit et al., 2007). Accordingly, we postulated that the Vitamin C assay might likewise serve as an animal alternative, predictive screening tool for other titanium oxide-containing compounds. To test the hypothesis, two different forms of potassium TO, magnes-ium potassium TO, and lithium potassium TO particulates were tested in the Vitamin C assay, using positive (P25) and negative (TiO2 control) particles. Using Vitamin C yellowing assay in silico methodology, the results were mixed – moderate surface reactivity for two potassium titanate compounds and low reactivity for lithium or magnesium potassium titanate particles. Thus, the data did not always correlate with low in vivo lung toxicity results on the same previously tested compounds. Based upon these results, the Vitamin C yellowing assay may be an effective screening tool for TiO2 particulates but not titanate (TO) particle-types.

1053 ACUTE TOXICOLOGICAL RESPONSES OF FISHER RATS TO NATURALLY OCCURRING ASBESTOS FROM THE UNITED STATES AND CANADA.
J. M. Cyphert1, D. J. Padilla-Cartin2, A. Nyska3, H. J. Shannahan1, M. C. Schladweiler4, U. E Kodavanti5 and S. H. Gavert1. 1Curriculum in Toxicology, University of North Carolina Research Program, Chapel Hill, NC, 2CHIS, DERT, NIEHS, Research Triangle Park, NC, 3JPHD, NIH/NIH, US EPA, Research Triangle Park, NC and 4Sahber School of Medicine, Tel Aviv University, Tel Aviv, Israel.

This study was designed to provide understanding of the toxicity of naturally occurring asbestos (NOA) including Libby amosite (LA), Sumas Mountain chrysotile (SM), El Dorado Hills tremolite (ED) and Ontario actinolite/tremocto- nolite cleavage fragments (ON). Rat-respirable fractions (aerodynamic diameter ≤ 2.5 μm) were prepared by water elutriation and delivered via a single intratracheal (IT) instillation at doses of 0.5 and 1.5 mg/rat. Bronchoalveolar lavage fluid (BALF), lung histopathology and baseline pulmonary function were analyzed 1 and 3 μg pos-IT. One day post-IT, low-dose NOA exposure resulted in a 3-4 fold in-crease in BALF cellularity compared to dispersion media (DM) controls, whereas high-dose exposure had a more severe effect on lung inflammation which varied by source. Although inducing less acute inflammation than ON and ED, exposure to either LA or SM resulted in increased eosinophilia, as well as a greater degree of acute lung injury. Additionally, an increase in Penh (correlated with airway resist-ance) was only noted in rats exposed to high-dose LA or SM. Three months post-IT, most BALF parameters had returned to DM control levels. Despite a relative re-turn to baseline of lung inflammatory and injury markers, the development of fibrosis, as determined histologically, was greatest in SM-exposed rats (SM>LA>ON>ED). Consistent with this, elevated Penh was only noted in high-dose SM-exposed rats. These data demonstrate that, in the rat, SM results in more significant fibrosis and impairment of baseline lung function than exposure to LA. This study suggests that there may be cause for concern for people at risk of being exposed to NOA from the Sumas Mountain landslide, and highlights the need for further study of sites where NOA is present. (This abstract does not represent US EPA policy).

1054 DETECTION OF NAPHTHALENE (NA)-DNA ADDUCTS IN MOUSE OLFARY AND AIRWAY EPITHELIAL TISSUES BY ACCELERATOR MASS SPECTROMETRY.
B. A. Buchholz1, M. J. Sarachine1, L. S Van Winkle2, D. Morin2 and A. R. Buckpitt1. 1Center for AMS, Lawrence Livermore National Laboratory, Livermore, CA and 2Veterinary Medicine, University of California Davis, Davis, CA.

Humans are exposed to the ubiquitous PAH, NA, through a variety of industrial and environmental sources. NA is a byproduct of fossil fuel manufacturing, is re-leased following the combustion of wood, gasoline, and tobacco and is a major component of jet fuel. NA metabolites are consistently detected in human urine. Concern over the potential health effects of NA focuses in part on a role in the de-velopment of lung cancer, which is the number one cancer killer of men and women. Chronic rodent exposure studies showed that NA causes tumors in mice and rats. However, the majority of standard in vitro short-term mutagenicity assays for NA are negative. Formation of both depurinated and stable DNA adducts in vitro and in skin painting studies has been reported. Skin is not a known target tissue for NA, however. NA-derived DNA adducts have not been demonstrated in the respiratory system of any species. The goal of this research is to determine if stable NA-DNA adducts form in target tissues. Dissected airway and nasal olfactory epithelial tissues were incubated with 50 μM 14C-NA for 1 hr. DNA was isolated and its purity veri-fied by A260/A280 ratios. DNA samples were analyzed for 14C by accelerator mass spectrometry. NA-DNA adduct levels were slightly increased in treated airways compared to control, indicating DNA adduct formation occurs at low levels. The nasal olfactory epithelial samples yielded too little DNA to generate conclusive data and tissues will be pooled in the future. This preliminary ex vivo work demonstrates the feasibility of AMS to measure these low concentrations. More ex vivo studies to eliminate the chance of protein contamination will be needed as will in vivo studies. These studies provide the necessary data in target tissues to establish whether stable naphthalene-DNA adducts form and potentially clarify the mechanism of action of naphthalene tumorigenicity in animal models. Supported by NIHES 04699 and NCRR 13461.

1055 PULMONARY RESPONSES AFTER INHALATION OF RESISTANCE SPOT WELDING FUME USING AN ADHESIVE.

Resistance spot welding (RSW) is commonly used in the automotive and aircraft industries where high speed, repetitive welding is needed and relatively thin metal sections are welded. Epoxy adhesives are applied as sealers to the seams of the met-als that are joined. RSW produces complex aerosols composed of both metals and volatile compounds which have caused respiratory symptoms, including bronchitis and asthma, in exposed workers. The goals of the study were to develop a RSW generation and inhalation system, characterize the generated aerosols, and expose laboratory animals to determine the potential mechanisms that may be involved with the development of lung toxicity. RSW was configured so that two aerosols were generated and compared: (1) high metal (HM) fume and (2) low metal (LM) fume (mostly volatiles). Male Sprague-Dawley rats were exposed to 20-50 mg/m3 of the aerosols for 4 h/d x 3 d. Control animals were exposed to filtered air. Bronchoalveolar lavage (BAL) was performed at 1 and 7 d after exposure, and lung injury and inflammation parameters were measured in the recovered lavage fluid (BALF). Mass median aerodynamic diameter was determined by a Micro-Orifice Uniform Deposit Impactor and found to be 0.77 and 0.93 μm for the HM and mostly volatile LM fume, respectively. The HM fume was composed of greater than 90 % Fe, whereas little to no metal was present in the LM fume. Volatiles present in
the LM fume included benzene, toluene, 2-propan-1-ol, acetone, and others. An increase in lung injury parameters (albumin and lactate dehydrogenase) in the BALF was observed at 1 d after exposure to the HM fume that had resolved by 7 d, whereas exposure to the LM fume had no effect on lung injury and inflammation. Initial findings of this pilot study indicate that the metal, and not the volatile, component of RSW aerosol may influence the development of lung injury. Additional inhalation studies are ongoing to determine if either of these components alters lung function.

1056 CARDIOPULMONARY HEALTH EFFECTS OF TRAFFIC-RELATED AIR POLLUTANTS.

J. E. Minowsky1, R. Pelletier2, M. Lippmann1 and T. Gordon1. 1Environmental Medicine, New York University, New York, NY and 2Environmental Health Science, University of Massachusetts, Amherst, MA.

There is emerging evidence that the inhalation of certain components of ambient air PM is associated with adverse health effects. These studies, combined with others that looked at the sources of toxicants, implicate traffic markers. Our study is designed to integrate the associations between health effects and exposures to traffic-related PM. In this case-control study, 11 healthy, non-smoking participants were recruited to measure pulmonary function (FEV1, FVC), exhaled NO, and blood pressure prior to, immediately after, and 24 hours after they walked along 3 diverse roadway types for 1.5 hours between July and September 2011. Prior to participation, volunteers went through a consenting process as determined by protocols approved by NYU’s IRB. The 3 roadway locations differ by traffic type: the George Washington Bridge (GWB) carries truck and car traffic, the Garden State Parkway (GSP) carries car traffic, and Sterling Forest, NY (SF) acts as a control location with little traffic influence. Levels of PM2.5, PM10, and BC were found to be 0.034 μg/m3, 0.043 μg/m3, and 8321 ng/m3 at the GWB; 0.017 μg/m3, 0.027 μg/m3, and 2452 ng/m3 at the GSP; and 0.017 μg/m3, 0.020 μg/m3, and 1496 ng/m3 at SF, respectively. Using a two-tailed paired t-test, p-values were generated between the GWB or GSP and SF results.

Despite the limited number of subjects, a trend of increasing eNO between the GWB and SF was observed (p=0.11 and 0.23) and a decreasing trend of systolic blood pressure both directly and 24 hours after the exposure between the GWB and SF (p=0.07 and 0.12) were observed. While no statistically significant differences in health effects were observed, a trend of increased eNO and decreased blood pressure at the GWB, in comparison to SF, suggests that PM10, and BC were found to be 0.034 μg/m3, 0.043 μg/m3, and 8321 ng/m3 at the GWB; 0.017 μg/m3, 0.027 μg/m3, and 2452 ng/m3 at the GSP; and 0.017 μg/m3, 0.020 μg/m3, and 1496 ng/m3 at SF, respectively. Using a two-tailed paired t-test, p-values were generated between the GWB or GSP and SF results.

Despite the limited number of subjects, a trend of increasing eNO between the GWB and SF was observed (p=0.11 and 0.23) and a decreasing trend of systolic blood pressure both directly and 24 hours after the exposure between the GWB and SF (p=0.07 and 0.12) were observed. According to the US Energy Information Administration, coal remains to be the number one source of electricity, it fueled about 48.5% of the world’s electricity production in 2008. This has many implications on the health of coal workers, such as increased risk of developing coal workers’ pneumoconiosis (CWP). Epidemiological studies have determined that the prevalence of CWP is much higher in the Eastern US than the Western US. This indicates that the chemical compositions of coal may have a great affect on the development and prevalence of CWP. Acidity and the amount of Bioavailable Iron (BAI) have been demonstrated to be two important contributing factors to the toxicity of coal. BAI is the result of the oxidation of pyrite (FeS2) and its stability is pH-dependent. Coals from the western US have a high levels of calcite (CaCO3), and subsequently high pH, and low BAI. Based on these findings, we hypothesize that by adding calcite into a coal suspension, the amount of BAI will decrease thereby decreasing toxicity of the coal. We determined dose-response effects of coal and calcite samples from PA and UT in three models: cell-free, cell culture (Beas 2B cells) and mouse (129/SvEsvTac).

The BAI in PA coal originally at 400 ppm, was significantly reduced to 3-5 ppm within 20 minutes of adding a 10% calcite solution suspended in water. Also, RT-PCR results show that calcite helps reduce EMT markers such as fibroblast-specific protein-1 (FSP-1) in the murine model. We also speculate that inflammatory markers such as IL-6 and IL-1α would be down-regulated in the calcite and PA coal solutions as compared to the PA coal solution. These results demonstrated that introduction of calcite into coals of eastern regions of US could help reduce the incidence of CWP. Future studies should be aimed to corroborate findings in humans, as well as investigate the potential preventive effects of calcite in pulmonary fibrosis upon coal exposure.

1059 CALCITE AS A PREVENTIVE AGENT FOR COAL WORKERS’ PNEUMOCONIOSIS.

M. M. Aladdin, X. Huang, Q. Yang, J. Jian and L. Chen. Nelson Institute of Environmental Medicine, New York University School of Medicine, Tuxedo, NY.

Exposure to airborne particulate matter (PM) pollution has been correlated with the development and exacerbation of asthma, especially in susceptible populations such as young children. Inhalation of polymeric aromatic hydrocarbon (PAH) rich particles exacerbates respiratory disease and has been shown to cause oxidative stress. Polymorphisms in various antioxidant enzymes have correlated asthma with exposure to traffic generated PM. PM is a dynamic mixture with source and temporal variations that confound systematic studies of acute effects. In response, we have developed a laboratory-based PAH rich ultratine particulate (PPF) atmosphere that is devoid of metals and allergens and can be replicated for use in animal models. We exposed 7-day old neonatal and adult rats to a single 6 hour dose of 22.4
228 SOT 2012 Annual Meeting

1061 TEMPORAL PATTERN OF INFLAMMATION IN NEONATAL AND ADULT RATS FOLLOWING INHALATION OF PARTICULATE MATTER.

Over 23 million children under age 18 live in counties with unhealthy levels of short term particulate air pollution. This can predispose to respiratory disease. In this study, 7 day old and 18 week old rats were exposed for 6 hrs to laboratory synthesized PM (170 μg/m3, mean diameter 190nm) or to filtered air (FA). Peripheral blood and bronchoalveolar lavage fluid (BAL) was collected at 2 and 48 hours post exposure to monitor local and circulating markers of inflammation. Serum was collected for a multiplex cytokine array exposing neonates and adults; interleukin (IL)-4 gene expression was significantly increased only in neonate airways at 48 hr. Within the lung tissue, gene expression of colony stimulating factor (CSF)-1 was significantly increased after 48 hr of exposure to PM in the airways of both neonates and adults. Interleukin (IL)-4 gene expression was significantly increased only in neonate airways at 48 hr. Baseline expression of IL-1alpha, IL-1beta, IL-4, IL-6, IL-10, granulocyte macrophage colony-stimulating factor (GM-CSF), IFN-gamma, IL-6 was significantly greater in adult airways and parenchyma, as was interferon (IFN)-gamma. White blood cell counts in the circulation were not significantly altered by exposure at either age. In adult animals exposed to PM, serum cytokine levels were significantly increased at 48 hr compared to FA for IL-1alpha, IL-1beta, IL-4, IL-6, IL-10, granulocyte macrophage colony-stimulating factor (GM-CSF), IFN-gamma, and tumor necrosis factor (TNF)-alpha. PM exposed neonatal rats had significant decreases of IL-2, IL-4, IL-6, IL-10 and TNF-alpha at 48 hr in serum. We conclude that: 1) local inflammatory responses, particularly PMNs, are more robust to the same concentration of PM in neonates than in adults and 2) circulating cytokines are more likely to be increased in adults than in neonates following an inhalation exposure to fine/ultrafine PM, even in the absence of lung cytotoxicity or elevation of BAL cells. Supported by USEPA RD-83241401, ES06700 and ES05707.

1062 PULMONARY TOXICITY OF AMINES USED FOR CARBON CAPTURE AND STORAGE.

D. Kracko1, J. McDonald1, M. Doyle-Eisele1, A. Rohr1 and E. Knipping2. 1Lovelace, Albuquerque, NM and 2EPRI, Palo Alto, CA.

Carbon dioxide (CO2) absorption with aqueous amine solvents is among the leading candidates for use in carbon capture and sequestration (CCS) techniques aimed at reducing greenhouse gas emissions from flue gases (coal-fired power plants, refineries, etc.). The environmental consequences this technology have been poorly characterized. A concern is that amines or degradation products that may form in the capture system or via interaction with flue gases may be emitted to the atmosphere and create unintended human exposures. The potential for these emissions to occur, the potential for the emissions to result in exposures, and the resulting health risk of these exposures are unknown. This study evaluated the potential health risks of inhalation exposure to amines and amine degradation products. Three model amines (monoethanolamine (MEA), methylidithiolanethanolamine (MDEA), piperazine (PIP) and their laboratory generated degradation products were used to create inhalation exposure atmospheres for exposures in mice. C57bl/6N mice were exposed for 7 days of inhalation to 25 ppm amines or the equivalent containing or degraded amines. Inflammatory response in lungs was assessed by counting inflammatory cells in lavage fluid and measuring cytokine expression in lung tissue. Inhalation exposure to degraded MEA resulted in significant increases in total cells, neutrophils, and lymphocytes compared to control mice. Significant increases in inflammatory cytokine expression were seen in mice exposed to the degraded MDEA atmosphere. These exacerbated inflammatory responses in mice exposed to degraded amines suggest that oxidative products of amines may produce increased toxicity. Work supported by the Electric Power Research Institute.

1063 COMPARISON OF HEALTH EFFECTS AND COMPOSITION OF SECONDARY ORGANIC AEROSOLS.

A. Rohr1, E. Knipping2, J. Seinfeld3, M. Doyle-Eisele1, J. Suratt4, D. Kracko1 and J. McDonald1. 1Lovelace, Albuquerque, NM, 2EPRI, Palo Alto, CA, 3Caltech, Pasadena, CA and 4University of North Carolina, Research Triangle Park, NC.

We present findings from the Secondary Particulate Health Effects Research (SPHERES) program, which was created to define the composition and resulting health hazard of secondary organic aerosol (SOA) synthesized under varying reaction conditions. Reaction conditions were varied to evaluate SOA derived from a biogenic (α-pinene) or anthropogenic (toluene) hydrocarbon precursor in the presence of NOx/sunlight. The reactions were conducted with/without the addition of SO2 that would add additional acidity, and then a subsequent exposure where ammonia was added to titrate the acidity. Target SOA exposures were conducted at 300 μg/m3 of particulate material. Direct comparisons of composition and toxicity were conducted with normalization of atmospheres to either total particulate matter or total organic particulate matter. Exposures were conducted for 7 days (6 hr/day) to ApoE mice (male, 8-10 weeks) down-stream of honeycomb de-nuders employed to remove ozone. Measurements of pulmonary inflammation (lavage white blood cells) and indicators of vascular injury and remodeling were assessed. The presence of SO2 led to differences in the observed SOA composition for both α-pinene and toluene. SO2 participated directly with α-pinene to form organosulfate compounds, and had an apparent modification of toluene chemistry that led to enriched amounts of organonitrates compounds. The vascular responses showed increased expression of metalloproteinase activity and collagen expression. In our model, high ozone flux plays a role in the site-specificity of this injury. To test this hypothesis, we determined that cyclic ozone exposure causes epithelial necrosis, squamous metaplasia, and neutrophilic rhinitis in the nasal airways of infant monkeys, a model for the developing nasal airways of children. These lesions are not uniformly distributed across the nasal airways and vary in location and extent, increasing injury at the nasal septum. The site-specificity is likely due to a complex relationship between tissue susceptibility and local ozone dose. The purpose of this study was to test the hypothesis that ozone flux plays a role in the site-specificity of this injury. To test this hypothesis, we developed a three-dimensional (3D) computational fluid dynamics (CFD) model of the left nasal cavity of a 6-month-old rhesus monkey. The computer model was used to simulate inspiratory airflow and ozone uptake. Simultaneously, 6-month-old rhesus monkeys were exposed to 1 cycle of ozone (5 days of filtered air + 9 days of 0.5 ppm ozone, 8h/day), 11 cycles of ozone, or filtered air. The left nasal passage was processed for light microscopy. The presence or absence of epithelial necrosis was plotted on the corresponding regions delineated on the CFD model. Model predictions of ozone flux were compared to lesion incidence along the perimeter of two transverse cross-sections by correlation analysis. In our model, high ozone flux was not limited to the regions of ozone-induced injury, but was also found in other regions of the nasal airways. As a result, ozone flux was not significantly correlated with ozone-induced epithelial necrosis. These findings suggest high dose alone is not sufficient for ozone-induced nasal airway injury, and that additional biological factors may render some sites more susceptible to injury after ozone exposure.

1064 CORRELATION BETWEEN COMPUTER-DERIVED OZONE FLUX AND OZONE-INDUCED INJURY IN THE NASAL AIRWAYS OF INFANT RHESUS MONKEYS.

S. A. Carey1, G. Garcia2, E. M. Postlethwaite1, L. R. Hadkern3 and J. S. Kimbell4. 1Michigan State University, East Lansing, MI, 2Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, 3University of Alabama at Birmingham, Birmingham, AL and 4University of North Carolina at Chapel Hill, Chapel Hill, NC.

The mechanisms by which ozone, the principal oxidant pollutant in photochemical smog, causes nasal epithelial injury are incompletely understood. We have demonstrated that cyclic ozone exposure causes epithelial necrosis, squamous metaplasia, and neutrophilic rhinitis in the nasal airways of infant monkeys, a model for the developing nasal airways of children. These lesions are not uniformly distributed across the nasal airways and vary in location and extent, increasing injury at the nasal septum. The site-specificity is likely due to a complex relationship between tissue susceptibility and local ozone dose. The purpose of this study was to test the hypothesis that ozone flux plays a role in the site-specificity of this injury. To test this hypothesis, we developed a three-dimensional (3D) computational fluid dynamics (CFD) model of the left nasal cavity of a 6-month-old rhesus monkey. The computer model was used to simulate inspiratory airflow and ozone uptake. Simultaneously, 6-month-old rhesus monkeys were exposed to 1 cycle of ozone (5 days of filtered air + 9 days of 0.5 ppm ozone, 8h/day), 11 cycles of ozone, or filtered air. The left nasal passage was processed for light microscopy. The presence or absence of epithelial necrosis was plotted on the corresponding regions delineated on the CFD model. Model predictions of ozone flux were compared to lesion incidence along the perimeter of two transverse cross-sections by correlation analysis. In our model, high ozone flux was not limited to the regions of ozone-induced injury, but was also found in other regions of the nasal airways. As a result, ozone flux was not significantly correlated with ozone-induced epithelial necrosis. These findings suggest high dose alone is not sufficient for ozone-induced nasal airway injury, and that additional biological factors may render some sites more susceptible to injury after ozone exposure.
PM composition as a result of the partition of semivolatile organic compounds (SVOCs) to the vapor phase once released into the atmosphere. Therefore, the aim of this study was to assess the difference in cardiovascular toxicity between semivolatile and refractory nonvolatile constituents of ultrafine PM. Apoprotein E knockout (ApoE-/-) mice, which are prone to develop atherosclerosis, were exposed to ultrafine concentrated ambient particles (CAPs), or to either its semivolatile components or to nonvolatile CAPs. Animals were exposed for 5 hours a day, 4 days a week, over an 8 week period, 100m downwind of a major freeway. A subset of animals was implanted with a telemetry device to record electrocardiograph (ECG) readings. Heart rate variability (HRV), a measure of autonomic cardiovascular function, was calculated from ECG readings during each experiment and compared to baseline values. The progression of atherosclerosis was determined by analyzing aorta tissue sections for plaque build-up and lipid accumulation. Serum levels of total cholesterol and protein carbonyls were also measured. Greater HRV changes from baseline were observed in mice exposed to unmodified CAPs and SVOC components. Removal of SVOCs present in ultrafine CAPs resulted in a reduction of both plaque formation and lipid accumulation in the aorta. No differences among groups were observed for total cholesterol and protein carbonyls. The results indicate that SVOCs are important contributors to the cardiovascular toxicity attributed to ultrafine PM. Further analyses will measure additional serum biomarkers (i.e. lipid peroxidation and CRP) and will attempt to correlate the physiological and biological endpoints with specific PM components (i.e. PAHs).

**PARTICULATE MATTER EXPOSURE MODULATES OXIDATIVE AND INFLAMMATORY PARAMETERS IN SPECIFIC REGIONS OF THE APOE-/- MOUSE BRAIN.**

L. Mendez, A. Campbell, A. Keebaugh and M. T. Kleinman.

Exposure to particulate matter (PM), present in urban environments, has been shown to induce pro-inflammatory central nervous system (CNS) effects in apoprotein E knockout (ApoE-/-) and Balb/c mice. In this study pro-inflammatory and oxidative stress responses in different regions of the ApoE-/- mouse brains were evaluated after a chronic exposure to fine (2.5-10μm) concentrated ambient particles (CAPs). ApoE-/- mice were exposed to either CAPs or particle-free air for 5 hours a day, 5 days per week, for a period of 6 months. Subset of animals were euthanized at 2, 4 and 6 months to evaluate the progression and persistence of pro-inflammatory and oxidative stress responses in the brain. To elucidate whether specific regions of the brain are more susceptible to the adverse effects of CAPs, brains were dissected into 3 regions (rostral, mid, and caudal) and each region was analyzed separately. Baseline levels of the pro-inflammatory cytokines IL-6 and TNFα and the transcription factors NF-κB and AP-1 were different based on the region analyzed and the exposure length. CAPs treatment did not significantly alter these baseline levels. Higher levels of IL-6 were observed in the rostral region after 2 and 6 months of exposure. Increases in TNFα were only seen after 6 months of exposure. Baseline levels of the anti-inflammatory cytokine IL-10 were higher in the caudal region and there was less evidence of inflammation in that region. Baseline levels of protein carbonyls were higher in the rostral region with an increase of protein oxidation after two months of exposure. The results indicate that different brain regions may respond uniquely to exposure to ambient air pollutants such as PM. To what extend these changes contribute to the pathology associated with different neurodegenerative diseases is the focus of our current research endeavors.

**A FOUR-WEEK INHALATION TOXICITY STUDY OF CUPROUS OXIDE IN RATS.**

The objective of this study, in which albino rats were exposed (whole-body) to cuprous oxide (Cu2O) aerosols for 4 weeks (5 days/week), was to evaluate inhalation toxicity with an emphasis on respiratory tract pathology. Exposure concentrations were 0, 0.2, 0.4, 0.8 and 2.0 mg/m3. Groups exposed at 0 and 2.0 mg/m3 were also evaluated following a 13-week recovery period. Pathological assessments consisted of hematologic, bronchoalveolar lavage fluid (BALF) evaluations, gross necropsy and organ weight evaluations and microscopic examination of selected tissues. Test article-related effects on quantitative endpoints included higher blood neutrophil counts and BALF total protein, lactate dehydrogenase and percent neutrophils at 0.2 mg/m3 and higher BALF total cell counts, lung weights (wet and dry) and lung histopathology in animals exposed to 0.4 mg/m3. Microscopic effects in the lungs consisted of alveolar histiocytosis (higher numbers of large, foamy macrophages) and acute inflammation at ≤0.2 mg/m3 and mononuclear cell infiltrates at ≥0.4 mg/m3. The lungs of animals exposed at 0 and 2 mg/m3 were also examined using Masson’s Trichrome stain, revealing slightly greater collagen staining relative to control in alveolar septa and alveolar ducts. Lymphoid hyperplasia of the lung draining lymph nodes was seen at ≥0.2 mg/m3. Microscopic effects in the nasal cavity were rare and limited to the 0.8 and 2.0 mg/m3 groups. At the 13-week recovery evaluation, the only effects were slightly higher lung weight and slightly greater collagen staining relative to control in alveolar septa. Results of these investigations indicate that Cu2O-related effects were found at all exposure levels. However, the microscopic findings in the lungs and lymph nodes represented a typical response in the rat to an inhaled insoluble dust, and there were no microscopic indications of alveolar epithelial injury or repair or of the presence of edema. Nearly complete resolution of findings was observed following a 13-week recovery period.

**EVALUATION OF INHALATION EXPOSURE TO AEROSOLIZED D-LIMONENE IN SPRAGUE DAWLEY RATS.**

D-limonene is a commonly used fragrance material that has been associated with dermal allergies. The study objective was to evaluate the potential toxic effects, including pulmonary inflammation, of aerosolized d-limonene when administered to Sprague-Dawley (SD) rats by nose-only inhalation at 10, 100, or 1000 ppm for 2 weeks (6 hours/day, 5 days/week). Standard endpoints included clinical observation, body and organ weights, hematology and serum chemistry evaluation, macroscopic/microscopic examination, and bronchoalveolar lavage fluid (BALF) analysis to determine pulmonary inflammation. Cytokines in BALF and serum were measured for immune-mediated mechanisms of action. For comparison to test compounds and to validate the utility of cytokine measures for evaluation of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). Consistent with published data, SD rats had higher lung weights and a time-dependent increase in pulmonary irritation, evidenced by increase in BALF and histopathologic parameters. For d-limonene, respiratory tract changes in the 1000 ppm group animals were minor. BALF parameters were unaffected compared to controls and to silica-treated animals. No inflammation was indicated by cytokine profiles in BALF and serum. Low thymus weights in the 1000 ppm group correlated with lymphoid necrosis/depletion in females, while low spleen weights in this group had no microscopic correlate. High-dose males had mild/moderate hyaline droplet accumulation in the kidney proximal tubules, common post oral ingestion. Exposure to 1000 ppm is higher than any occupational or consumer exposure scenario representing a threshold of response that inhalation exposure to d-limonene in the general population poses little to no safety concern.

**EVALUATION OF INHALATION EXPOSURE TO AEROSOLIZED 2, 3-PENTANEDIONE IN SPRAGUE DAWLEY RATS.**

2,3-Pentanedione is used in butter flavoring for consumer products. A related material, diacetyl, has been suggested to cause pulmonary effects associated with the development of bronchiolitis obliterans. The study objective was to evaluate the potential toxic effects, including adverse pulmonary effects, of aerosolized 2,3-pentanedione when administered to Sprague Dawley (SD) rats by nose-only inhalation at 8.8, 17.5, and 35 ppm for 2 weeks (6 hours/day, 5 days/week). Standard endpoints included clinical observation, body and organ weights, hematology and serum chemistry evaluation, macroscopic/microscopic examination, and bronchoalveolar lavage fluid (BALF) analysis to determine pulmonary inflammation. Cytokines in BALF and serum were measured for immune-mediated mechanisms of action. For comparison to test compounds and to validate the utility of cytokine measures for evaluation of pulmonary inflammation, a nose-only inhalation pilot was conducted with 25 mg/m3 amorphous silica (0, 1, 2, 5 or 10 exposures). Consistent with published data, SD rats had higher lung weights and a time-dependent increase in pulmonary irritation, evidenced by increase in BALF and histopathologic parameters. For 2,3-pentanedione, all animals survived and no pulmonary effects were observed (no microscopic, BALF or cytokine effects) Nasal
transitional epithelial hyperplasia, subacute inflammation and a dose-dependent in-
crease in hemorrhage, necrosis, and edema, as well as laryngeal sub-acute inflam-
mation, were noted at 17.5 ppm. It was previously reported that inhalation expo-
sure to >200 ppm diacetyl (6 hr/for 5 days) caused acute necrotizing rhinitis, er-
ose/necrotizing laryngitis and death. This study presents a threshold of exposure at
which the lowest dose tested, 8.8 ppm (>31 ppb STEL), failed to induce acute
necrotizing rhinitis/laryngitis.

1070 THE ROLE OF CLAUDIN 4 IN EPITHELIAL REPAIR FOLLOWING LUNG INJURY.
K. Sutherland 1, 2, M. Lafemina 1, J. B. Frank 1, 3, 1 University of Califor-
nia, San Francisco, San Francisco, CA and 2 San Francisco VA Medical Center,
San Francisco, CA.
Repair of epithelium in the lung is fundamentally important to recovery and sur-
vival in patients with acute lung injury and ARDS. Regulation of fluid balance in
the lung via paracellular pathways is managed by the Claudin family of tight junc-
tion proteins. While the involvement of Claudins in regulating ion and fluid trans-
port is apparent, other potential functions of these tight junction proteins is un-
clear. Previous studies have observed a marked increase in Claudin 4 (cldn4) mRNA
expression in mice following ventilation induced lung injury. Similarly cldn4 levels
have been shown to be induced in a variety of epithelial injury models, not specific
only to the lung. In our current study we utilized both in vitro and in vivo models to
study the role of cldn4 in response to epithelial wounding and to delineate spe-
cific pathways critical to the unique regulation of this protein and its involvement
in epithelial repair. Naphthalene (NA), a ubiquitous environmental pollutant,
causes selective toxicity of Clara cells lining the conducting airway of mice. At 24
hrs following NA treatment, we found that mice exhibited an increase in lung per-
meability coupled by a 4 fold induction of cldn4 protein. Cldn4 levels returned to
control levels as lung permeability was restored following epithelial repair. The in-
duction of cldn4 was inhibited by pretreatment of animals with an EGFR inhibitor,
indicating cldn4 acts downstream of EGFR in wound repair and likely is implicated
in cellular proliferation. In our cell culture model of epithelial injury, 16HBE cells
were induced for cldn4 mRNA and protein levels along the migrating edge of cells
following scratch wounding. Early events following scratch wounding included in-
creased tyrosine phosphorylation of cldn4. siRNA knock down of cldn4 was suffi-
cient to inhibit wound closure rates. We conclude from these studies that cldn4 is
induced with epithelial injury and is necessary for timely epithelial repair and resto-
arion of barrier function in pulmonary epithelium.

1071 AN INHALATION TOXICITY TIME-COURSE EVALUATION OF CUPROUS OXIDE IN RATS.
J. T. Weinberg 1, B. Danaisien 2, C. Mackie 3, D. T. Kirkpatrick 1 and J. B. Nold 1, 
1, 2, 3

For this study phase, albino rats were exposed to cuprous oxide (Cu2O) aerosols at
0 and 2.90 mg/m3 by whole-body inhalation for 1, 2, 3 or 4 weeks (5 days/week).
The objective was to evaluate possible temporal relationships between duration of
exposure and test article-related effects and whether a plateau was observed for ef-
ficacy differences related to NO exposure. These results suggest that in a healthy animal
model exposure to CO or NO alone, at levels reflecting concentrations found in
primary components of diesel emissions, on vascular function in systemic arteries.
We hypothesized that exposure to these monoxide gases, at concentrations similar to
those of diesel emissions, would reproduce the negative vascular effects seen pre-
viously. Whole body rodent exposures were conducted for both NO and CO or
room air for one or four hours. CO exposure was 0, 50 and 100 ppm; NO exposure
levels were 0 and 10 ppm. Vascular rings, two per animal, were isolated immedi-
ately after exposure, mounted on a force-transduction myograph and then chal-
lenged with potassium, phenylepherine (PE) and acetylcholine (ACh). The NO ex-
posures were conducted for one hour, preceded by N-acetylcysteine (NAC) or
vehicle supplementation (intraperitoneal injection; 200 μg/kg). Additionally, both
young (4-6 weeks) and old (4-6 months) mice underwent this one hour NO/NAC
exposure regimen. Vascular response to lower concentrations of ACh was enhanced
after CO exposures. NO inhalation did not alter the vascular responsiveness to ei-
ther PE or ACh in mice or rats, although rat plasma nitrate/nitrite levels were sig-
ificantly elevated after NO exposure. NAC supplementation did not produce the
enhanced plasma NOX levels previously seen with diesel emissions exposures. Old
mice had a noticeable decrease in vascular responsiveness overall, but showed no
differences related to NO exposure. These results suggest that in a healthy animal
model exposure to CO or NO alone, at levels reflecting concentrations found in
whole diesel emissions, do not have deleterious effects on systemic vascular reactiv-
ity.

1072 VASCULAR FUNCTION EFFECTS OF ACUTE INHALATION OF CARBON MONOXIDE AND NITRIC
OXIDE.
J. G. Buntz, S. N. Lucas and M. Campen, Pharmaceutical Sciences, University of
New Mexico, Albuquerque, NM.
Cardiovascular disease (CVD) remains a major cause of morbidity and mortality in
the developed and developing world. Exposure to emissions from diesel and gaso-
line engines is widely recognized as an important risk factor for CVD. In an effort
to determine the drivers of toxicity in the complex diesel exhaust mixture, we have
examined the effects of nitric oxide (NO) and carbon monoxide (CO), two of the
primary components of diesel emissions, on vascular function in systemic arteries.
We hypothesized that exposure to these monoxide gases, at concentrations similar to
those of diesel emissions, would reproduce the negative vascular effects seen pre-
viously. Whole body rodent exposures were conducted for both NO and CO or
room air for one or four hours. CO exposure was 0, 50 and 100 ppm; NO exposure
levels were 0 and 10 ppm. Vascular rings, two per animal, were isolated immedi-
ately after exposure, mounted on a force-transduction myograph and then chal-
lenged with potassium, phenylepherine (PE) and acetylcholine (ACh). The NO ex-
posures were conducted for one hour, preceded by N-acetylcysteine (NAC) or
vehicle supplementation (intraperitoneal injection; 200 μg/kg). Additionally, both
young (4-6 weeks) and old (4-6 months) mice underwent this one hour NO/NAC
exposure regimen. Vascular response to lower concentrations of ACh was enhanced
after CO exposures. NO inhalation did not alter the vascular responsiveness to ei-
ther PE or ACh in mice or rats, although rat plasma nitrate/nitrite levels were sig-
ificantly elevated after NO exposure. NAC supplementation did not produce the
enhanced plasma NOX levels previously seen with diesel emissions exposures. Old
mice had a noticeable decrease in vascular responsiveness overall, but showed no
differences related to NO exposure. These results suggest that in a healthy animal
model exposure to CO or NO alone, at levels reflecting concentrations found in
whole diesel emissions, do not have deleterious effects on systemic vascular reactiv-
ity.

1073 ALTERATIONS IN NEURAL TELOMERE SYSTEM FOLLOWING CHRONIC INHALATION EXPOSURE TO
COAL COMBUSTION.
E. S. Colombo 1, M. L. Pfaff 2, J. D. McDonald 1, M. D. Reed 1, J. Mauderly 3,
J. Griffith 1, K. Trijillo 1 and M. Campen 2, 1 School of Medicine, University of New
Mexico, Albuquerque, NM, 2 Pharmacological Sciences, University of New Mexico,
Albuquerque, NM and 3 Toxicology, Lovelace Respiratory Research Institute,
Albuquerque, NM.
Air pollution exposure is associated with premature mortality due to heart and lung
disease, an observation that has been well characterized epidemiologically. Recent
studies indicate a reduction in life expectancy related to particulate matter (PM) levels,
suggesting that the US population loses more than 7 months of life span for
every 10 μg/m3 of PM2.5. Additionally, telomere length in peripheral blood cells
has been found to be shorter in association with high pollution regions. Together
these observations suggest that air pollution may contribute to premature cellular
aging. In this study, we hypothesized that chronic exposure to a Simulated Downwind
Coal Combustion Atmosphere (SDCCA) would result in decreased telomere length and increased apoptosis in brain cortex. Brain tissue from rats ex-
posed daily for 6 months to low (100 μg PM/m3), medium (300 μg PM/m3), high
(1000 μg PM/m3), PM-filtered high and control (room air) coal combustion at-
mospheres were assayed for alterations to the telomere system. mRNA expression of
TERT was reduced by 70% (p<0.05) in the cortex of female rats exposed to high
levels of SDCCA compared to both control animals and male rats. This reduction
was partially ameliorated in female animals exposed to PM-filtered high SDCCA,
which had a 29% reduction in TERT mRNA expression compared to control ani-
mals. Males showed a more modest reduction in TERT (45% decrease) that was
also restored with the filtration of PM. TRF2 mRNA, but not TRF1, also showed
differences related to NO exposure. These results suggest that in a healthy animal
model exposure to CO or NO alone, at levels reflecting concentrations found in
whole diesel emissions, do not have deleterious effects on systemic vascular reactiv-
ity.

1074 THE EFFECTS OF COPPER PYRITHIONE ON DEVELOPING ZEBRA FISH EMBRYOS.
K. M. Almond and L. D. Trombetta, Pharmaceutical Sciences, St. John’s University,
Queens, NY.
Copper pyrithione, an active component in antifouling biocides predominantly
found in marine paints, has been shown to cause anomalies during early develop-
ment of mummichogs (Fundulus heteroclitus). Since a strict regulatory use of organ-
ants as antifouling agents has been imposed, a frequent substitute within the Japanese market has been the use of metal pyrithiones, principally zinc and copper. Zebrasfish (Danio rerio) embryos were exposed within the first hour after fertilization to increasing concentrations of copper pyrithione (2, 4, 8, 12, 16, 32 and 64 μg/L) for 24 hours. Morphological abnormalities at 30, 60, and 120 hours post fertilization were recorded. Hatchability was measured every 12 hours for 5 days. Following the 24 hour exposure, results showed morphological abnormalities, particularly of the notochord at concentrations of 12 μg/L and higher when compared to controls. Notochords were severely twisted as concentrations increased. Distortions of the notochord began in the caudal region and proceeded rostrally. Edema was observed in the cardiac and yolk sac regions at the 12 and 16 μg/L concentrations. Hatching rate also decreased in a dose dependent manner. At 120 hours post fertilization, 47 percent of embryos hatched, while all of the controls hatched by 96 hours post fertilization. Copper accumulated in whole embryo tissues and was significantly different in 32 and 64 μg/L CuPT treatment groups as compared to controls. Lipid peroxidation was also significantly increased in animals exposed to 32 and 64 μg/L of copper pyrithione. These results demonstrate that oxidative stress plays a partial role in the observed toxicity. Copper pyrithione has shown to be toxic to zebrasfish at concentrations of 12 μg/L or greater. The abnormalities and deformities observed in fish larvae would significantly decrease survival in non-controlled environments.

**1075 DIFFERENCES IN UPTAKE, METABOLISM, AND CLEARANCE OF ATRAZINE AND TAMOXIFEN IN A FISH AND A RAT SPECIES.**

Atrazine and tamoxifen are known endocrine-disrupting chemicals (EDCs) that have metabolites exhibiting biological activities that are equally or more potent than the parent compound. To evaluate if uptake, metabolism and clearance of such EDCs is a concern in interspecies extrapolation, plasma concentrations of these chemicals and major metabolites were compared over time in fish and rats treated with a single oral dose of atrazine (50 mg/kg) or tamoxifen (25 mg/kg). For atrazine, plasma samples were collected 0.25, 0.5, 1, 3, 24, 72, and 120 hours after gavage. Atrazine and metabolites were quantified using GC/MS. Atrazine was detected in rat and fish plasma within minutes, indicating rapid uptake in both species. Rats metabolized atrazine more slowly at 3 hours, than fish, demonstrating dissimilar concentrations than atrazine at all time points and concentration of the metabolite diaminochlorotriazine (DACT) in rat plasma was 30 times that in fish at 3 hours. In fish, atrazine was metabolized more slowly at 3 hours, atrazine predominated in fish plasma at concentrations over 100 times that in rat plasma. By 120 hours, only DACT was still detectable in both rats and fish. For tamoxifen, animals were sampled 1, 4, 8, 16, 20, 24, 48 and 72 hours post-dosing. Tamoxifen and metabolites in plasma were quantified using HPLC. Peak plasma concentrations of tamoxifen (about 600 ng/ml) were observed at 1 hour in fish and at 4 hours in rats, indicating a slightly faster uptake in fish. From 4 hours forward, tamoxifen and metabolite 4-hydroxytamoxifen were detected in fish plasma, but not rats, at each time point. In rat plasma, from 16 hours forward, tamoxifen and metabolite N-desmethyltamoxifen were prevalent, again at similar concentrations. These results indicate uptake and metabolism of environmental EDCs by different species can vary substantially and could be a significant issue when extrapolating effects across species.

**1076 TOXICITY OF LEGACY AND REPLACEMENT FLAME-RETARDANT CHEMICALS ON DAPHNIA MAGNA**

Chemical flame-retardants (FRs) have been added to consumer products and used extensively in California since the 1970s. Since the FRs are not covalently bonded to materials in which they are added, they leach into the environment and end up in animals such as humans and marine mammals. However, very little data exists about the toxicity of flame retardants in environmentally relevant concentrations that occupy the lower ranks of the food web, such as Daphnia magna. In this work, we determined the acute 48-hour toxicity of flame retardants to neonate D. magna. Flame retardants tested include banned legacy chemical pentabromodiphenyl ether (penta-BDE), related octa- and deca-BDE, and penta-P derivative’s formulation Firemaster®550 (FM550). We also tested FM550 components tetra-bromo phenyl (TBB), triphenyl phosphate (TPP), and Firemaster®7Z-54, which is a mixture of TBPB and tetra-bromo benzene (TBB). We found that FM550 has a higher acute LC50 to D. magna than its predecessor, penta-BDE. We also performed microarray gene-expression studies on adult daphnids at 1/10L C, and found that exposure to each chemical elicited a unique genomic response in the daphnids. It is therefore possible that these chemicals with very low water solubility could be acting via unique modes of toxicity instead of by a purely narcotic toxic effect.

**1077 ANXIOLYTIC EFFECTS OF FLUOXETINE ON THE STARTLE RESPONSE AND EXPLORATORY BEHAVIOR OF THE ZEBRAFISH.**

K. Thornton1, T. Gallagher1, R. Lock2 and M. A. Connaughton1, 1Biology, Washington College, Chesterton, MD and 2Chemistry, Washington College, Chesterton, MD. Sponsor: M. Reynolds.

Pharmaceuticals, including the antidepressant fluoxetine (Prozac) are released in waste-water effluent and are present in measurable quantities in effluent-impacted streams. Environmental exposure to pharmaceuticals may produce subtle aberrant behaviors that could impact the survival of affected individuals and populations. Fluoxetine, a selective serotonin reuptake inhibitor, is an anxiolytic and has been linked to decreases in social aggression, reproductive success and C-start (startle) behaviors in several fish species. Startle responses in fish vary, but often include changes in swimming velocity as the fish freeze or flee and decreased exploratory behavior. This study examines the effects of fluoxetine on the startle response and exploratory behavior of individual zebrafish following an acoustic/vibrational stimulus. Fish were exposed in tank water at an environmentally relevant low dose 0.1 μg/L or a high dose of 1.0 μg/L for 1 week or were injected with a pharmacological dose via IP microinjection at 10 μg/g body weight. The movement of individual fish in a 10 L tank digitally divided into 4 zones was tracked by computer (Ehrovision ver. 3.0) for 2 min. prior to and 2 min. following a startle stimulus (ball pendulum). Swimming velocities were used to assess baseline-swimming behavior and startle responses, while frequency of crossings between and total duration of time spent in each zone were used to assess exploratory behavior. Under the influence of fluoxetine, zebrafish showed a decrease in acute startle response intensity, decreased baseline-swimming velocity, more rapid recovery from startle behaviors and increased exploratory behavior. Such anxiolytic effects in the wild might increase the likelihood of a fish encountering a predator and decrease its likelihood of surviving an attack. Environmental and injection protocols produced disparate results, suggesting that acute treatments by injection might not be an accurate way to model environmental effects of pharmaceuticals on fish in the wild.

**1078 FISH TISSUE LEVELS OF FIVE METALS ASSOCIATED WITH CRUDE OIL FROM THE DEEP HORIZON WELL.**

A. C. Nichols and D. A. Steffy. Physical and Earth Sciences, Jacksonville State University, Jacksonville, AL.

Scad mackerel, TRACHURUS LATHAMI, were collected from the northern Gulf of Mexico as part of the 2010 NOAA Pelagic Trawl Survey. Fish tissues were analyzed by ICP for five metals associated with crude oil from the BP Deep Horizon Well. On samples analyzed to date, nickel concentrations ranged from 1.67 μg/g to 8.35 μg/g Vanadium levels ranged from 0.86 to 49 μg/g. Chromium, lead and thallium, the high values were 0.40, 0.63 and 1.30 μg/g respectively. Low values for each of these metals were not detected. Metal concentrations in these fish varied with sampling locations across the northern Gulf of Mexico.

**1079 APPLICATION OF EASILY-SYNTHESIZED INTERNAL STANDARDS FOR RAPID QUANTITATIVE ANALYSIS OF CYANOBACTERIAL BLOOMS FOR HEPATOTOXIC MICROCYSTINS BY MATRIX-ASSISTED LASER DESORPTION IONIZATION MASS SPECTROMETRY (MALDI-MS).**

A. E. Roeger1, B. Puschner1, M. Piriz2, B. Brena2 and G. Gonzalez-Sapienza2. 1Dept of Mol Biosciences, UC Davis, Davis, CA and 2Fac de Quimica, UdeLaR, Montevideo, Uruguay.

The ubiquitous freshwater cyanotoxins, microcystins, (MCs), pose a global public health threat with potent acute hepatotoxicity, persistence in drinking and recreational water, and potential chronic and neurotoxic effects. Over 80 congeners have been identified worldwide, yet most risk assessment and monitoring rely on one congener (MC-LR). To achieve sensitivity to recommended World Health Organization (WHO) guideline of 1 μg/L, analytical methods require substantial sample processing and concentration, resulting in undesirable time lags during SOT 2012 ANNUAL MEETING 231
bloom outbreaks. While existing ELISAs demonstrate capable congener detection, HPILC-MS requires individual standards and skilled technicians. In contrast, MALDI-MS requires little sample, short analysis time and demonstrates remarkably reduced matrix interference in raw samples; the major limitation for quantification application to surface water has been lack of an internal standard with similar crystallization and desorption properties. (S-hydroxyethyl-Cys(7))-MC-LR and -RR internal standards (IS) were synthesized within minutes from commercially available MCs at room temperature. Standard curves and limit of quantification (LOQs) were determined for spiked MC –LR, -RR and -YR. Quantitative analysis of MCs in raw surface water with IS was compared with ELISA and HPILC. Linear standard curves were reproduced across several orders of magnitude. Using the ratio of peak intensity of analyte to IS, LOQs were 5 μg L⁻¹, permitting quantification below the WHO limit after a 20-fold concentration. Limits of detection were consistently well below 0.1 μg L⁻¹. Eighty six to 94% of MC-LR was recovered from spiked raw waters. The minimal processing and concentration, easy synthesis of IS and ability to determine across concentrations of hydrophilic congeners will drastically reduce time needed to provide an estimate of total toxin concentration and congener-specific risk.

**1080 LOW-LEVEL KETOCONAZOLE INCREASES ESTROGENIC POTENTIAL OF IBUPROFEN IN H295R CELL LINE AND ORYZIAS LATIPES.**

Most of toxicity tests were made on individual chemicals, while pharmaceuticals found in the aquatic environment usually occur as mixtures. In the present study, we hypothesized that ibuprofen metabolism might be decreased due to CYP2C9 inhibition by low level ketoconazole exposure, leading to increase of estrogenic potential of ibuprofen exposure. After 48 hr exposure to 0.02-20 mg mL⁻¹ of ibuprofen alone or in combination with 5 ng L⁻¹ of ketoconazole in the human adrenocortical carcinoma (H295R) cell line, the production of 17β-estradiol (E2) and testosterone (T), the activity of aromatase, and the mRNA expression of steroidogenic genes and CYP2C9 gene were measured. In addition, concentrations of E2 and T in blood plasma, and the mRNA expression of steroidogenic genes were determined in male medaka fish after 14 days exposure to ibuprofen 0.02 and 0.2 mg L⁻¹ or in combination with 10 μg L⁻¹ of ketoconazole. Ibuprofen alone exposure increased E2 production, and enhanced both aromatase activity and expression of CYP11β2 mRNA in the cells. When 5 ng L⁻¹ of ketoconazole was added, the extent of increase in E2 production, aromatase activity, and expression of CYP11β2 mRNA became greater. In medaka fish, while ibuprofen exposure at 0.2 mg L⁻¹ did not cause any significant effects on E2 concentration compared to that of control, co-exposure to ketoconazole caused significant increase of E2 concentration. In addition, a combined exposure to ibuprofen and ketoconazole resulted in an elevated expression of CYP17 and CYP19β mRNAs in male medaka, compared to ibuprofen only exposure. The results of present study indicate that non-effective concentrations of ketoconazole can increase the potential for endocrine disrupting effects of ibuprofen exposure.

**1082 CLINICO-HEMATOLOGICAL RESPONSE TO EXPERIMENTAL INFECTION OF ESCHERICHIA COLI O157:H7 IN CLARIAS GARIEPINUS.**

E. Ajani1 and V. O. Adetunji2. 1Animal Science & Fisheries Management, Bowen University-Iwo, Iwo, Osun, Nigeria and 2Veterinary Public Health & Preventive Medicine, University of Ibadan, Ibadan, Oyo, Nigeria.

African catfish, Clarias gariepinus is one of the most suitable species for aquaculture in Africa. Information on pathogenesis of E. coli O157:H7 infection is scarce. This study therefore aims at elucidating information on pathogenesis and hematological response of C. gariepinus experimentally infected with E.coli. With the hope of giving a baseline information for possible production of a vaccine against E.coli. Hundred clinically healthy C.gariepinus of body weight 110-30 g were acclimated for 2weeks. 103, 104 and 105 cfu of E.coli were inoculated intraperitoneally into the test fish. Clinical signs and gross changes were observed throughout the experiment. Trend in bacteriological, hematological and plasma biochemical parameters were also observed using standard methods. Data generated were analysed using SAS package. The fish became lethargic and disoriented in swimming in the first 24hours. No significant differences were observed in PCV, Hb, RBC, platelet, lymphocyte, neutrophils, eosinopahils, total protein and albumin at 48hours. Significantly high WBC, globulin and monocyte counts were observed at 48hours in fish exposed to 105 cfu of E.coli. The significant increase at 48 and 96hours was observed in enzymes AST, ALT and ALP suggest liver damage. Significant decrease in WBC and platelet counts at 96 and 168hours suggests immune response to E.coli. At 36hours, further decrease was observed in platelet compared to the control. PCV and Hb dropped significantly from 168hours to 504hours but the reverse ensued in globulin and ALP when compared to control. At 336hours, a significant decrease was observed in AST, ALT and ALP. E.coli counts in log10 cfu/g were 5.079(27hr), 4.4(216hr) and 2.372(control). Although total protein was not affected at acute and chronic exposure to E.coli, the general physiology of the fish was adversely affected even at 105, this implies that C.gariepinus has a strong immune response which should be further investigated.

**1083 US EPA ECOLOGICAL STRUCTURE-ACTIVITY RELATIONSHIP (ECOSAR) MODEL—VERSION 1.1 RELEASE.**

The US EPA Office of Pollution Prevention and Toxics (OPPT) is responsible for implementing the Toxic Substances Control Act (TSCA). TSCA is the US law that regulates industrial chemicals in the US and OPPT evaluates both new chemicals entering commerce, as well as those chemicals that have been in existence for some time. In evaluating new and existing chemicals over the past 35+ years, OPPT has developed a strong knowledge base in structure-activity-relationships (SARs). The Ecological Structure Activity Relationships (ECOSAR) Class Program is a computerized predictive system that estimates aquatic toxicity. The program estimates a chemical’s acute (short-term) toxicity and chronic (long-term or delayed) toxicity to aquatic organisms based on their structural similarity to chemicals for which aquatic studies are available. Equations are available for fish, invertebrates and aquatic plants along with some terrestrial and marine organisms, where data were available. This poster highlights the new features of the ECOSAR v1.1 model which was released in September 2011 and is posted on the EPA website for free download. The new model includes expanded datasets, an enhanced user interface, and now contains ECOSAR class definition documents describing the boundaries of the class and training set chemicals which was previously not available. Through publication of the ECOSAR model, the US EPA provides public access to the same methods the EPA uses for evaluating aquatic toxicity of new industrial chemicals. These tools can be used by the public to prescreen new substances for environmental impacts and to inform R&D decision making. It can also be applied to prioritize existing chemicals for further testing to focus testing or identify greener alternatives. Disclaimer: This abstract represents the views of the authors and not necessarily the official position of the US EPA.
Anisakiasis is a zoonotic disease caused by parasites in fish provoked by larval stages of nematodes of the genus Anisakis, those can be present in people living in countries where fish is consumed raw or undercooked. Mugil inciliis was collected in the Bay of Cartagena, Colombia to investigate the possible influence of organochlorine pesticides in the histological changes of the liver, the spleen and existence of parasites in fish. The presence of organochlorine compounds were determined using the technique of headspace-solid phase microextraction (HS-SPME), showing amounts of organochlorine compounds in the muscle of M. inciliis as are the β-BHC, γ-BHC, heptachlor, aldrin, endosulfan, 4-, 4′-DDE and dieldrin, among others, indicating that the fauna of the Bay of Cartagena is exposed to these pollutants. Samples of liver and spleen were fixed, processed and embedded in paraffin. The most important changes in the liver and spleen were the presence of melanomacrophages and granulomas. Some morphological damage in the liver of M. inciliis was associated with the bioaccumulation of organochlorine compounds. Parasite abundance was discriminated as Anisakis sp (1.6%), Pseudoterranova sp (25.3%), and Contracaecum sp., (57.8%). Were found other parasites such as nematodes (15.3%) of genus Ascarocephly longa. There was no significant correlation between parasites and organochlorines. This study is the first in to correlate the presence of organochlorine compounds and histological damage in liver, spleen and the presence of parasites in fish from the Bay of Cartagena, Bolivar, Colombia.

Aryl hydrocarbon receptor (AhR) plays a profound role in the induction of cytochrome P450 1A (CYP1A) and dioxin toxicity. Our previous studies detected a significant positive correlation between accumulated levels of dioxins and related compounds (DRCs) with CYP1A expression levels in the liver of common cormorants (Phalacrocorax carbo) from Lake Biwa, Japan. This suggests that cormorant is activated by the accumulation of DRCs. Since legal and ethical concerns preclude the direct testing of DRCs in wild animals, the risk of DRCs has not been well assessed in wild populations. We have cloned two AhRs from the common cormorant (ccAhR1 and ccAhR2). To evaluate the species-specific responses to DRCs in cormorant, this study investigated the transactivation potencies of ccAhR1 and ccAhR2 by graded concentrations of individual DRCs including polychlorinated dibenzo-p-dioxins (PCDDs), furans (PCDFs) and coplanar PCBs (Co-PCBs) in C57-7 cels, where ccAhR1 or AhR expression plasmid and a luciferase reporter plasmid containing cormorant CYP1A3 promoter/enhancer were transiently transfected. For the congeners that exhibited ccAhR-mediated dose-dependent activities, 50% effective concentrations (EC50s) and 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (TCDD) relative potencies were estimated. Based on the REPs, TCDD induction equivalency factors were determined. Results suggested that ccAhR1 has more transactivation efficacies for most of the tested DRC congeners than ccAhR2. Cormorant IEFs obtained from this study showed that TCDD may not be the most potent congener for ccAhR1 and ccAhR2. According to the TCDD-EC50 obtained, ccAhR1 seems to be less sensitive to TCDD than AhR of other avian species. This study suggests that our in vitro approach may be a useful alternative to wildlife testing in toxicological researches.

Environmental estrogens (EEs) are chemicals in the environment that can elicit adverse effects on estrogen (E2) signaling through binding with the estrogen receptors (ERs). In largemouth bass (LMB), the physiological actions of E2 are primarily mediated via three receptors (ERα, ERβ, and ERβ). First we used binding and transfection assays to test the ability of the LMB ERs to bind and respond to 4,4′-[(4-hydroxyphenyl)-propionitrile (DPN), a mammalian ERβ-specific agonist, 2,3-bis(4-hydroxyphenyl)-propionitrile (DPR), a mammalian ERβ-specific agonist, bisphenol A (BPA), pp′-DDE, and dieldrin (model EEs). Our data shows that PPT and DPN were not isoform-specific agonists for the LMB ERs. E2 binds and activates the LMB ERs similarly, whereas differences were observed in the binding and activation of the receptors by the xenoestrogens. In the binding assay, dieldrin was not able to fully displace E2 from ERβ, and in the transfection
assays it acted as a weak partial agonist of the LMB ERβ, and a full agonist of ERα. Second, we determined the effects of the ERα on ERβ-regulated LMB gene expression using an in vitro liver slice assay. Liver slices from male LMB were exposed for 48 h to E2 (0-1 μM), pp'-DDE (0-100 μM), BPA (0-100 μM) and dieldrin (0-100 μM). Induction of ERα, vitellogenin (VTG) and zona radiata proteins (ZRP) mRNA were used as biomarkers of exposure to E2. A significant induction of VTG, ERα and ZRP was observed with exposure to E2, pp'-DDE and BPA. Dieldrin did not up-regulate ERα, VTG or ZRP mRNA. Moreover, two month dietary exposure of male LMB to 2.8 mg/kg body weight dieldrin appeared to inhibit the E2-mediated induction of ERα, VTG and ZRP mRNA by E2, pp'-DDE and BPA in liver slices.

Taken together, these in vitro assays can be useful tools to screen the relative potency and efficacy of E2s for fish receptors, as well as effects on ER regulated genes. This research may not reflect EPA Policy.

1089 DIPHALLIA IN PLOCOPURPURA PANSÁ (MOLLUSCA: NEOGASTROPOD) FEMALES EXPOSED TO TRIBUTYRL CHLORIDE.

D. Dominguez1, J. Medina Díaz, A. Patrón Soberano2, A. Rojas García1, J. Nieto Navarro1, V. Jesús Bernardino and M. Robledó Marconcón1, 1Laboratorio de Contaminación y Toxicología Ambiental, Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico, 2Instituto de Fisiología de la Unam, Universidad Nacional Autónoma de México, DF; DF; Mexico and 3Escuela Nacional de Ingeniería Pesquera, Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico.

Imposex is characterized by the development of male features, such as the penis and vas deferens, in female prosobranch gastropods and could be caused by organotin compounds. In this study, we experimentally tested the potential to induce imposex by tributylchloride (TBTCl) on Plcopurpura panza. Twenty females with similar size, without imposex, were collected from Olas Altas, Sinaloa, Mexico and were divided in two groups: one group was treated with TBTCl (10 μg Sn/L), and the other was used as a control. Each group was kept in 8-L glass beakers with artificial sea water for eight months and was fed every three days with squid bits. Organisms were searched monthly for imposex using stereomicroscopy. Among the exposed females, three presented imposex after two months: two developed a 1-mm long pseudopenis and the other showed three small warts (0.1 mm). Three months later, the pseudopenis of one imposexed female showed a spiral form, similarly to male pseudopenis and the other showed three small warts (0.1 mm). Three months later, males, three presented imposex after two months: two developed a 1-mm long pseudopenis and the other showed three small warts (0.1 mm). Three months later, males, three presented imposex after two months: two developed a 1-mm long pseudopenis and the other showed three small warts (0.1 mm).

1090 EFFECTS OF PARENTAL AND DIRECT METHYLMERCURY EXPOSURE ON FLIGHT ACTIVITY IN YOUNG HOMING PIGEONS (COLUMBA LIVIA).

J. K. Moye, C. R. Perez and C. Prisos, Agriculture, Nutrition and Veterinary Sciences, University of Nevada, Reno, NV.

Mercury is one of the most common metals found in contaminated ecosystems. It occurs naturally, but high levels found in contaminated areas derive from human use practices. Among the most vulnerable species to exposure are birds that live, nest, or feed in or near these contaminated ecosystems. Conventional avian toxicology models have shown impairment of cognitive skills from exposure to levels higher than those generally considered environmentally relevant, but little work has been conducted on low-level exposure effects. Because of the known neurological effects of mercury on birds, it is hypothesized that effects upon migratory ability would be evident after exposure to low levels of this metal, and effects may be exacerbated in young birds. Difficulties in following mercury exposed birds once they migrate away from contaminated areas have left investigators with insufficient data to establish exposure levels causing injury of migratory species due to migration disruption. With the understanding that compromised flying efficiency and migratory orientation may lead to negative effects on migratory bird species, homing pigeons (Columba livia) were chosen as the test species. Breeding pigeons were exposed to -1.0 mg/kg/day methylmercury via the drinking water, and first round offspring were trained to home after fledging, while also continually exposed to methylmercury. The young pigeons were released individually for three flights, and flight times were assessed and compared to control young pigeon flight times from 3.5, 9, 21, 53, 65, and 98 air miles as well as two individual flights at 50 air miles from multiple directions. Results indicate that methylmercury exposed birds exhibit slower flight times than controls during the initial flight, and generally improve on successive flights at each distance and direction. This may suggest orientation impairment and allude to migration disruption in migratory species. These studies were funded in part by USGS and the Nevada Agricultural Experiment Station.

1091 EFFECT OF DEEP HORIZON LIGHT CRUDE OIL EMULSION WITH AND WITHOUT THE DISPERANT, COREXIT, ON EARLY FISH DEVELOPMENT.

K. Kleinow1, A. Buí2, L. Thibodeaux2, R. Xiao1, A. Penn1 and S. Fritz - Kleinow1, 1Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA and 2Chemical Engineering, Louisiana State University, Baton Rouge, LA.

Louisiana light crude oil released into the Gulf of Mexico by the Deep Horizon (DH) incident underwent significant alterations by remediation attempts and weathering processes before reaching coastal marshes. These studies examined the effect of DH oil emulsions and Corexit dispersant concentrations alone and in combination upon development of fish embryos. Corexit alone at 0.0, 0.3, 3.0 and 100.0 mg/L did not alter the incidence of abnormalities or death in zebrasfish (ZF) embryos exposed through 8 days of development (near completion of organogenesis). Direct contact exposure of ZF embryos to DH emulsions “buttered” on a contact surface of 16cm2 (250mg) resulted in a high incidence of edema/axial deformities and subsequent mortality (40-90%) over a range of Corexit concentrations of 0.0, 3.0 and 100mg/L. Only the 100 mg/L Corexit treatment with emulsion resulted in a synergistic effect. Non-contact water exposures to emulsion (250 mg) resulted in axial changes alone and mortalities < 10% throughout the 0.0 to 100 mg/L. Corexit concentration range. Emulsion exposures of ZF during different developmental intervals indicate that early exposure (0-48hrs) is more inclined to affect genes involved in neurological system processes, visual perception, and response to abiotic stimuli while late exposure (48-96hrs) triggered genes associated with responses to a stimulus, especially a chemical stimulus. Exposure and development data suggest that an emulsified light crude effectively presents hazardous compounds to fish embryos under direct exposure conditions present in coastal marshes. Corexit had little effect on the developmental toxicity of oil emulsions except at the highest concentrations.

1092 RELATIONSHIPS BETWEEN CYTOCHROME P450 ACTIVITY AND EXPRESSION AND ALLELOCHEMICAL TOXICITY IN BUTTERFLYFISH (CHAETODON SPP.) OF DIFFERING FEEDING STRATEGIES.

A. Maldonado1, R. Lavado1, D. Schlenk1, S. Knutson2, G. Ostrander3, M. Starr1 and S. Ankeniy3, 1Environmental Sciences, University of California Riverside, Riverside, CA, 2University of Hawai‘i, Honolulu, HI and 3University of Mississippi, University, MS.

Cytochrome P450 monoxygenase (CYP) is the primary enzyme system for detoxification of xenobiotics including dietary chemicals and pollutants. Some herbivorous rious insects have the ability to detoxify toxic dietary chemicals by specific CYP forms. While thorough research has uncovered certain relationships between herbivorous insects and dietary chemicals, little is known about biotransformation and detoxification of allelochemicals derived from dietary products in marine organisms. Certain species of butterflyfish of the genus Chaetodon have been shown to feed on several species of chemically-defended corals including the soft coral Sinularia. This study examined the effects of the natural product, 5-episulupelidol (SE5) on the expression and catalytic activities of CYP3A, CYP2 in two butterflyfish species one of which is an obligate coral feeder and a generalist feeder that can feed on coral. Fish were gavaged 1.0 mg/kg and 3.0 mg/kg of SE5. Initial mortality indicated that C. multicinctus (obligate hard coral feeder), had 100% mortality in both doses. In contrast, 80% survival was observed in C. auriga (generalist feeder). Testosterone hydroxylase (TOH) (6 beta, 16 alpha, 16 beta) was 130-740 times lower in C. multicinctus relative to C. auriga. These results indicate an association between CYP2 (16-alpha TOH) and CYP3A (6 beta, 16 beta TOH) catalytic activities and detoxification of SE5 in butterflyfish with different feeding strategies which may provide a selective advantage in allowing generalists to feed on chemically defensed prey.

1093 HISTOPATHOLOGY AND GENOTOXICITY STUDIES IN Iguana iguana FROM A COAL MINING AREA IN COLOMBIA.

Colombia is the second largest coal exporter in Latin America. However, coal mining is threatening local ecosystems. Iguana iguana, known as iguana, is a common reptile in tropical areas and little is known about the effects of this activity on this species. The aim of this work was to describe histopathological lesions and to eval-
ulate the potential genotoxic damage in iguanas collected in La Loma, an important coal mine in the Department of Cesar, Colombia, comparing these results with those obtained for specimens captured in a natural reserve. Ten specimens from the coal mining area and eleven from the control site were euthanized and blood and tissue samples removed. The liver of iguanas from the control area presented normal characteristics, with some pigment laden macrophages. The presence of this pigment, possibly melanin, was greater in animals from the exposed area. Spleens from reference iguanas did not register tissue alterations, whereas samples from La Loma showed larger dense white pulp areas, several lymph follicles and extensive zones of B lymphocyte production, perhaps in response to foreign antigens or as an effect related to potential immunotoxicity. Regarding genotoxicity, the alkaline comet assay performed on whole blood cells evidenced that animals living near coal mines had greater percentages of DNA damage than those from reference sites. This was also shown by a significant increase in the number of nuclear buds in exposed iguanas. In summary, iguanas residing around coal production zones present greater risk of histopathological lesions in both the liver and spleen, as well as DNA damage in blood cells. Moreover, this species showed to be sensitive and useful to investigate the potential genotoxic damage in individuals. T en specimens from the Department of Cesar, Colombia, comparing these results with those obtained for specimens captured in a natural reserve. T en specimens from thirteen species were captured in marshes along the Dique Channel, a freshwater ecosystem in Colombia. A sample of 890 fish was obtained, of which 708 were analyzed for genotoxicity. In the present study, the effects of chronic exposure of AA on digestive organs including pancreas were evaluated in golden hamsters. A total of 90 female and 90 male hamsters were divided into three groups each, treated with AA at 0.06 mg/kg BW DON or 15ADON. After the absorption immediately. However, the bioavailability and emesis toxicity of these ADONs are still unknown. Acrylamide (AA) has been reported to show carcinogenicity in rats and mice, of which targets are various organs. On the other hand, a review and meta-analysis of epidemiologic studies concluded that there is no increased risk for common type of cancer from exposure to AA, but high occupational exposure showed relatively higher values of pooled relative risks for pancreatic and kidney cancers. Among rodents, certain kinds of chemicals have been demonstrated to induce pancreatic acinar cell tumors but not ductal ones in rats, and Syrian golden hamsters are sensitive to ductal carcinogenesis with N-nitrosobis(2-oxopropyl)amine. In the present study effects of chronic exposure of AA on digestive organs including pancreas were evaluated in golden hamsters. Trichothecene mycotoxin deoxynivalenol (DON) is a toxic secondary metabolite produced by Fusarium fungi in agricultural crops. In addition, acetylated derivative of DON, such as 3 and 15-acetyldeoxynivalenol (3ADON and 15ADON), are evaluated to have equivalent toxicity to DON because these ADONs convert to DON after absorption immediately. However, the bioavailability and emesis toxicity of these ADONs are still unknown. In this study, we compared the bioavailability and emesis toxicity between DON, 3ADON and 15ADON by oral administration test using pigs and the house musk shrew (Suncus murinus (SUR-Heris)). The pigs (10.7 ± 2.4 kg, male) were divided into a control group and mycotoxins (3 ADON, 15ADON or DON) feeding groups. The oral administration tests achieved with the diets containing 0.06 mg/kg BW DON or 15ADON. After the administration, pig serum was collected at 0, 5, 10, 20, 30 min and 1, 2, 3, 4, 8 hr. Then these sera were measured by LC/MS/MS. In ADONs feeding group, ADONs were not detected from all samples, suggesting that ADONs would be converted to DON in serum. However, Maximum drug concentration time...
The trichothecene mycotoxin deoxynivalenol (DON) is well known to cause food refusal in experimental animals. However, the relative anorexic potencies of structurally related 8-keto-trichothecene are not known. A simple food refusal bioassay employing the mouse was used to compare the effects of 8-keto-trichothecene following by oral and intraperitoneal (ip) exposure. The results suggested that, similar to DON, the anorexic effects of 3-acetyldeoxynivalenol (3-ADON) and 15-acetyldeoxynivalenol (15-ADON) were transient (lasting only a few hours) and food intake recovered within 16 h. In contrast, the food refusal responses to nivalenol (NIV) and fusarenon X (FX) were markedly different, persisting from 36 to 96 h depending on administration route. For both ADONs, the no observed adverse effect levels (NOAEL) and lowest observed adverse effect levels (LOAEL) were 0.5 and 1 mg/kg bw for ip, respectively, and 1 and 2.5 mg/kg bw for oral, respectively. The NOAEL and LOAEL for FX were 0.025 and 0.25 mg/kg bw, respectively, for both ip and oral exposure. The NOAEL and LOAEL for NIV were 0.01 and 0.1 mg/kg bw, respectively, for ip and 0.1 and 1, respectively, for oral exposure. To summarize, the anorexic effects of 8-keto-trichothecene followed the rank order NIV>FX>DON=15-ADON=3-ADON, based on the NOAEL and LOAEL, with FX effects being greater when administered ip as compared to oral exposure. 3-ADON and 15-ADON caused acute anorexia, similar to DON, whereas, the anorexic effects being greater when administered ip as compared to oral exposure. The trichothecene mycotoxin deoxynivalenol (DON) is well known to cause food refusal in experimental animals. However, the relative anorexic potencies of structurally related 8-keto-trichothecene are not known. A simple food refusal bioassay employing the mouse was used to compare the effects of 8-keto-trichothecene following by oral and intraperitoneal (ip) exposure. The results suggested that, similar to DON, the anorexic effects of 3-acetyldeoxynivalenol (3-ADON) and 15-acetyldeoxynivalenol (15-ADON) were transient (lasting only a few hours) and food intake recovered within 16 h. In contrast, the food refusal responses to nivalenol (NIV) and fusarenon X (FX) were markedly different, persisting from 36 to 96 h depending on administration route. For both ADONs, the no observed adverse effect levels (NOAEL) and lowest observed adverse effect levels (LOAEL) were 0.5 and 1 mg/kg bw for ip, respectively, and 1 and 2.5 mg/kg bw for oral, respectively. The NOAEL and LOAEL for FX were 0.025 and 0.25 mg/kg bw, respectively, for both ip and oral exposure. The NOAEL and LOAEL for NIV were 0.01 and 0.1 mg/kg bw, respectively, for ip and 0.1 and 1, respectively, for oral exposure. To summarize, the anorexic effects of 8-keto-trichothecene followed the rank order NIV>FX>DON=15-ADON=3-ADON, based on the NOAEL and LOAEL, with FX effects being greater when administered ip as compared to oral exposure. 3-ADON and 15-ADON caused acute anorexia, similar to DON, whereas, the anorexic effects of NIV and FX were more persistent.
1102 HEXABROMOCYCLODECANE (HBCD) STEREOSISOMERS IN US FOOD AND ADULT DAILY DIETARY INTAKE.

I. S. Birnbaum, A. Schecter, D. T. Szabo, I. A. Colacoine, T. Gent, N. Bass, O. Papke, L. S. Hyman, T. R. Harris and S. Maia. *National Cancer Institute, Research Triangle Park, NC, *University of Texas Southwestern Medical Center, Dallas, TX. 1US EPA, National Center for Environmental Assessments, Arlington, VA, 2Eurofins Gfa, Hamburg, Germany, 3University of Michigan School of Public Health, Ann Arbor, MI and 4Statistics Section, University of Texas Southwestern Medical Center, Dallas, TX.

Hexabromocyclododecane (HBCD) is a brominated flame retardant mixture used in polystyrene foams and as a replacement for Decabromodiphenyl ether. The commercial mixture has 3 major stereoisomers - α (~10%), β (~10%), and γ (~80%). HBCD exposure is associated with effects in animal and human studies. Food ingestion, especially of meat and fish, is a major route of exposure. This study was designed to measure HBCD stereoisomer levels in US food and estimate US HBCD daily intake. We previously measured total HBCD levels in 36 pooled food samples using high-resolution gas chromatography/low resolution mass spectrometry. Ten of these pools as well as 36 individual food samples were analyzed for HBCD stereoisomers using liquid chromatography tandem mass spectrometry. α-HBCD was detected in 13/36 new foods and all of the original pools; γ-HBCD in all 10 original pools but only 8/36 new foods; and β-HBCD was in 8/10 pools and 3/36 individual foods. Median levels for α-β- and γ-HBCD were 115, 16, and 59 pg/g ww, respectively. US Adult dietary intake of all 3 HBCD stereoisomers measured in these studies was estimated to be approximately 14 ng/day, primarily from meat consumption. Total HBCD levels are similar to those reported from European countries, and also show the stereisomeristic shift from γ- to α-HBCD. Further research is indicated to determine HBCD stereoisomer levels and daily intake from a larger and more representative sample of US food. (This abstract does not reflect NIH policy).

1103 LC-MS/MS DETERMINATION AND OCCURRENCE OF FUSARIUM MYCOTOXINS ENNATINAT, BEAUVERICIN AND FUSAPROLIFERIN IN PASTA.

E. Ferrer, B. Houda, A. B. Serrano and G. Font, Preventive Medicine, University of Valencia, Burjasot, Valencia, Spain.

Mycotoxins are toxic secondary metabolites produced by filamentous fungi, mainly Aspergillus, Penicillium and Fusarium species under appropriate environmental conditions. In the last years, the called emerging Fusarium mycotoxins were acquired importance, since their severe toxic effects on animal and human health, as enzymatic inhibition, cytotoxicity and teratogenicity. In this work, a new, rapid, sensitive, reproducible and reliable method for the determination of the emerging mycotoxins: Enniatins ENs (EN A, EN A1, EN B and EN B1), beauvericin (BEA) and fusaproliferin (FUS) by liquid chromatography-triple quadrupole-tandem mass spectrometry and their occurrence in pasta samples has been developed. Besides, three extraction techniques have been studied: Ultra-Turrax, ultrasonic and microwave and the time, temperature and the extraction solvent have been optimized. The best results were for Ultra-Turrax extraction with 3 minutes of acetone-trile. The chromatographic determination has been performed in reverse phase with C18 column, and acetone/methanol (20:80 ammnium formate) mobile phase. The recoveries ranged from 86-112%, with relative standard deviation lower than 15%; Limits of detection were lower and ranged from 0.02-0.15 μg/kg. In addition, application to the analysis of 73 organic and non organic pasta samples purchased from Spanish and Italian supermarkets and risk assessment associated to daily intake were studied. The results obtained showed that the 84% of the samples were contaminated and the incidence of BEA, EN A, EN A1, EN B, EN B1 and FUS was 23, 49, 50, 74 and 23% respectively. The higher incidence and concentrations were obtained in organic pasta samples. Acknowledgments: This study was financially supported by the projects AGL2010/17024/ALI (Science and Innovation Spanish Ministry) and PLAT/2009-012 (Valencian Government, Spain).

1104 ASSESSMENT OF THE SURFACE STABILITY AND AFLATOXIN SorPTION CAPACITY OF MONTMORILLONITE CLAY FOLLOWING FERMENTATION AND HEAT TREATMENT.

S. E. Elmore, N. J. Mitchell, A. Marroquin-Cardona, K. Brown, T. Mays, K. Zychowski and T. D. Phillips, Veterinary Integrative Biocience, Texas A&M University, College Station, TX.

Aflatoxin B1 (AFB1), is commonly found as a contaminant of crops such as maize and has caused concern for food safety and public health. This mycotoxin is listed as a Group 1 carcinogenic by the International Agency for Research on Cancer and may act synergistically when consumed with other contaminants, e.g., fumonisin B1 (FB1). Uniform Particle Size NovaSil (UPSN) clay, calcium montmorillonite, has been shown to bind AFB1, in both in vitro and in vivo studies, thus reducing its bioavailability. During a previous intervention trial in Ghana, UPSN was added to common Ghanaian dishes including Koko, maize porridge that is both fermented and boiled, as a strategy to reduce AFB1, and FB1, exposure in people. Our objective was to evaluate the stability of UPSN during the processing and preparation of Koko as demonstrated by its ability to sorb AFB1, prior to ingestion. Portions (50g) of maize meal were spiked with AFB1, in triplicate, at concentrations ranging from 5 to 1000 ppb with and without UPSN additive and were then used to prepare Koko. Extractions of AFB1, followed a modified procedure based on the USDA- FGIS Single Filtration Procedure for Corn using All assays immunofluorometric assays followed by fluorescence detection (Series 4 VICAM Fluorometer). UPSN significantly bound AFB1, with less than 10% recovered from samples containing the clay, while there was greater than 85% recovery in samples without clay demonstrating that UPSN was able to reduce AFB1, levels by more than 75%. These results confirm our recent cross-over study in Ghana and suggest that UPSN clay-AFB1 complex are stable under cooking and food preparation conditions. Importantly, this work confirms that UPSN can be used as a food additive to reduce exposure to AFB1, in populations at risk for aflatoxicosis and hepatocellular carcinoma. This research was supported by USAID LAG-G-00-96-90013-00 and NIH RO1MD005819-01.

1105 EVIDENCE FOR FUMONISIN INHIBITION OF CERAMIDE SYNTHASE IN HUMANS.

R. T. Riley1, J. L. Showker1, K. A. Voss1, J. Gelineau van Waed2, J. R. Maddox3, S. G. Gregory4, A. E. Ashley-Koch5 and O. Torres de Matute5, 6USDA-ARS, Athens, GA, 7Creighton University School of Medicine, Omaha, NE, 8Duke University Medical Center, Durham, NC and 9Centro de Investigaciones en Nutricion y Salud, Guatemala City, Guatemala.

Fumonisins are mycotoxins found in corn worldwide. Fumonisin B1 is the most common of the fumonisins. It is the cause of several farm animal diseases and is carcinogenic in rodents. Fumonisin B1 is poorly absorbed and is excerted primarily in feces and small amounts can be detected in urine. The mode of action is the inhibition of ceramide synthase a key enzyme in the biosynthesis of sphingolipids. Inhibition of ceramide synthase causes an accumulation of sphingoid bases and sphingoid base 1-phosphates in tissues and blood. In mice gavaged with fumonisin B1, sphinganine 1-phosphate (Sa1P) accumulates in red blood cells in a dose-dependent manner and there is an increase in the ratio of Sa1P:Sphingosine-1-phosphate (So1P). The purpose of the present IRB approved study was to determine the relationship between fumonisin B1 in the urine and the Sa1P/So1P ratio in blood spots collected from women living in communities consuming large amounts of corn potentially contaminated with fumonisin B1. In the human study approximately 640 urine and blood spot samples were collected and analyzed from three locations in rural Guatemala (Chimaltenango, Escuintla and Jutiapa) in March and June of 2011. Corn samples (n=57) from the same locations have been analyzed for fumonisins. The level of fumonisin in corn collected from local markets was significantly higher in Chimaltenango and Escuintla than Jutiapa. The urinary fumonisin B1 and the Sa1P/So1P ratio were also significantly higher in Jutiapa compared to Chimaltenango or Escuintla. The preliminary results show that fumonisin B1 in urine is significantly correlated with the increase in the Sa1P/So1P ratio in the blood spots. These results are consistent with the conclusion that fumonisin B1 disrupts sphingolipid metabolism in humans consuming large amounts of fumonisin B1 contaminated corn. Research supported by NIH grant # 1 RC4 HD067971-01.

1106 AGE AND GENDER ARE SUSCEPTIBILITY FACTORS IN DEOXYNIVALENOL-INDUCED ANOREXIA.

E. S. Clark1,2, B. M. Flannery1,2 and J. J. Pestka1,2,1, Food Science and Human Nutrition, Michigan State University, East Lansing, MI, *Center for Integrative Toxicology, Michigan State University, East Lansing, MI and 1Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI.

Deoxynivalenol(DON, vomitoxin), a trichothece mycotoxin, is a common cereal grain contaminant that is resistant to processing and can enter human and animal food. Regulatory standards have been established for DON based on its capacity to cause anorexia and suppress growth in the mouse. The aim of this study was to test the hypothesis that age and gender will affect the susceptability of mice to DON-induced feed refusal. Here we employed a mouse anorexia bioassay previously described by our lab to compare the effects of DON exposure to 1), weanling males (3 wk) vs adult males (4wk), 2) adult males (11 wk) for elderly male (22 months) and 3) adult females (11 wk) vs adult males (11 wk). Briefly, mice were acutely exposed to 0, 1 and 5 mg/kg bw via IP injection and food intake was monitored 36 h later.
post exposure to the toxin. Elderly mice were extremely sensitive to DON as evi-denced by a markedly lower food intake and significantly lower body weight gain of adults compared to those of adult and elderly males. Adult female mice were the least sensitive to DON exposure at recovery after doses. These data suggest the following rank order of susceptibility to DON-induced anorexia: elderly males > adult males > weanling males > adult females. This indicates age and gender might be important factors to consider when conducting risk assessments for DON and other trichothecenes.

1109 CONSUMPTION OF FOLATE DEFICIENT DIET DID NOT INCREASE NEURAL TUBE DEFECTS IN LM/Bc MICE EXPOSED TO FUMONISIN B₁
K. A. Voss¹, R. T. Riley¹ and B. Gelincus-van Waes². ¹Toxicology & Mycotoxin Research Unit, USDA, ARS, Athens, GA and ²Department of Pharmacology, Creighton University School of Medicine, Omaha, NE.

Fumonisins B₁ (FB₁), a mycotoxin produced by Fusarium verticillioides and F. proliferatum. It is found in corn and evidence suggests it is a possible risk factor for neural tube defects (NTD) in populations consuming large amounts of contami-nated corn-based foods. The mechanism(s) underlying NTD induction by FB₁ in the sensitive LM/Bc mouse is not well characterised. The purpose of this study was to compare the folate status and neural tube defect (NTD) incidence in LM/Bc mice fed moderate and high levels of folate as a part of the general toxicology study performed at Creighton University. The folate deficient diet is known to increase NTD incidence. The study was conducted to determine if the moderate level of dietary folate in the LM/Bc diet could reduce the NTD incidence.

1110 SAFETY ASSESSMENT OF AGARICUS SUBRUFESCENS SP AND THEIR PRODUCTS OF THERAPEUTIC INTEREST OR FOR DISEASE PREVENTION.
F. E. Creppy¹, S. Moukhel¹ and C. Ferandon¹. ¹Toxicology, University Bordeaux 2, Bordeaux, France and ²MycoSa, INRA, Villenave d’Ornon, France.

Agaricus subrufescens is a mushroom native to Brazil and France. It is found in corn and evidence suggests it is a possible risk factor for neural tube defects (NTD) in populations consuming large amounts of contaminated corn-based foods. The mechanism(s) underlying NTD induction by FB₁ in the sensitive LM/Bc mouse is not well characterised. The purpose of this study was to compare the folate status and neural tube defect (NTD) incidence in LM/Bc mice fed moderate and high levels of folate as a part of the general toxicology study performed at Creighton University. The folate deficient diet is known to increase NTD incidence. The study was conducted to determine if the moderate level of dietary folate in the LM/Bc diet could reduce the NTD incidence.

R,Monatin is a naturally occurring substance identified in Sclerochitin ilicifolius, a plant native to South Africa. To contribute data relevant to evaluation of the safety of R,Monatin salt during gestation days 6-21. The fetuses were examined for external, visceral, and skeletal malformations and variations. There were no fetal malformations or developmental variations that were attributable to R,Monatin salt at any exposure level, nor were there any test article-related effects on intrauterine survival. Maternal toxicity, as evidenced by lower maternal body weights, body weight gain, and food efficiency, was observed at 50,000 ppm. A developmental effect, in the form of lower mean fetal body weight, was noted in the 50,000 ppm group in the presence of maternal toxicity. Therefore, based on the results of this study, the no-observed-adverse-effect level (NOAEL) for maternal and embryo-fetal toxicity in Sprague Dawley rats resulting from dietary exposure to R,Monatin salt during gestation days 6-21 was 30,000 ppm (approximately 2,564 mg/kg bw/day) based on reductions in maternal and fetal body weights.

1111 SAFETY ASSESSMENT OF GENETICALLY MODIFIED, HERBICIDE-TOLERANT CANOLA DP-073496-4: 13-WEEK DIETARY STUDY IN RATS.

A 90-day rat feeding study was conducted as part of the pre-market safety assessment of genetically-modified (GM), herbicide-tolerant canola DP-073496-4 (73496). Metabolic inactivation of the herbicidal active ingredient glyphosate is
conferring by genomic integration and expression of a gene-shuffled acetyltransferase coding sequence, from this study the gene was nutritionally comparable to PMI® Certiﬁed Rodent LabDiet® 5002 were formulated by total functional replacement (e.g., protein, ﬁber, and energy equivalency basis) of de-hulled (DH) soybean meal, hulls, and oil with meal and oil from DH canola seed from untreated (73/496) and herbicide-treated (73/496+Gly) plants, the non-transgenic near-isogenic control, and four non-transgenic commercial varieties. To evaluate the potential health effects from long-term consumption of 73/496 canola, the experimental diets were fed to young adult SD rats (12/sex/group) for at least 91 consecutive days. Compared with rats fed diets containing meal and oil from the near-isogenic control canola, no diet-related adverse effects were observed in rats fed diets containing meal and oil from 73/496 or 73/496+Gly canola with respect to standard nutritional performance metrics and OECD 408 parameters (body weight/gain, food consumption/efﬁciency, mortality, clinical signs of toxicity, ophthalmological observations, neurobehavioral assessments, organ weights, and clinical and anatomic pathology). No health hazards were identiﬁed. These results support the nutritional equivalence and comparative safety of meal and oil from DH canola seed from GM herbicide-tolerant 73/496 canola and conventional, non-transgenic canola.

1112 NEONATAL PIGLETS AS AN ANIMAL MODEL TO EVALUATE SAFETY OF NEW INGREDIENTS IN INFANT FORMULA.

R. A. Thorpe1, A. D. Aulbach2 and A. S. Fasi3. Developmental and Reproductive Toxicology, MPI Research, Mattawan, MI and 2Clinical Pathology, MPI Research, Mattawan, MI.

Although breast-feeding is recommended for the ﬁrst year of life, infant formulas constitute the majority of the diet for most American infants. Infant formulas consist of two major types: dairy-based using bovine milk protein and soy-based made from soy protein isolates. Preclinical studies are a vital ﬁrst step to assess the safety and quality of ingredients, which may be new to infant formulas. Neonatal piglets are used as an animal model to evaluate the safety of baby formula ingredients, because the physiology of digestion is similar to that in humans. In addition, piglets thrive in the laboratory environment without maternal support just days after birth, which provides a practical means for infant formula testing. In the present study one-day old domestic Yorkshire-Crossbred piglets were fed with either Purina ProNurse or VetOne multispecies milk replacers for 3 weeks, based on manufacturer’s recommended feeding regimens. Growth rate, clinical observations, and clinical pathology parameters were evaluated. On arrival, animals were acclimated to feeding bowls, which were supplied with liquid feed via a customized infusion system. They were offered formula each day, every hour, for 14 hours. At receipt, animals weighed approximately 2 kg and clinical signs were unreproducible among groups. Hematological parameters during the ﬁrst 3 weeks of life showed signiﬁcant differences when compared to adult pigs. Most notable were dramatic increases in reticulocytes, reticulocyte percentage, and mean cell volume (MCV) with moderate decreases in lymphocyte counts. Increased average red cell size (MCV) and reticulocyte values correspond to accelerated erythropoietic production observed in suckling piglets which generally subsides by 2 to 6 months of age. In conclusion, this piglet design, optimized for growth and tested with different milk replacement formulas, demonstrated important differences in the infant data as compared to adults and conﬁrmed the practical use of this animal model for infant formula testing.

1113 RESPONSES OF TILAPIA TO CONTAMINATED DIETS SUPPLEMENTED WITH NOVASIL.

K. Zychowski1, A. Peredo2, A. Buentello2, M. Hume2, D. Gatlin1, A. Marroquin-Cardona1, S. Elmore1, N. Mitchell1, K. Brown1, T. May2 and T. D. Phillips1. 1Veterinary Integrative Biosciences, Texas A&M University, College Station, TX, 2Soil and Crop Sciences Department, Texas A&M University, College Station, TX, 3United States Department of Agriculture, Southern Plains Agricultural Research Center, College Station, TX.

The aquaculture industry is one of the fastest-growing food sectors in the world. However, like all farm-raised animals, ﬁsh are susceptible to food-borne toxins, including afatoxin B1 (AFB1). AFB1 is a mycotoxin mainly produced by the fungus Aspergillus parasiticus, which is well known for its adsorption to other crops. The high percentage of plant-based material in the feed of warm-water species warrants further investigation of species sensitivity to AFB1. Rainbow trout (Oncorhyncus mykiss) have been shown to be one of the most sensitive species to AFB1, developing tumors when exposed to levels as low as 0.4 ppm. Nile tilapia, Oreochromis niloticus, is a popular warm-water species known for their high resistance to disease. However, tilapia have susceptibility to AFB1 and demonstrate a decrease in body weight when exposed to AFB1. Enterosorption therapy using natural clay, such as NovaSil (NS) is among the novel strategies to reduce exposure to afatoxins in both farm-raised animals and humans. The objective of this study was to evaluate the capacity of NS clay to remediate the toxic effects of a chronic exposure to AFB1 in tilapia. Several parameters were tested at the end of 10 weeks to determine the effects of AFB1 and NS. Weight gain and mortalities were determined on a weekly basis. 1% NS caused a 10.87% and 8.58% increase in total body weight gain when compared to the 1.5 ppm and 3.0 ppm AFB1-exposed groups. Lipoygenase concentration in the plasma, and oxidative radical production in neutrophils and macrophages were determined. NS-supplemented diets showed an increase in oxidative radical production from neutrophils in blood compared to the AFB1-exposed groups (Supported by CONACYT ID No. 2010-020 and NIH 1RO1MD005819-01).

1114 SAFETY OF CALCIUM AND SODIUM BENTONITE CLAYS AS ENTEROSORBENTS FOR AFTOXIN.

A. G. Marroquin-Cardona1, Y. Deng2, J. F. Garcia-Mazcorro3, N. M. Johnson4, N. T. Mitchell1, L. Tang5, J. Wang6 and T. D. Phillips1. 1Veterinary Integrative Biosciences, Texas A&M University, College Station, TX, 2Soil and Crop Sciences Department, Texas A&M University, College Station, TX, 3Gastrointestinal Laboratory, Texas A&M University, College Station, TX and 4Environmental Health Sciences Department, University of Georgia, Athens, GA.

Bentonites can potentially protect against afatoxiscosis. NovaSil (NS) clay has been shown to sorb afatoxins in the gastrointestinal tract and to diminish both their bioavailability and their adverse effects in multiple and different model systems. Similarly, Na-bentonite has been shown to reduce exposure to afatoxins in farm animals however concerns about its potential interactions with nutrients warrant further research. We investigated the afatoxin sorption capabilities and the physiologival effects of a Ca-bentonite (Uniform Particle Size NS, UPSN) and a Na-bentonite (NaB) on young Sprague-Dawley rats were fed ﬁctions free of clay (control) or containing either UPSN or NaB at 0.25% and 2% (w/w) for 13 weeks. Growth performance, serum and blood biochemical parameters were measured along with serum vitamins (A and E), iron and zinc. Both clays showed similar AFB1 sorption characteristics based on isothermal analysis. Feed conversion efﬁciency and ﬁnal body weights were unaffected in either sex at the doses tested. Neither UPSN nor NaB-dependent differences in relative organ weights or gross appearance were observed. In both sexes of NaB groups, serum Na and K ratios were increased. Serum K was decreased in males of UPSN and NaB groups. Serum Zn was reduced in the 2% UPSN group, while this reduction was observed at both inclusion rates of NaB. Serum vitamin A was reduced in both NaB groups when compared to control. Serum vitamin E was increased in males and females of UPSN and NaB groups. None of these differences were dose-dependent and parameters fell within the normal clinical ranges. These results suggest that dietary inclusion of UPSN and NaB does not result in overt toxicity. Research supported by USAID LAG-G-00-96-90013-00 and NIH 1RO1MD005819-01.

1115 ETHANOL PRODUCTION FROM FUMONISIN-CONTAMINATED MAIZE GRAIN.

E. Bilsten1 and G. Munkvold. Plant Pathology, Iowa State University, Ames, IA.

The use of mycotoxin-contaminated grain in ethanol production can have multiple implications, including initiating co-product quality, dried distiller’s grains and solubles (DDGS), a co-product of maize ethanol processing, are an important livestock feed component. Due to the conversion of mass to ethanol and carbon dioxide during fermentation, the quantity of DDGS obtained from maize ethanol processing is approximately one-third of the mass of the original grain. Therefore, the concentration of fumonisins (a class of mycotoxins produced primarily by Fusarium verticillioides) is typically higher in DDGS than in the original grain. This is a result of fumonisin heat stability and lack of volatility under fermentation conditions. Fumonisins have detrimental health effects in a variety of livestock and, for this reason, their concentration in DDGS is concerning. The accepted “rule of thumb” for mycotoxin concentration in DDGS is a 3x increase from the original grain. A combination of ELISA and HPLC analysis of NDA-derivatized fumonisins was performed over three years of field trials revealing strong correlations between ground grain fumonisin levels and levels found in resultant DDGS (R ≥ 0.80 for all trials). The same analyses showed fumonisin concentration in DDGS to be 2X, rather than the aforementioned 3X levels in the original grain. This suggests that fumonisins may undergo structural alteration or degradation during fermentation. Analyses of naturally infected grain with zero, low (<4 ppm), and high (>4 ppm) levels of fumonisin contamination showed a trend of decreased ethanol production with increasing levels of fumonisins in the fermentation broth (R ≥ 0.80). Fermentation of fumonisin-contaminated maize can result in negative impacts on process efﬁciency and on the quality and subsequent marketability of DDGS. Direct effects of fumonisins on yeast activity need to be carefully evaluated.
Boric acid (BA) is a dietary component found naturally in the environment. Low levels reduce the incidence and mortality of prostate cancer. Our studies have shown that low doses of BA significantly inhibit proliferation of DU145 prostate cancer cells. At similar doses we see inhibition of calcium release from the ryanodine receptor (RyR) in the endoplasmic reticulum (ER) in response to RyR agonists.Stored calcium in DU145 cells was reduced by 22% when treated with 10 μM BA for 1 hour. Altered cellular calcium homeostasis can lead to acute ER stress and, as a result, unfolded protein response (UPR) can be triggered due to unfolded or misfolded protein accumulation. In this project our objective is to identify if physiological levels of BA influence ER stress and UPR in DU145 cells. This research may be a key to understanding the mechanism by which BA slows the proliferation of these cells. Preliminary analysis of DU145 cells treated with BA indicates the presence of ER stress and activation of the UPR. Multiple genes, including calreticulin, HERP, and EDEM1, which are controlled by the ER stress response element I (ERSEI) and II (ERSEII) and the UPR response element (UPRE), respectively, are significantly upregulated with 10 μM BA treatment. The UPR is detected through analysis of the activation of the three UPR branches: PERK, ATF6, and IRE1.

Further research will include using western blot analysis, real time pcr, and immunofluorescence to study the activation and regulation of the plethora of proteins and genes involved in these UPR branches.

BASIC PHARMACOLOGY, University of California Los Angeles, Los Angeles, CA.

1116 BORIC ACID INDUCES ER STRESS IN DU145 PROSTATE Cancer CELLS.
S. Kobylewski1, K. Yamada1, K. Henderson1 and C. Eckhert1. 1Molecular Toxicology, University of California Los Angeles, Los Angeles, CA and 2Environmental Health Sciences, University of California Los Angeles, Los Angeles, CA.

Boric acid (BA) is a dietary component found naturally in the environment. Low levels reduce the incidence and mortality of prostate cancer. Our studies have shown that low doses of BA significantly inhibit proliferation of DU145 prostate cancer cells. At similar doses we see inhibition of calcium release from the ryanodine receptor (RyR) in the endoplasmic reticulum (ER) in response to RyR agonists. Stored calcium in DU145 cells was reduced by 22% when treated with 10 μM BA for 1 hour. Altered cellular calcium homeostasis can lead to acute ER stress and, as a result, unfolded protein response (UPR) can be triggered due to unfolded or misfolded protein accumulation. In this project our objective is to identify if physiological levels of BA influence ER stress and UPR in DU145 cells. This research may be a key to understanding the mechanism by which BA slows the proliferation of these cells. Preliminary analysis of DU145 cells treated with BA indicates the presence of ER stress and activation of the UPR. The UPR is detected through analysis of the activation of the three UPR branches: PERK, ATF6, and IRE1.

Further research will include using western blot analysis, real time pcr, and immunofluorescence to study the activation and regulation of the plethora of proteins and genes involved in these UPR branches.

1117 PROCAGULANT AND PROTHROMBOTIC EFFECTS OF HERBAL MEDICINE, DISPACUS ASPER ON HUMAN PLATELETS.

Despite the growing popularity of herbal medicines and food supplements, their adverse effects on cardiovascular homeostasis remain largely unknown, especially regarding their pro-thrombotic risks. Here, through screening of the extracts from 21 herbal teas widely consumed, we discovered that Dispacus asper (DA), previously known to have analgesic and anti-inflammatory efficacy may induce procoagulant activity in platelets, a critical promoter of thrombosis. Dispacus saponin C (DSC) was identified as the key active ingredient for DA-induced procoagulant activities through activity-guided purification. Washed platelets were separated from healthy male donors’ blood. Procoagulant activity was measured. Exposure of phosphatidylserine (PS), microparticle (MP) generation, phospholipid translocation and intracellular calcium were measured by flow cytometry. ATP levels were applied to luciferin/luciferase assay. Mitochondrial membrane potential (ΔΨm), Bax translocation, cytochrome c release and caspase-3 activity were measured. In vivo venous thrombosis model, SD rats were treated with DSC (10 and 25 mg/kg, i.v.). DSC- and DA-induced procoagulant activities were achieved by the exposure of PS and MP generation that were caused from the alteration in activities of scramblase and flippase. These events were initiated by increased intracellular calcium and ATP depletion. Notably, DSC induced a series of apoptotic events including the disruption of ΔΨm, mitochondrial translocation of Bax, cytochrome c release, and caspase-3 activation. Key roles of apoptosis and caspase activation were demonstrated by the reversal of DSC-induced PS exposure and procoagulant activities with the pretreatment of caspase inhibitors. These results were also confirmed in vivo where the rats exposed to DSC exhibited ΔΨm dissipation and PS exposure in platelets. Most importantly, DSC or DA treatment led to increased thrombus formation in rat venous thrombosis model, demonstrating that herbal medicines or natural products like DA or DSC might have prothrombotic risks through procoagulant activation.

1118 SAFETY AND TOXICOLOGICAL EVALUATION OF A NOVEL, WATER-SOLUBLE UNDENERATURED TYPE II COLLAGEN (NATUC-II™).
M. Baechi1, O. Yoshinari2, H. Moriyama2, Y. Shiojima3 and P. A. Marone4.
1RoEL, NutriToday LLC, Mississauga, ON, Canada, 2Stouss Pharmaceutical University, Tokyo, Japan, 3Ruiyende & Co, Tokyo, Japan and 4EuroNutri/Product Safety Labs, New Jersey, NJ.

The present study was conducted to examine the safety of a novel, water-soluble undenatured type II collagen (NATUC-II), derived from chicken sternum cartilage. The presence of epopeptide in NATUC-II was confirmed by using a commercial kit, Native Type Collagen Capture kit (Axarta Biologies, LLC (WA 98073-2308, USA)). The present study evaluated the broad-spectrum safety of NATUC-II using a variety of toxicological assays including acute oral, acute dermal, primary skin irritation, and primary eye irritation toxicity. Under the conditions of the study, the acute oral LD50 of NATUC-II was found to be greater than 5,000 mg/kg body weight in rats, while the single dose acute dermal LD50 of NATUC-II was greater than 2,000 mg/kg body weight. The primary dermal irritation index (PDII) of NATUC-II was found to 1.8 and classified as slightly irritating to the skin. In primary eye irritation studies, the maximum mean total score (MMTS) of AC was observed to be 7.3 and classified as minimally irritating to the eye. Furthermore, two experiments were conducted to assess the potential of NATUC-II (5000 mg/mL was selected as the highest concentration) to induce mutations with and without metabolic activation at the mouse lymphoma thymidine kinase locus using the cell line L5178Y. No biologically relevant increase of mutants was found after treatment with NATUC-II. Also, no dose response toxicity was observed. Furthermore, colony sizing showed no clastogenic effects induced by NATUC-II under the experimental conditions. These studies demonstrated the broad spectrum safety of NATUC-II. (This study was sponsored by Ryuendo Co., Ltd, 2-12-1 Minami-ike-bukuro, Toshima-ku, Tokyo 171-0022, Japan)

1119 REVAMPING THE LAB EXPERIENCE IN A TOXICOLOGY COURSE.
M. I. Pomeroy-Black. Biology, LeGrange College, LeGrange, GA.

As a junior professor, it is difficult to create and implement Toxicology course-related laboratory activities that require the students to think critically about an experiment. This is compounded when resources and funding are limited. Using student feedback, a professor can revamp the laboratory experience from “cookbook” to “inquiry.” Lab activities used the first time the course was taught were taken from various sources such as books and articles. At the end of the course students indicated that the lab experiences did not give them a sense of what a toxicologist does and none of them seemed inclined to pursue graduate school. Improving students’ feedback and perception of toxicology required revamping the lab such that the activities were inquiry-driven. After establishing a baseline of knowledge, including serial dilutions and dose-response, the students designed and implemented an experiment that was completed during the semester. This lab experience yielded positive student feedback and nearly 25% of the class indicated they were considering pursuing graduate school in toxicology. Knowing of the successes and pitfalls of revamping a toxicology lab experience will allow the toxicology education community to improve students’ feedback and perception of toxicology, as well as encourage critical thinking.

1120 COMMUNITY RESEARCH RALLY BRINGS TOXICOLOGY EDUCATION TO A RURAL COMMUNITY IMPACTED BY ASBESTOS EXPOSURES.
J. C. Pflue1, K. Serve1, K. Rowe2 and B. Black3. 1Biological Sciences, Idaho State University, Pocatello, ID and 2Center for Asbestos Related Diseases, Libby, MT.

Educational outreach is a critical component of research using human populations that have been impacted by toxic exposure. The community of Libby MT has suffered health issues as well as psychological and economic impacts due to amphibole asbestos exposure from the mining of asbestos-contaminated vermiculite. Several strategies have been used by researchers over the years to increase the education and interaction with residents of Libby and surrounding areas. One of the most successful endeavors has been the Libby Research Rally. This annual event is free and open to the public, and in the fall of 2010, over 300 people attended from a community of under 10,000, ranging from young children to elderly adults. The 2011 rally will occur on October 13. The Rally consists of a) hands-on learning activities for all ages regarding asbestos and its toxic effects, physiology of the lung, and the kinds of testing that researchers are doing, b) booths manned by the researchers themselves, who answer questions about the objectives, methods, and current status of the research, c) open discussion panels of experts from EPA, ATSDR, physicians and researchers to field community questions and concerns. Participation is encouraged through the use of gifts, gift, prizes, and fun food. The Rally is hosted by the Center for Asbestos Related Diseases (CARD) in Libby, under sponsorship from federal grants supporting research in the community. The positive response and feedback from this event has demonstrated its success in improving community interaction with research and providing a forum that allows individualized access to research and toxicology information.
1121 EUROPEAN MODULAR EDUCATION AND TRAINING PROGRAM IN SAFETY SCIENCE FOR MEDICINES.

1Human & Environmental Toxicology, University of Konstanz, Konstanz, Germany.
2R&D, Sanofi, Vitry-Sur-Seine, Paris, France. 3R&D – Alderley Park, Alderley Park, Macclesfield, United Kingdom and 4R&D, GlaxoSmithKline, Ware, United Kingdom.

SafeSciMET presents a new and unique pan-European education and training network, developing and establishing a comprehensive modular Safety Sciences for Medicines Education & Training Program. SafeSciMET is a joint effort between academia and pharmaceutical industry and bridges crucial gaps in the education and training of scientists evaluating the safety of drug candidates and new medicines. SafeSciMET delivers a new, high quality and sustainable program for education and training in Safety Sciences for Medicines, with emphasis on actual industry case studies. The program encompasses training as a one week on-site course followed by one week worth of home assignments in translational and integrated safety assessments as needed in drug development and usage.

SafeSciMET courses are open to all scientists from industry, academia and regulatory agencies. The applicants should have an MSc degree in a Life Science discipline or equivalent. In addition, applicants are expected to have at least one year's work experience in a related discipline. For other participants no formal entrance requirements are set, although a scientific back-ground with at least an honors degree level is recommended.

SafeSciMET ensures that Europe's biomedical education landscape has maximum support in revolutionizing the conventional drug discovery and development paradigms. SafeSciMET provides novel communications in translational safety sciences, an aspect found largely lacking in today's educational programs. It leads to a new generation of safety scientists who are able to perform holistic and critical evaluations of the safety of drug candidates and new medicines. Linking animal and human data more effectively, in vitro and in vivo, will contribute to a better understanding of drug safety and how to bridge and make best use of animal and human data collected in drug development and safety assessment.

1122 USE OF BISPHENOL—A IN LABORATORY-BASED UNDERGRADUATE LEARNING EXPERIENCES.

M. E. Kirkpatrick. Psychology and Neuroscience, Wheaton College, Norton, MA.

Sponsor: T. Dodds-Butera.

Undergraduate education provides unique opportunities to expose students to current issues in toxicology in meaningful ways in both the laboratory and the classroom. In particular, students gain valuable experience developing research questions with a specific focus on hypothesis-testing and experimental design. Two projects were designed to involve students in toxicology research examining the impact of the proposed endocrine-disruptor, bisphenol—A (BPA), on hormone-dependent reproductive behaviors in female rats. Project 1: Independent Research: Three students worked with a faculty mentor to develop and execute a series of experiments focused on the behavioral impacts of BPA on estrogen-dependent reproductive behaviors in female rats. BPA, acting as an environmental estrogen, was hypothesized to affect the normal display of sexually receptive and protechnic behaviors. Different experimental paradigms were utilized to explore the effects of varied BPA doses, acute vs. chronic BPA exposure and possible role of endogenous hormone levels on the impact of BPA exposure. The student experience was extremely positive and resulted in presentation of data in both academic and professional meetings. Project 2: Classroom-based research project: Based on the success of the independent research project, a toxicology-based project will be added to be baviorial endocrinology unit of an upper-level laboratory behavioral neuroscience course. Students will work as a class to develop a simple experimental design testing the impact of acute BPA exposure on estrogen-dependent reproductive behaviors. Students will surgically remove ovaries from adult female rats and test the ability of ovarian hormones to reinstate spontaneous reproductive behaviors both in the presence of BPA and alone. Previous versions of this teaching module have been extremely successful and published in the Journal of Undergraduate Neuroscience Education. The addition of a toxicology-based hypothesis will serve to strengthen the activity and emphasize the application to lab research to “real-world” applications.

1123 COLLECTION OF WEB RESOURCES FOR THE TEACHING OF TOXICOLOGY.

N. Reynolds. Biology, Washington College, Chestertown, MD.

It is becoming increasingly clear that we need to enhance our education of toxicology at the undergraduate level. In order to aid in this process the Undergraduate Education Subcommittee for Web Resources is gathering toxicology teaching materials for instructor use. The committee has finalized criteria for the submission and review of these resources and is in the process of collecting the following resources: syllabi, lectures, lab activities, and assessment tools. These resources are currently being reviewed by the members of the subcommittee and organized in ToxChase to create a searchable database. I will highlight the resources collected by the group and discuss how they can be used by instructors for the development of new courses in toxicology at the undergraduate level. In addition, I will demonstrate how the group is utilizing ToxChase for the purposes of both resource organization and accessibility.

1124 DEVELOPMENT OF A CRITICAL THINKING TOOL FOR UNDERGRADUATES RELATED TO ONLINE DATABASE SEARCHES.

S. M. Ford. College of Pharmacy & Allied Health Professions, St. Johns University, Jamaica, NY.

An essential skill for students in scientific disciplines is information literacy, which includes identifying, locating, evaluating, and using needed resources. Standard 2 of “Information Literacy Competency Standards for Higher Education” (Association of College & Research Libraries, 2000) states “The information literate student accesses needed information effectively and efficiently.” Students enter college with a diverse set of skills for composing term papers and may be ill-prepared for literature searches required in science courses. The current learning instrument was developed to provide students in a 2nd year toxicology course with a self-paced assignment designed to improve information retrieval competencies and to promote critical thinking skills related to library research. Students are first oriented in the classroom to the resources available through the University library. They are then given the assignment - a “Library Scavenger Hunt” - comprised of ten questions which can be answered using the university's online databases. Questions guide students to compare search results using different strategies and databases, and to find answers to specific questions. The final question is a short test passage drawn from current events with instructions to formulate a question and a search strategy to answer it. Students have 7-10 days to finish the assignment, which is evaluated by the instructor and returned with feedback. At its completion, students: a) are familiar with the logic and logistics of the databases, b) have learned how to perform more effective searches, c) know how to obtain the articles retrieved by their searches, and d) have hands-on experience with different databases. By using a problem-based learning strategy, students are better prepared to execute sophisticated searches for their term papers and other assignments. The project is further described at http://stjohnscampusguides.com/Library/ScavengerHunt and was supported by a Department of Education Title III grant (P031A050301) to St. John's University.

1125 TOXICOLOGY AND PUBLIC HEALTH: A CONCEPTUAL FRAMEWORK FOR POLICY UTILIZING A LOGIC MODEL.

T. Dodds-Butera. Nursing, California State University, San Bernardino, College of Natural Sciences, San Bernardino, CA.

Background: Current threats to funding for various public health agencies may impact the discipline, education, and practice of toxicology. Addressing methods of presentation and evaluation of programs are needed for clarification of the value of targeted funding in toxicology. A logic model provides an illustration of an underlying conceptual framework and the logical connection within and between systems. Methods: A logic model was utilized to analyze the policy of decreasing spending for public health measures that impact selected programs for toxicology. An underlying assumption was that a range of toxicology programs serve core functions and provide essential public health services. Inputs included stakeholders and resources impacted by the policy to decrease public spending. The logic model also considers negative outcomes, when decreased funding levels lead to the elimination of access to various types of toxicology programs. Results: Immediate impact of decreased public spending would deny access to certain essential public health services, particularly significant to vulnerable populations. Short and long-term outcomes would include decreased utilization of appropriate resources when funding is cut for clinical toxicology services, and an accompanying increase in costs and imposition on emergency services and resources, respectively. In addition, there is an impact on the future strategies and directions for community environmental health, an absence of some preventive services, and obstacles presented for educating future toxicologists when a broad range of toxicology programs are considered. Conclusions: Logic models can be effective in establishing conceptual frameworks for shaping policy for public health, specifically addressing toxicology programs. The visual frame of reference clarifies the basis of fiscal policy, and gives perspective to long term impacts on budget, despite the short term reduction in spending.
1126 JACKSONVILLE ASH SITE TOXICOLOGY TRAINING TO IMPROVE KNOWLEDGE OF THE LOCAL COMMUNITY.

A. Becker1, S. Suther1, G. Pawlowicz2, F. Close3, K. Haire1, C. Michael1, G. Tucker2, C. Harris1 and A. Hillaard1. 1Institute of Public Health, Florida Atlantic University, Tallahassee, FL and 2Environmental Health, Duval County Health Department, Jacksonville, FL.

Introduction: For more than 60 years, the City of Jacksonville, Florida burned its solid waste in incinerators depositing lead, arsenic, polyaromatic hydrocarbons (PAHs), dioxins in landfills near residences, playgrounds, parks and schools. Contaminants in the surface water, ground water, sediments, contaminated fish and shell fish in contaminated creeks are of concern to the community.

Methods: The major goal of this project was to plan, develop, and implement a sustained community-based and culturally sensitive environmental health and toxicology educational program through proactive outreach and training of community stakeholders (train-the-trainer approach) impacted by the Jacksonville Ash sites. A pre-and post-test was developed to measure knowledge gained as well as a participant satisfaction survey. In all steps of the development of the Toxicology materials, the Duval County Health Department and community leaders had direct input.

Results: The majority of participants strongly agreed that the Community Toxicology Curriculum is a useful tool for promoting awareness of potential environmental risks in their community. Suggestions for improvement included using terminology more appropriate for the lay community, developing a website and a brochure for the communities impacted by the ash sites. Based on the pre/post test, there was a 24% average learning gain for the "train-the-trainer" session and a 46% average learning gain for the community resident training session.

Conclusion: Racial and socioeconomic disparities of minorities living near hazardous waste sites have historically and continue to raise health concerns regarding the disproportionate impact of probable and potential exposures to toxic substances emitted from these sites. One of the key gaps is the lack of knowledge regarding the toxicology and health impact of environmental contaminants amongst the community. Grant funded by ATSDR 5 R01/TS000108-02

1127 EXPLORING TOXICOLOGY: TEACHING HOW BASIC TOXICOLOGY IS PRESENT IN EVERYDAY LIFE.

K. Blanke1, B. Johnson and E. Shurtle1. Molecular & Environmental Toxicology Center, University of Wisconsin – Madison, Madison, WI.

The Molecular & Environmental Toxicology (MET) graduate program has participated in toxicology outreach events to promote a better understanding of toxicology to children and members of the local community. Graduate students provide learning opportunities through several activities which include a demonstration of "toxin" uptake in carnations and a game called Toxic Land. In the carnation activity, colored dye is added to the water of white carnations. As the carnations take up the water, the dye accumulates in the petals. Learning goals for this activity are age dependent and include the concept that plants take up "toxins" present in the water and soil. The concept of differential uptake rates is exemplified by the use of different dye colors. For more advanced groups, the concepts of bio-accumulation and partitioning are also presented. Toxic Land is a game that takes participants on a path through global events related to toxicology. During their journey, participants are given cards containing pertinent events that happen in daily life and are asked to determine if they will have positive or negative effects on people, animals, and the environment. These cards allow the participants to move forward and backward along the Toxic Land path while learning about toxicology at a personal level. The learning goals for Toxic Land include that participants are informed about toxicologically relevant events that have occurred at a global level and discuss how every day events have a toxicological effect on people, animals, and the environment. Both the toxin uptake activity and Toxic Land will be evaluated to determine if the learning goals of each event are achieved at after school programs in the Madison area. Elementary and middle school students at these after school events will fill out surveys, with questions specific to our learning goals, after participating in each event. The MET program will utilize the assessments to improve the activities and continue to inform the public about toxicology.

1128 RESOURCES FOR TOXICOLOGY K–12 EDUCATION OUTREACH: UPDATING THE SOT K–12 WEBSITE.

The Society of Toxicology’s Education K–12 subcommittee is updating our website to increase our support for K–12 education activities, to share resources across the membership and with the public, and to increase our effectiveness as we interact with educators, parents and students. One main goal is to work with the Society membership to create the most useful resource Website to help support excitement for toxicology through K–12 education outreach. Ideally, this Website would be accessible to the public, easily searchable and contain hands-on activities, PowerPoint presentations and recommendations for increasing K–12 education outreach. Many SOT members are active in toxicology outreach, and many more would like to be but don’t know where to start. Working with Society members, we will update the SOT Website to include links to successful activities, such as past Annual Meeting activities and ongoing Regional Chapter outreach activities. This resource Website will serve as a tool for those interested in getting involved in K–12 education outreach, as well as for those interested in learning more about what toxicologists do. The World Wide Web is a powerful tool that can educate and provide education and information. We want to utilize it to make K–12 education outreach available to members and educators across the globe. This presentation is an opportunity to make meaningful impacts throughout the Society to increase understanding of our efforts, to share the importance of our work, and to encourage future scientists who are dedicated to this work. We need your excitement and interest – get involved, contact us! The views expressed in this abstract are those of the author’s and do not necessarily represent the views or policies of the US Environmental Protection Agency or other affiliations.

1129 TEACHING TOXICOLOGY TO TEENS IN TUCSON.

M. Lindsey. Southwest Environmental Health Sciences Center, University of Arizona, Tucson, AZ. Sponsor: S. Lau.

Rationale and Scope: Tucson has a large Superfund site located in the Sunnyside School District (SUSD), where many of the student’s parents and grandparents were affected by illnesses associated with TCE contamination of the drinking water. The contamination occurred from improper waste disposal at the Tucson International Airport between the 1940s to the 1970s. A citizen’s group, the Unified Community Action Board (UCAB), was formed in the 1980s to monitor the contamination clean up. This project developed and implemented curriculum to improve high school education around environmental health and toxicology by focusing on the TCE contamination. Approach: In 2005, the UCAB requested the author, a board member; assist them teach the youth in Tucson about the issue of TCE contamination. They supported a grant application, awarded by the US EPA in 2008 (#NE09031010), to develop curriculum using an Understanding by Design (Wiggins & McTighe, 1998) approach. The UCAB developed the Essential Understandings to be taught. Teachers from the SUSD wrote interdisciplinary lessons, addressing toxicology in integrated science, biology, and chemistry lessons and environmental public health in social studies, government, and language arts lessons. (http://coep.pharmacy.arizona.edu/tce/). Results: Subsequently the author worked with some teachers to implement lessons in the high schools. In 2009 the school board mandated use of the lessons to teach about the TCE contamination. Students have created digital stories from family interviews; have demonstrated clean up methodologies to the UCAB, and have developed posters for public meetings, such as the opening of treatment plants. The author and one of the teachers presented the curriculum at the National Science Teachers Association in 2009, removing Trichloroethylene from the Groundwater. To achieve full implementation of the curriculum, an online training program for all teachers is being developed to facilitate teaching the lessons in 2012 spring semester. 1130 TOXICOLOGY K–12 EDUCATION OUTREACH: AN UNDERSERVED OPPORTUNITY WITH ENORMOUS POTENTIAL BENEFITS.

The Society of Toxicology’s Education K–12 subcommittee is partnering with K–12 education liaisons in each Regional Chapter in an effort to 1) increase our support for K–12 education activities in every region; 2) share resources across regions; and 3) increase our effectiveness as we interact with educators, parents and students. Forming this interaction will facilitate a functional understanding by the public of the essential role of toxicology in a diverse range of activities and challenges that affect our health and our environment. Summarized below are the goals of this partnership: Development of education sub-committees within Regional Chapters with the goal of mentoring students and conducting outreach activities as well as training others interested in participating in outreach activities; Establish K–12 educator advisory bodies to shape outreach efforts and identify outreach opportunities and to increase and assess effectiveness; Identify and partner
The mission of the (U.S.) National Library of Medicine (NLM) is to collect, organize, preserve, and disseminate health-related information. NLM’s efforts to assist first responders and others include three tools for emergency response that are provided free to users. These tools in NLM’s “disaster-response triad” include WISER (Wireless Information System for Emergency Responders), REMM (Radiation Emergency Medical Management), and CHEMM (Chemical Hazards Emergency Medical Management). WISER, REMM, and CHEMM are designed to be easy to use, intuitive, and able to provide accurate, trustworthy information when and where it is needed, e.g., on-site for first responders at an emergency. WISER’s focus is to assist first responders in hazardous material incidents involving chemicals, while REMM and CHEMM enable first responders, first receivers, and other healthcare providers to plan for, respond to, recover from, and mitigate the effects of mass-casualty incidents, and chemical and biological events, respectively. Each tool includes extensive educational and training resources. NLM’s efforts to provide easy access to this information include the development of downloadable and Web-based versions of WISER, REMM, and CHEMM, and the development of WISER and REMM apps for iPhone, BlackBerry, and Android smartphones. This poster focuses on presenting an overview of CHEMM’s educational and training components, which have been enhanced to evolve as CHEMM’s public release in July, 2011. WISER’s and REMM’s educational and training content will also be noted. (CHEMM and REMM are the result of collaborative efforts between the U.S. Department of Health and Human Services, Office of the Assistant Secretary for Preparedness and Response (ASPR) - Office of Preparedness and Emergency Operations (OPEO) and NLM’s Division of Specialized Information Services (NLM SIS)).

1133 INTEGRATING TOXICOLOGY AND ENVIRONMENTAL HEALTH INTO BASIC AND ADVANCED NURSING EDUCATION.

B. Satler. Environmental Health Education Center, University of Maryland School of Nursing, Baltimore, MD. Sponsor: T. Dodd-Butera.

The integration of toxicology and environmental health into nursing has been initiated with a number of activities. A multidisciplinary initiative was created to teach nursing faculty basic environmental health and toxicology principles. The University of Maryland created the first graduate program in environmental health in a nursing school. Nursing researches have been awarded applied research grants in environmental health including healthy homes and research on agricultural exposures, and the National Children’s Study. Nurses are including environmental exposure assessments in patient electronic health records; engaged in environmentally preferable purchasing decisions; and advocating for legislation to decrease environmental exposures from toxic chemicals.

All nurses must take pharmacology. A side-by-side comparison of the basic scientific principles of toxicology and pharmacology was created for nurses. Translational articles are being written by nurses. There is a distinct disconnect between the science that is published in environmental science and toxicology journals and what is published in medical and nursing journals. While some of the science has direct implications for clinical practice, it is rare that the translational articles appear in the journals that clinicians read.

The American Nurses Association (ANA) has created a set of environmental health principles and in 2010 the ANA created a distinct nursing practice standard for Environmental Health thus firmly placing environmental health in the nursing profession’s domain. In 2009, the Alliance of Nurses for Healthy Environments was created and an educational roadmap was developed for the integration of environmental health and toxicology into nursing education and a new webtool was created: www.enviRN.org. Nurses are the predominant employees in the health care sector. One in every one hundred Americans is a Registered Nurse. The benefits of having nurses to address environmental health, with a basic understanding of toxicology, can have a significant benefit.

1134 OUTREACH AND EDUCATION PROGRAMS DESIGNED TO IMPROVE THE DIAGNOSIS, TREATMENT, AND REPORTING OF PESTICIDE-RELATED ILLNESSES IN CALIFORNIA.

Although 1000-2000 cases of pesticide-related illness are reported annually in California, under-reporting remains a concern. To help address this problem, the Office of Environmental Health Hazard Assessment (OEHHA), as mandated by California law, has developed and implemented a program of medical education to inform physicians and other health care professionals of the diagnosis and the treatment of pesticide illnesses and the requirement to report them. OEHHA’s program consists of on-site presentations by staff; an on-line course in English and Spanish (www.medepesticide.org) that provides an overview of the recognition, management and reporting of pesticide illness; and a specialized on-line course on the California Medical Supervision Program, a cholinesterase monitoring surveillance program established in the 1970s to prevent acute illness among agricultural pesticide mixers, loaders, and applicators who handle the more toxic organophosphorus or carbamate pesticides. Medical professionals who have taken the courses include physicians, registered nurses, medical students and residents, physician assistants, and emergency first responders. Continuing medical education credits are offered for on-line courses. Other educational materials, including posters and brochures, specifically target the general public, and provide brief descriptions of symptoms and instructions for obtaining medical attention. Another specialized course, which will soon be available on-line, is for medical professionals who staff the California Poison Control System call centers. The call centers receive and log phone calls related to pesticide exposures and California’s Urban Pest Eradication Programs, and electronically report them to OEHHA, the California Department of Pesticide Regulation, and the local county health and agricultural departments. OEHHA is continuing to explore ways to enhance its educational offerings and outreach to inform the health care community of the availability of these resources.
1135 RISK AND DECISION MAKING: A WORKSHOP FOR ENVIRONMENTAL PROFESSIONALS.

In the early 1990s, a training workshop for environmental professionals was developed in USEPA Region 9. The workshop was successfully taught throughout Region 9, especially in California through collaboration with the California Department of Toxic Substances Control and other California regulatory agencies. We have updated the manual to introduce changes in risk assessment methods, including the evaluation of vapor intrusion into indoor air, benchmark dose, new cancer guidelines, inhalation toxicity criteria (USEPA RAGS Part F), ecological risk assessment, screening risk assessments, conceptual site models and data quality objectives. At the same time, we have maintained the popular workshop format in which students evaluate the information and draw conclusions, rather than being lectured on the "correct" answer. We have also maintained the case study approach to simulate realistic environmental issues. After an introduction to the case study facility, environs, and contaminants, students must plan a sampling strategy. Students are introduced to principles of toxicology and learn how to develop toxicity criteria based on hypothetical animal study results. Exposure pathways are identified by students who learn to develop quantitative estimates of exposure. Once students determine the pathways, they must determine appropriate alternatives. At the end of the evaluation process, role playing is used to develop risk communication skills. This workshop has proven to be effective for training new employees and providing continuing education for more experienced employees. It has been successful in training staff in consulting and in military organizations, as well as in a variety of regulatory settings. Participants in the workshop benefit from exchanging knowledge and viewpoints of a range of skills and backgrounds (supervisors, project managers, toxicologists, geologists, engineers, public participation experts, etc.). The workshop format fosters these exchanges and provides a dynamic learning environment for students.

1136 CONTRIBUTION OF PHYSOCHEMICAL PROPERTIES TO AUTOPHAGY PERTURBATION.

R. Ashoor, B. A. Jessen and S. Lu, Pfizer Inc., San Diego, CA.

Autophagy refers to the catabolic processes in eukaryotic cells that deliver cytoplasmic materials to lysosomes for degradation. This highly conserved process is involved in the clearance of long-lived proteins and damaged organelles. Consequently, autophagy is important in maintaining cellular homeostasis, providing nutrients to maintain cellular function under starvation, and promoting cell survival in various stress conditions. Multiple mechanisms have been shown to regulate autophagy, such as mTOR pathway modulation. However, the link between lysosomal functional impairment and the ensuing impact on the autophagy process has not been fully explored. Basic lipophilic compounds can accumulate in lysosome via pH partitioning and then perturb lysosomal function. We hypothesized that those compounds can disturb the autophagy process. Twelve drugs that have previously been shown to accumulate in lysosomes were selected. Cytotoxicity was evaluated using an ATP depletion assay and autophagy was assessed with LC3 immunofluorescent staining. All twelve drugs induced cytosolic vacuoles and increased staining of LC3. The connection between the increase in autophagosome staining and lysosomal dysfunction was studied using transcriptomic analysis. Gene expression profiles from all tested drugs revealed a downward trend of expression of plentiful long-lived proteins, including structural cytoskeleton and associated proteins, and extracellular matrix proteins, indicating a retardation of protein turnover. Interestingly, various antioxidant response element containing genes, including glutathione S-transferases, NADPH dehydrogenase, and quinone 1, were up-regulated, suggesting activation of the Nrf2 transcription factor. Our data indicate that lysosomal accumulation due to the basic lipophilic nature could contribute to the perturbation of autophagy process.

1137 ASSESSING SELECTIVITY OF COVALENT IRREVERSIBLE B-LACTAMS AND B-LACTAMASE INHIBITORS USING ACTIVITY-BASED PROTEIN PROFILING.

C. W. Scott1, D. Ehmann2, A. Kimsey3 and Y. Dragan4, Safety Assessment, AstraZeneca Pharmaceuticals, Waltham, MA and Infection Bioscience, AstraZeneca Pharmaceuticals, Waltham, MA.

A significant number of drugs and candidate drugs acylate catalytic amino acids (ser, thr, cys) in enzyme targets resulting in irreversible inactivation. Optimizing this mechanism of action requires balancing chemical reactivity (to minimize off-target binding) with target affinity. Assessing off-target binding using traditional one-target-one-assay approaches can be a challenge due to the large size and structural diversity of some enzyme families, e.g. serine hydrolases (SerH) contain > 200 members. Activity-Based Protein Profiling (ABPP) uses an enzyme class-specific and active site-directed probe to detect enzymes in the catalytically active state. ABPP can be used to assess inhibitor selectivity across an enzyme family using pure enzymes as well as complex biological samples (Nature Biotechnology, 2003, 21:687). Both b-lactams and B-lactamase inhibitors (BLIs) bind irreversibly to a catalytic serine in their bacterial enzyme targets, so off-target binding to the mammalian SerH proteome can be studied using ABPP. A biochemical fingerprint of active SerH in rat tissue extracts (brain, lung, liver, heart, kidney, testes) was generated using the probe compound fluorophosphorodihydroxyamine and utilizing SDS-PAGE with in-gel fluorescence scanning. Pretreating recombinant enzymes (thrombin, trypsin) and tissue extracts with tool compounds (thrombin and trypsin inhibitors, PMSF) blocked labeling by the probe, demonstrating specificity. Marketed BLIs (sulbactam, tazobactam, clavulanate) and a b-lactam (faropenem) did not affect the SerH biochemical fingerprint in rat tissues, consistent with their clean safety profile. In vivo BLI in clinical development (MK-7655) also showed a clean ABPP profile. This method for assessing off-target activity has application as an early in vitro screen to aid in series prioritization and lead optimization. In addition, ABPP can be performed in vivo to enable translational assessment of off-target binding.

1138 AUTOMATED IMAGE-BASED ACTION POTENTIAL AND CALCIUM TRANSIENT ANALYSIS FOR CARDIAC SAFETY ASSESSMENT.

E. Cerignoli, R. W. Whittaker, P. McDonough, R. Ingermanson, M. Mercola and J. H. Price, 1 Sanford-Burnham Medical Research Institute, La Jolla, CA and 2 Vala Sciences Inc., La Jolla, CA.

Currently available analysis for cardiac safety assessment rely on scarcely biological relevant high throughput assays or utilize complex and time consuming electrophysiological techniques that analyze only few cells or conditions at a time. The first approach downsize the importance of multiple ion channel activity on the Action Potential and the second is of scarce utility in the early phase of the drug development process. To enable High Throughput measurements of parameters relevant to cardiac activity, we have developed a Kinetic Image Cytometer (KIC) for simultaneous dynamic imaging and automated cell-by-cell analysis of intracellular Action Potential and Calcium Transient. The instrument automatically electrically field-stimulates and records fluorescence emitted from intracellular voltage and calcium probes from hundreds of cardiomyocytes per well in multi-well format. The associated software segments the acquired images and measures fluorescence dynamic on individual cells and performs statistical analyses on the entire cell population or gated subsets. Post-fixation staining and single-cell tracking enable direct correlation between dynamic parameters and cell subtype. Here we report the use of KIC for measuring the effect of Na+, K- and Ca2+ channel blockers (e.g. flecainide, E-4031, dofetilide and verapamil) and activators (NS 1463 and Bay K 8644) in hiPSC (human induced pluripotent stem cell)-derived cardiomyocytes. RH421 (Action Potential) and Fluo-4 (Calciump Transient) fluorescent probes were loaded simultaneously and acquired from the same field of view for each of 96-well plates. Post-recording staining with atrial, ventricular and nodal markers in mixed populations identifies kinetic characteristics and drug effects that are related to specific cardiac cell subtypes. Our results suggest that this new high content approach can have a profound impact in the field of early in vitro cardiac safety assessment.

1139 IDENTIFICATION OF DRUGS CAUSING CLINICALLY SERIOUS DRUG-INDUCED LIVER INJURY (DILI) USING IN VITRO APPROACH WITH PRIMARY HUMAN HEPATOCYTES.

J. Zhang1, D. Utkarsh1, M. Chen1, U. Lafortge1, H. Fang1, A. P. Li2 and W. Tong2, 1 NCTRFDA, Jefferson, AR, 2 AIFS Sciences Inc., Columbia, MD and 3 Tech. an ICF International Company as NCTR, Jefferson, AR.

Clinically serious DILI is a major cause of early termination of drug development and of FDA regulatory action against marketed drugs. The FDA's guidance expresses specific concerns about clinically serious DILI. In this study, we evaluated the utility of primary human hepatocytes in assessing it. The unique aspects of these study are: 1) a large number of drugs surveyed to predict serious DILI, 2) multiple doses used so that a cumulative measure of drug effect can be quantified by area under the curve (AUC), and 3) individual mechanistic endpoints evaluated to associate mechanism(s) with serious DILI. Based on the FDA Drug Labeling on DILI criteria (w/ or w/o liver failure (ALF) reports, 82 drugs were divided as serious DILI or not. Serious DILI drugs are those withdrawn from market or labeled with a Black Box Warning due primarily to hepatotoxicity as well as those implied as
causing DILI in the Warnings and Precautions or Adverse Reaction with associated ALF confirmed in at least two countries. Human hepatocytes were treated at seven concentrations and luminescence and fluorescence assays performed with four endpoints (ATP content, GSH depletion, Caspase 3 activity and ROS) at 24 hours. The data was normalized and AUC calculated. Assay performance was evaluated with Receive Operating Characteristic (ROC) and the results quantitatively reported as sensitivity with 95% confidence intervals. We found that only ATP content and Caspase activity had moderate prediction potential for serious DILI. However, ROS normalized with ATP content predicted serious DILI very well with 89 and 88% of sensitivity and specificity respectively, indicating that oxidative stress is one of the critical factors to cause serious DILI and specifically combined toxic endpoints (ROS/ATP) performed better than individual ones. The current assessment of this in vitro system indicates that it could provide a useful application in preclinical drug development.

**1140 A NOVEL HIGH-CONTENT SCREENING ASSAY TO PREDICT HUMAN DRUG-INDUCED LIVER INJURY.**

Clinical and nonclinical toxicity are major causes for failure of drug development programs in the pharmaceutical industry, as well as of drug withdrawals. Although adverse drug reactions manifest themselves in different ways and organs, drug-induced liver injury is relatively frequent. DILI has traditionally been difficult to predict because of the multitude and variety of risk factors involved, and because of the lack of sensitivity of animal models. Inspired by recent publications on high content screening cytotoxicity assays, we have developed a multi-parametric quadprobe assay with high predictivity towards human DILI. The assay is performed on primary human HepG2 cells and focuses on early molecular markers such as nuclear area, plasma membrane integrity, lysosomal activity, mitochondrial membrane potential, and mitochondrial area, in order to provide an integrated view of cytotoxicity. The assay is compatible with formaldehyde fixation to allow high throughput. We used a validation set of >60 marketed drugs classified according to their potential to cause hepatotoxicity: safe, moderately toxic, or severely toxic. When analysing the data with respect to total Cmax, our assay shows >80% correct predictions, a sensitivity of >65%, and no false positives, when incubating cells for 24h with drug. Corresponding numbers for 72h incubation with drug are 80% correct predictions, a sensitivity of >70%, and three false positives. False negatives comprise compounds which cause immune system-mediated DILI or which require extensive metabolism, both of which HepG2 cells are not covering. Hierarchical clustering using the multi-parametric data allows cytotoxicity similarity matching of new chemical entities with reference compounds/known drugs for better risk assessment during drug discovery. In summary, our newly developed high content imaging assay classifies drugs with potential to cause DILI, shows low numbers of false positives, and is believed to be a powerful screening tool for risk assessment during drug discovery.

**1141 ASSESSMENT OF TIME-KINETICS OF ENDOTHELIAL BARRIER INJURY BY IMPEDANCE TECHNOLOGY.**

Vascular leak syndrome (VLS) is an undesired side effect of some therapeutic monoclonal antibodies and therapeutic cytokines. Reduced integrity of the endothelial monolayer, i.e. separation of cells for a certain time then allows for a leakage of fluid from the circulatory system to the interstitial space finally resulting in interstitial edema, decrease in microcirculatory perfusion and organ damage. Soluble factors in the blood including IL-1beta, IL-2, and Thrombin have been shown to induce VLS by multiple mechanisms which lead to an endothelial cell contraction and disassembly of the interendothelial junctions. In the present study we designed an in vitro system based on human umbilical vein endothelial cells (HUVEC) as a model for the vascular wall to assess the potential of drug candidates to induce VLS. Drug-induced effects affecting monolayer integrity were then monitored by measuring electrical resistance over time on an xCELLigence® system able to capture morphological changes of cells producing a time-lapse impedance pattern termed ‘cell index’ (CI). Cells were cultured under conditions allowing cell-cell contacts confirmed by the expression of tight- and gap-junction proteins such as ZO-1, Claudin-5, and VE-Cadherin, and a constant CI. Thrombin decreased CI significantly and reversibly. Altered expression of ZO-1, Claudin-5 and VE-Cadherin measured by immunohistochemistry confirmed that the effect on CI was due to intracellular gaps following Thrombin exposure. To exclude unspecified cytotoxic effects co-treatment of non-endothelial cells (fibroblasts) was performed. The obtained results were compared to the current standard assay measuring flow-rate of FITC-dextran, respectively. Our results in a vitro approach chosen to assess VLS and we suggest real-time label-free impedance monitoring of vascular integrity as a simple, reliable and fast tool to assess the risk for VLS following drug treatment.

**1142 PREDICTING DRUG-INDUCED HEPATOTOXICITY IN ZEBRAFISH LARVAE: UNDERSTANDING THE COMPLEXITY.**

N. Mesen1, A. Crawford2, A. Menke3, C. Esguerra4, F. Van Goethem1, A. Wodzinski1, P. De Witte5 and J. Gompel1, 1Laboratory for Safety and Toxicology, Janssen Pharmaceutical Companies of Johnson & Johnson, Beerse, Belgium, 2Laboratory for Pharmaceutical and Biological Sciences, Catholic University of Leuven, Leuven, Belgium and 3Reproductive Toxicology, TNO Titelkliniek bv, Zest, Netherlands. Sponsor: PGuzze-Peck.

Zebrafish larvae represent an attractive lower animal test model to fill the gap between high throughput in vitro cellular assays and conventional preclinical animal testing. The model may in particular be useful in predicting human liver toxicity, as a huge drawback of cellular hepatotoxicity assays remains the single cell system they are based on and the consequent limited predictive capacity. It is however important to acknowledge the complexity of this whole organism. A phenotypic darkening of the liver may arise as part of an overt toxic or stress response. In addition, understanding the effects of hepatotoxins on the liver of a vertebrate larva is essential in order to study critical hepatotoxicity pathways. Testing thoroughly characterized reference compounds against a well defined endpoint and correlating with their known mechanisms of action may answer these questions. We show the systematic investigations of this approach. First, the expression of a liver specific protein fabp10 during development of control larva by in situ hybridization was explored. Subsequently, larvae were treated with 10 well characterized hepatotoxin and 5 non hepatotoxic compounds. The hepatotoxic compounds (acetaminophen, amiodarone, tetracycline, nefazodone, tamoxifen and others) could be identified by a statistical significant change in fabp10 expression or staining pattern of the liver region. Different patterns were observed: enlarged or reduced size, reduced intensity and absence of staining. Interpretation of these patterns required high throughput histopathological analysis of zebrafish larvae. After characterization of the histology of the liver region, treated larva were assessed for pathological effects on the liver, which were correlated with the staining patterns.

**1143 INVESTIGATION INTO THE ROLE OF OCTN2 IN DRUG-INDUCED TOXICITY.**

P. J. Calcraft, G. Smith, S. Stahl and J. Sidaway, Molecular Toxicology, AstaZeneca, Macclesfield, Cheshire, United Kingdom.

Cardiotoxicity is a leading cause of drug attrition at all phases of development and may be caused by a number of interrelated mechanisms. One such mechanism may involve the organic cation/carnitine transporter subtype 2 (OCTN2). Mutations in the OCTN2 gene result in primary systemic carnitine deficiency characterized by cardiomyopathy in man, and some xenobiotics are thought to cause secondary carnitine deficiency via inhibition of OCTN2. Drug-transporter interactions may have clinical implications due to altered disposition of a given drug and/or disruption of carnitine homeostasis. We therefore investigated, if cardiotoxic and non-cardiotoxic drugs inhibit OCTN2-mediated carnitine uptake and/or exhibited OCTN2-dependent cytotoxicity. 68 compounds (47 cardioxins, 21 non-cardioxins including non-toxic controls) were tested at a concentration of 100 μM. Inhibition of OCTN2-mediated 4H-acetyl-L-carnitine uptake was determined in HEK-hOCTN2 or empty vector HEK-control cells in 40 min incubations. Cytotoxicity was determined at 40 min and 24 hrs using an ATP viability assay. Inhibition and toxicity, expressed as percentage of control (0.5% DMSO), were defined as <80%, >carnitine uptake was Na+-dependent and inhibited by unlabeled L-carnitine (IC50 7 ± 1.5 μM). 9 compounds were excluded from the inhibition analysis due to confounding toxicity. Out of the remaining 59 compounds 14 inhibited OCTN2 activity: these were 10/39 (26%) cardioxins, 4/20 (20%) non-cardioxins including the known non-toxic substrate milderanort. 30/68 compounds exhibited cytotoxicity (24/47 cardioxins) after 24 hrs, but both HEK-hOCTN2 and HEK-control cells were equally sensitive. This suggests that OCTN2 does not enhance drug cytotoxicity and that none of the 30 toxins are potential substrates. These results suggest that OCTN2 may not be considered as a polyspecific drug transporter. Nevertheless, given the clinical impact of dysfunction of carnitine homeostasis and the observation of OCTN2 inhibition amongst cardioxins, in vitro evaluation of OCTN2-drug interactions may be useful for cardiotoxic hazard identification.
Mitochondrial toxicity is frequently investigated as a potential mechanism of drug-induced adverse events. Mitochondrial membrane permeability transition (MMPT) is an important endpoint of mitochondrial toxicity. As an early event in mitochondrial mediated apoptosis, MMPT leads to release of cytochrome c from mitochondria to cytosol thereby triggering downstream caspase activations. In this study, we assessed MMPT and its association with viability and mitochondrial membrane potential (MMP) in MolR4 cells exposed to known mitochondrial toxicants. Cells were exposed to various doses of the mitochondrial uncoupler carbonyl cyanide P-(trifluoromethoxy) phenylhydrazone (FCCP), the alternative electron acceptor menadione (MD) or doses of the mitochondrial uncoupler carbonyl cyanide P-(trifluoromethoxy) phenylhydrazone (FCCP), the alternative electron acceptor menadione (MD) or the complex III inhibitor antimycin A (AmA) for up to 24 h. MMPT was evaluated by cytometric assay potentially valuable in addressing mitochondrial toxicity in drug development.

Small interfering RNAs (siRNA) are used as a tool to knock-down gene expression in a sequence-specific manner, opening new possibilities for the development of siRNA as human therapeutics. While safe and effective delivery of siRNA to the target organ is the major challenge, there is also potential for side effects induced by the siRNA molecules themselves. These potential side effects can be grouped in three classes: (1) off-target silencing of genes; (2) interference of endogenous RNA silencing pathways or competition for the RISC complex; (3) undesired activation of innate immune responses, mediated by pattern recognition receptors (PRR) recognizing nucleic acids commonly found in pathogens, like Toll-like receptors 3, 7 and 8 (TLR3, TLR7, TLR8). While TLR3 and TLR7 are present in endosomes and detect siRNA based on the presence of short sequence motifs rich in uridine, TLR3 binds in a sequence-independent manner to dsRNA and is present in endosomes as well as on the cell surface of immune and non-immune cells. Here, we describe the establishment of a panel of in vitro assays to monitor the activation of TLR3 for safety evaluation during the development of therapeutic siRNAs. A combination of tests performed on human dendritic cells, NK cells and endothelial cells (eg. HUVEC cells) allow the evaluation of the risk of triggering innate immune responses due to the binding of siRNAs to TLR3 molecules present on the surface of these cells. Furthermore, the activation of other endosomal and/or cytoplasmic PRRs caused by potential internalization of siRNAs can also be assessed. PRR-mediated responses were assessed by measuring cytokine secretion and gene expression analysis upon stimulation of cell populations with specific activators or siRNAs. While dendritic and NK cells were found to be suitable models to analyze the siRNA activation of the innate immune system by various mechanisms, HUVEC cells were intensively characterized and selected to evaluate TLR3-specific mediated responses.

Mitochondrial toxicity is one of the leading causes of drug attrition at all phases of development. It is therefore important to understand the expression of transporters in the heart relative to transporter-rich tissues such as the liver and kidney. Next generation sequencing of the transcriptome (RNA-seq) offers a global snapshot of the RNA population enabling high-resolution comparisons between genes and across samples. Here we use RNA-seq to identify the relative expression of 47 ABCs and a subset of 70 SLCs with potential for drug transport. Total RNA was extracted from the atria, ventricles, kidney, liver and gastrocnemius of male Wistar rats (n = 2). Sequencing of samples was carried out on an illumina platform and reads mapped using Genomic Workbench (CLC bio). Gene expression values were filtered using a minimum cut off of 10 reads/gene. Values were normalised using the trimmed mean of M-values method. Hierarchical clustering identified 53 out of 117 genes expressed with an organ-specific bias with respect to either heart, kidney or liver (10, 28 and 15 respectively). Within the heart 7 genes represented transporters with potential for drug transport (members of SLC16, SLC22, SLCO, ABCBC and ABCB families). To determine whether any of these were heart-specific rather than muscle-specific, expression levels of each transporter were compared to skeletal muscle. As a result 4 transporters appeared to exhibit a heart-specific bias with regard to expression levels (>50% greater normalised RPM). It is therefore important to assess the drug-transporter interactions of these genes to further determine a role for transporters in cardiotoxicity.

Mitochondrial toxicity is frequently investigated as a potential mechanism of drug-induced adverse events. Mitochondrial membrane permeability transition (MMPT) is an important endpoint of mitochondrial toxicity. As an early event in mitochondrial-mediated apoptosis, MMPT leads to release of cytochrome c from mitochondria to cytosol thereby triggering downstream caspase activations. In this study, we assessed MMPT and its association with viability and mitochondrial membrane potential (MMP) in MolR4 cells exposed to known mitochondrial toxicants. Cells were exposed to various doses of the mitochondrial uncoupler carbonyl cyanide P-(trifluoromethoxy) phenylhydrazone (FCCP), the alternative electron acceptor menadione (MD) or the complex III inhibitor antimycin A (AmA) for up to 24 h. MMPT was evaluated by cytometric assay potentially valuable in addressing mitochondrial toxicity in drug development. Additionally, we have shown that MolR4 cells are an appropriate model for these investigations.
had increased by 50% or more during a 24-30 hour exposure. Data were rejected at lower values, which indicate excessive cytotoxicity. The cell permeability dye Ethidium monazide (EMA) was also assessed as a measure of cell viability. Compound exposure regimes producing any more than a 4 fold increase in EMA staining have a higher risk of producing misleading micronucleus induction data. Progenotoxins produced expected positive results in the 39 exposure protocol. The trials results demonstrate a high concordance of results between laboratories, and high reproducibility within and between laboratories. Discordant results were not associated with particular compounds, suggesting that the protocol is highly transferable. The ability of the MNT to predict the results of other in vitro and in vivo genotoxicity endpoints reflected findings from an earlier validation of a tube-based assay. In summary, in the three cases presented, MEA assays using hCMs or rCMs had excellent predictivity for cardiovascular outcomes, and were more predictive of results of other standard safety assays: three examples.

Using MEAs and cardiomyocytes derived from human induced pluripotent stem cells (hCMs) or rat fetus (rCMs), we evaluated the effects of three internal compounds from different programs whose in vitro cardiovascular outcomes were not predicted by standard in vitro safety assays. hCMs were purchased from CDI, and rCMs were isolated from E18 rats. Spontaneous field potentials (FPs) were recorded on MEAs following an equilibration period. FP beating rate (BR), waveform morphology and conduction time (CT) were analyzed with custom software written in Matlab. The first compound prolonged QT interval in safety pharmacology (SP) telemetry and EP studies (12% at 0.6 μM). A development compound in a second program reduced heart rate in humans at lower exposures than predicted based on SP telemetry studies. Mechanistic studies showed the compound was a direct inhibitor of sinusoidal node automaticity. The compound inhibited BR in hCM MEA assays by 27, 72 and 86% at 3, 10 and 30 μM, respectively, while inhibiting BR in rCMs by only 38% at 30 μM. The MEA assays were more predictive for heart rate slowing, and hCMs were more sensitive than rCMs. A development compound in a second program reduced heart rate in humans at lower exposures than predicted based on SP telemetry studies. In summary, in the three cases presented, MEA assays using hCMs or rCMs had excellent predictivity for cardiovascular outcomes, and were more predictive than standard assays. hCMs were more sensitive than rCMs depending on the mechanism.

Drug-induced organ toxicity is a major problem in new drug development and continues to be a significant issue in late stage attrition of development compounds. In vitro screening assays developed upon pathways and mechanisms linked to drug toxicity are widely used to predict some of these adverse effects in vivo. However, these cell-based models, however, do not take into consideration factors that regulate in vivo accumulation and distribution of drugs. Our in vitro screening data shows that 1) compounds that cause low-dose cytotoxicity in cell-based assays often exert such effects in cell lines independent of their in vivo organ expression; and 2) different cell lines showed different sensitivity toward certain compounds. This difference in sensitivity among cell lines may be partially due to differential expression levels of transporters. There is increasing evidence supporting their roles in drug disposition, therapeutic efficacy and adverse drug reactions. In this study, we profiled the gene expression levels of annotated transporters, which include approximately 2000 human and 1000 rat transporters, in five human cell lines and three rat cell lines using Affymetrix microarrays. We also evaluated the cytotoxicity of over 400 compounds with known rat in vivo outcome data in two liver cell lines, HepG2 and THLE. The relationship between differential expression levels of transporters among cell lines and differential sensitivities of compounds was investigated. Our preliminary data shows that differential expression levels of transporters can explain the differential sensitivity of, at least, some compounds in different cell backgrounds. This analysis will enable us to improve our in vitro predictivity by choosing the right cell model.

It has been proposed that many marketed drugs with clinical safety issues disrupt mitochondrial function. Knowing the primary mechanism of a compound on mitochondrial function early in development could prevent later stage attrition. However, comprehensive knowledge about the ability of a compound to perturb mitochondrial function and then identify the primary mechanism of mitochondrial perturbation has not been fully elucidated. To address this gap, a custom built mitochondrial function profiling platform was developed and used to test compound effects on electron transport chain complexes (I-IV), NADH oxidation, ATP synthesis (complex V), TCA (glutamate, succinate, pyruvate) and fatty acid (acyetyl-CoA, acetyl carnitine, butyryl-CoA, octanoyl-CoA, palmitoyl-CoA, palmityl carnitine) substrates oxidation, mitochondrial membrane potential, uncoupling (induction of the respiratory burst), mitochondrial permeability transition, calcium loading potential, citrate synthase activity, and oxidative stress (acetonate activity). 56 marketed drugs and 22 known mitotoxins were profiled. Several classical mitotoxins displayed characteristic effects (e.g., Antimycin A inhibited complex III); however, at higher concentrations, Antimycin A also inhibited complex V. Our results indicate there are relatively few potent (IC50 less than 1 μM) marketed drugs that had effects on any mitochondrial endpoint (9%) and none of these were electron transport chain inhibitors. However, mitochondrial uncouplers and substrate
1153 STRATEGIES TO IDENTIFY THE POTENTIAL SAFETY LIABILITIES OF COVALENT, IRREVERSIBLE INHIBITORS.

Covalent irreversible inhibition is an attractive strategy for pharmacological targets as it may offer unprecedented levels in selectivity, thereby reducing the chance of any undesired side-effects. Such an approach, however, requires the inhibitor to possess sufficient levels of electrophilicity that enable it to bind covalently with nearby nucleophilic residues, yet not too reactive that it binds non-selectively to other cellular proteins. Measurement of off-target protein binding is usually performed once a lead compound has been selected, typically through the identification of radiolabelled protein adducts. Such an analysis, however, is expensive and not applicable to the design stages of the drug discovery process.

We investigated three in vitro assays to determine the off-target reactivity of electrophilic compound groups; two were based on intrinsic thiol-reactivity, one utilizing Ellman’s reagent to detect untreated thiol and the other utilizing fluorescently-labeled glutathione to follow reaction kinetics. A third assay involved measuring activation of the Nrf2 transcription factor, which plays a critical role in inducing the Antioxidant Response Element (ARE). Using luciferase reporter methodology, levels of Nrf2 activation were measured in HEK293 cells on treatment with a variety of electrophilic compounds. Levels of Nrf2 activation correlated well with electrophilicity of the test compound, as measured by reaction with glutathione and detection by Ellman’s reagent. These three assays are being utilized to measure direct electrophilicity as well as to determine a functional cellular readout of thiol reactivity. As a result, several structural-activity relationships have been developed for cysteine-reactive functional groups, including maleimides, acrylamides and cyanamides. Application of all three approaches in compound screening may be useful in determining the optimal balance between target and off-target covalent binding.

1154 GAMMA-SECRETASE MEDIATED HEPATOTOXICITY: USING MULTIPARAMETER IN VITRO METHODS TO ASSESS TOXICITY AND INTERPRET MECHANISM.

J. Senn, J. Lane, T. Sullivan, M. Carioto and J. Clarke, Biogen Idec, Cambridge, MA.

In vitro and in vito hepatotoxicity evaluations were conducted on a novel gamma-secretase modulator (GSM); BIO-021169 (BIBO042, MW of 499.5). Three structurally-related molecules (BIBO042, BIO-017708, and BIO-021882) and two structurally-unrelated GSMs (BIO-026501 and BIO-027436) were evaluated using the CellCiphr® system in primary rat hepatocytes and human hepatoma cells (HepG2). All three BIBO042-related compounds were potent hepatotoxicants in vitro. The most sensitive effects in primary hepatocytes were: mitochondrial membrane potential changes and apoptosis/nuclear size changes (activity concentration 50% (AC50) for the most sensitive indicator was ~10.5 M M or 5.4 μg/mL). In HepG2 cells, stress-kinase activation, mitochondrial membrane potential and reactive oxygen species generation leading to cell cycle arrest, nuclear size changes and cell death was observed. The structurally unrelated molecules were significantly less hepatotoxic in primary hepatocytes and had a maximum tolerated concentration of 105.6 and 195.6 μM, respectively. However, in HepG2 cells, these compounds were slightly more potent with a cytotoxicity threshold of 26.1 and 70.8 μM (BIO-026451 and 027436, respectively) and were observed to have effects on both the mitochondria and activation of stress-kinases similar to BIBO042. This data correlates with in vivo studies with BIBO042 in rat and cynomolgus monkey where the doselimiting toxicity was hepatic and was observed at or near exposures (based on Cmax) in the range determined in vitro. CellCiphr analysis appeared to link toxicity in hepatocytes to direct effects on the mitochondria, perhaps leading to activation of stress-linked kinases and the intrinsic apoptotic cascade. Gamma-secretase is known to be expressed in the mitochondrial membrane and it appears that activity of this complex (particularly the presenilins) can have effects on mitochondrialf function and basal metabolic state, potentially linking the pharmacologic activity of this molecule to the toxicity observed.

1155 NONINVASIVE REAL-TIME MEASUREMENT OF OXIDATIVE METABOLISM IN VITRO ALLOWS SENSITIVE DYNAMIC READOUT OF DRUG RESPONSE.

W. Inman1,2, M. Weissinger1, J. Luyten1, S. B. Tannenbaum1,3, I. W. Hunter1 and L. G. Griffith2,1, Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA, 1Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA, 1Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA and 3Environmental Sciences and Engineering, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Disruption of cellular oxidative metabolism pathways is recognized as playing a critical role in a large number of drug safety-related problems. There are many methods for evaluating changes in cellular metabolism or mitochondrial function in vitro, but these assays are typically either invasive or require sampling at discrete intervals. Here, we report on the development of a noninvasive real-time measurement system for oxidative metabolism based on readouts of oxygen concentration at defined locations relative to the cells in culture. Specifically, fluorescence-based sensors were integrated into standard multi-well cell culture formats and their utility was evaluated in several experimental conditions mimicking effects on the oxidative metabolism. Importantly, this measurement method is not only suitable for static two-dimensional cultures, but is particularly useful for flow-based cell culture environments where human liver monolayers are often compared to 60% density with the Ames Assay. flow based liver cell culture environment. The concentration measurement results represent a simple yet highly sensitive and dynamic readout of an in vitro drug response. Because the measurement is conducted in real-time, this system is also amenable to determining the dynamics of the drug response and is not limited to discrete sample intervals; furthermore, it allows selection of an appropriate concentration and time point for detailed offline analysis during the experiment.

1156 NEXT GENERATION DEL ASSAY: CYTOTOXICITY AND GENOTOXICITY DETECTION WITH DEL-XG.

J. Riva1, L. Parfenova1 and R. H. Schiebel2,3, Environmental Health Sciences, University of California Los Angeles, Los Angeles, CA, 2Pathology, University of California Los Angeles, Los Angeles, CA and 3Radiation Oncology, University of California Los Angeles, Los Angeles, CA.

Generic instability is a hallmark of carcinogenesis. Furthermore, cells from patients carrying mutations conferring cancer prone phenotypes show a higher level of genetic instability, including DNA deletions. We have previously constructed and/or used assays (DEL assays) that select for DNA deletion events in yeast, human cells and in vivo in the mouse. In fact, the original yeast-based DEL Assay detects 92% of known human carcinogens as compared to 66% detection with the Ames Assay. Deletions occur by homologous recombination between two copies of a duplicated DNA sequence to delete the interrupting sequence together with one of the repeats. DEL events in all three formats are inducible by a wide variety of carcinogens including carcinogens that are negative in many other short-term tests. Furthermore, many cancer prone mutations highly elevated the frequency of DNA deletions in mice adding to the solid correlation between DEL events and carcinogenesis. Here we introduce the next generation DEL assay: a novel dual-read out Saccharomyces cerevisiae screen DEL-XG. Based on the original DEL assay, DEL-XG simultaneously assesses the compound’s genotoxicity and cytotoxicity properties. DEL-XG test strain cells contain a lacZ gene sequence with a region of homology interrupted by an auxotrophic gene; during an exposure to a genotoxic event (carcinogens, ionizing radiation, etc.) the sequence is excised and the lacZ gene recombines to a functional beta-galactosidase genotype that with an addition of the X-Gal substrate produces a detectable indole product. Here we compare the efficacy of the DEL-XG assay to the original DEL Assay. DEL-XG is a rapid and economical way to screen large chemical libraries for toxicity and carcinogenicity properties and enabling a screening “triage”: compounds with higher toxicity profiles will be subjected to additional screening as a first priority.

1157 ASSESSMENT OF HERG CHANNEL FUNCTION USING STEM CELL-DERIVED CARDIOMYOCYTES.

The vast majority of drugs withdrawn from the market due to association with TdP arrhythmia interfere with the Lkf repolarization current mediated through the HERG. Consequently, the ICH S7B guidelines recommend that all new chemical entities should be subjected to HERG repolarization assay, typically using cell lines.
that recombiantly express hERG protein. However, in the last decade it has become evident that not all hERG channel inhibitors result in TdP and not all compounds that induce QT prolongation and TdP necessarily inhibit hERG. In order to better understand and assess the different kinds of drug liabilities associated with hERG channel inhibition and modulation we have used a panel of drugs and compounds which (i) directly bind and inhibit hERG channel function (overt inhibitors); (ii) compounds which inhibit hERG as well as other channels and therefore compensate for the IKr block (covert inhibitors) and (iii) compounds which interfere with the trafficking of hERG channel protein to the plasma membrane (trafficking inhibitors). We have assessed the activity of these compounds using human induced pluripotent stem cell-derived cardiomyocytes (iPSC) together with a system that can measure the beating activity of the spontaneously beating cardiomyocytes. Our data clearly shows that overt hERG channel inhibitors disrupt the periodicity of beating of iPSC cardiomyocytes leading to plateau oscillations and a signature waveform that is typical of this class of compounds. Covert hERG channel inhibitors at physiologic concentrations do not appear to affect cardiac function and therefore appear to be safe. hERG trafficking inhibitors display a time-dependent effect on the periodicity of beating that manifests several hours after compound dosing. In summary, the results clearly show that dynamic monitoring of iPSC cardiomyocyte beating can be used in a predictive way to assess various types of hERG channel modulators and provide additional information to electrophysiological methods.

1160 UNBIASED APPROACH FOR THE DOSE-RESPONSE ANALYSIS OF SIGNAL TRANSDUCTION PATHWAYS.

H. N. Williams, J. Vrana, C. Kinzer and J. Boyd, Chemistry, West Virginia University, Morgantown, WV.

High throughput multiplex assays capable of quantifying signaling protein activities have led to a major increase in the availability of large datasets describing signal transduction networks. Computational models are often used to organize and interpret these large datasets into tractable biological knowledge. Data driven models often yield unanticipated results, and can be advantageous because prior biological understanding of the network need not be relied upon, minimizing variability and error that can result when biological information obtained from different treatment conditions, timescales, species, and cell types is used. In this study, computational modeling was used to assess the signal transduction networks associated with stress response. A unique aspect of this study is that the signal transduction networks were assessed from a toxicological point of view; that is, the protein networks were constructed based on changes in protein activities in response to increasing doses of inhibitors, independent of time. The phosphorylation response of HepG2 cells exposed to increasing doses of deguelin, potassium cyanide (KCN), staurosporine, SB202190, and SB202474 alone and in binary combinations was assessed via principal component analysis for 8 highly networked signaling proteins (MEK, ERK, AKT, JNK, p38, p53, HSF27, and p90RSK). Phosphorylation was quantified using a bead based multiplex ELISA assay. This data was then used to frame cellular network responses with regard to dose for 2 disparate toxicological examples: exposure to single-target vs. multi-target inhibitors and mixtures with greater than additive toxicity. Our results indicate that dose-to-dose protein activity is significantly different from the overall response; single target inhibitors lead to a more highly correlated protein response than multi-target inhibitors; and mixture additivity may be the result of low dose, non-toxic thresholds of the individual constituents. Overall this approach provides unique and unbiased toxicological insight into the signal transduction networks associated with stress response.

1161 ESTIMATING TEMPORAL BIFURCATIONS ASSOCIATED WITH CELLULAR SIGNAL TRANSDUCTION.

J. A. Vrana, H. N. Williams and J. W. Boyd, Chemistry, West Virginia University, Morgantown, WV.

The pharmacodynamic response of cells to xenobiotics is primarily coordinated by signal transduction networks, which typically follow a fundamental motif, the phosphorylation / dephosphorylation cycle mediated by kinases and phosphatases. Defining the temporal scale of critical signal transduction events post-dose is difficult, but may be possible by exploiting the intricate inter-relationship that exists between mitochondrial-driven energy metabolism and kinase response. Kinase signaling is an energy demanding process, and its reliance on phosphorylation results in the consumption of substantial amounts of available ATP. Further, it has been shown that ATP-production actually governs the majority of ATP-consuming processes in mammalian cells, and regulation is primarily driven by oxidative phosphorylation within mitochondria. Therefore, if one monitors the energy production processes in the cell, key time points of significant deviation may point toward critical kinase signaling events. Monitoring these responses without potentially disrupting sensitive intracellular activity is imperative; thus we have developed an extracellular approach to determine kinase signaling events on a temporal scale by estimating ATP production with kinetic data collected from real-time oxygen
consumption and NADH production assays. These data sets allow for stoichiometric
determination of ATP production in real-time. Preliminary results will be pre-
sented with data collected from HepG2 cells dosed with MEK inh II or TDZD-8
(GSK3β inhibitor) monitored over 24 hours at 10 minute intervals. We found key
bifurcations at 20 minutes and 500 minutes post-dose for MEK inh II, and bifur-
cations at 40 minutes and 600 minutes post-dose for TDZD-8. We then measure the
phosphorylation response of several proteins at these time points, and relate them
to 24 hour viability. In this study, we demonstrate the ability to estimate crit-
ical signaling events via temporal response using an extracellular, in vitro means of
estimating phosphate generation by exploiting stoichiometric relationships between
NADH and O2 to produce ATP.

1162 IDENTIFICATION OF EARLY SIGNAL TRANSDUCTION RESPONSES PREDICTIVE OF SURVIVAL.

J. Boyd, H. N. Williams, J. A. Vrana and X. Gao. Chemistry, West Virginia
University, Morgantown, WV.

The phosphorylation/dephosphorylation cycle, mediated by kinases and phos-
phatases, is responsible for the coordination of many cellular responses to xenobi-
otics. This simple cycle is embedded in networks which use positive and negative
feedback to generate extremely diverse functions like signal amplification, re-
versible/irreversible switches, and oscillations. One key irreversible switch is apop-
tosis, and both the signaling network and infrastructure surrounding the decision
to flip this switch is complex. Multiple signals generated by either external or inter-
nal stresses converge upon the mitochondria and result in outer membrane perme-
abilization, which is considered the point of no return for apoptosis. To determine the
drivers of apoptosis and nanofibrosis in vivo, we exposed HepG2 cells to several doses (1-100 μM) of a protein inhibitor (MEK inh II) and determined 24
hour viability. Next, we estimated the temporal response of protein phosphoryla-
tion by calculating the phosphate available for cellular signaling from oxygen con-
sumption and NADH generation in vitro. The results showed that apoptosis was induced when ATP production was severely hindered and was in general agreement with 24 hour viability measurements. Overall, this new approach can reasonably predict 24 hour viability at very early time points post-dose (+1 hour), by simply interpreting the dynamic activity of signal transduction networks in response to xenobiotics.

1163 MECHANISTIC INVESTIGATION OF B-RAF INHIBITOR-INDUCED HYPERPLASIA AND DEVELOPMENT OF A 3D HUMAN IN VITRO MODEL.

L. Marroquin, W. Evering, S. Koho-Reiter, J. Lee, V. Torti, A. John-Baptiste,

The Raf proteins play a role in the MAP/ERKs kinase signaling pathway, which regulates cell division, differentiation, and secretion. B-Raf mutations have been reported in various types of cancers in human; therefore selective inhibitors of B-Raf have been developed for tumor therapy. Although cell line and tumors that harbor the B-Raf mutant can be sensitive to these inhibitors, hyperplasia in several normal squamous epithelial tissues has been reported in animal studies. Here we re-
ported the development of an in vitro 3D model to replicate the proliferative effect seen in rodent studies and to better understand the biology. The 3D model culture of Reconstructed Human Epidermis (RHE) cells made by SkinEthics was evaluated in our study because of its histological similarity to that of the human epi-
dermis. RHE that was cultured in vitro was treated with DMSO or B-Raf inhibitor
and W. Hu.ing B-Raf inhibitor-induced hyperplasia and demonstrates the human relevance of
these findings from a two week study in rats.

1164 KINASE ACTIVITY PROFILING IN INVESTIGATIVE TOXICOLOGY.

P. Lord, L. Houkes, J. Oosterwijk-Wakka, E. Oosterwijk, R. Ruitenberg and
M. van Duuren. 1PamGene International, B.V., Hertogenburch, Netherlands
and 2University of Utrecht, Utrecht, Netherlands.

Molecular toxicology aims to link gene and protein expression profiles to estab-
lished end-points of toxic responses. These methods provide informative snapshots of what is occurring in response to toxicants but do not capture the dynamic nature of the responses. Peptide microarrays can assess functional consequences of trans-
scriptional/translational changes linked to pathogenesis. We study signal transduc-
tion mechanisms by monitoring signaling kinases, using dynamic peptide microar-
rays in order to find underlying mechanisms of toxic responses. Total protein was extracted from renal cell carcinoma and normal kidney tissues from patients treated with either of the anti-angiogenic drugs, sorafenib and sunitinib. Equal amounts of total protein (10μg) were analyzed for kinase activities on dynamic PanChip pep-
tide microarrays comprising 144 or 256 different peptides. Our results show that kinase activity profiles can be generated robustly from tissue extracts. Experiments showed signal dependence on protein extract concentration, ATP concentration and finally, modulation of the peptide phosphorylations by the drugs. Different phosphorylation profiles were obtained between tumour and healthy tissue from the same patient, showing higher activities in the former. Investigating both chemotherapeutics, similar profiles were found in tumour tissue, while clear differ-
ences were detected in the corresponding normal tissue. These are potentially linked to differences in toxicity between the drugs. Importantly, phosphorylation of peptides representing PDGFβR and EGFR was inhibited more in tumour than after sunitinib treated versus sorafenib treated patients. The observations indicate that this method could identify appropriate target proteins, but also off-target proteins possibly in-
volved in adverse drug reactions. This novel molecular approach has a good poten-
tial application in clinical and preclinical toxicological research. Clearly it provides
the means to study the dynamics of the adverse effect of pharmaceuticals, whether from cell lines or (animal or patient derived) tissues.

1165 LYSOSOME FUNCTION IMPAIRMENT AS A POTENTIAL MECHANISM OF RETINOPATHY.

S. Koho-Reiter, S. Sokolowski, B. Jensen and S. Lu. 1Pfizer Inc., San Diego,
CA and 2DSRD, Pfizer Inc., Groton, CT.

The retina is a highly structured tissue formed by seven different cell types arranged in layers. The photoreceptor cell is a specialized type of neuron in the retina that is capable of absorbing photon and converting light into signals that can stimulate bi-
ological processes. There is a constant renewal process for photoreceptors consisting of intermittent shedding of the distal tips of the photoreceptor outer segment and subsequent phagocytosis in the retinal pigment epithelia (RPE) cells. Rebuilding process is essential for vision and the survival of photoreceptors and RPE cells. Drugs with basic moity have the potential to accumulate in lysosomes and impair its functions including the phagocytosis process, which could hinder clearance of outer segment of the retina and ultimately induce retinopathy. To determine the prevalence of this cellular mechanism in retinal toxicity, a collection of proprietary compounds associated with retinal toxicity were put through a battery of in vitro tests using a human retinal pigmented epithelium cell line, ARPE. The tests included phagocytosis assay, Lysotracker staining, Bafilomycin A (BFA) rescue exper-
iments, and autophagosome staining. The compounds that induced retinopathy were identified to accumulate in the lysosomes. This accumulation coincided with phagocytosis inhibition and an increase in autophagosome staining, suggesting a blockage of the membrane trafficking process related to lysosomal functional im-
pairment following compound accumulation. A correlation between the phyto-
chemical properties and in vitro lysosomal pathway effects was also established. In addition, cytotoxicity of selected compounds was determined, and it was shown that treatment of BFA, further suggesting the involvement of lysosomes in the toxicity observed. This data reveals the importance of physiochemical properties and lysosome accumu-
lation as a common mechanism for drug induced retinopathy and demonstrates the potential usefulness of an in vitro screen in predicting this liability.

1166 NEW MODEL OF NONCLINICAL CARDIAC RISK ASSESSMENT.

J. W. Kramer1, G. J. Myatt2, C. Obejero-Paz, A. Breuning-Wright and A. M.
Brown. 1ChanTest Corp., Philadelphia, OH and 2Leadscope Inc., Columbus, OH.

Drug-induced inhibition of the cardiac hERG potassium channel is assumed to predict delayed cardiac repolarization (DR). The consequent QTc prolongation is a
powerful predictor of torsade de points (TdP), a rare but potentially lethal iatro-
genic outcome. Drugs with effective therapeutic plasma concentrations (ETPC)
within 30-fold of their hERG IC50s are thought to be dangerous despite the fact that multiple ion channel effects (MICE) can mitigate DR. Here we demonstrate that a logistic regression model, which integrates MICE, predicts TdP with much greater certainty than the hERG safety ratio (hERG IC50/ETPC) alone. Safety ratios were calculated for 41 drugs (20 +TdP and 21 -TdP) from multiple classes by dividing their hERG, Nav1.5 and Cav1.2 IC50 values by each drug’s ETPC. Two logistic regression models were constructed; one using the hERG IC50/ETPC ratio alone (Model 1), the other integrating hERG IC50/ETPC + Nav1.5 IC50/ETPC + Cav1.2 IC50/ETPC data (Model 2). The predictive power of each model was evaluated by performing leave-one-out cross validations. Each model’s accuracy for discriminating +TdP and -TdP drugs was determined by comparing their receiver-operator characteristics (ROC, true vs. false positive rates). Model 1 had a 52% False Positive Rate associated with a 90% True Positive Rate and a ROC area under the curve (AUC) of 0.74. Model 2 significantly improved accuracy showing a 14% False Positive Rate associated with a 90% True Positive Rate and a ROC AUC of 0.88. We propose that models that incorporate quantitative drug effects on multiple cardiac ion channels will be robust nonclinical predictors of cardiac risk.

Cardiovascular (CV) toxicity is a leading contributor to drug withdrawal and late-stage attrition. Earlier and broader screening is a validated approach to build-in CV safety, as demonstrated with hERG screening to reduce drug-induced arrhythmia. There is an urgent need for novel in vitro assays to extend this success to contractility, heart rate, hypertrophy, structural damage, and non-hERG arrhythmia. Recent advances in label-free cellular impedance technology now enable tracking of spontaneous synchronized beating of cultured cardiomyocytes. Analysis of beating allows integrated detection of electrical and mechanical aspects of contraction. Here, we evaluate impedance cardiomyocyte assays against criteria required for drug screening. The throughput and sensitivity allowed for rapid assay development and identification of critical optimization parameters with rat neonatal cardiomyocytes including cell seeding density and serum levels. Once optimized, consistent stable beating for at least three days was straightforward to achieve. In tests of ligands spanning a breadth of target classes, the potency values showed excellent precision, wide dynamic range, and consistency across multiple experiments. Impedance data could be analyzed for beat rate, amplitude, and beat rise slope with each parameter yielding similar precision. Potency values calculated by beat rate and amplitude were highly correlated for most compounds although selected compounds displayed unique profiles indicative of different mechanisms. Evaluation of a set of drugs selected based on established CV activity in humans revealed concordance between impedance and clinical findings for 20 of 21 compounds. Thus, impedance assays combining features including sensitivity to contractive activity, versatility data analysis, and robust/translatable data can be utilized to address critical gaps in CV drug screening.

Cardiovascular toxicity remains one of the leading causes of late-stage drug attrition and drug withdrawals. Drugs of the tyrosine kinase inhibitor class have received particular attention in this regard (Force et al. (2011) Nat Rev Drug Discov 10, 111-26). The cytochrome P450 isoform 2J2 (CYP2J2)-epoxyeicosatrienoic acids (EETs) pathway regulates key aspects of cardiovascular function and plays an important cardioprotective role under stress conditions linked to mitochondrial function (Karragoda et al. (2009) J Mol Cell Cardiol 46, 867-75). We investigated the hypothesis that this pathway may be linked to drug-induced cardiotoxicity. We validated a CYP2J2 inhibitor assay based on commercially-available CYP2J2 super-somes (BD biosciences) and substrate (Promega). A known reference compound (terfenadine) gave an IC50 value of 315 nM (mean pIC50 6.50 ± 0.02; n = 34). IC50 data (n = 2) for 114 clinically-relevant drugs annotated for organ toxicity were generated. A number of inhibitors were identified, where at a threshold of IC50 <1 μM, 6 were associated with cardiotoxicity, compared to 2 that were associated with hepatoxicity, 1 associated with both toxicities and 1 with low organ toxicity. Strikingly, 3 of 4 cardiotoxic tyrosine kinase inhibitors tested were potent 2J2 inhibitors with IC50 values of 79, 336 and 872 nM (imatinib, sorafenib, dasatinib), the remaining kinase inhibitor IC50 value was 10 μM (sunitinib). Drugs were tested for ATP depletion in the cardioid-derived rat H9c2 cell line and in H9c2 cells adapted for increased mitochondrial aerobic activity (using a galactose energy source to circumvent the Crabtree effect (Marroquin et al. (2007) Toxicol Sci 97, 539-543)). The 3 cardiotoxics also potent CYP2J2 inhibitors were more cytotoxic to the H9c2 cells with a galactose energy source compared to normal H9c2 cells. These data suggest a potential association between using 30 μM as a cut-off of BR20 could correctly flag all 17 compounds. These results suggest the beat rate change is a more sensitive predictor and more translational biomarker of potential ECG alterations. Hence, including the beat rate analysis adds additional predictive value to this cardiomyocyte arrhythmogenesis model in assessing the likelihood of compounds to cause ECG alterations in the down-stream in vivo studies.

1169 HEMODYNAMIC FLOW AND HETEROCELLULAR CELL COMMUNICATION ARE NECESSARY FOR PREDICTING HUMAN VASCULAR DRUG RESPONSE IN PRECLINICAL VASCULAR IN VITRO SYSTEMS.

B. R. Wamhoff1, 3, N. Hastings2, M. Simmers2 and B. R. Blackman1, 2
1Biomedical Engineering, University of Virginia, Charlottesville, VA and 2HemoShear LLC, Charlottesville, VA. Sponsor: E. LeChuyes.

Pre-clinical animal models are poor predictors of the human response and fail to deduce vascular cell-specific responses and mechanisms. Moreover, current in vitro systems do not incorporate fundamental in vivo parameters; such as hemodynamic forces and complex, heterotypic cell-cell interactions, i.e. endothelial and smooth muscle cell. In this study, molecular and functional responses to multiple FDA-approved drugs (statins, Ca2+ channel blockers, NSAIDs, thiazolidinediones, NO-donors) were investigated in a human primary vascular cell system. The technology imposes MRI-human-derived, region-specific, vascular hemodynamic patterns onto human primary vascular endothelial cells that are co-cultured with vascular smooth muscle cells. The cells are physically separated by a thin porous membrane, which allows for both interaction between and separation of both cell types and collection of secreted factors. Results: 1) compared to traditional culture methods, hemodynamic culture enhances human primary vascular cell arrival and re-establishes vascular bed specific endothelial and smooth muscle cell morphology and molecular phenotype, consistent with biology in intact arteries. 2) Molecular responses in the technology correlate to human drug responses whereas traditional culture responses are often misleading. 3) Functional responses (e.g., nitric oxide signaling, vasoactivity, permeability) varied depending on the nature of the hemodynamic flow pattern, e.g., small arteriole versus large conduit artery. Thus drug class-specific, differential responses were observed and correlated to human clinical response. Finally, non-human species cells (e.g., rat, dog, monkey) and hemodynamics can be utilized for comparison to human to assist in validating vascular cell-specific, vascular bed-specific properties of compounds, improving decision making of both positive and negative effects at the molecular and functional levels. NHLBI R43HL102951, R44HL102955
some forms of drug-induced cardiotoxicity, inhibition of the CYP2J2-EETs pathway and mitochondrial dysfunction, particularly for these cardiotoxic tyrosine kinase inhibitors.

**1171 IN VITRO SAFETY PHARMACOLOGY PROFILING IN EARLY DRUG DISCOVERY: MITIGATION OF ADRS.**

In vitro safety pharmacology has been applied in different forms to drug discovery. However, recent developments in assay technologies, automation and in silico sciences transformed a panel of target-based assays into a powerhouse of early safety profiling with a unique ability to support mitigation based on off-target SAR. In vitro safety pharmacology applies a panel of selected human targets associated with clinical ADRs to lead selection and optimization. The panel covers a broad pharmacology-chemistry space, employs biochemical and functional assays and has the capacity and quality to provide information on pharmacological promiscuity and predicts major liabilities. In silico tools are also available to predict off-target characteristics and link pharmacology with chemical structures. Information generated in the safety pharmacology panels should be considered together with PK/PD data and correlated with clinical observations obtained from marketed drugs with similar safety pharmacology profile. We will demonstrate the various utilities of in vitro safety pharmacology in the prediction of clinical ADRs.

**1172 AEROSOL DELIVERY TO A MICROFLUIDIC HUMAN BREATHING LUNG-ON-A-CHIP FOR INHALATION TOXICITY.**

D. C. Leslie1, 2, K. Domansky1, J. Fraser1, M. Khan1, G. A. Hamilton1, A. Bahinski1 and D. E. Ingribe1, 2. 1Wyss Institute/Harvard University, Boston, MA, 2Children’s Hospital Boston and Harvard Medical School, Boston, MA and 3School of Engineering and Applied Sciences, Harvard University, Cambridge, MA.

In vitro model systems that accurately predict drug efficacy, bioavailability and toxicity in humans are needed to replace costly and time-consuming animal studies to speed development and regulatory approval of new and safer medical products. Although advances have been made in cell culture models, these methods, in many cases, still fail to accurately predict toxicity in humans mainly due to insufficient re-construction of the key structural and mechanical features of the whole organ. Recently, we demonstrated a biomimetic microfluidic device that reproduces the alveol-capillary interface of the human lung under physiologically relevant cyclic mechanical strain and flow conditions. But aerosol drug delivery to cells at an air interface in a physiologically relevant manner constitutes a challenge, especially on the microscale. We address this challenge and report delivery of aerosolized microdroplets into a microfluidic device with human cells at an air-liquid interface. A commercial prescription nebulizer generates aerosolized liquid droplets. A design incorporating a miniature impactor delivered the respirable fraction to the alveolar epithelial monolayer. We have demonstrated cell vitality after aerosol delivery. Using this method, drugs, particles and toxins can be administered to human lung cells cultured at an air interface in microfluidic channels, where the environment closely mimics the in vivo mechanical and structural environment. Integration of this aerosol delivery system with the breathing lung-on-a-chip microdevice provides a new method to measure pulmonary absorption, efficacy and toxicity of aerosolized drugs, particles and toxins. Ultimately, aerosol drug delivery to biomimetic cell culture devices should provide a more accurate model for drug and toxicity screening.

**1173 PROTEOMIC ANALYSIS OF CARBONYLATED PROTEINS IN THE KIDNEYS OF TRICHLOROETHENE-EXPOSED MRL+/+ MICE.**

X. Fan1, G. Wang1, R. English2 and M. Khan1. 1Pathology, University of Texas Medical Branch, Galveston, TX and 2Biomolecular Resource Facility, University of Texas Medical Branch, Galveston, TX.

Trichloroethene (TCE), a common environmental and occupational pollutant, is associated with multi-organ toxicity leading to diseases like cancer and autoimmune diseases. Kidney is one of major target organs affected as a result of TCE exposure. Our previous studies have shown that exposure to TCE causes increased protein oxidation (protein carbonylation) in kidneys of MRL+/+ mice, and suggested a potential role of carbonyl stress in TCE-mediated toxicity. However, identity of carbonylated proteins and potential changes in their structural and functional properties remain unknown. To assess the impact of chronic low dose TCE exposure on protein oxidation, particularly to identify the carbonylated proteins in kidney, we treated with TCE at the dose of 2 mg/kg via drinking water for 36 weeks and kidney protein extracts were analyzed for protein carbonyls and carbonylated proteins identified using proteomic approaches (2D gel, Western blot, MALDI TOF/TOF MS/MS, etc.). TCE exposure led to significantly increased protein carbonyls in the kidney protein extracts (20,000 g pellet fraction). Interestingly, among 18 identified carbonylated proteins, 10 were found only in the kidneys of TCE-treated mice, whereas other 8 were present in the kidneys of both control and TCE-treated mice. The identified carbonylated proteins represent skeletal proteins, chaperones, stress proteins, enzymes, plasma protein, and proteins involved in signaling pathways. These findings provide a map for further exploring the role of carbonylated proteins in TCE-mediated nephrotoxicity.

**1174 PROFILING PROTEIN CARBONYLATION IN A MURINE MODEL OF ALCOHOLIC LIVER DISEASE.**

J. Galligan1, R. L. Smathers2, J. D. Gomez2, K. S. Fritz3 and D. R. Petersen2. 1Pharmacology, University of Colorado, Aurora, CO and 2Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado, Aurora, CO.

Hepatic oxidative stress is a well recognized result of sustained ethanol consumption. The resulting formation of lipid peroxidation end-products has been proposed to play a role in pathogenesis of alcoholic liver disease (ALD). These reactive electrophiles are well documented to form covalent adducts with protein side-chains (e.g. protein carbonylation) potentially leading to altered protein activity, structure and/or localization. To investigate the role of protein carbonylation in ALD, a 6-week ethanol feeding regimen was employed in C57BL/6 mice. Ethanol-fed mice displayed a 2-fold increase in hepatic TBARS while immunohistochemical analysis for the reactive aldehydes 4-hydroxynonenal (4-HNE), 4-oxononal (4-ONE), malondialdehyde (MDA) and acrolein (ACR) revealed a significant increase in the staining of modified proteins in the ethanol-treated mice. Increased protein carbonyl content was confirmed utilizing subcellular fractionation of liver homogenates followed by biotin-tagging through hydrazide chemistry. This revealed approximately a 2-fold increase in aldehyde-modified proteins in microsomal and cytosolic fractions. Novel targets of protein carbonylation were identified utilizing avidin binding followed by 2-dimensional liquid chromatography tandem mass spectrometry (2D LC-MS/MS). Our results have identified 414 protein targets for modification by reactive aldehydes in a mouse model for ALD; these data have also confirmed the presence of novel in vivo sites of protein modification by 4-HNE, 4-ONE, MDA and ACR. Bioinformatic analysis was also performed on a composite list of protein identifications and elucidates key pathways associated with the pathogenesis of ALD including lipid homeostasis, fatty acid metabolism, amino acid metabolism and protein acetylation. (R37 NIH/AA009300 & F31 AA018660).

**1175 PROTEOMIC IDENTIFICATION OF CARBONYLATED PROTEINS IN RAT HIPPOCAMPS AFTER 1-BROMOPROPANE EXPOSURE.**

Z. Huang1, S. Ichihara2, S. Oikawa2, J. Chang2, L. Zhang1, K. Subramanian1, S. Sheik Mohideen1 and G. Ichihara2. 1Nagoya University Graduate School of Medicine, Nagoya, Japan, 2Mie University Graduate School of Regional Innovation Studies, Tsu, Japan, 3Mie University Graduate School of Medicine, Tsu, Japan and 4Guangdong Prevention and Treatment Center for Occupational Diseases, Guangzhou, China.

1-Bromopropane (1-BP), an alternative to ozone-depleting solvents, is neurotoxic both in animals and humans. Previous proteomic analysis of hippocampal tissues from rats identified alteration of protein expression and pathways involved in oxidative stress, suggesting that oxidative stress may play a role in 1-BP neurotoxicity. The present study investigated the contribution of oxidative stress to 1-BP neurotoxicity at protein level. Male F344 rats (n=9/group) were exposed to 1-BP at 0, 400, or 1000 ppm, 8 hrs/day for 1 week or 4 weeks. Protein carbonyl assay, two-dimensional gel electrophoresis, immunoblotting, and matrix-assisted laser-desorption ionization time-of-flight mass spectrometry (MALDI-TOF-TOF/MS) were utilized to analyze quantitatively protein carbonylation in the rat hippocampus. Advanced glycation end products (AGEs) level was detected in the hippocampus and plasma by ELISA assay. Hippocampal protein carbonylation increased significantly after 1-BP exposure at 1000 ppm for 4 weeks, demonstrating 1-BP-associated induction of oxidative stress. MALDI-TOF-TOF/MS identified 10 carbonylated proteins whose levels significantly increased (p<0.05; fold change ≥ 1.5) with 1-BP exposure. The identified proteins were involved in biological processes such as glycolysis, ATP production, tyrosine catabolism, GTP binding, guanine degrada-
Reactive dicarbonyls, such as methylglyoxal (MG), are present in blood and react with arginines (R) of target proteins, leading to diabetic micro- and macrovascular complications. Normal MG plasma concentrations are estimated to reach 4.5 μM, with these values tripling as diabetic complications progress. Dicarbonyls irreversibly modify R residues, resulting in a net loss of positive charge via hydroimidazolone formation. Shotgun LC/MS/MS proteomics analysis of human serum, reacted with 5 mM MG (18 hrs at 37°C), produced adducts on 7 different plasma proteins: albumin, transferrin, fibrinogen, haptoglobin, apolipoprotein A-1, α1-acid glycoprotein and plasminogen (PLG). Although PLG was the least abundant plasma protein modified by MG, it was second only to fibrinogen in the number of modified peptides (R504, R561, R610, R637, R712, R638, R712, R677, R779, and R789). Albumin, present at concentrations -104 greater than PLG, yielded far fewer modified sites (R218, R257, R410, R428, R485). The findings indicate that Rs within the tail region of PLG are particularly susceptible to MG-mediated modifications. While the basis for this is unclear, molecular modeling revealed that R561 is solvent exposed, rendering this specific site highly susceptible to MG modification. Modified R561 in PLG is of particular biological interest because of its role in the thrombolytic cascade, being the site of cleavage from plasminogen to plasmin. Consistent with the data obtained from human serum, reactions of PLG with as little as 50 μM MG (48 hrs at 37°C) reproduced the modified R561 adduct. Modification of PLG was further confirmed by western blot analysis using an anti-MG antibody. The data demonstrate that R561 is a hot spot on PLG, the modification of which may disrupt the thrombolytic cascade thereby contributing to vascular complications associated with diabetes. The functional significance of the MG-mediated R561 adduction of PLG is under investigation. (R24DK083948, ABRC, ES016652, T32ES070791, P30ES006694).

253 DICARBONYL ADDUCTION OF PLASMINOGEN: POSSIBLE ROLE IN DIABETIC CARDIOVASCULAR COMPLICATIONS.

O. Kinsky, M. J. Kimzey, G. Tsapralis, T. J. Mons and S. S. Lau, Southwest Environmental Health Science Center, Department of Pharmacology/Toxicology, University of Arizona, Tucson, AZ.

254 POSTTRANSLATIONAL MODIFICATION AND INACTIVATION OF MITOCHONDRIAL COMPLEX I IN KAINATE NEUROTOXICITY.

K. Ryan, L. Liang, D. Backos, P. Reigan and M. Patel, Pharmaceutical Sciences, University of Colorado Denver, Aurora, CO.

Chemoconvulsants such as the excitoxotic glutamate analogue, kainate, can result in acute and chronic hippocampal neurotoxicity resembling damage associated with temporal lobe epilepsy (TLE). We aimed to investigate the role of mitochondrial oxidative stress in the rat kainate model of TLE, specifically its contributions to mitochondrial dysfunction and consequential development of spontaneous seizures (ie. epileptogenesis). We hypothesized that persistent mitochondrial oxidative stress decreases mitochondrial protein function and bioenergetics [mitochondrial redox status (CoASH/CoA), bioenergetics (ATP/ADP), complex I (CI) activity and post-translational modifications to CI subunits] that contribute to epileptogenesis. To address this theory, indices of mitochondrial function were measured in hippocampus of saline and kainate (11mg/kg) treated rats shortly after administration (48hr), prior to the development of epilepsy (1wk), and during epilepsy (6wk). The CoASH/CoA ratio decreased ~70-80% at all time points while CI activity and the ATP/ADP ratio decreased 20-30% at 48hr and 6wk. Furthermore, arginine 76 (Arg76) was oxidatively modified to a semi-glutamatic aldehyde (GSA) product (ie. carboxylation) on the 75kDa subunit of CI, Ndufs1 (75kDa) modification was identified with an Agilent 6510 QTOF LC/MS system and MS/MS peptide data was dually analyzed with Mascot 2.2 (Matrix Science) and SpectraMill (Agilent). A correlation was observed between total mitochondrial carboxylation via biotinylated carbamoylation, specific Ndufs1 carboxylation at Arg76, and inhibition of CI activity. Molecular modeling studies reveal that Arg76 is located in the active site of CI and its carbonylation impacts local protein folding and decreases active site interaction energy (zRank score) by 15%. This irreversible modification has been considered a biomarker for oxidative stress-induced cellular damage and may be a future therapeutic target for chemoconvulsant neurotoxicity. (RO1NS039578).

255 POSTTRANSLATIONAL MODIFICATION AND REGULATION OF GLUTAMATE CYSTEINE LIGASE BY S-GLUTATHIONYLATION.

C. C. Franklin, K. S. Fritz, D. S. Backos, D. R. Peterson and P. Reigan, Department of Pharmaceutical Sciences, University of Colorado Health Sciences Center, Denver, CO.

The glutathione (GSH) antioxidant defense system plays a critical role in maintaining cellular redox homeostasis and counteracting the deleterious effects of oxidative stress. GSH can also be utilized in disulfide exchange reactions resulting in formation of mixed protein-glutathione disulfides and S-glutathionylation of proteins is gaining recognition as an important signal transduction mechanism during oxidative stress. The first and rate-limiting step in GSH biosynthesis is catalyzed by glutamate cysteine ligase (GCL), a heterodimeric holoenzyme composed of a catalytic (GCLC) and modulatory (GCLM) subunit. While cellular GCL activity is highly sensitive to relative GCL subunit expression levels, we and others have demonstrated that post-translational modifications of the GCL subunits may play a major role in the acute regulation of GCL activity. In this study, purified recombinant proteins were utilized to demonstrate that GCLC and GCLM are both direct targets for reversible S-glutathionylation in vitro. S-GLutathionylation increased GCLC activity -2-fold, yet had little effect on GCLM holoenzyme activity. Furthermore, while S-glutathionylation prevented GCLM holoenzyme formation and activity, it did not dissociate the GCLC holozyme complex. The masking of relevant cysteine residues may account for these apparent discrepancies as prior formation of GCLM holoenzyme significantly reduced S-glutathionylation of both GCLC and GCLM subunits. Mass spectrometry analysis identified multiple residues on both GCL subunits that are modified and may be functionally relevant based on in silico molecular modeling. In aggregate, these findings demonstrate that GCLC activity and GCLM holoenzyme formation and activity can be regulated via direct post-translational S-glutathionylation of the GCL subunits in vitro. This novel post-translational regulation of GCL activity could significantly affect cellular redox homeostasis and signal transduction during periods of oxidative stress.

257 PLASMA PROTEIN NITRATION: A USEFUL BIOMARKER FOR DETECTING UNDIAGNOSED COPD IN TOBACCO SMOKERS.

R. C. Zangerl1, H. Jin1, B. Webb-Robertson1, D. Bigelow1, M. Schloand2, J. Hoidal2 and J. Pounds1, 1Cell Biology and Biochemistry, Pacific Northwest National Laboratory, Richland, WA and 2Health Sciences Center, University of Utah, Salt Lake City, UT.

Chronic obstructive pulmonary disease (COPD) affects millions of Americans, with as many as 10 million undiagnosed cases. Early detection of COPD improves long-term prognosis and health, suggesting a need for a simple screen for detecting COPD in high-risk subjects, particularly current and past smokers. We evaluated nitrotyrosine in 25 individual plasma proteins as markers for early detection of COPD. A custom antibody microarray platform was developed to analyze the levels of 3-nitrotyrosine modifications on 24 proteins. Samples from 282 smokers were analyzed, including 193 with COPD and 89 without COPD (nonCOPD). We observed a consistent increase in nitrotyrosine levels in smokers with COPD that is presumably associated with chronic inflammation. When using only the nitrotyrosine protein data, a classification accuracy of 77% in an independent test set could distinguish between smokers with and without COPD. A more favorable classification could be achieved by combining clinical measures with the nitrotyrosine data. In these analyses, age, BMI, systolic and diastolic blood pressures, years smoking and carboxyhemoglobin levels were included. The final classification model was derived from an iterative variable selection routine which found that four variables (age, BMI, nitrated ceruloplasmin and nitrated surfactant protein A) could classify nonCOPD from COPD with an accuracy of 86% in the independent sample set. These data were also examined using receiver operator characteristic (ROC) curves. The ROC curves produced area-under-the-curve values that ranged between 0.55 and 0.69 for the four individual variables, but was 0.81 for the combined variables. Thus, nitrated plasma proteins have promise as biomarkers for identifying subjects that are at high risk for having undiagnosed COPD. Supported by NIEHS Exposure Biology Program, U54 ES016015.
1180 2D-LC-MS ANALYSIS OF OXIDIZED LIPID SPECIES: APPLICATION TO THE STUDY OF CARDIOLIPIN IN APOPTOSIS AND DAMAGED TISSUE.

A. Samhan-Arias1, V. Yturri1, Y. Yturri1, H. Bayir2, V. Kagan1 and A. Amoscato1.
EOH, University of Pittsburgh, Pittsburgh, PA and 2Critical Care Medicine, University of Pittsburgh, Pittsburgh, PA.

Oxidized lipid species are important signaling molecules that usually exist in low abundance in biological tissues. Along with their inherent stability issues, these oxidized lipids present themselves as a challenge in their detection and identification. These oxidized lipid species can co-chromatograph with non-oxidized species making their detection extremely difficult. In this study, a normal-phase and reverse-phase two dimensional HPLC-mass spectrometric system was applied to separate oxidized phospholipids from their non-oxidized counterparts, allowing unambiguous detection in a total lipid extract. We have utilized bovine heart cardiolipin as well as commercially available tetratenoyleoyl cardiolipin oxidized with cytochrome c and hydrogen peroxide as well as with lipoxygenase to test the separation power of the system. We found that oxidized and nonoxidized phospholipid species can be clearly separated from in this two dimensional system. We utilized two biologically relevant model systems, namely rotenone treatment of lymphocytes to induce mitochondrial damage and cell death as well as traumatic brain injury, to separate and identify cardiolipin oxidation products, critical to the cell death pathways in these tissues following cellular stress/injury. We identified oxidized linoleic acid chains (50%) as the preferred moieties for oxidation in cardiolipin, followed by arachidonic (31%) and docosahexaenoic acid chains (18%). The ability of the two-dimensional HPLC-mass spectrometric system to detect and characterize oxidized lipid products will allow new studies to be formulated to probe the answers to biologically important questions with regard to oxidative lipomics and cellular insult. Supported by NIOSH OH008282; NIH U19 A068021, HL70755, HL094488, ES020693, ES021068.

1181 CELL-BASED ANALYSIS OF LIPID PEROXIDATION AND LIPID PEROXIDATION-DERIVED PROTEIN MODIFICATIONS USING FLUORESCENCE MICROSCOPY.

Oxidative stress plays an important role in the progression of several diseases including inflammation, atherosclerosis, aging and age-related degenerative disorders. Reactive oxygen species damage membrane bound lipids including unsaturated fatty acids like linoleic acid and arachidonic acid to form lipid electrophiles, which can rapidly react with proteins and DNA to form adducts. Cell-based measurements of lipid peroxidation and protein carbonylation by fluorescence microscopy provide a powerful platform to quantitate lipid peroxidation in cells and also monitor spatial distribution of damage caused by lipid peroxides. Here, we used 2 different approaches to measure lipid peroxidation in cells. 1) A ratiometric determination of lipid peroxidation using a fluorescent ratiometric lipid probe for live cells which is incorporated into cellular membranes and emits at 590 nm. Under oxidative stress conditions, the oxidation of the dye results in a shift of fluorescence to a peak emission of 510 nm. 2) In a click chemistry based approach, unsaturated fatty acid analogs like linoleic acid alele or arachidonic acid zide are incorporated into the cellular membranes and probe modifications from oxidation, like LINE and DODE can readily modify DNA or proteins. The modified proteins are then analyzed by click reaction using fluorescent tagged alkynes or azides. Using these approaches, we measured lipid peroxidation caused by oxidants like tert-butyl hydroperoxide, cumene hydroperoxide, menadione, hemin and lipopolysaccharide in BPAE and RAW macrophage cells. The oxidants produced 2-3 fold increase in lipid peroxidation and protein modifications when compared to controls. The lipid peroxidation and the lipid peroxide-derived protein modifications were successfully inhibited by using anti-oxidants like tt-tocopherol and mixed tocopherols. The 2 strategies described here to measure lipid peroxidation and the derived protein modifications provide powerful tools to measure oxidative stress in cells.

1182 MALDI MASS SPECTROMETRIC IMAGING OF CARDIOLIPIN AND ITS OXIDATION PRODUCTS DIRECTLY FROM TISSUE SECTIONS IN A LUNG OXIDATIVE DAMAGE MODEL.

L. J. Sparvero, A. Amoscato, B. Pitt and V. Kagan. EOH, University of Pittsburgh, Pittsburgh, PA.

Molecular understanding of lipid functions and signaling mechanisms has created the need for tissue selective assessment for localization of phospholipids and their oxidation products while maintaining tissue integrity. Cardiolipin (CL) is a mitochondria-specific anionic phospholipid that plays key roles in normal mitochondrial functions but also in cell death pathways. The molecular diversity of endogenous CL in some tissues and the low abundance of its individual species, particularly oxidized derivatives, makes in situ analysis challenging. Current Mass Spectrometry protocols using lung homogenates (LC-MS) have greatly enhanced our ability to explore molecular species of CL and its oxidized products. However location-specific information on oxidation cannot be determined from homogenates assuming that oxidative lipidomics analysis of acute lung injury will directly benefit from MALDI-MS imaging, we assessed possible advantages of this frontier technology in characterization of structural lipid changes in the lung. MALDI-MS imaging was performed on thin lung sections from both naive mice and ones receiving glucose oxidase (GOX) intratracheally as a model of oxidative injury. Scanning was at the diameter of the laser beam (20 microns), and each location scanned generated a complete mass spectrum that correlated with tissue location. A strong increase in oxidative degradation products of CL was observed by MALDI-MS imaging. Light microscopy confirms the preservation of tissue structure (without fixation). Serial sections were homogenized and analyzed by LC-MS to confirm the CL species identified by MALDI-MS Imaging. Assignment to an anatomical region suspected to be injured (e.g. airways) has been achieved. Supported by NIOSH OH008282; NIH U19 A068021, HL70755, HL094488, ES020693, ES021068, CCGS-P30 CA047904.
pression from preconfluency to postconfluency. We demonstrate that the pro-oxidant menadione causes dissociation of GSTA1-JNK complex and JNK activation in preconfluent Caco-2 cells only, whereas postconfluent cells are predominantly resistant to menadione-mediated complex dissociation. Our results provide novel evidence that GSTA1 plays a direct role in regulating JNK activation through complex formation. Preconfluent cells are more sensitive than postconfluent cells to menadione-induced cytotoxicity. Additionally, menadione induces transient JNK activation and following the removal of stimulus GSTA1 re-associates with JNK and significantly reduces cellular cytotoxicity. Modulated levels of GSTA1 affect GSTA1-JNK complex association and N-acetyl cysteine blocks menadione-induced JNK activation in Caco-2 cells. These results suggest that the mechanism of menadione-mediated JNK activation involves the production of reactive oxygen species and that the level of intracellular GSH plays an important role in preventing menadione-induced GSTA1-JNK complex dissociation.

1185 MENADIONE-INDUCED OXIDATIVE AND NITROSATIVE STRESS IN C2C12 MYOTUBES.

PS

Department of Biochemistry, University of Texas Health Science Center San Antonio, San Antonio, TX.

Skeletal muscle cells are subject to frequent oxidative challenges due to rapid changes in energy demand and oxygen flux, high metabolic activity, and the presence of high levels of heme-containing proteins. Nitric oxide synthases (NOS), which contain heme, can reduce redox-cycling compounds, which then reduce molecular O₂ to superoxide anion radical(O₂•-), depleting molecular O₂ and causing free radical-mediated oxidative injury and peroxynitrite formation. O₂ reacts with NO to form peroxynitrite, thus potentially decreasing bioavailable NO. Here, we study the effect of the redox-cycler, menadione (Mn), on C2C12 myotubes and the involvement of NOS in Mn-induced oxidative stress using a general and an NOS-specific inhibitor, L-NAME (3 mM) and ETPI (100 μM), respectively. Quantitative real time PCR of myotubes treated with Mn (10 μM) for 24 hours showed slightly increased nNOS expression (~25%), which increased to >2.3-fold with NO inhibitors. Such behavior may indicate that the cells compensate for decreased bioavailable NO with an increase in nNOS expression. Immunohistochemical analyses with Mn +/- NOS inhibitor treatment demonstrate increased nNOS protein expression when compared to myotubes, untreated or treated with NOS inhibitor alone. The expression of cavelin 3 (Cav3), a protein shown both to be necessary for myotube formation and to cause inhibition of NO synthesis by nNOS, was significantly decreased (73%) with Mn treatment. In the presence of ETPI, Cav3 is dramatically decreased (82%), indicating that myotubes may actively down-regulate NOS-inhibitory proteins to increase bioavailable NO. Additionally, Akt1, NFKB1 and INOS were also decreased by 40-50%. With Mn, GPX1 expression was decreased significantly but SOD1 expression was not affected. With NO inhibitors, GPX1 levels were restored whereas SOD1 levels increased more than 2-fold. Further studies are being performed exploring the mechanism involving Mn-induced oxidative/nitrosative stress (Supported by NIH GM052419 to SSM and LJRR).

1186 DETERMINATION OF NITRITE USING A MODIFIED FERROUS OXIDATION-XYLENOL ORANGE (FOX) ASSAY: AN INTERFERENCE TURNED INTO A USEFUL METHODOLOGY.

S. Uppu1, A. D. Logan1, R. M. Uppu1-4 and M. O. Fletcher Claville2-3.
1Chemistry, Southern University, Baton Rouge, LA and 2Environmental Toxicology, Southern University, Baton Rouge, LA.

The Fe²⁺-oxidation-xylanol orange (XO) method of determination of hydroperoxides (ROOH, where R = H, alkyl or aryl moiety), popularly referred to as the FOX assay, is known for its robustness, sensitivity, and adaptability for high throughput screening. The assay is based on the principle that under moderately acidic conditions (pH=1-2) where there is negligible autoxidation of Fe²⁺, there is stoichiometric oxidation of Fe²⁺ to Fe³⁺ by ROOH and the Fe³⁺ so formed can be measured photometrically at 560 nm following complex formation with XO. A number of variations have been sought in the past to expand the application of this basic methodology to ROOH coming from oxidation of lipids, proteins, and nucleic acids. During the course of customizing the FOX assay, we noticed that NO₂⁻ present as an inadvertent contaminant in peroxynitrite (PN) interferes with the determination of ROOH. The NO₂⁻ interference could be abolished when ammonium sulfamate (AS), a chemical scrubber that removes HNO₃, or its putative NO²-carrier ([H₂NO₃]⁺, was added prior to the reaction of Fe³⁺ with ROOH. While the AS pretreatment increased the yields of Fe³⁺-XO complex, it was realized that the FOX assay with some modifications could be used to determine NO₂⁻ with detection limits that are similar to those reported for typical ROOH. The formation of Fe³⁺-XO complex was linear over the NO₂⁻ concentration range of 1 to 20 μM and the addition of AS completely abolished the increase in A₅₆₀ nm at all concentrations of NO₂⁻. These results indicate the specificity of the FOX assay for NO₂⁻ through use of AS-treated controls. These findings are important and timely in view of an ever increasing interest in the physiology of NO₂⁻ and numerous pathological states (urinary tract infections and pediatric acute kidney injury) wherein simultaneous determination of NO₂⁻ and H₂O₂ is indicated. [Support from NSF (HRD1043316 and HRD 0847742) and the US Department of Education (P031B040030) is acknowledged].

Tissues and organs express different levels of antioxidants, such as glutathione (GSH). Exposure to environmental toxins and/or pharmaceutical drugs induces differential organ-specific responses and/or damage. Acetaminophen (APAP) is an analgesic and antipyretic drug that can cause severe liver damage when high doses are administered. The damage is caused by the depletion of intracellular GSH and an excess of N-acetyl-p-benzoquinone imine (NAPQI) metabolite that reacts with cellular and mitochondrial proteins producing cell damage and tissue necrosis by mechanisms involving oxidative stress. In this study, we analyzed the response to an intraperitoneal (i.p.) injection (300 mg/kg) of APAP at 1, 2 and 3 h after administration in the livers, brains, and kidneys of BALB/c male mice. We observed a significant decrease in the levels of GSH in the livers and kidneys, and an increase in the transcription of Nrf2 and Grx-1 in the liver. In the brain, we found an increase in the transcription of Grx-1 and Trx-1 associated with NP-kB nuclear migration. In the kidney, the up-regulation of these antioxidant proteins was not observed, which coincides with the significant increase in lipid peroxidation.

PS

1188 COMPARISON OF N-ACETYLCYSTEINE, S-METHYL-CYSTEINE AND AMINOMETHANESULFONIC ACID FOR THE ABILITY TO ATTENUATE ACETAMINOPHEN-INDUCED CHANGES IN PLASMA INDICES OF OXIDATIVE STRESS IN THE RAT.

S. Koganti, M. C. Parikh and C. A. Lau-Cam.
Pharmaceutical Sciences, St. John's University, Jamaica, NY.

Three sulfur-containing compounds representing an analog of cysteine (N-acetyl-cysteine = NAC, S-methylcysteine = SMC) or homolog of taurine (aminomethanesulfonic acid = AMSA) were compared for the ability to attenuate changes in plasma indices of oxidative stress induced by acetaminophen (APAP) in a rat model. Sprague-Dawley rats (225-250 g), assigned to groups of n = 6, were treated with a single, 800 mg/kg, i.p. dose of APAP. The treatment compounds (2.4 mmol/kg, i.p.) were administered 30 min before APAP. At 6 h after APAP administration, the rats were sacrificed by decapitation and their blood collected over sodium heparin. Control groups received only physiological saline (PHS, 2 mL, i.p.) or only APAP. The plasma fractions were assayed for malondialdehyde (MDA), lipid oxidation (NO₂, reduced (GSH) and oxidized (GSSG) glutathione contents, and for antioxidant enzymes (catalase, glutathione peroxidase, superoxide dismutase), glutathione reductase and glutathione S-transferase activities. APAP elevated the plasma levels of MDA and NO₂, reduced those of GSH, and GSSG and inhibited the activities of antioxidant and GSH-related enzymes to a significant extent (all changes by ≥±3%, p<0.001) compared to corresponding values for rats receiving only physiological saline. Without exceptions, these alterations were attenuated by a sulfur-containing treatment compound, with the order of potency usually decreasing in the order NAC>SMC>AMSA. These results suggest that small molecular weight sulfur-containing compounds (1-3 carbon long) containing a sulfonate or a sulfonic acid group (AMSA) or the cysteine structure plus a S-acyl (SMC) or N-acetyl (NAC) substituent can offer different degrees of protection against oxidative
1189 ALL-TRANSRETINOIC ACID AFFORDS CYTOPROTECTION AGAINST REACTIVE OXYGEN SPECIES-INDUCED RENAL INJURY.

J. Sapir1, J. Lord-Garcia2, Z. Ita1, A. Gallegos1, R. D. Canatsey1, T. L. Monks1 and S. S. Lau1. Department of Pharmacology/Toxicology, University of Arizona, Tucson, AZ

Ischemia reperfusion injury (IRI) and chemical-induced nephrotoxicity are major etiologic factors of acute kidney injury during which reactive oxygen species are released. 11-Deoxy-16,16-dimethyl-prostaglandin E2 (DMD-PGE2) protects against 2,3,5-tris(glutathione-5)-phylloquinone (TGHQ) induced ROS-dependent cell death in LLC-PK1 cells. Immuno blotting and proteomics analyses revealed that DMD-PGE2 cytoprotection was associated with a time-dependent increase in retinol binding protein (RBP) synthesis, suggesting that retinoid signaling is engaged during this process. Pharmacological manipulations that abolished the ability of DMD-PGE2 to induce RBP abrogated its cytoprotective effects, further indicating that RBP is necessary for DMD-PGE2 mediated cytoprotection. While both all-trans-retinoic acid (ATRA) and 9-cis-retinoic acid (9-cisRA) possess biological activity, pretreatment with ATRA, but not 9-cisRA, afforded cytoprotection in LLC-PK1 cells, following TGHQ treatment. Moreover, the cytoprotective kinetics of ATRA and DMD-PGE2, were identical, with maximal RBP induction and cytoprotection occurring at 12 and 24 hours, respectively. Chemical hypoxia was established in LLC-PK1 cells to recapitulate IRI conditions by exposing cells to 0.1 or 1 μM antimycin A for 1 hr followed by glucose-free media. Consistent with the effects of ATRA on TGHQ-induced cytopotoxicity, ATRA pretreatment completely protected hypoxic cells from cytoxicity as assessed by a mitochondrial dehydrogenase enzyme activity assay (MTT). Moreover, ATRA significantly reduced 8-oxo-deoxyguanosine levels in human kidney HK2 cells after TGHQ challenge. Collectively, these data reveal that ATRA protects renal cell injury, at least in part, via suppression of ROS-mediated oxidative damage. Therefore, ATRA may provide an effective therapeutic strategy in chemical-induced renal injury or pathological conditions where ROS contribute to the disease progression. (ES006694, ES016578).

1190 ALIPHATIC ALCOHOLS MAY PRODUCE NEPHROTOXICITY VIA OXIDATIVE STRESS(OS) AND INFLUENCE SIRT1 AND FOXO3A EXPRESSION IN VIVO.

A. Patel1, V. Lawana2 and S. D. Ray1, 2. 1Pharmacological Sciences, AMS College of Pharmacy, Brooklyn, NY and 2Pharmaceutical Sciences, Manchester College School of Pharmacy, Fort Wayne, IN.

Most tissues survive in hostile environments by activating stress-responsive transcriptional regulators that coordinately increase production of protective factors. Sirt1 is a key player in this pathway which dictates the regulation of important intracellular proteins such as, p53 and FOXO3A; FOXO3A inturn regulates antioxidant enzymes, such as, catalase & MnSOD. This study explored whether a series of aliphatic alcohols (methanol, ethanol, isopropanol & t-Butanol) produce OS and influence key members of the Sirt1 pathway (FOXO3A, p53, AROS & HIC1). To explore the underlying mechanisms, LD40 doses (25% soln in H2O) of these alcohols were administered orally via gavage to mice. Sirt1, p38 and ERK1/2 inactivation was observed following Cr6+ exposure. Western blot analysis revealed Butanol decreased Sirt1 expression, whereas it increased p38 phosphorylation and ERK1/2 activation, as indicated by ERK1/2 phosphorylation. Cr6+ induced ROS generation since 5 min until 1 h, and at 6 h ROS level was as a control. ROS were induced in the cells simultaneously treated with alpha-tocopherol only at 5 and 10 min, and notably in presence of alpha-tocopherol ERK1/2 was not activated. Our results showed a clear relationship between the induction of ROS and the activation of ERK1/2 in NRK-52E cells; these effects was associated with the internalization of occludin and changes in the Dextran-FITC flux.

1191 ROLE OF OXIDATIVE STRESS AND MAPK SIGNALING PATHWAY IN OCCLUDIN SUBCELLULAR DISTRIBUTION IN THE NRK-52E CELLS.

E. Hassoun1, J. Carolyn2 and A. Al-Dieri1. Pharmacology, University of Toledo, Toledo, OH.

Dicluroracetate (DCA) and trichlororacetate(TCA) are byproducts formed during the process of drinking water chlorination and were previously found to induce phagocytic activation and oxidative stress in the hepatic tissues of B6C3F1 male

1192 METABOLISM-LINKED MACROPHAGE ERYTHROCYTE COCULTURE ASSAY TO PREDICT THE HEMOLYTIC POTENTIAL OF 8-AMINOQUINOLINE ANTIMALARIALS IN G6PD-DEFICIENCY.

J. M. McMillan1, 2, N. A. Schulte1 and D. C. McMillan3. 1Pharmacology and Experimental Neuroscience, University of Nebraska Medical Center, Omaha, NE and 2Environmental, Agricultural, and Occupational Health, University of Nebraska Medical Center, Omaha, NE.

Existing preclinical toxicology procedures have been poorly predictive of the hemolytic potential of 8-aminoquinoline antimalarial drug candidates that are subsequently found to cause hemolytic anemia in patients with hereditary deficiencies of erythrocytic glucose-6-phosphate dehydrogenase (G6PD). A major limitation of existing in vitro approaches to predict hemolytic potential is that they do not reproduce the in vivo response, namely premature removal of oxidatively-damaged erythrocytes from the circulation by macrophages in the spleen. We hypothesize that an ex vivo human G6PD-deficient erythrocyte-macrophage co-culture system can overcome this limitation and provide a screening tool to support 8-aminoquinoline antimalarial drug development. To test this approach, we incubated human normal and G6PD-deficient erythrocytes ± pooled human liver microsomes (HLM) with primaquine (500 μM) for 1 hr at 37°C. After the incubation the erythrocytes were collected and co-incubated with J774A.1 murine macrophages for 24-48 hr to determine phagocytosis. Phagocytic uptake was assessed by 51Cr/PK4H6 labeling of erythrocytes. Uptake of erythrocytes exposed to primaquine in the absence of HLM was not significantly different from uptake of controls. In the presence of HLM, primaquine induced a significant increase in phagocytosis of normal erythrocytes, and this response was enhanced significantly in G6PD-deficient erythrocytes. These results suggest that a metabolism-linked human erythrocyte-murine macrophage co-culture system can serve as a valid model for assessing parent drug effects on human G6PD-deficient erythrocytes. Supported by UMiss subcontract (USAMRMC W81XWH-07-2-0095).

1193 INDUCTION OF PHAGOCYTIC ACTIVATION BY MIXTURES OF DICHLOROACETATE AND TRICHLOROACETATE IN MICE AFTER SUBCHRONIC EXPOSURE.

E. Hassoun, J. Carolfo and A. Al-Dieri. Pharmacology, University of Toledo, Toledo, OH.

Dichloroacetate (DCA) and trichloroacetate(TCA) are byproducts formed during the process of drinking water chlorination and were previously found to induce phagocytic activation and oxidative stress in the hepatic tissues of B6C3F1 male
mice after subacute and subchronic exposure. In order to determine the effects of mixtures of DCA and TCA on phagocytic activity, groups of male Balb/c mice were treated daily, by gavage, with 3 different mixtures (Mix I, Mix II and Mix III) of the compounds for 13 weeks. The concentration of each compound in Mix I, II and III corresponded respectively to that producing 15%, 25% and 35% of maximal induction of various biomarkers of phagocytic activation, including superoxide anion (SA) and tumor necrosis factor (TNF)-alpha production and myeloperoxidase (MPO) activity in the subchronic studies. The mice were euthanized at the end of the treatment period and peritoneal lavage cells were collected and assayed for the levels of SA and TNF-alpha, as well as for MPO activity. While the effects on all of the biomarkers in response to Mix I and II were additive, they were less than additive in response to Mix III. DCA- and TCA-induced phagocytic activation by the compounds was previously suggested as an adaptive response to protect against their long term hepatotoxicity, hence the resultant effects may be viewed as adaptive/protective in response to Mix I and II, and as a protection failure in response to Mix III. (Supported by NIH/NIEHS grant # R15ES013706-01A2)

1194 AGE-RELATED AND CIRCADIAN CHANGES IN THE REDOX CYCLE IN MALE SPRAGUE DAWLEY RATS.

F.Y. Mohammed, W. Day and D. Zamorano. Biology, University of Texas Pan American, Edinburg, TX.

It is apparent that a major protective role against the reactive chemical intermediates, which are generated by bireduction and cause oxidative stress by redox cycling, is provided by the ubiquitous glutathione (GSH) redox cycle. In this study we have investigated the age related and circadian fluctuations in the levels of GSH and those of lipid peroxides in normal male Sprague Dawley rats. Normal rats (~200 g) were divided into different groups of 4-5 animals each. For circadian changes the groups animals were killed at 4 hours intervals within a 24 hour cycle. Blood and the organs studied exhibited distinct circadian variation both in GSH concentrations and peroxidation of polyunsaturated fatty acids. There was a great variation among organs in the periodicity and amplitude of the fluctuations in GSH concentrations. Liver displayed the highest variation (50%) followed by stomach (~37%), heart (~25%) and kidney (~19%). The changes in other organs were significant but of less magnitude. For age-related changes various tissues of animals of different age groups (1-36 months) were used. At all ages the GSH content in the liver was 3-10 times higher that of other tissues. In the oldest group (36 months) of rats the GSH content of all tissues studied were lower (35-60%) than that in 2.5 month old rats. The lipid peroxide levels increased by age in all tissues studied. Implications of such variations and caution in interpretation of experimental results in response to the exposure of animals to xenobiotics are significant. The studies also indicate that general characteristics of aging tissue may include a decrease in GSH content and increase in lipid peroxidation showing a decrease in redox cycling in senescence.

1195 GELSOIN’S FUNCTIONS IN HEAVY ACUTE RADIATION INJURY MOUSE AND CELL MODELS.

R. Min, J. Wang, Y. Cheng, D. Sun and M. Li. Naval M, Second Military Medical University, Shanghai, China. Sponsor: E. Zhou.

Background Many factors involved in pathological process of heavy acute radiation injuries remain to be revealed to reduce mortality during treatment. Actin is suspected releasing to tissue gap and blood pool from damaged tissues and cells during radiation damage and would result in a secondary pathologic effect including dynamic change of blood flow, blood vessel wall damage and other cytotoxicity. Gelsolin as one of main actin scavenging proteins had been found with antiinfection and antioxidation functions. Understanding potential function of gelsolin in radiation damage might be helpful to find new way to reduce pathological damage and improve survival rate of heavy acute radiation syndrome. Methods BALB/c mice whole body and cultured human intestinal epithelial cells (HEC) in vitro were exposed to a 137Cs γ-ray source with different doses and a fixed dose rate. The changes of plasma GSN (pgGSN) level in peripheral blood of the mice and cytoplasmic (cGSN) level in cultured cell line were respectively determined. A recombinant pgGSN was injected into irradiated mice body through tail vein after irradiation and prothrombin time (PT), activated partial thromboplastin time (APTT), glutathione (GSH) and malonaldehyde (MDA) indexes which could respectively indicate coagulation and oxidative damage in tissue were analyzed at different times post radiation and pgGSN given. Results Radiation induced pgGSN level decrease in peripheral blood of the mice and cGSN level increase in cultured HEC with a dose-dependent manner. Giving of recombinant pgGSN to radiated mice after radiation, bleeding effect ameliorated as indicated by PT and APTT and antioxidative ability increased as indicated by GSH and MDA indexes. Conclusions GSNs might have involved in pathologic proceeding of acute radiation damage and recombinant pgGSN supplement to the heavy injured mice might act some protective functions by improving coagulant and antioxidative mechanisms.

1196 INCREASED OXIDATIVE STRESS STATUS IN NEURONAL CELLS EXPOSED TO XENOESTROGEN BISPHENOL A.

S. Babu, A. C. Raghavamenon and R. M. Uppu. Environmental Toxicology, Southern University, Baton Rouge, LA.

Bisphenol A (BPA) is a semi-persistent organic pollutant in industrial and urban environments. Epidemiological studies have shown that urinary levels of BPA are positively associated with higher incidence of cardiovascular disease, diabetes, and abnormal concentrations of liver enzymes in non-institutionalized US populations and increased expression of oxidative stress markers in postmenopausal Korean women. Male albino rats exposed to low levels of BPA were shown to have decreased antioxidant enzymes. To understand the significance of oxidative stress in BPA-induced toxicity, in the present study, we examined formation of intracellular peroxides and superoxide anion (O2·−) in murine GT-17 hypothalamic neurons exposed to low levels of BPA. It was found that GT-17 neurons exposed to BPA (25-100 μM) have increased levels of intracellular H2O2 or other peroxides (DCF fluorescence) when compared to control, vehicle-only exposed cells. The production of peroxides in BPA exposed neurons was comparable to that observed in cells exposed to menadione (25 μM; positive control) and was found to be linear for periods up to 8 h. When co-incubated with N-acetyl-L-cysteine (NAC; 5 mM), in both BPA- and menadione-exposed cells, there was little or no increase in the generation of peroxides. In contrast, exposure to 1,4-Diamino-2-butanone (DAB), a putrescine analogue, is highly toxic to various cell lines and peroxides in BPA exposed neurons was comparable to that observed in cells exposed to menadione (25 μM; positive control) and was found to be linear for periods up to 4 h. Co-incubation with Trol ox (0.5 mM) also markedly decreased the production of O2·− in these neuronal cells. Taken together with results of our previous studies wherein it was shown that BPA phenolate radical has strong pro-oxidant properties, these results suggest that BPA induces the cellular oxidative stress presumably by promoting oxidation of cellular redox carriers and increased production of intracellular O2·− and peroxides.

1197 PRO-OXIDANT ACTIVITY AND CYTOTOXICITY OF 1, 4-DIAMINO-2-BUTANONE TO MAMMALIAN CELLS AND TRYPANOSOMA CRUZI.

1 Gênicas Esatas e da Terra, Universidade Federal de São Paulo, Diadema, Brazil, 2Biogeorgia, Universidade de Sao Paulo, Sao Paulo, Brazil, 3A.B. Hancock Jr. Memorial Laboratory for Cancer Research, Vanderbilt University, Sao Paulo, Brazil.

1,4-Diamino-2-butanone (DAB), a putrescine analogue, is highly toxic to various microorganisms including Trypanosoma cruzi. However, little is known about the molecular mechanisms underlying its cytotoxic properties. Here we show that DAB undergoes aerobic oxidation in phosphate buffer, pH 7.4, catalyzed by Fe(II) and Cu(II) ions yielding NH4+ ion, H2O2 and 4-amino-2-oxobutanal. Propagation of DAB oxidation by superoxide radical was confirmed by the inhibitory effect of added SOD and stimulatory effect of xanthine/xanthine oxidase. EPR spin trapping studies with 5,5-dimethyl-1-pyrroline-1-oxide (DMPO), revealed the intermediary of an adduct attributable to DMPO-HO· radical, and with α-(4-pyridyl-1-oxide)-N-tert-butylnitrone (POBN), a 6-line adduct assignable to POBN-DAB radical. DAB (0.05 - 10 mM) showed to be more toxic to RKO (human colon carcinoma) cultured cells (IC50 ~0.3 mM DAB, 24 h incubation) than to LLC-MK2 cells (IC50 ~ 1.5 mM DAB, 24 h incubation), derived from Rhesus kidney epithelium. Changes in redox balance and stress response pathways were induced by increased expression of Nrf-2, HO-1, NQO1 and xCT proteins. Caspase 3 and PARP cleavage products suggested DAB-triggered apoptosis in RKO cells. Similarly, DAB (0.05 - 5 mM) treatment of trypomastigotes, the infective stage of T. cruzi, led to a decrease of cell viability (IC50~0.2 mM DAB, 4 h incubation), and thiol redox imbalance dependent on the DAB concentration, parallel to an increase in T. cruzi SOD activity. Accordingly, host cell invasion by trypomastigotes was also hampered by DAB administration. Altogether, these data support the hypothesis that DAB exhibits a toxicological profile comparable to the current large spectrum of microorganisms, including T. cruzi. Support: FAPESP, CNPq, INCT Redoxoma, and NIEHS 5P01ES013125.
**1198 SULFUR DIOXIDE PROMOTES A PRO-OXIDANT SHIFT IN IL-10-DEFICIENT MICE WITH AIRWAY INFLAMMATION.**

A. L. Reno¹, L. M. Hallberg², W. C. Spear³, J. L. Parks¹, M. F. Prince³, E. G. Brooks³ and B. T. Ameredes¹.

¹Internal Medicine, University of Texas Medical Branch, Galveston, TX; ²Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX and ³Pediatrics, University of Texas Health Science Center, San Antonio, TX. Sponsor: C. Ellerlink.

**RATIONALE:** Inhaled sulfur dioxide (SO2) at low concentrations (1-5 ppm) can produce bronchospasms in asthmatics, linked to increased oxidative stress, airway inflammation (AI), and airway hyperresponsiveness, potentially because they are deficient in IL-10 production. We tested this hypothesis in IL-10-deficient C57Bl6 (C57), and IL-10 knockout (+/-) mice, with experimentally-induced AI. METHODS: AI was induced by sensitization and challenge with ovalbumin (OVA), +/- inhaled SO2 (either during sensitization or post-sensitization (PS) with simultaneous OVA challenge, 1 ppm for 6 hr/day over 10 days). Bronchoalveolar lavage fluid (BALF) was analyzed for leukocyte counts; a pro-oxidant/anti-oxidant balance (PAB) assay provided an index of oxidative stress, and heme oxygenase-1 (HO-1) in lung homogenates was measured by ELISA, as a stress indicator. RESULTS: BAL macrophages remained unchanged across OVA and SO2 treatments, except for IL-10+/- mice, in which OVA + SO2 increased maces by 35% (P<0.05). As expected, BAL eosinophils (eos) were significantly increased by OVA challenge, but with OVA + SO2, eos were decreased in C57 mice (40%; P<0.05), and increased nearly 3-fold in IL-10/- mice (P<0.05). In IL-10/- mice, HO-1 expression was positively correlated with eos (Rsq=0.72; P<0.01), but not in C57 mice. OVA-challenge did not alter the PAB in C57 mice, and remained unchanged with SO2 during sensitization, but increased nearly 2-fold toward pro-oxidative, with SO2 + OVA PS (P<0.05). In the absence of IL-10, this balance was further shifted toward pro-oxidative, by another 14% (P<0.05). CONCLUSIONS: The results indicate that IL-10 is a critical factor in the eosinophilic and oxidative stress responses of the airway to SO2 inhalation, and its lack may be why asthmatics experience detrimental effects at low SO2 concentrations.

**1199 SELENOPROTEIN P REGULATES PCB3 METABOLITE-INDUCED CYTOTOXICITY IN HUMAN KERATINOCYTES.**

We previously showed 2-(4-chlorophenyl)-benzo-1.4-quinone (4-ClBQ), a metabolite of PCB3, forms a semiquinone radical, which in presence of oxygen generates superoxide leading to oxidative stress-induced DNA damage, inhibition in proliferation, and enhanced toxicity. This study was designed to investigate whether specific oxidative stress responsive genes regulate cellular responses to 4-ClBQ treatments. Microscopic observations showed significant change in the cytoskeleton of 4-ClBQ (1-3 μM, 1-5 days) treated human immortal keratinocytes, which was accompanied with a decrease in proliferation and an increase in cytotoxicity. 4-ClBQ treatments exhibited a G2-delay. Flow cytometry measurements of MitoSOX and MitoTracker oxidation demonstrated elevated levels of mitochondria (e.g. CuZnSOD, EcSOD, GPx-3, and DUSP1) in 4-ClBQ treated cells. Twenty-four hours after 2-hour exposure to 4-ClBQ, the expression of CuZnSOD, EcSOD, GPx-3, and DUSP1 was significantly decreased in all the down-regulated genes. SEPP1 is a major Se-protein that is known to reduce phospholipid hydroperoxide as well as transport Se. Sodium-selenite pre-treatment among all the down-regulated genes. Results suggest that 4-ClBQ-induced decreases in GPx1 mRNA in spite of up-regulation of other antioxidant enzyme mRNAs. This change was also observed in soleus skeletal muscles of rats treated with MeHg. MeHg-induced decrease in GPx1 mRNA was not suppressed by the co-addition with antioxidant Trolox but by the pretreatment with sodium selenite, suggesting that the decrease in GPx1 mRNA was due to MeHg-induced relative intracellular selenium deficiency. This notion was supported by the inhibition study of nonsense-mediated mRNA decay (NMD), which recognizes a UGA codon for selenoproteins on GPx1 as a nonsense codon and degrades GPx1 mRNA in selenium-deficient condition. In contrast, thioredoxin reductase 1 (TrxR1), another antioxidant selenoprotein, was likely skipped by NMD because of a UGA codon in the last exon. However, TrxR1 activity was decreased despite mRNA up-regulation, which was probably due to the synthesis of aberrant TrxR1 protein without selenocysteine. Changes in selenoproteins GPx1 and TrxR1 mRNAs were observed earlier than was the incidence of oxidative stress and upregulation of other antioxidant enzyme mRNAs. Results indicated that the MeHg-induced relative selenium deficiency condition affects the major antioxidant selenoproteins GPx1 and TrxR1 through a posttranscriptional effect, resulting in the disturbance of cellular redox systems and the incidence of oxidative stress.

**1200 POSTTRANSCRIPTIONAL DEFECTS OF ANTIOXIDANT SELENOENZYMES CAUSE OXIDATIVE STRESS UNDER METHYLMERCURY EXPOSURE.**

F. Usuki¹, A. Yamashita² and M. Fujimura³. ¹Clinical Medicine, National Institute for Minamata Disease, Minamata, Japan; ²Department of Microbiology and Molecular Bioinfomeric Research, Yokohama City University School of Medicine, Yokohama, Japan and ³Department of Basic Medical Sciences, National Institute for Minamata Disease, Minamata, Japan. Sponsor: A. Nagamune.

The critical role of oxidative stress in the pathogenesis of methylmercury (MeHg) cytotoxicity has been clarified, but the molecular mechanisms underlying MeHg-mediated oxidative stress remain to be elucidated. Here we demonstrate a posttranscriptional effect of MeHg on antioxidant selenoenzymes by using a myogenic model cell line showing apoptosis by exposure to MeHg. Quantitative real-time PCR analysis showed down-regulation of the major antioxidant selenoenzyme, glutathione peroxidase 1 (GPx1) mRNA in spite of up-regulation of other antioxidant enzyme mRNAs. This change was also observed in soleus skeletal muscles of rats treated with MeHg. MeHg-induced decrease in GPx1 mRNA was not suppressed by the co-addition with antioxidant Trolox but by the pretreatment with sodium selenite, suggesting that the decrease in GPx1 mRNA was due to MeHg-induced relative intracellular selenium deficiency. This notion was supported by the inhibition study of nonsense-mediated mRNA decay (NMD), which recognizes a UGA codon for selenoproteins on GPx1 as a nonsense codon and degrades GPx1 mRNA in selenium-deficient condition. In contrast, thioredoxin reductase 1 (TrxR1), another antioxidant selenoprotein, was likely skipped by NMD because of a UGA codon in the last exon. However, TrxR1 activity was decreased despite mRNA up-regulation, which was probably due to the synthesis of aberrant TrxR1 protein without selenocysteine. Changes in selenoproteins GPx1 and TrxR1 mRNAs were observed earlier than was the incidence of oxidative stress and upregulation of other antioxidant enzyme mRNAs. Results indicated that the MeHg-induced relative selenium deficiency condition affects the major antioxidant selenoproteins GPx1 and TrxR1 through a posttranscriptional effect, resulting in the disturbance of cellular redox systems and the incidence of oxidative stress.

**1201 TIME-DEPENDENT EFFECTS OF URANIUM ON CELLULAR OXIDATIVE STRESS MARKERS.**

Oxidative stress is a common mechanism of many heavy metals but is poorly described concerning a particular one, Uranium (U). This mechanism is regulated by transcription factors, in particular Nrf2, which induces transcription of many antioxidant enzymes namely catalase (CAT), Copper, Zinc Superoxide Dismutase (Cu, Zn SOD) or Heme Oxygenase 1. The aim of this work was to study how U induces a cellular disturbance of pro/antioxidative equilibrium and cell death at different times (1 to 24 hours) and different concentrations (10 to 1000 μM) on a Human liver hepatocellular carcinoma cell line (HepG2). Antioxidative enzymes, Nr2, caspases and cell death were evaluated at mRNA and activities levels. After 24 hours of exposure with 500 μM of U, cell death was enhanced 10 folds (p<0.001). Furthermore, activity of caspases 3 and 7 was increased 4 folds (p<0.05), suggesting a cell death by apoptosis pathway. No cell death or caspase activation were observed at lower range.

Gene expression of CAT showed first at 50 μM of U an increase (4 folds, p<0.05) after one hour, whereas a decrease after 2 (45% as compared to control, p<0.01) and 4 hours of exposure (-76% as compared to control, p<0.01) was observed. The study of another antioxidant enzymes Cu, Zn SOD underlined the same variations (p<0.05) as CAT for one and 2 hours. Accordingly, gene expression of Nr2 was similarly modified at 50 μM of U, an increase of 5 folds after 1 hour and a decrease of 80% after 2 hours of contamination (p<0.05) and 90% after 4 hours (p=0.01).

Regarding these data, contamination of U seems to induce Nr2 and antioxidant enzymes at low concentrations without leading to caspase activation. For higher U concentrations, activation of caspases and death cell were observed. Kinetics results suggest that adaptive mechanisms of antioxidative system could be set up at low concentration.

**1202 INVESTIGATION OF NOVEL ROLES FOR HEME OXYGENASE IN RESISTANCE TO CADMIUM-INDUCED OXIDATIVE STRESS.**

C. George and M. Jenny. Biological Sciences, University of Alabama, Tuscaloosa, AL.

Cadmium (Cd) is a toxic metal capable of causing severe oxidative stress. Cd-resistant cells, when exposed to a variety of chemicals capable of inducing oxidative stress, exhibit significantly lower occurrences of apoptosis compared to non-resist-
ant cells, suggesting that Cd-resistance is at least in part an adaptation to oxidative stress. To begin investigating the role of hiruligin-hirulin recycling in adaption to Cd-induced oxidative stress, we exposed the human HepG2 Tet-On (Clontech Laboratories, Inc) cell line continuously during culture to 1 or 5 μM of Cd for a period of 12 weeks. Several papers routinely dosed HepG2 cells with Cd concentrations ranging from 5 to 120 μM and have proposed a 24 h LC50 of ~24μM (Shimoda et al 2001, Tox Sci) and an IC50 of ~14 μM as determined by the MTT assay (Lawal and Ellis, 2010, J. Toxicol Sci). Based on these studies, we dosed the control and Cd-adapted HepG2 cell lines with 1, 5, 10 and 25 μM of Cd for 4 hours before measuring gene expression. qPCR was used to determine the expression level of metallothionein (MT-1b) and heme oxygenase 1 (HO-1), the rate limiting enzyme in the catabolism of heme to bilirubin, in response to the additional Cd treatments. Interestingly, although overall expression of MT-1b and HO-1 was significantly increased in both the 1 μM and 5 μM HepG2 cell lines at all dose compared to control HepG2 cells, all three cell lines had an inverted U-shaped dose response curve with maximum induction of gene expression at 1 μM and suppression at the higher concentrations. A similar dose-response curve was assessed using a regular HepG2 cell line and the same U-shaped dose response curve was obtained. New dose-response experiments with the control, 1 μM and 5 μM HepG2 Tet-On cell lines were performed with Cd concentrations ranging from 20 nM to 1 μM and yielded classic dose-response curves. These data suggest that HepG2 cells may be even more sensitive to Cd toxicity than previously determined. Current efforts are underway to create a HO-1 stable transfected cell line to assess the role of HO-1 in Cd adaptation. [R00E50170404]

1203 THE BODY WEIGHTS AND FLUORIDE CONCENTRATIONS IN THE URINE OF ICGN MICE AND ICR MICE AFTER SUBACUTE ADMINISTRATION VIA DRINKING WATER.

1Preventive Medicine, Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan, 2Preventive Medicine and Public Health, Iwate Medical University School of Medicine, Morioka, Iwate, Japan and 3National Institute of Health Sciences, Tokyo, Japan.

The contaminations of ground water by fluoride (F) have been reported in China and India. Many inhabitants who drink well water with high concentrations of F are suffering from endemic fluorosis. F is excluded from the kidney. Greater accumulation of F occurs in ICR-derived glomerulonephritis mice (ICGN) which have impaired renal function and affects them more seriously in our previous study. The xenobiotics of F in animals with impaired kidney function is not elucidated. The F concentrations in the urines of ICGN and ICR mice were determined in this study. F was administered to ICGN mice at 0, 50, 100 and 150 ppm and ICR mice at 0, 100 and 150 ppm in drinking water for four weeks. When a mouse died, the data of the day of death or nearest to the day of death was assigned. The body weight of each mouse were monitored daily. The urine of each mouse was sampled once a week by using a metabolic cage. F in the urine were determined by a flow injection apparatus with a F-selective electrode as the detector. All ICGN mice exposed to 100 and 150 ppm died during the observation period. The mean body weight in the 100 and 150 ppm ICGN mice was significantly lower than those in the 0 and 50 ppm. For each ICGN group, there were no significant differences in the urine F concentration in the between the beginning and the end of the observation. For ICR mice, no mice died, and the mean body weight were not significantly different among the groups. The mean urine F concentration at the end was significantly higher than that at the beginning in the 150 ppm group. F in the drinking water at 100 ppm and more was lethal for the ICGN mice. Fluoride in the urine at the end was higher compared to the beginning in ICR mice but not in the ICGN mice, suggesting the impairment of the exception of F in the ICGN mice.

1204 INCREASED KIDNEY TUBULAR DAMAGE MARKERS IN RATS EXPOSED SUBCHRONICALLY TO FLUORIDE.

C. Cardenas, L. Del Razo and O. Barbier. Department of Toxicology, Cinvestav, Mexico City, Mexico.

Fluoride (F−) is a frequent contaminant in drinking water. Some in vivo and in vitro studies employing tissue samples are employed to assess the early injury caused by toxic agents. The aim of this study was to determine the kidney injury induced by the F− exposure at environmental relevant concentrations. Male rats recently weaned, were exposed through drinking water at two concentrations of F− (15 and 50 mg/L) for 40 days. At the end of the study, blood and urine samples were collected, and urinary injury biomarkers (β-2-Microglobulin, clusterin, Kim-1, cystatin C, osteopontin) were measured using Lumexin xMAP technology. Mean urine F− levels were 0.88, 5.68 and 18.17 μg/g creatinine for the control and exposed low and high F− groups, respectively. The rats exposed to F− showed an increase of the median Kim-1 excretion in urine 2.39 (0.63-5.29), 3.39 (2.35-7.83) and 4.86 (0.66-14.83) ng/24h for groups exposed to 0, 15 and 50 μg/L, respectively. Moreover, the urine level of clusterin was also increased as follows: 192.6 (111.8-304.6), 238.6 (161.1-368.3) and 269.6 (206.6-632.1) ng/24h for groups exposed to 0, 15 and 50 μg/L, respectively. These results show for the first time that F− exposure at environmentally relevant concentrations is able to increase some novel especially sensitive and specific markers of tubular injury, suggesting that F− could be a risk factor in the promotion or progression of renal diseases and have likewise an enhanced sensitivity to nephrotoxins like some antibiotics. 1205 IDENTIFICATION OF PRENATAL KIDNEY INJURY BY THE DETECTION OF EARLY BIOMARKERS IN AMNIOTIC FLUID.

T. Jacobo, M. Cárdenas-González, A. De Vizcaya-Ruiz and O. Barbier. Toxicology, Cinvestav, Mexico City, Mexico.

Over recent years, nephropathies have been rising in infants and newborns in Mexico, and worldwide. Prenatal exposure to cadmium (Cd2+)−, a nephrotoxic agent ubiquitous in the environment, could be related to some of these cases as it has been demonstrated that it can be freely diffused through placenta and accumulate in the kidney. Amniotic fluid, mainly formed of fetal urine, contains proteins whose concentrations change depending on the developmental stage of the fetal kidney. Some of these proteins could be used as biomarkers of congenital renal pathologies. However, amniotic fluid as a potential matrix to diagnose kidney injury has yet not been considered. Pregnant Wistar rats were exposed to Cd2+ (gavage, 0.6 mg/kg/day) and gentamicin (subcutaneous injection, 75 mg/kg/day), both well-known nephrotoxins, during gestational days (GD) 8-20. On GD20, rats were sacrificed and samples of the fetuses’ plasma and amniotic fluid were obtained. Creatinine was quantified using Jaffe’s reaction. Cd2+ and gentamicin treatments significantly raised plasma creatinimic levels in fetuses (0.76±0.03 vs. 0.92±0.05 respectively, vs. 0.62±0.02 mg/dL, P<0.001 (mean±S.E.). However, no difference was observed in amniotic fluid. Cystatin C, β2-microglobulin (β2-MG) and Kidney Injury Molecule-1 (Kim-1) levels on amniotic fluid were determined with kits based on immunofluorescence. We observed a decrease of β2-MG levels in the dams exposed to gentamicin, yet it was not statistically significant. Cystatin C levels remained unchanged whereas Kim-1 showed a non-statistically significant rise on its levels when the dams were exposed to Cd2+, but gentamicin induced a significant increase (22.28±4.73 vs. 6.29±1.74 pg/mL, P<0.01). These results suggest that Cd2+ is possibly affecting the glomeruli and, to a lesser extent, the proximal tubule whereas gentamicin seems to be damaging both glomeruli and proximal tubules in fetuses. The rise of Kim-1 levels on amniotic fluid points out its potential use to diagnose fetal kidney injury on proximal tubule before birth.

1206 HYALINE DROPLET NEPHRAPHONY INCREASED DIFFERENT RENAL BIOMARKERS DEPENDING ON COMPOUND AND TIME.

Kinter1. 1Global Safety Assessment, AstraZeneca Pharmaceuticals, Wilmington, DE, 2Patient Safety Sciences, AstraZeneca Pharmaceuticals, Wilmington, DE and 3Global Safety Assessment, AstraZeneca Pharmaceuticals, Wallingford, MA.

Hyaline droplet nephropathy (HDN) is a male rat specific lesion induced when a compound or metabolite binds to alpha-2-microglobulin. The objective of this project was to investigate the impact of HDN on a set of renal biomarkers (BM) approved for inclusion in male rat toxicity studies. Rats were dosed (po) 7 days to 1) determine if HDN altered renal BMs using vehicle, and 3 HDN positive agents: 1000 mg/kg/day 2-propanol, 100 mg/kg/day potassium bromate or 300 mg/kg/day d-limonene (dL) with necropsy on day 8 (n = 5/group), 2) determine sensitivity of HDN BMs to different induction protocols, necropsy on day 8 (n = 5/group), 3) determine reversibility of HDN and renal BMs using vehicle or 300 mg/kg/day dL with necropsy on day 8, 15, 29, 57 and 85 (n = 6/group). Rats treated with 2-propanol had HDN = 1.7 (average severity score using 1-4 scale) without increased renal BM levels. Potassium bromate treated rats had HDN = 3, and possibly increased clusterin (54%), ΔT 300 mg/kg/day treated rats had HDN = 4.0 and increased GSTβ1 (759%), GSTβ1 (182%) and albumin (539%). All three compounds induced HDN with different BM patterns. DL induced a dose dependent increase in HDN
